# Performance Improving Factors on E-Business System Stages

*Kiho Park*  
*Hoseo University, Republic of Korea*

## Abstract

The e-business strategies ultimately pursue creating the maximal value for customers through the competitive advantages and business opportunities newly created on the basis of information technologies. For the realization of e-business strategies, the successful implementation and operation of e-business system must be the crucial activities in and out of an organization. Therefore, in physical world, there were lots of interests that what kind of key factors can lead the success of e-business system. Moreover, in the field of academia also, there have been many research results for investigating and finding out the key success factors for e-business system. However, the perceptual level of the significance of key success factors that organization members perceive can be changed over each phase of system life cycle(hereafter "SLC") such phases as introduction(1st stage), growth(2nd stage), maturity(3rd stage), and decline(4th stage). This study investigated that there might be significant differences in the perceptual level regarding importance of success factors among phases of SLC.

## Introduction

According to system development life cycle(hereafter "SDLC") methodology, after completed system development and deployed at workplace, the age of e-business system will rise up (O'Brien, 2005; Choi, 2005). On the system maintenance process, the reason why system age gives the crucial implications to an organization is for that efforts in the process of operations are required more than in system development (Hana, 1993; Swanson & Dans, 2000). Companies, therefore, have to periodically assess the remnant life expectancy (Swanson & Dans, 2000). From the beginning of system operations, system maintenance will be sustained and repeatedly performed the system upgrading (Chappin, 1988). Thus, the e-business SLC can be defined as system age from deployment after finishing development to system replacement or major upgrade. The SLC may be dependent upon organization sizes, system types, or the purpose of system. Zvegintzov (1984) had suggested five reasons for replacing software with new one: (1) it is no longer needed; (2) it no longer runs on its hardware; (3) its hardware should be replaced; (4) it is not adaptable to changing physical fields; (5) the alternative software is developed or available for purchase. In our research, considering the situation of Korean companies, we classified the system ages into four phases such as first phase as below one year after deployment, second phase, between one and two years, third phase, between two to four years, and fourth phase, more than four years.

The many literatures related to the e-business system success have presented a variety of key success factors, which those were in early stage of deployment. These factors, however, have been in one lump sum without any division with e-business system ages or phases of SLC. Because, according to the system ages, the perceived importance regarding these factors can be changed. Namely, although, in initial stage of system deployment, some factors were dealt with the crucial things, as time passed, those may lose their gravity or be not important (Park, 2004). Based on previous study, the key success factors in ERP system, for example, are top manager's support and intention, the alignment between business and system strategies, innovation of business process, and system competence in an organization (Park & Cho, 2004; Chang et al., 2000; Davern & Kauffman, 2000; Akintoye, 2000; Markus & Tanis, 2000; Nah & Lah, 2001). Through this research, we suggest ten elements as core influential factors like managerial supports, strategic alignment with business, cooperative relationship with partners, project planning capability, system competence in organization, change management, proper system design for fieldwork, collaboration among teams, standardized business process, and competitive investment in IS(information system (Park & Cho, 2004).

Drawing from these basic intentions, we are especially interested in investigation on which there might be significantly different from the perceptual level regarding importance of success factors among phases of SLC. Thus, according to the phases of SLC, organizations have to focus on the crucial factors in each phase. We believe that the findings of research can give vital implications for the successful e-business strategies and maintenance processes.

## **E-Business System Evolution**

In generally, the e-business SLC or system age implies software's residual life consisting of information system. Because hardware components can be easily upgraded, however, the advanced features of software should be newly redeveloped or have to purchase new version products. Thus the e-business system life cycle is just the life of software (Park et al., 2006, Chappin, 1988).

According to researcher's experience, as the system age may be dependent upon companies' traits or cultural characteristics, it is difficult to clearly classify each phases of system evolution. However, this study proposed four stages for system ages based on system deployment period.

*Phase One (introduction): less than one year after IS deployment*

We defined first phase of system age as below one year after system development or deployment. Generally, when organizations newly start on system operation, they need to educate and train employees for adaptation and solve organizational conflict and adaptive period. In addition, during this period, possible software errors like programming errors or logic errors should be fixed and modified (Choi, 2005).

*Phase Two (stabilization): from one to two years*

This phase, under two years, is the stabilized period of system, which completely fixed errors and stabilized. At this phase, almost employees are familiar with system environment. In this phase, successful achievement of system investment should be based on alignment between business goals and system strategies (Segars and Grover, 1998). And collaborative relationship with business partners might be critical and vital process (Davernport, 1998; Brynjolfsson and Kemerer, 1996; Bingi et al., 1999).

*Phase Three (accustomed): from two to four years*

If the system fully stabilizes and end-users accustom themselves to the system, there may not be improperness or inconvenience to use. Without system, all of business activities can not be sustained. At this phase, rapid change of organizational structure and business environment may positively drive system upgrading or new development.

*Phase Four (upgrade): more than four years*

The fourth phase, which hardware and software should be upgraded or newly developed, can be defined as phase that gradually decrease system usability in an organization.

## **E-Business System (hereafter "IS") Payoff Assessment**

The issues of IS investment payoff has been important research areas of work over last two decades (Bakos, 1991; Christiaanse and Venkatraman, 2002). As for the business value, some researchers focused on efficiency gains from deployment of powerful dedicated systems in mid-1980s (McFarlan, 1984; Porter and Millar, 1985). Meanwhile, the possibility of deploying IS for revenue enhancement was emphasized through business scope changes in mid-1990s (Venkatraman, 1994). Three views including such as organizational performance, industrial organization, and information economics perspectives as for theoretical perspectives were proposed by Bakos and Kemerer (1992). The potential and realized value obtained after implementing IS systems are emphasized the importance of considering both types of values for both *ex ante* project selection and *ex post* investment evaluation (Davern and Kauffman, 2000). The effects of electronic data interchange (EDI) technology were analyzed into just-in-time (JIS) delivery and performance (Srinivasan et al., 1994). A few researchers focused on the process-driven values such as capacity utilization, inventory turnover, quality, price, and innovation under the context of EC (electronic commerce) technology investment (Barua et al., 1995). And the values of IS as cost savings, improvements in quality, customer service, and new product developments were identified (Brynjolfsson and Hitt, 1998).

As diversity of the views, the heterogeneity of corporate characteristics causes diverse assessment views and approaches and value gaps in most cases. Harris and Katz (1989) examined the usefulness of two information technology managerial control ratios as discriminating factors for differentiating between levels of organizational performance in a set of insurance companies. The control ratios were the IS cost-efficiency ratio, defined as the ratio of IS expense to premium income, and the IS expense ratio, defined as the ratio of IS expense to total operating expense. The dependent variable, the operating expense ratio, defined as the ratio of no interest operating expense to premium income, served as an inverse measure of profitability and productivity. And companies can have several their own approaches to measuring IS payoff that may be suited to the level of investment or the nature of industry.

## Research Model and Hypotheses

### Research Model

This research established the research model as below figure and hypotheses. In order to verify research model, I proposed nine hypotheses. Also, on the basis of researcher's field experiences and survey results, the system ages were classified into four phases.

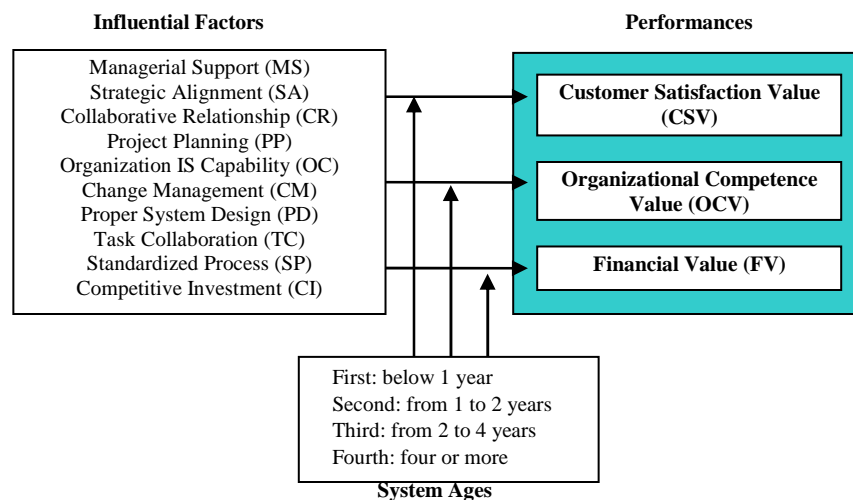

FIG. 1: RESEARCH MODEL

## Hypotheses

### Managerial Support (MS)

Many researchers have suggested the key success factors of IS investment. However, it might be true the structured researches about the unpredicted factors inducing the value gap during information system operation are relatively lack. In order to succeed the IS strategy, top-management support has been frequently emphasized by lots of researchers and consistently proposed as one of IS success factors (Smith, 1988; Yoon et al., 1995; Jang et al., 2000).

H1: According to each of the system phases, the cognitive level of importance of the MS (managerial support) affecting organizational performances is different.

H1a: The cognitive level of importance of the MS affecting CSV is different in each system phase.

H1b: The cognitive level of importance of the MS affecting OCV is different in each system phase.

H1c: The cognitive level of importance of the MS affecting FV is different in each system phase.

### Strategic Alignment(SA)

Generally accepted that one of key IS success factors is the close linkage of the IS strategy and business strategy (Segar and Grover, 1998; Henderson and Venkatraman, 1993).

H2: According to each of the system phases, the cognitive level of importance of the strategic alignment affecting organizational performances is different.

H2a: The cognitive level of importance of the SA affecting CSV is different in each system phase.

H2b: The cognitive level of importance of the SA affecting OCV is different in each system phase.

H2c: The cognitive level of importance of the SA affecting FV is different in each system phase.

#### **Collaborative Relationship(CR)**

By extending interorganizational networking, whether easiness of interrelationship between seller and buyer, seller and seller, buyer and buyer and so on exist or not became crucial factor in IS valuation. For example, not only intrafirm BPR but also interfirm process reengineering and the mutual sharing of process importantly played a role in ERP system environment (Davernport, 1998; Brynjolfsson and Kemerer, 1996). And in SCM environment, interactive information sharing and strong collaborative relationship with business partners should be continuously emphasized and conducted (Rhonda et al., 2000).

H3: According to each of the system phases, the cognitive level of importance of the strategic alignment affecting organizational performances is different.

H3a: The cognitive level of importance of the CR affecting CSV is different in each system phase.

H3b: The cognitive level of importance of the CR affecting OCV is different in each system phase.

H3c: The cognitive level of importance of the CR affecting FV is different in each system phase.

#### **Project Planning and Management Capability (PP)**

To maximize the effects of IS investment, the project planning capability is important (Markus and Tanis, 2000; Nah and Lah, 2001). Also, through the right man in the right place, the active communication among related teams, and the adequate IS investment, needs, which satisfy field workers, can elevate the effect of system investment (Cameron and Meyer, 1998; Bingi et al., 1999).

H4: According to each of the system phases, the cognitive level of importance of the project planning and management capability affecting organizational performances is different.

H4a: The cognitive level of importance of the PP affecting CSV is different in each system phase.

H4b: The cognitive level of importance of the PP affecting OCV is different in each system phase.

H4c: The cognitive level of importance of the PP affecting FV is different in each system phase.

#### **Organizational IS Capability(OC)**

In general, new technologies change the existent equilibrium state within organizations. Information systems, specifically ERP, SCM, have the potential to significantly change the work practices and procedures in the production, logistics, and distribution. In the progress of change, role ambiguity is possibly generated.

H5: According to each of the system phases, the cognitive level of importance of the organizational IS capability affecting organizational performances is different.

H5a: The cognitive level of importance of the OC affecting CSV is different in each system phase.

H5b: The cognitive level of importance of the OC affecting OCV is different in each system phase.

H5c: The cognitive level of importance of the OC affecting FV is different in each system phase.

#### **Change Management Capability (CM)**

To successfully stabilize rapid changes in the managerial environment in organization, sharing the information and communication should be patiently progressed (Cummings and Huse, 1989). Against the organization-wide changes, there must be conflicts from conservative persons. Under this situation, whether these conflicts could be overcome or not can be the influential factors in occurring IS performance discrepancy. Also, inadequate incentive system or process design can be barriers against effective system use (Davern and Kauffman, 2000).

H6: According to each of the system phases, the cognitive level of importance of the change management capability affecting organizational performances is different.

H6a: The cognitive level of importance of the CM affecting CSV is different in each system phase.

H6b: The cognitive level of importance of the CM affecting OCV is different in each system phase.

H6c: The cognitive level of importance of the CM affecting FV is different in each system phase.

### **Properness of System Design (PD)**

The factors that create the end-user's satisfaction and influence the effects of IS investment are quality of IS, quality of reported information, and properness for field task processing (Seddon and Kiew, 1994; Delone and Mclean, 2003). Therefore,

H7: According to each of the system phases, the cognitive level of importance of the properness of system design for fieldwork capability affecting organizational performances is different.

H7a: The cognitive level of importance of the PD affecting CSV is different in each system phase.

H7b: The cognitive level of importance of the PD affecting OCV is different in each system phase.

H7c: The cognitive level of importance of the PD affecting FV is different in each system phase.

### **Interdepartmental Task Collaboration (TC)**

The degree of cooperation is important in order to reduce the potential conflict which may jeopardize the implementation of strategic IS plans (Henderson, 1990). In SCM system, the interdepartmental information sharing and the close cooperation between teams must be the vital factor to improve the effect of system investment (Robert & Kilpatrick, 2000).

H8: According to each of the system phases, the cognitive level of importance of the interdepartmental task collaboration affecting organizational performances is different.

H8a: The cognitive level of importance of the TC affecting CSV is different in each system phase.

H8b: The cognitive level of importance of the TC affecting OCV is different in each system phase.

H8c: The cognitive level of importance of the TC affecting FV is different in each system phase.

### **Business Process Standardization (SP)**

The process-centric perspective argues that IS creates value for the organization by improving individual business processes, or inter-process linkages, or both. Consequently, the greater the impact of IS on individual business processes and on inter-process linkages, the greater will be the contribution of IS to firm performance (Tallon et al., 2000). Thus,

H9: According to each of the system phases, the cognitive level of importance of the standardized business process affecting organizational performances is different.

H9a: The cognitive level of importance of the SP affecting CSV is different in each system phase.

H9b: The cognitive level of importance of the SP affecting OCV is different in each system phase.

H9c: The cognitive level of importance of the SP affecting FV is different in each system phase.

### **Competitive Investment (CI)**

By the exploratory study, lots of companies, unfortunately, experienced the failure of IS investment cause of imitative or competitive investment (Cho and Park, 2003). The unclear goal of system deployment or inter-organizational conflict as barrier factors against successful IS implementation arise from imitative or competitive investment (Ginsberg, 1988). Hence,

H10: According to each of the system phases, the cognitive level of importance of the interdepartmental task collaboration affecting organizational performances is different.

H10a: The cognitive level of importance of the CI affecting CSV is different in each system phase.

H10b: The cognitive level of importance of the CI affecting OCV is different in each system phase.

H10c: The cognitive level of importance of the CI affecting FV is different in each system phase.

## **Research Findings**

### **Data Collection**

The data for this study were collected from 315 questionnaires completed by 48 Korean domestic companies using IS systems such as SCM, ERP, or CRM. Two incomplete questionnaires were eliminated from analysis. The total survey period took one month. To ensure a high response rate and reliability, surveys were conducted in person. After factor analysis, excluding the CI (competitive investment), Cronbach's alpha as criteria of reliability of independent variables was above .70, indicating construct unidimensionality.

The collected sample consists of 216 current system users and 97 system developers. The IS usage period after deployment consists of 2-4 years (40.6%) followed by 1-2 years (30.7%), and above 4 years (12.5%)

sequentially. The majority of the respondents deployed the foreign-made solution (58.5%) followed by subcontracted development (15.7%), and in-house development (14.4%). The percentage of domestic packages (10.5%) is lower than foreign-made solutions (58.5%). The job title of respondents consists of 39.9 percent as managers, 29.6% as senior employees, 28.4% for employees working for 2-3 years, and 1.6% as directors.

TABLE 1: RELIABILITY AND VALIDITY OF MEASURES

Factor and items	Eigenvalue	Loadings	Cronbach's $\alpha$
<b>Factor 1. Management support (MS)(H1)</b>	14.176		0.8935
Participation in operation		0.827	
Participation in development		0.808	
Interest in system user satisfaction		0.686	
Emphasis of strategic importance to employees		0.671	
Financial support		0.614	
Human resource support		0.592	
<b>Factor 2. Strategic alignment (SA)(H2)</b>	2.757		0.8701
Emphasis of IS importance to top management		0.748	
Degree of strategic investment		0.740	
Clear goals of investment		0.592	
Organizational consensus of IS role		0.566	
Understandability of strategic benefits of IS		0.555	
Connectivity with strategic goals		0.548	
Perceptual level of business strategy of IS employees		0.523	
<b>Factor 3. Collaborative relationship (CR)(H3)</b>	1.989		0.8864
Co-working to solve problems		0.838	
Cooperative participation in developing process		0.778	
Perceptual level of common goals		0.767	
Easy to share operational information		0.724	
<b>Factor 4. Project planning (PP)(H4)</b>	1.729		0.8652
Rationale performance evaluation criteria		0.734	
Reasonable forecasting skill of investment effects		0.710	
Collaborative level with system users		0.667	
Acceptability of requirement from field workers		0.611	
Flexibility of risk management		0.604	
<b>Factor 5. Organization IS capability (OC)(H5)</b>	1.58		0.861
Clear role assignment of operating team		0.658	
IS professionals		0.621	
Clear goal of development team		0.603	
Evaluation skill of vendors or company outsourced		0.561	
Capability of IS usage		0.555	
Understandability of IS technology		0.546	
Clear goals in resource allocation		0.485	
<b>Factor 6. Change Management (CM)(H6)</b>	1.51		0.7925
Perceptual level of necessity of change		0.824	
Positive activities for solving conflict against change		0.723	
Persistent training of reason for change		0.706	
<b>Factor 7. Proper system design (PD)(H7)</b>	1.312		0.8027
Easy to maintain		0.744	
Scope of adaptability		0.594	
Easy to use		0.562	
<b>Factor 8. Interdepartmental task collaboration (TC)(H8)</b>	1.155		0.8375
Easy to cooperate within an organization		0.824	
Sharing the necessary information		0.810	
<b>Factor 9. Business process standardization (SP)(H9)</b>	1.047		0.8155
Code standardization in identical industry		0.856	
Business process standardization in identical industry		0.788	
<b>Factor 10. Competitive investment (CI)(H10)</b>	1.021		
Competitive and imitated investment		0.941	

Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization. Rotation converged in 8 iterations.

TABLE 2: SYSTEM-RELATED FREQUENCIES

	Freq.	Percentage	Valid percent	Cumulative percent
<b>Role</b>

ASP	3	1	1	100

**Hypotheses Test**

Linear Regression estimates coefficients of the linear equation, involving one or more independent variables, which best predict the value of the dependent variable. This study used a stepwise procedure for variable selection. As criteria of variable selection, F-value was used and some of predictors as entered variables were selected with more significant level than  $\alpha=.05$ , otherwise removed from regression equation.

To determine whether the multicollinearity exist or not, as the statistical criteria, the tolerance (TOL) or variance inflation factors (VIF) are used in general. As the tolerances of each regression model were greater than .10. the multicollinearity problems of predictors did not exist. First of all, not considering the system age, I conducted the multiple regression analysis to investigate relationship and principal factors between system performance and independent variables. I determined three variables (CSV, OCV, and FV) as the dependent variables and ten variables (managerial support, collaborative relationship with business partners, etc) as independent variables. Null and Alternative hypotheses for this study are as follows:

$$\text{Null hypothesis (H}_0\text{): } \beta_0 = \beta_1 = \dots = \beta_n = 0$$

$$\text{Alternative hypothesis (H}_a\text{): not all of } \beta_i \text{ are zero.}$$

As depicted in ANOVA table, hypothesis (H<sub>0</sub>) is not supported at significant level ( $\alpha=0.01$ ) because all of significant probabilities are .000 for three dependent variables. This implies that the critical success factors significantly affect the performances including CSV, OCV, and FV. The explanatory powers concerning three regression models are .347, .431, and .339 each. The critical influential factors influencing CSV are project management, strategic alignment with business strategic goals, and proper system design for field work. Project planning, interdepartmental task collaboration (TC), strategic alignment (SA), and proper system design (PD) may be principal and significant to improve the OCV. To improve the FV, the critical success factors are SA, SP, PP, and OC.

TABLE 3: ANOVA BETWEEN FACTORS AND PERFORMANCES (W/O DEMARCATON OF SYSTEM AGE)

Dependent Variable		Sum of Squares	df	Mean Square	F	Sig.	R	R <sup>2</sup>	Adj. R <sup>2</sup>
CSV	Regression	34.021	5	11.340	53.425	.000 <sup>a</sup>			
	Residual	63.892	301	.212			.589	.347	.341
	Total	97.912	305						
OCV	Regression	29.692	4	7.423	56.411	.000 <sup>b</sup>			
	Residual	39.212	298	.132			.656	.431	.423
	Total	68.904	302						
FV	Regression	25.491	4	6.373	38.392	.000 <sup>c</sup>			
	Residual	49.632	299	.166			.583	.339	.330
	Total	75.123	303						

- a. Predictors: (Constant), project planning, strategic alignment, proper design, Dependent Variable: customer satisfaction
- b. Predictors: (Constant), project planning, task collaboration, strategic alignment, proper design, Dependent Variable: organization capability
- c. Predictors: (Constant), strategic alignment, standardized process, project planning, IS capability, Dependent Variable: financial value

To determine whether the multicollinearity exist or not, as the statistical criteria, the tolerance ( $TOL$ ,  $TOL_i = 1 - R_i^2$ ) or variance inflation factors ( $VIF$ ,  $VIF_i = 1 / TOL_i$ ) are used in general. As the tolerances of each regression model were greater than .10. So, the multicollinearity problems of predictors did not exist.

TABLE 4: REGRESSION COEFFICIENTS (W/O DEMARCATON OF SYSTEM AGE)

Dependent Var.	Factors	Non-standardized		Standardized	t-value	Multicollinearity	
		B	Std. Error	Beta		Tolerance	VIF

	Strategic Alignment	0.270	0.058	0.276	4.621 <sup>***</sup>	0.606	1.650
	Proper System Design	0.186	0.052	0.217	3.581 <sup>***</sup>	0.593	1.687
OCV	(Constant)	1.318	0.147		8.940 <sup>***</sup>		
	Project Planning	0.125	0.047	0.173	2.680 <sup>***</sup>	0.457	2.189
	Task Collaboration	0.148	0.042	0.190	3.551 <sup>***</sup>	0.665	1.504
	Strategic alignment	0.187	0.047	0.227	4.009 <sup>***</sup>	0.593	1.686
FV	Proper System Design	0.163	0.043	0.225	3.788 <sup>***</sup>	0.539	1.854
	(Constant)	1.221	0.172		7.084 <sup>***</sup>		
	Proper System Design	0.204	0.054	0.238	3.801 <sup>***</sup>	0.563	1.776
	Standardized Process	0.192	0.052	0.212	3.712 <sup>***</sup>	0.677	1.477
FV	Project Planning	0.109	0.050	0.145	2.165 <sup>**</sup>	0.493	2.030
	IS Capability	0.102	0.050	0.127	2.027 <sup>**</sup>	0.560	1.785

\*\* $p < .05$ , \*\*\* $p < .01$ .

Concerning the relationship between system age and organization performances, by passing time of system operation, we assumed that the critical factors influencing system achievements may be different. Table shows that all of regression models on system age each have statistical significance.

TABLE 5: ANOVA BETWEEN SYSTEM AGE AND FACTORS

System Age	Performance	SS	df	MS	F	Sig.	R	R <sup>2</sup>	Adj. R <sup>2</sup>	
First (< 1 year)	CSV	Regression	4.946	1	4.946	19.967	.000	.538	.290	.275

		Total	9.855	37						
	FV	Regression	4.344	3	1.448	9.654	.000	.678	.460	.412
		Residual	5.100	34	.150					
		Total	9.444	37						

First, for the customer satisfaction value(CSV), factors affecting the CSG, CR with business partners at first phase, CR and PP at second phase, PP, SA, and PD at third phase, and for fourth phase, SA, TC, OC, and CR were significant at .01 or .05 level each. Thus, hypotheses H2a, 3a, 4a, 7a, and 8a are supported.

Second, for the organization capability value(OCV), factors such as PD for work and SP at first phase, PD and CM at second phase, PP, TC, and PD at third phase, and SA, TC, OC, and CR at fourth phase at significance level of 1%, 5% each were influential factors to the OCV. Thus, the hypotheses, H2b, 3b, 4b, 5b, 6b, 7b, 8b, 9b were supported.

Third, for the financial value discrepancy (FV), factors affecting FV were such as SP and PD at first phase, CR and SA at second phase, OC, PP, and SP at third phase, and at fourth phase, SA, CI, and CR at fourth phase were influential factors to the OCV. Thus, the hypotheses, H2c, 3c, 4c, 5c, 7c, 9c, 10c were supported.

## Implications and Conclusion

In an organization, we are interested in which factors are the principals for gaining organizational performances based on the phases of SLC. On the basis of previous researches, we divided the SLC into such four phases as introduction (less than one year), stabilization (between one and two years), accustomed (between two and four years), and upgrade (more than four years). For empirical analysis, we suggest ten elements as core influential factors like managerial supports, strategic alignment with business, cooperative relationship with partners, project planning capability, system competence in organization, change management, proper system design for fieldwork, collaboration among teams, standardized business process, and competitive investment in IS. We are especially interested in investigation on which there might be significantly different from the perceptual level regarding importance of success factors among phases of SLC. Thus, according to the phases of SLC, organizations have to focus on the crucial factors in each phase. We believe that the findings of research can give vital implications for the successful e-business strategies and maintenance processes.

Differently with the previous research results, the managerial support factor was not significant for performance in all phases. This implies that the informatization of firms can not be strange any more and the managerial support, not principal factor. The variable, the strategic alignment, as a whole (CSV in third and fourth phase, OCV in fourth, and FV in second and fourth), influences the dependent variables. This also suggested that the positive effects from IS strategic aligning with business strategies indeed need not short term but long term period. Next, the cooperative relationship affects CSV in first and second, OCV in third and fourth, and FV in second and fourth phase each. This means that the cooperative relationship may be understood a very important factor for customer satisfaction in early phase. Moreover, as time passed, this variable gradually influences OCV. From early stage (first, second and third) in system age, the principal and the crucial variable affecting improving OCV was proper system design for fieldworks.

In summary, almost independent variables except for the managerial support were influential factors that showed the differences in statistical significance on each phases of SLC. At first phase, the significant variables influencing performances were the cooperative relationship with partners, the proper system design for fieldworks, and the standardization of business and task processes. Differently with first phase, at second phase, the strategic alignment with business strategies, the cooperative relationship with partners, the project planning competence, the change management, and the proper system design for fieldworks. The principal factors at third phase were the strategic alignment, the project planning, the IS competences, the task collaboration, and the business process standardization. Lastly, at fourth phase, the strategic alignment, the cooperative relationship, the IS competences, the task collaboration, and the competitive investment. Accordingly, based on the above research findings, we found out that the influential factors may be different from on each system phases. Thus, firms should focus system investment on those factors for raising the organizational performances.

The limitations of this research are as follows. First, as the system ages were defined by author's field experience or subjective judgment, not based on the general criteria, the system age should be classified with more reasonable and valid criteria. Second, the system age may be different in organizational size, system platform, or system usage. The reason is why we guess that the smaller organization size is, the more sensitive the perceptual level of importance concerning the key success factors is. However, we did not take into account the firm's size, so research findings may have weak reliability and validity. Third, in addition to firm's size, we excluded the industry types. Further researches should be investigated to get more reliable results with the SLC strictly classified by criteria like organizational size and industrial types as pointed out above limitations.

# Expressing Emotions on Blogs: A Content Analysis Comparison between the U.S. and Mexico

Juan Antonio Vargas-Barraza, [corporación.sintetica@gmail.com](mailto:corporación.sintetica@gmail.com)  
Universidad de Guadalajara, Mexico  
Laura Serviere, [lauraserviere@hotmail.com](mailto:lauraserviere@hotmail.com)  
University of Texas-Pan American, U.S.

## Abstract

Internet users have emoticons as a way to use images to show their emotions. Emoticons are usually found among Internet blogs, which are user-generated website where entries are made in journal style and displayed in a reverse chronological order. Despite the quantity of free information available users from different countries may express and interpret online information in a different manner, such as some users employ more often images than words to express their feelings and ideas. This study addresses emoticon usage of personal blog postings from the U.S. and Mexico. The results supported the hypothesis that cross-country differences do exist in the use of emoticons between the U.S. and Mexico. The results showed that Mexican users employ emoticons more frequently to express their emotions than their American counterpart. In addition, Mexican users showed a larger preference to use a large variety of emoticons to express their emotions.

## Introduction

As a web-based communication tool, the term "blog" is a blend of the words web and log (Web log). A blog entry is a diary-style site in which the author, a "blogger", writes and post ideas or short articles displayed in a chronological order (Lamb and Johnson, 2006). In addition, the blogger can link other web pages that he or she finds interesting which are usually posted in reverse chronological order (Perrone, 2005).

Blogs either provide commentaries or news on a particular subject, such as food, politics, or local news or function as personal online diaries. A typical blog combines text, images, and links to other blogs, web pages, and other media related to its topic. The ability for readers to leave comments in an interactive format is an important part of earlier blogs. Most blogs are primarily textual, although some focus on photographs (photoblog), sketches (sketchblog), videos (vlog), or audio (podcasting) (Blog, 2007).

The word *emoticon* is the mixture of words "emotion" and "icon" and invented in 1981 by Scott Fahlman (Tanskanen, 1998) used to express an emotion (Mallon and Oppenheim, 2002). Initially, emoticons were also called smileys, which were a series of typed characters that, when turned sideways, resemble facial expressions. However, the set has extended to many other characters not only involving faces but also other body parts, such as "thumbs up" (Serviere, Hernandez, and Minor, 2005). As DeFranco (2005) mentioned, "*Emoticons are shorthand feelings. Their purpose is to express non-verbal attitudes, which are lost or misunderstood in simple text messages. A statement made with a smile is often better received and remembered than one without emotion*" (pg. 6). Hence emoticons may be useful to express feelings that might be expressed through tone of voice or behavior in speech (Mallon and Oppenheim, 2002).

Consumption is now seen as involving a constant flow of fantasies, feelings, and fun encompassed by what is called the "experiential view." This experiential view considers consumption as a primarily subjective state of consciousness with a variety of symbolic meanings, hedonic responses, and esthetic criteria (Holbrook & Hirshman, 1982).

## Literature Review

Nowadays the consumers require marketing products providing experiences for the consumer (Schmitt, 1999). The consumers may be able to make valid perceptions or affective distinctions among several brands (Holbrook & Hirshman, 1982). Internet is a mean that provides such experiences, and the possibility to reach consumers from the entire world, using several marketing tools for the consumers.

The previous efforts of marketing were always transmissions from the companies, one way communications, intended for target the highest quantity of visitors as possible, such as announcements, emergent windows in Internet and alike. Marketers use banner ads, design websites to be reminiscent of product brochures, and make available “show rooms” to consumers (LaFerle et al., 2002).

With blogs, the site becomes closer to the customers, since each blog reader is doing it for his/her own desire, each reader is choosing to interact with the business and each reader wants to listen more about the business (Wright, 2007). The acceptance and use of images to represent an idea may be different from country to country. Choong and Salvendy (1998) made an experiment between the U.S. and China. It was determined that in cognitive questions, the American participants had advantages over the Chinese participants when textual models were used. However, when models with graphics were used, the Chinese participants performed better. Moreover, for certain cultures the use of images is more valuable than the use of texts. Such uses of images over text emphasize the cultural differences that have to be accounted for in the design of a site. This is because different cultures might expect a certain web design and when they encounter a different one, they might react differently (Fang and Pei-Luen, 2003). For example, if the design of a website is displeasing, the visitors might simply choose not to revisit the site, leading to losing potential customers.

As part of research on online images, some studies have been conducted regarding the usage of emoticons. The research addressing gender differences in emoticon use in newsgroups by Wolf (2000) found that female users, when in a predominantly female group, were more emotional than male users as they utilized emoticons in a more frequent and varied manner. However, once in a mixed-gender newsgroup, male users employed emoticons at the same rate of their counterparts. On another study, Serviere, Hernandez, and Minor (2005) compared the underlying set of emotions expressed by five Latin American online community users, particularly users from Argentina, Chile, Mexico, Peru, and Venezuela. The results strongly suggested that the use of emoticons and the sense of freedom provided by the Internet highly motivated online users to express their emotions. Among the five Latin American countries included in the study’s sample, Argentina, Mexico, and Venezuela exhibited the highest number of emoticons. Among these countries, Argentina and Mexico were the countries with the largest variety of emotions expressed (Serviere, Hernandez, and Minor, 2005).

## Methodology

Richins (1997) defined an emotion as an affective reaction to perceptions of situations. According to this definition, the criteria followed in the selection of emoticons were based on Richins’ (1997) criteria and adapted where necessary. The criteria utilized to identify the emotions expressed included all kinds of emoticons. Although labeled as a cognitive state, the emoticon for “confusion” was included in the criteria because this is a commonly used emoticon referring to this emotion.

The technique used for the content analysis was netnography (ethnography on the Internet) as proposed by Kozinets (2002). This marketing research technique was appropriate since it was particularly developed for the analysis of the content of online communities. Furthermore, this technique was appropriate for this study because the purpose was to investigate and identify insights into the emotions expressed by bloggers of two culturally different countries: the U.S. and Mexico. The netnographic data collection procedure requires the selection and extraction of data from online postings which in this case were extracts from blogs.

To test the hypothesis for this research a content analysis was conducted. The analysis started with the selection of blogs where *emoticons* were used as part of the comments for a post. The sites where no *emoticons* were showed were discarded. The hypotheses tested were:

H1: There is a significant cross-country difference in the use of emoticons between Mexico and United States.

H2: There is a significant cross-country difference in the use of different emoticons between Mexico and United States.

## Data Collection

A total of 61 personal blogs that showed emoticon usage were selected for each country. To be able to collect a sufficient amount of postings, a total of 244 blogs had to be reviewed. To conduct the data collection process, the comments or responses that people posted about a blog were reviewed. Because of the quantity of comments that might be posted after an author has placed his or her personal entries, a specific date, April 8<sup>th</sup>, 2007, was selected for reviewing the postings. To be selected for the study, the postings should have been generated between April 2006 and April 2007. Only the response posts displayed in the first page of each blog showing an emoticon were reviewed and counted. The Mexican blogs were personal blogs gathered from www.blogsmexico.com. As a blog was opened, the posts and their comments were analyzed to check if they had emoticons. It was determined that for every four blogs, only one had comments with emoticons. A total of 244 blogs were reviewed of which 61 were collected. This represents a 25% of emoticon usage based on the first pages count. For the American blogs, the selection criterion was the same as the one followed for the Mexican blogs. American blogs were gathered from www.blogger.com. For every 13 blogs, only one had emoticons in its comments. From a total of 793 blogs reviewed, only 7.69% blogs were using emoticons.

To increase research objectivity, three independent persons were reviewing the comments and counted the emoticons in the selected postings. This was done to accomplish the minimum of three judges proposed by Kassirjian (1977) for content analysis.

## Statistical Analysis and Results

The statistical analysis program STATGRAPHICS + Version 4 was used to test hypotheses 1 and 2. The results showed that for American blogs, 126 emoticons were used in 523 comments. In Mexico, there were 237 emoticons found within the 517 comments that were reviewed. The relationship of comments with emoticons per type is showed in the Table 1.

TABLE 1: TYPE OF EMOTICONS IN COMMENTS PER COUNTRY

Emoticon	Emoticon Type in characters	Descriptor	Total of comments using <i>emoticons</i> per type in blogs from USA	Total of comments using <i>emoticons</i> per type in blogs from Mexico
	= ] or :-) or :) or =) or :^)	Happiness	110	183
	:-S or :S	Confusion	1	10
	:-( or :( or =( or D:	Sadness	9	31
	XP or >:-O or >:-:( or >:[ or >:E	Mad/Angry	0	3
		Support	1	6
	¬3¬ or ¬w¬ or ¬.¬ or ¬¬ or ¬¬	Sarcastic	5	4
Total of comments with <i>emoticons</i> in 61 blogs			126	237
Total of <i>emoticons</i> used in total of comments			126 / 523 comments	237 / 517 comments

For H1, a Hypothesis Test was run. The size for the U.S. sample consisted of 61 observations with a mean of 0.28 and a standard deviation of 0.14. Mexico's sample size consisted of 61 observations as well, with a mean of

0.5, and a standard deviation of 0.24. The computed t statistic equals -6.18413. Since the P-value for the test is less than 0.05, the null hypothesis is rejected at the 95.0% confidence level. The confidence interval shows that the values of  $\mu_1 - \mu_2$  supported by the data fall between -0.290436 and -0.149564. Therefore, our sample provided support for H1. Overall results indicate there is a significant cross-country difference in the use of emoticons (TABLE 2).

TABLE 2: HYPOTHESIS TEST RESULTS FOR H1

	USA	Mexico
Sample Means	0.28	0.5
Simple Standard Deviations	0.14	0.24
Simple Sizes	61	61
95.0% confidence interval for difference between means:	-0.22 +/- 0.070436 [-0.290436, -0.149564]	
Null Hypothesis:	Difference between means = 0.0, $\mu_1 - \mu_2 = 0.0$	
Alternative Hypothesis:	Not equal, $\mu_1 - \mu_2 \neq 0.0$	
Computed t statistic:	-6.18413	
P-Value:	8.92496E-9	
Reject the null hypothesis for alpha	0.05	

Multifactor ANOVA was performed to test H2, which addresses differences in the frequency used per type of emoticon per country. The frequency on the use of emoticons was used as a dependent variable and contrasted with type of emoticon per country. The ANOVA table decomposes the variability of Frequency into contributions due to various factors (TABLE 3). The contribution of each factor is measured having removed the effects of all other factors. The p-values test the statistical significance of each of the factors. Since 3 P-values are less than 0.05, these factors were deemed to have statistically significant effect on Frequency at the 95.0% confidence level. There is a significant difference between the use of emoticons and the countries, having the Mexican blogs the highest amount of them (FIGURE 1), and there is also significant difference between the quantities of emoticons per type used in the two countries, being the Mexican blogs were most of them are used (FIGURES 2 and 3).

For both countries, the most used emoticon was happiness (FIGURE 4). After happiness, the usage of emoticons was as follows for Mexican blogs: mad, sad, sarcastic, support, and confusion. For American blogs, the usage was: sad, sarcastic, support, and confusion.

TABLE 3: RESULTS FOR MULTIFACTOR ANOVA FOR FREQUENCY

Source	Sum Of Squares	Df	Mean Square	F-Ratio	P-Value
Main Effects					
A: Country	0.467555	1	0.467555	34.36	0.0000
B: Emoticon	8.30713	5	1.66143	122.08	0.0000

FIG. 1: FREQUENCY OF EMOTICONS VS. COUNTRIES

FIG. 2: TYPE AND FREQUENCY OF EMOTICONS PER COUNTRY

FIG. 3: TYPE AND FREQUENCY OF EMOTICONS PER COUNTRY

FIG. 4: FREQUENCY OF EMOTICONS IN BOTH COUNTRIES.

## Discussion

The results supported the hypothesis that cross-country differences do exist in the use of emoticons between the U.S. and Mexico. The results showed that Mexican users employ more frequently emoticons to express their emotions than their American counterpart. Out of 517 comments reviewed, Mexican users employed 237 emoticons as part of their postings. In contrast, American users only employed 123 emoticons on a set of 523 postings. The fact that Mexican users almost double their usage of emoticons when compared to American users perhaps denotes a more expressive society. We cannot infer that Mexican users are more emotional only from their higher usage of emoticons, but it does seem that they are a more expressive online community. It appears that the Mexican users prefer visual aides to express their views, concerns, and emotions.

From these results, it seems appropriate to recommend that online campaigns aimed towards Mexican users use a great deal of visual aids to attract and keep interest of potential consumers. This preference for emoticons uncovers a person that prefers to be highly expressive through visual tools. Online design, such as web pages, ads, and emails, should try to communicate not only with words but, with the support of vivid imagery. This approach

would contrast with the one aimed towards the American user who denoted a preference for written content only. The lesser usage of emoticons of the American user should not be interpreted as a sign of a less expressive user. American users can be as expressive as the Mexican users but American users chose words rather than images to convey their feelings and thoughts.

Regarding the usage of a large variety of emoticons, Mexican users showed a larger preference for these. In addition, Mexican users showed a larger preference to use a large variety of emoticons to express their emotions. Their usage included a wide variety of emoticons such as the ones available to denote happiness, confusion, sadness, anger, support, and sarcasm. The American user opted for a smaller variety of emoticons showing again their preference for a communication style that largely prefers words.

The limitations of the study are inherent to the nature of online data. Since most of the data required to post comments on blogs is optional, our study was not able to provide demographic information such as gender, age, level of education, and income. This encourages future research to collect additional postings to obtain a larger sample size in order to achieve more generalized results. Profiles of Internet users by country based on their emotions expressed should also be considered. In addition, analyses could also be performed to study how online users make decisions or form attitudes based on their emotions.

## Abstract

This article tries to reveal how India's IT industry will sustain in this high-tech competitive world, i.e. survival of the fittest. So to keep fit India, this study tries to highlight and investigate the hidden treasures of driving forces that plays a great role behind the sustainability of IT industries in India and to gain the competitive advantage. What are the major factors that influence the India's IT industry that has been discussed in this paper followed by governmental incentives, human resources, clustering and so on.

## Introduction

To sustain in this modern competitive world and also to keep pace with the continuously increasing complex network of social, political and economic entities is not an easy job. On the other hand achieving success is also no longer a simple task for an individual firm and to get a best position in a global market. Though it's not easy to get success but still there some success stories that inspire us to know. Behind every success always there are some motivating factors that stimulate to get success. This article is going to deal with one such success story, i.e., the sustainability of Information Technology (IT) industries in India. Recently it has been observed that India's IT sector is moving very fast to compete globally in compare with other sectors. Now the question arise what makes India's IT sector so powerful to meet the global challenges? And how India can keep on go ahead its progress in near future. This article will try to answer of all these questions.

This article argues that how the different motivating factors, especially the *governmental incentives, human resources, and clustering* providing a major contribution to the IT industries in India. How these factors are adding values by aligning various strategies and driving forces with business needs and connecting people from divergence. Finally this article tries to give a special reference of Bangalore, as an example how it becomes a special hub of IT industries in India with the existence of IT cluster that foster high levels of productivity and innovation and lays out the implications for competitive strategy and economic policy. Economic geography in an era of global competition poses a paradox. Today's economic map of the world is characterized by what Porter calls clusters: critical masses in one place that linked industries and institutions [1-3].

## Overview of IT Industry in India

This article is going to talk about the success of India's IT industry so we must know about the status and position of India's IT industry. Over the past decade, Information Technology (IT) industry in India has become one of the fastest growing industries in India as well as the fastest growing segment of the Indian economy. The software and IT Enable services (ITES) raises the exports in India from US\$12.9 billion to US\$ 17.7 billion in the year 2004-2005. Strong demand over the past few years has placed India amongst the fastest growing IT markets in the Asia-Pacific region. The Indian software and ITES industry has grown at a Compound Annual Growth Rate (CAGR) of 28 % during the last five years. The industry's contribution to the national Gross Domestic Product (GDP) has risen from 1.2 % to a projected 4.8 % during the year 2005-06.

India has a competitive advantage with respect to this sector owing to cost advantage, skilled manpower advantage, reasonable technical innovations, Indian domestic market growth, and multi- country service delivery capabilities among others. It is expected that the contribution of IT and IT Enable services (ITES) of national GDP

will rise up to 7% by 2007-08 against 4.8% in 2005-06. The total number of IT and – Business Process Outsourcing (BPO) professionals employed in India has been estimated that have grown from 284,000 in 1999-2000 to 1,287,000 in the year 2005-06. It is growing by 230,000 in the last year alone. In addition, it has been observed that Indian IT - ITES have also helped to create an additional 3 million job opportunities through indirect sources and induced employment opportunities.

TABLE 1: PRODUCTION AND GROWTH OF IT INDUSTRIES IN INDIA [4]

Year	Production (Rs. Crore)	Growth (Percentage)
2000-01	68,850	31.3
2001-02	80,124	16.4
2002-03	97,000	21.1
2003-04	118,290	18.2
2004-05	152,420	28.8
2005-06	185,660	21.8

According to National Association of Software and Services Company (NASSCOM), Indian IT software and services sector grew by 31.4% during 2005-06. It is notching up the aggregate revenue up from US\$ 22.5 billion in 2004-05 to US\$ 29.6 billion in 2005-06. This performance of the IT sector in India in 2005-06, encouraged the IT and ITES sector to be more confident enough to achieve the US\$ 60 billion milestone in export by 2010 [4]. The continuous production and growth trends of IT sector in India during the last five years shown above in Table 1 that gives us an idea about the progress of India's IT industry.

### What makes India's IT Industry Competitive?

In our previous discussion we have already seen the trend of progress of India's IT industry that makes us curious to know what are those driving forces or factors behind this success that makes India to be competitive in compare with other competitors. We know that there cannot be a single factor that enhances the progress of India's IT industry. A bundle of factors or forces are always remaining behind every success. In case of India's IT industry also occurred the same situation. Through research it has been observed that there are several different factors lying behind India's success that enable India's IT industry to gain competitive advantage. Now the question is what is meant by competitive advantage? Competitive advantage can be described as the unique position of an organization or a region which develop a relative competition among its competitors. According to Michael Porter, "The competitive advantage theory not only considers the factor endowments such as human resources, physical resources, knowledge resources, capital resources or the infrastructure inherited by organizations industries or regions, but also it emphasizes how these factors are creating and upgrading consistently". Thus competitive advantage becomes sustainable when it resists erosion by competitive behaviour and when the resources and capabilities enhance its market opportunities [5].

So let us see those factors that makes India's IT industry so competitive are as follows:

- ◆ Governmental incentives
- ◆ Human resources
  - *Low labour cost*
  - *Brain circulation*
- ◆ Clustering
- ◆ Outsourcing
- ◆ Time difference

Thus we can say that all these above mentioned number of factors seem to be propelled India to maintain the position of a dynamic IT player in the world.

**Governmental Incentives**

Under governmental incentive it has been observed that Government of India (GOI) has taken a major step towards promoting the domestic industry to achieve the full potential of the Indian IT entrepreneurs through venture capital by the formation of a new ministry for IT. It is necessary to highlight some major activities of GOI that open our eyes that what GOI is doing to make India's IT to be successive. As an example we can say that to promote the Indian IT industry, the Government has set up a National Task Force on IT and Software Development to examine the feasibility of strengthening the industry. The Government of India is also actively providing fiscal incentives and liberalizing norms for Foreign Direct Investment (FDI) and raising capital abroad. Recently, an IT committee was set up by the Ministry of Information Technology, Government of India, comprising Non Resident Indian (NRI) professionals from the United States to seek expertise and advice and also to step up U.S. investments in India's IT sector. Government of India is stepping up the number and quality of training facilities in the country to capitalize its extraordinary human resource. It is estimated that India has over 4 million technical workers, over 1,832 educational institutions and polytechnics, which train more than 67,785 computer software professionals every year that helps the Indian economy to sustain higher rate of growth and the policy makers are fully aware of this achievements [6].

**Human Resources**

Another important force or factor for the rise and growth of IT industry in India is human resource that we must agree, which is also a great advantage of India. As we all know that the international competitiveness of a firm mainly depends on its backbone, i.e. strength of human resources to respond and to face the competitive pressures in international markets that already exists in India.

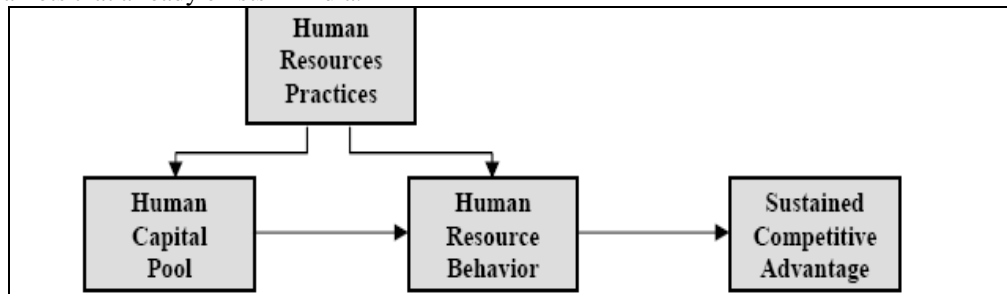

FIG.1: A MODEL OF HUMAN RESOURCES AS A SOURCE OF SUSTAINED COMPETITIVE ADVANTAGE [7].

From the above mentioned Fig. 1 we can have a look that in India how Human Resource (HR) is adding value to the business houses through its large pool of human capital, human behaviour that lead India towards competitive advantage. Explicitly, it ensure the presence of competent employees that enable an enterprise, i.e. IT industries in India to build its competitiveness that motivate those employees concerning to their development.

**Low Labor Cost**

According to resource-advantage theory of Hunt and Morgan [8], a firm strives for superior financial performance by enabling its resources to capture a position of competitive advantage in a certain market or market segment. This position is captured if two conditions are satisfied: (1) if the firm can creates more customer value than competitors do, and (2) if the firm has lower investment costs than competitors. In the case of India's IT industry this two conditions were satisfied and facilitate India to gain the competitive advantage.

The low labor cost appears to be the most convincing factor that worked in favor for the progress of India's software companies. From a global perspective, it can be said that salary levels in India are comparatively lower than in Western nations which is also benefiting India to achieve success. Research shows that he entry level of professionals in India are amongst the lowest (if not the lowest paid) in the Asia Pacific region. Research shows that India has a vast pool of talent comprising educated and computer literate personnel, where every year approximately 9.1 million students are enrolled for tertiary education in India. However, recruiting the right candidate for the right job remains a challenge [5].

### Brain Circulation

India has also benefited in great deals from immigrants of Indian origin who had pursued technological careers in developed economies. This brain circulation not only helped in transfer of technology through movement of the skilled personnel or through the companies they helped and start, but has proved to be a unique factor for the development of this sector [5].

### Clustering

According to Porter, “an industrial cluster is a set of industries related through buyer-supplier relationships, or by common technologies, common buyers, common distribution channels, or by common labour pools.” Such type of relationship leads to improve the efficiency and international competitiveness of micro small and medium enterprises (MSMEs). Porter claims that clusters have the potential to affect competition in three ways [9]:

- By increasing the production of the companies in the cluster.
- By driving innovation in the field.
- By stimulating new business in the field.

In general cluster has three kinds of embedding. Namely: *Institutional embedding* relates the impact of regulation and norms of conduct, taxes, subsidies, legal system, infrastructure, schooling, research and labour market. *Structural embedding* relates the features of networks, density, centrality and the stability of the structure i.e. the rate of entry and exists. *Relational embedding* relates the social network to build the linkage between one firm and another that strengthen the ties, bonds and alliances of the inter-organizational relationships [10]. Clustering is also another important aspect behind the success of India’s IT industry. On the other hand it can also be said that clustering is a part of networking. Clusters are defined as concentration of activities belonging to the same sub sector. So without any hesitation we can consider the presence of cluster in India is also another major driving force, that has a great influence behind the success of India’s IT industry.

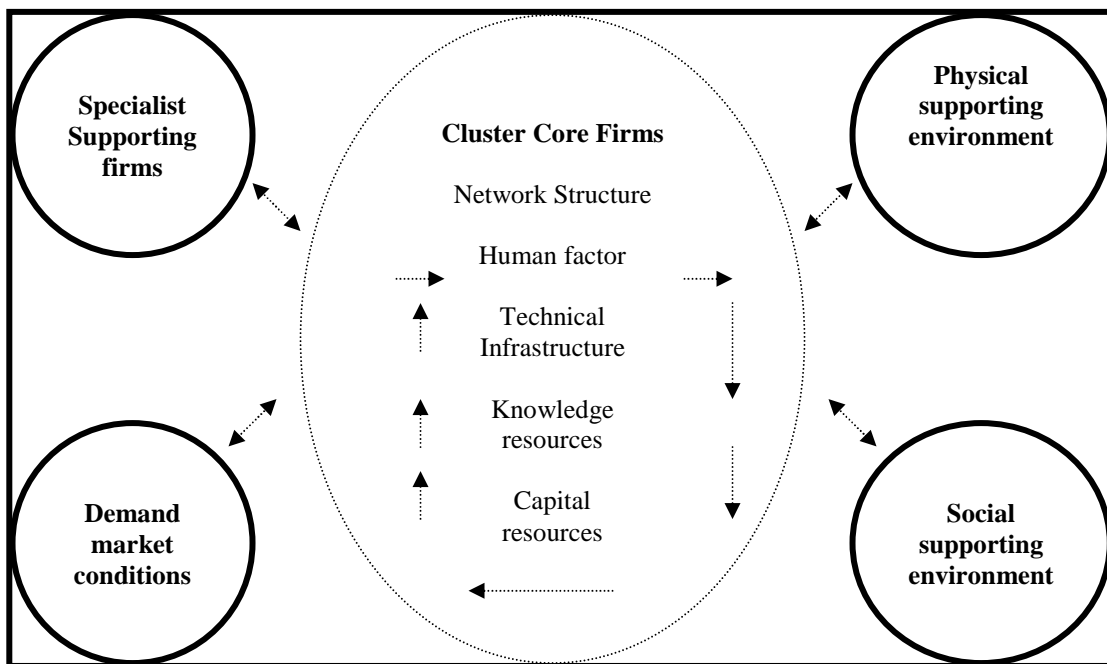

FIG. 2: THE INTEGRATED MODEL OF CLUSTER MAP [1]

The above mentioned Fig. 2 is an example of main driving forces of a cluster that facilitate the IT industries in India. Basically a *cluster core firms* has five main factors i.e., *the human factor, the technical infrastructure, the network structure, capital resources and knowledge resource*, which become more competent with the existence of certain supporting conditions like (a) specialist supporting firms, (b) physical supporting environment, (c) social supporting environment and (d) demand market conditions that has a great impact on innovation and competitiveness of firm's management. These five "balloons of competitiveness" are interrelated. Each of them measures the competitiveness of a firm. Each condition has a close inter-relationship between them to make an efficient and effective firm [1].

#### **Outsourcing**

Outsourcing is another aspect of a new business model and undoubtedly a business niche that is an advantage or plus point for India, which leads India to face the competitive world. A survey conducted by Sobol and Apte in 1995 [5], revealed that a significant proportion of the US companies had outsourced at least one of their information system function to a domestic provider, i.e. India. India's outsourcing business is based on the country's decade old experience in this area, i.e. the fluency in the English language, supportive government policy infrastructure, and high quality offerings.

#### **Time Difference**

Time difference between the clients and the service providers in India added a round-the-clock proposition to the business and reduced total cycle time. With the advancement of telecommunications infrastructure in India, the software developers in the US and Europe could send application specifications to India at the close of their business [5]. And then the Indian programmers start working on the same program on the other side of the world and delivered the code before the US developers could resume work the next day. This needs to be counted for the sustainability of IT industry in India.

In a nut shell we can say that the above mentioned all facts and figures enable us to give a clear vision about the driving forces that enable India's IT industries to be competitive. Observing all these situations government of India (GOI), took the initiation to build and create an enabling environment to enhance the emergence of IT cluster in India especially in Bangalore.

### **Bangalore IT Cluster: Case Study**

The rise of the Bangalore IT cluster is a concrete example of the success story of IT industry in India that guaranteed us the possibilities of India's IT industry will be more competitive. Bangalore have some positive externalities that were generated by agglomerations through the availability of (i) skilled labour and inputs; (ii) certain types of infrastructure; and (iii) innovation generating informal exchanges that makes Bangalore a special hub of IT industries (Fig.3) that enable India to sustain its IT industries.

This process of networking and clustering contribute to the competitiveness and growth of the "participating" firms in Bangalore. Industrial clustering in India has a number of benefits like: rapid interchange of information and knowledge (about best practices, about market opportunities), locational economies (it is cheaper to provide infrastructure to a cluster of software firms than to the same number of firms that are scattered), and a raised marketplace profile [11].

FIG.3: SPECIAL HUB OF IT INDUSTRIES IN INDIA [12]

Research shows that GOI has taken the initiative for IT industry in Bangalore by creating a special group. Where the group will [6]:

- Monitor global IT developments and refine Indian IT policy to meet global requirements.
- Promote the growth of human resource development in the IT sector with the aim of creating quality-based education;
- Promote R&D in the sector by identifying thrust areas and drawing up a blueprint for action.

On the other hand from the clustering point of view research shows that 40% of country's industrial output and over 30% of direct exports goes through clustering, the rise of Bangalore IT cluster has become successful. So we can say once again that the above mentioned factors like clustering are really enhancing the sustainability of IT industries in India.

The ICT cluster in Bangalore, India has also attracted much research and media attention as it is often referred to as the Silicon Valley of India, where it boasts over 1500 IT firms like Infosys, Wipro, Texas Instruments and Hewlett Packard [13]. Hence from the above mentioned discussion it shows that around one third of all India's software exports are from the city of Bangalore that open our eyes how India is taking the upliftment with the existence of cluster. Above mentioned brief picture of Bangalore will clear our ambiguity and ensure how it will be possible for India to be more competitive and successive.

### How India's IT Industry will become more Competitive?

We have already discussed in our earlier part of this article about the factors and driving forces behind the success story of India. Now the question arises is it possible for India to be more competitive with those above mentioned motivating factors? If so, then how? This study allows us to ensure that yes it is possible for India to become more competitive with those motivating factors by following ways as follows:

1. Building networks and reducing the cultural difference
2. Building and creating an enabling environment by public policy

3. Linking multinational firms and large private firms:
4. Linking the relationship between Academy and Industry
5. Inter and Intra-Cluster linkages

#### **Building Networks and Reducing the Cultural Difference**

Study shows that building networks enables a firm to be competitive and on the other hand it also reduces the gap of cultural differences. For example in India it has been observed that the talented and skilled immigrants who have studied and worked abroad, while back home they transfer not only technology and capital but also their managerial skills and institutional know-how. They try to link the local producers directly to the market opportunities to enhance the networks and reduce the cultural barriers. As a result in India that many entrepreneurs have started companies like Mastech, Syntel and Information Management Resources (IMR) in U.S. that relied on Indian programmers to provide support to the domestic clients. Bangalore IT industry is an example discussed in earlier part of this article where there are 71 to 75 multinationals in Software Technology Park (STP) were headed by Indians who lived and worked overseas.

#### **Building and Creating an Enabling Environment by Public Policy**

Public policy means the role of government's initiative is one of the main and most important criteria that will benefit the IT industries in India. As like Bangalore if GOI will take the same or more initiation like (i) establishing number of universities, institutions and colleges; (ii) trade protection and liberalization for exports and export – oriented foreign investment; (iii) set-up electronic parks and infrastructure to meet the demand at an international level one day obviously India will be more competitive. Government must take initiative for creating a physical supporting environment, modern and diverse transport systems and advanced technical communication systems other than Bangalore to facilitate the India's IT market.

#### **Linking Multinational Firms and Large Private Firms**

In earlier part of this article we have already mentioned about the various activities of cluster that enhance a firm's competitiveness where small firms can get in touch with the large firms. As result small IT firms in India have started to offer their workforce on project basis to the large firms in an arrangement of contact basis. Such as System Logic, Datacons Pvt. Ltd, Intertec Communications and Nataraj Technologies are lending a part of their workforce to the multinational firms as Texas Instruments (TI) Hewlett Packard (HP), Robert Bosch to get the work done efficiently and effectively within a short period of time. Thus we can say that this is also another way how India can be more competitive to get the optimum level of outcome and to sustain in the long run.

#### **Linking the Relationship between Academy and Industry**

Another important aspect to be more competitive is to link the relationships between the academicians and the industrialist to uphold the performance of IT industries, which is possible through clustering. In our earlier study we have seen that India has a large pool of knowledgeable manpower, so government should take initiative to open more institutions and technical universities near to the Software Technology Park (STP) complex or in other parts of India. So that fresh candidates can easily absorb in the professional field and provide their modern knowledge and skills to the industries. It has been observed that academia-industry linkages in Bangalore make Bangalore a special hub of IT industries.

#### **Inter and Intra-Cluster Linkages**

Inter and Intra-cluster linkages of India's IT cluster also build a strong relationship among the same category of firms. It is to be noted that Bangalore IT firm has a close network system within India and even outside India that boost the social as well as the political stability in India to avoid labour conflicts, to establish a techno park, improving the physical infrastructure [11,13 -14]. As result we have seen IT cluster in India derive more benefits due to their proximity with customers and suppliers. So we can say that the above mentioned different paths can facilitate India to be more competitive. As Bangalore IT cluster is a special reference of all these above mentioned paths.

## **Conclusion**

Finally we can conclude that above mentioned all factors and ways are the means how India is progressing to sustain in this dynamic world with the help of various above mentioned factors specially with government incentives, with its large pool effective and efficient manpower and with clustering that broaden the scope of networking of IT industries. It gives us an insight about the competitive advantage of India's IT industry. It necessary to say that cluster in India represent a new way of thinking about national, state, and local level that provides a new role for companies, government, and other institutions for enhancing the competitiveness of a firm. India's IT industry is not exception of it.

Though we have viewed in our previous discussion that how India's IT industry is moving forward, but it is also need to keep in mind that nothing in the world remain static so to keep pace with the ever changing world GOI must keep its eye open and develop more network and effective cluster based firm to reach every corner of the world. To maintain and to uplift the India's present status certain things need to be taken into account such as:

- Human capital that determines the growth of every industry. Without the creation of high quality human capital, other advantages are not going to be of much helpful. Government of India must invest more to build high quality educational institutions for high quality personnel.
- Location is also a positive aspect of any industry. As we have seen due to locational advantage Bangalore becomes a hub of IT industry. So government of India should also search for another new location which will be suitable for building another software technology park like Bangalore.
- Technology is also another important aspect that plays a vital role. Government of India must invest more on research and development for technological upgradation and to keep pace with the changing environment.
- Ultimately, despite locational advantages, what matters is quality. It has to be remembered the largest concentration of IT companies in the world are in locations like Bangalore with the highest level of quality certifications.
- Last but not the least it might be good to create a competition among different IT clusters in the same country. Most of the IT clusters in India are viewing with each other in attracting new startups. Thus the local governments are prodded further and further to have ever increasing proactive roles which has immensely benefited India as a whole

# Intelligent Information Processing for Educational Funding Institutions

Nooraini Yusoff, nooraini@uum.edu.my  
Fadzilah Siraj, fad173@uum.edu.my  
Universiti Utara Malaysia, Malaysia

## Abstract

There are number of educational funding institutions such as PTPTN, JPA, MARA and state institutional bodies (SELO) that support learning of higher education in Malaysia with loan or scholarship to students for their allowances and fees. In every intake, the funding institutions have to process, screen and approve loan applications. For this purpose, several processes and decision makings are required for ensuring loans or scholarships are granted to an eligible student with a sufficient of amount. The funding institution usually employs loan officers to make credit decisions or recommendations for that particular institution. These officers are given some hard roles in processing and evaluating the worthiness of each application. As the number of applications increases every year, the loan processing and approval tasks have become more challenging and difficult especially for the funding institutions which are still practicing manual or semi-manual processing. In addition, due to inefficient filing system, some funding institutions face a problem in tracing back the higher learning leavers for payment back purpose. As a result of interviews, observation and analysis, this study suggests the educational funding institutions to employ a web-based intelligent information system that integrates 3 systems, namely web based office automation system, knowledge-based system and artificial neural network. Hence, with integration of those three systems, the institution would be able to improve its services and reduce the time, cost and manpower to manage loan application process.

## Introduction

Loan or scholarships are required in supporting the teaching and learning of higher education. Certain amounts of fund are given to students for their allowances and fees, thus learning institutions can provide more facilities for a well conducive learning environment. Nowadays, there are number of institutions that offer loans or scholarships including PTPTN, JPA, MARA and state intuitional bodies. Prior to mortgaging loan or scholarship, a few processes and procedures are required for ensuring loan or scholarship are granted to an eligible student with a sufficient of amount. The institution usually assigns loan officers to make credit decisions or recommendations for processing and screening submitted application. These officers are given some hard roles in evaluating the worthiness of each application. As the number of applications increases every year, the loan processing and approval tasks have become more challenging and difficult especially for the funding institutions which are still practicing manual or semi-manual processing. This may delay the loan or scholarship payment for students of higher learning institution. In addition, due to inefficient filing system, some funding institutions face a problem in tracing back the higher learning leavers for payment back purpose.

In improving routine office tasks that include data processing and reporting, a number of applications have been invented such as Microsoft Word, Access and Spreadsheet. In addition, various information systems also developed to meet specific organization's needs. Nevertheless, today's demands are not only for documenting and reporting, most of organizations' tasks deal with decision-making which some decisions that may require the presence of experts in the domain. For office tasks automation purposes, existing information systems are useful in summarizing data, processing data to information and representing diagnostics information but it lack of prediction and explanation capability which some organizations might need this facilities to answer questions such as why did July's sales drop down? or can sales be increased next month?, and what is the characteristic of students enrolled in this May or what types of student will be registering next May?. The answers can only be provided by the experts in that particular domain who have years of experience to predict and explain certain occurrences.

Hence, one of the principal courses of action in making modern automated systems of the organizational-information type more efficient is to lend them a measure of intelligence (Kozichev, 2004). This means that in

addition to the usual functions of collecting, storing, accumulation, searching, processing and transmission of data, information systems should also include analysis, advisory and forecasting facilities which form the basis of intelligent information systems (IIS). IIS consists of knowledge base, database, and model base (Potter, Somasekar, Kommineni & Rauscher, 1999). The model base includes decision support models, forecasting models, and visualization models that require appropriate techniques.

On the other hand, the needs to mimic or replicate human thinking processes have motivated the research in Artificial Intelligence (AI). The capability of AI techniques in predicting, diagnosing and advising has made AI becoming popular. A number of AI techniques have been integrated into various information systems including Knowledge-based Systems (expert systems) (KBS), Fuzzy Logics and Artificial Neural Network (ANN).

In this study, an integration of web-based office automation system and AI techniques specifically knowledge-based system and ANN is proposed. Web-based automation system can assist both applicants and management in performing loan application processing, while the AI techniques can be as helpful tools in loan approval decision making.

#### **Intelligent Information Processing**

Information systems can be defined as computer-based systems which access a variety of computer-stored or generated base data, and select and process that data to provide specific information to aid management in their routine tasks (Mahling, Craven & Croft, 1995). However, in the computing tasks needed to support higher levels processing such as analysis, decision support and forecasting, artificial intelligence techniques are essential, since the regularity appropriate to algorithmic approached is typically lacking in ordinary information system. Due to this, a number of AI techniques have been integrated with information systems in various domain that such system known as intelligent information system.

Among discussed IISs include Qiang, Bing and Yijun (2005) that incorporated artificial neural network technique specifically Amnestic Neural Network, which simulates human cognitive behavior of forgetting, to solve the problem of cross-temporal data selection. The effective of Amnestic Neural Network was tested by the application on stock price prediction experiment in the stock market of China. Meanwhile, Patel and Ranganathan (2001) integrated ANN, KBS and Fuzzy Logic for intelligent control of urban traffic that is important in providing a safe environment for pedestrians and motorists. The performance of the proposed IIS was evaluated by mapping the adaptable traffic light control problem. The results of extensive simulations using the three approaches indicate that the integrated system provides better performance and leads to a more efficient implementation. For similar integration, Weiren, Lixu, Li and Xin (2003) had also employed ANN, KBS and Fuzzy Logic in evaluating the potential public works based on both quantitative and qualitative factors to assist the decision makers to make the right decision for the sake of providing the government with an optimal prediction.

In medical domain, Liping and Lingyun (2005) discussed the use of ANN, KBS and Rough set integrated in IIS specifically for prognosis of coronary artery disease. The system correctly classified 83.75% of the testing set at a tolerance level of 0.25, and 85% at a tolerance level of 0.30. In another application, Lin, Yurong, Yanhui and Hong (2006) presented web based intelligent system for spare parts joint replenishment in a nuclear power plant. They integrate the artificial neural network and gene algorithms-based spare parts criticality class identifying system to confirm the target service level, and the web-based joint replenishment system to obtain reasonable inventory control parameters that can be helpful for reducing of total inventory holding costs. The proposed IIS was successful in decreasing inventories holding costs significantly by modifying the unreasonable purchase applications while maintaining the predefined target service level.

Since in educational loan processing tasks require the use of forecasting and advising techniques, there is a natural tendency to integrate artificial neural network and knowledge-based technique techniques with web based office automation system that such integration can be beneficial to assist the decision maker in making decisions regarding loan application. ANN provides a means for discovering the relationships in historical data, while ensuring those relationships discovered will generalize to the future data. In addition, knowledge based system supports the management by performing reasoning that can provide decision explanation which ANN is not good at this due to its "black box processing" mechanism. This integration is useful in assisting loan officers of educational funding institutions to determine whether to accept or reject an application.

## Background and Motivation

In general, application for loan or scholarship is announced in every academic term each year. A funding institution announces the release of the application form via newspaper and or media, but there are still institutions that require applicants to go to the main office to get and to return the application form personally with an amount of price.

Starting from the submission, funding institution staffs will collect all the application forms and calculate the merit for each complete application form. Merit is given by accumulating the total mark for each applicant based on the criteria defined by the institution. The range of merit that indicates the eligibility of the applicants is determined by each institution. The list of eligible applicants will then be tabled in the institution committee board meeting. In the meeting, the number of applicant selected is based on the quota allocated for each public and private university. For the number of applicant that is less than the university's quota, the applicant will be selected based on the rank of merit. Once the approved applicants are selected, the offer letters and the agreement will then be posted to them. When the acceptance letters are received from the applicants, their profiles will be stored in files for further use. The application process will take about couple of months, starting from the submission of application up to listing out those approved applicants.

From the managerial point of view, every application of loan needs to be processed and revised for every criteria defined by particular funding bodies. As number of applicants increases year by year, the application processing has become challenging and difficult, which creates problems when most of the processes are still done manually with no systematic filing system and database. Instead of using hardcopy form, a few managements have moved to online form for the application purposes (Kozichev, 2004; Jingtao & Chew, 2001). This may reduce the task of encoding and storing applicants' information into a database. However, evaluation to select or shortlist applicants are still consuming more time as number of application increases every year.

In addition, any funding institutions that are still practicing manual merit system will have more workload as number of applicant increases. The approval of any loan or scholarship is time-consuming as the evaluation is done manually based on human judgment. There was an issue due to qualified student were not granted applied loan or scholarship. This could be due to inconsistency in judging the loan or scholarship. Inefficient file system also could create problems in tracing the student's status for the payment back purposes. This issue had also been raised in our media that reported the funding institutions are facing problems regarding loan payment back by the graduated students. In addition to student unawareness of this issue, the inefficient of file system also contributes to the same problem.

With the rapid evolution of electronic technology, information systems were developed that provided for the storage, manipulation, computation, reporting, and transmission of large amounts of information (Baker, 1996). These information systems were designed as a single piece of stand-alone equipment or as a work station or terminal linked to a mainframe, mini-computer, or local area network. Nowadays, information systems are integrated with AI techniques to provide facilities that require intelligence as most organizations are constantly faced with making important decisions and almost always uses prior knowledge or experience in determining them. In addition, the necessity to solve problems of practical nature and size, always arrive at correct solutions, and adapt to the changes in the application environment are the main reasons AI techniques have been applied in various domains. There are two common approaches for intelligent information system, one based on learning systems, such as the ANNs, and the other based on knowledge-based systems. In a learning system, the decisions are computed using the accumulated experience or knowledge from successfully solved examples meanwhile in knowledge-based system, decision is based on stored rules captured from the domain expert (Patel & Ranganathan, 2001).

During knowledge acquisition, the knowledge base is formed with the aid of an expert interacting with a knowledge engineer. The knowledge acquisition process consists of subtasks that include knowledge extraction, formal representation of knowledge, coding and validation. Since the quality of knowledge representation affects the efficiency, speed, and maintenance of the system, the method of knowledge representation is critical. The choice is usually limited by the application domain, the preferences of the knowledge engineer, and the expert. In learning systems such as ANNs, the knowledge acquisition task is performed by the training process. However, the training

process, in most cases, is a time-consuming task requiring the application of input training patterns in an iterative manner (Sima & Cervenka, 1998).

An important aspect in intelligent information system design is decision explanation, which involves supplying a coherent explanation of its decisions (Kasabov, 2002). This is required for acceptability of the solution and correctness of the reasoning. The knowledge-based systems can explain the reasoning process by evaluating the trace generated by the inference engine or by analyzing the rule base (which typically use IF THEN rules). In learning systems such as ANNs, knowledge is represented in the form of weighted connections, making decision tracing or extraction difficult. Thus, using an ANN or a knowledge-based system approach to intelligent information system leads to different levels of performance depending on the model as well as the application. By integrating the two approaches, it is possible to overcome the deficiencies associated with using a single approach.

### Knowledge Based Systems

Knowledge-based systems (KBS) (Fig. 1) use human knowledge to solve problems normally requiring human intelligence. The aim is to model and implement human expert knowledge. A knowledge-based system can act as a human expert in diagnosing and troubleshooting of certain problem. Due to this, most of the KBSs developed are concentrating in advising that the main purpose is to automate such facility as well as to provide consistent decision. In addition, the deployment of the KBS may also be able to assist the administrative in decision-making, thus to succeed they should possess performance at the same level as the human expert.

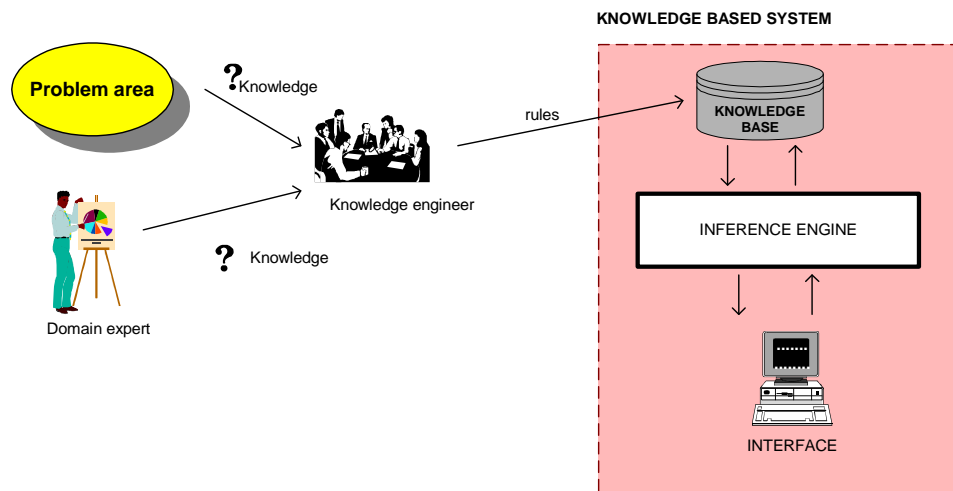

FIG. 1: KNOWLEDGE BASED SYSTEM

Among researchers that discussed the use of KBS include McGowan, Gleeson & McGowan (1998) that highlighted “expert” admissions system that was developed to screen and evaluate applicants’ information (e.g., undergraduate college, grades on specific courses, etc.) for American Medical College Admission. In addition, Harlan (1994) also proposed the Automated Student Advisor, a KBS that provides the user with an accurate picture of the progress a student has made towards graduation and to assist in selecting courses for the upcoming semester. Meanwhile, McAninch (1998) proposed Principia Student Advisor, an expert system for advising on course prerequisites, all college requirements and off campus study program of Computer Science majors at Principia College. As an advisory system, KBS has the capability to explain and justify the “why” and “how” certain decision is inferred. These are suchalso systems that have been used in industry and finance (Pomykalski, Truszkowski & Brown, 1999), and government (Shrobe, 1996)) for many years.

### Artificial Neural Networks

With the advent of modern computer technology and information science, sophisticated information systems can be built that can make decisions or predictions based on information contained in available past data. Such systems are called learning systems and are currently used for the purpose of classification and prediction (Principe, Euliano & Lefebvre, 2000). ANN are popular AI techniques for classification and prediction problem.

An artificial neural network system is an artificial intelligence model that replicates the human brain's learning process. Tsoukalas & Uhrig (1997) define a neural network as: "A data processing system consisting of a large number of simple, highly interconnected processing elements (artificial neurons) in an architecture inspired by the structure of the cerebral cortex of the brain."

In an artificial neural network, a number of inputs, or attributes, and their corresponding outputs, or classes, are given. A training algorithm uses these sample inputs, called the training set, to design a decision function that can accurately predict the class for any sample thereafter. The algorithm response is compared to the actual response to determine how well the classifier performs (Barker, Trafalis & Rhoads, 2004).

Nodes are used to represent the brain's neurons and these nodes are connected to each other in layers of processing. Fig 2 illustrates the three types of layers of nodes: the input layer, the hidden layer or layers (representing the synapses) and the output layer. The input layer contains data from the measures of explanatory or independent variables. This data is passed through the nodes of the hidden layer(s) to the output layer, which represents the dependent variable(s). A nonlinear transfer function assigns weights to the information as it passes through the hidden layer nodes, mimicking the transformation of information as it passes through the brain's synapses. The goal of the artificial neural network model is that the effect of these weights will result in a response that is equivalent to the response that would result from the relationship that really exists between the input independent variables and the output, or dependent, variable(s).

FIG. 2: NEURAL NETWORK ARCHITECTURE

In contrast, a traditional knowledge-based system would have rules encoded within it that a designer has previously identified. The advantage of artificial neural network systems is that it is not always possible for a human designer to express and encode rules in a reasonable time-frame or even express them at all. A further disadvantage of knowledge-based systems is that if the rules change for some reason then it is necessary for the designer to reincorporate the new rules within the rule-base (Barker *et al.*, 2004)

Integration of artificial neural network had been discussed by Mullier, Moore and Hobbs (2002) that proposed an automated system for predicting the grade and the questions in a tutorial with minimal input from the human teacher. In addition, Cripps (1996) discussed the use of artificial neural networks to predict degree program completion, earned hours, and GPA for college students. Carlson (2000) also proposed the deployment of artificial neural network to predict which applicants are likely to enroll at Hopkins College. The use of artificial neural network also may be able to help administrators with a variety of other planning chores, such as precisely predicting the demand for student services, or estimating how much space on the campus to devote to which uses.

Another applications of ANNs found in literature also include in business (Hanke & Reitsch, 1998; Hall, 2000; Siraj, Zakaria, Ab Aziz & Abas, 2003), economy (Siraj & Junoh, 2002), financial (Kaastra & Boyd,1996; Perez,1999; Surkan, 1999; Siraj, Zakaria, Yasin & Ishak, 2000; Jingtao & Chew, 2001), and education (Whitson, 1999; Carlson, 2000; Mullier,2001; Gonzalez & Des Jardins, 2002; Siraj &Asman, 2002; Siraj & Rahman,2003; Siraj & Sudin, 2003; Yusoff & Siraj, 2006; Barker, 2004).

### Intelligent Information System for Educational Funding Institution

In improving the capability of information system this study suggests funding institutions to integrate two AI techniques namely, knowledge-based system and artificial neural network. In essence, the potential use of such a system can be accelerated to promote any organizations as an efficient and effective organization that has competitive advantage. Fig. 3 illustrates the intelligent information system.

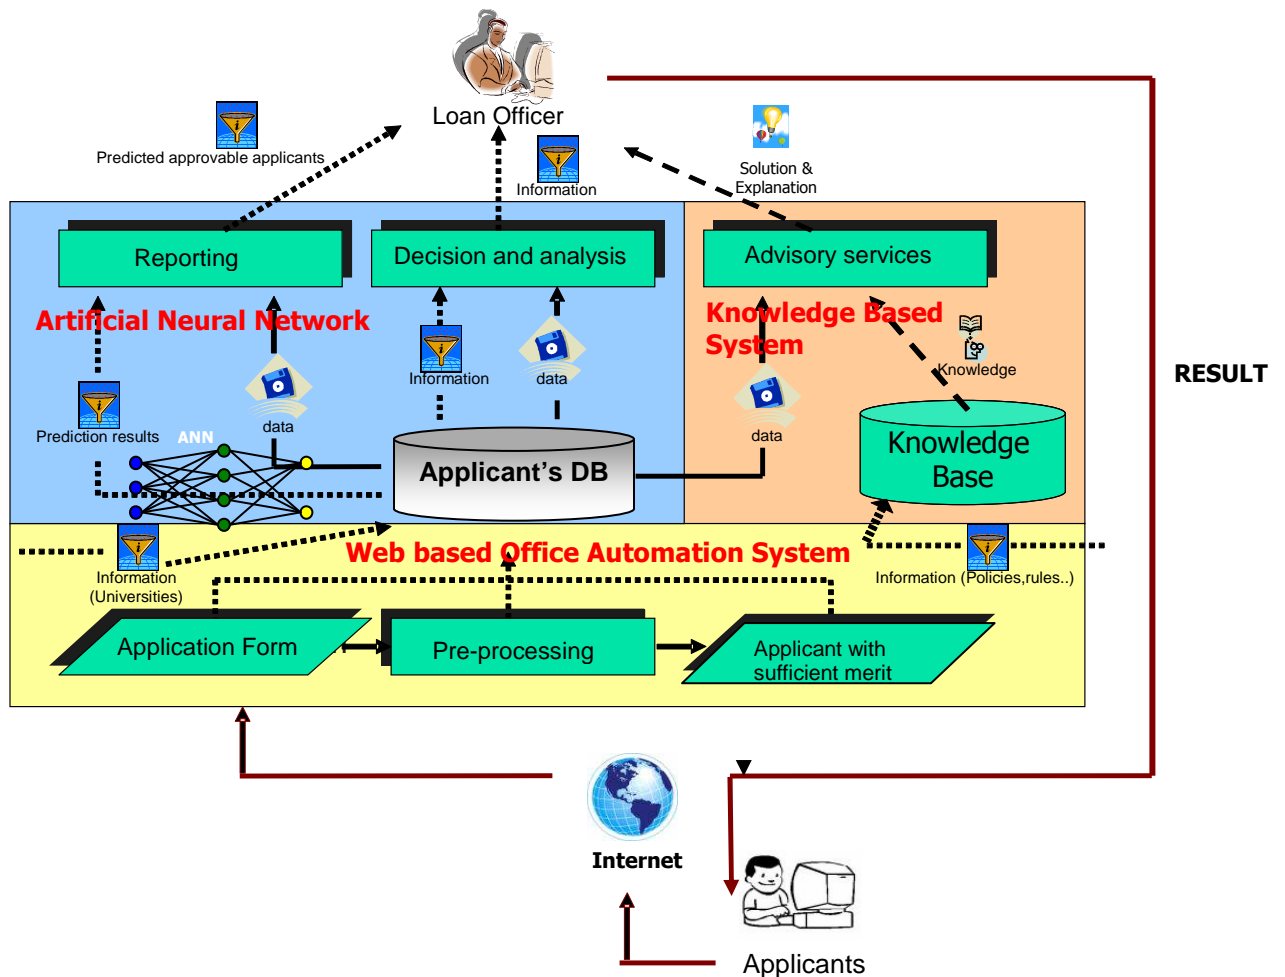

FIG. 3: INTELLIGENT INFORMATION SYSTEM FOR EDUCATIONAL FUNDING INSTITUTIONS

As depicted in Fig. 3, the proposed intelligent information system comprises 3 main subsystems; Web based Office Automation System, Knowledge-based System and Artificial Neural Network.

#### **Web-based Office Automation System**

Web based office automation system can be implemented to ease the loan application access with some payment mechanisms such as online payment. The form application can filled up and submitted through online. As an application submitted, the information will automatically be stored into the system database. Before evaluation takes place, the merit calculation for each application can be done automatically whenever the management needs the information. Even the acceptance letter can be generated automatically. The stored information can accessed easily with some authorization procedures when the evaluation to be performed.

#### **Knowledge-based Approach**

The integration of knowledge based system can provide advisory services to the management in loan approval decision making. The system consists of rules that explicitly explain why an application is recommended to be accepted or rejected. In addition to knowledge-based system, artificial neural network system can help the management to predict which application to accept or reject. This can be done as ANN has trained previous batch of loan application data and stored association between application characteristics (attributes) that explains which applications were accepted and rejected. The association in previous data can predict the new current application data with same characteristic but no loan acceptance result (Garret & Leatherman, 2000; Baesens, Van Gestel, Stepanova & Vanthienen, 2003; Handzic, Tjandrawibawa & Yeo, 2003).

#### **Artificial Neural Network Approach**

In this study, the NN approach involves 2 main processes that include data training and prediction. Data training involved in obtaining a set of weight coefficients ( $[v]$  and  $[w]$ , see Fig. 4) from historical data collected earlier. The sampling consists of 1062 records of previous loan application from Lembaga Basiswa Negeri Kedah (LBNK), one of the state educational loan bodies that have been accepted and rejected. Many of the questions found on the survey closely resemble student attributes appearing in the LBNK's loan application form and other educational research. The data set consists of respondents' academic, demographic, and socio-economic backgrounds have been identified as the number of input nodes in the input layer. The target output or the classification variable is divided into two categories of loan application status, reject or accept. The collected data was pre-processed and cleansed prior to training. The result from training indicates that ANN obtained 99.06% prediction accuracy.

Once training is completed, the web based prediction module is able to predict the status of an application (accept or reject) using a feedforward Neural Network algorithm. The algorithm uses the weight obtained from the training process and also the Binary Sigmoid Function (as 1) to predict the educational loan application status.

$$\text{Application status, } y_k = 1/(1 + \exp^{-y_{\text{in}}^k}) \quad (1)$$

Prior to predicting the application status, the user of the prediction system has to respond to some questions based on his/her academic, demographic, and socio-economic background. During the testing phase, 200 hundreds of applications can be processed and predicted the acceptance status in less than half an hour. The ANN process can be illustrated in Fig. 4.

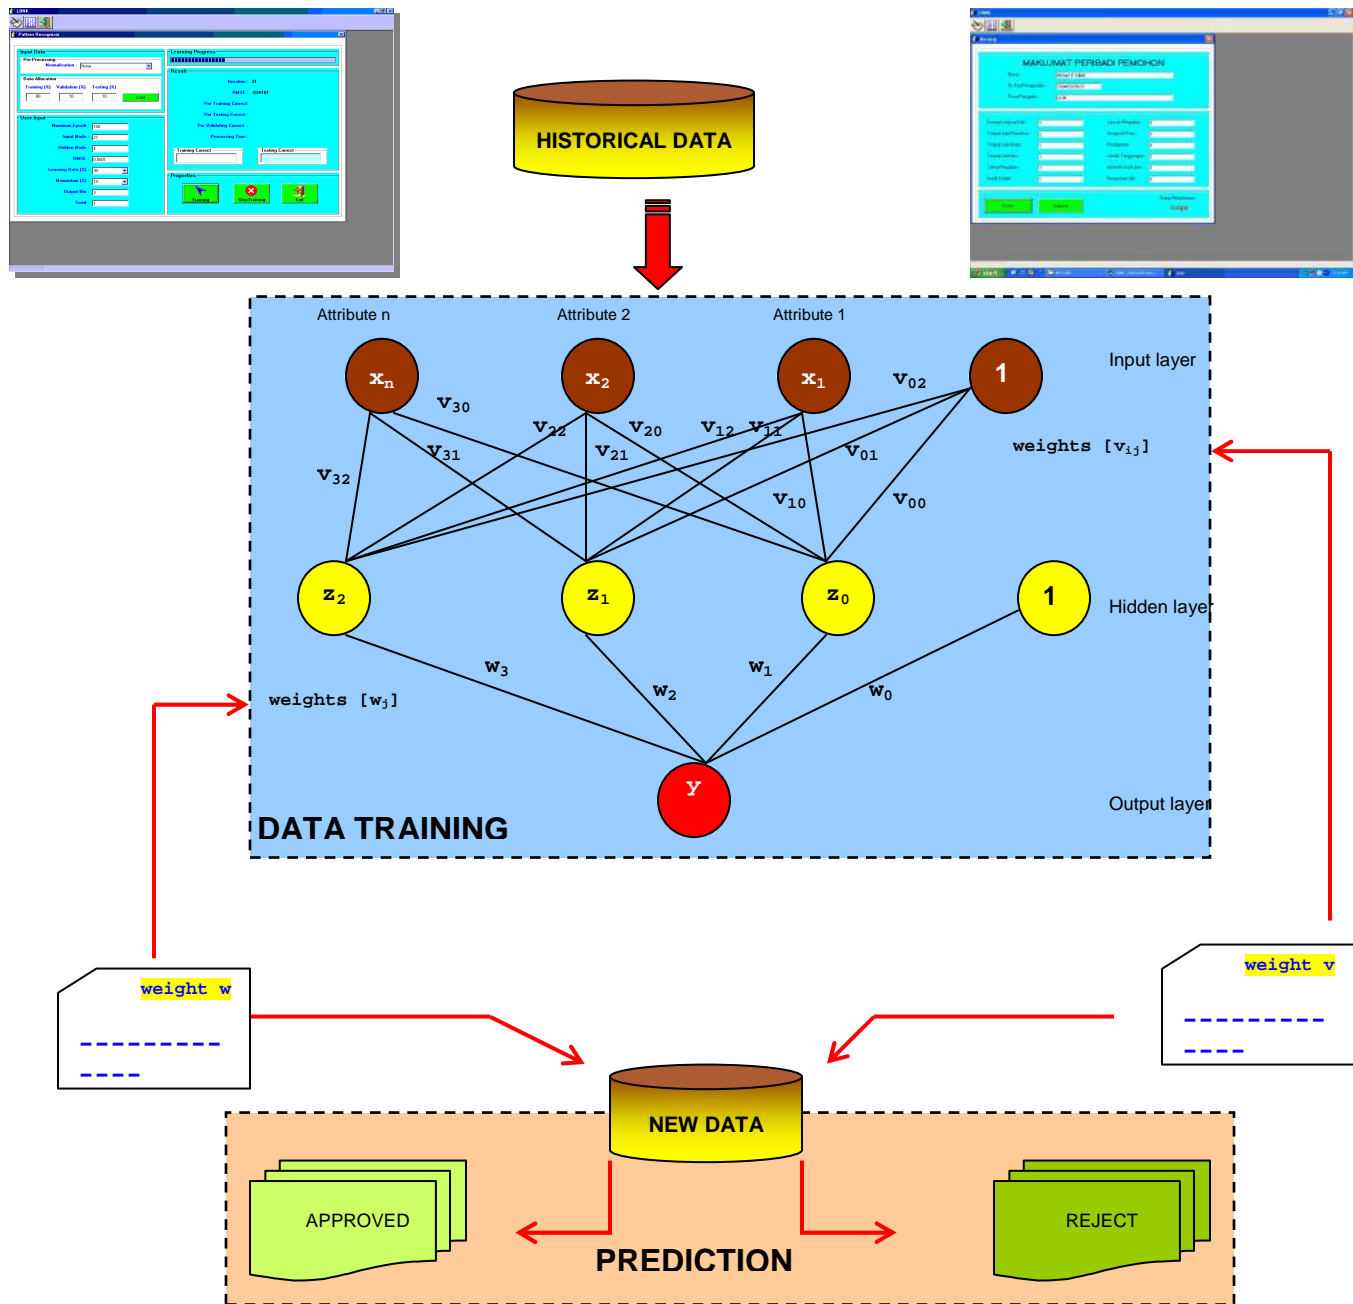

FIG. 4: ARTIFICIAL NEURAL NETWORK PROCESS

ANN and knowledge-based systems have been extensively explored as approaches for decision making. While the ANNs compute decisions by learning from successfully solved examples, the knowledge-based systems rely on a knowledge base developed by human reasoning for decision making. It is possible to integrate the learning abilities of an ANN and the knowledge-based decision-making ability of the KBS. Both knowledge-based and ANN system can assist the management in evaluating application. The management only needs to agree or disagree to the system recommendations and advices without reviewing each application one by one. All the information and explanation provided by system are based on human represented knowledge or previous loan application results. The proposed integration can be beneficial in reducing the time required for loan application processing and with efficient database management system, the information can be updated easily that can ease the process of tracing the graduated students for payment back purposes.

## **Conclusion**

This study focuses on loan or scholarship application processing, emphasizing on the information management perspectives, specifically the way the educational funding institution manages loan application processes. From the information management point of view, this study identifies several flaws in loan application processing. One of the apparent problems is the time taken for processing application forms. Since the number of staffs that have to deal with the applications is small, the processing time is bound to increase as the number of applicants increases from year to year. Therefore, the importance of automation system in loan application processing is undeniable. Consequently, once the automatization of the information system takes place, the paper-based management can be transformed into paperless management which form web based office automation system. In effect, the cost of providing application forms is reduced and the number of staff required is minimal.

However, as the result to overcome lacking in existing information system, an intelligent information system has been presented in this study. The system consists of web based automation system, artificial neural network and knowledge-based system. Web based office automation system is useful that it may ease the loan application process. The form application can be filled up and submitted through online. As an application submitted, the information will automatically be stored into the system database. For initial screening purpose, the merit calculation for each application can be done automatically whenever the management needs the information. ANN can be used to predict an application is to be accepted or rejected. This can be done as ANN has trained previous batch of loan application data and stored association between application characteristics (attributes) that explains which applications were accepted and rejected. From experiment of data training that had been conducted in this study, it was shown that ANN has achieved satisfactory result with 99.06% classification accuracy. The result indicates that ANN has strong potential as a forecasting technique in classifying educational loan application. Meanwhile the integration of knowledge-based system can provide advisory services to the management in loan approval decision making. The system consists of rules that explicitly explain why an application is recommended to be accepted or rejected. Nevertheless, the final decision is based on the management whether to agree or disagree with the system's recommendations.

By integrating this system into any funding institutions' systems, inevitably it can ease the decision-making for the institutions especially in the loan process application. This system can also assist in screening for eligible applicant. Hence, with integration of those three systems in funding institution information system, the institution would be able to improve its services and reduce the time, cost and manpower to manage loan application process.

## Abstract

Internet evolution has affected all industrial, commercial, and especially learning activities in the new context of e-learning. Due to cost, time, or flexibility, e-learning has been adopted by participators as an alternative training method. By development of computer-based devices and new methods of teaching, distance learning has been emerged. The effectiveness of such program is depended on powerful learning management systems. In this paper, a neuro-fuzzy approach is proposed based on evolutionary technique to obtain an optimal learning path for each learner. Therefore, the neural network approach has been applied to make personalized curriculum profile based on individual learner requirements in a fuzzy environment. **Keywords: e-learning, optimal path, distance learning, neuro-fuzzy**

## Introduction

Internet has significantly impacted the establishment of Internet-based education, or e-learning. Internet technology evolution and e-business has affected all industrial and commercial activity and accelerated e-learning industry growth. It has also fostered the collaboration of education and Internet technology by increasing the volume and speed of information transfer and simplifying knowledge management and exchange tasks. E-learning could become an alternative way to deliver on-the-job training for many companies, saving money, employee transportation time, and other expenditures. An e-learning platform is an emerging tool to corporate training. Employees can acquire competences and problem solving abilities via Internet learning for benefits among business enterprises, employees, and societies while at work.

Currently e-Learning is based on complex virtual collaborative environments where the learners can interact with other learners and with the tutors or the teacher. It is possible to give to the learner's different synchronous and asynchronous services. The former group includes virtual classrooms and individual sessions with the teacher or tutors. The latter group includes the classic didactic materials as well as Web-based seminars or simulations always online. These functions can be usually accessed by the means of software platforms called Learning Management Systems (LMSs). Among the other functions, the LMS manages learners, keeping track of their progress and performance across all types of training activities. It also manages and allocates learning resources such as registration, classroom and instructor availability, monitors instructional material fulfillment, and provides the online delivery of learning resources.

User and student modeling is a fundamental mechanism to achieve individualized interaction between computer systems and humans [Paiva, A., 1995]. It is usually concerned with modeling several user related issues, such as goals, plans, preferences, attitudes, knowledge or beliefs. The most difficult task in this context is the process of interpreting the information gathered during interaction in order to generate hypotheses about users and students behavior [Paiva, A., 1995], and involves managing a good deal of uncertainty. Interactive computer systems deal in general with more meager and haphazardly collected users' data than it usually happens when humans are engaged in face-to-face interaction [Jameson, A., 1996]. Thus, the gap between the nature of the available evidence and the conclusions that are to be drawn is often much greater [Jameson, A., 1996]. Numerical techniques have been employed in several cases in order to manage uncertainty, [Beck, J., Stern, M., Woolf, B.P.,

1997; Conati, C., Gertner, A., Vanlehn, K., 2002; Hawkes, L.W., Derry, S.J., 1996; Herzog, C., 2005; Katz, S., Lesgold, A., Eggan, G., Gordin, M., 1992; Lascio, L.D., Gisolfi, A., Loia, V., 1998; Panagiotou, M., Grigoriadou, M., 1995], and neural networks have been used in order to add learning and generalization abilities in user models and draw conclusions from existing user profiles [Chen, Q., Norcio, A.F., Wang, J., 2000; Harp, S.A., Samad, T., Villano, M., 1995; Magoulas, G.D., Papanikolaou, K.A., Grigoriadou, M., 2001; Mengel, S., Lively, W., 1992; Mengel, S., Lively, W., 1990; Posey, C.L., Hawkes, L.W., 1996; Stathacopoulou, R., G.D. Magoulas, M. Grigoriadou, 1999; Yasdi, R., 2000].

According to Self, [Self, J., 1991], student modeling is the process of creating and maintaining student models. It is divided into the design of two different but tightly interwoven components [VanLehn, K., 1988]: (1) the student model which, in its simplest form, is a data structure that stores information about the student; (2) the diagnostic module which performs the diagnostic process that updates the student model. Student models are distinguishing features of Artificial Intelligence, (AI), based computer-based instructional systems.

This work focuses on an application of student modeling in Intelligent Learning Environments (ILE). ILEs are considered as generalization of traditional Intelligent Tutoring Systems (ITSs), which are based on objectivist epistemology, and embrace instructional environments that make use of theories on constructivism and situated cognition [Akhras, F.N., Self, J.A., 2002]. Naturally, a ground for building student models for ILEs is provided by research conducted in the area of ITSs [Brusilovski, P., 1994]. The student model-centered architecture is also proposed for ILEs in order to support student driven learning and knowledge acquisition [Brusilovski, P., 1994].

Ideally, the student model should include all the aspects of student's behavior and knowledge that have repercussions for their performance and learning [Wenger, E., 1987]. In practice, the contents of the student model depend on the application. It includes learner goals and plans, capabilities, attitudes and/or knowledge or beliefs, and is used as a tool to adapt ILE's behavior to the individual student [Holt, P., Dubs, S., Jones, M., Greer, J., 1991]. Inferring a student model is called diagnosis because it is much like a medical task of inferring a hidden physiological state from observable signs [VanLehn, K., 1988], i.e. the ILE uncovers the hidden cognitive state (student characteristics) from observable behavior.

Evidence shows that human teaching is not based on fine-grained diagnostic behavior [Reusser, K., 1996]. In particular, studies in human tutoring have found little evidence to suggest that human tutors build detailed cognitive models as a basis for understanding student performance and adapting their tutoring strategy [McArthur, D., Stasz, C., Zmuidzinas, M., 1990; Putman, R.T., 1987]. More recently, researchers have tried to identify the constructs that tutors use to classify and discriminate among different students states for the purpose of adapting tutoring to student individual differences [Derry, S.J., Potts, M.K., 1998].

The neural network-based fuzzy model presented in this paper investigate the optimal path for a student in a distance learning educational system based on items such as capabilities, attitudes, knowledge level, motivation and learning style. Fuzzy logic is used to provide a mode of qualitative reasoning, which is closer to human decision making since it handles imprecision and vagueness by combining fuzzy facts and fuzzy relations, whilst neural networks provide a convenient way to achieve adaptability of the diagnostic process for reasoning and judgments.

## **Fuzzy and Neural Approaches to User (Instructor) and Student Modeling**

As already mentioned a variety of numerical techniques have been employed in user and student modeling systems in order to handle the imprecise information provided by the users, and reason under vagueness and uncertainty; a comparative review of techniques can be found in [Jameson, A., 1996]. For example, Bayesian networks have been successfully used to relate in a probabilistic way user's knowledge and characteristics with user's observable behavior. The key to success with all Bayesian network models lies in accurately representing the probabilistic dependencies in the task domain [Conati, C., Gertner, A., Vanlehn, K., 2002]. Fuzzy logic techniques have also been used for this task effectively. When considering the use of such techniques in a user or student modeling system, the addressed arguments do not concern in principle the question of whether or not fuzzy logic provides accurate or useful results by rather the usability of fuzzy logic techniques in the design of the specific system, in terms of

knowledge engineering requirements, programming effort, empirical model adjustment, computational complexity, human-likeness, interpretability and justifiability [Jameson, A., 1996].

One of the first attempts in using fuzzy student modeling has been made by Hawkes et al. [Hawkes, L.W., Derry, S.J., 1996]. In this context fuzzy logic has been proposed as a flexible and realistic method to easily capture the way human tutors might evaluate a student and handle tutoring decisions, which are not clear-cut ones. Clearly, the capability to deal with such imprecision is a definite enhancement to both ITSs and ILEs. This approach, which has been revised some years later [Hawkes, L.W., Derry, S.J., Rundensteiner, E.A., 1990], was used to evaluate students in a system called TAPS, and applied degrees of membership to linguistic labels that match student's solutions to "acceptable" solutions with the use of informal fuzzy reasoning.

Towards this direction, several other attempts have been proposed in the literature. In Sherlock II [Katz, S., Lesgold, A., Eggen, G., Gordin, M., 1992] and in the MDF tutor [Beck, J., Stern, M., Woolf, B.P., 1997] the uncertainty in student's performance was managed using fuzzy distributions and a set of rules for their formulation and update. Several other systems have been employed based on fuzzy logic concepts. In an ITS for the physics domain, the, so called, "Knowledge and Learning Student Model" [Panagiotou, M., Grigoriadou, M., 1995] has been proposed to infer student's knowledge level and cognitive abilities through processing and aggregating membership functions that represent teacher's assessments. Fuzzy rules have been proposed in the BSS1 tutoring system [Warendorf, K., Tsao, S.J., 1997] to implement a general fuzzy logic engine that can better manage student's learning, and in SYPROS [Herzog, C., 1994] to help determine student's plans. A fuzzy algebraic structure has been proposed as a dynamic model of user's states during navigation to monitor cognitive variables of the user model in a multimedia tutoring system [Lascio, L.D., Gisolfi, A., Loia, V., 1998].

The development of fuzzy logic in user or student modeling systems was motivated largely by the desire to make the arbitrary specification of precise numbers unnecessary [Jameson, A., 1996]. For certain types of problems, such as learning to interpret complex real-world sensor data, neural networks are among the most effective learning methods currently known [Mitchell, T.M., 1997]. In the user or student modeling field, neural networks have been proposed in the literature mainly due to their ability to learn from noisy or incomplete patterns of users' or students' behavior, generalize over similar cases, and then use this generalized knowledge to recognize unknown sequences [Chen, Q., Norcio, A.F., Wang, J., 2000; Yasdi, R., 2000]. Particularly in student modeling, neural networks have been originally proposed to simulate student's cognitive process of performing subtraction with the aim to predict student's responses and errors [Mengel, S., Lively, W., 1992].

A problem, which comes up when trying to apply a neural network in modeling human behavior, is knowledge representation [Yasdi, R., 2000]. The fact that student models need to be inspectable, [Wenger, E., 1987], explains the small number of neural network-based student models as opposed to symbolic approaches [Sison, R., Shimura, M., 1998].

Neural networks and other numeric-based AI methods have been criticized as unable to support learning interactions because they only allow for implicit understanding [Self, J., 1995]. However, several attempts have been made to incorporate the powerful learning abilities of neural networks in existing student modeling systems taking advantage of synergies with other AI methods. A hybrid approach, where each node and connection has symbolic meaning, has been proposed in TAPS [Posey, C.L., Hawkes, L.W., 1996]. The back-propagation algorithm has been used to modify weights that represent importance measures of attributes associated with student's performance, in order to refine and expand incomplete expert knowledge. Another approach combining ideas from neuro-fuzzy systems has been proposed [Shi, Y., Mizumoto, M., Yubazaki, N., Otani, M., 1996]. In [Magoulas, G.D., Papanikolaou, K.A., Grigoriadou, M., 2001], the model of [Shi, Y., Mizumoto, M., Yubazaki, N., Otani, M., 1996] has been expanded to incorporate evaluation mechanisms that used multi-attribute decision making for synthesizing various judgments to estimate student's knowledge levels and personal characteristics in order to plan the content of a Web based course.

The proposed model allows exploiting and efficiently processing structured knowledge in the form of linguistic rules. Of course it is not always possible to elicit this knowledge from the teachers. Teachers, sometimes, although they can easily classify students by observing their actions, they cannot articulate rules that reproduce their decisions. In addition, teachers are able to classify students with respect to specific characteristics, whilst in the case of ILE-supported learning students' behavior cannot be defined accurately. To alleviate these problems, a neural

network-based implementation of the diagnostic process is adopted. Specialized neural networks are trained through examples of existing students' profiles, or using examples that represent teacher's experience.

Knowledge is represented by developing association of student's behavior patterns with particular characteristics through neural network learning and is expressed, if necessary, with fuzzy IF-THEN rules. Thus, it is possible to encode structured and non-structured knowledge.

#### **The Fuzzy-based Diagnosis System**

Student's observable behavior is considered important source of diagnostic evidence to both human tutors and ILEs. In the terminology of ILEs, student's behavior refers to a student's observable response to a particular stimulus in a given domain. The response, together with the stimulus, serves as the primary input to the student modeling system [Sison, R., Shimura, M., 1998]. The input can be an action or the result of that action, and can also include intermediate results [Sison, R., Shimura, M., 1998]. However, it is not generally clear what type of information is available during interaction, and which features of student's behavior should be selected as inputs to the diagnostic process. Human tutors obtain diagnostic information from observing what students would say and do, and how something is said and done, i.e. tone of voice, inflection, hesitancy, etc. [Derry, S.J., Potts, M.K., 1998]. Studies in human tutoring found that tutors use as diagnostic evidence for adapting their tutoring not only errors and student's responses to queries, but also features of interaction, e.g. the timing of student responses, the way of delivering a response and others [Derry, S.J., Potts, M.K., 1998].

In order to alleviate the problem of limited information that is caused by the restricted communication channel between student and ILE, our system implements a close monitoring mechanism of student's actions over time, where each response such as keystroke, mouse move or drag can be timed and recorded. In this manner student's observable responses are summarized into  $n$  groups. Each group contains information about student's behavior of a specific type of knowledge data, chronometric data, try data or navigation data. A teacher usually defines specific types of responses that enable him or her to discriminate among students with regards to a particular characteristic.

The set  $B = \{B_1, B_2, \dots, B_i, \dots, B_n\}$ , where  $B_i$  ( $i = 1, 2, \dots, n$ ) is a word or a sentence describing the  $i^{\text{th}}$  type of response that is observed, describes linguistically the  $k$  aspects of student's observable behavior that will serve as inputs to the diagnostic process. The term observable, here, stands for measurable. The  $n$  measured responses constitute a set of numeric information that represents student's behavior. Each type  $i$  ( $i = 1, 2, \dots, n$ ) takes its values in a set of positive numbers  $U_i$ . The numerical input  $X = \{x_1, x_2, \dots, x_i, \dots, x_n\}$ , where  $x_i \in U_i$  and  $U_i$  is the universe of discourse of the  $i^{\text{th}}$  input; each  $U_i \subset \mathfrak{R}^+$  ( $i = 1, 2, \dots, n$ ) represents the measured values of  $B_i$  and formulates an input to the diagnostic process.

The output of the diagnostic process updates the student model regarding  $L$  different student learning characteristics  $H_1, H_2, \dots, H_L$ , such as student's abilities, motivation or learning style. Student's evaluation regarding each characteristic  $H_l$  ( $l = 1, 2, \dots, L$ ) is described qualitatively with the use of linguistic values. Depending on the  $l^{\text{th}}$  characteristic we use a different number  $m_l$  of linguistic values that describe  $H_l$  ( $l = 1, 2, \dots, L$ ). Student's evaluation regarding each characteristic is assessed by processing the numerical input  $X = \{x_1, x_2, \dots, x_i, \dots, x_n\}$ , of student's behavior. The process consists of three stages: fuzzification, inference, and defuzzification (see Fig. 2). In the first stage a qualitative description of student behavior is obtained by transforming the numeric input data into linguistic terms. The  $i^{\text{th}}$  fuzzifier  $i = (1, 2, \dots, n)$  transforms the numeric input  $x_i$  into membership degrees of the linguistic values that describe  $B_i$ . In the second stage, the inference process provides a fuzzy assessment of student's characteristics,  $H_1; H_2; \dots; H_L$ , by assessing membership degrees to the linguistic terms that describe each characteristic  $H_L$ . To this end, an ensemble of specialized fuzzy systems, where each system infers about a particular characteristic  $H_L$  is used to make a fuzzy assessment from a fuzzy precondition. A fuzzy system of this type combines linguistic values and realizes fuzzy relations operated with the *max-min* composition. These relations represent the estimation of a human tutor to the degree of association between an observed input  $X = \{x_1, x_2, \dots, x_i, \dots, x_n\}$ , and a fuzzy assessment of a particular student characteristic  $H_l$  ( $l = 1, 2, \dots, L$ ). Finally, in the third stage, the fuzzy assessments are defuzzified to non-fuzzy values, i.e. evaluation

decisions for the characteristics  $H_1, \dots, H_L$  by using a defuzzifier from the ensemble of the  $Q$  defuzzifiers. Each defuzzifier has a different number of inputs. Therefore, depending on the number of linguistic values  $m_l$  of each characteristic  $H_l$  ( $l= 1, 2, \dots, L$ ) a different defuzzifier  $Q$  is used in order to evaluate student's characteristic.

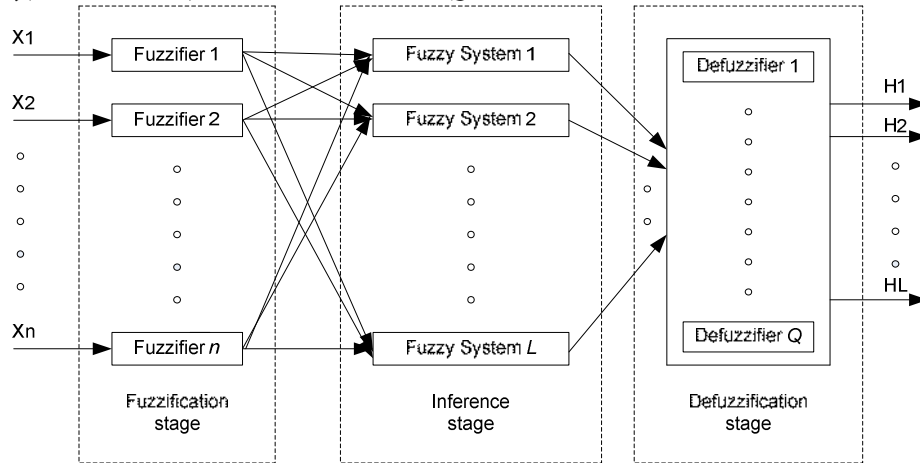

FIG. 1: SCHEMATIC OF THE FUZZY DIAGNOSIS MODEL

#### Fuzzification Stage for Fuzzy Knowledge Representation

This stage represents in linguistic form teacher's subjective description of student's responses when acting face-to-face communication during instruction (e.g. the time needed to solve the exercises was short; the student answered enough questions during instruction). The types of responses  $B_1, \dots, B_i, \dots, B_n$  are treated as linguistic variables. Each variable  $B_i = (i= 1, 2, \dots, n)$  can take different number of linguistic values  $f_i$ . The number  $f_i$  of the linguistic values and their names  $V_1, V_2, \dots, V_{f_i}$  are defined by the developer with the help of experts, and depend on each variable. The set  $T(B) = \{V_{i1}, V_{i2}, \dots, V_{if_i}\}$  is the term set of  $B_i$ . For example, let us consider the linguistic variable  $B_i =$  "time on task". The corresponding term set could be  $T(B_i) = T(\text{time on task}) = \{Short, Normal, Long\}$  including three ( $f_i=3$ ) linguistic values, or any classification such as  $T(B_i) = T(\text{time on task}) = \{Very Short, Short, Normal, Long, Very Long\}$  including five ( $f_i=5$ ) linguistic values, depending on the required resolution.  $T = \{T(B_1), \dots, T(B_i), \dots, T(B_n)\}$  is the set of all term sets that represent the overall observable behavior  $B$  (for all  $B_i; i = 1, 2, \dots, k$ ). Thus, the numeric input  $X = \{x_1, x_2, \dots, x_i, \dots, x_n\}$ , that represents the measured values of  $B_1; \dots; B_i; \dots; B_n$  is fuzzified by means of linguistic values  $V_{11}, V_{12}, \dots, V_{1f_1}; V_{i1}, V_{i2}, \dots, V_{if_i}; V_{n1}, V_{n2}, \dots, V_{nf_n}$ . Hence, the student behavior  $B$  is represented as a set of numeric values  $Y = \{(y_{11}, y_{12}, \dots, y_{1f_1}), \dots, (y_{i1}, y_{i2}, \dots, y_{if_i}), \dots, (y_{n1}, y_{n2}, \dots, y_{nf_n})\}$  in  $[0,1]$ , which represent the degree of membership of each numeric value  $x_i$  ( $i = 1, \dots, n$ ) into the term set of  $B_i$  with linguistic values  $V_{i1}, V_{i2}, \dots, V_{if_i}$ .

#### Inference Stage for Fuzzy Knowledge Representation

This stage represents teacher's reasoning in categorizing students qualitatively according to their abilities and personal characteristics, such as attentive, rather slow, good, etc. Teachers' can provide a series of IF-THEN rules that approximates their reasoning. For example, *if the time spent to read the theory is short and the number of correct answers is high, and few attempts to find the correct answers have been made then the student learning rate is fast.*

In our model, a qualitative description of student's characteristics  $H_1, H_2, \dots, H_L$  is performed by treating student's characteristics as linguistic variables. Each linguistic variable  $H_L$  can take a different number of linguistic values  $m_l$ .  $T(H_l) = \{H_{l1}, H_{l2}, \dots, H_{lm_l}\}$  is the term set of  $H_l$ . The expert-teachers set the number  $m_l$  of the linguistic values and their names  $H_{l1}, H_{l2}, \dots, H_{lm_l}$  for each characteristic  $H_l$  according to their personal judgment. For example, if we treat the linguistic variable  $H_1$  "learning rate of the student" using five linguistic values ( $m_1=5$ ) then the term set could be:  $T(H_1) = T(\text{learning rate}) = \{\text{Slow, Rather Slow, Normal, Almost Fast, Fast}\}$ . In this way, a mode of qualitative reasoning, in which the preconditions and the consequents of the IF-THEN rules involve fuzzy variables [64], is used to provide an imprecise description of teacher's reasoning:

*IF  $B_1$  is  $V_{1I_1}$  AND  $B_2$  is  $V_{2I_2}$  ... AND  $B_n$  is  $V_{nI_n}$  THEN  $H_1$  is  $H_{1L_1}$  AND  $H_2$  is  $H_{2L_2}$  ... AND  $H_L$  is  $H_{LL_L}$*

where  $I_1 = 1, 2, \dots, f_1; I_2 = 1, 2, \dots, f_2; I_n = 1, 2, \dots, f_n; L_1 = 1, 2, \dots, m_1; L_2 = 1, 2, \dots, m_2; L_L = 1, 2, \dots, m_L$ .

All possible combinations in the preconditions, denoted as PCP below, are represented by the Cartesian product of the sets in  $T = \{T(B_1), T(B_2), \dots, T(B_n)\}$ :  $PCP = T(B_1) \times T(B_2) \times \dots \times T(B_n)$ , and the number

$N = f_1 \times f_2 \times \dots \times f_n$  of possible cases in the preconditions equals to the number  $N$  of elements of PCP. Each fuzzy system  $l$  (see Fig. 2) infers a fuzzy assessment of a different characteristic  $H_l$  ( $l = 1, 2, \dots, L$ ). Within each fuzzy system, the intersection (corresponding to the logical AND) between the membership functions associated with the linguistic values of each precondition is the *min* operation, and results in the numerical truth-value  $p_n$  of the precondition. Thus, student's current behavior is described by a vector  $P = [p_1, p_2, \dots, p_n]$ , where  $p_1, p_2, \dots, p_n$  are in the interval  $[0,1]$ , representing degrees of fulfillment of preconditions. By means of a fuzzy relation, [44,45], as described below,  $P$  is translated into fuzzy assessments by exploiting teacher's subjective judgments (denoted by the symbol  $R_l$  in the relation right below) with respect to a characteristic  $H_l$

$$P \circ R_l = H_l,$$

where  $H_l$  is an  $m$ -dimensional vector  $H_l = [h_{l1}, h_{l2}, \dots, h_{lm_l}]$  with  $h_{l1}, h_{l2}, \dots, h_{lm_l}$  in  $[0, 1]$  representing the fuzzy assessment of student's characteristic  $H_l$ , i.e. an assessment with membership degrees  $h_{l1}, h_{l2}, \dots, h_{lm_l}$  on each linguistic value ( $H_{l1}, H_{l2}, \dots, H_{lm_l}$ ) of the linguistic variable for the characteristic  $H_l$ ;  $R_l$  is a  $n \times m_l$  weight matrix representing teachers' estimations of the degree of association between precondition  $P$  and the linguistic values of student's characteristic  $H_l$ ; the symbol  $\circ$  denotes the *max-min* composition operator.

#### Defuzzification Stage

This stage represents teacher's final decision in classifying a student in one of the predefined linguistic values  $H_{l1}, H_{l2}, \dots, H_{lm_l}$  of the characteristic  $H_l$ . This process is performed by weighting the fuzzy assessment. Depending on the number of linguistic values  $m_l$  of each characteristic  $H_l$ , we use an appropriate defuzzifier from the ensemble, i.e. implementing a different defuzzification procedure that "imitates" a teacher's subjective decisions. Teacher's decisions may be clear-cut or marginal.

#### Neural-network Based Implementation of the Fuzzy Model

##### Fuzzification

Depending on the linguistic variable  $B_i$  and the linguistic value  $V_{i1}, V_{i2}, \dots, V_{if_i}$ , we subjectively define different membership functions, which assign to each element  $x_i$  of the universe of discourse  $U_i$  ( $1, \dots, n$ ) a degree of membership  $y_{if_i}(x_i)$  to the linguistic value  $V_{if_i}$  of  $B_i$ . In this way they contribute to the semantic rule that associates each linguistic value  $V_{if_i}$  of  $B_i$  with its meaning [Zadeh, L.A., 1972]. In general, the form of a membership function depends on experts opinions [Zadeh, L.A., 1965].

In our case, we have adopted an approach that simplifies the implementation by approximating the membership functions using a library of regular shapes and implementing the fuzzifier stage as a group of fixed weight neural networks that calculate such regular shapes. Since membership functions are subjective and generally

context-dependent, [63], a set  $M = \{m_1, m_2, \dots, m_n\}$  of parameters that adjust the membership functions [53] is defined to allow a range of adaptations to teacher's subjective judgments. Thus, for each one of the linguistic values of the set  $T = \{T(B_1), T(B_2), \dots, T(B_n)\}$ , the fuzzifier stage calculates the output  $Y$  of numeric values in  $[0, 1]$  based on the input vectors  $X = \{x_1, x_2, \dots, x_i, \dots, x_n\}$ , and  $M = \{m_1, m_2, \dots, m_n\}$

$$Y = \left\{ \left\{ y_{11}(x_1, m_1), y_{12}(x_1, m_1), \dots, y_{1f_1}(x_1, m_1) \right\}, \left\{ y_{21}(x_2, m_2), y_{22}(x_2, m_2), \dots, y_{2f_2}(x_2, m_2) \right\}, \dots, \left\{ y_{n1}(x_n, m_n), y_{n2}(x_n, m_n), \dots, y_{nf_n}(x_n, m_n) \right\} \right\}$$

Thus, in our implementation, shown in Fig. 2, we have used sigmoid functions ( $\alpha$ ) as membership functions for the extreme linguistic values  $V_1, \dots, V_{f_i}$ , and the pseudo-trapezoidal function (composed of two sigmoid functions) for the intermediate values,  $V_2, \dots, V_{f_{i-1}}$ ; the adjusting parameter  $m_i$  is the expected mean value of a measured value  $x_i$ , as estimated by the teacher of the specific teaching subject.

FIG. 2: THE IMPLEMENTATION OF A FUZZIFIER

Each fuzzifier  $i$  ( $i = 1, 2, \dots, n$ ) of Fig. 1 is implemented with a network of the type shown in Fig. 2. The network of Fig. 2 is used to calculate the membership grades of the linguistic values  $f_i$ , when  $x_i = x$  and  $m_i = m$ . The left and the right extreme fuzzy sets are given by

$$y_1(x, m) = \frac{1}{1 + \exp(-w_{g1}(x + w_{c1}m))}, \quad w_{g1} < 0;$$

$$y_f(x, m) = \frac{1}{1 + \exp(-w_{gi}(x + w_{ci}))}, \quad w_{gi} > 0;$$

where  $i = 2(f-1)$ . An intermediate set  $j$  is given by

$$y_j(x, m) = \frac{1}{1 + \exp(-w_{gi}(x + w_{ci}m))} - \frac{1}{1 + \exp(-w_{gi'}(x + w_{ci'}m))},$$

where  $j = 2, \dots, f-1$ ,  $w_{gi} > 0$ ,  $w_{gi'} > 0$  ( $i = 2(j-1)$ ;  $i' = i+1$ ).

In the above relations,  $x$  indicates the current measurement of the observed response;  $w_{ci}$  and  $w_{gi}$ , are defined in advance according to human teachers opinions;  $w_{ci} \cdot m$  ( $i = 1, \dots, 2(f-1)$ ), is the central position of the sigmoid function;  $w_{gi}$  ( $i = 1, \dots, 2(f-1)$ ) is the gradient of the sigmoid function.

### Inference Stage

The preconditions  $P = [p_1, p_2, \dots, p_n]$  are produced by a single layer of  $n, n = f_1 \times f_2 \times \dots \times f_n$ , nodes. The network realizes the intersection by performing the *min* operation on the membership functions ending at each node. Thus, each node is activated to the degree of the numerical truth value  $p_n$  of the precondition in  $[0, 1]$ .

Each fuzzy system  $l$  (see Fig. 1) contains a precondition layer and realizes a fuzzy relation  $P \circ R_l = H_l$  which is implemented by a two layer network with  $n, n = f_1 \times f_2 \times \dots \times f_n$ , input nodes and  $m_l$  output nodes. The output nodes perform the *max-min* composition and the synaptic weights  $r_{il} (i = 1, \dots, n; l = 1, \dots, m_l)$  are the elements of the  $R_l$  matrix.

### Defuzzification

We have used a neural network-based approach, which allows the system to adapt the defuzzification to individual teacher's opinion by training. A three layer neural network with  $m_l$  input and  $m_l$  output nodes and a hidden layer was trained with a modified back propagation algorithm that uses variable step size, called BPVS [Magoulas, G.D., Vrahatis, M.N., Androulakis, G.S., 1997]. Training the network results in encoding teachers' unstructured knowledge, and during operation the network acts as a "generalizer" that defuzzifies in a way that imitates teachers' decision procedure.

## The Proposed Neuro-Fuzzy Learning System for Students

Automatic definition of a model starting from of numerical data can be done efficiently through methodologies in the area of Soft-Computing, a new computing paradigm which synergically integrates different information processing methods, such as neural networks, fuzzy systems and evolutionary programming, in order to deal with uncertainty, typical of real-world domains, while preserving characteristics of processing and robustness. Especially, considerable work has been done to integrate the learning capabilities of neural network with explicit knowledge representation given by fuzzy systems, resulting in the neuro-fuzzy modeling approach [Arons, A.B., 1990].

As it is represented in Fig. 3 in this model, students are considered to choose the best curriculum for themselves regarding to the profile of each course and their requirements. The neural network is used to obtain student's curriculum within a distance learning educational system. In the former system a fuzzy based management (diagnosis) system is applied for the qualitative items in order to reach the optimal learning path for a student in such a system. The first layer, which is considered as the input layer, is the number of students who want to select the courses for a semester. The second layer is the number of courses that are offered in a semester. Those courses have instructors for varied levels of students, Strong; Moderate; Weak, i.e. students can choose a course with one of those instructors regarding to their capability as the following (if .... then) fuzzy rules that are being constructed in the management system:

- If a student chooses instructor with "strong" title then the weight is 3, •*
- If a student chooses instructor with "moderate" title then the weight is 2, •*
- If a student chooses instructor with "weak" title then the weight is 1, •*

And also students choose their courses regarding to the criteria such as capabilities, attitudes, knowledge level, motivation and learning style by their preferences according to TABLE 1:

TABLE 1: COURSE PREFERENCES AND THEIR RELATED NUMERICAL VALUES

Preferences	Numerical value
Extremely Preferred	9
Very Strongly Preferred	7
Strongly Preferred	5
Moderately Preferred	3
Equally Preferred	1
Preferences among the above preferences	2,4,6,8

The fourth layer shows the excessive facilities that the educational system provides for the students, such as e-library, e-lab, different workshops, and etc. The next layer is a fuzzy rule based diagnosis (management) system that is used to analyze the qualitative items. The last layer shows the optimal path for each student according to their own profiles.

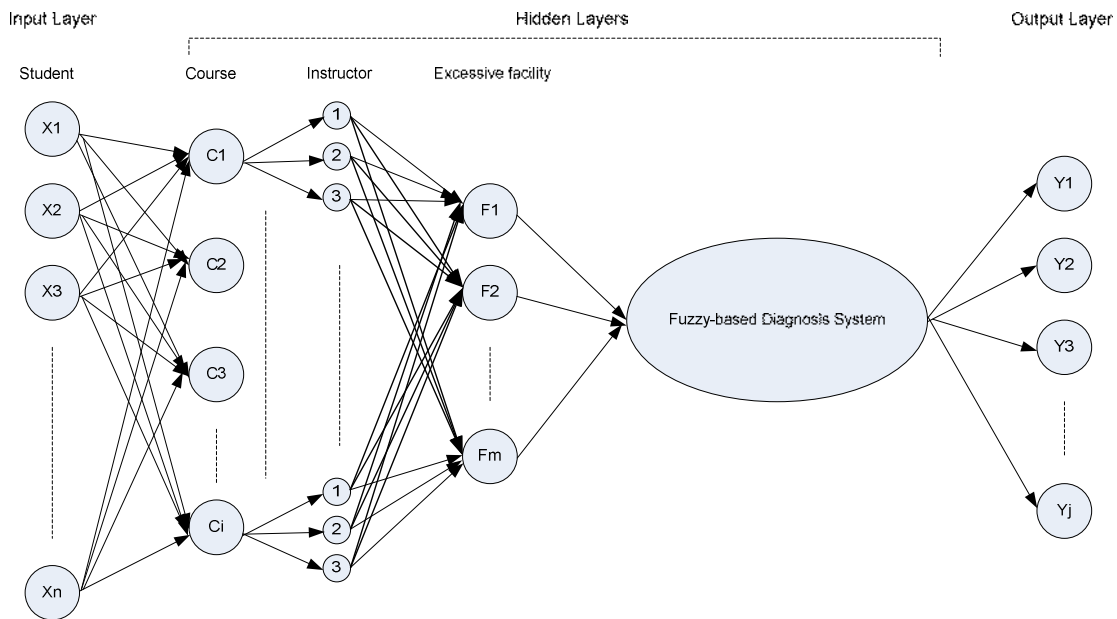

FIG. 3: THE NEURO-FUZZY LEARNING SYSTEM

Considering the above descriptions the optimal path for student is a path that enables a student to use the maximum amount of services that the educational system provides considering the students requirements and criteria.

- $F_m$       The  $m^{th}$  facility
- $Y_j$       The  $j^{th}$  path
- $W_i$       The weight for course  $i^{th}$
- $W_p$       The weight for instructor  $p^{th}$

Decision variables:

$$\psi_{ni} = \begin{cases} 1 & \text{If student } n \text{ choose the course } i \\ 0 & \text{O.W} \end{cases}$$

$$\phi_{nm} = \begin{cases} 1 & \text{If student } n \text{ use facility } m \\ 0 & \text{O.W} \end{cases}$$

$$\text{Max} \sum_i \sum_p (\sum_n W_i \psi_{ni} W_p + \sum_m \phi_{nm}) \tag{1}$$

S.t:

$$X_1 + X_2 + \dots + X_n = A \tag{2}$$

$$L \leq C_i \leq U \tag{3}$$

$$0 \leq F_m \leq M \tag{4}$$

Equation (1) is the objective function which presents the maximum service of the educational system that is the optimal learning path. Equation (2) specifies the number of students who try the course selection. Equation (3) identifies the lower and upper bound for course numbers. Equation (4) presents the number of facilities that the educational system prepare for being used by the students.

The noticeable parameters are  $W_i$  and  $W_p$  that are the weights of the criteria in the course selection. The  $W_p$  is based on the fuzzy rule-base engine that explained before but  $W_i$  s will be identified by a multi criteria decision making approach. In this paper the analytical hierarchy procedure (AHP) is applied to find the weights.

#### **Determining Weights by AHP Approach**

The analytical hierarchy procedure (AHP) is proposed by Saaty (1980). AHP was originally applied to uncertain decision problems with multiple criteria, and has been widely used in solving problems of ranking, selection, evaluation, optimization, and prediction decisions [Golden, Wasil, & Levy, 1989]. Harter and Vargas (1987) stated that ‘‘AHP is a comprehensive framework designed to cope with the intuitive, rational, and the irrational when we make multi-objective, multi-criteria, and multi-factor decisions with and without certainty for any number of alternatives.’’

The AHP method is expressed by a unidirectional hierarchical relationship among decision levels. The top element of the hierarchy is the overall goal for the decision model. The hierarchy decomposes to a more specific criterion a level of manageable decision criteria is met [Meade & Presley, 2002]. Under each criterion, sub-criteria elements relative to the criterion can be constructed. The AHP separates complex decision problems into elements within a simplified hierarchical system [Shee, D. Y., Tzeng, G. H., & Tang, T. I., 2003].

The purpose of the AHP enquiry in this paper is to construct a hierarchical evaluation system based on the independent factors as capabilities, attitudes, knowledge level, motivation and learning style, the AHP method could gain factor weights and criteria, and then obtain the final effectiveness of each course.

The AHP usually consists of three stages of problem solving: decomposition, comparative judgments, and synthesis of priority. The decomposition stage aims at the construction of a hierarchical network to represent a decision problem, with the top level representing overall objectives and the lower levels representing criteria, sub-criteria, and alternatives. With comparative judgments, users are requested to set up a comparison matrix at each hierarchy by comparing pairs of criteria or sub-criteria. A scale of values ranging from 1 (Equally Preferred) to 9 (Extremely Preferred) see Table 1, is used to express the users preference. Finally, in the synthesis of priority stage, each comparison matrix is then solved by an eigenvector method for determining the criteria importance and alternative performance. The following list provides a brief summary of all processes involved in AHP applications:

- Specify a concept hierarchy of interrelated decision criteria to form the decision hierarchy. .1
- For each hierarchy, collect input data by performing a pair wise comparison of the decision criteria. .2
- Estimate the relative weightings of decision criteria by using an eigenvector method. .3
- Aggregate the relative weights up the hierarchy to obtain a composite weight which represents the relative importance of each alternative according to the decision-maker's assessment. .4

One major advantage of AHP is that it is applicable to the problem of group decision-making. In group decision setting, each participant is required to set up the preference of each alternative by following the AHP method and all the views of the participants are used to obtain an average weighting of each alternative.

In this paper regarding to the stated criteria, the following hierarchy is proposed. The aim is to obtain the weight for each course to be used in the objective function of optimal path. The hierarchy is presented in Fig. 4.

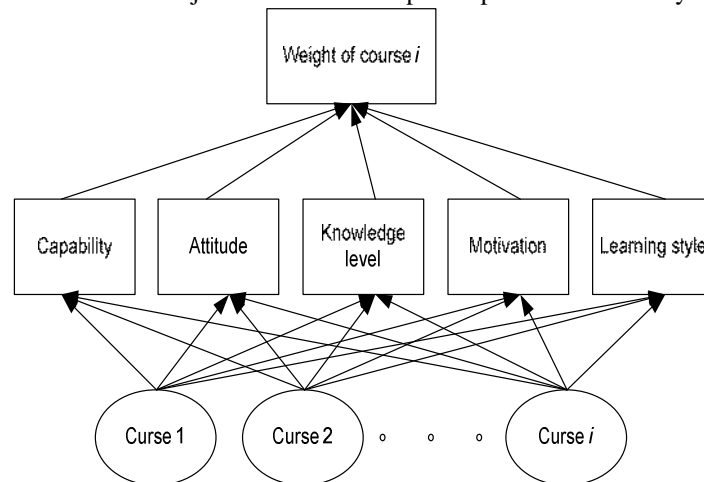

FIG. 4: THE HIERARCHY OF THE PROPOSED MODEL

According to Fig.4 the following matrix is used to calculate the weights ratio each of the criteria i.e. courses are evaluated ratio capabilities, attitudes, knowledge level, motivation and learning style based on the preference numbers ( $A_{bc}$ ) of the courses considering Table 1:

Matrix 1

Capability	Course 1	Course 2	Course <i>i</i>
Course 1	1	$A_{12}$	$A_{1i}$
Course 2	$1/A_{12}$	1	$A_{2i}$
·	·	·	·
·	·	·	·
Course <i>i</i>	$A_{i1}=1/A_{i1}$	$A_{2i}=1/A_{i2}$	1

The same matrix is used for other criteria (attitudes, knowledge level, motivation and learning style) we call this dual comparison of courses. After calculating the above matrixes, a matrix that indicates the weights ( $W_{bc}$ ) of the courses for the mentioned criteria is formed as follows:

Matrix 2

	Capability	Attitude	Knowledge level	Motivation	Learning style
Course 1	$W_{11}$	$W_{12}$	$W_{13}$	$W_{14}$	$W_{15}$
Course 2	$W_{21}$	$W_{22}$	$W_{23}$	$W_{24}$	$W_{25}$
·	·	·	·	·	·
·	·	·	·	·	·
Course <i>i</i>	$W_{i1}$	$W_{i2}$	$W_{i3}$	$W_{i4}$	$W_{i5}$

After that the criteria dual comparison matrix is configured as follows:

Matrix 3

	Capability	Attitude	Knowledge level	Motivation	Learning style
Capability	1	$A_{12}$	$A_{13}$	$A_{14}$	$A_{15}$
Attitude	$1/A_{12}$	1	$A_{23}$	$A_{24}$	$A_{25}$
Knowledge level	$1/A_{13}$	$1/A_{23}$	1	$A_{34}$	$A_{35}$
Motivation	$1/A_{14}$	$1/A_{24}$	$1/A_{34}$	1	$A_{45}$
Learning style	$1/A_{15}$	$1/A_{25}$	$1/A_{35}$	$1/A_{45}$	1

Now we reached the weight of each criterion by the above matrix. Therefore, the weight for each course considering the criteria is achieved as follows:

$$\text{Total weight for course 1} = W_{11} \times W_C + W_{12} \times W_A + W_{13} \times W_K + W_{14} \times W_M + W_{15} \times W_L$$

$$\text{Total weight for course 2} = W_{21} \times W_C + W_{22} \times W_A + W_{23} \times W_K + W_{24} \times W_M + W_{25} \times W_L$$

·

·

$$\text{Total weight for course } i = W_{i1} \times W_C + W_{i2} \times W_A + W_{i3} \times W_K + W_{i4} \times W_M + W_{i5} \times W_L$$

Where  $W_C$ = capability's weight,  $W_A$ = attitude's weight,  $W_K$ = knowledge level's weight,  $W_M$ = motivation's weight,  $W_L$ = learning style's weight, that are obtained by matrix 3. In this way the weights are calculated to be used in equation (1) and the optimal path for students will be identified after solving the simple mathematical model.

## Conclusions

In this paper a neuro-fuzzy model of the diagnostic process was proposed for inferring student characteristics and for identifying the optimal path of students in applying distance learning courses based on their profile. A main advantage of the new approach is that the neuro-fuzzy model allows creating an interpretable knowledge

representation, which can be developed on the basis of rules when reasoning is well defined, as well as it can be trained when the reasoning strategy is purely intuitive and ill-defined. In addition the model can be easily tailored to a teacher's personal view. This approach can be used to implement an open student model, which will be interactively adjusted by the teacher.

AHP approach is applied to find the optimal path in the proposed virtual learning environment based on the qualitative parameters regarding to the students characteristics. Our current work targets the extraction of knowledge from existing student profiles to drive model's adaptation during operation with the aim to adapt the feedback and pedagogical strategy to students' learning style. Future works will be about the implementation of the model and the experimental results which will represent the pros and cons of our model.

### Abstract

This study compares the online services currently delivered by the Official National Tourism Organisations (NTO) portals of the 25 EU states, to assess their capability in evolving into powerful marketing communication tools. A conceptual framework that identifies 129 online service quality attributes is developed based on the 2QCV3Q model (Mich and Franch, 2002) and on four different perspectives: *marketing*, *customer*, *technical* and *information for the destination* (So and Morrison, 2004). The 25 portals are compared by means of content analysis. Our rankings provide a first time assessment of the NTO online offerings and indicate high variability in their performance. Surprisingly, Greece and Italy, two of the most popular tourism destinations, underperformed with respect to all of the four perspectives examined. We provide out-of-sample evidence that affluence levels explain the variation in the observed scores, while e-readiness, popularity of tourism destination and cultural richness are not statistically significant.

### Introduction: the Role of National Tourism Organisations' Portals

Among the Destination Management Organisations (DMO), prominent is the role of the National Tourism Organisations (NTO<sup>1</sup>) in marketing a destination at a national level. Prior to the Internet era, the DMOs, have been rather passive and limited to the distribution of printed tourist promotional material on demand (So and Morrison, 2004; King, 2002). However, the adoption and the diffusion of e-commerce applications, has provoked unprecedented changes (Wöber, 2003). All the EU countries, have invested in the development of websites with different levels of interactivity (Morgan *et al.*, 2002). Essentially, these portals undertake the management of "content information" relating to a tourist destination, arriving from a wide variety of different sources (Turban *et al.*, 2004: 322). By assuming the role of on line brokers of information providers, they become responsible for matching cross culturally demand of individual tourists with the destinations' tourism service supply (Scharl *et al.*, 2004).

Different studies indicate that NTO portals should not be perceived exclusively as information seeking facilitators (Morgan *et al.*, 2002). Instead, they should aim to evolve into powerful interactive marketing communication tools (Griff and Palmer, 1999<sup>2</sup>; Cano and Prentice, 1998) that have the potential to enhance the overall attractiveness of a travel destination and to evoke an optimal experience for their on line users, offering to different customer groups' superior value (Nysveen *et al.*, 2003). However, while the trend of internet being the first point of embarkation for prospect tourists is gaining *momentum* (Buhalis and Licata 2002) and the presence of NTOs through internet is becoming better established (Feng *et al.*, 2002), there is still a *paucity* of research regarding the online offerings and the internet marketing strategies undertaken from them.

Under the recognition that it is important to examine NTOs in an *exploratory way*, where the dimensions of online quality from a customer perspective will serve as a framework, this study compares the official European NTO portals online offerings. The aim is to examine what information and services of value added each of the 25 EU NTO portals is offering and what do these offerings reveal regarding the underlying internet marketing strategies currently adopted. To this end, as first objective, there were identified the online services that may facilitate the tourist search, evaluation of information and purchase of services via the NTO sites, based on a deep inspection of the e-SQ literature (paras 2-3). Secondly, these portals were compared by means of content analysis (paras 4-6), in order to document what information and online services currently are provided, allowing to make inferences as to up to which extent they are using their potential as customer-led marketing tools.

## Extant Approaches in Measuring E-service Quality

The way e-SQ is conceptualized is still at an exploratory stage. Researchers not only have tried to combine known dimensions that influence product quality and SQ, but also to discover some unique factors, relevant to the virtual operations only. The e-SQ attributes seem to depend on the level of web-based technology readiness of the different users (Zhu *et al.*, 2002) and do not to demonstrate a linear relationship, since “more” of an attribute is not necessarily perceived as better (O’Neill *et al.*, 2001).

In order to define e-SQ, some authors take into account both the *pre* and *post* web sites services aspects (Santos, 2003; Liu and Arnett, 2000), while others consider only the interaction with the site itself (Zeithaml *et al.*, 2002). Additionally, in contrast to the traditional service offerings, online users tend to regard e-SQ more as an universal concept, deriving from their overall online experience, rather than from sub-processes (Van Riel *et al.*, 2001).<sup>3</sup> The *focus* of each individual research (e.g. consumer buying procedure), as well as the *types of web sites* used (e.g. portals, retailing sites, etc.); determine how the definition of e-SQ may be conceptualised (Kim *et al.*, 2006). Given that the NTO portals’ core activity is to help customers at different stages in the information search process, the definition of website quality used in this study is based on the concept of value added services as provided by Nysveen, (2003) and Lexhagen (2005): “Services giving access to various forms of information about the tourism products offered on a website”, disregarding approaches tailored for e-commerce shopping (Zeithaml *et al.*, 2002), or based on an ex-ante definition of e-services (Santos, 2003: 235).

Not only defining, but also measuring the multidimensional construct of e-SQ continues to generate increased academic debate. Many different scales have been proposed during the last eight years based on different classifications of quality dimensions and attributes (O’Neill *et al.*, 2001; Madu and Madu, 2002; Zhu *et al.*, 2002; Yoo and Donthu 2001; Santos, 2003; Zeithmal *et al.*, 2002; Parasuraman *et al.* 2005, etc.), either emphasizing the *human and soft* elements of service quality or the *technical dimensions* of on line efficiency, or both (Sigala, 2004).

An extended framework, which incorporates many of the e-SQ dimensions proposed by previous approaches, has been developed by Madu and Madu (2002). Their model included some of the product quality dimensions according to Garvin (1984), as well as the 5 quality dimensions of the SERVQUAL scale (Parasuraman *et al.*, 1988), while it identified some unique, new dimensions, appropriate only for virtual contexts. Even if the proposed dimensions have never been tested empirically, it is interesting the evolutionary approach it adopts, encompassing both product and services features.

Barnes and Vidgen (2000)<sup>4</sup> based on 54 students’ evaluations of British online bookstores, have extended the SERVQUAL scale of Parasuraman *et al.*, (1988) to an online context, encompassing softer service related attributes by introducing 24 different measurement items under their index named WebQual. They focused on the following aspects: *reliability, competence, responsiveness, access, credibility, communication and understanding*. Later on, Loiacono *et al.*, (2002)<sup>5</sup> proposed the WebQual<sup>TM</sup> scale which emphasised again the technical aspects of the website in the evaluation of its online quality, developing 12 web design features. This approach has been criticised by Zeithaml *et al.*, 2002 and Parasuram *et al.*, 2005, for having limited capabilities in capturing important quality dimensions (e.g. “fulfilment”, customer service), since these scales have been produced by using convenience samples of students rather than actual online purchasers. A further drawback derives from the fact that the participating students have rated researcher specified categories that had not emerged through a qualitative study.

Parasuramam *et al.*, (2005) recently have developed the well known E-S-QUAL model. Under the latter, e-service quality dimensions have been divided into 7 categories: efficiency, fulfilment, privacy, service recovery dimension, compensation, contact. A recent application of the E-S-QUAL model has been undertaken by Kim *et al.*, (2006) which evaluated the performance of 111 US apparel retail websites in providing on line service attributes that facilitate efficient and effective shopping, purchasing and delivery of garments. Such on line service attributes were examined by means of content analysis, by considering the E-S-QUAL categories, accommodated to include other dimensions: *personalisation, information and graphic style*, regarded relevant for the specific retail context. Overall, it was found that the e-SQ level of the sample companies was unsatisfactory.

## Empirical Literature on DMO

Previous studies have investigated tourism websites from three different perspectives: a) from a business, b) from a customer perspective and c) a combination of the previous two. The former implies that the on line quality is evaluated as superior according to where the business is in the transformation process: *if a site is only informative or whether it offers more advanced features such as on line booking services, etc.* (Hart *et al.*, 2000<sup>6</sup>; O' Connor, 1999<sup>7</sup>; Doolin *et al.*, 2002). Representatives of this strand: Doolin *et al.*, (2002), extended and applied an internet commerce adoption metric (eMICA) developed by Burgess and Cooper (2000)<sup>8</sup> for bench marking the relative maturity of 26 New Zealand's Regional Tourism Organisations (RTO) websites and concluded that the majority of them displayed moderate to high levels of interactivity. The customer perspective encompasses two different approaches: the former, assesses the websites according to their level of customer support during the information searching process, thus following a "consumer behavior theory"; whereas the latter, according to their level of design features superiority. Finally, under the last approach the business and customer perspectives are combined together, within different contingent evaluation frameworks, ranging from technical approaches, such as the Balanced Score Card (Morrison *et al.*, 1999; Ismail *et al.*, 2002; Feng *et al.*, 2002; So and Morrison, 2004), to more theoretical ones, such as the Marketspace model (Blum and Fallon, 2002), which emphasized the marketing mix and the customer relationships.

Moreover, so far, research in assessing websites effectiveness in the tourism sector, has been mainly focused on either a) opinions of experts of tourist services providers (Chung and Law, 2003; Hudson and Lang, 2002; Jung and Butler, 2000) or b) end users (tourists) evaluations (e.g. Jeong *et al.*, 2003, Tierney 2000<sup>9</sup>) or c) by applying quantitative measures (e.g. Scharl *et al.*, 2004, Wöber, 2003). Regardless of whether the end users or the tourist experts have been focused upon, both directions' research findings seem to converge in one common admittance: *the importance of the online content* in terms of richness of information, features and services (Huizingh, 2000; Scharl *et al.*, 2004; Cai *et al.*, 2004b) and *content quality* (Aladwani and Pavia, 2002) as critical success factor of tourism websites. In particular, as far as destination portals are concerned, their content has been broadly recognised (Doolin *et al.*, 2002, Cano and Prentice, 1998) as being responsible for creating the perceived image of the destination. Finally, there is also a recent research stream (Skadberg *et al.*, 2005; Chen and Wells, 1999, Hoffman and Novak, 1996<sup>10</sup>) who supports that since tourism is mainly experiential, the overall web site effectiveness depends on the flow experience of the online visitors in tourism destination websites.

It can be argued that even though different studies *did* include some DMO websites in their sample, very few have been focusing on the evaluation of them *per se* (Cano and Prentice 1998; Bauer and Reid, 2000<sup>11</sup>; Doolin *et al.*, 2002; Mich and Franch, 2002; Morrison *et al.*, 2002, Ismail *et al.*, 2002; So and Morrison, 2004). Moreover, only a few comparative studies have been carried out (Mich and Franch, 2002, 2003; Feng *et al.*, 2002, Ismail *et al.*, 2002; So and Morrison, 2004) and none of them has covered the enlarged EU as a whole. Namely, Cano and Prentice (1998) examined by means of content analysis, through a questionnaire survey addressed to 14 area tourist boards and 32 local authorities, 983 different Scottish websites and concluded that a variegated image of Scotland is promoted world wide, where the absence of a common communicative style and a distinctive design style contributed to the underselling of the whole Scotland as a tourist destination product.

Recently, Feng *et al.*, 2002, Ismail *et al.*, 2002 and So and Morrison, 2004, in three papers, by means of content analysis, compared the performance of DMO websites of different countries, based on the Balanced Scorecard Approach, developed by Kaplan and Norton (1996)<sup>12</sup>. These studies acknowledge tourism website performance in a holistic way, encompassing four different perspectives. The first study compared 36 Chinese DMO websites to 30 US DMO websites and concluded that the latter were superior in terms of marketing strategies and destination information provided. The second study examined website's information content and photos from a cultural point of view, while the third one compared 15 East Asian NTO sites, concluding that none of them had been particular effective as an online marketing tool.

Finally, Mich and Franch, 2002 have developed a meta-model 2QCV3Q, to compare the regional tourist boards (RTB) websites in the area of Alps. In their approach, quality of web site has been identified as the ability to satisfy the needs and objectives of all the online users involved. Their model by asking a set of questions identifies

seven dimensions of quality, according to which the tourism websites' overall quality was assessed, revealing a poor performance in terms of dissemination of information and use of modern technology.

From the above e-SQ and empirical literature, it can be concluded that regardless of the numerous different approaches developed through the last years, there still does not exist a detailed framework that provides a comprehensive understanding of e-SQ which could be used for the evaluation of websites and portals *independently* of sector of belonging. A common practice instead, has been to tailor the different e-SQ models according to the specific research areas each time. However, in the case of tourism websites, to the extent of our knowledge, no empirical study has defined and confirmed through surveys specific qualitative attributes which could be particularly relevant to the assessment of the NTO portals.

## Research Method, Sample and Coding Instrument

In order to carry out the comparative analysis of the online offerings of the NTO portals in EU, content analysis was used since it allows, from a customer perspective, to capture and quantify both the richness of the NTO's information content and the number of useful services provided to the customers, which in turn shape important e-SQ dimensions.

Our sample consists of the 25 EU Official National Tourism Organisations (NTO) portals, evaluated between June and July 2006. The latter organisations have been chosen, due to their unquestionable importance as primary suppliers of online information and services to market a destination and as coordinators of the other local/regional tourism authorities' initiatives (Ismail *et al.*, 2002; Cai *et al.*, 2004a). By observing the global tourism statistics (UNCTAD, 2005; WTO, 2005), in terms of number of international arrivals and volume of tourist receipts, it was decided to focus on the whole population of EU states NTO portals since it was confirmed that the majority of the most significant tourism markets (e.g. France, Italy, UK, Spain, Germany, Austria, etc) are found among those.

According to Weber (1985: 21–25), content analysis requires a process of creating and testing a coding instrument to know when a particular category occurs. This process includes the following: a) define the categories; b) define the recording unit; c) test code on a sample of text; d) assess reliability; e) revise the coding rules; f) repeat steps 3 to 5 until reliability is satisfactory; g) code all text; h) assess achieved reliability.

A prior-research driven approach (Boyatzis, 1998: p. 99) was followed in order to define the coding categories. The developed conceptual framework has emerged after taking into account the e-SQ literature discussed above and previous empirical studies on website evaluation. More analytically, the initial list of evaluation criteria was formed by incorporating the majority of the quality characteristics defined by the 2QCV3Q model (Mich and Franch, 2002), best practices recommended by the World Tourism Organisation (WTO, 2005) and a series of evaluation criteria used by Davidson and Yu, (2005), Kim *et al.*, (2006); Feng *et al.*, (2002); Ismail *et al.*, (2002) and So and Morrison, (2004) in tourism related websites evaluation studies. Together, it was generated a list of 129 attributes which were accommodated into 4 qualitative categories: *destination information, marketing, customer and technical perspective*, following the framework of the modified Balance Score Card, as applied by So and Morrison, (2004). The latter, was chosen due to its strong emphasis on customer service and marketing, both important features in evoking high levels of perceived e-SQ in tourism portals. Fig. 1 and Tab. 6 illustrate the four categories and the full list of items, respectively. The material analysed consisted of the English homepage including links, pictures and text information. However, links as hypertexts within a unique resource locator (URL) that would lead to a separate and independent web page, were not further considered. Neither it was analyzed information accessible to registered users.

TABLE 6: LIST OF PERFORMANCE ITEMS

	Frequency in percentage		Frequency in percentage
<b>Marketing perspective (43)</b>	<b>51</b>	Management of information	61
Segmentation	51	Option to search for lodging by type (e.g. stars)	72
No hotel lodging alternatives	88	Directions of how to reach destinations	36
Spa	92	List of "highlights" (e.g. main attractions)	56
Fitness	60	Option to request material on line	56
Dining per categories	48	Option to download on line	84
Nightlife	44	Printing options (e.g. full page, some areas etc.)	80

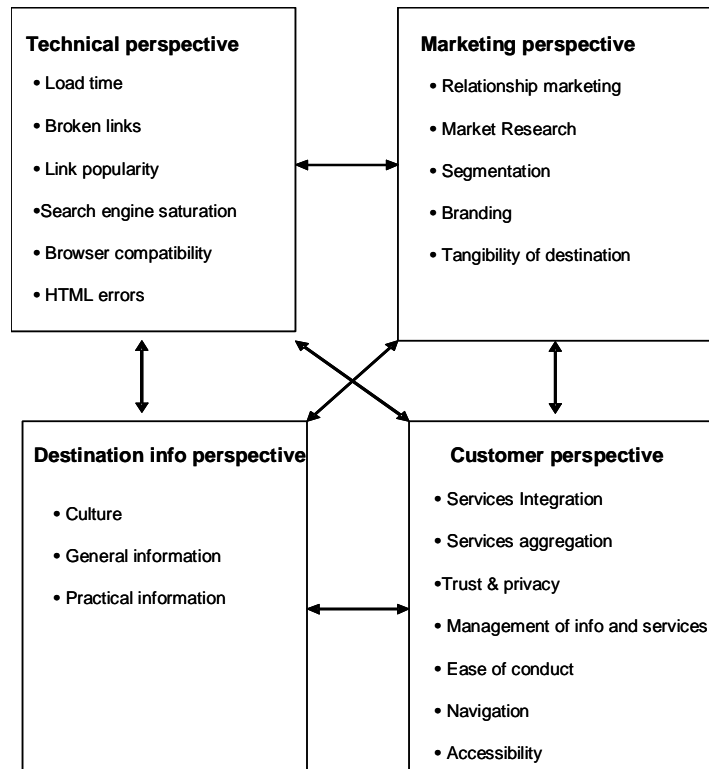

FIG. 1: BSC FRAMEWORK

## Reliability Assessment, Scoring System and Determinants of NTOs' Performance

In performing content analysis it is essential to refine the coding instrument until a satisfactory level of reliability is achieved (Krippendorff, 1980). From the three types of reliability. a) *stability over time*; b) *accuracy*; c) *inter-coder reliability*; the last has been demonstrated through the assessment of the coefficient of agreement and the Krippendorff's alpha coefficient. Two randomly chosen websites were analysed independently by the second author and 23 pairs of disagreement were found, out of a total number of 246 (123 criteria for each portal). This implied a coefficient of agreement of 0.90 per cent, well above the cut off value of 70 per cent recommended by the literature (Boyatzis,1998:156). Similarly, Krippendorff's alpha, has been found 81.29 per cent, again above the suggested limit.

The coding unit is represented by the single items. Contrary to web evaluation based on a Likert type scale (Davidson and Yu, 2005; Morrison *et al.*, 1999), a binary code (Mich and Franch, 2002; Feng *et al.*, 2002) was followed where a score of 1 was given if the item was available, and 0 if not. According to the coding instrument's rules, multiple references of the same item were ignored. Following coding, the overall score (*Score*) for each of the three categories (*j*) was quantified as follows:

$$Score_j = \sum_k S_k / TOTS \quad (1)$$

where: *j* = the perspective category, *j* = 1, 2, 3; *k* = the item subscript, *k* = 1, ...,129; *s<sub>k</sub>* = the number of items found in each NTO portal (answered as "yes"); TOTS = the total maximum number of possible items for each perspective (i.e 45 for customer perspective). Based on this score, each portal, within each of the 3 perspectives (marketing, destination information and customer), was ranked in a descending order from 1 to 25, with means assigned to ties. Only, in the case of the technical perspective, each portal has been ranked within each of the 6 technical criteria used, six different times (Tab. 1).

TABLE 1: TECHNICAL RANKINGS

NTO EU member state	HTML errors <sup>a</sup>		Compa tibility Problems <sup>b</sup>		Link Popularity <sup>c</sup>		Search Engine Saturation <sup>d</sup>		Down loaded time at 56K <sup>e</sup>		Broken Links <sup>f</sup>		Sum of Rankings

Hungary	24	14	15	13	21.189	14	5.650	21	241,22	25	38	16	103,0

Notes: a) refers to the number of errors, as estimated by www.netmechanic.com; b) refers to any unsupported HTML tags and attributes that block viewing on specific NTOs' browsers, as estimated by www.netmechanic.com; c) refers to the number of pages in each search engines index that contains a link to a portal's domain, as estimated by www.marketleap.com; d) refers to the number of pages a given search engine has in its index for the NTO website domain, as estimated by www.netmechanic.com; e) refers to the download times (seconds), as estimated by www.watson.addy.com; f) refers to the total links, as estimated www.netmechanic.com.

Kendall's Coefficient of Concordance (W) was calculated to test the degree of association among the 4 different rankings as follows (Siegel and Castellan, 1988: 271):

$$W = \frac{\sum_{i=1}^N (\bar{R}_i - \bar{R})^2}{N(N^2 - 1)/12} \quad (2)$$

where: N = the number of portals to be ranked;  $\bar{R}_i$  = the average of the ranks assigned to the *ith* portal,  $\bar{R}$  = the average (or grand mean) of the ranks assigned to a portal across all the categories. Since the sample consisted of 25 EU NTO portals, this coefficient can be approximated by a chi-square distribution ( $X^2$ ) with 24 degrees of freedom.

A univariate analysis was conducted to investigate the extent to which country context variables could explain differences in the NTOs' performance. Namely, the following independent variables were considered: a) *popularity of a tourism destination*; b) *level of affluence*; c) *e-readiness level*; d) *cultural richness*. As no one of the empirical literature relates e-SQ to NTO portals and because there may be different competing explanations, the following null hypotheses have been stated:

- H 1. *Tourism popularity*. The on line offerings performance (in terms of marketing, destination information, customer and technical perspectives) of NTO portals' is equal in popular tourist destinations and in less popular tourist destinations, within the EU;
- H 2. *Affluence levels*. The on line offerings performance of NTO portals' is equal, in affluent destinations and in less affluent destinations, within the EU;
- H 3. *E-readiness*. The on line offerings performance of NTO portals' is equal in e-advanced destinations and less e-advanced destinations, within the EU;
- H 4. *Cultural richness*. The on line offerings performance of NTO portals' is equal in cultural rich destinations and in less cultural rich destinations within the EU.

In order to test the hypotheses, the sample of portals' was split into the 8 independent groups as illustrated in Tab.2.

## Findings and Analysis: Destination Information Category

The results of the BSC approach to evaluate the EU NTO portals are summarised in Tab. 3. It emerges that Denmark achieved the best overall ranking (4.8), implying that currently the Danish portal is the most customer led one, whereas the Latvian (19.9) and the Greek portal (21.1) occupy the last positions, with the latter being the worst of all in terms of the marketing perspective.

TABLE 3: OVERALL RANKINGS THROUGH THE BSC FRAMEWORK

EU Member state	URL	Marketing Ranking	Customer Ranking	Destination Info Ranking	Technical Ranking	Total
Denmark	<a href="http://www.visitdenmark.com">http://www.visitdenmark.com</a>	3	1	2,5	12,5	4,8

Slovakia	<a href="http://www.slovakiatourism.sk">www.slovakiatourism.sk</a>	20	17	11,5	16	16,1
Portugal	<a href="http://www.visitportugal.com">http://www.visitportugal.com</a>	14	15	19,5	18	16,6
Poland	<a href="http://www.poland-tourism.pl">http://www.poland-tourism.pl</a>	20	24	21,5	2	16,9
Italy	<a href="http://www.enit.it">http://www.enit.it</a>	20	19,5	25	6	17,6
Lithuania	<a href="http://www.travel.lt">http://www.travel.lt</a>	24	19,5	19,5	11	18,5
Latvia	<a href="http://www.latviatourism.com">http://www.latviatourism.com</a>	23	24	11,5	21	19,9
Greece	<a href="http://www.visitgreece.gr">http://www.visitgreece.gr</a>	25	24	21,5	18	22,1

Kendall's coefficient of concordance was found  $W=0.410$ , considering the four rankings of the BSC approach, adjusted for ties, and equal to 0.647 excluding the technical ranking. It is evident that this value is not perfect, however  $X^2$  (39.35) is statistically significant at 5 per cent level and it can support the conclusion that the Danish portal has the best performance in terms of the four perspectives combined.

Tab. 4 presents the descriptive statistics of our sample. The average scores in the three categories indicate that the NTOs' performance was higher in terms of Destination information in comparison to the Marketing and Customer categories of the BSC approach. Of the overall sub-categories of the scoring list, "culture" and "navigability" are the ones with the highest performances, averaging 76 and 73 per cent respectively (consult Tab. 6 for the sub-totals and frequencies of the single items).

TABLE 4: DESCRIPTIVE STATISTICS

Perspectives	Minimum	Maximum	Mean	Std. Deviation
Marketing	0.28	0.77	0.507	0.146
Customer	0.29	0.73	0.478	0.130
Information	0.17	0.86	0.674	0.143
Technical	30.00	103.00	60.760	16.741

Figure 2 shows the distribution of Destination information scores across the 25 portals. It reveals that the NTO portals are performing quite similarly, implying high degrees of standardisation in the levels of information provided online. This pattern may be further investigated by considering Tab. 6. For example, as expected, the vast majority of NTO sites provide practical advices covering basic useful travelling information (e.g. transportation, public holidays, entry requirements, etc.). However, less than half of them (40%) show increased sensitivity for the tourists' needs by including useful tips, such as information regarding tourist discounts, or information regarding foreign embassies and consulates in their country (36%).

FIG. 2: DISTRIBUTION OF BSC SCORES ACROSS PORTALS

The Dutch portal manages better to promote Holland through the provision of an impressively rich and well organised content. The practical advices provided go beyond the “typical” basic practical information before visiting the destination, covering aspects such as immigration and work permit regulations. The last place in this category is occupied by the Italian NTO portal since the latter fails completely to transmit a comprehensive picture about the diversity of the different Italian regions and it gives very limited attention to the Italian cultural assets such as local events. In addition, its content is poor and sometimes even outdated. By consulting the sub-category *Culture* (Tab. 6), it emerges that the EU countries have understood the power of internet for marketing their own culture. All the websites maintain separate sections where the artistic heritage of the destination such as castles, churches, museums, as well as the local culinary traditions are thoroughly described. Moreover, the majority of them (21 portals) is in the

position to provide an updated database, which covers the main incoming local events, with a particular emphasis on the small characteristic local festivals. Although it is evident that some destinations put more effort in marketing online their culture more extensively (e.g. Belgium, Netherlands, etc.), again it can be argued that the cultural cues used to promote a destination are characterised by relatively high degrees of standardisation. Only when it comes to examining the promotion of local handicrafts, trades and local food recipes, some higher degrees of individualism arise, with only 64% of them promoting the former and 40% of them providing the latter. Finally, interestingly enough, the relatively low destination information percentages of countries possessing rich cultural heritage such as Italy, France, Greece and Spain imply that the latter do not appear to leverage particularly successfully their NTO portals to promote it. Thus, it is confirmed the realisation of the Ismail *et al.*, (2002: 175), that there is no evidence of particular effectiveness of NTO websites from destinations with high number of cultural attractions and resources. The latter statement has been tested statistically in section 6.

## Customer Perspective Findings

Among the 25 portals, Denmark and UK scored higher within this category with the former having 33 out of the 45 identified items (73.3%) and the latter having 31 (68.9%) respectively. Both these NTO have realised the importance of “one site shop” as a driver of superior customer service for the contemporary demanding and time sensitive visitors. Both of them are offering direct online booking for accommodation, holiday packages and even more specialised vacation items, such as theatre and other attraction tickets. In addition, the British portal supports the acquisition of airplane tickets and it is offering a well organised online shop, where buyers can track the state of their orders.

By consulting the sub-category *Privacy and trust* (Tab. 6), it emerges that a) a “terms of use” section, b) a “privacy statement” for the collection of personal data and c) a “security certification” are often missing. In particular, the lack of the above, combined with: “neglecting to stating the source of information provided” in 19 out of 25 portals (76%), and to “guarantee any last updating date for the site’s content, antecedent of the last 2 months” in a stunning: 23 out of 25 portals, definitely influence the building of trust between the entity behind the website and its online visitors. Since trust and control of online users have been regarded as key components of e-SQ (Parasuraman *et al.*, 2005; Nysveen *et al.*, 2003) it exists a big margin for improvement.

The three web sites with the most disappointing performance in the customer perspective are the Latvian, the Polish and the Greek one (Fig. 2). These portals can be regarded as “product driven” ones, where emphasis is given on the presentation of as much as possible information about the country, failing to organise this information and to “empower” their visitors, through the provision of advanced search engines which allow them to discover on their own *only* that kind of information they are mostly interested about.

Disappointing is the picture regarding the measures undertaken by the portals for assuring *accessibility*, accommodating different users’ needs and capabilities. More specifically, while the majority of the websites under examination (17) include sufficient information regarding accessibility for travellers with special needs, only 2 of them (the Spanish and the British NTO) declare that their portals are adhering with the legal imperatives for accessibility according to the web content accessibility guidelines (<http://w3.org>). This is consistent with the findings of Williams *et al.*, (2004) who found discouraging low levels of accessibility for tourism related websites in Germany and UK. A further category where the sample portals are performing particularly weakly is *service integration*, averaging 12 % across the total sample. Virtual communities are recognised as services of value added (Nysveen *et al.*, 2003; Hjalager, 2001) however, only 2 NTO websites (the Slovenian and the Irish one) are making use of them. As far as it concerns the category *management of information* the majority of portals (23 portals, or 92%) make extensive use of modern internet applications such as interactive maps, whereas less than half of them (9 portals or 36%) offer a complete value added service including the provision of directions of *how* to reach different destinations and/or a route planner (10 portals, or 40%) and even fewer are providing directions for alternative ways of transporting. Finally, it is worthy mentioning that, regardless the portals’ large size, the majority of them (73%) include functions which enhance navigability.

## Marketing and Technical Perspective Findings

As Fig. 2 reveals, the UK NTO website has scored higher in the marketing category, with 33 out of the 43 examined items (76,7%) being present. It appears as highly interactive with strong brand identity and satisfactory information customisation and personalisation features. Moreover, its design effectively supports market research and targeted marketing activities, and finally it assists the tangibility of destination through the provision of a wide variety of helping cues. On the other hand, the Greek and the Lithuanian portal have the poorest on line presence in terms of marketing functions (27.9% and 32.6% respectively) and need urgently to improve their efforts in marketing segmentation, tangibility of destination and market research. Finally, many websites such as the NTO portals of Estonia, Italia, Poland, Luxembourg and Slovakia have scored equally low (37,2%) implying the existence of significant margins for improvement.

A closer examination of the single items highlights some specific features within the *relationship marketing* category. First of all, it can be argued that the websites employ relatively low levels of interactivity, with only 11 or 44% of them supporting online feedback forms, and only two of them (Slovenia and Portugal) including users' ratings on: a) price offers and/or b) usefulness of the information received. Once more, very few of them (only 3) seem to have realised the importance of "word of mouse" and provide the possibility to browse other users' experiences and comments on certain issues. Similarly, there have been detected varying levels of customisation and personalisation of information. In terms of personalisation items, the sample websites did not perform well since only 36% of them (9 portals) are allowing online visitors to select, organise, and store personal interest information into a "favourites section" and even less (12% or 3 portals) maintain in memory previous settings such as "choice of language".

As far as it concerns the *segmentation category*, the vast majority of them (23), in conformity with one of the strongest trends of the last years, are providing extensive information for spas and fitness centres, in an attempt not only to satisfy better the needs of their online users, but also to target more effectively the most valuable market segments. Moreover, slightly more than half of these portals (52%) are including a city break section, another important trend gaining popularity among the time sensitive tourists of nowadays. On the other hand, segmentation according to lifestyle is not extensively used. Indeed the provision of a separate nightlife section, with information regarding entertainment options is a less strong trend (only: 44% or 11 portals). The other emerged targeted segment is business tourism, with 21 portals (84%), providing separate, specialised web-sites within their main portal. In terms of the number and kind of cues used to enhance the *tangibility of the destination*, although almost every portals makes use of tools such as maps (100%) and photographs of landscapes of different regions (88%), more sophisticated and advanced tools such as virtual tours (10 portals or 40%) or video clips (13 portals or 52%), and webcams (3 portals or 12%) are not yet fully employed.

Eight items have been used to examine whether the NTO are *branding* their site sufficiently. Among these: a logo is included in the homepage of all the portals(100%), as well as in the rest pages (84%). However, the sites often miss a quality certification (only 7 out of 25 portals do have one), failing to assure their visitors for the content of the information provided. Finally, they hardly include data on their use, such as number of registered users, number of hits, etc. (1 out of 25 portals only). By consulting the *marketing research and customer database* category, it emerges that the majority of the NTO portals (76%) are maintaining a customer database since they allow their visitors to register online. A less popular way to gather personal data regarding their visitors, is through online competitions (12 portals or 48%). In terms of market research and targeting: 52% of the websites (in total 13 portals) track the country of origin of the different visitors and 11 portals provide multiple versions of their website, with content adjusted to reflect the local tourist market conditions of each country.

As Tab. 3 reveals, the Dutch NTO portal was the one which scored higher in the technical perspective. Indeed, the latter portal gained the highest ranking position in terms of HTML errors and browser compatibility problems, an equally high classification in terms of broken links and overall downloaded time at a 56K speed connection (3<sup>rd</sup> position), and the 4<sup>th</sup> position in terms of search engine saturation (Tab. 1). On the other hand, the Hungarian website was rated as the least technically sound NTO portal with serious delays in downloading time. Finally, the high positions of some of the accession states, such as the 2<sup>nd</sup> position of Poland, the 3<sup>rd</sup> position of

Czech Republic in contrast to the lower classifications of more e-advanced nations such as Sweden and Ireland (Economist, 2005) support the position that Internet empowers new players and boosts competitiveness regardless the smaller internet penetration rates of the latter.

## Hypothesis Testing

The Wilcoxon-Mann Whitney has been calculated to test whether the online performance were equal in the 8 groups of countries defined in para. 4.2. It emerged that the variable affluence (see Tab. 5), has a significant influence on the online performance in terms of marketing, destination information and customer perspective. The Austrian, French, German, Belgian, Danish, Finish, Irish, British, Italian, Dutch, Swedish, Spanish and the Luxembourg NTO portals with a mean rank of 16.31 in terms of marketing, 15.85, in terms of customer and 16.96 in terms of destination information, perform almost twice as the portals from the less affluent countries (Greece, Portugal and the ten Accession states) with a mean rank of 9.42, 9.92 and 8.71, respectively. On the contrary, the “affluence” variable does not have any significant influence on the online performance of the NTO portals in terms of technical perspective. The remaining three independent variables were not found to have a statistically significant influence on the NTO portals’ online performance.

TABLE 5: WILCOXON-MANN WHITNEY TEST

Perspectives	Groups	N	Mean Rank	Sum of Ranks	Z
Marketing	Affluent	13	16.31	212.0	-2.352 <sup>***</sup>
	Less affluent	12	9.42	113.0	
Customer	Affluent	13	15.85	206.0	-2.017 <sup>**</sup>
	Less affluent	12	9.92	119.0	
Information	Affluent	13	16.96	220.5	-2.817 <sup>***</sup>
	Less affluent	12	8.71	104.5	
Technical	Affluent	13	13.31	173.0	-0.218
	Less affluent	12	12.67	152.0	

<sup>\*\*\*</sup> and <sup>\*\*</sup> indicate statistical significance levels of 5 percent and 1 per cent , respectively, in two-tailed tests

Finally, an univariate correlation analysis was performed to assess the relationship between the four perspectives. All correlation coefficient were positive, except between customer and technical and between technical and destination information perspectives. Marketing was the most significant contributor to the total score at 0.907 ( $p < 0.01$ ) followed by the customer category at 0.765 ( $p < 0.01$ ). Moreover, a positive and high correlation (0.749) was found between the Marketing and the Customer perspective ( $p < 0.01$ ), a realistic result since e-marketing excellence by definition is closely related to customer orientation. The correlation among the other perspectives was low and insignificant.

## Conclusion and Further Research

This study analyses the on line offerings of 25 EU NTO using a framework that captures four e-quality categories. It is found that NTOs have realised that by just including basic information on their websites and waiting for online visitors to arrive is not a viable solution anymore. However, even if the vast majority of them demonstrate “acceptable” levels of online performances significant margins for improvements do exist. In particular, there were observed relatively high degrees of standardisation in the areas of: content of information for the destination and cultural cues used to promote the destination. This implies that the NTOs are failing, up to a certain extent, to create a “unique sales proposition” to promote their destination. In most of the cases, some basic features necessary to promote “trust” for the online users were missing. In addition, basic features enhancing accessibility for *all* online users were almost absent. Lastly, some further areas to work on are: a) interactivity among the users and the portal, b) service integration applications and virtual communities. The results support the hypothesis that the affluence

variable has a significant influence on the online performance in terms of marketing, destination information and customer perspective.

This research is a necessary *first step* in order to make inferences about the current level of online offerings and e-quality provided by the NTO web sites. *Customer perceptions* of e-quality need to be explored as well in order to form a complete picture of online quality. Thus, future research could concentrate on increasing our understanding of: *which of the information and services present here contribute the most* in achieving a high level of overall service quality, as perceived by the end users and b) if the latter perceptions are *culturally sensitive*. A survey could be addressed to online users with the scope to capture which of the identified on line services are rated as most important by prospect tourists when seeking tourism information on line and in what order of importance. The latter would be of particular value to the NTO, since it would reveal eventual gaps between their current offerings and customers preferences of on line value added services. A further interesting direction would be: to examine if these findings can be generalized in *other categories of tourism websites* more profit oriented.

Due to the dynamic nature of web sites the reported results can be considered valid only for a limited period of time. As Feng *et al.*, (2002) comment they provide only a snapshot in time. Thus, it would have been necessary to monitor how their content and consequently also their online service quality evolve through time.

# Glocalization of bilingual websites of global corporations

*Miranda Y.P. Lee*  
*The Hong Kong Polytechnic University, Hong Kong*

## Abstract

Glocalization, as a portmanteau of globalization and localization, means the co-presence of both universalizing and particularizing tendencies (Robertson, 1997). It highlights the fact that the globalization of a brand is more likely to succeed when the brand is adapted to the locality or culture it is marketed in. Internet as a global communication medium is often used by a global corporation to market its product or service and to promote its image for local communities. Corporate website becomes the major medium to present a corporation's messages to local communities around the world, and to demonstrate its understanding of the social world of the local communities. A well-designed corporate website therefore has to 'be global and speak local'. The term 'speak' here is interpreted as communicating with the local communities in their way of speaking, such as their tone and style. In order to meet the expectations and to follow the linguistic and cultural conventions of diverse communities, the local or the subsidiary websites of a global corporation often adopt rhetorical strategies which may differ from those adopted on its main or master website. The rhetorical strategies including discourse, rhetorical devices and register may even vary among polities speaking the same language, such as within the Greater China region.

## Background and Objective

In recent decades, an overwhelming number of global corporations have expanded their market to Greater China and many of them have established subsidiary websites for readers in the region. However, comparative analyses of bilingual websites targeting diverse local communities in Greater China are very limited. This preliminary study seeks to examine how the top global corporations localize their websites targeting readers in Greater China, and how they demonstrate their concerns and understanding of diverse local communities. The content selection and the ways of presentation may differ between the main and the subsidiary websites which are in different languages, as well as among the subsidiary websites of different polities. Findings from the study demonstrate certain patterns of how the top corporations glocalize themselves on their corporate websites, and provide a useful reference for drafting websites that communicate effectively with diverse local communities, especially those in Greater China. Specific objectives are as below:

1. to examine how global and local elements co-present on corporate websites;
2. to identify inter-linguistic and inter-cultural differences in rhetorical strategies of websites targeting western and Chinese readers, by comparing the bilingual (English and Chinese) versions; and
3. to analyse intra-linguistic and intra-cultural variations of websites in Chinese, through comparing different Chinese versions targeting readers of Mainland China, Hong Kong, and Taiwan.

## Methodology

The study analysed the main and the subsidiary websites of global corporations targeting respectively the English speaking communities and the Chinese speaking communities in Greater China. In order to make the data more representative and to ensure a broad coverage of different business nature, I selected global corporations from various industries or fields including automobile, banking, electronics and electrical appliances, food and catering, information technology, insurance, logistics, and petroleum. As a preliminary study, the top two corporations in each of these industries from the list of Fortune Global 500 in 2006 which have their subsidiaries or branches established in Greater China for more than a decade were chosen as samples. Bilingual websites of 16 global corporations in total formed the corpus for analysis (see Table 1 below). The analysis concerns mainly the rhetorical patterns

including the discourse, rhetorical devices and register adopted in the corporate slogans, corporate history and profile on the websites.

TABLE 1: CORPORAT WEBSITES ANALYZED IN THIS STUDY

Industries / fields	Corporations	
Automobile	Toyota	Ford
Banking	Citigroup	HSBC
Computer & Information technology	Dell	Microsoft
Electronics and Electrical appliances	Siemens	Hitachi
Food & Catering	Nestlé	PepsiCo
Insurance	AXA	ING
Logistics	Maersk	FedEx
Petroleum	Exxon Mobil	Shell

### Co-Presence of ‘Global’ and ‘Local’ Elements

A global corporate website serves as a useful medium to establish the corporation’s global image, and at the same time to show its understanding of local communities. Many global corporations have expanded their business to Greater China and set up their websites for local communities there. This section illustrates the successful examples of some of these global corporations in designing their subsidiary websites for Greater China, and seeks to provide a reference for other global corporations which plan to develop their websites for the Greater China communities.

‘Global’ and ‘local’ elements often co-present on the bilingual websites of multinational corporations operating in Greater China. HSBC is one of the typical examples embracing both ‘global’ and ‘local’ elements on its main website as well as on its subsidiary websites for diverse local communities. Its corporate slogan “the world’s local bank” illustrates its ambition to ‘be global and act local’. Its Hong Kong website states in the corporate profile page in English and Chinese that:

“At the Group’s core around the world are domestic commercial banking and financial services, which fund themselves locally and do business locally.”

“集團在世界各地以商業銀行及金融服務作為核心業務。此兩項業務以本土市場作為資金來源和經營地區，並運用技術提高效率，提供符合當地客戶需要的各種國際產品及服務。”

Similarly, on its Taiwan website, HSBC highlights the importance of ‘local’:

“We never underestimate the importance of local knowledge.”

The corporate website of AXA also demonstrates “interconnections of both global and local institutions and cultural practices” (Holton 2005, p.130). The website for the Mainland community displays a high degree of attachment to and support of local culture. As noted by Roudometof (2005, p.126), “such an attachment and support for local culture are likely to take a variety of different forms depending upon the specifics of different national cultures around the globe”. For instance, AXA relates its contributions to the economic development of China. Its mission stated on the China website is:

“承諾發展，貢獻中國”

(*committing to the development, contributing to China*) (researcher’s translation)

AXA China stresses its attachment to the local society and aims to develop as a “nation-wide insurance company”. On the other hand, AXA is marketed differently for the Hong Kong community. It emphasizes its global leadership in the industry – “a worldwide leader in financial protection”, and writes: “In Hong Kong, we are one of

the top general insurers with over 170 years of experience in Asia.”. The local tendencies are not so apparent on the Hong Kong website than on the China one.

The co-presence of global and local elements is not confined to banking and insurance industries. It is also common across different industries. Siemens on its website for the Taiwan community shows its global and local commitments – “global innovation, local partnership” (創新全球 在地夥伴).

## Inter-Linguistic and Inter-Cultural Differences between English and Chinese

The above mentioned ways such as adopting words of ‘world’, ‘international’, ‘domestic’ and ‘local’, and listing the facts of the ‘global’ and ‘local’ achievement of the corporation are explicit means to glocalize a corporate website. There are other means which can be considered as implicit for achieving the goal of glocalization. A corporate website may display how ‘local’ the global corporation is through adopting the way of ‘speaking’ of the local communities on its subsidiary website. This section compares the bilingual (English and Chinese) versions of the main and the subsidiary websites of the same corporations, and focuses on rhetorical comparisons between two language versions targeting communities from distinct linguistic and cultural backgrounds.

The English and the Chinese versions of the same corporations may differ in the foci of messages presented. The English version often provides a detailed history of the corporation; while the Chinese one tends to skip the details and adopts a simplified version instead. The latter often explains the corporate logo and the origin of company name. Such examples as Citibank of which its main website in English lists a detailed timeline of the history with a caption “The story of Citigroup: 100 countries. 200 years”. Its Chinese versions for the Hong Kong and the Taiwan communities on the other hand give only a brief introduction to the history but add an explanation of the logo of ‘red umbrella’. Similarly, Hitachi Hong Kong shows how the company name is formed on its Chinese version, but not in its English one:

“HITACHI由兩個漢字拼合而成：「HI」代表「日」，而「TACHI」代表「立地」，象徵人類通往直前，立地前瞻初昇的旭日，計劃更美好的生活與未來。”

*(Hitachi is formed by two Chinese characters: ‘Hi’ represents ‘sun’ and ‘Tachi’ represents ‘standing on the earth’, symbolizing that humans move forward, standing on the earth facing the rising sun, and plan for a better life and future.)*

ING also mentions its logo in the corporate profile on its Taiwan Chinese website:

“ING集團的表現就如其企業標誌 – 獅子般耀眼”

*(The performance of ING is as outstanding as the lion on its corporate logo.)*

While the above explanations or references to the corporate logo or name are popular in the Chinese versions, they are not so common in the English ones.

The second distinctive feature between the English and the Chinese versions can be identified in the presentation of the message from top management. Examples include the corporate websites of AXA and Toyota. There is a webpage of “Message from Top Management” on the main website of Toyota in English. However, webpages of this kind are absent on the websites for the Mainland and the Hong Kong communities. In addition, messages from top management are often presented in more vivid and lively manner in the English than in the Chinese versions. For example, the main website of AXA in English uses direct quotes:

“ ‘We have chosen a demanding business... Our vision of the business is what guides our daily work. It reflects the social and human aspects of Financial Protection, whose value to people has never been greater.’ Henri de Castries – Chairman of the AXA Management Board”

Instead of presenting the corporate mission or vision in the form of direct quotes, the Chinese versions in Greater China adopt a rather descriptive and factual approach. Consider below the examples extracted from respectively the Hong Kong and the Taiwan websites:

AXA為客戶提供經濟保障及管理服務，……了解他們在不同階段的需要。

*(AXA provides financial protection and management services for customers, ...understand their needs at various stages.)*

AXA集團秉持為顧客提供財富保障及管理服務為信念，提供全面性的保險服務，……

*(AXA's mission is to provide financial protection and management services, as well as comprehensive insurance services for customers...)*

The third major difference between English and Chinese lies in the varying degrees of formality. The Chinese version tends to be relatively more formal than the English one. Parallel structure and formal register become some of the common rhetorical characteristics of websites in Chinese. Parallel structure or parallelism refers to a similarity of structure in a pair or series of related words. It is one of the typical rhetorical features adopted in phrasing Chinese slogans (Lee and So, 2007). It reinforces the message presented and gives readers an impression of a high degree of formality in Chinese (Lee et al, 2006). On the other hand, the English version adopts less formal register. Compare the English and Chinese slogans below:

The world's local bank (HSBC)

環球金融 地方智慧

Creating opportunities in global commerce (Maersk)

展望全球 創建商機

Be life confident (AXA)

生活無限 自有把握

Moving forward (Toyota)

車到山前必有路 有路必有豐田車

Each of the above Chinese slogans is presented in parallel structure – a pair of expressions containing the same number of characters.

Apart from slogans, headings in Chinese are often in parallel structure. For instance, ING adopts a strict structure for headings on its website in Chinese but not in English. Some of the Chinese examples include the following which are structured in pairs of four-character expressions:

櫃台服務 最為貼心

*(The most comprehensive front desk service)*

主動出击 了解您心

*(Be proactive and understand what you think)*

## **Intra-Linguistic and Intra-Cultural Variations in Greater China**

One may expect that the rhetorical patterns of corporate websites are similar among the Mainland, Hong Kong and Taiwan since the main readership of these websites is Chinese speakers. In fact, the content, foci and register differ across polities in the Greater China region. Since Chinese communities in these polities have diverse expectations and varied cultural and linguistic norms, corporate websites need to adopt rhetorical strategies that are considered appropriate for the local communities. A comparative analysis of websites across different polities in Greater China can help illustrate how global corporations localize themselves, i.e. how they make themselves look local.

In terms of the availability of language versions of websites, there exist assumptions that a global corporation provides only a Chinese version for the polities in Greater China, and that bilingual versions are not common there since an English version is already available on the main website of the corporation. However, my investigation reveals that not all sampled global corporations offer a Chinese version for the local communities in Greater China. Some of the corporations offer only an English version, for the Hong Kong community in particular, such as Ford. In addition, bilingual versions in both English and Chinese are common in Hong Kong but not so

common in other two polities (see Table 2). Microsoft is an example of this kind.

The above findings reveal the corporations' positioning and their response to the different expectations of diverse communities within the Greater China region. English is a common medium of business in Hong Kong whereas Chinese is still the major language used in other two polities, Mainland China in particular. Certain global corporations may attempt to enhance their local relevance by providing only a language version which is widely accepted by the local communities. In fact, for those corporations which offer only monolingual versions for their subsidiary websites, many of them are in Chinese for the Mainland and the Taiwanese readers, but not for the Hong Kong group. Examples include Ford, Toyota, etc.

Table 2. Language versions provided by the sampled corporate websites

Corporations *	Language versions of websites					
	Mainland China		Hong Kong		Taiwan	
	<i>English</i>	<i>Chinese</i>	<i>English</i>	<i>Chinese</i>	<i>English</i>	<i>Chinese</i>
AXA	✓	✓	✓	✓	✗	✓
Citigroup	✓	✓	✓	✓	✓	✓
Dell	✓	✓	✓	✓	✓	✓
Exxon Mobil	✗	✓	✗	✗	✗	✗
FedEx	✓	✓	✓	✓	✓	✓
Ford	✗	✓	✓	✗	✗	✓
Hitachi	✓	✓	✓	✓	✗	✓
HSBC	✓	✓	✓	✓	✓	✓
ING	✗	✓	✓	✓	✗	✓
Maersk	✓	✓	✓	✗	✓	✓
Microsoft	✗	✓	✓	✓	✗	✓
Nestlé	✓	✓	✗	✓	✗	✓
PepsiCo	✗	✓	✗	✗	✗	✗
Shell	✓	✓	✓	✓	✗	✓
Siemens	✓	✓	✓	✗	✓	✓
Toyota	✗	✓	✓	✗	✗	✓

\* Corporations are listed according to alphabetical order of the corporate names.

In order to fulfil diverse expectations of different communities, global corporations tend to vary the content and adopt different foci on their websites. One distinctive feature among the three polities is an emphasis on awards for the Mainland and the Taiwan websites but not for the Hong Kong one. For instance, Citibank Taiwan lists its awards in a rather elaborate approach but Citibank Hong Kong does not choose awards as the main content for its website.

“花旗銀行在台灣卓越的表現，連續多年獲得Finance

Asia雜誌『最佳外國商業銀行』的肯定。2006年，花旗銀行更連續十二年榮獲天下雜誌評選為『銀行業最佳聲望標竿企業』！”

*(The outstanding performance of Citibank Taiwan has been recognized by Finance Asia as the Best Foreign Commercial Bank in Taiwan. Citibank has also been recognized by Common Wealth Magazine as “The most respected bank” for 12 years.)*

Citibank Taiwan lists its awards in detail on its website. Similarly, HSBC China and Taiwan emphasize HSBC's achievement by listing her awards on their websites. While corporations like Citibank and HSBC have been well-established in Hong Kong but are relatively new in the Mainland and Taiwan, more emphases on the achievement, especially the concrete one as represented by awards, become essential for the latter two polities.

The third distinctive feature among the three polities is the relevance to the local government. Websites for the Mainlanders often highlight the corporations' relations with the local government and display the support gained from it. For instance, Ford China shows the support from the former President of PRC in its corporate profile:

“福特汽车当时的董事长亨利·福特二世于1978年得到了邓小平先生的见，……”

*(Henry Ford, the Chairman of Ford, had a meeting with Mr. Dang Xiao-ping in 1978...)*

Microsoft China demonstrates its mission to collaborate with the local government by stating that:

“协助政府发展中国软件产业

积极参与政府和企业进行信息化建设”

*(It assists the government in developing the software industry in China.*

*It actively participates in the government's and the corporations' development of information technology.)*

Siemens China also shows its contribution to the local economy in both its Chinese and English versions. Its websites write:

“西门子是中国经济不可分割的一部分，也是积极帮助中国完成主要基础设施建设和实现工业现代化忠实而可靠的合作伙伴。”

“Siemens is an integral part of the China economy and a reliable, committed and trustworthy partner of China actively contributing to major infrastructure developments and industrial modernization.”

The above characteristic of a particular relevance to the local Chinese government is not common in other two polities. It is rather culturally specific in the Mainland in which collaboration with the Chinese government and gaining its support are essential for the success of doing business in China.

Another intra-cultural dissimilarity is the varied emphases on corporate citizenship. Corporate citizenship is interpreted differently across the three polities. Concrete actions on achieving social responsibility are highlighted on the Taiwan websites, as illustrated by example of Citibank Taiwan:

“本著取之於社會，用之於社會的精神，長期贊助喜憨兒基金會、公共電視種籽教育基金、亞卓市，...

... 以扮演良好的企業公民為己任，希望為台灣建立一個更美好的未來。”

“Since 1995, Citigroup has been actively involved in both education and community development in Taiwan, sponsoring many programs such as the Elementary School Financial Education, Dollars and Sense - a financial education program for teenagers, ... These programs have been well received by the public and demonstrate Citigroup's long-term commitment to the community in which it lives and runs its businesses.”

However, corporate citizenship is not the major concern in Mainland China. As a result, it is only briefly mentioned on the websites for the Mainlanders.

The fifth distinctive feature is the varying degrees of formality in register among the three polities. Numbers are often presented in a full form, i.e. Chinese characters, on the Mainland website, but are in an Arabic presentation for other two polities. Compare below the different presentations of numbers on the websites of respectively Mainland China, Hong Kong and Taiwan:

“花旗以全球领先的金融服务经验在一百多个国家约为二亿客户提供金融服务。”

*(Citibank is a global leader of financial services, providing services for two hundred million customers in more than one hundred countries.)*

“客戶約達200,000,000人，業務遍佈全球100多個國家。”

*(Our customers reach 200,000,000. Our service covers more than 100 countries.)*

“目前共有3200名員工及11家分行，……”

*(Currently there are 3200 staff and 11 branches, ...)*

Websites for the Mainland Chinese and the Taiwanese communities adopt relatively more formal register as compared to the Hong Kong websites. A use of pronoun, such as ‘we’ or ‘us’ for addressing the corporation, is regarded as less formal than using the corporate name. For the title or caption of introducing the corporation, the websites for the Hong Kong community tend to use “關於我們” (About us) while those for the other two polities use the corporate name, such as “關於花旗” (About Citibank).

Another point relating to the address form of the corporation is the language code presenting it. There is a tendency for the Mainland websites to use the Chinese code. On the other hand, websites for the Hong Kong and the Taiwanese communities often switch the codes, firstly use Chinese and then switch to the English names of the corporations. AXA is one of the examples. Only the Chinese corporate name “金盛” but no English name “AXA” is used on its Mainland website. However, the corporate name is firstly presented in the Chinese code, “安盛” and “瑞泰” respectively for the Hong Kong and the Taiwan websites; and then switch to its English name “AXA”. The code-switch phenomenon is rather common in Taiwan. To take Ford Taiwan as an example, its website firstly uses “關於福特” as the caption for the corporate profile. In the context of the profile, it switches to use “FORD”. When introducing the corporate history, “Ford 歷史” becomes the caption. On the other hand, the code for the corporate name is relatively consistent in the Mainland. “福特” is used throughout the whole website.

The last linguistic feature which merits discussion is the deployment of rhetorical devices. Websites for the Mainland were found to adopt more parallel structures than those for the other two polities. For instance:

卓越银行服务

*(Outstanding banking service)*

备受全球信赖

*(Globally trusted)*

The above examples are some of the captions or headings on the website of Citibank China, in parallel structures of six-character expressions. Similarly, AXA China adopts a parallel structure for its values:

专业 创新 务实 团结 诚信

*(professionalism, innovation, pragmatism, integrity, trust)*

While many parallel structures were identified on the Mainland websites, the construction of expressions is not so strict in other two polities. A strict structure of expressions is a manifestation of a high degree of formality in Chinese, as a means to show respect for readers. This finding is in line with that relative to the address form for the corporations discussed above. The register of the Mainland websites is more formal than that of other two polities.

## Conclusion

A corporate website can be considered as a mirror of a corporation for projecting its corporate image to its stakeholders. It also helps promote corporate culture and illustrates its concerns for local communities. In order to achieve a common goal of multinational corporations for projecting global image and practicing locally, certain rhetorical rules and patterns need to be observed in designing websites for diverse communities.

This paper has attempted to generalize some inter-linguistic and inter-cultural patterns between the English and the Chinese versions, as well as some intra-linguistic and intra-cultural variations of the Chinese communities in Greater China. It succeeds in raising awareness of these variations in glocalizing a corporate website, and in providing a useful reference for effective communication through websites targeting diverse communities in Greater China. Findings were obtained from observations on bilingual websites of some top global corporations. They are preliminary and may not be universally applicable. The rhetorical strategies in fact are rather corporate culturally specific, highly dependent on the unique corporate culture and positioning. Nevertheless, the study offers a prelude for future investigations which may involve more corporate websites from diverse industries, so as to verify if the glocalized patterns identified on the sampled websites and if inter-linguistic and inter-cultural differences between English and Chinese, as well as intra-linguistic and intra-cultural variations in Greater China apply to other global corporate websites.

## Abstract

Analyzing Quality Function Deployment (QFD) based on voice of customer aims to provide an advanced machine planning methodology based on QFD principles, for identifying and minimizing the risks of project failures due to failure in complying with the voice of the customers. This study focuses on the development of general QFD for machine specification selection so that it later can be used for any kind of machine evaluation prior to purchasing the machines. A set of questionnaires was used as an instrument and was distributed to 223 respondents. NN models were generated and statistical methods were used to explain the relationship between attributes used in this study. The findings from the experiments conducted exhibit that the significant correlations of QFD with customer voices help to explain the relationship between attributes used in the study. The study also indicates that NN forecasting model has been established with 12.30 percent misclassification error in determining the customer voices based on QFD. This indicates that the approach has the potential in explaining the relationship between QFD and the customers, as well as predicting the type of customer if QFD information is provided. Hence, the study reveals the type of machine and type of operation that are favourable to customer prior to acquiring the machines for their industrial usage. **Keywords:** Quality Function Deployment (QFD), Voice of Customer, Neural Network, Machine Planning

## Introduction

QFD is one of the techniques that aim to fulfil the customers' satisfaction at the very beginning, namely the product design phase. It enables the companies to become proactive to quality problems rather than taking a reactive position by acting on customer complaints. QFD technique is used to plan and design new or improved products and services. According to Wikipedia (2006), Quality function deployment of QFD is a flexible and comprehensive group decision making technique used in product or service development, brand marketing, and product management. QFD can strongly help an organization focuses on the critical characteristics of a new or existing product or service from the separate viewpoints of the customer market segments, company, or technology development needs. The results of the technique yield transparent and visible graphs and matrices that can be reused for future product/service development.

This study presents alternative ways to identify the relationship QFD and customer voices. It also aims to build QFD forecasting model with respect to different types of customers. The combination of effort in QFD and the utilizing of neural network as a tool of IT in manufacturing and product development will torch the light towards the creation of the QFD forecasting model. Some statistical techniques may be utilized to support the findings in this study.

## Related Works

QFD takes the voice of the customer from the beginning of product development and deploys it throughout the firm. Through QFD, the voice of the customer aligns the company's resources to focus on maximizing customer satisfaction. Customer satisfaction is influenced by product development outcomes which, in turn, are influenced by the technical and organizational dimensions. Basically, QFD is aimed to fulfil the customer's expectation of the product or service. San Myint (2003) describes a framework of an intelligent quality function deployment (IQFD) for discrete assembly environment of QFD as well as the project's profile. They used Taguchi experimental design for manufacturing process optimization using historical data and a neural network process model (Wimalin &

James, 2005). QFD with applied statistics techniques are employed to facilitate the translation of prioritized set of customer requirements into a set of system level requirements during conceptual design (Yu & Fu, 2004).

QFD is a proven tool for process and product development, which translates the voice of customer (VoC) into engineering characteristics (EC), and prioritizes the ECs based on the customer's requirements. Conventional QFD evaluates these targets for crisp weights of the customer attributes (CA), identified from the VoCs. Fuzzy logic approach to prioritize engineering characteristics in QFD (FL-QFD) addresses the issue of defining non-crisp customer attributes in the QFD. It is an innovative method of determining optimum rating of engineering characteristics (EC) by simulating the QFD matrix for randomized customer attributes (CA) in the fuzzier range (Rajam & Selladurai, 2004). Vivianne & Hefin (2000) reviews methods and techniques to assist QFD by integrating fuzzy logic with it since fuzzy logic exhibits some useful features for exploitation in QFD

Engineering systems have become increasingly complex to design and build while the demand for quality and effective development at lower cost and shorter time continues. The study employs neural networks based approach in QFD process to prescribe a new methodology to generate a conceptual design baseline. A generalized neural networks oriented conceptual design process is introduced and a hybrid intelligent system combining neural networks and expert systems for conceptual design. Statistical regression methods adopted in the past is computationally inexpensive but with poor accuracy (Yu & Fu, 2004).

Zhang *et al.* (1996) have proposed a machine learning approach to QFD, in which a neural network automatically evaluates the data by learning from examples. The suggestion is to incorporate the engineering solutions of the product (the in-house and the competitor's product), within the neural network to find weighting that represents the customer's satisfaction. The techniques such as fuzzy logic, artificial neural networks, and the Taguchi method can be combined with QFD.

Neural Network (NN) is an important technology of Artificial Intelligence, which have been widely used, in recent years, for manufacturing process monitoring using output pattern recognition (Guh and Tannock, 1999). Neural networks are found to be a good alternative to traditional analytical techniques, for the modelling of complex manufacturing process. This is because of the number of process variables involved, and the non-linear nature of problems. One major application with neural network is forecasting since they can provide a valid alternative to such conventional approaches as time series and regressions. Compared to the traditional statistical methods, neural network are apparently bare of priori assumptions supposedly underlying the models, more capable of addressing problems in the nonlinear domain where the dependent and independent variables are not realized with linear relationship, and rather more general and flexible to approximate any desired accuracy (Zhang *et al.*, 1998).

They have also been used, less frequently, for process modelling (Heider *et al.*, 2002; Jimenez-Marquez *et al.*, 2003), the approach which has been adopted in this study. A number of successful implementations of neural networks process modelling have been reported in Table 1.

TABLE 1: THE APPLICATION OF NEURAL NETWORKS IN PROCESS MODELLING IS SUMMARIZED

## Methodology

The main research design in this study is a survey type that would be used to build QFD modelling and carrying out the analysis. In order to meet the objective of this study, a QFD methodology described by Clausing & Pugh, 1991 is adopted (see Fig. 1).

FIG. 1: A PROPOSED ARCHITECTURE FOR ANALYZING QFD FOR CUSTOMER VOICE

For survey purposes, an instrument used is a questionnaire that contains two main sections, a customer profile and possible customer requirements. For customer profile, there are three parameters used namely, name of company or institution, type of customer and type of work piece material used. For customer requirements, there are six (6) sections according to machine standard specification, machine control, machine safety, machine performance, machine maintenance and machine after sales services. The important subject to focus is the target selected to model of QFD for industry which is type of customers. These include professional, management level, maintenance and an operator. A questionnaire was constructed based on the study by Abd Rahman & Mohd Shariff (2003) regarding the application of QFD method for pultrusion machine design planning. It has also been adopted from Khodabocus (2003). Khodabocus study indicates that the most important for QFD questionnaire design for the service is the subject matter under investigation and the statistical analysis employed in the study. This questionnaire is also based on the success factors of QFD projects by Herzwurm *et al.* (1997).

Neural network and statistical tools was employed to carry out the analysis. The approach for building forecasting model is adopted from Integrated QFD model methodology (see Fig.2) which was introduced by San Myint (2003). The NN technique is used to overcome QFD weakness in subjective judgments of relationship values with the help of human expert.

FIG. 2: STEP TO CARRY OUT FOR BUILDING FORECASTING MODEL

## Results

The survey was conducted to investigate and obtain information concerning Quality Function Deployment for general machine planning. The information obtained as a result of data mining activities could serve as guideline for future attempts to build forecasting model of QFD. The goal of the survey was to collect data from four different target type's voice of customers, professional, management, maintenance and operator. They are from engineering and technical background with industrial experience, concerning their views of the resources needed for successful machine planning process in the different areas addressed within the core organizational system, in alignment with its strategy and with particular reference to the experiences in their respective organization.

A total of 300 questionnaires were distributed to various customers, and 223 questionnaires were returned (74.3%). The distribution of customers with respect to their group type is illustrated in Fig.3. Based on Fig.3, the highest percentage for type's voice of customer contributed by operator (45%).

FIG. 3: PIE CHART OF TYPE OF CUSTOMERS

Professional group comes from those who are really involved in teaching how to operate the machine, either in terms of theory or practice. This group is selected from KUKUM, POLIMAS (Mechanical Engineering Department) and ILP, Jitra and 20% from overall sample. It is about 45 persons from three selected institution above. Management is for those who are really involved as a decision maker, such as the Dean and Deputy Dean for a faculty, Managing Director, Senior Executive, Engineer and Assistant Engineer. This group usually has more experience in handling the heavy machine, and also involved in selecting or forecasting the need for a machine at their institution. About 41 person or 18% are willingly to involve as a respondent for this study.

Maintenance group are globally expert from small to big matter in operating machine. They also ready to settle and troubleshoot a problem happen while machine was operated. For this study, around 36 people (16%) from 100% work as the industrial technician almost 10 years. The operator comes from POLIMAS student, the student who has already worked before pursuing their study. They are in final semester and have a good technical knowledge to joint this survey. They gave the exact answer for all questions. 101 operators (45.3%) were selected from 3 different classes (DKM 5B, DTP 6A, DTP 6B).

#### Types of Work Piece and Voice of Customers

Further analysis was conducted to explore the relationship between *types of work piece* with respect to voice of customers (see Table 2). Based on Table 3, all significant correlations at the 0.01 level (1-tailed) are highlighted. The significant attributes include *wood* ( $p = 0.00$ ,  $r = 0.776$ ), *plastic* ( $p = 0.00$ ,  $r = -0.266$ ) and *composite* ( $p = 0.00$ ,  $r = 0.402$ ) out of six type of work piece used. Out of these, *wood* has the strongest (0.776) relationship with voice of customers. This shows that customers prefer *wood* type to other work piece of material. This may be due to the fact that wood is cheaper in price, and easily available. Furthermore, the *wood* specimen can be bought in various sizes and types. The other three types of work piece that do not have significant correlations are *metal*, *mixed*, and *product assembly*.

TABLE 2: TYPE OF PIECE MATERIAL USED/PROCESSED

Type of Work Piece Material Used	Correlation Coefficient (N = 223)	Type Of Customer
<b>Wood</b>	<b>.000</b>	<b>.776**</b>
<b>Plastic</b>	<b>.000</b>	<b>-.266**</b>
Metal	.449	.009
<b>Composite</b>	<b>.000</b>	<b>.402**</b>
Mixed	.183	.061
Product	.000	-.304

\*\* Correlation is significant at the 0.01 level (1-tailed).

\* Correlation is significant at the 0.05 level (1-tailed).

#### Possible Customer Requirements

This section describes machine specification requirement specified by the customers. Results based on Spearman's rho correlation for each machine specification categories are discussed in accordance to the section written in the questionnaire.

#### Machine Standard Specification

For *machine brand*, several are investigated such as from *US made*, *German*, *Europe*, *Japan* and *Taiwan*. The significant correlation coefficient between type of customer and *US machine manufacturer* is  $p = 0.00$  and ( $r = -0.324$ ), *German made*  $p = 0.004$ , ( $r = 0.179$ ), *Japan made*  $p = 0.001$ , ( $r = -0.216$ ) and *Taiwan made*  $p = 0.00$ , ( $r = 0.578$ ). All the correlations stated above are significant at 0.01 levels (1-tailed). The result shows that Taiwan made (0.578) has the strongest relationship among machine brand name or manufacturer.

Among *low duty*, *medium duty* and *heavy duty* items, only *operation type* of *heavy duty operation type* achieved a significant correlation  $r = .208$ , ( $p = 0.001$ ). The result indicates that customers prefer *heavy duty operating type* of machine. This type of machine normally is more robust, and can be used to perform multiple tasks such as sanding, sawing, cutting, pivoting, threading, dowelling and drilling process.

For machine standard specification, *electrical*, *hydraulic* and *manual* machine drive type have significant correlation at  $p = 0.007$ , ( $r = -0.163$ ),  $p = 0.00$ , ( $r = 0.332$ ) and  $p = 0.00$ , ( $r = .229$ ). The hydraulic drive type at  $p = 0.00$ , ( $r = 0.332$ ) is the most significant relationship among this drive type. Only pneumatic drive type does not have a significant level out of four drive type categories. According to the *power in kilo Watt* for machine standard

specification, all types of power consumption had been selected by all type of customer as significant value. *Low power* is defined as *below 1 kilo Watt*; *medium* is *1-5 kW* and *high power* is *above 5 kW*. *Low*, *Medium* and *High* powers have significant correlation in both 0.01 levels and 0.05 levels. *Low power* and *medium power* have significant correlation at  $p = 0.042$ , ( $r = 0.116$ ) and  $p = 0.050$ , ( $r = 0.110$ ), and *high power* has correlation that is significant at  $p = 0.00$ , ( $r = 0.353$ ). *High machine power* is the most significant at  $p = 0.00$ , ( $r = 0.353$ ) rather than low and medium power.

The *table and clamp configuration* usually designed in two types, *horizontal/vertical (xy) axis* and *flexible (xyz) axis*. From the analysis, only *flexible axis clamp configuration* has a significant correlation at  $p = 0.00$ , ( $r = 0.343$ ). The *clamp types* have 3 different clamping, *pneumatic*, *electrical* and *hydraulic*. For this study, all clamp type have a correlation coefficient at  $p = 0.00$ , ( $r = 0.289$ ) for pneumatic,  $p = 0.00$ , ( $r = 0.245$ ) for electrical clamp and  $p = 0.00$ , ( $r = 0.308$ ) for hydraulic clamp. The *hydraulic clamp type* is the strongest (0.308) relationship similar to *hydraulic drive type*.

In general, the *pressure (Nm)* for machine standard specification is divided into three main types, *low pressure*, *medium pressure* and *High pressure*. The *high pressure machine* has the strongest (0.362) relationship with customers' voice compared to other type of machine pressure. The findings of the survey also indicate that customers preferred machine with *Low torque spindle speed* ( $r=0.318$ ,  $p=0.00$ ) to medium and high torque spindle speed. In addition, they also preferred *low load capacity* ( $r=0.13$ ,  $p=0.034$ ), and positioning accuracy ( $r = 0.520$ ,  $p=0.00$ ).

*Dimension* machine standard specification decision is the important categories to locate whether the machine is in the product or process layout. In other words, it should suit the size of the area allocated by the shop floor of machine. From this study, the findings indicate that it dimension of the machine that has *more than 1000 mm<sup>3</sup>* has the strongest significant correlation at  $r = 0.414$  and  $p = 0.000$ . The findings also reveal that the significant *weight* of the machine is more than 2000 kg ( $r=0.414$ ,  $p=0.00$ ).

#### Machine Control

A *machine control* criterion was generated based on the control system for the machine as proposed by Abdul Rahman & Mohd Shariff (2003). With reference to three choices of control system, only *manual control system* has significant correlation at ( $p = 0.000$ ,  $r = 0.332$ ) rather than fully and semi-automated. The machine with *visible control located within hand reach* has correlation coefficient at ( $p = 0.000$ ,  $r = -0.315$ ) at the 0.01 significant level (1-tailed). *LCD display interface* has correlation coefficient at ( $p = 0.031$ ,  $r = -0.125$ ), that is significant. For the *user storage for programs and data* and its correlation coefficient is ( $p = 0.011$ ,  $r = 0.154$ ). For machine control option, it concludes that only four out of fourteen criteria achieved the significant value for correlation coefficient (see Table 4).

TABLE 4: MACHINE CONTROL

	Correlation Coefficient (N =223)	Type Of Customers
<b>Manual</b>	<b>.000</b>	<b>.332**</b>
<b>Visible control located within hand reach</b>	<b>0.000</b>	<b>-.315**</b>
<b>LCD display interface</b>	<b>0.031</b>	<b>-.125*</b>
<b>User storage for programs and data</b>	<b>0.011</b>	<b>.154*</b>

Based on the correlation results, *Manual* is the strongest type of control system for machine specification. This could be due to the reason that the process involved in manufacturing process with wood work piece selected before comes from manual machine control. In addition, all types of customers either technical or non-technical background inevitably would be able to operate this manual control machine.

#### Machine Safety

*Machine safety* is the third important segment for general machine specification. Only four criteria out of ten have four significant correlations at 0.05 levels (1-tailed) as shown in Table 5. *Foot Brake Switch* has the strongest

(0.235) relationship with type of customer. This criteria is preferable to other machine safety type since it is the most commonly used for wood material. It seems reasonable that this type of machine safety achieves significant correlation due to the facts that most material used is wood as indicated earlier.

TABLE 5: MACHINE SAFETY

	Correlation Coefficient (N =223)	Type Of Customer
Earth and insulation to prevent electric shock	0.007	-.164**
Emergency stop button	0.003	-.187**
Foot brake switch	0.000	.235**
Exhaust fan for cutter	0.007	.165**

#### Machine Performance

Machine performance have thirteen important elements that consist of *Sensors for Warning, Alarm Signal for Machine Error, Simple Mould Replacement, LED Display to Show Current Operation, High Production Speed, Can Accommodate Different Types of Product, Utilize Small Amount of Resin, Rigid and High Damping, Minimum Noise and Vibration, Zero Resin Spillage, Able to Whist and Continuous Operations, Reasonable Power Consumption and Low Operational Cost*. Among these elements, four of them have significant correlations with customer's voice, and their correlations coefficients and respective significant values are exhibited in Table 6.

TABLE 6: MACHINE PERFORMANCE

	Correlation Coefficient (N =223)	Type Of Customer
Simple mould replacement	0.013	.149*
Utilize small amount of resin	0.000	.289**
Rigid and high damping	0.001	.201**
Zero resin spillage	0.000	.242**

#### Machine Maintenance

Machine Maintenance contains several precaution steps in preserving lifetime of a machine. In this questionnaire, machine maintenance is measured by several items such as *Easy Lubrication Points, Easy Replacement Parts, Simple Part Replacement, Simple Assembly and Disassembly, Self and Periodic Diagnose and Calibration, Coolant System and Lighting, Quick Mould Change and Set-up and Easy Trouble Shoot*. Out of these items, *Easy Lubrication Points* ( $p = 0.011$ ,  $r = -0.154$ ), *Simple Part Replacement* ( $p = 0.024$ ,  $r = -0.133$ ), *Simple Assembly and Disassembly* ( $p = 0.032$ ,  $r = -0.125$ ) *Easy Trouble Shoot* ( $p = 0.030$ ,  $r = -0.126$ ) have significant correlation with customers voices (see Table 7). However, the strongest negative correlation is shown by *Easy Lubrication Points*.

TABLE 7: MACHINE MAINTENANCE

	Correlation Coefficient (N =223)	Type of Customer
Easy lubrication points	.011	-.154*
Simple part replacement	.024	-.133*
Simple assembly and disassembly	.032	-.125*
Easy trouble shoot	.030	-.126*

### Machine after Sales Services

For machine after sales services, there are 7 items, including *Speed of Supervisory/Technical Person*, *Speed of Spare Part Delivery*, *Reasonable Spare Part Price*, *Continuous Technical Consultancy*, *Near Service Center*, *Availability of Spare Parts*, and *Alternative Offer*. Among these 7 items, *Availability of Spare Parts* shows significant correlation with voice of customer ( $p = 0.027$ ,  $r = -0.129$ ). The results indicate that when customers show an interest in buying a specific machine, one of the most important criteria that they would consider is after sales services. This is to ensure that the machine they bought can be maintained, serviced or replaced the parts whenever it is necessary. Therefore, the *Availability of Spare Parts* becomes important item in machine after sales services section.

### QFD Neural Network Model

The analysis using Neural Network (NN) is performed in two ways. First, each individual entry of the questionnaire would be considered as an attribute for each pattern in NN dataset. The second method is to get the average value for each section in the questionnaire as an entity for NN attributes.

### Individual Entry

In order to determine the most suitable number of hidden units, the dataset was trained with various hidden units ranging from 2 to 20. The results illustrated in Fig. 8(a) indicate that hidden unit 2 and 11 obtained highest test and least training accuracy for both training and testing. A set of networks with hidden unit 2 and 11 were further trained to determine which hidden is more appropriate to be used in the next experiment. The results depicted in Fig. 8(b) show that a network with 2 hidden units obtained higher average classification accuracy than a network with 11 hidden units (53.36% versus 43.88%).

FIG. 8(A): CLASSIFICATION ACCURACIES FOR DIFFERENT NUMBER OF HIDDEN UNITS

FIG.8(B): AVERAGE CLASSIFICATION ACCURACIES FOR NETWORK TRAINED WITH HIDDEN UNIT 2 AND 11

Experiments have been conducted to determine the suitable number of epoch prior to determining the backpropagation training parameters. For experimental purposes, the learning rate is 0.1 and the momentum rate was set to 0.3. Based on the results exhibited in Fig. 9(a), epochs 600, and 700 obtained the highest test results with 96.25% and 86.59% classification accuracy. These two number of epochs were further investigated by varying weight seeds in order to determine the most suitable number of epoch for the problem at hand. The results displayed in Fig. 9(b) show that a set of network trained up to 600 epoch achieved the highest average test result with 87.696% accuracy or 12.304% misclassification error.

FIG. 9(A): CLASSIFICATION ACCURACIES FOR DIFFERENT NUMBER OF EPOCH

FIG. 9(B): AVERAGE CLASSIFICATION ACCURACIES FOR NETWORK TRAINED UP TO 600 AND 700 EPOCHS

Similar experiments were conducted to determine the learning rate and the momentum rate for Backpropagation learning algorithm. The experimental results show that learning rate 0.1 obtained 40.01% classification accuracy whilst momentum rate of 0.3 achieved 44.78%. Once again the number of epoch was investigated based on the selected training parameters of Backpropagation. The Neural network architecture and training parameters for classifying QFD machine planning datasets are summarized in Table 8 and Table 9.

For the average value (Table 9), the best learning rate is 0.2 while 0.2 for the best momentum rate. Sigmoid activation function has been chosen as it produced the highest test percentage. For the best epoch, 100 is selected as it represents the highest test percentage that is 87.621%. Based on results displayed in Table 8, the best learning rate is 0.1 while 0.3 for the best momentum rate. Sigmoid activation function has been chosen as it produces the highest test percentage. For the best epoch, epoch of 600 has been selected as it represents the highest test percentage that is 87.696%.

The summary of the NN parameters to classify the QFD for machine planning datasets individual entry is listed as below:

TABLE 8: NN PARAMETERS

Parameter	Value
Architecture	Multilayer Perceptron
Learning Algorithm	Backpropagation
Input Node	97
Hidden Node	2
Output Node	4
Learning Rate	0.1
Momentum Rate	0.3
Activation Function	Sigmoid
Number of Epoch	600

#### Average Value

Similar experiments have been conducted by averaging values of items for Type of Workpiece, Machine Standard Specification, Machine Control, Machine Safety, Machine Performance, Machine Maintenance and Machine after Sales Service. For brevity, the results are summarized in Table 9.

TABLE 9: NN MODEL FOR AVERAGE VALUE

Parameter	Value
Architecture	Multilayer Perceptron
Learning Algorithm	Backpropagation
Input Node	97
Hidden Node	4
Output Node	4
Learning Rate	0.2
Momentum Rate	0.2
Activation Function	Sigmoid
Number of Epoch	100

Hundreds of experiments have been conducted to establish a forecasting NN model in this study. For both models, the architecture of NN model can be expressed as 97-2/4-4 or 97 input nodes, 2 or 4 hidden nodes and 4 output nodes. Both models used sigmoid activation function, backpropagation learning algorithm with slightly different learning and momentum rates. To this end, the performances of both models are presented in Table 10. Based on the results, the datasets with individual value achieves higher percentage accuracy (87.696%) or lowest misclassification accuracy (12.304%). Therefore, NN model summarized in Table 10 is chosen to represent the QFD model based on voice of customer with architecture of 97-2-4.

TABLE 10: NN MISCLASSIFICATION ERROR

Multi-Layer Perceptron (MLP) (Individual Value)	Multi-Layer Perceptron (MLP) (Average Value)
12.304%	12.379%

## Conclusion

There are few reasons why we need to build QFD forecasting model and identification of relationship between type of customer and QFD:

- QFD forecasting model is to help the manufacturer to find the best machine specifications.
- QFD forecasting model gives the customer to give a response on a product/service with no limit in computerized form.
- Help the designer to concentrate much more on identifying customer satisfaction towards the design specification of the product. The data gathering from customers will be easier to understand and analyze.

The findings presented in this paper may benefit all purpose of measurement related to customer satisfaction and needs. The future application may be applied into new product development, product liability, ISO9000 series, process assurance, services, part suppliers, material and processing equipment manufacturers, reliability and technology deployment. In summary, the findings from the experiments conducted indicate that the significant correlations with customer voices are summarized in Table 11.

TABLE 11: CORRELATION SUMMARY

Section	Significance item	Significant values	Spearman's rho Correlation
Type of workpiece material used	Wood	$p = 0.000$	$r = 0.776$
Machine Standard Specification	Heavy Duty Operation Type	$P = 0.001$	$r = 0.208$
Machine Control	Manual Control System	$P = 0.000$	$r = 0.332$
Machine Safety	Foot Brake Switch	$P = 0.000$	$r = 0.235$
Machine Performance	Utilize Small Amount Of Resin	$P = 0.000$	$r = 0.289$
Machine Maintenance	Easy Lubrication Point	$P = 0.011$	$r = -0.154$
Machine After Sales Service	Availability of Spare Parts	$P = 0.027$	$r = -0.129$

These correlations help to explain the relationship between attributes used in the study. To complete the study, NN forecasting model has been established with 12.304% misclassification accuracy in determining the customer voices based on QFD. The study indicates that the approach has some potential in providing some information regarding the relationship between QFD and the customers, as well as predicting the type of customer if QFD information is provided. Hence, the study reveals the type of machine and type of operation that are favourable to customer prior to acquiring the machines for their industrial usage.

# Evolution of Network Governance: Control & Coordination in a Network Context

Emanuela Todeva, [E.Todeva@surrey.ac.uk](mailto:E.Todeva@surrey.ac.uk)  
University of Surrey, UK

## Abstract

This paper builds upon the work on comparative governance systems (Todeva, 2005), and on the development of business network theory (Todeva, 2006, 2007). Business networks are dynamic agglomerations of interconnected firms, where there is an overlap between contractual relationships, inter-firm resource flows, and joint and collaborative activities. For our analysis we suggest that network governance is a system / mechanism for allocation of resources, control and coordination of economic activities at network level. On these grounds this paper attempts to address the questions of the governance of interconnected and interdependent firms using collaborative relationships. We compare the institutional arrangements for the governance of the Japanese *Keiretsu* and *Sogo-Shosha* business networks. The main conclusions from this analysis relate to the efficiencies generated by an institutional and relational environment that supports sharing of risks and information, and the alignment of interests via optimisation of benefits across the network.

## Introduction

Most of the discussions on corporate governance have been dominated by the scholarship research that focuses attention on the Anglo-American corporate system based on publicly traded assets, distributed ownership, separation of ownership from control at corporate level, and the distribution of rents among investors and other residual claimants. The economic and strategic management literature that engages with these issues has argued for the supremacy of the Anglo-American model of corporate governance over the 'welfare capitalism' (Germany, Japan). The theorising has built upon an efficiency argument that lead to a believe that financing and control of corporate activities is best undertaken within the institutional environment associated with the stock market, and that the wealth creation for shareholders and stakeholders is maximised under the conditions of 'perfect' markets and competitive relations. The fundamental market imperfection is treated as an illness of the system that can be remedied with various regulatory efforts by the state.

The discussion under this leading stream in corporate governance theory has been dominated by concerns with the effectiveness of the boards of directors that represent shareholders' interests and exercise a monitoring and control function against the opportunistic behaviour of managers. The future development of the shareholder system has been sought mainly through alignment of the interests between managers and shareholders and through improvement of the information asymmetry between them. The present crisis of the system is attributed mainly to weak boards and lack of independency of the outside directors in order to exercise their governing role (Gupta, 2002). The remedy of the system is sought to be enhanced by more active regulatory intervention on behalf of government and regulators, by stock market self-regulation, and by positive action of the corporations themselves to enhance transparency and to re-build the trust with their stakeholders.

This discussion ignores the fact that the modern corporation in its present form is a business network of *interconnected* and *interdependent* units, *embedded* in different business systems scattered throughout the world. The multinational enterprise (MNE) that controls assets in multiple markets is tied in contractual relationships with multiple host-governments and local suppliers, customers and institutions beyond the reach of its home governance structure. The adversarial and competitive relationships in one market are not replicated in another, where different context of the competitive environment applies. Hence, the corporate governance mechanisms put in place to control strategic management decisions in the home environment may be no longer binding the strategic choices of remote units in host countries.

The interdependence between strategic business units and alliance partners is fundamentally underpinned by technological linkages, value-added chains, resource dependencies, and numerous other ties that induce strategic

choices that are more aligned to the conditions in these interdependent environments, rather than to efficiency considerations. The strategic choices and strategic decisions (and their implementation), that are ultimately responsible for the value-creation and wealth creation by multinational enterprises (MNEs), are framed by resource and operational interdependencies, and by their embeddedness in the institutional and the relational environment surrounding each autonomous business unit.

This paper attempts to go beyond the efficiency argument in relation to different corporate governance systems. We do not want to argue for supremacy of one mechanism over another. We take a holistic approach to the corporate governance mechanism, as a set of institutional arrangements (mechanisms, tools and practices) that have evolved to facilitate the allocation of resources for corporate activities. We base our analysis on the definition of corporate governance as a system / mechanism for allocation of capital and corporate resources, for co-ordination and control of economic activities at firm level that facilitates: strategic direction, accountability, transparency, wealth creation (Todeva, 2005). We also distinguish that modern MNEs represent complex business networks, and their governance can no longer refer to them in singularity. Network governance builds upon everything we know about corporate governance, but recognises that any governance mechanism applicable to a modern MNE is conditioned by multiple institutional and relational environments. Its effectiveness depends heavily on the structure of the corporation and on the actor's attributes, or these resources and capabilities that are employed in the value-creation process, including their development and growth through learning and knowledge sharing.

Our in-depth analysis of the governance systems and practices in two cases – the Japanese *keiretsu* networks and *sogo-shosha* networks - aims to demonstrate the challenges that corporate governance theory is facing. The governance mechanisms employed in these cases promote the argument that collaborative inter-firm relationships are effective tools for information sharing, for risk and resource sharing, for learning and development of intra-corporate capabilities, and for effective management under the conditions of uncertainty and rapid change.

## **Determinants of Network Governance**

The efficiency arguments that derive from the neo-classical economic theory commence with the assumption that shareholders are these entrepreneurs that invest their capital in efficient manner, and managers are another type of entrepreneurs, that take risk and make strategic decisions by which they achieve the ultimate corporate objectives for enhanced performance and profitability. The evidence however, of the source of efficiency in this scenario is very inconclusive. In addition to managers and shareholders, there are numerous other stakeholders that have direct impact on the value creation process and the subsequent corporate performance. These are employees (implementing the strategic decisions), middle managers (coordinating operations and activities in efficient manner), suppliers and clients (directly affecting the value creation and the value-realisation processes).

Wealth creation for shareholders and stakeholders is also a derivative of the overall environmental conditions that the corporation is facing on a global scale. Performance is affected not only by the strategic decisions and the mechanisms of financing and control, i.e. a particular corporate governance system, but also by the market conditions and location advantages in international business operations of the MNCs. The performance of each business unit is dependent on the local input and output markets. The overall corporate performance depends on the cumulative effects of both – the global market trends and the local market conditions.

Hence, both firm performance and wealth creation are hugely dependent on the intra-firm and inter-firm structures and relationships that facilitate decision-making and decision implementation, and the overall coordination of activities. They are simultaneously a function of governance, strategic decision making, environmental context, and internal resources and capabilities (Fig. 1). Corporate performance is also directly affected by environmental factors such as institutional and relational embeddedness.

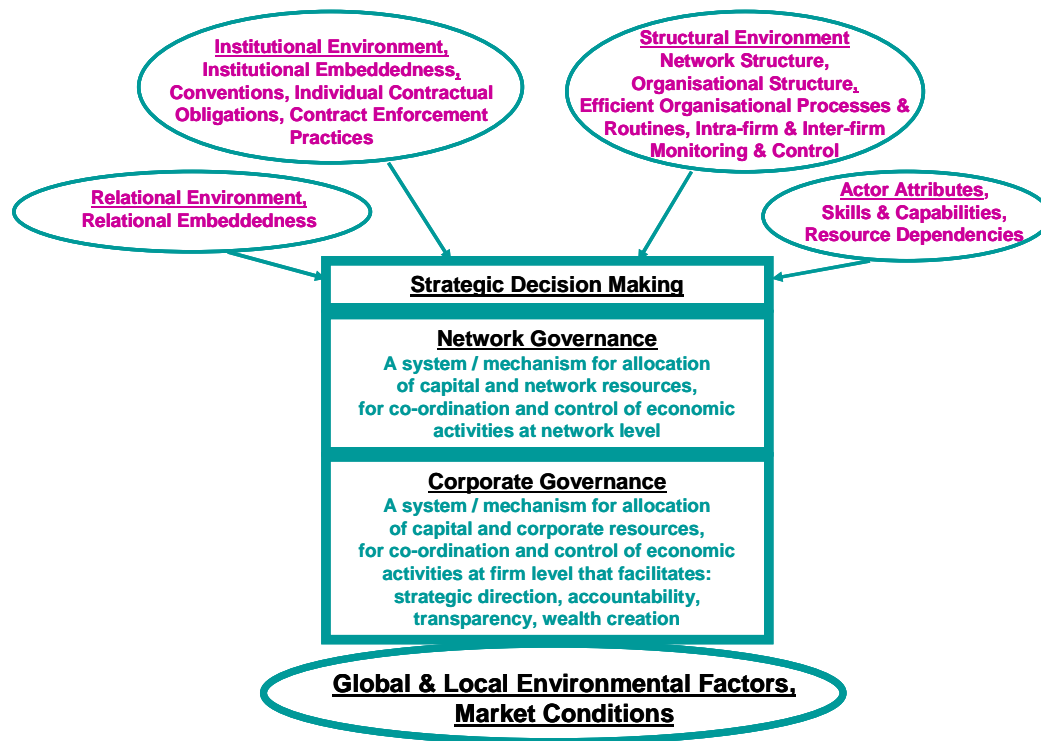

FIG. 1: FACTORS AFFECTING THE NETWORK GOVERNANCE SYSTEM: A CONCEPTUAL FRAMEWORK

Another critical question omitted from the discussion on corporate governance is the scale of operations of the MNEs. The very fact that some large multinational firms have annual turnover exceeding the budget expenditure of developed national economies suggests that the scale of co-ordination and control within the corporation requires extremely high level of administrative efforts. As a network of activities, the MNE has to apply a multitude of internal control mechanisms, including using financial targets, performance based targets, budget allocation, and other planning tools. The mesh of intra-organisational and inter-organisational relationships requires network governance aiming at relationship management as much as at resource management.

The model in Fig. 1 describes these fundamental factors that have a direct impact on the network governance and strategic decision making. *Network governance* is defined in the context of our definition of corporate governance - *as a system / mechanisms for allocation and control of capital and network resources and their employment in economic activities at corporate network level*. This system evolves in a rich institutional context of the business system in the host country, or country of origin of the parent company, combined with the institutional arrangements for each business unit. The institutional embeddedness is complemented by relational and structural embeddedness of the strategic decision making, where resource flows and the resource dependencies throughout the network structure are coordinated using administrative and non-market tools. This puts the MNE at a focal point in the mesh of multi-lateral stakeholder relations spread across the world. The effectiveness of these control and coordination efforts is therefore determined by the entire set of relational and institutional conditions, as well as by the local market conditions and business environments for each business unit where its activities are located.

In order to understand better this process, by which the leading corporate actors manoeuvre across multiple relational environments while governing resources, we will examine some definitions of the firm that throw light on

the nature of the corporate activity. Then we will look at the internal environment of the MNEs, its structure, competence base and resource dependencies. Ultimately, strategic decisions are framed both by the internal and the external environment, including institutional and relational context.

In Williamson's view of the firm (1975, 1988, 1991), it is the organizational structure that economises on transaction costs, rather than the governance structure. The governance structure has evolved merely as a substitute to compensate for the inefficiencies that emerge from the separation between the ownership and control.

Different theories refer to different definitions of the firm. Whitley (1993) defines firms as centres of economic power that combine *allocative decision making* with *authoritative coordination* of economic activities and as such they add value to human and material resources through collective organisation of work. Firms are seen as dominant units of strategic decision making and planned coordination that combine *differentiated skills, capabilities and knowledge*, and embody a *collective organisation* which transforms human and material resources into productive services. Intra-firm networks represent even more complex structure of layers and modules of differentiation that require coordination.

Mark Casson (1998) gives another definition of the firm – as an institution that specialises in coordination of business functions using a single locus of responsibility as a legal entity, and a structure designed to harmonise the decision making efforts of a group of people. Business networks on the contrary represent a system of multiple focal areas of responsibilities where the power and influence of the headquarters are challenged by localised institutional arrangements. There are many descriptions of complex inter- and intra-organisational agglomerations and many classifications of organisational structures that attempt to synthesise this knowledge (see Todeva, 2006). The most important aspects of these classifications are that there is an evolution of organisational forms from more simple to more complex systems, where the relationships between the constituent parts represent different configurations – from modular and nested structures, to dispersed formations utilising both strong and weak links to interact between each other. Each type of structure accommodates different forms of power and different monitoring and control mechanisms. Structures are responsible for the effective contract enforcement within each organisation and between organisations within the network.

The M-form or multi-divisional form of organising that is associated with multinational corporations was invented in the context of the General Motors corporation in the US to encompass: central control and ownership; vertical integration of the production; formal internal coordination through vertical and horizontal linkages; corporate head office function and specialized staff concentrated in departments and sub-units. The M-form of structure represents an evolution and adaptation of organisational hierarchy under the conditions of complexity and uncertainty of operations. The M-form of structure enables the internationalisation of the firm and the emergence of the trans-national corporate network with centralised governance and modular type of coordination of activities.

The M-form is challenged mainly by the hybrid or network type of organisation, based on intra- and inter-organisational relationships partnerships and strategic alliances that generate a complex system of interdependent business activities. The main principles in hybrid network organisations and heterarchies described by Hedlund (1986) are the following:

- co-ordination is through *lateral referrals* and lateral decision process and integrating mechanisms;
- key skills are *dispersed* through the network;
- communication and co-ordination is based on *shared values and normative integration*;
- co-ordination and control is based on *dynamic strategy-structure adjustments* in response to changes in performance and changes in the environment; and
- balance is sought between *horizontal and vertical integration* using simultaneously output based and behaviour based control.

While the economic theories of the firm look at the firm as a black box, as a unit processing inputs into outputs, the behavioural theory of the firm (BTF) looks at what happens inside the firm, how the throughput takes place as economic activity, and how decisions are made regarding production, scheduling, and inventory. In its essence BTF can be described also as a network theory of the firm, where decisions are interpreted as a sequential process which includes both rational and non-rational aspects, relationships and resource dependencies.

All these new theoretical work on organisations indicates that the modern corporation is no longer characterised by pre-specified and stable relationships, instrumentality of goals, additivity of parts, uni-directionality of command,

universality of communication flow, and synergy in activities. The network type of organisation resembles dynamic relationships, continuously re-negotiated goals, dispersed control and multi-directional flow of communications and resources.

The board of directors of such business network can not bring value added to the corporation, unless it takes direct responsibilities over strategic decision making and implementation. Its monitoring and control function may not enhance corporate performance directly, or add value. Sanctioning managers for opportunistic behaviour is not a value adding activity by itself, but a final resort when crisis is imminent. The true value-adding activities derive from the co-ordinated actions of managers, workers, investors, suppliers and customers among other stakeholders. The empirical research by Pettigrew and McNulty (1995) also shows that the power of outside directors to exercise a positive effect on the corporation is affected by a multitude of factors such as: personal capabilities and legitimacy; the need to maintain a positive attitude in this collaborative settings; political will and interpersonal skills in building Board coalitions; the need to subscribe to norms and expectations that derive from the role of outside director; the learning time required to grasp the complexity of the corporation; the interpersonal dynamics that emerge as an outcome of the selection of board members. The effectiveness of the Board as a monitoring and control device (or institution) has been questioned with this research.

Another critical factor that frames strategic decision making and implementation at corporate level is the institutional environment. Although almost all market economies have attempted to establish stock market institutions and governance relations of the Anglo-American type, it is clear that there are significant differences both at the level of institutional requirements, incentives and constraints, and at the level of coordination and control practices. These variations derive from the evolution of a large number of relationships that bond economic actors in a network system, and that provide framework and context to all resource-allocation decisions. The evolution of these relationships establishes a framework of enactment of ownership rights, control functions, and their coordination across the entire relational system. Fligstein and Freeland (1995) describe this relational system as tensions between: 1) the control relationship between management and workers, 2) relationship between management and shareholders; 3) division of labour and the subsequent division of power and responsibilities within the corporation or intra-corporate intra-management relationships, 4) relationship with investors and capital markets, 5) relationships with suppliers, 6) relationships with competitors, 7) relationships with the state, with governments and other public institutions.

If we look at the corporate governance as a mechanism for allocation of resources in the economy and for creating value-added, then we need to consider all relations between economic agents that are critical in determining productivity and efficiency. The relations between shareholders and managers (ownership and control) no doubt are fundamental to financing corporate growth. Relationships with shareholders and investment fund managers are also important as they need to have trust in the working of capital markets and the market for corporate control in order to make their funds available. Managers and workers and all other actors involved intra-management and intra-corporate relations need to have consent over the operations and the strategic directions of the firm in order to expropriate the invested capital in the most efficient way. Relations with suppliers are critical to achieve superior quality and to increase competitive advantage. Relations with government are critical for the legitimacy of the corporate activities and therefore affecting relations with all other stakeholders. Even relations with competitors are important for determining industry standards and as a form of self-regulation, avoiding costly and deadly collisions in the market place, and co-ordination of the direction of technology, product and process innovation.

Managing each of these relationships employs parallel political processes of negotiations and influence. Independent political processes take place simultaneously inside the corporation (affecting decision making and decision implementation), inside the Boardroom (affecting the function of the independent directors and the entire Board as an institution), and inside investment funds (affecting investors' attitudes and the certainty of capital supply). Clearly political processes affect not only the allocation of capital to productive assets, but also the efficient expropriation of this capital for wealth creation.

These political processes take place in a specific institutional environment that produces stable behavioural patterns and expectations that reduce monitoring and control costs. Among the elements of the institutional environment that shape behaviour and strategic choices are: *contracts, rules, procedures, practices, roles, positions, norms, expectations, constraints* and *incentives*, or the normative framework that governs behaviour and

interactions. These concepts represent different mechanisms whereby a particular normative element exercises pressure on actors, and as such, it frames their motives for action, their choices of partners, and their patterns of interactions with these partners.

Although each of the concepts describing the normative framework invites multiple definitions and interpretations, there is a fundamental understanding that *contracts* usually specify incentives and constraints in the form of responsibilities, liabilities and rights for each actor. Contracts are explicit agreements that are formulated in texts and legal documents. *Rules* and *procedures* are also explicit statements governing practice as they indicate required behaviour. They are employed in hierarchical structures, but can be incorporated in any relational settings which are governed by authority, or by contracts and agreements. Contracts, rules, and procedures represent the formal side of the institutional framework, including expected behaviour, where monitoring and control of this behaviour are possible.

The interactions between network actors start with some agreements and repeat over time for the duration of the agreement. Repetitive agreements lead to the emergence of conventions that are observed as business *practices*. Some agreements are sealed by formal contracts, while others are acknowledged as informal and implicit commitments that translate into action. Practices represent accepted or legitimate behaviour motivated by the implicit commitments that each actor undertake. Practices are established in the context of a set of constraints and incentives and implicit or negotiated rules and procedures, and they generate mutual expectations.

The diffusion of certain practices and interactions in a network is uneven process, where actors play different *roles*. Roles are simultaneously assigned from one actor to another, and/or voluntarily adopted by each actor. Roles in business networks are ascribed to individual actors by the headquarters and by the set of network relationships in which individual actors are embedded. Negotiations of roles between actors represent informal agreements between them. Role performance and role enactment are the internalisation of these agreements.

Interaction and transaction patterns over time crystallise at differentiation of *positions*, where different actors occupy different positions according to their involvement in the transaction path, or the value chain of activities. Roles and positions induce status for individual actors, which represent another institutional mechanism that governs behaviour and generate expectations.

Although positions are specific actor's attributes and network characteristics, a position is changing by the activities of the actors. Both roles and positions are communicated across the network and give signals to the other network members regarding the potential for a relationship. Positions and roles are accepted by other interacting parties and hence are elements of the normative framework that governs all interactions and behaviour.

*Norms* are cultural artefacts that emerge on the basis of shared values, beliefs, and expectations within cohesive groups of actors. Norms are elements of the corporate culture which are known to impose constraints on actors that have internalised specific values.

Constraints can be interpreted both in terms of physical or technical boundaries, and in terms of institutional prescriptions. The awareness and acceptance of these boundaries and limitations suggests to actors particular choices and decisions, or a particular course of action. While constraints regulate behaviour and activities of network members, incentives generate new motives for action. *Incentives* are classified as internal and external to the network.

## **The Japanese *Keiretsu* and *Sogo-Shosha* Corporate Networks**

The aim further in this paper is to compare two Japanese cases of governance of corporate networks – the *Keiretsu* governance and the *Sogo-sosha* governance with the purpose to identify specific institutions and mechanisms within the welfare capitalism that facilitate economic growth and wealth creation.

### **Japanese Zaibatsu /Kkeiretsu**

The history of the big business groups in Japan *keiretsu* starts with their pre-war establishment as family-controlled business networks called *zaibatsu*, or giant trading conglomerates that ran most of pre-World War II Japanese industry. The historical Japanese family business *zaibatsu* resembled a closed intra-family corporation, where family

investors were not able to take back their own investments, and some family businesses remained undivided for more than 300 years (Numazaki, 2000).

As a form of business organisation, *zaibatsu* was controlled by a family council *Shacho-kai*, and the change of the number of partners took place only through family adoption, by marriage, or by birth and death. The inheritance law in Japan, is perhaps one of the most significant factors historically that led to the consolidation of the family power in Japan and Korea, compared with its relative fragmentation in other countries in the region.

The *zaibatsu* institution combined the wealth of rich merchant families, the organizing capabilities of warriors, and the expertise of university graduates in order to create large-scale family controlled conglomerates. *Zaibatsu* represented also a corporate network and was an organisational form, that emerged in response to market failures at the time of Japan's early industrialization after the Meiji Restoration in 1868 (Hirschmeier and Yui, 1981, Imai and Itami, 1984, Lynn and Rao, 1995). The market failure at that time is described as the inability of capital markets to allocate efficiently resources to entrepreneurs because of the lack of an infrastructure to mobilize savings and to facilitate risk assessment for investment in new business ventures, especially, in industries such as mining, steel and shipbuilding (Lynn and Rao, 1995). Jacoby (2000) also puts forward the arguments that Japan, like Germany, France and other European countries experienced the pressures of late industrialisation catch-up, and the state played an active role to mobilise national resources in order to level up with already industrialised Britain. The relational governance system allowed the Japanese government to protect infant industries and to allow them to grow. Although with the development of Tokyo stock market an alternative mechanism of financing investment and growth was established, the old tradition prevail until the most recent consolidation across the financial sector in Japan.

The new enterprise system in the 20<sup>th</sup> century comprised of narrowly focused and inter-linked factories, effective at transferring new technologies between the Western economies and the Japanese economy (Imai, 1992), and possessing 'permeable boundaries' that enabled them to gain economies of scope (Fruin, 1992). Part of the system were the *zaibatsu* in-house 'organ banks', insurance and trust companies, that enabled the *zaibatsu* to overcome the weakness of the Japanese stock exchanges, and to mobilize and channel financial resources to entrepreneurial ventures (Lockwood 1954). The retained profits were allocated to new ventures through internal finance and budgeting systems, which facilitated endogenous growth.

On the one hand, the *zaibatsu* controlled constituent units through stock held by the holding company, through centralized purchasing and sales functions, and through despatching directors to manage subsidiary units. The holding company exerted authority over the constituent units to reconcile incongruent goals and aspirations. On the other hand, the *zaibatsu* were market-like organizations to the extent that constituent units behaved independently and competed for resources, and some of them acted as entrepreneurial organizers of economic activity (Gerlach, 1992a, Lynn and Rao, 1995).

In the post-War period, serious attempts to dismantle the Japanese holding companies were made by General MacArthur and the occupation forces in 1946. Subsequently, encouraged by government industrial policies, the reunification of formerly connected businesses through cross-shareholding and mutual business dealings under the name of *keiretsu* took place. Many of the *zaibatsu* practices, traditions, and network formations were resurrected under the new governance form.

- Institution-centred 2-tier governance system
- Multi-level boundaries of corporate units with interlocking ties
- Resource & capabilities-based division of labour
- Managing through co-ordinating interdependence

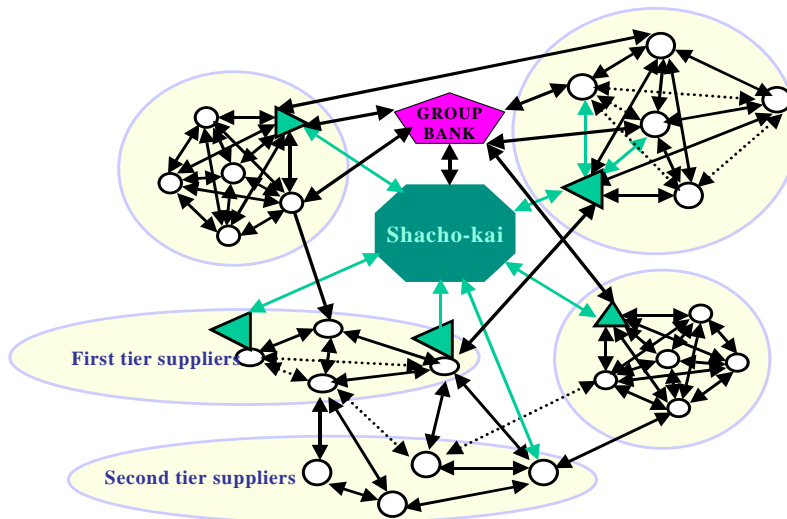

FIG. 2: JAPANESE *KEIRETSU* BUSINESS NETWORKS

The present *Keiretsu* networks comprise of close, long-term business relationships established by large corporations with selected groups of smaller firms, financial and trading institutions. They represent a web of overlapping financial, commercial, and governance relationships, initiated from a central core to pull-in large segments of the Japanese economy (Gerlach, 1992a, 1992b). Present Japanese inter-corporate *keiretsu* relationships are considered in terms of three different structural conditions to facilitate interactions: corporate groups, with financial centrality, and industrial interdependency through value chain activities. These corporate groups are not conglomerates as the holding companies are illegal under Japan's post-war commercial law. The companies are independent and publicly traded. However, they are linked through cross-shareholding investment and the exchange of personnel, through shared debt and equity, and mutual strategic plans. The strategic leadership resides within the presidents' club *Shacho-kai*, where implicit rules and shared understandings in unstated "gentlemen's agreements" lead to co-ordination and general co-operation for mutual benefit (Futatsugi, 1986, Kester, 1991, Gerlach 1992b, Shimotani, 1995, Tezuka, 1997).

*Shacho-kai* as an institution represents the interests of the inner circle of the *keiretsu* as a clique of firms whose reciprocal commitments stem from long association and strong collective identity (Lincoln, *et.al.*, 1996). This association of the presidents holds monthly meetings to discuss group strategy. It supports group solidarity, mediates intra-group activities, and settles intra-group disagreements. *Keiretsu* members can thus develop plans based on activities that other *keiretsu* members are pursuing. Although it appears that *Shacho-kai* facilitates insider trading and may be called ineffective allocation of resources, it does provide an efficient platform for managing intra and inter-corporate relationships, which is a major contributor to wealth creation within the corporate group.

Numerous firms lacking *shacho-kai* seats are also tied to the group through their financial and commercial ties, and through various forms of monitoring and governance practices. For example, middle managers of *keiretsu* firms meet monthly to discuss operations and to co-ordinate corporate activities. This is another effective

mechanism for intra-group knowledge management that facilitates learning and innovation within the group, as well as sharing skills, capabilities, best practices on a wider scale.

Other direct linkages within the *keiretsu* are represented by the stable corporate cross-shareholdings, by dispatch of managers to insider director positions, and by director interlocking as control relations that are superimposed on the network of business dealings (Lincoln *et.al.*, 1996). All these mechanisms lead to alignment of interests among managers within the group and strengthening of the governance framework. In addition, these co-operative relations bring intrinsic value to the corporate network as they smoothen the internal negotiations between agents, and member firms. These relationships also facilitate co-ordination for innovation, development, and growth.

Regarding the cross-shareholding within *keiretsu* networks, share ownership is a symbol of commitment and mutual obligation, rather than motivated by expectations of dividends and returns on investment (Tezuka, 1997). A typical *keiretsu* core company will have 20% to 40% of its stock owned by other companies within the *keiretsu*. Long-term shareholding agreements with other corporations create a situation whereby 60% to 80% of the *keiretsu* stock is never traded (Industry Week, 1992). As the stock market is not the main source of financing for the corporate group, this limited trading of shares of large Japanese multinational groups is not necessarily a detriment, but could be interpreted as a spare and underutilised mechanism that can be employed in cases of financial difficulties.

In addition to these direct forms of relational governance, there are a number of other indirect ties that bond the commercial and investment activities within the *keiretsu*, such as: (1) the selection of *keiretsu* trading partners, (2) the amount of borrowing from group banks, (3) the extent of shareholding by group banks and corporations, (4) the selection of board members from the management of big leading firms (Lincoln, *et.al.*, 1996). These represent specific governance mechanisms that enhance international operations, generating both internal and external synergies.

Overall financial and commercial dependencies exist both ways: on the group banks for borrowed capital, and on the group manufacturers and trading firms as buyers and sellers of products and services. However, the 'relational-insider' governance system appears to be better equipped to manage interdependencies, as it has established institutions, mechanisms and platforms for negotiations, information sharing and enhanced intra-corporate learning.

There are numerous classifications of Japanese *keiretsu*, emphasizing on specific aspects of the network formation – vertical, horizontal, supplier-based, bank-centred. Overall there is an overlap between different categories, and most features are observed in each of the *keiretsu*. A supplier *keiretsu* is a vertical group of companies, centred along a major manufacturer, such as Sony, Honda, and Matsushita, which run multi-tier supplier networks. As an example of this form of business organisation Toyota has more than 60 percent of its parts and subsystems supplied by external contractors – tied in long-term contract relations, and Canon is outsourcing nearly 90 percent of the value added components in its copiers to related companies (Industry Week, 1992). The vertical *keiretsu* represents formation that is highly vertically integrated along the value chain. It is held together by a complex mix of inter-linked people, financial resources, information flow, parts and product exchanges, and joint technology development agreements. Toyota has established a first-tier suppliers' group, the *Kyokukoukai* (176 companies); Nissan has its *Takarakai* (104 companies). Members of the vertical *keiretsu* have had little choice but to accept this combination of co-operation and competition. Vertical *keiretsu* is a way to create competitive teams of inter-linked suppliers, engaged in product and process development (Tezuka, 1997, Kim and Limpaphayom, 1998). This governance form delivers both cost efficiencies (within the supply network) and enhanced productivity from co-ordination of business activities, technologies and practices.

Ownership is only a part of this linkage: most lead firms have minority shares in their suppliers. The lead firm encourages the second or third supplier to match the first supplier's cost and quality, often passing along important technical and process information on the first supplier's operations – a clear example of sharing competences and capabilities between competitors, which creates added value to the group.

The lead firm tries to avoid monopoly power in its network, thus stimulating all suppliers to be more efficient and price competitive. Suppliers in the same *keiretsu* group co-operate in projects, and yet compete with each other and with outside suppliers to excel in quality, delivery, reliability, and cost performance (Tezuka, 1997).

This dynamic is an evidence of the positive effect of managed expectations that creates collaboration among competitors, and can be attributed clearly to the 'relational-insider' governance system.

The bank-centred *keiretsu* are larger than the supplier-only *keiretsu* and include those headed by the four largest pre-war industrial groups or *zaibatsu* (Mitsui, Mitsubishi, Sumitomo, and Fuyo) and the two major bank-centred groups, Dai-Ichi Kangyo Group and Sanwa Group. They are also called Mutual Insurance Systems (Tezuka, 1997). Their member companies come from a variety of industries, and they seek to integrate not only vertically, but also horizontally. Although there is a deep restructuring of these *keiretsu* groups triggered by the consolidation of the financial sector in Japan and the most recent merger of their group-banks, the literature has described sufficient details of their governance system at the pre-consolidation stage.

Financial or horizontal *keiretsu* represent a two-tier corporate governance system, where corporations are linked together through an extensive network of corporate cross-shareholdings, and corporate members have close ties to a main bank. The *keiretsu* bank not only provides member firms with debt financing, but also owns a substantial amount of each firm's equity (Kim and Limpaphayom, 1998).

In normal situations, usually the first stage of group governance intervention is in place, and corporate shareholders provide mutual monitoring through the linkages and institutions described above. When firms are performing well, *keiretsu* financial institutions do not restrain leverage levels, and *keiretsu* formations encourage cross-investment and collaboration among corporate members. Both corporate owners and managers take responsibilities for the higher leverage and for the expansion of trade credits and account receivables as a common source of short-term financing (Prowse, 1990, Kim and Limpaphayom, 1998). At this stage there is no significant relationship between ownership structure and financial leverage as banks approve and handle most transactions (Kim and Limpaphayom, 1998).

In situation of crises and reduced profitability the *keiretsu* network reacts with a second-stage governance intervention. The bank assumes control to reduce debt, and acts as an ultimate disciplinarian (Hoshi, *et.al.*, 1990). *Keiretsu* banks can reduce financial leverage levels of their member firms in several ways: (1) allowing interest concessions, (2) providing equity infusions, and/or (3) writing off outstanding loans. Financial institutions act as both debt- and equity holders, and allow their member firms to carry more debt (Kim and Limpaphayom, 1998). The recent mergers of *keiretsu* banks are expected to have a positive impact towards increased financial discipline and reduced debt. This can reduce the banks' bail-out powers, but it will not negate the other financial mechanisms that have been used in the past to assist group members in crisis situations.

*Shacho-kai* membership ties, as well as trade, debt, and equity ties are stable relations that increase the possibilities for assistance when a partner firm encounters difficulties. Member companies usually maintain or even increase their equity in the troubled firm. Directors are transferred from the main bank and major trading partners to the firm's board to assist in strategic and operational decisions. Network suppliers and customers adjust their contracts to favour the target firm and transfer technical personnel to its operating divisions. Network members may in addition mandate exclusive purchases from the target firm's product line until the crisis has passed (Lincoln, *et.al.*, 1996). Enhanced financial discipline as a result of the banking consolidation is expected to raise the criteria for assistance, but it does not change fundamentally the governance system, and may have a limited impact on these practices of cash-flow assistance.

*Keiretsu* equalizes the fortunes of their members, smoothing inequality in financial returns across participating firms. Members are not able to maximise their benefits, i.e. extraction of profits and rents, but instead have been obliged to optimise output measures. *Keiretsu* networks are seen as clusters of large firms charging each other "efficient" prices (i.e., prices in line with their respective opportunity costs) while collectively extracting other market benefits through a collective action for maximizing the joint welfare of all member firms (Lincoln, *et.al.*, 1996).

*Keiretsu* members face lower risk than independent companies in Japan, because the whole *keiretsu* group shares individual risks. *Keiretsu* companies obtain lower interest rates from both *keiretsu* banks and from other financial institutions, and tend to have higher debt ratios than either independent Japanese companies, or their U.S. counterparts (Tezuka, 1997).

*Keiretsu* groups also claim to be an effective organisational system of minimising transaction costs, and reaping efficiency gains by economizing on information and control through regularized communication and

exchange (Williamson 1985). They avert the threat of over-organization by keeping their contractual arrangements implicit and their modes of monitoring and intervention informal and flexible (Lincoln, *et.al.*, 1996). *Keiretsu* membership can be interpreted as a 'hedge against future failure' (Aoki 1988:280). The advantages of *keiretsu* governance system are: their flexibility, adaptability, facilitated information and knowledge exchange, access to a range of alternative sources of financial assistance, and collaborative attitude to problem solving. These are an asset to the Japanese *keiretsu* groups not only in their home market, but also in their international operations. By integrating the political process within the system, *keiretsu* governance offers a valuable mechanism in building relationships with host governments in international business ventures, and other partner firms in multinational alliances, or with their foreign subsidiaries.

#### Japanese Trading Networks - Sogo Shosha

Japanese trading companies *Sogo Shosha* emerged since the 17<sup>th</sup> century and have further evolved from providing services as middlemen to their clients and *keiretsu* members to diversifying in different business areas with higher risk. In building diversified business portfolios *shosha* have settled as hubs in large business networks, controlling complex flows of resources. At various times *shosha* have acted as commission agents, importing and exporting on behalf of clients; as dealers, trading in their own right; as middlemen in transactions between members of a *keiretsu* network; as financiers, lending money to smaller *keiretsu* members; as facilitators and intermediaries in negotiations with foreign partners; and more recently as investment-trust managers, venture capitalists, and business consultants (The Economist, 1995). This description suggests that *shosha* represent the ultimate entrepreneurs, transforming every business opportunity into a profitable venture, relying both on own financial resources and raising capital from the stock market.

FIG. 3: JAPANESE *SOGO SHOSHA* BUSINESS NETWORKS

- Intermediary-centred governance system utilising mixed ownership & connectivity role
- Blurred ownership and control boundaries
- Asset-based division of labour
- Managing through controlled autonomy & controlled interdependence

Many *shosha* are relying on their expertise as oil traders, and are currently repositioning themselves from being traders to operators in infrastructure industries, such as electricity generation, telecommunications, television broadcasting, and even satellite communications. Their current metamorphosis means shedding their past 'low-margin' role as agents and petty financiers towards businesses with high profit margins. They often form alliances with foreign companies in preference to alternative *keiretsu* partners. Their networks of partners are much more multinational than traditional *keiretsu*.

As hubs in their own business networks *shosha* have always held large shareholdings in other companies. Some of their investments represent shares in *keiretsu* firms (The Economist, 1995), some holdings are in their own independent subsidiaries (the *shosha* have generally preferred to run their own subsidiaries as non-core activities). Now *shosha* exhibit the new role of Venture Merchants. Each of the leading *shosha* has between 10 and 20

subsidiaries that are eligible to be listed on the Tokyo stock market. Share trading appears to be an attractive business for *shosha*, and a powerful mechanism for the growth of their business network.

The main governance mechanisms of the *shosha* holding networks appear to be: flexibility in financing both through own capital and using financial instruments available at the stock market; close hub-and-spoke co-ordination of related as well as unrelated business operations; 'employing' trust relations through family linkages or other informal associations between managers of individual businesses; actively using stock market financial instruments not only for enhancing their return on capital (ROC), but also for reinvestment of this capital in productive assets and business operations, and the endogenous growth of their business portfolio.

## Discussion of Cases and Conclusions

Both cases of *Keiretsu* and *Sogo Shosha* resemble much more a holding formation, and offer two independent alternatives to the multidivisional form (M-form) of corporation with public limited liabilities and financed through trading on stock markets. Both cases demonstrate that the same socio-economic and institutional environment in Japan has nurtured two distinctive forms of governance, each of which offers different forms of bundling of ownership and control functions. Under the *Keiretsu* governance system there are two institutions engaged in monitoring and control, and both exercise ownership rights, and actively participate in strategic decision making and resource allocation. The *Keiretsu* Bank and the Presidents' Association *Shacho-kai* are the main stock-holders that assume responsibilities and liabilities. Within the *Keiretsu* system they manage collectively the complex and multi-level network of corporate assets, utilising resource and capabilities based on division of labour, interlocking resource ties, optimisation strategies, and co-ordination of interdependencies.

The literature on *Sogo Shosha* does not give many details on the institutional arrangements of their governance system. However, from the scarce descriptions of their operations we may induce that their governance system is centred in the trading firm, which utilises a mixed ownership and connectivity function, controlling and directing the trading operations of its subordinate assets. The trading firms itself have neither full ownership, nor full control of the independent firms under their sphere of influence. However, *Shosha* clearly generates value added by facilitating trading and operability of these firms. Its network incorporates asset-based division of labour which allows the centre trading firm to coordinate multi-level operations. *Shosha's* relationships with its subordinate firms exhibit a mixed form of controlled autonomy and interdependence.

Clearly both cases demonstrate governance systems that generate economic efficiencies beyond the specialisation between owners and managers and the effective control over the managerial function. Re-bundling of ownership and control within the relational-insider system facilitates good reinvestment of capital into economic growth and creates a number of institutions that facilitate smooth negotiation of contract commitments and outcomes. The lack of transparency, attributed to this system may be associated with limited accountability, but it is also associated with effective intra-corporate information sharing, learning and innovation.

Regarding their international operations, their governance flexibility and adaptability are a strong advantage compared with the MNC that originate from the Anglo-American stock-market system. The MNCs subject to the strict regulatory environment of the stock-market capitalism have evolved as a multidivisional form (M-form) of incorporation of subsidiaries, where full ownership and control is the most desirable relationship from the perspective of the 'parent' company. The network formation diminishes the costs of hierarchical control and coordination, and creates a more fluid structure of interlinked assets. On this basis it can be claimed that the governance costs of networks are lower compared with the M-form of corporation. Flexibility in financing investment and growth strategies is another advantage of network governance. Network formations also allow for more adaptable approach to managing relationships with subsidiaries, which will be a particular advantage in international operations.

Among the evidence of convergence between the 'stock-market governing system' and the 'relational-insider system' are the changes that are taking place in Japan. These are: the large and liquid market for corporate equities, the governance reforms in the 90's permitting a number of stock-market practices established in the US capital markets (such as equity swaps and stock purchases by corporations), and banks engaged in liquidating

shareholdings (Jacoby, 2000). However, these changes are reported to be slow and superficial, as they do not lead to a radical transformation of the corporate governance system. Jacoby (2000) also reaches the conclusion that there are limits to convergence, and that a path which is locally efficient is not necessarily globally efficient.

There are mechanisms which act as complementarities and substitutes in different historical and institutional settings. For example the very high innovation rates in Japan are a result of big-company funding and corporate spin-offs, rather than venture capital like in the US (Jacoby, 2000).

If we consider that venture capital is one of the attributes of the stock-market capitalism then it is very difficult to explain that it has high profile in the US economy and its profile in the UK has diminished. This is evidence of divergence within rather than convergence across governance systems. Arguments about the superiority of one of the governance systems discussed above are difficult to sustain due to fundamental differences in the pace of economic growth. At the same time comparative research can identify specific governance mechanisms within each system that enhance efficient allocation of resources and effective control over the management of these resources.

Both *Keiretsu* and *Sogo-Shosha* resemble business networks coordinated from a centre that is not constrained by the division between major shareholders and executive managers. *Shacho-kai* is an institution developed to handle corporate responsibilities and strategic decision making. *Shosha* is a firm that is controlling both repetitive and market transactions, and is engaged directly and indirectly in operations management. Both cases exhibit a form of re-integration of the ownership and control function. How does this apply to MNCs and global business networks?

The MNCs have to handle and control multiple transactions in remote locations adopting a variety of co-ordination mechanisms – most of which have been invented for the purpose of effective administration and management of economic activities in organizations and institutions. The complexity of MNC operations requires a complex set of tools used by individual and collective agents – all engaged in a complex allocation of resources for operational and strategic purposes. In this context the discussion of the decision making power of the individual members of the Board of Directors, or the accountability of insider agents to outsider shareholders and stakeholders merely reaches the paradox that there are no boundaries to managerial opportunism, and enhanced control that assumes tentative opportunism, generates merely more sophisticated evasive manoeuvres from executives entrusted to handle operational risks.

Collaborative governance demonstrates an alternative way for re-alignment of interests of all economic actors, and shortens the cycle for reinvestment of capital into productivity and growth, compared with the portfolio investment mechanism within the stock-market governance system. It facilitates information sharing, learning and innovation that ultimately brings comparative advantage to an MNC,

Ownership rights do not produce automatically enhanced accountability or ethical behaviour. Both of these outcomes require institutional support from a social canvas that evolves historically and in a particular legal and socio-economic context. Governance mechanisms taken out of this context may not work and may not be applicable to other systems. In addition to that, systemic changes are always costly to implement, and require radical approach.

This comparative analysis of the governance mechanisms that have evolved under the ‘relational-insider’ governance system illuminates some of the advantages of an economic system that have facilitated rapid growth and rapid internationalisation particularly after the Second World War. The criticisms of the welfare governance have been usually raised from a narrow perspective.

Further research into the governance mechanisms behind *Sogo-shosha* is essential in order to explain the success of this form of business growth. The growing popularity of holding companies in the rapidly developing economies is evidence of the importance of this corporate form for growth and wealth creation. Most of the governance mechanisms discussed in the paper are subject to evolution, particularly under the influence of the on-going consolidation of the financial sector in Japan, and the changes in the regulatory environment. The existing research on *Keiretsu* governance will need updating in the context of the recent merger wave across *Keiretsu* group banks. Comparative and longitudinal analysis is expected to enlighten the debate not only on systemic changes in Japan, but also on global convergence, and the conceptual framework in this paper is an effort to present a systematic view on the factors that affect corporate governance outcomes.

## Abstract

**The purpose of this article is to examine if there exist relationships between international practices of open source software (OSS), piracy and national culture. A number of existing data bases are integrated for empirically test. The article shows that Hofstede's national cultural dimensions have varying influences on international practice of OSS across cultures in high-income level countries. The findings of this research are useful for both business and R&D functions of open source software companies and commercial software vendors. Future research on the subject is discussed.**

## Introduction

In recent years, open source software (OSS) has gained an increasing attention in industry and academia. OSS systems allow people to work together by making the source code open to everyone and Linux<sup>1</sup> operating system is the best known example (Economist, 2004). Furthermore, OSS products can be downloaded, distributed and shared freely (Krishnamurthy, 2003) among OSS community members. These features do not characterize traditional proprietary software. Opposite to OSS, traditional software licenses prohibit open access and free knowledge sharing (Barton and Nissanka, 2001). OSS products are often developed by volunteers and often cost nothing to use (Economist, 2006). Regardless of OSS often being free, OSS has been developed into a huge business sector and about one third of servers in American firms run on Linux, for example (Lacy, 2006). OSS can bring significant savings to the corporate world and to society as well, IBM can save around \$900 million per year by spending \$100 million per year on Linux development (Tapscott and Williams, 2007).

Activeness of OSS community members towards on-line surveys is important as the development of OSS products is dependent very much on the activity of OSS users and developers. OSS developers may have less incentives and resources to advertise their products than proprietary software counterparts because the former do not get direct profit from the use of OSS products (Comino and Manenti, 2005). Therefore word-of-mouth is a crucial marketing practice for OSS (Krishnamurthy, 2003). For example, Linux users often proactively promote Linux to their personal networks. Mustonen (2003), however, argues that the OSS programmers do not adequately pay attention to whether the software is used outside the OSS community. Most importantly, according to Comino and Manenti (2005) the competition between commercial software and OSS happens only among the consumers who know about the existence of OSS.

As OSS distribution, development and marketing is dependent on the activity of users and developers themselves, often across national boundaries, it is important to look at the factors that could influence the international activity of OSS. This information could be used as a proxy to evaluate potential adoption rates across different countries and market potential for OSS in different national markets. Thus it is important to study the behavior of OSS community members towards international surveys concerning OSS. This can provide marketing professionals valuable information concerning the OSS markets in both practical and theoretical terms.

The purpose of this article is to study the impact of national cultural characteristics on activity of open source software (OSS) community members in on-line surveys concerning themselves. We intend to answer three research questions: (1) What economic and cultural variables would influence the activity of OSS member? (2) Does piracy affect the activity of OSS community members? and (3) What national culture characteristics would provide a breeding ground for OSS community members? The data used in this research is obtained from a number of publicized databases representing the activity of OSS community members in separate on-line surveys. We intend to

integrate these databases to provide a broader platform to achieve the purpose of this study. The data consists high-income level countries (GNI per capita higher than USD \$10066 in 2004).

In the rest of this article we first discuss OSS and the relationships of culture and intellectual property (IP) including piracy. Then we develop hypotheses concerning relationships between national culture, economic development, piracy, information and communication technology (ICT) infrastructure and education level on activity of OSS. This is followed by methodology, results, discussion, and conclusions. We conclude this article by discussing its limitations and suggesting future research.

## **OSS, Piracy, and National Culture**

OSS refers to software whose source code is available to everyone (Krishnamurthy, 2003) compared with commercial software companies that guard their software source code in order to be able to sell their products (Economist, 2004). In OSS there is no risk of being locked-in to a single vendor (Bruggink, 2003; Economist, 2003; Murphy, 2004) and OSS can provide flexibility and more choices (Brandl, 2004; Krishnamurthy, 2003). However, despite of its flexibility and availability, OSS comes with a license as well and it is copyrighted (Krishnamurthy, 2003).

The licensing terms of software defines what the user can and cannot do with the software. A good source for OSS license requirements is the Open Source Initiative (OSI). OSI (2007) gives general requirements and definition for OSS licenses and they list OSI approved OSS licenses on their web site. Some OSS licenses (such as GPL<sup>2</sup>) do not give the right to use the source code inside a proprietary software, whereas some licenses, such as BSD, allow the use of the source code even in proprietary software products (Krishnamurthy, 2003; West, 2003). OSS users can make improvements, fixes and modifications if they wish to do so. The interaction between users and developers makes the OSS a community movement rather than an organization (Krishnamurthy, 2003).

OSS movement is driven by the technical and economical merits of OSS, whereas Free Software Foundation (or FSF) base their arguments on moral and ethical principles (Hicks et al., 2005). However, the ideological motivations do not adequately explain the large population of developers in the OSS (Mustonen, 2003). Details of OSS community and products are discussed in the following sections while developing the hypotheses concerning international activity of OSS community members.

National culture, in addition to economic variables, affects national attitude towards innovativeness (Herbig and Dunphy, 1998; Lee, 1990), intellectual property (Marron and Steel, 2000; Shore et al., 2001; Yang, 2005) and adoption of technology (Slowickowski and Jarrat (1997). Although OSS is essentially related to IP issue national culture's influence on OSS has rarely been studied.

In this article national culture's impact on activity of OSS community members is examined by using Hofstede's (1984) national cultural dimensions. It is noticed that Hofstede's culture theory has been criticized in number of research articles (e.g., Fang, 2003, 2006; Gallivan and Srite, 2005; McSweeney, B. 2002). But as Fang (2006) also stated, Hofstede's dimensions are useful for testing hypothesis in cross-country comparison. It is based on this understanding that this article sets out to map several important OSS communities and their product characteristics based on Hofstede's cultural dimensions. We focus on Hofstede's four cultural dimensions: Individualism-Collectivism (IDV), Masculinity-Femininity (MAS), Uncertainty avoidance (UAI) and Power Distance (PDI). The fifth dimension (long-term vs. short-term orientation) is excluded given its limitations (Fang, 2003).

Fang (2006) proposed a dialectical approach to understanding national culture. In his view national cultures embrace paradoxical values. Opposite cultural orientations coexist within national cultures depending on situation, context and time. This approach will also be useful in understanding the influence of culture in the context of OSS as well, for example, by explaining the seemingly paradoxical behaviors related to OSS community members and activities – in one situation a person is a user and in another situation the same person can be a developer.

Another issue related to culture is the influence of culture on piracy. In the software industry piracy is a common problem influencing the businesses of software companies all over the world. Business Software Alliance (BSA, 2004) reports piracy rates as high as 92% in China and Vietnam, and lowest 22% in USA. Researchers have

studied the relationship between piracy and culture and a number of economic variables (Depken and Simmons, 2004; Husted, 2000; Marron and Steel, 2000; Shin et al., 2004; Shore et al., 2001). Earlier studies have also found that the individualism-collectivism dimension affects piracy rates, although the impacts of other cultural dimensions have received only varying support. Piracy per se is not an issue in OSS (Krishnamurthy, 2003), but it may have an effect on OSS because pirated software are also low cost or freely available and as such competitors for OSS. In addition piracy rate and OSS popularity may be tied together through people's attitudes towards IP.

## Hypotheses

In some countries it seems impossible to purchase legit proprietary software as Ghosh (2003) demonstrated with the effective costs of a popular commercial operating system and office suite. Thus, unfortunately, another option for sometimes costly commercial software is pirated commercial software. Illegal copying of software is often referred as software piracy (Tang and Farn, 2005). Piracy includes unauthorized copying of software, using one license to install software on several computers and purchasing illegal copies of software (Prasad and Mahajan, 2003). Piracy rates and income level have relationship (higher income level countries have lower piracy, see Husted, 2000; Marron and Steel, 2000; Shin et al., 2004). Husted (2000) writes that software is vulnerable to illegal copying because it can happen with very low costs. According to BSA (2004) some countries have piracy rates more than 90% and world average was as high as 36%. Piracy itself is not an issue in OSS (Krishnamurthy, 2003), although it may have an impact on its popularity as pirated software are also popular and cheap, albeit illegal, alternatives. This relationship is likely to associate OSS with piracy, thus:

1. International activeness of OSS community members is affected by the piracy rate in the country. OSS is cheap (Economist, 2003). OSS represents a low cost and/or free alternative to commercial software.

From the point of view of cost, national economic development should be accounted in this study as well, even though this study is limited to high-income countries. Would the relative popularity of OSS be higher in lower income countries than in higher income countries? For users in lower income countries it seems more relevant to embrace OSS products, such as Linux, as OSS products are mostly free-of-charge (e.g. downloadable from the Internet). However, due to piracy OSS may not be seen as attractive as commercial software from the costs point of view either: by pirating commercial software one can get a real bargain with the same price as an OSS product, which will likely lower the overall interest towards OSS.

2. International activeness of OSS community members is affected by the income level (GNI per capita) of the country.

However, the effect of economic development of the country is not limited only to the effect through the piracy and software costs. Because OSS is most often distributed over the Internet and the development is done in Internet communities, thus the country's Internet or more generally the ICT infrastructure should be developed enough to support the distribution of large software packages such as Linux operating systems. Moreover OSS support is often provided by Internet communities, which may further indicate the influence of adoption of Internet on OSS activities. Naturally the more country has Internet users more chances there are that they have stumbled upon OSS. The activity of OSS community members could depend on the Internet infrastructure or more general communication network infrastructure, because a) to show their activity OSS members must get on-line to take part in the on-line surveys used in this research, and b) to acquire Linux or take part in OSS development an Internet connection is likely to be necessary.

To access Internet there are three common mediums: broadband, modem (fixed land lines) and mobile phone networks. OSS developers may require frequent and fast Internet access, thus, in the focal research the number of broadband subscribers is also accounted. Broadband can be up to 50 times faster than modem (or dial-up) connection and it is always on (Savage and Waldman, 2005). Modem or mobile phone connections might be enough for casual Internet surfing and e.g. filling in the surveys used in this research. Broadband access is not a requirement for Linux users as, for example, some Linux distributions, such as Ubuntu<sup>3</sup> also offer free shipments of CDs, that you can order from their website. In addition some Linux distributions are also sold in shops.

Related to the Internet adoption and on-line activity of OSS community members, the number of computers in a country could be important variable. There is a practical reasoning behind this: one needs a computer to use and install Linux – of one hundred computers only at most one hundred can be Linux computers. Most importantly the user must have the right to install software to the computer he or she wants to have Linux installed on. Thus the higher the adoption rate of PCs is in the country the higher chances are that more users have the right to install software on them (e.g. more home users). This is more so concerning the OSS developers – they are very likely to require administration rights to the computer they develop software.

In this article, the effect of overall ICT infrastructure on the international activity of OSS community members is tested on four indicators, namely, broadband subscription per 1000 people, fixed and mobile phone lines per 1000 people, Internet users per 1000 people, and PCs per 1000 people. World Bank uses three last ones as ICT indicator in the Millennium Development Goals (MDG). In this research they are included separately because of their potential varying effect on OSS activities (e.g. developer may require broadband access whereas a modem connection may be sufficient for a user). Based on the above discussion the hypotheses concerning the relationship between ICT infrastructure and the activity of OSS community members are as follows:

3. International activeness of OSS members is affected by the broadband subscription rate (per 1000 people) in the country (provides high-speed Internet access).
4. International activeness of OSS members is affected by the telecommunication infrastructure (fixed and mobile phone lines per 1000 people) in the country (provides low-speed Internet access).
5. International activeness of OSS members is affected by the Internet users rate (per 1000 people) in the country.
6. International activeness of OSS members is affected by the availability of computers (per 1000 people) in the country.

Some findings about OSS suggest that education level may have some effect on the popularity of Linux, e.g. OSS is often targeted to sophisticated users (Krishnamurthy, 2003; Lerner and Tirole, 2002) and in the last decade it has been popular in the market for high-end/professional users (Comino and Manenti, 2005).

OSS is typically developed by communities in the Internet (Hars and Ou, 2002). According to Krishnamurthy (2003) OSS is supported by a growing OSS community and it is a global movement. In non-English speaking countries, due to language barriers, OSS could be more popular among educated people (or lead users could be highly educated). For instance in a study concerning OSS developers by David et al. (2003) 95.02% of the respondents stated being fluent enough in English and 36.72% of them had master's or doctor's degree. In Ghosh et al. (2002) 85.71% of the respondents (likewise OSS developers) stated being able to speak English and 37.66% of them had master's or doctor's degree. If OSS users are mainly high end and educated users, then the activity level of OSS community members may relate to the education level in the country. Moreover, if pirated software are competitors for OSS, then higher education would, also through decreased piracy, increase the market interest towards OSS (Marron and Steel [2000] noticed that piracy rate is lower in countries where education level is higher).

7. International activeness of OSS community members is affected by the education level in the country.

OSS concerns both developers' and users' individual initiatives and freedoms. But paradoxically, OSS is also about achieving the collective good by sharing individually created knowledge with the entire OSS community. For instance, OSS can be customized as the source code is available (Bruggink, 2003; Economist, 2003) and OSS provides more choices to users and it is more flexible (Brandl, 2004; Krishnamurthy, 2003). OSS products can be downloaded, distributed and shared freely (Krishnamurthy, 2003). As opposite to OSS, traditional software licenses are often restricting (Barton and Nissanka, 2001). Herbig and Dunphy (1998) argued that collectivistic cultures value freedom less than individualistic cultures. Thus, when comparing OSS and traditional software, users in individualistic cultures could prefer the freedoms OSS provides. However according to Marron and Steel (2000) individual ownership of intellectual property is valued in individualistic cultures, which is an opposite what OSS stands for – OSS is community owned. West (2003) stated that OSS developers give up their rights to profit from their R&D work. According to Jacobs et al. (2001) sharing is perceived as more Asian, whereas IP protection, e.g.

copyrights and patents, are viewed as Western. Thus, they continue, new ideas and technologies belong to the public and cultural esteem may be stronger incentives for creativity than material success.

Of the above two examples the first one (freedom) is inclined with individualism, but the latter one (public ownership) is very much against it. In individualistic countries, users would like the freedoms OSS provide, but why would one from an individualistic culture develop something to be given away? This seems to support Fang's (2006) hypothesis that people can choose contradicting values and behaviors in different situations. It seems possible that while using OSS a person identifies himself with the individualistic values OSS stands for and when developing software he or she is more inclined with the collectivistic characteristics. Even efforts to develop OSS could mean energies of individualism

Krogh et al. (2003) argued that OSS development has characteristics of collective action. Majority of the respondents in study by Lakhani and Wolf (2003) had strong sense of group identity. Additionally, two of the main motivational factors among Linux developers, according to Hertel et al. (2003), are "a more general identification as Linux users" and "a more specific identification factor as a Linux developer" among others. Hars and Ou (2002) identified intrinsic motivation, altruism, identification with the community, direct compensation and expected future returns as important factors. However, they write, professional developers (i.e. salaried and contract programmers) were less motivated by altruism and community identification than student and hobby programmers (two different situation – at work and a hobby). Hofstede (1997) argued that individualism-collectivism dimension relates to the degree by which individuals are integrated into groups. Clearly, based on earlier findings, for OSS developers groups seems to have some importance. It is important to note that OSS developers are also users, thus in one situation they could be motivated by collectivistic characteristics where as in another situation (as users) they might be driven by the individualistic characteristic. Although Krishnamurthy (2002) found out that many OSS projects have only one developer.

How about other frequently shared software? Shore et al. (2001), Husted (2000), Shin et al. (2004), Marron and Steel (2000), and Depken and Simmons (2004) found out that piracy rate gets lower in more individualistic cultures. Piracy is sharing other's intellectual property for free and illegally, whereas OSS is sharing one's own and others' IP legally freely. Moreover, pirated software and OSS are competitors. As piracy and collectivism has relationship, and higher level of piracy might decrease popularity of OSS, thus individualism-collectivism and piracy together may influence the activity of OSS actors as well.

8. International activeness of OSS community members is affected by individualism-collectivism dimension of the culture.

OSS seems to be influenced by both masculine and feminine cultural characteristics. In masculine cultures material success and progress are important values (Hofstede, 1997). OSS developers, as discussed earlier, surrender their rights to profit from the software. They arguably do this in order to increase the speed of diffusion and the speed of development, which paradoxically has both masculine characteristics (progress) and feminine characteristics (giving for free can be seen as the opposite of material success). Giving for free and free distribution of software suggest care for others and for society at large. In addition openness and sharing of software source code guarantees continuity. According to Hofstede (1997) caring for others and preservation are dominant values in feminine cultures. However, as pirated software were considered to be a cheap competitor for OSS and Shore et al. (2001) found relationship between masculinity and piracy (the higher the masculinity the lower the piracy), thus, when both piracy rate and masculinity get lower we could expect higher OSS activity. Also Husted (2000) found same sign in his study.

9. International activeness of OSS community members is affected by masculinity-femininity dimension of a culture.

As pointed out earlier, OSS is developed in communities, support is provided by communities etc. and even the companies are part of the communities that has the power. The strength of the community is indicative from Dahlander and Magnusson's (2005) argument that the software code is controlled by the community, where companies co-exist, and the community has the knowledge to create software. Moreover, users can make modification and fixes in OSS, if they wish to do so (Krishnamurthy, 2003). If everyone can take the software source code and make changes etc., then it is likely to lower the inequality between the actors in the OSS community – especially between users and developers. Power distance cultural dimension means the unequal

distribution of power between the members in organizations or institutions and how they accept it (Hofstede, 1997). What makes OSS and power distance interesting is that actors in OSS have possibility to proactively shape and modify the technologies (Jesiek, 2003). It is quite opposite in closed source software, as Jesiek (2003) states that limited groups and users possess only a little negotiation power. In addition, OSS provides more choice and several kinds of freedoms as came up earlier. Thus high power distance cultures may somewhat easier accept restricting commercial software licenses, whereas low power distance cultures could expect to have more control of the software one uses. Interestingly, in higher power distance cultures people are more willing to choose to “steal” software as the findings by Depken and Simmons (2004) suggest, which should be taken into account as well. Likewise Shore et al. (2001) found positive relationship between power distance and piracy.

10. International activeness of OSS community members is affected by culture’s power distance index.

Human society has created technologies among other things to decrease anxiety (uncertainties). In uncertainty accepting cultures people are more tolerant to different and innovative behavior and ideas. (Hofstede, 1997) Low uncertainty avoidance cultures are more willing to take risks associated with new methods and procedures, thus, for example, in low uncertainty avoidance cultures people could be more willing to try new information technology before it is proven elsewhere (Shore and Venkatachalam, 1996). There is a greater technological uncertainty when the technology changes fast or it is new (Moriarty and Kosnik, 1989), and both developers and buyers are not familiar with the newest technologies (Meldrum and Millman, 1991). Development process of OSS, its distribution and support systems are quite different/innovative from commercial software and it is a rather new phenomena. Barton and Nissanka (2001) and Suzor et al. (2004) have expressed that licensing may have some uncertainties in OSS (e.g. termination of OSS license), which might be seen unfavorably in some cultures. As earlier stated piracy may also affect OSS popularity. According to Shore et al. (2001) piracy increases when culture’s uncertainty avoidance increases. By pirating software users can test software with very low costs (decreasing uncertainty), which puts pirated software in competing position with OSS as both are cheap to try.

11. International activeness of OSS community members is affected by the uncertainty avoidance dimension of a culture.

The above discussions show that many of the values that OSS represents simultaneously reflect both poles of each of Hofstede’s cultural dimensions. The entire OSS movement is therefore permeated with dialectical properties. On the one hand this can mean that Hofstede’s cultural dimensions may not be appropriate for analyzing OSS as it shows complicated relations between OSS characteristics and culture. On the other hand, if culture is perceived in dialectical terms with paradoxical values and behaviors coexisting in the same culture depends on the situation, context and time (Fang, 2006), the relationships between OSS and culture can be better explained.

## **Methodology**

In this research international activeness of OSS community members was tested among OSS developers and Linux Counter users. The data is obtained from a number of publicized databases representing piracy rates, ICT and economic variables, and the activity of OSS community members in separate on-line surveys, namely, BSA (2004), World Bank (2007, 2006), OSS developers study by Ghosh et al. (2002) and David et al. (2003), and Linux Counter Project (2007). Cultural indices of each countries in this study are from Hofstede (1997) and [www.geert-hofstede.com](http://www.geert-hofstede.com) (2007). Countries/cultures included in the analysis are listed in Table 1.

TABLE 1: COUNTRIES AND CULTURES INCLUDED IN THE RESEARCH. \*ESTIMATES AND \*\*REGIONAL ESTIMATES FOR ARAB WORLD FROM WWW.GEERT-HOFSTEDE.COM

Australia	France	Italy	Netherlands	Spain
Austria	Germany	Japan	Norway	Sweden
Belgium	Greece	Korea	New Zealand	Switzerland
Canada	Hong Kong	Kuwait**	Portugal	United Arabs Emirates**
Denmark	Ireland	Luxembourg*	Saudi Arabia**	United Kingdom
Finland	Israel	Malta*	Singapore	USA

BSA (2004) reports estimated piracy as the percentage of pirated software of the software installations in each country. In the focal research piracy was taken as a comparative measurement. According to Husted (2000) there is no indication that BSA would report higher piracy rates in certain areas than in others. BSA data is commonly accepted measurement for software piracy in the industry and a number of researchers (e.g. Husted, 2000; Marron and Steel, 2000; Shin et al. 2004) have employed BSA data in studying software piracy issues.

World Bank's (2006) Information and Communication for Development report concerning ICT global trends and policies is used to obtain information concerning the ICT infrastructure of each country. The report offers data from 144 countries and it is from year 2004. ICT report authors express that they have taken considerable measures to standardize the data and the data they have collected is from the sources thought to be most authoritative. World Bank ICT study includes data about Internet users per 1000 people, number of PCs per 1000 people, broadband subscribers per 1000 people, fixed telephone lines and mobile phone subscribers per 1000 people and GNI per capita. ICT report was used as the primary source for these variables, in case of missing values World Bank's Internet database (2007) were queried. Tertiary education enrollment rate was obtained from World Bank's Internet database (2007).

Ghosh et al.'s (2002) study data had 2784 respondents (OSS developers) from year 2002 and David et al.'s (2003) study had 1588 respondents (year 2003). Both of these studies had respondents from more than 60 countries. In the analysis term 'Floss' is used to refer to OSS developers data (from Ghosh et al., 2002 and David et al. 2003). Ghosh et al. (2002) mainly covers European respondents. Ghosh et al. (2002) suspect that there is a possible bias towards more motivated developers in their study. In addition some nationalities may be over-represented while others under-represented (especially Asian countries). Their survey announcement was translated to several languages (five European languages in addition to English) and the survey was posted on various developer websites (14 sites). David et al. (2003) tried to reach more respondents outside Europe. This study was also, according to researchers, probably skewed towards more motivated OSS developers. Their survey announcement was submitted to nearly 50 websites and mailing lists and translated to English, Dutch, German, Italian, Russian, Spanish, Portuguese and Chinese. In both of the studies majority of respondents were from Europe. Countries that didn't have respondents to the surveys are taken not to have active OSS developers, thus they are counted in the analysis as zero (i.e. not as missing values). In the analysis these two sets of developers data are combined into one variable.

Linux Counter is a website where Linux users can, voluntarily, register their Linux systems. Linux Counter Project (2007) started from 1993 (the organization was started in 1999) onwards and as of 12.02.2007 had 138003 Linux users counted from almost 200 countries. Linux Counter Project's (2007) main website is in English, but their international<sup>4</sup> Website is also translated to 14 alternative languages (13 European languages). Linux counter data most likely suffers from self-selection bias and is likely to include the most pro-Linux enthusiasts. To increase

reliability of the data Linux Counter cleans it from 'dead' Linux users based on their deletion policy, e.g. accounts that have not been accessed within two years and reminder has been send at least three months ago. Linux counter data is referred as 'Counter' in the analysis.

The raw data (absolute number of Linux users/developers) from Counter and Floss data were unusable as such. In the analysis proportions of OSS developers and Linux users to the number of Internet users in each country were used. This is considered appropriate because both OSS and surveys used for data collection are highly dependent on the Internet. By using the number of Internet users as the denominator we get comparable values across countries. Proportion to the total population is not appropriate because of e.g. the dependency of OSS on the Internet. For instance, in Tuomi's (2004) study concerning Linux Kernel developers, Luxembourg had the highest (populated weighted) growth rate of Linux Kernel developers which is due to small population of the country as the author pointed out.

The acknowledged skewness of either Floss or Counter data does not create problems to the focal study because users' and developers' activity in the international OSS community in each country/culture is under investigation. In fact, possible self-selecting is useful, because we can find out in what kind of national cultures internationally active OSS developers/users can be located. A person who fills in the survey 100 times is more active than a person who fills the survey only one time. Analysis is conducted in a sample that includes high-income countries. These countries were selected because they presents various cultural and political backgrounds, but still the economical variation is limited by the GNI per capita constraint.

## Results

The population in this study includes high-income level countries (in 2004). However only countries/cultures that had individualism, power distance, uncertainty avoidance and masculinity-femininity dimensions of Hofstede's cultural index data available are included. In addition to Hofstede (1997) also [www.geert-hofstede.com](http://www.geert-hofstede.com) website was consulted for cultural dimensions data, which resulted additional estimates for a few countries. In the analysis 30 countries had all the necessary variables. Data covers 72.5% of the respondents in OSS developers studies and 62.6% of Linux Counter users.

First, descriptive statistics were counted. Data was analyzed by using correlations and linear regression models. In the tables abbreviation are used for some of the variables: IDV stands for individualism-collectivism dimension, MAS for masculinity-femininity, PDI for power distance and UAI for uncertainty avoidance. Table 2 has the means and standard deviations of each variable. Tertiary enrollment rate had three missing values (Canada, Germany and Singapore). Missing values for tertiary enrollment rate were replaced with values from 2002 data for Canada, and with the mean in the analysis for Germany and Singapore. Replaced values were compared with other educational data (such as literacy rate and primary education) to make sure they would have minimal effect in the analysis. Piracy rate was missing from Luxembourg and for the analysis it was replaced with the regional average value (Western Europe, 36%) provided in the BSA piracy study.

TABLE 2: MEANS AND STANDARD DEVIATIONS OF THE VARIABLES (N = 30)

<i>Variable</i>	<i>Mean</i>	<i>SD</i>
<i>Floss/net users</i>	1.106e-5	9.609e-6
<i>Counter/net users</i>	3.053e-4	2.219e-4
<i>Piracy rate (N = 29)</i>	0.3786	0.1166
<i>GNI per capita</i>	28948	11470
<i>Broadband subscribers/1000 people</i>	105.34	64.80
<i>Fixed and mobile/1000 people</i>	1389.63	266.06
<i>Internet users/1000 people</i>	430.47	143.31
<i>PCs/1000 people</i>	425.70	200.40
<i>Tertiary education enrollment rate (N = 28)</i>	57.32	21.32
<i>Individualism (IDV)</i>	59.23	21.3
<i>Masculinity (MAS)</i>	49.57	20.67
<i>Power distance (PDI)</i>	46.63	20.2
<i>Uncertainty avoidance (UAI)</i>	63.1	25.48

In Table 4 (in Appendix A) there are the correlations between independent and dependent variables. Correlation matrix shows some significant correlations between a number of variables. OSS developers had significant correlations with piracy rate, GNI per capita, fixed and mobile phone lines, and individualism index. Linux Counter data had significant correlations with GNI per capita, fixed and mobile phone lines, tertiary education enrollment rate, individualism, and power distance indices. There was also a strong correlation between OSS developers and Linux Counter users.

Linear regression models are solved with both data sets separately. In both cases backward selection model is used to choose the best factors for the linear regression model. In the backward selection probability of F less than or equal to 0.05 was used to keep the variable. In Table 3 the model summaries are represented for both OSS developers and Linux Counter users. In Table 3 variables that are excluded from the models are omitted and the hypotheses the variable refers to is marked in the brackets e.g. H1 refers to hypothesis 1.

TABLE 3: LINEAR REGRESSION MODEL SUMMARIES FOR OSS DEVELOPERS AND LINUX COUNTER USERS. BACKWARD ELIMINATION PROBABILITY OF F LESS THAN OR EQUAL TO 0.05. \*\*\* P < 0.001, \*\* P < 0.01, \* P < 0.05

	<i>OSS Developers</i>			<i>Linux Counter</i>		
	<i>Estimate</i>	<i>t-value</i>	<i>VIF</i>	<i>Estimate</i>	<i>t-value</i>	<i>VIF</i>
<i>Intercept</i>	3.695e-5	3.550**		8.785e-4	5.273***	
<i>Piracy rate (H1)</i>	-4.081e-5	-2.925**	1.898			
<i>GNI per capita (H2)</i>	4.664e-10	3.729**	1.528	8.218e-9	2.965**	1.465
<i>Broadband (H3)</i>	5.967e-8	2.449*	1.185			
<i>Internet users (H5)</i>	-5.649e-8	-4.286***	2.648	-7.227e-7	-3.316**	1.413

<i>PDI (H10)</i>				-4.955e-6	-3.280**	1.350
<i>R<sup>2</sup></i>	0.65			0.6496		
<i>Adjusted R<sup>2</sup></i>	0.577			0.5936		
<i>F-Statistics</i>	8.913			11.59		
<i>df</i>	5			4		
<i>Model p-value</i>	6.836e-5			1.846e-5		

As can be seen from Table 3 some of the factors have significant effect on the OSS developers' and Linux Counter users' international activity. In both cases GNI per capita showed significant influence. Technological development in the form of broadband adoption seems to have positive effect in OSS developers' international activity. Interestingly number of Internet users seems to have a negative effect on OSS developers' and Linux Counter users' international activity. Only masculinity and power distance indices of cultural dimensions showed influence in the models. In both cases international activeness of OSS community members is affected by the culture's level of masculinity. Masculinity dimension had a negative sign, which indicate higher level of femininity increases international OSS activities. Power distance index had influence only among Linux Counter users data. Linux Counter users seem to be more active in lower power distance cultures. Model for OSS developers explains 57.7% of variation and for the Linux Counter users the model explains 59.4% of the variation. P-values for each model are less than 0.001.

## Discussions

In this article, attempt was made to study international activeness of OSS community members across cultures, which was measured by their activity to take part in on-line surveys concerning themselves, i.e. an active member of OSS community responded to the on-line survey. A set of existing databases was integrated and utilized and it was skewed as noted. Reasons for skewness could include different language skills of OSS community members, actual differences in OSS activity or some other reasons. Differences in language skills could be a potential reason, because Linux Counter project is available in English and mainly in other European languages. Likewise data

collection for OSS developers was announced in English and in several European languages, although some other languages were used as well. The analysis included only high-income level countries, thus the regression models may not be accurate for low-income level countries.

Activity of OSS developers and Linux Counter users to take part on the on-line surveys correlated with a number of variables. Regression models revealed that piracy rate, income level, broadband adoption rate, Internet adoption rate, and two cultural dimensions, namely, masculinity-femininity and power distance have influence in OSS community across counties/cultures. Hypothesis 1 (piracy rate), 3 (broadband users per 1000 people) and 10 (power distance dimension) received support at least in one of the two the models. Hypotheses 2 (GNI per capita), 5 (Internet users per 1000 people) and 9 (masculinity-femininity dimension) are supported in both of the models.

The influence of piracy rate indicates that in countries where piracy rate is higher there is less OSS developers. This should not come as surprise, OSS developers create IP whereas piracy destroys the value of IP. It is natural that software developers value IP and thus do not engage in piracy as easily as other users. In addition to open source software OSS developers may also develop proprietary software, thus they have natural interest in IP issues. Interestingly, though, piracy seems to have effect only in OSS developer data, not in OSS community in general.

Although income level of the countries was used as limiting factor, it still showed influence among both OSS developers and Linux Counter users. GNI per capita was used as a measurement for income level of a country. GNI per capita had positive effect depicting that in higher income countries there are more active OSS community members. This probably indicates that the costs of the software is not an important characteristic of OSS (i.e. in high income countries there would be less demand for free, as zero costs, software, if the costs were important factor), or perhaps in higher income level countries people have more time to fiddle around with challenging OSS projects on their free time.

The effect of ICT infrastructure on the international activity of OSS community members was measured with four variables. Two of these variables, namely, PC adoption, fixed lines and mobile phone subscription rates did not indicate influence in neither of the models. Internet adoption rate had a negative effect in both of the models. One possibility for this might be the chronological diffusion of Internet technologies, for example, countries with higher Internet adoption rate may have started the adoption earlier, but not until recent years OSS has become mature competitor for proprietary software, thus countries that have adopted Internet later has an easier path to adopt OSS as they have not been locked-in to proprietary systems. So, in countries that has adoption process later, users have had the possibility to choose between OSS and proprietary software whereas earlier adopters (e.g. decade ago) may not have had this choice, which could reflect in the activity of OSS community members as the 'inverse' effect of Internet adoption indicates. In contrast, broadband adoption had a positive impact in the model for the OSS developers. For OSS developers broadband access is important or even necessary to share and follow the software projects. Moreover broadband access is somewhat newer than the Internet as a whole and perhaps the adoption of broadband connections has occurred more simultaneously across countries included in this research. OSS community members' activity to register themselves to Linux Counter was not influenced by broadband adoption as indicated by the model for Linux Counter users.

Education level was considered to be one factor that affects the international activity of OSS community members. The effect of education level was measured with the tertiary education enrollment rate. According to the analysis education level did not show influence on the international activeness of OSS community members in neither of the models.

Culture's impacts on international activeness of OSS community members was studied by utilizing Hofstede's cultural dimensions. Some of the cultural dimensions had influence in both models. Individualism and uncertainty avoidance dimensions showed no influence in neither of the models. Masculinity and power distance, however, showed influence.

Negative influence of masculinity indicates that more active OSS community members can be located in more feminine cultures. OSS developers give the fruit of their work for free, the distribution of the products is free, and OSS guarantees continuity, which suggests some feminine values, even though OSS is also embedded with some masculine values.

Power distance showed influence in the model for Linux Counter users. There can be various reasons for it, for instance the differences could be due to difference of the nature of surveys (Counter project is a continuous survey), but, most importantly, we have to also keep in mind that Linux Counter respondents includes both Linux users and developers, whereas Floss data was only about developers. As discussed earlier OSS seems to lower the power distance between developers and users due to the nature of the software and the rights granted for the users. Besides in OSS users have possibility achieve far greater power than in proprietary software.

Differences between OSS developers and Linux Counter requires more attention. The differences may indicate that the values related to the same OSS phenomena influence differently in different adopter groups or persons' behavior in different situations reflecting different cultural values. Different influences of the power distance dimension in the two groups seem to support Fang's (2006) idea of cultural behavior being paradoxical and dependent on time, situation and context. As an example, in the model for OSS developers power distance is absent. This may be because software developers can develop software by themselves, i.e. if they need a calculator they can program one that fits their needs. Users on the contrary, can either buy a ready calculator software that may or may not fit their needs or they can use open source calculator. In the first case they can suggest ideas to the original developer, however only the developer can make the changes (this was pointed out e.g. by Krishnamurthy [2003]). In the latter case, however, they can make changes by themselves or ask any developer to make necessary changes, thus it significantly decreases the power distance between developers and users because the original developer cannot keep the strings too tight. In OSS if the original developer is not willing to make changes, then the user can always take the source code and go – with proprietary software the users can only hope the developer listens. In lower power distance countries more users may require this option, so there exists the negative influence of the power distance index in the model for Linux Counter users.

## **Conclusion**

We need to acknowledge that the competition between commercial software and OSS happens only within the informed computer users (Comino and Manenti, 2005). Thus OSS users in one country might be more than in another country because of the greater number of informed computer users - not only because of the economical or development level of the country etc. This is why knowledge about the activity of existing OSS users and developers is important in overall assessment of OSS adoption and market potential. If a user takes active measures participating in on-line survey then, perhaps, he or she also promote OSS usage among their acquaintances. In this research international activeness of OSS community members was tested among OSS developers and Linux Counter users. The latter one may also include users in addition to developers. GNI per capita, Internet adoption rate and masculinity-femininity dimension showed influence in both OSS developers and Linux Counter users regression models. Piracy rate, broadband adoption rate and power distance dimension influenced at least in one of the two the models.

Commonly attached characteristic to OSS community and the development process is their collective nature. Regardless of the collective characteristics, OSS developers' nor Linux Counter users' activity did not depend on the individualism-collectivism dimension of the culture. Likewise, earlier findings by Krishnamurthy (2002) also indicate that many OSS developer work alone. However, culture has impacts on the OSS community in terms of masculinity-femininity and power distance dimensions. Lower level of masculinity seemed to increase OSS activity among OSS community members. More important is the finding that culture showed different influences among Linux Counter users and OSS developers. Among developers only masculinity dimension had an effect, but among Linux Counter users power distance was influential factor as well. Thus marketers and software developers should take culture's potential impacts into account when conducting business across cultures whether it is development or promotion of OSS products. Proprietary software vendors could also take advice and consider the effect masculinity and power distance dimensions have in the commercial software markets when they are competing with OSS. The contradicting influences of cultural dimension on the same phenomena (OSS), but in different role of the person as user and developer, is an important finding that lends support to Fang's (2006) conceptualization of culture which embraces paradoxical values and behaviors.

Interestingly, the effect of Internet adoption rate (as users per 1000 people) in the country had a negative effect in the models. This could be because of the lock-in to proprietary systems some countries are experiencing due to their earlier Internet adoption and lack of competition at the time. OSS has brought competition only in the recent years, thus countries that have adopted Internet later have had the ability to try OSS before potential lock-in to proprietary systems. This needs further investigations to draw conclusions. In opposite, broadband subscription rate had positive influence in the international activeness of OSS developers and it seems rather natural as OSS development is highly dependent on Internet and a fast Internet access may be a requirement for OSS developers to keep up with the latest developments. Piracy showed influence only among the OSS developers, which is natural effect as OSS developers create IP whereas piracy destroys the value of IP.

Our study has a number of weaknesses. The empirical data on which the study is based comes from an integration of a number of existing databases. The data represents only a fraction of the OSS community members. It may represent the cohort of early OSS adopters and the most passionate OSS advocates, thereby as making the data suffer from biases.

Hofstede's (1997) cultural dimensions indices which are developed in the 1960s and 1970s maybe outdated. In addition Hofstede's cultural indices may not be fine grained to measure complicated phenomenas such as OSS. Moreover, Hofstede's theory is based on bipolarizing cultures giving little room to understanding culture in dialectical terms. However, due to the availability and its usability in testing hypothesis Hofstede's dimensions are considered relevant in this study. To assess actual cultural values of OSS developers and non-OSS developers, and OSS users and non-users primary data collection and measurement for their cultural values should be used. This would prevail the softer values behind the affection towards software freedoms. However, the results of this study provide strong indication and leads the way for understanding OSS activities across cultures.

In this research several background variables were included, but as visible from explanation power of the regression models the differences in activeness of OSS community members across cultures include also some other variables than those in this study. Future research is needed to identify such potential variables as foreign language skills (more fine grained analysis of education level), political orientation, or attitudes towards technology in general etc. However the scope and range of variables in this study are limited because the respondents are only from the population who can access the Internet and current research is limited to high-income countries. Future research should be conducted to cover the activity of OSS community members from lower income countries. More important, this article suggested that culture may have a paradoxical influence on OSS. Future research needs to address in more detailed the dialectical properties of OSS movement and their implications for industry and academia.

# Challenges of Technology Protection for Chinese Private Enterprises

*Wenqi Liu, wenqiliu@gmail.com  
Jianming Mao  
Zhejiang Shuren University, P.R.China*

## Abstract

Chinese private enterprises have created substantial wealth in recent years. During expedited globalization, Chinese private enterprises encounter a few of challenges in the regions of technology protection and management. Currently, due to lack of consciousness to protect technologies, the technology protection and management systems have not been established well until now in many private enterprises. As a result, a few of them are inadequate to deal with suits they involved which probably incurred losses as well. Therefore, technology protection is being critical for their survival and development. It is also of great significance for local governments to provide policy supervision at right time to help private enterprises to conquer these difficulties.

## Introduction

Since the implementation of the market-oriented reform and open policy in China, Chinese private enterprises have been playing an active role in the social economy. In these years, the GDP contributed by the private economy increases continuously, and the advantages of private enterprises emerge gradually as well. Although more and more private enterprises devote themselves to technology innovation, their core competence still far lags behind that of large state-owned enterprises in China and their counterparties in developed countries. Presently, the enterprises with their independent technologies only account for 0.03% among all the enterprises. [1] Simultaneously, private enterprises are faced with many other challenges, such as the deficient technology protection and management systems, the imperfect legislation and enforcement, the insufficient supports and assistance provides by the government and associates, and so on. Therefore, in order to promote competitive abilities of private enterprises and to increase their market share, both the private enterprises and Chinese government should take positive policies to conquer these difficulties, to facilitate the innovation and to protect technologies.

## The Challenges of Technology Protection for Private Enterprises

### The Weak Awareness and Consciousness of Intellectual Property Right (IPR) Protection

Many private enterprises in China pay little attention to IPR protection, which is showed in the following folds. Firstly, enterprises' awareness and consciousness of IPR protection is especially weak. Quite a few of them appreciate the importance of the increase of tangible asset; however, they ignore protection for IPR including patents, copyrights, technological secrets, and so on. As a result, an amount of technologies are lost. It is reveal that the enterprises have made no study on the roles of IPRs in economic activities, thus not understanding how to use the patent system to improve technical innovation mechanism, product quality and high-tech contents for developing and protecting market. Secondly, the consciousness of maintaining the validity and effectiveness of their patents is not strong enough. Some enterprises have only concern about the amount of the patents filed and granted, but think little of patent validity, patent quality and actual value of their patents. Patent validity means a patent is maintained effectively before its term expired. It reflects the technological innovation abilities and competitive abilities of enterprises and a nation. The patent holder is only willing to pay maintenance fee to keep the validity of patents which have market value. Therefore, the number of valid patents represents the technological level more factually than the number of patents granted. Chinese Patent Law stipulates that the duration of patent rights for inventions is twenty years, and the duration of patent rights for utility models and design is ten years. However, the validity period of many patents is less than maximum period prescribed by law. According to the data investigated and

statistically analyzed by Patent Office of the People's Republic of China, the patents granted by Chinese authority with valid periods less than seven years account for 66.3% among all the Chinese patents, and the patents with valid periods more than 10 years only account for 17.5%. Nevertheless, the two corresponding proportion mentioned above are respectively 41.9% and 29% in foreign countries. [2] Thirdly, the utilization of IPR is simplified. Most of private enterprises limit to use their IPR in production by themselves, but few of them make profits through cooperation, license, technology transfer, and other ways, which are usually adopted by multinational corporations.

#### **The Insufficient Experiences in Dealing with Suits Related to Technology Protection**

IPRs are powerful weapons for many private enterprises. In Chinese domestic trial experiences, more and more cases involving technology protection happen annually. On the one hand, private enterprises have recognized gradually that it is critical to protect their IPRs. It can be seen that many enterprises will bring an accusation actively against infringement. On the other hand, some private enterprises do not respect IPRs owned by others well enough; consequently, they are probably accused as defendants due to their infringements. Currently, there are two obvious characters in the cases involving IPR disputes as follows. Firstly, the number of cases is creasing in the recent years, and the majority of the cases are related to technologies. For example, there are 400 cases registered in the Intermediate People Court of Hangzhou in 2006, and 370 cases have been ended. Among them, 212 cases are about patent issues. The amount of these cases has reached the culmination in the trial history in this court. Similar situation has also occurred in the Intermediate People Court of Nanjing, Shanghai, and Beijing. [3] Secondly, current cases are more complex and more difficult than the cases happened in several years ago. The scope of disputes has been extended from the traditionary areas, such as patents and copyrights, to some advanced areas, including plant variety rights, rights of discovery, and so on.

In the cases involving the IPR issues, private enterprises are usually faced with the following troubles. Firstly, it seems that many private enterprises are reluctant to solving disputes and protect IPRs through judicatory proceedings. In China, both the judicial proceedings and administrative enforcement constitute the whole system of remedy for infringed IPRs. Above all, intellectual property rights are important civil rights. In civil infringement cases, the people's court is empowered to order the infringer to bear civil responsibility for the cessation of the infringement. Moreover, if the infringement of intellectual property rights is so serious that it has disrupted the economic order and constitutes a crime, the infringer's criminal responsibility is investigated and dealt with according to law. Both of them are the practical and effective judicial protection method. In addition to judicial practices, Chinese intellectual property rights administrative departments exercise their legally stipulated powers and functions to safeguard law and order within the field of intellectual property, encourage fair competition, mediate disputes, settle cases involving violations of intellectual property rights, and protect the interests of the broad masses of the people by maintaining a good social and economic environment. In China the administrative procedures for solving disputes concerning intellectual property rights are simple and convenient. Cases can be quickly filed for official examination and possible prosecution, investigation follows promptly, and efficiency in handling the case is high. This is advantageous to the owners of the rights. [4] In comparison, judicial proceedings is the final means of claiming remedies, is more powerful than the latter. Whereas, if enterprises choose to enter into judicial proceeding, they will be confronted with several risks of too cumbersome and time-consuming courses, difficulties in bearing the burden of proof, and high legal cost. Just due to the factors mentioned above, many enterprises, especially medium and small enterprises, are more willing to take actions by administrative proceeding. It should be noted that administrative authorities can only provide conciliation and mediation services for remedies, instead of making judgments. As a result, most of the IPR holders cannot obtain a satisfying economic compensation. Secondly, in many cases, the plaintiffs sue for a large amount of money, which leads to a big gap between their claims and the judgment made by courts. Some private enterprises know little of litigation rules, so that their claims are unreasonable. Moreover, sometimes they cannot provide evidence of their loss caused by the sued infringement convectively. Hence, their claims cannot be supported by courts. Thirdly, some private enterprises' capabilities of dealing with suits are quite weak. At present, a few of international corporations have established their strategic systems to protect their IPRs. Especially, some of them engage some searchers to find out whether their IPRs are being infringed in various markets in China. In contrast, Chinese private enterprises have not paid enough attention to IPRs. Not only do they conduct infringements, but also they prepare little for coping with the boring suits in which they are possible defendants. According to the statistics provided by the Intermediate People Court of

Nanjing, the failure rate of such suits in which the domestic enterprises are defendants reaches 83% amazingly. [5] One of the important reasons resulting in failure of suits is such a passive defense reaction.

#### **The Absence of Reasonable Management System of IPRs and Excellent Professionals**

An intellectual property (IP) management system defines the principles that IPRs are designed to serve and how patent matters and other IP matters are handled within the enterprise. It includes the management of the creation, ownership, protection, and commercial exploitation of IP. The purpose of IP policy is to support the business operations of an enterprise. Neglecting IPRs may turn into a threat to development in an internationally expanding business. However, the reasonable management system of IPRs is rarely established in numerous Chinese private enterprises. In many large-sized enterprises in developed countries, there are hundreds of professionals who are well versed in management and protection of IPRs. They are dedicated in studying the laws, ideology, economic status, and custom of different countries. [6] Based on such a powerful and efficient system, their technologies are often implemented in an optimal way. In comparison, the management in Chinese private enterprises still needs further improvement. A complete and effective mechanism for management and protection of IPRs hasn't been formed within many private enterprises. Majority of them choose the familiar management method, which lacks special persons in charge of affairs related to IPRs. Even though some private enterprises engage managers for IPR protection, a quite few of these managers only provide part-time services. Such an unprofessional and logy management system cannot ensure the necessary consultation.

Additionally, the IP professionals with abundant legal knowledge, experience and technological background are extremely rare in China. The persons who are trained well for IPR services are less than 1,000 annually. [7] Additionally, many experts flow to foreign-invested enterprises and lawyer's offices. It is of great importance and urgency for private enterprises to recruit such excellent professionals.

## **Proposals for Improving Protection and Management System for Technologies**

### **Accelerating the Construction of Protection and Management System for Technologies**

It is necessary for private enterprises to strengthen their awareness and consciousness of IPR when they enter into the competitive market. Enterprises should guard against potential infringements to maintain their hard-own market share. Enterprises shall vigilantly refrain from infringing other's rights as well; otherwise, they will suffer from great loss due to atonement and punishment caused by their prudential rough torts. Therefore, enterprises shall try their best to develop an effective system of technology management. Such a system will be helpful to improve the competitive abilities of enterprises, to maintain the economic value of technologies, to enforce IPRs and to monitor torts. Additionally, enterprises shall be always striving to promote their mechanisms for coping with suits. Besides using of arbitration and mediation, the current legislation and enforcement in the area of IPR in China encourage enterprises to fully protect their technologies by judicial means. The criminal, civil and administrative liabilities can deter and combat the infringement effectively. Simultaneously, some proceedings in litigation, such as preliminary injunction, evidence preservation, and attachment of property prior to entry into judgment, can protect the rights of technology holders in time, which will guarantee the legal remedy. In particular, the Supreme People's Court and the Supreme People's Procuratorate have jointly issued the Interpretation of Several Issues Relating to Specific Application of Law to the Treatment of Criminal Cases of Intellectual Property Infringement No. 2 which came into force on the same day. This Interpretation aims to further strengthen the protection of intellectual property rights in China. [8] With regarding to the importance of judicial proceeding, private enterprises shall prepare constructively for trial and can contribute positively toward their defense. Such a prudent attitude to suits is necessary. Enterprises should gather necessary evidence to substantiate their claims. The disputes related to technologies and IPRs are generally esoteric, so that it is also essential to consult a lawyer or legal center and research the specific laws. Finally, enterprises shall recruit professionals who are specialized in searching, viewing, and analyzing of IPR data collections worldwide, in managing and protecting technologies, and enacting particular strategies for technology protection. The excellent human sources can be obtained through introducing and training staffs, or cultivating special talents by cooperating with other enterprises.

### **Enhancing the Function of Agencies and Associations to Assist Private Enterprises for Technology Protection**

Agencies of IPR provide a series of professional services and handle technologies -related affairs, such as preparing patent application, analyzing actions and preparing responses to actions, providing status reports related to IPRs for clients as needed, and taking necessary actions to keep IP holders in good standing in China and around the world. Agencies shall be approved by the State Intellectual Property Office of the People's Republic of China, and their work shall comply with the laws and regulations. Associations for IPRs protection are nongovernmental organizations, which are dedicated to promoting a better understanding of the creation and utilization of Intellectual Property. They are made up of individuals, businesses, institutions, and organizations involved with the development, promotion, protection, and utilization of Intellectual Property. In the recent years, the IPR Protection Association of China, the Patent Protection Association of China, the Trademark Protection Association of China, and many other associations have been constructed. These associations function as coordinators to harmonize the benefits between enterprises and the government, and function as supervisors to maintain the fair competition in markets. It can be seen that agencies and associations play an important role for private enterprises to protect their technologies. However, a short development history of agencies and associations in China leads to the absence of authoritative status and strong cohesion. Moreover, many private enterprises have no confidence in services provided by agencies and associations, so that it is difficult for the latter to perform their inherent function. In contrast, some agencies and associations with abundant experiences in developed countries perform an important function in the related area. For enterprises, they give advices on management and dealing with special cases, make investigation in the actual markets, and mediate disputes. For the central and local governments, they report the remand of industries, propose the industry standard, and assist legislation and enforcement. These experiences shall be learned from by agencies, associations, and private enterprises in China.

#### **Reinforcing Guidance and Improving Assistance Provided by the Governments**

Firstly, the central government and local governments should set up a proper administrative system. Above all, the governments shall strengthen the enforcement to protect the rights of technology holders. It is also practical to develop information systems to report acts of violation of the laws and regulations. Based on the information they obtain, the governments have an obligation to publish it for private enterprises' reference. At the same time, the governments shall help enterprises avoid the risks in the international technological trade and investment, give directions in commercial issues, and carry out professional training to improve the abilities of staffs in private enterprises.

Secondly, the governments shall develop an open and expedite information channel for giving better access to government services. Most of IP information comes from the governments and their departments. Compared with enterprises and individuals, the governments act as an electronic clearing house for information on other sources of assistance, including private sector experts, educational and training institutions, and investors and companies interested in partnering. Therefore, the accurate classification, careful edition, and prompt reports of IP information are all critical for enterprises, which can provide private enterprises convenience and save their valuable time.

Thirdly, the markets of agencies and associations should run under the laws and supervision provided by Chinese authorities. Above all, the professional qualification of agencies shall be evaluated termly. Moreover, the governments shall guide agencies and associations to do some academic research for the purposes of providing high quality services. Additionally, when making policies, the governments shall promote communication with agencies and associations, and consider the opinions from them, which reflect the problems in practices. Finally, the governments shall encourage agencies and associations to discuss difficult and disputable issues with private enterprises, and to make suggestions for them. Such actions will increase confidence of enterprises in services offered by agencies and associations.

Finally, government can assist private enterprises human resources development by sponsoring exchanges of business, scientific and technical information, and by strengthening and supporting the role played by teachers, trainers and private sector consultants and management consultants in the area of IP management. Moreover, the educational propaganda of IPR protection shall be carried out by the governments, enterprises, organizations, and all the social forces. These instructive actions will be significant to build a good environment of respecting IPRs and protecting technologies.

## Conclusion

The challenges in the regime of technology protection posed by technical development for Chinese private enterprises are obvious. Although private enterprises have made some efforts to conquer the challenges, the abilities of technology protection still lag far behind the requirements of the new knowledge-economy era. Therefore, Chinese private enterprises should pay more attention to the establishment and perfection of their management and protection systems for technologies. They should utilize all available resources to improve the level of technology protection. Moreover, the central and local governments, agencies, and association also have obligations to provide necessary services for private enterprises to cope with difficulties composedly.

*Kanika T Bhal*

*IIT Delhi, India*

*Namjae Cho, njcho@hanyang.ac.kr*

*Hanyang University, Seoul, South Korea*

## Abstract

A code of ethics is a formal document that states an organization's primary values and the ethical rules it expects its employees to follow. Researchers have found that a well-written ethical code could serve to convey the organization's commitment to ethical conduct (Molander (1987). The study explores the influence of formal codes on individual's behavioral intention of indulging into unethical activity of software piracy in the work place. For this purpose data has been collected by structured questionnaire from 379 respondents working in different IT companies located in South India, West India and North India. To find out the influence of codes of ethics on intention to act for software piracy, correlation was computed on perceived ethicality and intention to act for piracy. Along the direct relationship of formal codes with the intentions to act for piracy we have also studied the interactive effect of formal code with attitude to predict the intention as an outcome.

## Introduction

Organizations can guide members' ethical behavior by developing formal codes of ethical conduct. A code of ethics is a formal document that states an organization's primary values and the ethical rules it expects its employees to follow.

Research is inconclusive regarding effectiveness of the formal codes in changing attitudes or behavior. It suggests that codes of ethics must be consistent with the organizational culture and must be enforced in order to be effective (Trevino, 1986). In a 1979 survey of Fortune 1000 corporations three fourths of the companies had codes how ever only one half of the companies distributed the codes beyond the level of officers are "key employees" (White and Montgomery, 1980). Weaver and Ferrell, (1977) found that codes of ethics were more likely to affect beliefs about what is right, than behavior and that enforcement of corporate policy was necessary to change ethical behavior. Hegarty and Sims (1979), in a laboratory experiment found that an organizational ethics policy significantly reduced unethical decision. On the other hand many researchers have found that code of ethics don't any impact on person's ethical/ unethical behavior. Cressey and Moore (1983) analyzed the conduct codes of 119 corporations; they concluded that codes did not relieve organizational pressure to be unethical. Cleek, and Leoward (1998), conducted a survey of 150 business students and concluded that code of ethics is not influential in determining a persona ethical decision making behavior.

## Software Piracy

We consider it wrong to steal chocolate from a shop, however it seems to be quite different when we consider stealing information from a floppy disk (Wong, 1995). Software piracy has become a major problem for the software industry and for business, it has been estimated that software piracy results in between 2 to 10 illegal copies made for every legitimate copy sold (Conner and Rumelt, 1991).

Software piracy is defined as the unauthorized copying of an organization's internally developed software or the illegal duplication of commercially available software in order to avoid fees (Straub and Collins, 1990). It is

the illegal act of copying software for many reasons, other than back up, without explicit permission from and compensation to the copyright holder (Gopal and Sander, 1998). Piracy is claimed to be a major problem for the microcomputer software industry. Industry sources estimate the losses from piracy of commercial software at over \$1 billion per year and many fear that rapidly increasing losses will threaten the financial viability of the whole software industry (Bequai, 1987).

The pervasiveness of software piracy throughout the world is having a profound effect on the software publishing industry and the development of digital intellectual properties and technologies especially in developing countries where the piracy rates are extremely high (Gopal and Sanders, 1998).

Software piracy, the illegal copying of computer software, has received increased attention as a form of unethical behavior in recent years and has become a widespread problem universally, in government and business environments (Sims, Cheng and Teegen, 1996). The 1980s witnessed a virtual explosion in the use of microcomputer for business, education and personal / home functions. This spread of hardware has been accompanied by a proliferation of software, much of which "pirated" is i.e., unlawfully reproduced.

## **Intention**

Intention refers to the subjective probability of one's engagement in any behavior (Fishbein and Ajzen 1975). Stronger the behavioral intention, the more likely the execution.

Accordingly to Fishbein and Ajzen (1975) intention to act is determined by the individual's attitude and perceived social pressure from significant others. Glass and Wood (1996), in their study showed that variations in resource gained through the software exchange influence an individual's intentions to provide his or her legal copy of software to another for purpose of illegal copying.

## **Attitude**

Attitude toward the behavior refers to the degree to which the person has a favorable or unfavorable evaluation of the behavior in question (Ajzen 1989). Early theorists tended to use the term affect to denote an attitude's valence, i.e., overall degree to favorability (Thurstone's, 1931). To avoid confusion (Ajzen and Fishbein, 1980) proposed to use the term "attitude" to refer to the evaluation an object, concept, or behavior along a dimension of favor or disfavor, good or bad, like or dislike.

Many researchers (Schultz and Oskamp, 1996) in their studies have found that attitude leads to behavioral intentions. Prislina and Ouellette (1996) found that highly embedded attitudes towards preservation of the environment were more strongly related to an aggregate measure of behavior intentions than were low embedded attitudes. In an IT ethical context, if individuals view stealing software as wrong, they are unlikely to intend to steal it.

## **Methodology**

Since the focus of the study was using information technology, it was assumed that the level of familiarity with IT was likely to influence the responses. To address this issue an attempt was made to choose a sample that was homogeneous in terms of familiarity with IT, the study was conducted on the software professionals working in 16 software organizations based in North, South and West regions of India. These organizations varied in terms of ownership and respondents from Indian multinational and government organizations were included in the study.

### **Participants**

This study was conducted on professionals working software organizations. Altogether 379 executives from 16 organizations constituted the sample for this study. The data was collected via questionnaires that were administered in the organizations. The employees were assured of confidentiality and were informed that the information would

be used for academic and research purpose solely. Age and gender wise distribution of the sample is given in Table 1.

TABLE 1: AGE-GROUP AND GENDER WISE PROFILE OF THE RESPONDENTS

Age-Group	Gender		Total
	Male	Female	
20-25	98	54	152
25-30	164	37	201
30-35	17	4	21
40-45	2		2
45 -50	3		3
Total	284	95	379

It can be seen that the sample had mainly young professionals in the age group of 25 –30 years. It needs to be mentioned here that the age of the respondents is reflective of the actual age profile of the software professionals. However, the actual population probably has a larger share of female professional as compared to this sample.

Further, an attempt was made to collect data from, the different parts of the country to make the finding more universally representative. 131, 142 and 106 respondents were from Western, Southern and Northern parts of India. Respondents' belonged to different types of organizations 160 were from Indian Private Organizations 189 were form Multinationals and 30 were from Government Organizations.

FIG. 1: REGION WISE DETAILS OF THE SAMPLE

FIG. 2: ORGANIZATION WISE DETAILS OF THE SAMPLE

## Instruments Used

### Piracy Situations – Attitude and Intention

Based on (Shore, Solorzane, Burn and Hussan, 2001) two situations of software piracy were adopted. Both the situations are related to corporate piracy (piracy for organization). The attitude and behavioral intention for each situation was measured by using 3- items each. Attitude was assessed in terms of perceived ethicality and intention through likelihood of indulging in the activity. The rating was done on five point likert scale with responses ranging 1= Always to 5= Never. Reliability (cronobach's alpha) of attitude and intention for both the situations are reported in Table 2.

### Code of Ethics

The five items of code of ethics was adopted from Pierce and Henry (1996). One items where on ordinal scale, (*Does your company have a formal code of conduct*) where yes and no type. Rest four items were placed on a five point Likert Scale with responses ranging from strongly agrees =5 to strongly disagree =1. Reliability alpha of four items are reported in Table 2.

TABLE 2: SCALE CHARACTERSTICS OF THE VARIABLES INCLUDED IN THE STUDY

SCALE	Mean	St. Deviation	Alpha	No. of items
<b>Piracy</b>				
<b>Situation 1</b>				
Attitude	3.2	1.16	.93	3
Intention	3.3	1.08	.88	3
<b>Situation 2</b>				
Attitude	3.5	1.09	.92	3
Intention	3.4	1.05	.88	3
<b>Code of Ethics</b>	3.21	.615	.58	4

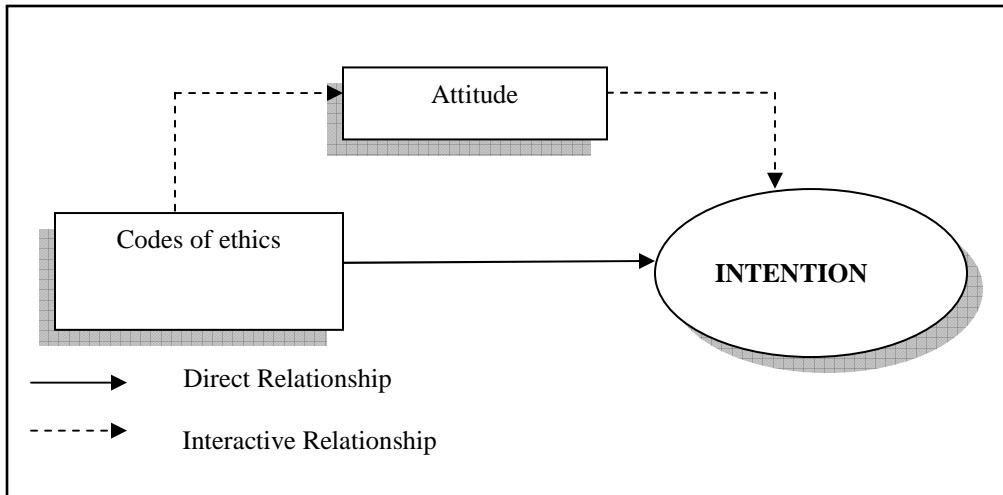

FIG. 3: RESEARCH MODEL

It was hypothesized that code of ethics would affect the perceived ethicality (attitude) and intention of individual decision-making regarding software piracy. Code of ethics can serve three major purposes in organization. These include demonstrating a concern for ethics by the organization, transmitting ethical values of the organization to its members and impacting the ethical behavior of these members (Wotruba, Chonko and Loe, 2001).

## Results

Presence of formal code was assessed through a yes/no response format. When we asked respondents whether they are aware of formal code of conduct in their company 320 respondent out of 379 said that they were, whereas 55 respondents said they were not. ( $\chi^2$  which is significant at  $P < .01$ ). Thus, it seems that most companies had a formal code of conduct.

Next to find out the influence of codes of ethics on intention to act for software piracy, correlation was computed between codes and intention to act for software piracy. Table 3 shows the results of correlation analysis.

TABLE 3: CORRELATION BETWEEN CODES OF ETHICS AND BEHAVIORAL INTENTION.

	Piracy Intention	
	Situation 1	Situation 2
Codes of Ethics	.103*	.147**
	(365)	(365)

Note: figures in parenthesis represent  $N$  (sample size). \* =  $P < .05$  \*\* =  $P < .01$ .

It can be seen from Table 1 that code of ethics has a significant correlation with intention to act for software piracy for both the situations.

### Interaction Effect of Code of Ethics and Attitude

So far we have discussed the direct relationship of code of ethics with the intentions to act for piracy. In this section we discuss the interactive effect of code of ethics with attitude to predict the intention as an outcome. To test the independent effects of code of ethics and attitude were included as the first 2 predictor and the interaction between the two was added as the third one. Only in case where the interaction term was significant further relationship was explored. It has been seen that out of two software piracy situations; in one situation code interacts with attitude to predict behavioral intention providing partial support for interaction hypotheses. Table 4 and 5 shows the results of this interaction.

TABLE 4: BETA COEFFICIENTS FOR TWO WAY INTERACTION OF CODE OF ETHICS TO PREDICT INTENTION

	SITUATION 1	SITUATION 2
(CODE) X (ATTITUDE)		-1.997* (.047)

Note: N= 379, figures in parentheses indicate the significance level, \*=p<.05

To see the direction of the results mean are identified. Significant interaction was further analyzed graphically. It needs to be mentioned here that the graphical representation shows the direction of the interaction effect. For the graphical purpose data are grouped into qualitative categories (low and high). Table 5 lists the mean scores on codes of ethics for different combination low and high of attitude. The same data is shown graphically in figure 4.

TABLE 5: MEAN SCORES: INTENTION AS A FUNCTION OF INTERACTION BETWEEN CODES AND ATTITUDE (SITUATION 2 OF PIRACY)

	Low Codes	High Codes
Low Attitude	3.36	3.64
High Attitude	3.97	3.87

Result of the interaction between Codes and Attitude to predict the mean values of Intention are depicted in Table 5. It can be seen that Intention to indulge in piracy is high when codes are low and attitude towards piracy is high. Figure 4 depict that Intention to act increases with increase in Codes.

FIG.4: MEAN SCORES: INTENTION AS A FUNCTION OF INTERACTION BETWEEN CODES AND ATTITUDE (SITUATION 2 OF PIRACY)

## Conclusion

In the present study we have taken ethical issues of software piracy and tried to assess the impact of code of ethics on unethical/ethical decision making regarding the issue, at the same time we are also tried to assess the interactive effect of codes with attitude to predict the intention as an outcome.

At the first level, there is a significant correlation between the codes of ethics and intention to act for software piracy. Hence it proves our hypothesis, that the stronger the code of ethics lower will be the intention to indulge in software piracy. Along the direct relationship of formal codes with the behavioral intention to act for piracy in the present study we have also studied the interactive effect of formal codes with attitude to predict the intention as an outcome. Thus our second hypothesis receives only partial support as, the interactive relationship were significant only for the second situation of software piracy.

Many researchers have found that a company code of ethical conduct has several benefits to the organization. It helps maintain and promote public trust, promotes "...greater managerial professionalism, protects against improper employee conduct, defines ethical behaviors in light of new laws or social standards, and ensures the maintenance of high ethical, standards in the face of changing corporate culture and structure" Pelfrey and Peacock (1991). In such cases organizations need to have a well-defined policy of personal computing behavior, which should be clearly communicated to its employees. If the organization doesn't have strong codes and policies, it will give opportunity to its employees to engage in unethical activity of software piracy.

# Integrating Digital Forensics into the Workplace

*BJ Gleason, BGleason@asia.umuc.edu  
University of Maryland, USA*

## Abstract

More crimes than ever before are leaving a trail of digital evidence behind. However, if an organization is not prepared to recognize, preserve, collect, and analyze this evidence, the criminals may never be caught. Now, more than ever, organizations need to take a proactive approach and start integrating digital forensics processing into their standard operating procedures. However, by the time investigators arrive at the scene of the digital crime, the evidence often has been wiped clean. This paper examines the issues and difficulties faced by organizations trying to incorporate digital forensics into the work environment. The author also proposes a new methodology for collecting and preserving potential evidence before an incident even occurs.

## Introduction

Although it is easy to believe that most of the computer attacks originate from outside one's network and organization, the truth is often just the opposite. While an exact number is not known, computer crimes performed by insiders accounts for 50–85% or more of all computer crime (Whitman & Mattord, 2007). While the actual malicious attacks by insiders appear to be fewer in number, there have been numerous cases of pirated software, child pornography, mishandling of classified data, computer viruses, Trojan horses, and copyright infringement (Little, 2005; Svan, 2006; Wait, 2006; Weckerlein, 2006). Crimes and attacks are being committed on both sides of the network, by insiders and outsiders, and they all have to be properly addressed, since all represent real threats to the operations, stability, and security of the computing environment.

Whether collecting physical evidence, such as fingerprints or DNA, or digital evidence, an investigator must follow certain laws and procedures. Digital forensics is the application of methodical investigatory techniques to solve criminal cases involving computer systems (Casey, 2004). Digital forensics deals with the preservation, identification, extraction, documentation, interpretation, and presentation of data collected from a computer system. Digital evidence is hard to destroy but easy to damage. If not collected and preserved properly, the evidence, digital or otherwise, often cannot be used in a legal proceeding (Casey, 2004; U.S. Department of Energy, 2000; Vacca, 2005; Whitman & Mattord, 2007).

The National Institute of Standards and Technology has recommended that all organizations start incorporating digital-forensics processing into their incident-handling procedures (as cited in Kent, Chevalier, Grance, & Dang, 2006). In addition to the precautionary measures that sure procedures provide in the event that legal actions are necessary, forensic tools and techniques can be used for data recovery and troubleshooting. The major premise of Kent et al.'s report, however, was that "organizations should ensure that their [information technology] IT professionals are prepared to participate in forensic activities" (p. ES-2). They stressed that incident handlers and first responders should receive forensics training and education so they know what they should and should not do when responding to a potential incident. They need to be prepared to cooperate with law enforcement and to make sure that they do not hinder the investigation or damage the evidence.

Digital evidence collection, preservation, and analysis are complex and time-consuming tasks. Forensic training is demanding and costly. The U.S. military faces even more challenges and problems with their global operations, shifting assignments, frequent rotations, and a constant barrage of cyberattacks from virtually every country on the planet.

## **The Growing Problem**

The threat to the military's computer infrastructure is growing daily. In the 1980s and 1990s, most of the threats seemed to come from teenaged hackers who saw breaking into computers as a rite of passage (McCormick, 1996) and gaining access to the Pentagon as the Holy Grail (Christensen, 1999). Often, however, intermixed with these teenagers were terrorists, both foreign and domestic, with other agendas. Although the numbers are hard to come by for security reasons, according to a report in *Newsweek* (Vistica, 2000), the Pentagon computer systems were attacked over 250,000 times a year. At least 500 of those are considered to be serious attempts aimed at classified computer systems (Vistica, 2000). As the result of a major international taskforce, the leader of a Romanian computer hacking team was just charged with breaking into more than 150 U.S. government computer systems. It is believed that the main reason the group kept attacking U.S. government computers systems is that they are considered to be "some of the securest machines in the world" (Associated Press, 2006).

In addition, computer hacking has become state sponsored, with many countries establishing information warfare teams to penetrate other countries' computer networks. Dr. Byeon Jae-Jeong of South Korea's Defense Ministry's Agency for Defense Development (as cited in "N. Korea's Hackers Rival CIA," 2005) indicated that his analysis of the 500- to 600-member North Korean hacker unit revealed that they had abilities comparable to those of the Central Intelligence Agency and could take over the U.S. Pacific Command and Control Center as well as the power grid for much of the United States. These North Korean hackers may be responsible for a 450% jump in attacks on computers in South Korea in 2003 (Magnuson, 2006). Although not widely discussed, it is well known that China, while enjoying status as a "most favored nation" trading partner, has been hacking into military computer systems for years (Thornburgh, 2005).

Whereas at first it seemed as if the hackers simply wanted to steal secrets or shut down the systems, it now appears they have more devious purposes. The computers are hijacked and used by the hackers for identity theft, spying, theft of information, distributed denial of service attacks, and as zombie servers (Magnuson, 2006).

## **Incorporating Digital Forensics in the U.S. Forces Korea**

The U.S. Forces Korea currently has only two fully qualified computer forensic specialists supporting over 26,000 computers. Thus, it is often impossible to respond properly to all the potential incidents that would require digital-forensic processing in a timely and efficient manner. To assist the forensic specialists, a small team of 10–20 IT specialists spread throughout the country can be called upon to perform some typical, first-responder data collection tasks.

Under the current system, local first responders are contacted by the Regional Computer Emergency Response Team (RCERT) when they have detected an anomaly on the network that needs to be investigated. The RCERT typically specifies the target System of Interest by its Internet Protocol address. The first responder must determine the machine's physical location and then, schedule permitting, travel to the System of Interest, which can be located anywhere on the Korean peninsula, and run a program to collect the system logs. Depending on their other duties, the time of day, and other factors, the time elapsed from receipt of the call until the logs are collected can be up to 48 hours. Once the logs are collected, they are e-mailed back to the RCERT for analysis to determine what additional actions, if any, need to be taken next. If the incident is deemed severe, and the system is to be seized, the responder is contacted, and the process is repeated. This time, however, upon arriving at the site, the computer is shut down, seized, and turned over to the forensic specialists. This entire process, from first call until seizure, can span a week or more (R. Henderson, personal communication, October 15, 2006).

During that time, no additional controls are being enforced on who is using the computer system. During the process of normal daily operations, thousands of files are being created, destroyed, overwritten, and modified. Potential evidence is lost or damaged, and since no chain of custody has been initiated, much, if not all, of the evidence collected from the system will be useless in a legal proceeding (Casey, 2004; Vacca, 2005).

If and when the computer is seized, the user is often left without a computer system, and all of the user's documents and e-mails have been taken along with the system. In some cases, the computer is not seized, but the

hard drive is wiped and the operating system reloaded to ensure that all traces of malicious code or classified data are erased. This procedure has the side effect of removing all of the user's data as well (A. Johnson, personal communication, November 1, 2006).

These "slash and burn" techniques are being used for several reasons: None of the incident responders have any formal forensic training, there is a heavy workload, and wiping and reloading the system typically is the fastest way to close out the incident (R. Henderson, personal communication, October 15, 2006; A. Johnson, personal communication, November 1, 2006). However, in the process, almost all of the digital evidence is lost, making it almost impossible to perform any true forensic analysis or even a simple root-cause analysis to find the initial vector of the problem, in order to prevent a recurrence (Whitman & Mattord, 2007).

## **Preparing the Troops**

A potential solution to this problem would be to identify more IT specialists who perform first-responder duties and to provide them with training on the proper collection of digital evidence. If enough first responders could be trained, the workload should be decreased, and the evidence should be preserved properly, allowing for a more detailed analysis, while restoring the user's system to an operating state. An additional benefit to preserving the digital evidence would be to include a copy of all the user's files and e-mails, which then could be returned to the user, provided those files were not directly involved with the incident.

Each unit in the military has at least one information management officer (IMO) who is the equivalent of the system administrator in the corporate environment. The IMOs are typically the first people called when users are experiencing problems with their computers. When IMOs arrive at the site, their primary goal is to correct the problem and get the system back online as soon as possible. However, if they detect any potential signs of suspicious computer activity, they have to secure the computer until they receive further guidance from an information assurance manager or the RCERT. A conflict can occur because a mission-critical system often needs to be brought back online as soon as possible, but that process typically destroys any digital evidence on the system.

Although the IMOs receive some required online computer security training, the bulk of their computer security training is done during a 2-week training class offered three or four times a year, schedule permitting. As most IMOs are only in Korea for a 1-year tour of duty, they may not receive any training for up to 4 months, depending on when they arrived. Moreover, this course focuses only on the general legal aspects of computer investigations and does not address evidence-preservation issues and techniques (P. Riopel, personal communication, August 17, 2006).

According to the Federal Bureau of Investigation, the amount of digital evidence processed from Fiscal Year 200 to Fiscal Year 2005 has increased 3,060% to a staggering 1,426 terabytes of data. During the same time, the number of forensic examiners only increased by 182%, to a total of 264 (Talley, 2006). Shreeve (2005) also indicated that the field is growing at an exponential rate, and that police and government agencies are not prepared to handle the increase. In fact, a large percentage of cases dealing with digital evidence are being outsourced to private organizations, due in part to the lack of properly trained law enforcement professionals and increasing demand for digital-evidence processing.

To address the growing interest in digital forensics, many colleges and universities are implementing digital-forensics programs (Gottschalk, Liu, Dathan, Fitzgerald, & Stein, 2005), but many of these are multiyear programs and go far beyond the scope of what would be needed by IMOs to collect digital evidence. Unlike what is seen on TV shows such as "CSI," most crime-scene technicians only collect the evidence and do not analyze it—that is the job of the forensic specialist (Horswell, 2004; Roane & Morrison, 2005; Saferstein, 2004). The IMOs would play a similar role; they would be responsible for the proper collection of digital evidence. This would require only what Armstrong and Russo (2004) referred to as a Level 1 education, typically required by new recruits and police officers on the beat.

## **A Proposal: The Digital Forensic Precrime Evidence Collection Unit**

In the 2002 Steven Spielberg, film, “Minority Report,” loosely based on a Philip K. Dick short story, Tom Cruise stars as a “precrime” officer, who, with the use of psychics, can predict when a crime is going to happen. Using sophisticated computer technology and a team of specialists, his precrime task force is able to get to the scene just before the crime is committed, save the victim, and arrest the soon-to-be perpetrator.

No matter what precautions we take, some attacks are going to break through our defenses. Due to the nature of the attacks—zero-day exploits, the time to find solutions, time to implement fixes, and so on—it may be days if not weeks before the malware or an incident is actually detected on a system. In a recent attack by the polymorphic Storm Worm, the worm had created over 42,000 variants of itself during 12 days in order to evade detection, and it worked. The worm was able to evade 27 different antivirus programs; only 4 were able to detect it (Larkin, 2007). The Sony digital rights management software, XCP, installed a rootkit to prevent its discovery and opened up a backdoor on the system; the worm might have gone undetected for up to 4 months before being discovered. It went undetected by all the standard antivirus, malware, spyware, and other security packages. Via an analysis of domain name system requests, the worm infected more than an estimated 500,000 computer systems world-wide, including military and government PCs (Norton, 2005). It was only detected by the author of a rootkit detector program who inadvertently had installed the rootkit on the system on which he was developing the software (Russovich, 2005).

So, not only can these malware packages be residing undetected on systems for days, weeks, or even months, evading all of the sensors, but they also can be causing performance degradation and system crashes. Russovich (2005) indicated that the Sony rootkit was so poorly written and used such unsafe procedures calls that it would cause the system to crash, resulting in the dreaded “Blue Screen of Death.” Even if the malware does not cause the system to crash, it can slow down the system. If multiple malware applications from competing organizations are loaded, the system can slow to a crawl, becoming unusable.

### **The New Three Rs: Reboot, Reinstall, and Reload**

When faced with unknown problems, users and technicians alike often apply the same methodology: Reboot, reinstall, and reload. First, they try rebooting the system. It seems to have become common knowledge that rebooting the computer system will fix most problems. Even the helpdesk personnel seem to believe this (Seebach, 2006). Unfortunately, from a forensic point of view, rebooting destroys any evidence residing in RAM. If the reboot does not solve the problem—and with a malware infestation, it typically does not—the user may try to reinstall a specific application that is causing problems or the last application installed. This usually does not help either. If the malware was installed with an application, the malware will stay even if the primary application is removed. With the reinstall or uninstall having failed to make a difference, the next step is the one that does the most damage from the forensic point of view.

Given the time pressure to get a system back online, the limited troubleshooting skills of most first-level technicians, and the ease of reloading a standard system image, it is becoming more prevalent to reload the entire system from an image server, such as a Symantec Ghost or Acronis True Image Server. With the user’s data residing on the a local file server, the disk can be wiped, and the operating system and applications can be reloaded from a standard configuration disk image over the network, from a DVD, from a USB hard drive, or from a hidden partition on the system itself. Depending on the size of the image and speed of the channel, the system can be reloaded, rebooted, and operational in less than 20 minutes.

However, if an update of the scanning software signature database reveals a malware infection or some other incident involving this specific system, chances are that most, if not all, of the evidence has been eradicated via the reloading of the image. Although it may be possible to use some forensic tools to try and reclaim fragments from the unallocated clusters on the hard drive, it would be difficult to associate those fragments with the event.

### **Implementing a Digital Forensic Precrime Evidence Collection Unit**

Having experienced too many of those “after-the-fact” moments, the author wished that there was some way to turn back the clock and collect the evidence before the system was reloaded. Thus, a new methodology is being developed to do just that: The “evidence” is collected before the system is reloaded. Of course, this evidence collection is just a precautionary measure, but in several incidents this technique already has yielded positive results.

As noted earlier, one of the primary cornerstones of digital forensic evidence collection is data duplication. However, using even high-speed forensic duplicators, large hard drives can take hours to duplicate and verify, a process that most users would not be willing to tolerate simply as a precautionary measure. Thus, this research has taken a different approach. Before a system is reloaded, the hard drive is replaced with a clean, wiped drive of similar specifications. The old drive is placed in a read-only USB container, and a chain-of-custody form is started. The new drive is loaded with the image, and the old drive is secured. This process only takes a few more minutes than a simple reload but provides numerous advantages:

- The process is simple and should be able to be performed by entry-level technicians with minimal training.
- Old drives can be scanned with additional tools unavailable on the original host system.
- Old drives can be subjected to tests that would take too long on the original host system.
- As new signatures are released, the old drives can be rescanned.
- Old drives are still available for data retrieval, in case the users had stored documents locally.
- Old drives should still be forensically sound and unmodified since they were collected.
- The old drive is the original evidence, not a copy. The chain of custody has preserved its integrity.
- The process provides a larger window of time in order to conduct the investigation
- After a set time frame, perhaps 90 days, drives not involved in ongoing cases could be wiped and reused.

Despite some additional costs associated with this methodology, such costs would be reasonable. They would vary, of course, with the size and type of hard drives in the organizations, the retention time frame, and how often the systems were reloaded. Yet, even 100 hard drives of 160GB would only cost approximately \$6,000 in addition to the other forensic tools and software already acquired.

This is a new methodology, and developers are still consulting with legal counsel. So far, it is believed to be legally sound, provided certain precautions are taken. This process has to become part of the standard operating procedure and has to be applied to all systems. It needs to be fairly automated and consistently performed. Once the old drives are acquired, they should all be treated the same, unless the additional scans or tests indicate otherwise. They must always be in a read-only container, and the chain of custody should be maintained. In these cases, the old drives could still be used in legal proceedings and treated the same as archival backup tapes and files, such as in the cases *Medtronic v. Michelson* (2003), *Zubulake v. UBS Warburg LLC* (2003), and *Alexander v. Federal Bureau of Investigation* (2000).

This methodology also should address the concerns stated by the National Institute of Standards and Technology (as cited in Kent et al., 2006). Kent et al. indicated that step-by-step procedures should be developed for routine tasks: “Guidelines and procedures should support the admissibility of evidence into legal proceedings, including information on gathering and handling evidence properly, preserving the integrity of tools and equipment, maintaining the chain of custody, and storing evidence appropriately” (p. ES-2).

Although employees have a Fourth Amendment right to a reasonable expectation of privacy in the workplace, that right is not absolute. Cases such as *O'Connor v. Ortega* (1987), *United States v. Simons* (1998), and *United States v. Monroe* (2000) have sided with the employer and the government. For the most part, if a technician discovers an illegal activity during the normal course of events, investigation is acceptable and admissible. However, it is important to make sure that technicians do not just start “poking around” in these hard drives looking for evidence, which would clearly violate the employee’s expectation of privacy. Before implementing any potential evidence collection methodology, organizations should review it with legal counsel.

## About the Author

BJ Gleason is a Ph.D. candidate in Information Science at Nova Southeastern University and currently working as a System Administrator for Group W, under contract to the U.S. military in Korea. Mr. Gleason has taught undergraduate computer science courses at the New Jersey Institute of Technology and The American University in Washington, DC, and is currently an Adjunct Associate Professor with the Asian Division of the University of

Maryland, University College, in Seoul. He is a Certified Computer Examiner, International Society of Forensic Computer Examiners.

# The Cognitive Basis of Systems Integration: the Eclipse of “Core” and the Emergence of Redundancy

Massimo Paoli, [massimo.paoli@fastwebnet.it](mailto:massimo.paoli@fastwebnet.it)  
Simone Poledrini, [spole@unipg.it](mailto:spole@unipg.it)  
University of Perugia, Italy

## Abstract

Over the last few years, research has developed a new theoretical framework called systems integration. To date, systems integration has been developed from different perspectives, such as theoretical, historical and managerial. However, not many contributions have dealt with the cognitive aspects of systems integrator. The aim of this article is to shed light on the cognitive aspects of systems integration. In particular, it shows that a systems integrator should retain and dominate, in-house, many knowledge bases and competences as well as a whole range of contexts. In order to do this, firstly, the article defines the key elements of the cognitive nature of systems integration and provides an epistemological reflection on both the personal and social nature of the knowledge involved in successful systems integration. Finally, it attempts to show that strategic control over the technological and commercial evolution of the value chain requires full control of the processes of systems integration.

## Introduction

The objective of this work is to offer some considerations on how the control of systems integration can really be maintained and also on how innovating it is towards more conveniently retained paths. In opposition to the predominant ideology of “core” (by now the common sense of management, especially in Europe), the basic idea is of redundancy, of knowledge basis, therefore of agents as profiles of adequate professional bearers of such knowledge, but also of contexts, “*organizational containers*”, predisposed to allow agents and their knowledge basis to be integrated in order to construct the fundamental business axis of systems integration. This fundamental axis resides in the capability of vision-construction to change and its marching direction (a change that is used as a “club” competitive strategy).

Inherent evolution and change in the integration system itself, a dynamic activity by its very nature and role, of a systems integrator, are always ready to decline in the mere assembling of parts whose technological course is suggested by others. Nowadays, although systems integration has received much attention from scholars from different perspectives, such as the theoretical one within the context of evolutionary economics (Prencipe, Davies, & Hobday, 2003), the historical one by showing the changing role of individual firms specializing in systems integration (Pavitt, 2003) or the managerial one by showing how systems integration relates to competitive advantage (Prencipe, 2003) the cognitive nature of systems integration has not been focused on enough by scholars. Therefore, the aim of this article is to shed light on the cognitive nature of systems integration.

In order to do this, section 2 provides a simple definition and the historical origin of systems integration. It identifies the main factors that characterised its initial development and explains what systems integration is today. Section 3<sup>1</sup> gives a definition of the traditional model of individual knowledge, which lies at the basis of the paradigm “efficiency without intelligence”, which is still mainly common sense. In sections 4 and 5, an attempt is made to outline an interpretation of different types of human knowledge, from whose nature other foundations descend from which to choose a “redundancy of intelligence” paradigm as opposed to an “efficiency” one, without forgetting the economic reasons for efficiency, by putting them back in the right place, which is always behind cognitive reasoning. In section 6, we try to focus again on the concept of systems integration which has been too often reduced to a mere problem of design in recent years. In section 7 we try to justify, on the basis of the principle of systems integration control, the superiority of the reasons for the “redundancy of intelligence” in those firms that

want to remain or become systems integrators. Finally, in section 8 we present our conclusions and summarize our main findings.

## **Systems Integration: an Emerging Approach within Industrial Organization**

According to Hobday et al (2003) systems integrators are those firms that leave part of their production to specialized suppliers but keep their own design and integration capabilities. In other words, the role of a systems integrator can be divided into two main aspects (Prencipe, Davies, & Hobday, 2003). On the one hand, it subcontracts part of its production to specialised suppliers: those companies supplying systems rather than just products, for example, aircraft engine manufacturers that outsource production of parts of their aircraft engine. These aircraft engine components are multifaceted and involve complex technology that needs to be produced by specialists (Prencipe, 2000). This side of systems integration is similar to a (reduced) outsourcing process in which a systems integrator manages a division of labour among a network of specialised suppliers through the value chain.

On the other hand, a systems integrator should have the capabilities and knowledge to integrate and control these systems and to develop design ability. These activities are produced in-house and so this aspect of the organization is similar to an integration process through the value chain. This is the main task of a systems integrator because it allows a systems integrator to control all the value chain. As pointed out by Brusoni et al (2001), the division of labour among firms does not mean a division of knowledge. Indeed, in the case of systems integration, knowledge is maintained and controlled by the systems integrator. Otherwise, a systems integrator would be an assembler of multi-technologies and multi-products. In other words, there is a “big” distinction between an assembler and a systems integrator. The former is able to put together different components and systems of a product, while the latter maintains the capabilities and knowledge to control all the knowledge process through the value chain and in order to introduce new product architectures.

Following the concept of architectural knowledge (Henderson & Clark, 1990), systems integration is the ability to know how to integrate and link together into a coherent whole the new technologies and components as they are produced. To do this, a systems integrator needs to know and control the steps of its value chain (Paoli, 2003). A systems integrator can be seen as a kind of industrial organization with two faces (Hobday, Davies, & Prencipe, 2005): vertical integration and outsourcing. Indeed, as Hobday et al (2005 p.1111) pointed out: “systems integration capability is not merely the counterpart to outsourcing, but the capability needed to manage outsourcing as well as “joint sourcing” and “insourcing” to enable the systems integrator firm to gain the advantages of both outsourcing and vertical integration through different phases of the product life cycle”.

Systems integration was developed for the first time by the American Military Industry, following the Second World War. Mainly, the cold war induced the production of new and sophisticated weapons that needed considerable collaboration among many firms and different subjects. Moreover, new technologies started to cross dissimilar disciplines. Both of these aspects pushed for a new kind of organization that used multidisciplinary groups of researchers and engineers to work together on systems integration. Through it, new skills and knowledge were developed in producing multi-technology and multi-component systems (Sapolsky, 2003).

Over time, engineers, physicists, and chemists joined together diverse tasks to integrate different technologies into one product. They discovered that complex products needed different competences and know-how at the same time, so they formulated a new organization based on a systems engineering-integration approach. This kind of organization was able to manage the complexity of new productions by building teams of engineers, that were composed of scholars from different firms and disciplines, while the previous organization was based on a strict division of labour inside firms and among firms as well (Johnson, 1997).

However, the breakthrough of systems integration took place when the new engineering practices were transferred from the mainly military sector to the civilian one, such as the aerospace industry where some firms were involved in both military and civilian sectors. At that stage systems integration changed from a mere engineering task to a business organization tool and various non-military industries started to adapt their organizations according to the division of labour and knowledge of systems integration, such as Texas Instruments and IBM (Sapolsky, 2003). Indeed, as Prencipe et al (2003) pointed out, systems integration has become a business activity; therefore, it

needs of managerial skills to direct those involved in the systems integration and to increase its internal capabilities of integrating and developing systems. Nowadays, systems integration has become part of the organization strategies within the world's leading corporations, such as General Electric, Dell, Ford, IBM, HP, Siemens, Nokia, Rolls-Royce and Boeing (Hobday, Prencipe, & Davies, 2003).

Indeed, broadly speaking (Kash & Rycraft, 2000), when products or systems depend, above all, on the production of different technologies and knowledge, for example, to manufacture an aircraft or a space station, firms need various different technologies and capabilities from diverse disciplines. These kinds of products are the combination of systems and each system usually requires different technologies and knowledge to be produced that can only be managed by a systems integrator. The nature of systems integration and the structure of a systems integrator greatly depend on the nature of the knowledge involved to manage the technological evolution of the system.

## **The Traditional Concept of Individual Knowledge**

The concept of knowledge - of man and within man - has long been the stable center of monumental reflections in various fields. In economy and above all in management studies, its "statute" - or in other words its contents - has never been made overly clear. Even today neoclassical economics, management and, lastly, common sense are based on a conception of individual knowledge which is essentially what was devised in the twentieth century by the epistemology of neo-positivism and logic empiricism; knowledge is made up of information, information has the same nature as knowledge, even if it is found at different hierarchical levels of the cognitive system. Therefore, a coherent togetherness of information (parts of a jigsaw, bits, etc...) forms knowledge.

In other words, it is enough to put the pieces of a mosaic (information) together and knowledge appears as a result of the sum of the pieces. All this is based on the assumption that good common sense would essentially translate to:

- reality is outside of us and is accessible, that is to say, it informs us of its sense (by observations or experiments);
- formal (language) systems, that we use to represent theories, describe reality and do so in a way that the first ones to express it do not have syntactical problems (they can be logical or complete, it is enough to be particularly accurate in elaborating them);
- there are no ambiguities in attributing meaning to theories (also when they are still hypotheses), to observations and to the languages used to describe them; therefore, there are no problems attributing common and shared meanings to theories when they become universal truths;
- from a methodological point of view, it is necessary and sufficient to follow the Aristotelian/Cartesian principles of the distribution of economy solving, or rather, it breaks up the problem, starts to resolve the smallest and easiest problems, when it may seem that it has resolved everything (or a substantial part) it reconstructs, given that to reconstruct is only the analogous opposite to deconstruct (there are no differences in the quality of the process).

In the course of the twentieth century, this explanatory paradigm, that is still the basis of good common sense prevalent also in management, was annihilated by dynamic epistemology. Bachelard (1938; 1953; 1996) has made us understand the inconsistency of the fourth point. Rebuilding is a construction of diverse meanings and it cannot be compared at all to breaking it down. Thanks to this breaking down process we will never know what we lose from the 'whole' object of decomposition, given that we break things down when we still do not know anything, while thanks to the re-adding process, re-integration itself will give the observer/re-integrator completely new motives to attribute previously unknown meanings to the whole inconceivable before (it is in any case the systematic principle that the 'whole' is more than the sum of its parts).

Duhem (1914) and Quine (1969) dissolved the third point, indicating the impossibility of giving the theory a single heading. Gödel (1931)<sup>2</sup> stripped down the second showing how formal systems are complete and how they are contradictory, or are not contradictory, but then must be incomplete. Maturana and Varela have fundamentally dismissed the first by the concepts of autopoietic system and structural coupling. Therefore, we find ourselves

forced again to reconstruct a different meaning to individual knowledge laces, a sense exceptionally rich in implications.

## Assigning Meanings and the Concept to an Autopoietic System

An important part of modern neurophysiological studies point out that individuals are *autopoietic systems* (Maturana & Varela, 1980; 1987; Varela, Maturana, & Uribe, 1974), that is, brains and bodies that can only operate thermodynamic exchanges with each other and with the environment. Brains are connected by filters that select the stimuli that the central nervous system interprets without the possibility to access reality (i.e. the environment or the world) or the other autopoietic systems (i.e. other individuals). According to this view (also labelled *structural coupling*) individuals can only exchange thermodynamic expressions like: vibrations in the air (a phenomenon perceived in a very narrow global spectrum of audible frequencies), light in different wavelengths (and also in this case a phenomenon perceived in a very narrow global spectrum of visible wavelengths), chemical particles which make up smells, pressures on the skin (i.e. pressures on our tactile receptive system under the skin).

In other words, individuals can only exchange thermodynamic impulses, supports for “languages”, and supports that we can consider hand in glove with the language<sup>3</sup> only by oversimplification. In any case pure languages (sequences of symbols ruled syntactically) are only significant, linguistic expressions, such as words, images, sounds, behaviours, in other words *information*<sup>4</sup>. Information cannot give sense, it needs sense. Knowledge is your personal system of meanings. Knowledge is the matrix that allows you: to recognize a sequence of symbols as interrelated to each other and not symbols at random, to form one or more significant transporting piece of information, to apply sense to the significant that transports information (a process depending on your capability to interpret, i.e. on all that you already know).

These significances may become Vivaldi’s Four Seasons or a troublesome noise, the strange look of an anonymous face or the beautiful smile of your son, the sumptuous bouquet of a good wine or the stench of rotten fish, according to the ‘sense’ that it is given by the single individual. It is the individual’s knowledge that gives them some meaning, and only specific meanings. Individuals produce sense even if they do not want to (they think, they know, they learn even if they do not want to); they survive because they produce sense continuously, which is not necessarily the right sense, of course. An *autopoietic system* can never know if it is right or not, because the sense created about any phenomenon it interfaces is always a hypothesis of the world and it remains forever a hypothesis, whether it is stronger or whether it is weaker. This system is continuous and greatly independent from will because it continuously serves the behaviour of men, their continuous intervention on the world. In fact, individuals always behave, even when they decide not to (even in this case we cannot thoroughly investigate the theme).

Individuals cannot share meanings because they can only “speak about them”, they can emit significance. As a consequence of this regime of exchange, *autopoietic systems* cannot measure their semantic distance or proximity and cannot communicate and share any meaning but only information (i.e. linguistic expressions) that does not carry any objective meaning *per se*. In fact, a meaning makes sense for an emitting system and sense for each of the million other systems that receive the meaning. “Red” has a meaning for the emitting individual, and millions of meanings for the millions of potential or actual receivers; thus, it can neither have “one” meaning nor a “shared” meaning. *Autopoietic systems* making up an organization, therefore, cannot share any rule or any other organisational routine or “memory”; they cannot share any actual *vision* of the *system* (product or process), because they do not share meanings. Furthermore, they cannot exchange meanings (not even about “the syntax of the rules” to share in order to form an “organization”), and they cannot exchange meanings about the distance or the proximity of their processes of convergence (if there were one) because they only produce languages, syntax and meanings in a strange spiral cycle in which the more they are aware of the uselessness of the effort to communicate something to someone, the stronger is the effort to communicate<sup>5</sup>.

We cannot thoroughly investigate the consequences on organization, but this phenomenon allows us to introduce the idea that individuals in social systems (fewer and fewer systems of men, more and more systems of contexts) do not form organizations but systems of relationships among *micro-meso-macro-contexts* (physical, socio-technical, cultural and so on). The illusion of sharing is often created in organizations by the effort to conform

to what each individual believes to be dictated by the need to co-ordinate behaviour. They are, nonetheless, *convergent* because they are originated by the same context (constructed by each participant for himself, in parallel, but together in the same context). At the most you have convergence, not sharing, and you have convergence of languages (words, behaviours and so on). It is the same process with which operational slang emerges, for example, or the dialects that are almost transformed into *common spirits*, the languages of *veterans*, the languages of *war stories* (Cohen et al., 1996). The concept of organisation implodes into its action.

The social system (ex-organization) becomes a hierarchical system of continuous "formatting" patterns of action and not a separate entity, which applies such patterns (Argyris & Schon, 1978). In this framework, the system that should be integrated is not out of you, somewhere in an objective reality. It is *in* your mind. Each individual who takes part in the systems integration process has a different system in mind and, most of all, has a different vision of its conceptual and technological dynamics. It is important not to mistake the actual sharing of significances with the convergence of linguistic behaviour. Many times, the last seems to put even some senses or values in common, but it is a pure linguistic illusion. Language convergence does not mean that you share meanings, and in particular that you share significances about a process like systems integration (and its dynamics).

The system you have produced (product or process) is not the product of *shared* meanings and it is not in an actual *common* vision. It lies in its specific design: a more or less sophisticated linguistic product. Like every other linguistic product, the design is a complicated product-artefact. Systems integration is a process and, above all, if you want to use it as a competitive weapon, it is dynamic, like the conceptual and technological evolution of the system. Therefore, it is a complex process.

## **Knowledge as a Process of Processes Involving Systems of Systems Based on Memory**

Reflection on individual knowledge needs complexity. Let us attempt to follow a logical, coherent line of thought, especially in trying to compensate for and overcome the considerable difficulties and the traps set by the limitations of any language.

A person's knowledge is a dynamic and complex system, composed of at least four other large systems:

1. the deep system of meanings which is continuously produced and tied to the self-reference of the psyche<sup>6</sup>;
2. the system of memory creation-processing-activation processes (use and production of significances);
3. the system of memory processing-activation-creation products<sup>7</sup> (from significances to linguistic expressions/perceptions and vice versa);
4. the system of relationships among 1-2-3.

When the concept of system is given the meaning of a complex unit, because it is intrinsically dynamic, relational (the system emerges from these, and is not seen as the static equivalent of its parts or of its structure) and organized (again, held together by processes), then one has a *unitas multiplex* (Angyal, 1941). Here, the foremost and fundamental complexity is created by conjugating, in a dynamic relational perspective, the idea of unity with that of diversity, multiplicity and irreducibility of its characteristic unitary "system" properties to its component parts, individuality combined with decomposability (or "quasi" decomposability). The latter, however, is obtained at the price of decomposing and transfiguring the system itself, despite the fact that such a system cannot be reduced to its component parts because the whole is more than the "sum" of its parts (Atlan, 1972; Simon, 1962; von Forester, 1962) and, conversely, the parts cannot be reduced to the system because the whole is actually less than the "sum" of its parts (Morin, 1983).

In order to grasp the nature of the complexity we are dealing with, it is indispensable to appeal to what has been termed the concept of emergence<sup>8</sup>: a phenomenon linked to the process of transforming the parts into a whole which, by this very process, forms and transforms (transforms and forms) (Le Moigne, 1990, p. 48), maintains and organizes complementary tendencies, creates diversity, forges links between and organizes antagonisms, organizes antagonism within complementarity (Lupasco, 1962, p. 332), controls organizational entropy, allows variety to spread out and repetitive order to be re-established and transformed into organizational reliability, i.e. it is the very survival capacity (Atlan, 1974) of the knowledge-system itself.

In other words, knowledge is the continuous emerging sense of things, meaning that has intrinsic value, independently of how or through what means it is created and stored. Sense is the cornerstone allowing construction of our interpretations of the reality which surrounds us, without which it would be impossible to plan and evaluate our continuous interventions in the world. But how can we be without memory?

“I don’t know – I don’t remember,” are equivalent as far as the execution of any action in this interpreted world is concerned. We certainly have many forms of memory, but today the impression that memory-knowledge is all above “sense-meaning” (emotional as well, obviously<sup>9</sup>) is clearer than ever. Memories are not files; it is a permanent action of reconstructing meanings. Bringing a memory to mind is therefore an act of “constructing” sense, with certain aspects which are completely invented, true “stopgaps” of memory activation, and not an act of mere “reproduction”. Construction of this largely depends on the meanings (or on the meaningful role) which we would now (and not then) like this memory to have. But while memories based on active contents of an explicit type depend mostly on the state of activation of the memory (it’s easier to forget), the long-term knowledge-abilities which are activated by procedural memories are almost never forgotten; on the contrary, even after a long period of non-utilization, when the activity is resumed, the ability is restored – barring some initial difficulty which is rapidly overcome – practically at the same level at which the ability was “left off.” This is true in the motor sense – simply think of riding a bicycle – as well as in the interpretive sense; just thinks of one’s ability to solve polynomials or equations, or of diplomatic mediation.

Procedural knowledge-memories (and declarative long-term memories) seem to be more important to us, and have pre-eminence over others (always from the viewpoint of survival of the autopoietic system); precisely because they make us “proactive” with respect to the environment itself, to such an extent that we sometimes believe we “control” it. Knowledge-memories either have a “sense” or they do not survive long, or are actually never even formed. If you accept all this reasoning, what are the consequences for companies that aim to control and drive the technological dynamics of their multi-tech systems’ (products/processes), or, in other words, in this regime of the nature of knowledge, how is it possible to maintain the control of systems integration?

## Systems Integration

The systems integration process is a meta-super-cognitive-negotiative-dynamic process among individuals distributed in several firms’ contexts that are composed of specific physical attributes, but also of the knowledge of the agents themselves, their linguistic interactions, their organizational rules, incentives, power distribution, beliefs, myths, cultures and so on (the constituents of the “formatting” power “in” and “of” these contexts).

Agents can construct at the same time the systems integration process of a multi-technological artefact (process or product) and as a consequence its global evolutionary path. The dynamics of the artefact-product/process-system, in fact, arises from the joined and superimposed technological trajectories of the *whole* and its *parts*. Moreover, it is the result of multidisciplinary convergence-divergence and integration-disintegration, both at the technological and scientific level. This phenomenon constitutes a further level of evolution, endowed with the remarkable *generative capacity* of: a) autonomous scientific and technological trajectories-opportunities, b) continuous reconfiguration of the dependence and influence of relationships between scientific and technological fields. Regarding the latter, it is worth highlighting that it greatly affects to a great extent the dependence and influence that relationships have among system, subsystems and parts.

In this light, the evolution of the product/process-system (and, therefore, the activity of systems integration) can be identified as a continuous destruction-reconstruction of hierarchical and functional orders which over time affect the ways of the conceptual and ideal decomposition<sup>10</sup> of the product-system itself. In this framework, systems integration is a macro-process of conceptualisation, by which several problems regarding the design of the product or the engineering of its manufacturing may emerge, but the relationship between the dynamic of the conceptualisation and the following problems of design is the same as what you can observe between knowledge and the linguistic artefacts called information. Thus, systems integration can never be reduced to a problem of design, even if it may be expressed only by design, just like knowledge that can never be reduced to information-language, even if it may only be expressed by language.

In this framework, we introduce the key distinction between the capacity of designing and producing the product-system, which is at the most *complicated*<sup>11</sup> (a product/process design completed in every aspect is only a *complicated* linguistic artefact), and the effort to master systems integration and its evolutionary dynamics which is the *complex strategic problem*<sup>12</sup>. In effect, understanding which step is best to take along the invented trajectories of parts, the trajectories of the system, the trajectories of the relationships between parts and system, the trajectories of systems integration, is actually a complex construction. At this point it may be useful to establish, with a certain degree of automatism, a corresponding classification of agents' constructions. More specifically, one finds two contrasting orders of complication/complexity for the composition of observed systems (Le Moigne, 1990, p. 27):

TABLE 1: TWO DIFFERENT ORDERS OF CONSTRUCTING (COMPLICATION/COMPLEXITY)

<i>System/Phenomenon</i>	<i>Representation</i>	<i>System/Phenomenon</i>	<i>Representation</i>
<i>Decomposable</i>	<i>Complicated</i>	<i>Indecomposable</i>	<i>Complex</i>
<i>By Disjunction</i>	<i>Application/decomposition</i>	<i>By Conjunction</i>	<i>Combination/composition</i>
<i>Decomposed</i>	<i>Simple</i>	<i>Indecomposed</i>	<i>Implex</i>

The complicated construction-model obtains by the simple view of the "fragmented" (reduced) phenomenon disjunction-decomposition. The complex construction-model obtains an implex vision (non-decomposable) of a non decomposed phenomenon by composition-combination. The former may be decomposed and the job divided (to photocopy a great number of pages, for example), the latter cannot be decomposed and it is much better if you do it by yourself (to write a paper, for example).

Any process of modelization, however much it makes use of sophisticated forms of codification and language, is an eminently and irreducibly "personal" process through which different alternative readings-interpretations of phenomena can be *created*. This means that there are no complex phenomena, but complex constructions of phenomena that have been *observed*, i.e. *created*, (*dans notre tête*). We can outline the creation process (and complexity creation) as the flow of becoming what relinquishes the idea of *analysis* of something perceptible in order to assume the idea of intentional constructive *conception* (deliberately systemic), which is in turn composed of instrumental representations of phenomena *created* and understood as complex and, therefore, indecomposable except at the risk of mutilations. Such a process consists of the transition (Le Moigne, 1990, pp. 27-28,) from the figure of the analyst to that of the conceptualizer-constructor, from the decomposable object to the conceivable project, from decomposition into simple passive elements to composition of implex actions.

Firms, as social systems composed by autopoietic systems, can deal with the problem of mastering the systems integration process (and its dynamics) only by *creating complexity* in the *constructions*<sup>13</sup> that they build and that in some ways affect the path (or, more precisely, the paths) of the product-system's change. *Constructions* are the result of hard, more or less chaotic/ruled negotiations, among agents in an organization legitimated to speak about the technological trajectories that the systems (and therefore the systems integration) potentially could assume.

For these reasons, the task of system companies is to keep redundant knowledge bases in house. It is worth underlining, however, that the judgment on the importance of the knowledge basis relies heavily on the complexity that the *system company* has been able to create in the past. But it is for greater convenience that we are using (and we shall use later on) the label "system company". In effect, we always refer to the continuous negotiation among "visions" of individuals (autopoietic systems) in the organizations of those firms, and the continuous dynamics of their knowledge basis. There are not "firm" knowledge bases; there are only knowledge bases possessed by men. The path we are referring to is the path of each of their knowledge bases and the path of the equilibrium points to which negotiations among these visions in the organizations converged over time.

This path, which is *ex-ante* uncertain and *non-definable*, is the *process* of the evolution of the artefact envisaged by the system company and selected in the marketplace. Even if the historical path of the organization and the effectiveness-efficiency achieved by the organizational mechanisms are of great importance, the latter has to be distinguished by the technical-scientific 'quality' of the individuals belonging to the organization. The knowledge basis possessed by individuals, the history of these and their organizations, find the roots to create complexity. In other words, the knowledge bases should be considered as *generators* of the complexity required to create the

evolutionary path (or paths) of the systems of systems. To create complexity means to generate a greater number of different potential *states of the world*, that is to say, technological alternatives for parts, subsystems, and the whole architecture of the system, and their relationships, for the future "n" time units, during which you imagine the evolution of the system itself.

An important part of knowledge basis consists of expertise, that is theoretical elaboration and hands-on knowledge which is heavily dependent on the *generative contexts* it refers to<sup>14</sup>. Moreover, in this framework, the distinction between knowledge related to the nature of the nature (scientific knowledge usually deriving from fundamental or long-term research) and ways of manipulating it (technologies commonly growing out of applied research and industrial development) tends to blur and, as a consequence, gives rise to unitary and global knowledge which is no longer decomposable. This process ends up being both effect and cause of the emergence of a new concept of integrated and transdisciplinary knowledge, that merges from methodologies and sociology of classic sciences, but it is triggered by applications with which the emergence of scientific-technological disciplines (*science-tech*) are associated<sup>15</sup>.

To be able to command its integration and, therefore, its evolution, it is necessary to: possess the knowledge basis regarding the subsystems, possess the knowledge basis regarding the architecture of the system which represents a separate part of the system itself, command knowledge bases regarding the interfaces among different technologies which the system's architecture anticipates.

But what does possessing the knowledge basis to be able to generate effective competence and specific 'know-how'<sup>16</sup> mean for a business? According to the definitions we have given in this paper it means that in a business-organisation there are men with profound knowledge at least in the single and fundamental scientific-technological disciplines for the forming of a knowledge basis (of the subsystems, architecture and of interfaces). Moreover, the organisation places at its disposal the contexts (laboratories, product processes, organisational machine rules, work methodologies, incentives, languages, schools, economic resources, power and dynamic distributions, paradigms, myths, beliefs, stories, etc.) necessary to be able to express such knowledge (we go from individual to multidisciplinary<sup>17</sup> task forces, an interdisciplinary<sup>18</sup> team, a stable trans-disciplinary<sup>19</sup> group).

In any case, knowledge to support the capacity of systems integration emerges from the application of all knowledge in all effective contexts (not only in R&D, but also in the production of the components and of the system, in the planning, etc.) on the basis of the re-composition that we can imagine, given the system's breakdown which is carried out in order to reconstruct. All these are activities that can clearly be described as the fruit of interactions among agents, physical systems and other people *in a specific context* (Greeno & Moore, 1993, p. 49; Vera & Simon, 1993, pp. 46-47), namely that pertaining to the specific agent. If the latter is a social system or an organization<sup>20</sup>, then the overall picture also includes the fact of its "being" history and the developmental path of its routines, of its decision-making mechanisms and the roles of the different interest or power groups and ideologies (taken as the ideal direction to which visions of the future should point) present in the organization itself<sup>21</sup>.

Thus, if you do not keep a sufficient number and variety of redundancy contexts in the firm, you drastically diminish your capability of systems integration (you are moving towards roles of assembling, not systems integration). But such capacity diminishes whenever you gain knowledge. It diminishes without anyone being aware of it. It is the metaphor of the blind man who does not know what he does not see. So, whoever loses contexts loses knowledge connected to them, and becomes less and less capable of constructing complexities in his interpretations of the integration system and, therefore, of the evolutionary dynamics of the system, but knows less than what he thinks he may know or know nothing at all. Awareness appears individually when someone who we have always beaten (perhaps at chess) finally beats us. It happens from a social point of view (perhaps playing football) when the team that has never won before finally beats us.

However how many defeats will make it necessary to become aware that it was not fate or anything else. Also, in a special way, in the case of businesses, how many signals will be wasted before someone realises that defeats are the effects of a loss of competitive ability due to a lack of knowledge, due to the loss of context, perhaps in homage to the ways of outsourcing, of making core choices, of creating a lean or flat organization. They are certainly themes that cannot be underestimated but also bases for choices with strategic consequences that cannot be underestimated either.

## The Relevant Strategic Problem: Maintaining Control of Systems Integration

Not only does knowledge tend to be represented even more in unique (transcending the classic base-applied dichotomy) and transdisciplinary (transcending the classic boundaries between disciplines) ways, but it is even more important if the *linguistic outcomes* of cognitive activities (not only R&D, but also design, production marketing and so on) are more or less appropriable in economic terms, the cognitive *processes* that may lead to processes of production of knowledge (in its articulations, bases, competences, expertise) are *always* appropriable because they are *agent-specific* and therefore firm-specific. In fact, competencies and historical paths of learning are specific to each autopoietic system forming the social group called "organization". They are linked to the evolution of organization and to the system company's specific organizational setting in terms of number, variety, redundancy of (cognitive) contexts and their constituents. The latter, in their turn, can be considered as generators of *robust* views of the world or, rather, of richer constructions of possible options in its evolution. The more the processes have completely been internalized over time, the deeper those possible options are rooted.

Bearing these things in mind, we can apply this summarizing scheme to a systems integration 'cognitive' strategy that we can put forward as an exemplary case:

- Given a product/process-system or its family;
- Its systems integration evolutionary dynamics, conceived as an ability to introduce innovations (to be measured not only in quantitative terms, incremental or radical, but also in qualitative terms, modular, interface, architectural, systemic) and, therefore, as a capacity to compete through and by means of innovation, can be described with complex models<sup>22</sup>. These models are *specific* to those particular individuals and through organizational specifications of those particular groups in specific organizational contexts in which those particular individuals are working;
- The degree of complexity of those constructions is a function of processes of relevant knowledge which are absolutely tacit in nature. Moreover, complexity depends on specific situations: (1) of the *two way (circular)* relationships among scientific (and its state, namely descriptive, predictable, etc.), technological, applied, and integrated knowledge (Reismann, 1992, p. 110), and (2) of elaboration of experience (all contained in contexts);
- In any case, regarding the system companies' abandoning support to cognitive processes and context activities (R&D for example, but also manufacturing of components and subsystems) and shifting towards a general assembling organization means losing the capacity of modelling the possible evolution of the systems integration. Put differently, this leads to the often irreversible loss of the ability to create complexity in modelling the evolutionary path of the system and, as a result, to the loss of strategic control of the evolution of its integration. The actual risk is that you could lose the role of systems integrator<sup>23</sup>, becoming a simple assembler without you realizing it<sup>24</sup>.

Naturally, other considerations, predominantly economic or strategic, may, in any case, lead to the adoption of different or alternative solutions concerning structure, level and nature of vertical integration and/or of the various possible internalizations. But from the point of view of experience-expertise and of the knowledge necessary for strategic dominion over evolution of the artefact-systems integration, it may prove to be extremely dangerous to entertain the illusion that the cognitive results (of R&D for example) can systematically be purchased-transferred (which would mean disregarding the fact that the underlying processes cannot be bought-transferred), just as it would be equally risky to believe that the division of innovative labour and of labour in general, together with the sale or transfer of innovative activity and manufacturing techniques (above all if accompanied by abandonment of research and design efforts) need not be systematically considered as *the surrender of cognitive processes, a transfer of generative contexts*<sup>25</sup>, *jeopardizing world-creating ability*. Failure to realize this peril would inevitably result in diminished capacity for the "imagination-creation" of alternative paths of opportunity. The costs and strategic implications of such transfers (or more generally, of non-possession, even if seen in a networking context) should always be evaluated in and by the decentralizing decision-making processes in such a way as to mitigate the weight of "economicistic" evaluations and, thereby, extenuate the idea that networking to the point of virtualizing systems integration is also systematically virtuous (Paoli & Prencipe, 1999).

The ability to retain institutional continuity depends primarily on learning from experience, in cumulated expertise and capacity to integrate of diverse knowledge bases<sup>26</sup>. Such ingredients make it possible to engage in strategic elaboration in order to overcome the distinction between content-process and context of strategic elaboration itself (Dodgson, 1989, pp. 1-10). This is because learning about the context defines the content of innovative strategic behaviour, while implementation of the latter, with the ensuing learning, redefines, or rather, re-creates a new context, thereby blurring the demarcation between the definition of the content of technological strategy and its implementation<sup>27</sup>. Without experience there can be no learning (non decomposable and therefore non-sharable unitary processes), and without learning there is a failure or, at the very least, a decrease in the capacity-ability to continually re-create the spectrum of exploitable opportunities along the path that is continually being re-created. Such a spectrum must possess the breadth required by current competition conditions, or required by the strategic position the firm has assigned itself in a more or less illusory fashion. This means that it could, in fact, be pointless for a firm to specifically adopt a strategic position of being offensive, defensive, leader or follower, broad or narrow front (Harris, Mowery, & Pavitt, 1990, p. 24), because this will, to a large extent, depend on the nature and level of integrated-accumulated knowledge bases and competences (Dodgson, 1989, p. 4) (held in common, not sharable in a network) which, taken together in specific but adequate contexts (in-house), endow a firm with greater - or lesser - capacity to maintain the control and direction of systems integration, to create technological and market opportunities for subsequent exploitation, as compared to its competitors, and enable the firm to be more - or less, as the case may be - dynamic, broader or narrower in its spectrum (different technologies, different scientific fields, integration of technologies and spectrum, etc.).

## Conclusion

We have argued that in complex products and systems and other high-technology goods, systems integrators control the dynamic trend of technological trajectories of multi-component and multi-technology goods. Moreover, the role of a systems integrator is to manage the control of trajectories of systems integration itself. Therefore, a systems integrator differs from an assembler, because the latter is not able to control the dynamics behind systems integration throughout the entire value stream.

In addition, we proposed that at the base of systems integration capabilities there is an emerging view of knowledge as redundancy of intelligence. This concept underlines the role and importance of *structural coupling* in understanding the role of systems integrator and organizational context as containers that allow agents to produce their knowledge. In other words, systems integration is the capability of constructing visions of technological trajectories within a value stream of critical components, parts and subsystems.

The concept of redundancy of intelligence is based on a vision of knowledge that is different from the traditional one. Basically, as we imagined, the latter considers knowledge and information to be similar and it does not take into account the importance of context in developing the knowledge of each agent, while the former perceives individuals as bearers of knowledge and organizational contexts as the “place” where agents develop their knowledge.

## End Notes

- <sup>1</sup> All these considerations are more developed in Part I of Paoli (2006).
- <sup>2</sup> See Nagel and Newman (1992, p.93).
- <sup>3</sup> In this chapter we do not have the opportunity to develop this problematic level of the relationship between supports and languages.
- <sup>4</sup> In this framework, knowledge does not have the same nature as information. The first is pure sense and it cannot be shared, the second is language, syntax, information carried by meanings without any objective sense, vehicles that transport symbols (in any form) to which the emitting subject has applied a meaning, and to which each of the receivers will apply his subjective meaning (too many senses = no sense).
- <sup>5</sup> We converge on Weick's idea according to which organizations do not exist, but there is only the effort to organize.
- <sup>6</sup> The sense of things with "us" at the centre (from the moment in which we are conscious we are naturally at the centre of our respective universes) (Gregory, 1991, Arduini, 1998).
- <sup>7</sup> In our opinion even behaviour is a linguistic product.
- <sup>8</sup> Emergence is a quality, a property, a product (of the organization in a system), globality (since it cannot be dissociated from the systemic unit), an event (it arises discontinuously once the system has been formed), a novelty (in respect of the parts), irreducibility (cannot be decomposed without the risk of its own decomposition which, as in system decomposition, is also transformation into something else), indeducibility (cannot be deduced from the quality-functions of the parts) and finally implexity. (Morin, 1983, p. 139-143, Le Moigne, 1990, p. 48, Churchland & Sejnowski, 1992, p. 13).
- <sup>9</sup> Who knows why we've removed emotion from the processes of knowledge production, as if a scientist, an engineer or a technician learned without emotions. It has become certain on the other hand that the most effective learning takes place when emotions are involved. Do you remember how easy it was to "do well" in the subject taught by a friendly, enthusiastic professor?

10 Decomposition is conceived here as *modelling*: «Action d'élaboration et de construction intentionnelle, par composition de symboles (to which we add also non-symbolic schemes), de modèles susceptibles de rendre intelligible un phénomène perçu complexe, et d'amplifier le raisonnement de l'acteur projetant une intervention délibérée au sein du phénomène; raisonnement visant notamment à anticiper le conséquences de ces projets d'action possibles» that in the system dynamics is *modeling* of a complexity for which it is true the distinction: «Pour comprendre (donner du sens à) un système compliqué on peut le simplifier - pour découvrir son intelligibilité (explication). Pour comprendre un système complexe on détruit a priori son intelligibilité» (Le Moigne, 1990).

11 And, therefore, conceived, designed and defined.

12 And, therefore, non-definable, uncertain and undefined.

13 In this chapter the notions of Program and Representation (only indirectly considered) do not have the common meanings of cognitivism; here they always mean “*construction*”.

14 The notion of context is extremely important in this paper. A famous definition can clarify its nature: «...context as collective locus for all the events that indicate to the organism-agent the set of options within which the latter must do further choice. » (Bateson, 1976). The nature of the context is somehow generative of the learning. Losing or abandoning a context entails losing its cognitive generative capacity.

15 *Transfer sciences* are disciplines where the knowledge on the nature of the nature and on the ways of manipulating it is blended indivisibly.

16 Without knowledge basis you cannot aspire to the systems integration, competences are not sufficient, and vice versa.

17 We have the multidisciplinary attitude when we are called to work, according to our own knowledge basis in a specific area of a task with a spirit that we could define as ‘advising’, in fact everyone is responsible on their behalf while there is normally a ‘command centre’ that integrates everyone’s work and responsibility.

18 We have the interdisciplinary attitude even if bringing our own specific knowledge, everyone’s work is however to occupy yourself with the entire task, including the integration that is anticipated in this operative order as a collective operation undergone by all the participants. Everyone is responsible for the task. This set up generally allows disciplinary fusions.

19 The transdisciplinary attitude not only uses permanent work structures, but it also nourishes disciplinary fusions to give life to knowledge bearers which are not reduced to discipline anymore. For example, in a multidisciplinary order a problem of fluid-dynamics can be faced by statistics, physics, chemicals, mathematics, etc. In a transdisciplinary order that has a history of interdisciplinarity before and transdisciplinarity after, the work group will be constituted only by fluid-dynamics.

20 It is important to note that even as far as scientific knowledge is concerned the idea of the disembodied scientist or the organization is oversimplified.

21 «...knowledge is about meaning. It is context specific and relational. », (Nonaka & Takeuchi, 1995, p. 58).

22 The lower the complexity of the representations, the more the loss of competitive capacity through innovation.

23 A systems integrator is whoever decides which evolutionary trajectory the system takes.

24 With regard to this phenomenon it seems very representative the dynamics of the evolution of technology and in parallel of the roles among assemblers (almost all ex-systems integrators) and componentists in the automotive sector.

25 The abandonment of an excessively “mentalistic” approach to competence has led to an absolute enhancement of the context as a co-generator of context. The so-called *activity theory* (and the *multiple intelligence theory*) defines activities as syntheses of mental and behavioral processes, but it does not reduce them to mere mental or behavioral phenomena. They are analysis units within which the agents’ competence can be assessed in socially organized contexts. The object of the analysis is the interaction process of the agents themselves with the reference environment. The analysis unit is therefore practical action which incorporates (it activates, one might say) the environment-context (which, therefore, is defined, in this work, as *generative*). There is no learning without context. That is to say, there cannot be a learning dissociated from the context in which the practical action-activity will produce it (Vigotsky, 1978,

Leontieff, 1981, pp. 37-71, Gardner, 1983). « In order to explain the march of the blind [and naturally explain his learning], then the road, the stick and man are required; road, stick and man and so forth, recursively » (Bateson, 1976, p. 470).

In this regard, it can be likened to the concept of *formative contexts*: each business routine refers to a formative context from which it receives meaning and which makes it “natural” or “plausible” (Lanzara, 1993, p. 38).

On this issue, see also Unger (1987) and Ciborra and Lanzara (1988).

26

«Whatever the source of technological breakthrough, it is company wide-ranging R&D expertise that are more likely to recognize (to create) the significance and potential of both incremental and radical technological developments, Broad R&D competences and skills are a method of dealing with discontinuities turbulence; a way of technology watching and keeping options open.» (Dodgson, 1989, pp. 4-5).

27

Implementation of strategic technology is therefore an integral part of its definition.

# Subjectivity and Cognition: An Explorative Review on an Inherent Problem of Knowledge Management

*Martin Rahe, mrahe@eada.edu  
EADA, Spain*

## Abstract

Knowledge has become the most important production factor in the companies, since value creation is considered being the key element for sustainable advantage. Knowledge results from cognitive processes which are influenced by stereotyping, awareness, motivation and the external environment. These factors create a multitude of different perceptions, interpretations and understandings between individuals in general and between individuals of different cultures in particular. The present paper discusses the impact of subjectivity in knowledge management by analysing the influencing factors on knowledge creation. Different mind sets and mental models increase the probability of misunderstanding and also the effectiveness of knowledge management. Apart from knowledge creation, the transmission of knowledge is damaged when communication is codified and standardized. Finally, knowledge management is far from being management of objective truth. The paper highlights theoretically on management slacks in knowledge management and, in doing so, indicating areas of inefficiency in knowledge management.

## Introduction

In 2005, UNESCO stated that diversity is in danger. Instead of maintaining cultural differences, globalisation tends to homogenize cultures and promotes the disappearance of regional knowledge and languages. Especially threatened are small and geographically localised cultural identity groups or cultures without enough global presence. Often, these groups possess local or indigenous knowledge that has evolved over generations and persists in people's minds thus becoming the general knowledge of the society. As cultures become extinct, knowledge disappears and as a consequence so does the variety of culturally different mind sets.

The run for innovation through technological progress and research reinforces the supremacy of technological and scientific knowledge and weakens traditional elements of knowledge. If this kind of knowledge (spiritual, emotional, etc.) and along with it local languages as transmitters of knowledge are lost, then the idea of cultural diversity will be seriously undermined. UNESCO identifies a “great divide” between technological and scientific knowledge on the one hand and traditional, indigenous knowledge on the other, and it puts an emphasis on the fact that the loss of knowledge and language always entails a loss of cultural identity and vice versa.

Advances in information and communication technologies such as computer-supported cooperative work systems, groupware, internet and intranet prove that technologically the management of knowledge is no longer a critical issue. The ongoing challenge concerns the content of knowledge itself. Diversity among cultures creates a multitude of different perceptions, interpretations and reflections, which affect individual cognition. This may end up making mutual understanding and communication more difficult and consequently knowledge management as well. In order to overcome such obstacles, which have evolved especially as a result of globalization, the knowledge society has developed communication standards which are used worldwide. As a result, some knowledge becomes codified and common sense while other types of knowledge remain invisible and could eventually disappear. What we now see is an upcoming global-local dialectic arising from the tension between local knowledge production and its use in the global environment. The impact for knowledge management is twofold; on the one hand, we may lose knowledge which is crucial for sustainable management. The saying “think global, act local” neglects the fact that local thinking may become an important skill and a competitive advantage for companies due to a better understanding of local particularities. The American company Monsanto serves as an example of how insufficient knowledge and adaptation to European culture hindered their entrance into the European transgenic food market. On the other hand, communication suffers when people lose their native language and express themselves in a foreign one. Technically speaking, the transmission of codified “hard” content into a foreign language may work, but it

becomes difficult when we transmit “weak” emotions and feelings. UNESCO is very much aware of this problem and defends multilingualism as a way of maintaining the diversity of languages and of knowledge.

The disappearance of local knowledge and local languages affects the continuity of local cultures because it eliminates part of their cultural heritage. From the point of view of foreign companies a reduction in knowledge and language diversity reduces transaction costs but increases the risk of misunderstanding and not connecting to the local market.

This study aims to discuss the factors which influence understanding and transform objective information or signals into subjective knowledge. The first assumption is that knowledge results from a process which is influenced by three relevant factors: the contextual environment, individual cognition and communication. Due to its role as a subjectivity filter, individual cognition denies the creation of objective knowledge. In this sense, knowledge management is an attempt to deal with a disparate bundle of mental models, trying to codify and transmit subjective knowledge. The second assumption is that knowledge diversity negatively affects the effectiveness of knowledge management because it involves different understandings and interpretations.

After a brief overview of research developments in knowledge management, chapter 3 goes on to look at stereotype thinking, awareness and rationality as relevant factors which affect the internal process of cognition (the inner dimension). Chapter 4 focuses on the external environment, which influences knowledge creation through the existence of institutions and values. In knowledge management, knowledge sharing is a complementary component to the creation of knowledge. Chapter 5 then comments on communication and its importance for the quality of knowledge. The theoretical analysis finishes off with some reflections concerning findings that are relevant to knowledge management. The final chapter focuses on the American multinational company Monsanto as a practical example which highlights certain aspects that were dealt with previously in the theoretical discussion.

Methodologically speaking, this paper is based on a review of the literature in the field of behavioural economics and where it overlaps with economics and psychology. The term “diversity” is used in its broadest sense as an expression for being different and refers to different mind maps due to individual cognitive processes and the influences of the environment. This research aims to stimulate and contribute to the debate around knowledge management and wishes to open the way for further research.

## **Traditional Concepts of Knowledge Management**

Since the advent of globalization and the necessity of companies to boost value creation, knowledge has proved to be the major source of sustainable competitive advantage. An overview of the research on knowledge shows that most studies emphasize the organisational dimension, focusing on the creation, administration and dissemination of knowledge. Different theoretical currents are concerned with the organisational perspective and these can be classified into three groups: a) organizational learning theory, b) resource based theory of the firm, and c) knowledge creation theory. All these approaches have in common that they place special emphasis on the importance of managing knowledge. The primary objective of knowledge management has been first of all, to increase the effectiveness of human capital through knowledge sharing and knowledge synergies and secondly, to improve organisational flexibility towards change and innovation. Polanyi as well as Nonaka and Takeuchi strongly emphasize the distinction between tacit (weak) and explicit (hard) knowledge. Explicit knowledge can easily be codified and transmitted through formal and systematic processes which are provided by different IT-tools. This knowledge is technical and represents a quasi-public good, which means that users of this knowledge can hardly be excluded. Therefore, for companies the problem is finding ways to get the maximum benefit out of published knowledge. Legal restraints such as patents and intellectual property rights are attempts to internalize profits ensuing from explicit knowledge. In contrast, tacit knowledge is personal and has a cognitive component that intervenes in perception and learning. This knowledge belongs to specific contexts and, therefore, to specific communities or identity groups. A proper understanding of tacit knowledge requires contextual expertise.

Given the increasing importance of the knowledge resource, concepts and models have been developed, which try to measure and balance organisational competencies. A frequently cited example of successful KM is the Swedish company Skandia. Already in 1993, Leif Edvinsson divided the company's intellectual capital into three

segments: organisational capital, customer capital and human capital and identified its value in relation to five key areas of success: Finance, customers, process, innovation and human resources. Similar to the Skandia Navigator, the Balanced Scorecard follows the same idea of analysing corporate vision, strategy and performance from the different perspectives of finance, customer relations, internal processes and learning and growth. Critical success factors are defined for each specific area and are used as a basis for constructing performance indicators. Considering the impact of group dynamics on knowledge flows, communities of practice place emphasis on the creation of focus groups for problem solving. The concept of a community of practice refers to the process of social learning that occurs when people who share a common interest in a certain matter or problem collaborate over an extended period of time to share ideas, find solutions, and build innovations. A more holistic model of KM has been developed by CIDEM, the Centre of Corporate Innovation and Development in Catalonia, Spain. The model relates different components of organisation, culture and strategic vision, people, technology and processes with KM. Within the academic field, Riverola developed a model which demonstrates how corporate learning and problem solving work together. Finally, Zahra and George studied how knowledge and learning potentials help companies to maintain their strategic flexibility.

All these concepts have one thing in common. They all focus on the effectiveness of KM at the organisational level but without taking into account individual knowledge creation within different contexts. While research on cross-cultural management reflects visible, action based individual performance related to different cultural environments, research on knowledge does not raise questions concerning diversity. Nevertheless, if knowledge is regarded as a crucial asset, knowledge management must also take into account different contexts and their influence on the way individuals produce, exchange and modify their knowledge.

## **Diversity in Cognitive Processing**

In the Literature, knowledge is defined as the result of a process which combines ideas, rules, procedures and information. The outcome of this process is based on reasoning and understanding and therefore made by the mind, whereby the process itself reflects information through experience, learning or introspection. Mind made mental models involve “a homomorphic mapping from one domain to another, resulting in an "imperfect" representation of the thing being modelled.” If we acknowledge that imperfectness is an inherent element of mental modelling, then cognitive processes are not only highly subjective but also incomplete reflectors of reality. This means that every effort to manage organisational knowledge takes place under the restrictions of subjectivity and incompleteness. This becomes particularly important when team performance is required. The fact that cognitive processes are carried out independently by each individual based on their experience, expectations, etc. means that team performance will suffer when there is no overlap between different mental models. The opposite also holds true. Team performance is optimal when there is a complete overlap of mental models. In such a situation, communication and coordination within the group becomes easier due to fewer misunderstandings and misinterpretations. But as Banks & Millward point out, a high match of individual mental models within a team leads to inefficient duplication of knowledge and to a reduction of communication. Instead of increasing team performance through knowledge synergies, team output is hindered by knowledge parallels. Hansen studied the effectiveness of knowledge sharing among the different business units of a company and considered connectivity at the knowledge creation level, which means different but connected, and at the infrastructure level, which requires formalized linkages among the business units as crucial conditions. Both can be supported by task-specific knowledge networks. Banks & Millward put forward arguments along the same lines and state that team performance achieves better results when mental models are different but connected in such a way that knowledge is able to flow between the team members. As an essential prerequisite for understanding, the connected team members should partially share their mental models. This means that each member has their own individual knowledge zone except for a part which overlaps with the knowledge zones of the other partners in the team. This overlapping area assures communication and understanding.

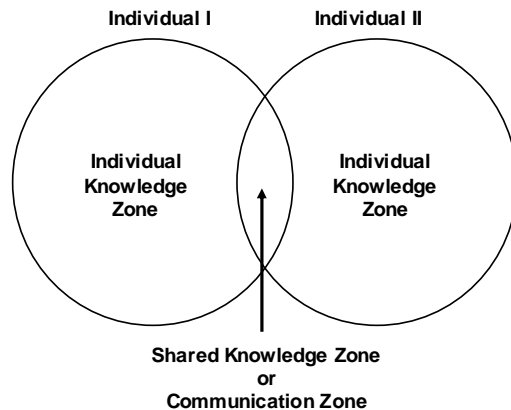

FIG. 1: KNOWLEDGE SHARING BETWEEN DIFFERENT INDIVIDUAL MINDSETS

## Knowledge Management and Knowledge Creation

Reducing complexity, mental processes are structured in semantic networks on different levels. Spiridonov makes the distinction between two different “worlds” which affect individual thinking and problem solving. The premium world is the complex intellectual potential of an individual which enables a person to reflect on problems. Existing knowledge is supported by memory content and involves associations, functional meanings of objects, images, etc. Knowledge is structured through combinations of factors (high order variables) that carry information about stable or regular relationships and determine the features of problem solving. According to Spiridonov the second world of cognition is the conceived world, which repackages complex and diverse content into comfortable units that are clearly structured and easy to work with. The conceived world aims at reducing mental complexity by ignoring ambiguous, contradictory or incomprehensible constructions. Learning processes are channelled through hierarchical mental structures and all recalled knowledge units (from memory) have to pass through these knowledge channels. With cognitive structures such as these, inflexibility concerning the unknown becomes the rule. Ignorance of knowledge elements which are not connected with the existing mental structure supports mental stability on the one hand, but also encourages stereotype thinking.

### Stereotype Thinking

In his book *The Sensory Order*, Hayek outlined the strong interdependence between cognition and environment and explained its limiting influence on intellectual endeavour. The merit of this work is that it draws a connection between mental structures and the external framework of culture and institutions and in doing so it is a precursor of the economic theory of institutions, which explains rational decision making and human behaviour in the light of the surrounding environment. Following Hayek, we come to the conclusion that within the symbiotic relationship between mind and culture, culture is an influential factor for stereotyping. This conclusion is in line with the existence of mental structures as discussed above and what Bruner has termed the phenomenon of readiness of categories. A different view to that of Hayek is put forward by Donald, whose standpoint is that the form of the individual mind constrains the type of culture that any given species will produce. Culture, institutions and environment may have an influence on thinking but do not condition human cognition. Our ability to disconnect thinking from the environment differentiates human beings from animals. Donald argues that animals access their

memory, or perhaps better, recall their instinct, in certain situations that occur in their environment. Animals react when they are confronted with something whereas human beings are able to voluntarily access their memory independently of the environment. An example which illustrates this difference is that of an animal moving through a forest, where its behaviour is determined by the external environment. In contrast, humans can move through the forest, thinking about something totally unrelated to the environment. The discussion shows that cognitive processes and the creation of knowledge are influenced by the environment, but that our thinking is not completely determined by it. Environments create mental stereotypes, but these stereotypes can be recalled in any situation. The mental inflexibility created by stereotype thinking can be somehow compensated through flexible access to memory (auto cuing). This discussion leads to the conclusion that a conversation between two individuals with different mental structures may end up in misunderstanding because of different ways of thinking and different knowledge bases. In order to improve the communication, a third person with sufficient capacity to mediate between these two individuals needs to intervene. If stereotype thinking is based on culture, this third person must be someone with cultural experience from both environments and the ability to mediate between both. Due to auto cuing, the mediator is able to access at least one part of his/her memory that is not related to the present environment.

#### **Awareness**

Cognitive processes, even if influenced by the surrounding culture, are a highly subjective matter. In his theoretical study, Bonanno analyses the role of information and belief for mental awareness and extends the discussion about cognition to non rational components. Bonanno defines information as objective signals from the environment which forms the basis for knowledge production. Taking a simple example from literature, Bonanno shows that the awareness and interpretation of signals may vary entirely from one individual to another and that the creation of knowledge may therefore differ, even if both individuals share the same information (signals). In Conan Doyle's novel *Silver Blaze* a horse was stolen from the stable and footprints were discovered on the ground. Sherlock Holmes remarked that it was very strange that the dog did not bark at night. His counterpart replied that the dog did nothing at night-time and Holmes insisted that this was very strange. This example gives us an idea of how far the same signal - the dog that did not bark - is subject to very different evaluations, interpretations and therefore awareness. Karp describes this subjective awareness as consciousness, which he defines as the individual's ability to perceive the relationship between oneself and one's environment. Even if cognitive processes are based on rational logic or reasoning and even if signals are objective, the resulting knowledge may be very different. Hence, reality has two different outlooks, on the one hand the objective exterior dimension which is made up of signals and information, and on the other hand the subjective interior dimension, which is the outcome of cognition and reasoning. The conclusion here is that reality transmitted from one individual to another is automatically manipulated by the individual's inner reality. In order to obtain true facts we need to identify the interior dimension of reality.

But knowledge is not only about rationality, logic and reasoning but also about beliefs. This irrational component has its origin in information as well, "but (beliefs) are not fully justifiable on the basis of it." Additional components are intuition, guessing or something else that cannot be explained by rationality and these components are often rooted in cultural tradition and rituals. Meindl, Stubbart and Porac stress the importance of rational and irrational components in knowledge building processes and therefore in judgement and decision-making.

#### **Motivation**

In liberal economics the principle of rationality refers to behaviour that is oriented towards individual benefits. From the point of view of methodological individualism, rationalism results from a subjective perspective of the environment which takes into account the individual's preference structure. Following the paradigm of rational choice theory, knowledge creation depends on the individual cost of information gathering and the expected benefit from the use of information. This approach does not analyse cognitive structures but connects knowledge about the environment with decision-making and therefore with behaviour.

Under the premise of rationalism, it is not convenient for the individual to maximise information gathering. Although necessary for decision making, the cost-benefit rule suggests that we should search for information until the marginal cost reaches the marginal benefit from information gathering. Converting information into knowledge creates additional costs because of the time taken up by the cognitive process. As regards the cost side, routine and experience are factors that reduce costs due to the learning effects from earlier processes. Rational information

behaviour theory reaches the conclusion that the individual is already satisfied with their limited view of the whole picture, which in turn implies that ignorance of surrounding information is an important skill for rational behaviour.

In psychology, this behaviour had already been investigated by Tversky, who explained in his “elimination-by-aspect” approach that individuals quite schematically follow a subjectively defined standard of preferences and desires, and squib all alternatives which do not match in a concrete situation. As early as five decades ago, Thibaut/Kelley, Simon as well as Cyert/March presented arguments along the same lines saying that individuals seek out rank happiness, which means that satisfaction is not an absolute value, but relative. They found that individuals feel good or bad when they compare themselves with others. In addition to that, Selten focussed on the capacity of individuals to adjust their expectations once they recognise that their original expectations cannot be achieved. The conclusion is that rationality in the cognitive process is based on the individual's perception of expectations and consequences and that it is therefore future oriented.

## **Knowledge Management and Values**

Values build the normative structure which orientates people in decision making situations. In this sense, values have an impact on cognitive category building as mentioned by Hayek and in doing so they also influence learning processes. From this perspective, learning is an instituted process of interpretation and evaluation, which applies existing and creates new cognitive frames. Within the wide range of values, some values can be rationally explained through reasoning while others are rationally inexplicable and create beliefs and myths. Rational, logic based values like humanity and irrational, emotional values like Christianity converge into the orientation system for individual activity. Generally accepted and shared values in society increase the transparency of behaviour because there is a clear distinction between normatively correct and incorrect behaviour.

Bush defines values based on rationality, reasoning and consciousness as instrumental values. These are established in order to solve problems and to contribute to the progress of society. One example is a country's constitution, which represents the society's commitment towards humanity, the community, etc. and which is a normative compass that enables the society to distinguish between tolerated and penalized behaviour. In contrast, societies also generate values unconsciously, which evolve over time. These values are transmitted from generation to generation and their justification is based on tradition, rituals, beliefs, etc. According to Bush, these are ceremonial values, which are characterized by conservatism and prudence towards change.

The relationship between instrumental and ceremonial values is contradictory if ceremonial values obstruct progress founded on scientific and technological reasoning but it can also be complementary in cases where scientific research manages to explain the formerly unexplained and, in doing so, turns ceremonial values into instrumental ones. Similarly, the relationship between these two types of values is complementary when the outcome of scientific or technological progress becomes tradition and is converted into common sense. It is evident that the maintenance and renewal of values are two driving forces and that society advances due to the creation of new applicable knowledge. A society's conservatism towards change is a manifestation of the predominance of ceremonial values. Progress on the other hand is a result of the cognitive potential to convert information and signals into knowledge. According to North, progress always entails a loss of traditional and therefore of ceremonial values. The logical conclusion is that the management of people always entails the management of competitive or complementary value systems. This is particularly important for multinational companies in high value societies such as Islamic or Christian societies or under high value regimes such as Marxism or National Socialism.

In economic theory, institutional economists like North regard generally accepted values as normative institutions which are established formally (instrumental values) or informally (ceremonial values). From the point of view of institutional economics, institutions direct behaviour by means of social commitments and increase the predictiveness of individual activity by setting up routines and reducing uncertainty. According to Rutherford “an institution is a regularity of behaviour or a rule that is generally accepted by members of a social group, that specifies behaviour in a specific situation, and that is either self-policed or policed by an external authority.” The efficiency of institutions can be measured by how far they reduce the cost of social life through rule setting. Normative institutions, either formal (instrumental values) or informal (ceremonial values), need to be cognitively

implemented in order to become a parameter for individual behaviour. Rituals and belief, informal constraints, embodied in interpersonal ties, play an important role in people's relations, especially in societies with a weak formal setting of institutions or a strong influence of tradition.

## **Knowledge Management and Communication**

The Austrian writer and journalist Karl Kraus fought all his life against the simplification and misuse of language. Born in 1874, he devoted his efforts to elucidating the interconnection between language and thinking. According to Kraus, rather than a mere tool for transmitting pre-prepared opinions, language is a medium of thinking and critical reflection. Language verbally embodies what is thought and makes cognitive processes explicit. Kraus was convinced that people speak the way they think. The deterioration of linguistic capacity is a consequence of the simplification of thinking. This means, in a positive sense, that elaborate language proficiency helps one to express oneself in such a way that complex content can be transmitted without losing information.

This capacity is especially important in knowledge sharing processes, where diverse mindsets are required to exchange expertise and where complex cognitive patterns need to be verbalized. In such a situation the quality of knowledge management largely depends on the quality of communication. Codified communication in international business, for example the worldwide use of the English language as a vehicle for the exchange of information and data, runs the risk that communication is imperfect and of low quality in the case of non-native speakers. A foreign language that is learnt through schematic techniques will not enable a foreigner to understand all the sentimental and emotional patterns conveyed by the language and which have evolved over thousands of years, influenced by history and culture. In situations where the correct use of language is important, tools are applied in order to ensure the quality of information transfer. International comparative studies for example, which are based on empirical data research often use the back translation technique to make sure that the wording of questions has the same meaning in different languages. If this were not the case, data from different countries could hardly be compared and information would be lost along the way.

But communication is not only a matter of verbal expression, but also of visual images. Gesture is a form of visual behaviour which supports verbal messages and, in doing so, adds importance to them. The dialectic relationship between verbal and visual representation is processed in the mind and forms people's understanding. In the arts, visuality through images is of particular importance for transmitting messages without using words. The Canadian artist Geneviève Cadieux in his object "Hear With Your Eyes" vividly describes the impossibility of verbal communication in certain emotional states. For proper understanding to take place, observation and interpretation of gestures are crucial in order to compensate for the lack of verbal communication. Reading facial expressions, exaggerated expressions or ritualizing small things may often become a necessary skill in intercultural communication. The artist Gary Hill from California focuses on the phenomenon of understanding. In his work "Remarks on colour", his young daughter Anastasia reads Ludwig Wittgenstein aloud without understanding the contents of what she is reading. The girl tries to pronounce the philosopher's complex words correctly and to use the right intonation in reciting the phrases. Nevertheless, she does not always succeed and the text's meaning gets lost. Gary Hill's work highlights the difficulties of understanding and making sure that one is being understood.

The issue of understanding is also raised by Martin Gannon, whose book "Understanding Global Cultures" presents a metaphorical analysis of 17 countries from all the continents. In contrast to other cultural studies such as those of Hofstede, his interest is not centred on items and scales which measure cultural differences. His approach is based on observation, cultural particularities and metaphors that are linked with a country's image. Instead of empirical objectivism, what he delivers is a subjective view on culture. For Gannon there are several culture-creating factors such as religion, language, geographical proximity, the educational system, socialization, the form of government, history, social class structures and the rate of technological change, but he considers the use of a common language as probably the key integrating factor. Sharing a common language helps people to feel comfortable, define in-groups and out-groups and communicate both thoughts and emotions. The opera as a metaphor for explaining Italian culture points to the importance of language and voice in Italian social life. The subtle use of word endings and inflections in the Japanese language distinguish insider from outsider status and a

person's relative status in society. The Belgium conflict between the French and Flemish languages relates directly to the controlled and balanced behaviour that Belgians manifest in everyday life. According to Gannon, these are only three examples of what is probably a long list of examples which could demonstrate the importance of language as a culture-forming mechanism. Coming back to Karl Kraus, his assumption about the link between speaking and thinking is very interesting when we consider that some words in certain cultures do not exist in other cultures. The word "privacy" has no appropriate translation in Italian. Similarly, it is difficult to find a correct translation for "cosiness" in the Spanish language. According to Kraus, this shows the relatively minor importance that a culture gives to certain aspects of living.

## **Consequences for Knowledge Management**

By way of summing up the above discussion, the management of knowledge involves highly subjective factors in knowledge production as well as in knowledge transfer. These factors belong to processes, which are either internal, within the individual's mind when processing information or external, when communicating knowledge to others. It is evident therefore that knowledge management is much more than simple data mining. In fact, it is a complex task of managing people's knowledge related individuality. The obstacle is that knowledge is created through internal processes which are not transparent to others. As a consequence, what is probably the most important part of knowledge management, knowledge content, eludes management. The challenge for knowledge managers is to deal with parameters that are not controlled by the management.

As we mentioned previously, the parameters are divided into two dimensions whereby one segment refers to the cognitive dimension and the other to the communication dimension. With regard to the cognitive impact on knowledge, three parameters bear an influence on the inner dimension of knowledge creation.

- Categorization and auto cuing are both aspects that describe one's ability to select information in such a way that situations become less complex. The ability to ignore (categorization) and abstract from reality (auto cuing) are tools of complexity reduction through simplified selective perception. This means that any knowledge that is created, shared, administered and stored in a company passes through an internal cognitive filter, which prepares the information in such a way that makes it appropriate for the individual's use. Managing knowledge on a global scale means dealing with knowledge which has been processed by a variety of different filters influenced by the cultural environment and which is incomplete compared with reality. According to Senge, people's behaviour is always in tune with their mental models. If mental models promote complexity reduction through ignorance and there is no overlap of mental models in a team, then we can expect mutual ignorance regarding other people's knowledge, experience and perception. Finally, this would depreciate the value of knowledge management and would affect behaviour and team performance. Knowledge management in culturally diverse groups has to take into account diverse mind maps and has to find ways of harmonizing them in order to achieve a mental overlap and to create commonly shared knowledge zones.
- The reflection about oneself within a specific context creates awareness and consciousness regarding the things that happen around us. As mentioned in the Sherlock Holmes example above, the interpretation of a particular situation can be completely different depending on each individual's awareness of it. Awareness and consciousness play a crucial role in the priority setting of knowledge. The same knowledge content may have a different impact on different people and consequently a different impact on working with knowledge.
- The motivational factor drives individual behaviour and influences the individual's participation in knowledge management. Following the rationality approach, the cost-benefit relationship is decisive for carrying out activities. Sharing knowledge is considered positive if the individual receives a benefit, which is considered higher than the cost of participation. Factors that influence motivation in knowledge management are specialization, experience, responsibility, image and prestige. Specialisation and experience are very sensitive factors as they determine the uniqueness of knowledge. Possessing unique knowledge in the company improves the individual's negotiating power when this knowledge is of

importance for the organisation. In this sense, the price of knowledge, reflected in the person's salary, is higher than the salary of employees without any specialisation. In such situations there is probably no incentive for employees to share their specialised knowledge with others because this would depreciate their value for the company. Concerning image and prestige, the personal benchmark with colleagues at the workplace is an important driver for increasing or lowering an individual's effort or involvement in knowledge management.

- The communication dimension is strongly influenced by language, which is comprised of factors such as native like proficiency, gesture and the ability to express oneself. A low degree of native like proficiency and ability to express oneself together with a rich mixture of different cultural gestures makes knowledge sharing difficult and reduces the information load that is transferred in each message. Additionally, transmission, understanding and interpretation are also determined in cases where certain verbal expressions do not exist in some languages for certain situations. The communication aspect is absolutely crucial when a company wants to improve its organisational knowledge.

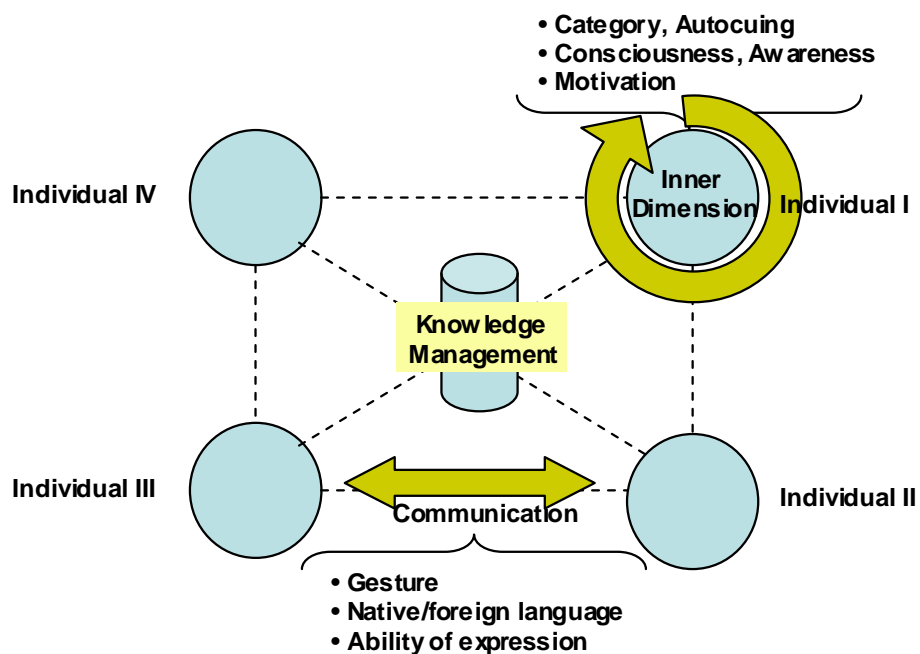

FIG. 2: COGNITION AND COMMUNICATION BARRIERS IN KNOWLEDGE MANAGEMENT

The conclusion is that knowledge management is far away from being the management of true reality. Instead of objective information, what is being managed is reality that is manipulated through individual perception. Even if one attempts to come as close as possible to objective reality, it is often impossible for foreigners to perceive and understand all the details from regionally restricted knowledge zones. If the environment has an impact on cognitive processes, then people who have grown up in different environments are more likely to use different forms and levels of complexity reduction. Mind making based on category thinking, awareness and motivation differs in different cultures. What's more, language always plays a crucial role in transmitting knowledge when individuals

with different native languages communicate. In such situations knowledge content runs the risk of being lost during the transmission process. This is especially the case when tacit knowledge needs to be codified in a foreign language, where one's ability of expression is limited.

Monsanto is an example of a company that decided to enter into the European market based on an erroneous knowledge base. Confiding in their American experience, Monsanto underestimated the backlash against their products from European consumers. Misperceptions, misinterpretation, misunderstanding and bad communication were mistakes that were made by the company's management.

## **Monsanto: The Failure of the Free Market Argument**

Monsanto is an American multinational agricultural biotechnology company that was founded in 1901 by John Francis Queeny, a veteran of the pharmaceutical industry. Already in 1919, the company started its expansion towards Europe by establishing an alliance with a chemical plant in Wales. Since 1971, Monsanto has produced and successfully commercialised its star product "Roundup", a herbicide glyphosate. In 1982, tests were started on genetically modified plant cells with the aim of developing genetically modified grains and crops that were resistant to "Roundup". The overall idea was to offer a herbicide/plant package which would increase crop productivity. Today, Monsanto has over 16,000 employees worldwide and an annual revenue of US\$7,344 billion reported for 2006. The company is by far the biggest producer of transgenic seeds, with a market share of 70% – 100% in some markets.

In May 1996, Monsanto received authorization from the European Community to export transgenic soybeans to the European market. The product was treated as a commodity, which means that the European Community did not classify the product as dangerous for people's health. Nevertheless, some months later, protests from ecologists and non-governmental organisations (NGO's) against the import of transgenic food raised awareness among consumers and led to a massive boycott of products containing genetically modified soybeans. The company's image as well as its economic results came under pressure and at the end of 1997, the general manager of Monsanto in Europe, Carlos Joly, apologized for the big mistakes that were made during the introduction of transgenic products in Europe. According to Joly, the company had underestimated the cultural differences between the United States and Europe concerning technology and in particular biotechnology. This came as a surprise, given the company's long standing tradition in doing business in Europe.

The motto "think global, act local" probably sums up the company's expansion approach very well, but it also reveals its arrogance in neglecting local thinking. Furthermore, Monsanto is an example of how rational arguments are bound to fail in emotional debates.

### **The Inner Dimension**

Even if this approach refers to individual thinking, it can be easily applied to corporate policy if we consider that each policy is developed by human brains and that there is always somebody who takes the decision based on available information.

Mental categorization and awareness: Monsanto grew within the American cultural context. Even though it is a multinational company, Monsanto relied on the American market and American legislation when it came to considering whether a product was economically and legally approved. The company has a strong belief in instrumental values which are related to American society and closely linked with openness towards innovation, belief in technology and an orientation towards the future. In contrast, Europe has always been known for a certain degree of scepticism towards new technology and demonstrated cautiousness and prudence towards technology innovation. Especially in the case of transgenic food, the discussion was led emotionally with a nostalgic touch concerning the role of farmers as food producers and protectors of nature. In contrast to the American belief in technology, the European belief in historical experience and confidence makes it more likely for Europeans to reject change. Monsanto ignored these differences and applied the American way of thinking to Europe. This reduced the complexity of business but also revealed awareness building based on insufficient data. The ability to pursue one's own business model without taking into account regional particularities is an example of auto cuing, a human phenomenon which allows the individual to disconnect his thinking from the surrounding reality.

Motivation: Monsanto's strategy has always focussed on markets and competition. The company positioned and benchmarked itself as a privately operating company. As an advocate of free markets, Monsanto's moral approach was based on utilitarianism and libertarianism. Monsanto postulated the importance of freedom of choice and argued that consumers are able to decide whether they want the product or not. Nevertheless, European consumers got the impression that they did not have any freedom of choice because of a lack of transparency and because they had not been consulted about the introduction of these products in Europe.

#### **Communication**

The communication policy of Monsanto was poor compared to the effort it had made in the United States. Relying solely on information and experience from the American market, European citizens were not invited to give their opinion nor was there an information campaign about biotechnology. This sharply contrasted with the information campaigns in the United States where a variety of initiatives such as open door events in the laboratories, education and information videos about biotechnology and articles in journals were undertaken in order to convince the American public. From the European point of view, ignorance and lack of communication were interpreted as an insult against European interests. Finally, Monsanto was accused of spreading North-American economic and technological imperialism. The company had also underestimated the impact of verbal expressions such as “genetic revolution” on the European public. Many people interpreted these types of expressions as an attack on nature.

#### **Conclusion**

Based on a review of the literature, this study has looked into the relationships between subjectivity, knowledge and knowledge management. The initial premise was that with globalisation, cultural diversity has become increasingly more important and that different understandings and interpretations of the same thing evolve. As the study shows, this is due to individual, highly subjective factors that come into play, transforming objective information into subjective knowledge. Knowledge management in general and organisational learning in particular entail the management of diverse cognitive processes. But since cognition is an internal process that occurs in the inner dimension of human behaviour, organisational knowledge management has no direct access. What may happen is that with globalisation there is an increased risk of failure in the management of knowledge. Taking the American company Monsanto as an example, one can see that decision making based on misguided assumptions, interpretations and understanding of important interest groups may damage a company's image.

This explorative study should be seen as a preliminary research effort which opens up the field to further in-depth empirical analysis. Scales can be developed in order to measure quantitative information about cognitive categorizing, awareness, motivation and communication from culturally diverse samples. Such research helps us to clarify the risk of misunderstandings in global knowledge management and therefore to relativise the effectiveness of knowledge management under global conditions.

## Abstract

Numerous studies have attempted to examine technological structure and linkage as a network. Network analysis has been mainly employed with various centrality measures to identify core technologies in a technology network. None of the existing centrality measures, however, can successfully capture indirect relationships in a network. To address this limitation, this study proposes a novel approach based on the analytic network process (ANP) to identification of core technologies in a technology network. Since the ANP is capable of measuring the relative importance that captures all the indirect interactions in a network, the derived “limit centrality” indicates importance of technologies in terms of impacts on other technologies, taking into account all the indirect influences. Using patent citation data as proxy for interactions between technologies, a case study on telecommunication technologies is presented to illustrate the proposed approach.

## Introduction

Due to the intractable complexity and volatility of modern technologies, it is of increasing importance to examine technological structure, and grasp technological trends and advances. Identifying and assessing technological advances critical to the company’s competitive position is now recognized as a crucial activity for achieving and maintaining competitive positions in a rapidly evolving environment [10]. Since technology systems are characterized by strong interdependence [1], there have often been attempts to examine technological structure and linkage as a form of network [36][40][42].

What is at the core of measuring technological interdependence or linkage is patents. Patents have been the representative proxy for technology [37]. A number of studies have been conducted to identify current technology structure and make a projection of technological future trends by using patent analysis [1][2][3][7][13][17]. Several measures have been employed for measuring technological linkage with patents, such as co-classification [6][16], co-word [9], and keyword vector similarity [42]. Among those, citation analysis has been the most popular one in spite of controversial discussions about its validity. The underlying assumption is that there exist technological linkages or flows between the two patents if a patent cites another patent.

Network analysis has often been used in conjunction with patent citation analysis with the aim of grasping the overall relationship and structure in a network. What is at the center of interest is to identify important or core technologies in a technology network [36]. As a quantitative measure of importance in a network, centrality measures can be deployed in network analysis. Among various measures, degree centrality has been implicitly deployed as an indicator of importance of technologies in the previous studies [38]. However, it does not take into account indirect relationships despite the fact that indirect citations as well as direct citations play a crucial role in characterizing technology networks [40]. None of the existing centrality measures can successfully capture indirect relationships and produce meaningful results for identifying core technologies in a patent citation-based technology network.

To address these limitations, this study proposes a novel approach based on the analytic network process (ANP) to identification of core technologies in a technology network. Since the ANP is capable of measuring the relative importance of technologies that captures all the indirect interactions in the technology network, the derived

“limit centrality” can be used as an implicative centrality measure characterizing a network and showing core technologies in the network.

The remainder of this paper is organized as follows. Section 2 deals with the previous studies on patent citation network analysis. The underlying methodology of the proposed approach, the ANP, is briefly introduced in Section 3. The proposed approach is explained and illustrated with a case study in Section 4. The paper ends with conclusions in Section 5.

## Patent Citation Network Analysis

Patents and patent statistics have long been used as technological indicators [15]. Although patents have been the representative proxy for technology as direct output of R&D activities, there has been a ceaseless controversy about the use of patent analysis since patents have advantages and disadvantages like any other technological indicator [1]. The pros and cons of patent analysis are not explained here in detail, but can be found in the literature by Archibugi and Pianta [1], Ernst [11], Griliches [15].

The most common method for early patent analysis was to simply count patents and to compare how many patents had been assigned to each entity, e.g. nations, firms, and technological fields [40]. The basic idea is the more patents belong to different entities, the more important the entity is. Due to the highly skewed distribution of patent values, however, judgments on importance based on simple patent counts could be biased to a large extent in many cases [21]. It is also incapable of measuring importance that mirrors influences or linkages among entities.

Thus, what has become the center of interest in patent analysis is citation information. Patent citation analysis is based on the examination of citation links among different patents [30]. The use of citation information in patent analysis boosts studies from various streams. One of the main research topics is to measure the values of patents based on the number of citations of patents in subsequent patents. It is validated by a number of evidences that more frequently cited patents have higher technological and economic value [5][31][37]. In this context, many studies have employed the number of citations as an indicator of patent quality [11][22][26][33]. Firm's value can also be measured based on the values of patents belonging to the firm [18]. Another subject of studies with patent citation information is to identify similarities between technologies. The similarity information can be used for identifying technology overlaps with collaborative firms [29], and proposing a new classification system by clustering patents [25]. The use of patent citation information in this study is in line with the other research stream, analyzing technological knowledge flows or technological linkages based on patent citation relationships. The underlying assumption is that there exists a linkage or a flow between the two patents if a patent cites another patent. However, patent citation analysis alone cannot grasp the overall relationship and structure among all the patents because it merely captures individual links between two particular patents [42].

To address this limitation, network analysis has often been used in conjunction with patent citation analysis to measure technological knowledge flows between entities and identify important or core entities. In general, the interactive relationships among actors can be portrayed as a network composed of actors (nodes) and interactions (edges) [14]. The structure of relations among actors and the location of actors in the network provide rich information on diverse aspects of an individual actor, a group of actors, and an overall network [27]. Thus, network analysis has attracted considerable interests from the social and behavioral science community in recent decades, and has also been applied and proved fruitful in a wide range of disciplines [41]. A patent citation-based network is one of the areas where network analysis is effectively employed with the aim of measuring technological knowledge flows among actors. An actor can be an individual patent or patents are assigned to a corresponding entity such as a nation or a technology class as an actor. Then, the citation relationships among patents represent interactions among actors. A number of studies have employed the patent citation network analysis at various levels, such as national level [23], industry level [20], firm level [19], and technology class level [36].

To characterize either holistic network characteristics or individual actor's positions in a network, various centrality measures can be calculated. Three common measures of centrality are degree centrality, closeness centrality, and betweenness centrality [12]. Among those, degree centrality has been implicitly deployed as an indicator of importance of technologies in the previous studies [38]. Degree centrality can be defined as the number

of ties incident upon a node. However, none of these centrality measures take into account indirect relationships [4]. Whereas in traditional network theory indirect links are in general of less value than direct links, this does not hold true in the case of patent citations [40]. Therefore, it is required to develop a new centrality measure that can capture indirect relationships in a network.

## ANP

The ANP is a generalization of the AHP [35]. The AHP, also developed by Saaty [34], is one of the most widely used multiple criteria decision making (MCDM) methods. The AHP decomposes a problem into several levels that make up a hierarchy in which each decision element is supposed to be independent. The ANP extends the AHP to problems with dependence and feedback. It allows for more complex interrelationships among decision elements by replacing a hierarchy in the AHP with a network [28]. Therefore, in recent years, there has been an increase in the use of the ANP in a variety of problems [24].

The process of the ANP is comprised of four major steps [8][28][35].

(1) Network model construction: The problem is decomposed into a network where nodes correspond to clusters. The elements in a cluster may influence some or all the elements of any other cluster. These relationships are represented by arcs with directions. Also, the relationships among elements in the same cluster can exist and be represented by a looped arc.

(2) Pairwise comparisons and priority vectors: Elements of each cluster are compared pairwise with respect to their impacts on an element in the cluster. In addition, pairwise comparisons are made for interdependency among elements outside clusters. When cluster weights are required to weight the supermatrix at the next stage, clusters are also compared pairwise with respect to their impacts on each cluster. The way of conducting pairwise comparison and obtaining priority vectors is the same as in the AHP.

(3) Supermatrix formation and transformation: The local priority vectors are entered into the appropriate columns of a supermatrix, which is a partitioned matrix where each segment represents a relationship between two clusters. The supermatrix of a system of N clusters is denoted as the following:

$$\mathbf{W} = \begin{matrix} & \begin{matrix} C_1 & \cdots & C_k & \cdots & C_N \\ e_{11} \cdots e_{1n_1} & \cdots & e_{k1} \cdots e_{kn_k} & \cdots & e_{N1} \cdots e_{Nn_N} \end{matrix} \\ \begin{matrix} C_1 \\ \vdots \\ C_k \\ \vdots \\ C_N \end{matrix} & \begin{pmatrix} \begin{matrix} e_{11} \\ \vdots \\ e_{1n_1} \\ \vdots \\ e_{k1} \\ \vdots \\ e_{kn_k} \\ \vdots \\ e_{N1} \\ \vdots \\ e_{Nn_N} \end{matrix} & \begin{matrix} \mathbf{W}_{11} & \cdots & \mathbf{W}_{1k} & \cdots & \mathbf{W}_{1N} \\ \vdots & & \vdots & \ddots & \vdots \\ \mathbf{W}_{k1} & \cdots & \mathbf{W}_{kk} & \cdots & \mathbf{W}_{kN} \\ \vdots & & \vdots & \ddots & \vdots \\ \mathbf{W}_{N1} & \cdots & \mathbf{W}_{Nk} & \cdots & \mathbf{W}_{NN} \end{matrix} \end{pmatrix} \end{matrix}$$

where  $C_k$  is the  $k$ th cluster ( $k= 1, 2, \dots, N$ ) which has  $n_k$  elements denoted as  $e_{k1}, e_{k2}, \dots, e_{kn_k}$ . A matrix segment,  $\mathbf{W}_{ij}$ , represents a relationship between the  $i$ th cluster and the  $j$ th cluster. Each column of  $\mathbf{W}_{ij}$  is a local priority vector

obtained from the corresponding pairwise comparison, representing the importance of the elements in the  $i$ th cluster on an element in the  $j$ th cluster. When there is no relationship between clusters, the corresponding matrix segment is a zero matrix.

Then, the supermatrix is transformed into the weighted supermatrix each of whose columns sums to one. A recommended approach to obtaining the weighted supermatrix is to determine a cluster priority vector for each cluster, which indicates relative importance of influences of other clusters on each cluster. This can be done by conducting pairwise comparisons among clusters with respect to the column cluster.

Finally, the weighted supermatrix is transformed into the limit supermatrix by raising itself to powers. The reason for multiplying the weighted supermatrix is because we wish to capture the transmission of influence along all possible paths of the supermatrix. The entries of the weighted supermatrix represent only the direct influence of any element on any other element, but an element can influence a second element indirectly through its influence on a third element that has the direct influence on the second element. Such one-step indirect influences are captured by squaring the weighted supermatrix, and two-step indirect influences are obtained from the cubic power of the matrix, and so on. Raising the weighted supermatrix to the power  $2k+1$ , where  $k$  is an arbitrarily large number, allow convergence of the matrix, which means the row values converge to the same value for each column of the matrix. The resulting matrix is called the limit supermatrix, which yields limit priorities capturing all the indirect influences of each element on every other element. For more details on supermatrix characteristics and theory, see the text by Saaty [35].

(4) Final priorities: When the supermatrix covers the whole network, the final priorities of elements are found in the corresponding columns in the limit supermatrix. If a supermatrix only includes components interrelated, additional calculation should be made.

## **ANP-Based Technology Network**

### **Overview of Proposed Approach**

The ANP underlies the novel approach to identification of core technologies in a technology network. The ANP and network analysis has the keyword, 'network', in common, but they are markedly different in ultimate objectives and nodes that make up a network. The ANP is a MCDM methodology aimed at setting priorities of alternatives or selecting the best alternative. A network model in the ANP is composed of decision elements such as goal, criteria, and alternatives. On the other hand, the purpose of network analysis is to grasp the overall structure of a network consisting of a variety of types of actors by visualization and quantification. When a network is constructed to only visualize the overall relationships among actors, the ANP has nothing to do with network analysis. If measuring importance of actors or identifying core actors is intended in network analysis, however, the ANP can also be employed for the same purpose by viewing actors as alternatives. Then, the centralities or importance of actors are equivalent to the priorities of alternatives.

The overall process of the proposed approach is as follows. Firstly, the scope and level of a technology network is determined and patent data on selected technologies are collected. Then, a citation frequency matrix is obtained based on the citation relationships among technologies. Finally, the ANP is applied to obtain importance of technologies, which is named "limit centrality" that captures all the direct and indirect influence among technologies. In this section, the proposed approach is explained with a case study on telecommunication technologies.

### **Technology Selection and Patent Data Collection**

Since, on any measure, the information and communication technology (ICT) industry has been at the forefront of industrial globalization [32], analyzing the ICT network is expected to provide valuable implications. However, the scope of ICTs is so wide that we narrow down the scope of the network to telecommunication technologies.

Patent data were collected from the United States Patent and Trademark Office (USPTO) database. The USPTO has classified granted patents into corresponding technology classes defined by the USPC (United States Patent Classification). Each subject matter division in the USPC includes a major component called a class and a minor component called a subclass [39]. A class generally delineates one technology from another and consists of subclasses that delineate processes, structural features, and functional features of the subject matter encompassed

within the scope of a class. There also exists a hierarchy among subclasses in a class. Every subclass has an indent level as a shorthand notation for illustrating dependency, represented as a series of zero or more dots. A subclass having an indent level of zero is called a mainline subclass which is set in capital letters and bold font in a class schedule. Subclasses having one or more dots are the child of a mainline subclass. In this study, a mainline subclass is treated as a building block of the technology network. Since the child subclasses inherit all the properties of their parent subclass, it does not make sense to treat all the subclasses at the same level.

A series of discussions with telecommunication technology experts led to selection of classes in the USPC as telecommunication technologies. For the convenience of illustration of the proposed approach, only four classes, as shown in TABLE 1, were selected, they are not exhaustive though. The titles of mainline subclasses are attached in Appendix A.

TABLE 1: TELECOMMUNICATION TECHNOLOGY CLASSES

Class	Title	Number of mainline subclasses
370	Multiplex communications	7
375	Pulse or digital communications	14
379	Telephonic communications	20
455	Telecommunications	12

Documents of all the granted patents assigned to the four classes were collected from the USPTO database and stored in a database. Since the number of patents is so huge that we cannot collect all of them in manual, the own-developed JAVA-based web document parsing and mining program was used for automatically downloading patent documents.

**Citation Frequency Matrix**

The next step is to construct a citation frequency matrix which represents citation relationships among mainline subclasses. It indicates technological knowledge flows or influences among mainline subclasses. The basic form of a citation frequency matrix is shown in TABLE 2 where  $f_{NiMj}$  denotes the number of patents in  $i$ th mainline subclass of class N that patents in mainline  $j$ th subclass of class M cite. As a citation has a direction from a citing patent to a cited patent, the matrix is asymmetric.

TABLE 2: FORM OF CITATION FREQUENCY MATRIX

		Class M (Citing)					...
		...	1	2	...	m	
...	...	...	...	...	...	...	...
Class N (Cited)	1	...	$f_{N1M1}$	$f_{N1M2}$	...	$f_{N1Mm}$	...
	2	...	$f_{N2M1}$	$f_{N2M2}$	...	$f_{N2Mm}$	...
	...	...	...	...	...	...	...
	n	...	$f_{NmM1}$	$f_{NmM2}$	...	$f_{NmMm}$	...
...	...	...	...	...	...	...	...

To examine the current structure of the telecommunication technology network, citations made by patents only granted from 2000 to 2004 were considered. The number of citations for each cell was calculated by manipulating the database storing the collected patent documents. Since the number of mainline subclasses of the four classes is 53, the resulting citation frequency matrix is a 53×53 matrix, but not shown here due to the space limit. Only the citation frequency matrix at the class level is shown in TABLE 3.

TABLE 3: CITATION FREQUENCY MATRIX AT THE CLASS LEVEL

Cited class \ Citing class	455	379	375	370
455	15487	166	6804	744
379	1392	368	132	190
375	6469	29	19587	1380
370	1815	58	3151	1827

## ANP

### Network Model Construction

Basically, a network model in ANP is constructed based on expert judgments to model an abstract decision problem. The network in the proposed approach is made on the basis of citation relationships represented in the citation frequency matrix, as is in the case of network analysis. A cluster in the ANP network corresponds to a class, and elements in a cluster are equivalent to mainline subclasses in a class. In the ANP context, then, the resulting network model only includes alternative clusters, contrary to the general network model in the ANP comprised of a goal cluster, criteria clusters, and alternative clusters. Thus, the importance of alternatives is only evaluated with respect to impacts or influences on other alternatives, not with respect to criteria or a goal, which is the same as the idea of centrality measures in network analysis.

An arrow indicates a citation relationship between classes or mainline subclasses. For example, an arrow which leaves class A and enters into class B is added to a network if some of the patents in class A cite some of the patents in class B. What this also means is class B has some influences on class A; thus, subclasses of class B should be pair-wisely compared with respect to impacts on each subclass of class A.

FIG. 2 shows the telecommunication technology network for ANP including the four classes. Every class has influences on each other, and includes a feedback loop that represents citation relationships among mainline subclasses in the class itself. Though the network can be elaborated more by describing citation relationships at the mainline class level, it is not represented due to its complexity.

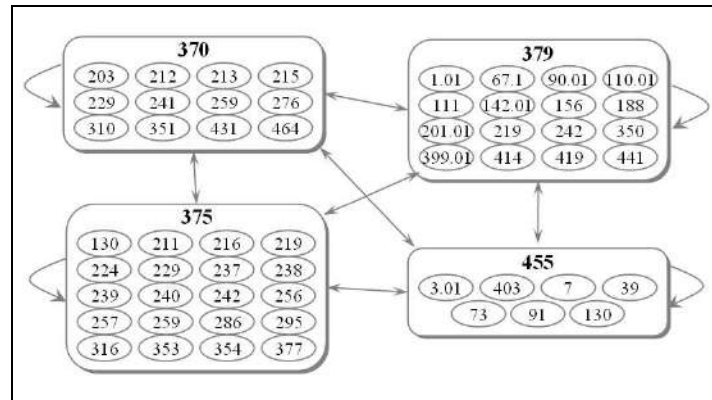

FIG 2: TELECOMMUNICATION TECHNOLOGY NETWORK FOR ANP

### Pair wise Comparisons and Priority Vectors

The next step deals with obtaining priority vectors. Firstly, cluster weights are determined through comparisons at the cluster level. The basic form of measurement in the ANP is a pairwise comparison with a scale of 1–9 since subject judgments have to be made on qualitative aspects. When the measurements derive from judgments based on experience and understanding, they are obtainable only from relative comparisons, not in an absolute way [Saaty, 1996].

However, pairwise comparisons do not have to be done in the proposed approach since the importance of elements can be directly measured from the citation frequency matrix. For example, TABLE 3 shows that the number of citations made by patents of class 379 is 58 for the patents of class 370, 29 for the patents of class 375. This can be interpreted that class 370 is twice ( $=58/29$ ) more important than class 375 in terms of impacts on class 379. Then, the number 2 is inserted to position (370, 375) and reciprocal value, 0.5, is assigned to position (375, 370). In this way, the pairwise comparison matrix with respect to class 379 among the four classes can be obtained as shown in TABLE 4. Then, the priority vector for class 379 is derived from the eigenvector method. This priority vector is naturally the same as the vector of the number of citations that the four classes received divided by total

number of citations made by the patents of class 379. This is because the pairwise comparison matrix is a completely consistent matrix.

TABLE 4: PAIRWISE COMPARISON MATRIX WITH RESPECT TO CLASS 379 AND RESULTING PRIORITY VECTOR

<379>	455	379	375	370	Priority vector	Normalization
455	1	0.45	5.72	2.86	0.2673	=166/621
379	2.22	1	12.69	6.34	0.5926	=368/621
375	0.17	0.08	1	0.50	0.0467	=29/621
370	0.35	0.16	2	1	0.0934	=58/621

Therefore, the priority vectors for every pairwise comparison can be directly obtained from the citation frequency matrix. TABLE 5 shows the cluster weights derived, which will be used to obtain the weighted supermatrix.

TABLE 5: CLUSTER WEIGHTS

	455	379	375	370
455	0.6155	0.2673	0.2293	0.1797
379	0.0553	0.5926	0.0044	0.0459
375	0.2571	0.0467	0.6601	0.3333
370	0.0721	0.0934	0.1062	0.4412

Secondly, local priority vectors for mainline subclasses are obtained. In ANP, basically, pairwise comparisons are made among elements of a cluster an arrow enters with respect to each element of a cluster from which an arrow leaves. For a feedback loop, elements in a cluster are pair-wisely compared with respect to each element in the cluster itself. For each pairwise comparison supposed to be made, local priority vectors can be directly derived without pairwise comparisons as mentioned above. For example, the importance of mainline subclasses of class 370 on each mainline subclass of class 450 is obtained by transformation of the citation frequency matrix, as shown in TABLE 6. What is important here is normalization of columns has to be done for each cluster. The resulting set of priority vectors, a priority matrix, will be imported to the supermatrix.

TABLE 6: CITATION FREQUENCY MATRIX AND ITS TRANSFORMATION INTO PRIORITY MATRIX

(A) CITATION FREQUENCY MATRIX									(B) PRIORITY MATRIX									
		455									455							
		455/3.01	455/403	455/7	455/39	455/73	455/91	455/130			455/3.01	455/403	455/7	455/39	455/73	455/91	455/130	
370	370/203	0	38	0	16	12	36	63	370	370/203	0	0.054	0	0.116	0.075	0.225	0.108

	370/215	0	0	0	0	2	1	6		370/215	0	0	0	0	0.013	0.006	0.01	
	370/229	0	22	0	0	0	0	1		370/229	0	0.031	0	0	0	0	0	0.002
	370/241	0	9	0	4	3	2	9		370/241	0	0.013	0	0.029	0.019	0.013	0.015	
	370/259	0	10	1	0	2	3	4		370/259	0	0.014	0.017	0	0.013	0.019	0.007	
	370/276	1	34	5	14	32	9	72		370/276	0.059	0.049	0.083	0.101	0.2	0.056	0.124	
	370/310	3	350	41	21	52	43	152		370/310	0.176	0.501	0.683	0.152	0.325	0.269	0.262	
	370/351	6	104	2	10	4	1	6		370/351	0.353	0.149	0.033	0.072	0.025	0.006	0.01	
	370/431	2	40	2	3	3	8	35		370/431	0.118	0.057	0.033	0.022	0.019	0.05	0.06	
	370/464	5	90	9	67	50	57	230		370/464	0.294	0.129	0.15	0.486	0.313	0.356	0.396	

### Supermatrix Formation and Transformation

The supermatrix is constructed with local priority vectors obtained from the previous step. TABLE 7 shows the form of the supermatrix for the telecommunication technology network, which is a 53x53 matrix composed of 16(=4x4) blocks. A block corresponds to a set of priority vectors, a priority matrix. The priority matrix in TABLE 6 is equivalent to  $W_{4l}$  in the supermatrix. The whole supermatrix is not represented due to the space limit.

TABLE 7: FORM OF SUPERMATRIX FOR TELECOMMUNICATION TECHNOLOGY NETWORK

	455	379	375	370
455	$W_{11}$	$W_{12}$	$W_{13}$	$W_{14}$
379	$W_{21}$	$W_{22}$	$W_{23}$	$W_{24}$
375	$W_{31}$	$W_{32}$	$W_{33}$	$W_{34}$
370	$W_{41}$	$W_{42}$	$W_{43}$	$W_{44}$

The supermatrix then needs to be transformed into the weighted supermatrix. Each matrix segment of the supermatrix is multiplied by the corresponding cluster weights shown in TABLE 5. For example, all the elements of  $W_{11}$  are multiplied by the weight of class 455 for class 455 itself, 0.6155,  $W_{41}$  is multiplied by 0.0721, and so on. However, the resulting matrix is not column stochastic because there are several matrix segments that have columns all of whose entries are zero. When this is the case, the weighted column of the supermatrix must be renormalized [Saaty, 1996]. The renormalized matrix, which is now column stochastic, is what is called the weighted supermatrix. A part of the weighted supermatrix is shown in TABLE 8.

TABLE 8: WEIGHTED SUPERMATRIX (EXCLUDING CLASS 379 AND 375)

**Limit Centrality**

As the supermatrix covers the whole network, the columns in the limit supermatrix (TABLE 9) represent final priorities, namely, limit centrality. That is why it is called limit centrality. Due to the nature of limit priorities in ANP, the limit centralities of all the elements sum to one. The limit centrality indicates importance of technologies in terms of impacts on other technologies, taking into account all the direct and indirect influences. TABLE 10 shows the limit centrality of 53 mainline subclasses. The limit centrality of a class is the sum of mainline subclasses belonging to the class.

TABLE 10: LIMIT CENTRALITY OF 53 MAINLINE SUBCLASSES

Class 455	Limit centrality	Class 379	Limit centrality	Class 375	Limit centrality	Class 370	Limit centrality
455/3.01	0.000670	379/1.01	0.000892	375/130	0.047675	370/203	0.015783

		379/188	0.004292	375/238	0.001695	370/276	0.007402
		379/201.01	0.005496	375/239	0.002604	370/310	0.036503
		379/350	0.005229	375/240	0.007805	370/351	0.010078
		379/399.01	0.003691	375/242	0.004499	370/431	0.006361
		379/414	0.000000	375/256	0.000159	370/464	0.051279
		379/419	0.008376	375/257	0.000792		
		379/441	0.001678	375/259	0.049151		
				375/286	0.004466		
				375/295	0.041154		
				375/316	0.150020		
				375/353	0.000352		
				375/354	0.068507		
				375/377	0.001981		
	0.362786		0.089857		0.413314		0.134046

At the mainline subclass level, the one with the highest limit centrality is 455/130 (receiver or analog

modulated signal frequency converter), and the next is 375/316 (receivers). It is obvious that these technologies have significant impacts on other technologies, and therefore they are considered as the core technologies of the telecommunication technology network. On the other hand, the limit centrality of 379/414 (transmission line conditioning) is zero since the patents of 379/414 have never been cited by all the patents of the four classes. The class whose limit centrality is the highest is 375 (Pulse or digital communications), followed by 455, 370, and 379.

## Conclusions

The proposed approach measures the limit centralities of technologies with the aim of identification of core technologies in the technology network. A case study on the telecommunication technology network was presented to illustrate the proposed approach. After constructing the citation frequency matrix based on patent data collected from the USPTO, the ANP network model was constructed and local priority vectors were obtained. Forming and transforming the supermatrix led to converged priorities, limit centralities.

The main contribution of this study is to apply the MCDM methodology, ANP, to a technology network. Since ANP captures the relative importance that mirrors all the direct and indirect interactions, the limit centrality measures importance of technologies in terms of impacts on other technologies in the technology network, taking into account indirect impacts or relationships, which is very difficult or tedious with the conventional centrality measures. The applicability of limit centrality is not limited to a technology network. For any type of social networks, the limit centrality can be used as an implicative centrality measure characterizing a network and showing core actors in the network.

Nevertheless, this research is still subject to some limitations. The drawback of the proposed approach is it cannot be used for undirectional networks where an edge has no direction and only represents the existence of a relationship between two nodes since relationships in a network of ANP must have directions depending on the influence between elements or clusters. The problem with the case study presented is the four patent classes selected are by no means exhaustive; they cannot cover the whole range of telecommunication technologies. More patent classes need to be included in the network. These limitations could serve as fruitful avenues for future research. Applications of the proposed approach to a variety of networks can be a worthwhile area for future research as well. A dynamic analysis on the telecommunication network is also expected to provide useful information on the change of the network structure and technological trends.

# The Emergence of Technology Entrepreneur and Economic Growth

*Guoqiang Li, GQLi@umac.mo  
University of Macau, China*

## Abstracts

Based on Yang and Ng's model, this paper will study the emergence of technology entrepreneur from the perspective of saving transaction cost. Inframarginal analysis (total cost-benefit analysis across corner solutions in addition to marginal analysis of each corner solution) of the model has formalized the Coase-Cheung theory of the firm. It is shown that firm can be used to improve transaction efficiency and to promote the division of labor by excluding the activity with the lowest transaction efficiency from being directly priced and traded. The analysis of the emergence of technology entrepreneur has found the conditions for the existence of technology entrepreneur and its implications for economic growth.

## Introduction

This paper employs Yang and Ng's analysis framework (Yang and Ng, 1993; 1995) to investigate the existence of technology entrepreneur<sup>1</sup> in the line of Coase and Cheung's firm theory. (See also related contributions by Borland and Yang, 1995; Liu and Yang, 2000; Yang, 2001.)

Since firms play a very important role in the growth of modern economies, it is unusual for outsiders to economics to take it for granted that there exists a well-developed theory of the institution of firm (Hart, 1996). However, we fail to deal with the problem of economic organization successfully. The mission of firm in economy is to "find the efficient level and pattern of division of labor in order to reduce scarcity by trading off the productivity gains against transaction costs" (Yang and S. Ng, 1998). Therefore, we are very familiar with the function of the price system in allocating resource,<sup>2</sup> rather than the function of the price system in coordinating specialization and division of labor (Yang, 2001).

Actually, most formal models of "domestic firm" are rudimentary, and some other models with "real world features of corporations" fail to be accepted by the theoretical mainstream due to the lack of precision and rigor (Hart, 1996). Therefore, we cannot obtain enough help from the existing theories of "firm" when we try to explore the emergence of technology entrepreneur. We will turn to a new classical framework.

There are two alternative ways to coordinate production: one is the external market, which is decentralized and achieves resources allocation through the price mechanism; the other is the internal organization of firm, which suppresses the mechanism with central planning and direct control (Coase, 1937). Cheung (1983) interprets Coase's firm theory in the light of contractual arrangements.<sup>3</sup> Cheung argues that "we do not exactly know what the firm is—nor is it vital to know. The word 'firm' is simply a shorthand description of a way to organize activities under contractual arrangements that differ from those of ordinary product markets." He claims that "The growth of a firm may then be viewed as the replacement of a product market by a factor market, resulting in a saving in transaction costs."

Yang and Ng (1995) and Yang (2000) refine Coase theory of firm. In Yang and Ng's model and Yang's model, one intermediate good is needed in the production of final goods. The intermediate good can be produced inside a firm, or it can be purchased from the market outside. Yang and Ng interpret Cheung's argument of the replacement of product market with labor market as a necessary condition for the existence of firm.

The rest of the paper is organized as follows: In section 2, the model with one intermediate good is introduced and two types of the production of the final goods are assumed. In section 3, all the possible market structures are analyzed and their corner equilibrium solutions are derived. In section 4, the emergence of technology entrepreneur is presented and we provide a brief conclusion in section 5.

## The Model

Let us consider an economy with  $M_1$  *ex ante* identical consumer-producers. There are one consumer good  $y$  and one intermediate good  $x$  (we can interpret  $x$  as technology). The amount self-provided of the consumer good and intermediate good are  $y$  and  $x$  respectively. The amount of the two goods sold to the market are  $y^s$  and  $x^s$  respectively. The amount of the two goods purchased from the market are  $y^d$  and  $x^d$  respectively.

An individual's production function for the final good is

$$y + y^s = \left[ (x + t_x x^d) l_y \right]^a, \quad 0.5 < a < 1 \quad 4$$

where  $t_x$  is the transaction efficiency coefficient of the intermediate good market.  $1 - t_x$  is transaction cost coefficient,<sup>5</sup> which "disappears" in transaction.  $t_x x^d$  is the net amount an individual receives from the purchase of this intermediate good.  $x + t_x x^d$  is the total amount of the intermediate good employed in the production of the final good  $y$ .  $l_y$  is the labor share in producing the final good and  $y + y^s$  is the output of this final good. A person's labor share in producing a good is defined as his level of specialization in producing this good.

A production function is said to display economies of specialization if the total factor productivity of a good increases with a person's level of specialization in producing the good (Yang, 2001). The total factor used to produce the final good  $y$  is  $(x^d)^{0.5} (r l_y)^{0.5}$  and the total factor productivity is  $y^s / \left( (x^d)^{0.5} (r l_y)^{0.5} \right) = (x^d r l_y)^{a-0.5}$  which increases with  $l_y$  if  $a > 0.5$ . The parameter  $a$  is the indicator of the degree of economies of specialization in producing the final good.

The production function of the intermediate good is

$$x + x^s = (l_x)^b, \quad b > 1$$

where  $x + x^s$  is the output of the intermediate good and  $l_x$  is a person's level of specialization in producing the intermediate good. If  $b > 1$ , the production function displays economies of specialization. Similarly, the parameter  $b$  represents the degree of economies of specialization in producing the intermediate good.

We assume that each individual is endowed with one unit of labor, so we have

$$l_x + l_y = 1, \quad 0 \leq l_i \leq 1, \quad i = x, y$$

The utility function of each individual is given by

$$U = y + k y^d$$

where the amount self-provided of the final good is  $y$ .  $y^d$  is the amount purchased from the final good market and  $k$  is the transaction efficiency coefficient of the final good market.

Finally, personal budget constraint for each individual is

$$P_x x^d + P_y y^d = P_x x^s + P_y y^s$$

where  $P_y$  is the price of the final good and  $P_x$  is the price of the intermediate good.

Free entry for all individuals into any sectors and a very large  $M_1$  are assumed. Free entry implies every individual can choose to become a technology producer or become a worker, who transforms the technology into the final good.

## Market Structure and Corner Equilibrium

### Technology Producer's Possible Choices

Each individual makes a decision about which goods to produce and on his demand for and supply of any traded good to maximize his utility. A given structure of production and trade activities for any individual is defined as a configuration. There are  $2^6 = 64$  combinations of zero and non-zero values of  $x, x^s, x^d, y, y^s, y^d$  and therefore 64 possible configurations. The combination of the configurations of the  $M_1$  individuals in the economy is defined as a market structure. A feasible market structure is composed of a set of choices of configurations by individuals such that the market clearing conditions can be maintained. Each market structure has a corner equilibrium solution. Corner equilibrium is defined as a set of relative numbers of individuals choosing different configurations such that (1) market clearing conditions can be maintained; (2) each individual maximizes his utility at a given prices for a given market structure.

Using Kuhn-Tucker sufficiency theorem, we can rule out interior solutions and many corner solutions from the list of candidates for optimal decision. Yang and Ng (1993) and Wen (1998) used Kuhn-Tucker conditions to establish following lemma (See also Yao, 2002 and Diamantaras and Gilles, 2004 for the results under more general conditions).

**Lemma:** *An individual sells at most one good and does not buy and self-provide the same good. he self-provides the consumer good if he sells it. If  $b > 1$  and  $a \in (0.5, 1)$ , he does not self-provide the intermediate good unless he produces the final good.*

After having considered the Lemma, we can identify four possible structures: autarky, technology transferor, technology specialist and technology entrepreneur. Structure of autarky and structure of technology transferor are non-firm mode of production, as shown in Fig. 1 and Fig. 2. Structure of technology specialist and structure of technology entrepreneur are firm mode of production as shown in Fig. 3 and Fig. 4.

In the structure of autarky,<sup>6</sup> Each individual spends some time to self-provide intermediate good  $x$ , and then he uses his remaining time and  $x$  produced to produce the final good. In the structure of technology transferor, markets for the intermediate good  $x$  and the final good emerge. Some individuals are specialized in producing  $x$  and the others are specialized in producing the final good. In the structure of technology specialist, worker is the owner of a firm and technology producers are employed to produce technology in the firm. And the technology producers hired by firms are called technology specialists. In the structure of technology entrepreneur, technology producer is the owner of a firm and workers are employed to transform the technology into the final good. So this technology producer as the owner of a firm is called technology entrepreneur.

### Technology Producer's Utility from Different Choices

In the structure of technology entrepreneur as shown in Fig. 4, technology producer is the owner, who produces the technology and hires workers from labor market to produce the final good. He claims the residual of the contracts between him and the employees. This is denoted by configuration  $(x/l_y)$ . Let  $(l_y/y)$  denote a configuration, in which an individual sells his labor, becomes a worker, and buys the final good. In Fig. 4, ovals represent configurations, and lines represent the flow of labor and the final good. Dotted circle represents the institution of firm.

In configuration  $(x/l_y)$ , technology entrepreneur's utility can be represented by

$$\begin{aligned} \text{Max } & U_x = Y \\ \text{s. t. } & Y + Y^s = Ny^s \quad (\text{total output of the firm}) \\ & y^s = (x^d r l_y)^a, l_y = 1 \quad (\text{production function of every employee}) \\ & x^d = x^s / N \quad (\text{intermediate good used by every employee}) \\ & x^s = (l_x)^a, l_x = 1 \quad (\text{owner's production function}) \\ & P_y Y^s = w l_y N \quad (\text{budget constraint}) \end{aligned}$$

where  $Y$  is the residual return claimed by the owner,  $Y^s$  is the total amount of the final good sold to the employees.  $N$  is the number of the workers hired.  $y^s$  is the output of the final good produced by each employee,  $l_y$  is employee's level of specialization in producing the final good.  $x^d$  is the intermediate good used by each employee,  $x^s$  is the total amount of the intermediate good produced by the owner.  $w$  is the wage rate.  $r$  is the transaction efficiency coefficient of the labor market for workers.

In configuration  $(l_y/y)$ , employee's utility can be represented by

$$\begin{aligned} \text{Max } & U_y = k y^d \\ \text{s. t. } & P_y y^d = w l_y, l_y = 1 \quad (\text{budget constraint}) \end{aligned}$$

where  $y^d$  is the amount of the final good needed by each employee.  $k$  is the transaction efficiency of the final good market.

In corner equilibrium, the owner's utility should be equal to employees' utility due to the assumption of ex ante identical consumer-producers. Solving the corner equilibrium solution, we can obtain the technology entrepreneur's utility:

$$U_{TE} = a^a (1-a)^{1-a} r^a k^{1-a}$$

We can do the similar analyses to obtain technology producer's utilities from the other three choices. They are summarized in Table 1.

TABLE 1: TECHNOLOGY PRODUCER'S REAL INCOMES FROM DIFFERENT CHOICES

Choices	Technology producer's real incomes	Meaning of the coefficients
Autarky (A)	$U_A = b^{ab} (1+b)^{-a(1+b)}$	
Technology transferor (TT)	$U_{TT} = a^a (1-a)^{1-a} t^a k^a$	$t$ : transaction efficiency of technology market $k$ : transaction efficiency of final good market
Technology specialist (TS)	$U_{TS} = a^a (1-a)^{1-a} (r_{ts}^a)^a k^a$	$r_{ts}$ : transaction efficiency of market for technology specialists
Technology entrepreneur (TE)	$U_{TE} = a^a (1-a)^{1-a} r_w^a k^{1-a}$	$r_w$ : transaction efficiency of market for workers

## The Emergence of Technology Entrepreneur

From above analyses, we can find that standard marginal analysis of interior solution does not work and corner solutions are allowed in our model. Therefore, we need a three-step inframarginal analysis. In the first step a list of candidates for an individual's optimum decision are identified by excluding all inefficient interior and corner solutions. In the second step all the solutions for possible corner structures will be derived. The third step is total cost-benefit analysis. After we have obtained the corner equilibrium solutions for four market structures, we can find the relevant conditions under which technology entrepreneur will emerge.

In all the four corner structures, the fourth structure as shown in Fig. 4 is the structures of technology entrepreneur. If it is the general equilibrium structure, we can say that technology entrepreneur emerges. Now, let us look at the conditions for the emergence of technology entrepreneur.

The reason for the structure of technology entrepreneur to be the general equilibrium structure is that it can generate the highest per capita real income for all the individuals in the economy. We have  $U_{TE} > U_i$ ,  $i = A, TT, TS$ .

If  $U_{TE} > U_A$ , we have  $r_w k^{a-1(1-a)} > a^{-1} (1-a)^{-(1-a)a^{-1}} b(1+b)^{-(1+b)}$ . This inequality shows that the structure of technology entrepreneur can generate more income than the structure of autarky when the transaction efficiency of the labor market for workers and the efficiency of the final good market are high enough. Although there are no transaction costs in the structure of autarky, technology entrepreneur still emerge if the economy of specialization can overweigh the transaction costs incurred in the structure of technology entrepreneur.

If  $U_{TE} > U_{TT}$ , we have  $r_w > tk^{2-a^{-1}}$ . If this inequality is satisfied, the structure of technology entrepreneur can generate more income than the structure of technology transferor. Compared with  $t$ , the transaction efficiency of technology market, if  $r_w$ , the transaction efficiency of market for workers is high enough, this inequality will be satisfied. Between these two market structures, efficient labor market for workers is the sufficient condition for the emergence of technology entrepreneur.

If  $U_{TE} > U_{TS}$ , we have  $r_w > r_{ts}^a k^{2-a^{-1}}$ . This inequality indicates that when the labor market for workers is very efficient, the structure of technology entrepreneur can generate more income than the structure of technology specialist, and technology entrepreneur will emerge. Since the labor market for workers is relatively more efficient, without doubt, the ideal structure must make full use of this more efficient labor market. Naturally, the structure with the workers as the owners of firms is not the ideal structure.  $r_w > r_{ts}^a k^{2-a^{-1}}$  can also be written as

$r_{ts} < r_w^{a-1} k^{a-2(1-2a)}$ . This inequality shows that when the labor market for technology specialists is not efficient, it is better to avoid measuring the efforts made by technology specialists hired by firms. In this case, the structure of technology entrepreneur will be the ideal structure.

## Conclusion

This paper has refined Coase's ideas about transaction costs. Coase claims that the institution of the firm can be used to reduce transaction costs. This claim should be interpreted from the perspective of marginal analysis of growth or shrink of the firm. Compared with the structures of Autarky and the structure of technology transferor, the structure of technology specialist and the structure of technology entrepreneur have more market transactions and entail more transaction costs. The institution of firm will emerge as long as increased economies of division of labor outweigh the increased transaction costs.

The basic conditions for the emergence of technology entrepreneur is that the transaction efficiency of the good market for technology and the transaction efficiency of the labor market for technology specialists are not sufficiently high, so that the ideal structure should avoid the direct pricing and trading of the technology, and avoid using of the low efficient labor market for technology specialists. This condition implies that technology specialist should be the owner of firm. The evolution of economic organization from the structure of autarky to the structure of technology transferor, to the structure of technology specialist and finally to the structure of technology entrepreneur implies that our economy grows discontinuously.

## End Notes

- <sup>1</sup> Please see Bull I., Thomas H. and Willard G. (1995) for the development and comments on the theoretical framework of entrepreneurship and Glancey K. S. and Mcquaid R. W. (2000) for entrepreneurial economics.
- <sup>2</sup> Yang and Ng (1993) refer to Marshall's neoclassical economics as "economics of resource allocation".
- <sup>3</sup> The main objective of both Coase's paper "The Nature of the Firm" and Cheung's paper "The Contractual Nature of the Firm" is to explain the reason of why the institution of the firm exists.
- <sup>4</sup> If  $a > 1$ , intuitively, the owner will hire all the individuals in the economy. This is not realistic.
- <sup>5</sup> We do not explicitly model the source of the transaction costs. Here, iceberg type transaction costs are assumed. Yang and Ng (1995) point out that the exogeneity of transaction costs allow us to capture in a simple way the main ideas which seem to have emerged from the transaction cost literature, namely that transaction costs exist and that they may differ across goods and factors and across institutional structures for production and exchange. The transaction cost includes four types of costs: the brokerage cost of finding a correct price; the cost of defining the obligations of parties in a contract; the risk of scheduling and related input costs; and the taxes paid on exchange transaction in a market (Rugman, 1980). Transaction efficiency depends on transaction technology, institution arrangements, urbanization of a country and etc.
- <sup>6</sup> A criticism by Auerbach (1988) focuses on the disjointed way in which Coase and his followers see firms and markets, in particular the presupposition of the existence of markets and failure to see the role of firms in the making of markets. Therefore, it is necessary to begin with the studies of market structures from autarky.

# Usage of Time of an Entrepreneur

Mikki Valjakka, mikki.valjakka@lahdenyliopistokeskus.fi  
Lahti University Consortium  
Lappeenranta University of Technology, Finland

## Abstract

Does the actual usage of time of an entrepreneur coincide with the wishes (theoretical) usage of time? What is the length of a workday? The workday was divided into eight elements and 44 statements: Planning and managing company operations (4 statements); Development of customer- and market-oriented functions (5); Development of human resources (5); Development of financial administration (9); Personal Development (6); Performing different roles (4), Operating with people (6) and Operating in different places and/or with equipment (5). Is there any difference based on age, gender, education or parenthood? How much time is spent doing house work, taking care of children, studying, and sleeping? The 656 owner-entrepreneurs examined are dissatisfied with their usage of time – most of their time was spent by “Performing different roles” instead of “Planning and managing company operations”. The results show significant differences based on gender and education. The respondents work 11 hours a day and want more time for housework and leisure.

## Introduction

Values, skills and usage of time are important factors of wellbeing of entrepreneurs. Values demand prioritization of one's actions, which show in usage of time. It is important for the quality of life of entrepreneurs to feel to be in control of their lives. It means that they have sufficient time for the important tasks and a balance between what they want or aim to do and what they actually do. The right usage of time gives the feeling of being in control, satisfaction, motivation and willingness to develop. If entrepreneurs can manage their work time properly and in a way they appreciate, the company will progress and entrepreneurs will also inspire people around them, as well as leading to improved self-confidence and better mental capacity.

Societal success depends on the success of its companies; therefore it is important to study entrepreneurial usage of time. This increases the awareness of the needs and wishes of entrepreneurs and their readiness to be leaders. Balancing usage of time increases the chances of leading a healthy life mentally and physically and the ability to work well. Therefore, it makes sense to research entrepreneurial usage of time. Numerous studies have examined entrepreneurial work content, but fewer have studied actual and theoretical entrepreneurial usage of time. This study aims to chart and analyze the judgments of entrepreneurs regarding their own usage of time – the present and future states.

This paper aims to shed more light on the profile of a Finnish SM entrepreneur and increase the amount of research. The perspective is individual centered, more precisely entrepreneur centered.

## Objects and Questions

There is no consensus concerning the minimum tasks entrepreneurs must do and where to spend time. Even general items concerning many entrepreneurs are difficult to define because of the different demands depending on the branches of activity and environment. In addition, phase of a life cycle and a size of a company (the resources available) place different demands on tasks.

This study focuses on Finnish owner-entrepreneurs, so the survey charted the entrepreneurial tasks based on the “*Demands for the vocational qualification of an entrepreneur*” (Allardt - Asp - Heikkonen - Rautkallio - Vuorinen 1984, 7) Allardt et al state that managing as an entrepreneur one must master certain thematic entities like

planning and managing operations, company and society, entrepreneurship and development as an entrepreneur and financial administration and marketing.

To carry out the study the entrepreneurial thematic entities to manage time have only focused on the eight elements listed below. The contents of the elements (single statements) are shown in Appendix 1.

The examined elements are (44 statements included, see Appendix 1):

1. Planning and managing operations (4)
2. Development of customer- and market-oriented functions (5)
3. Development of human resources (5)
4. Development of financial administration (9)
5. Personal development (6)
6. Usage of time in different roles (interpersonal -, disseminator-, decision-making - and technical roles – 4)
7. Usage of time with different people (other owners of the company, employees, fellow entrepreneurs, customers, people belonging to interest groups, private individuals – 6)
8. Usage of time in different places and with equipment (5)

Both present and future states were examined. Additionally dividing the 24 hours between working, doing housework, taking care of children, studying, and sleeping were studied.

This paper aims to answer the following questions:

1. **How is the workday of an entrepreneur divided between different elements and how one wants it to be divided?** - Differences are based on age, gender, education or parenthood?
2. **How are the 24 hours divided and how one wants them to be divided?**
  - Length of workday?

## Methodology

The study follows the quantitative and descriptive tradition. The data was gathered using a questionnaire sent by e-mail to 3, 253 e-mail addresses. These e-mail addresses of owner-entrepreneurs were provided by two Finnish Company Organizations in two provinces in Finland. 660 owner-entrepreneurs returned the questionnaire of which 656 were accepted, the response rate being 20.2 %. So the sample consists of 656 observations including 163 female and 493 male owner-entrepreneurs. (Entrepreneur Profile See Appendix 2)

The usage of time was examined and analyzed by calculating the means. Explorative Factor analysis was used to test and confirm the statements, and the Mann-Whitney-U test was used for the comparisons. The usage of time (the actual and theoretical) were rated using a four-step scale. Present state: I spend time... *very little* = 1; ...*some* = 2; ... *quite much* = 3; ...*very much* = 4. Theoretical: My usage of time is *OK* = 0. I wish I could spend a *little more* time = +1; ... *moderately more* time = +2; ...*much more* time = +3. There was also a box for comments.

## About the Usage of Time

The contents of the work and tasks of managers and their usage of time have been studied since the 1950s. The study published by Fayol (1925) “*Administration industrielle et generale*” and the study published in the 1930s by Gulick (1937) “*Science, values and public administration*” and perhaps also some of the studies in 1940s resolution /conclusion school could possibly be considered as studies of usage of time. Herbert Simon (1947) found decision-making to be the most critical managerial function. Moreover, Carlson published his first study of usage of time in 1945.

Next are some significant “old” studies from the last millennium, studies of managerial work and usage of time. As a link to the studies of the 1950’s, Carlson’s study “*Executive Behavior*” (1951, reprint 1991) must be mentioned, where the diary method was used for the first time. The study describes the first systematic study ever made of top managers at work. According to Tengblad (2003) it is regarded as a classic. Other studies from the 1950s are Gibb, C. (1954) “*Leadership*” and Guest, R. (1956) “*Of Time and Foreman*”. From the 1960’s significant

researchers include Neustadt (1960), Sloan 1963, Sayles 1964, and Stewart's large study from 1967 and Carlson's follow-up study from 1969. From one of the significant studies from **1970's** the most famous is "*The Nature of Managerial Work*" by Henry Mintzberg written in 1973. His study "*The manager's job: folklore and fact*" in 1975 is also notable. From the **1980's** important studies include Mintzberg (1980), Kotter (1982), Hales (1986), Stewart (1988), and Moss Kanter (1989). From **the 1990's** they include Mintzberg (1991) "*Managerial Work: Forty years later*", Stewart (1991) "*Managing Today and Tomorrow*", and Panko (1992) "*Managerial Communication Patterns*". Also Therese Macan's study focused on usage of time, Routamaa & Hakuli & Ryhänen (1992) examined the tasks of managers. Other studies on usage of time and work include Adam (1995), Stewart (1996), and Kotter, John P. "*What Effective General Managers Really Do*" (1999, first published 1982).

The comparison of studies is not easy while in some studies the (1) Top Managers (CEO), that is the executive managers of multinational companies, (2) Middle Manager, (3) Lower Managers, (4) Division Managers, and (5) Professionals have been differentiated and not in some studies. Additionally, as mentioned earlier, the phase of the life cycle and the size of a company (the resources available) place different demands on tasks, as well as the branch of activity and environment.

How people organize time can be examined in several ways. Firstly, one can ask people about their usage of time, life, interpretations of the past and visions of the future. Secondly, one can study facts made by people and thirdly, one can observe people and their behavior. The data of studies of managerial usage of time usually comprise questionnaires, interviews, notes from usage of time diaries, and observations.

### **Comparison of Seven International Studies of Managerial Usage of Time**

There follows a description of managerial usage of time and tasks based on seven significant studies: **1.** and **2.** Tengblad, Stefan (2002) "*Time and space in managerial work*" and Carlson, Sune (1951) "*Executive Behavior*"; **3.** & **4.** Mintzberg, Henry (1973 and 1980) "*The Nature of Managerial Work*" and Mintzberg, Henry (1975) "*The manager's job: folklore and fact*"; **5.** Farmer, P.L. (1978) "*Managerial Work and the Growth and Development of the Firm*" **6.** Kotter, John P. (1982 and 1999) "*What Effective General Managers Really Do*"; **7.** Stewart, Rosemary (1988) "*Managers and their jobs*".

(**1and 2**) Stefan Tengblad (2002) carried out his study of usage of time in 1998 – 1999 using the scope and methods of the investigation similar to those in "*Executive Behavior*" (1951) by Sune Carlson and tried to identify similarities and differences, quantitative as well as qualitative, between the Carlson study and his own. Tengblad's participants were eight Swedish large-scale company managers and Carlson had nine. The workdays examined by Tengblad were 19.9 days, 246 work hours and 218 functions. Two of Tengblad's participants represented metal engineering (three of Carlson's), one forest industry, one utilities, one retailing, two banking and insurance, and one media production (this industry did not exist in 1951 so was not in Carlson's study).

The most striking difference between the two studies concerning the workplace is the big increase in time spent on traveling. The results also indicate that the work time increased from Carlson's 11 hours 42 minutes to Tengblad's 12 hours 22 minutes, working alone in own office decreased and was 3 hour 49 minutes by the time of Tengblad's study (Table 1).

TABLE 1: THE PLACE AND LENGTH OF MANAGERIAL WORKDAYS

	Carlson: average times			Tengblad: typical times	
	time spent	%	range (%)	time spent	%
Office	4.48	41	18 - 52	3.49	31
Elsewhere within company	1.45	15	5 - 32	2.06	17
Within own company	6.34	56	28 - 70	5.55	47
Working at home	0.57	8	1 - 11	0.31	5
Transportation	0.22	3	9 - 27	2.33	21
On visit outside company	3.46	33	6 - 32	2.03	16
Elsewhere outside company	-	-	2 - 22	1.19	10
Total		<b>11.42</b>			<b>12.22</b>

The contemporary managers (Tengblad’s participants) spent most of their time communicating - 7 hours 20 min in personal communicating and much time was also spent in meetings with more than one person (5 hours 45 min). Contemporary managers most often met shareholders and institutional investors, while Carlson’s participants spent their time meeting people belonging to interest groups (like governmental agencies because in the beginning of the 1950s there were many rules and regulations affecting business) and customers. (Tengblad, 2002, 543 – 565)

In the four research weeks, Tengblad’s participants had 105 meetings, of which 78 were internal (in 42 meetings some of the managers were reporting directly to the CEO). In Carlson’s study, there were 176 meetings, of which 127 were internal and 42 were reporting meetings. The number of meetings decreased. Financial affairs took most time, from roles took most time functioning in the dissemination role. According to Carlson’s study, the work time was very fragmented and frequently disturbed by phone calls and visitors, on average the undisturbed work time was only eight minutes while in Tengblad it was 18 minutes. The fragmentation of *time* seems to change over five decades to fragmentation of *space*. The time for personal development was only 4 minutes in Tengblad’s study. (Tengblad, 2002, 543 – 565)

(3.) The third significant study (Mintzberg 1973, article 1975) examined the nature of managerial work, focusing mainly on the (ten) roles. Three of the manager’s roles come directly from his formal authority and involve basic interpersonal relationships (Mintzberg 1975, 54) (TABLE 2)

TABLE 2: THE MANAGER’S ROLES			
↓	Interpersonal roles	Informational roles	Decision-making roles
<b>Formal authority and status</b>	- figurehead	- monitor	- entrepreneur
	- leader	- disseminator	- disturbance handler
	- liaison	- spokesman	- resource allocator
		- negotiator	

The managers’ ten roles are not easily separable, they form a gestalt, an integrated whole. The framework cannot remain intact if any role is taken from it. Mintzberg’s participants spent 40 % of their contact time in the dissemination role and 12 % in the figurehead role attending many ceremonial events. In the study’s conclusions Mintzberg notices that in order to be better managers, they should find systematic ways to share their privileged information, avoid superficiality by paying serious attention to the issues requiring it, take better control of their own

time by delegating and participate in managerial training. (Mintzberg 1975, 60 – 61) Mintzberg's study has been severely criticized (Carroll & Gillen 1987, 39 – 40) and to some extent it has been considered controversial.

(4.) Mintzberg also conducted 1980 a study of the content of managerial work and (condensed) found six characteristic features:

- Great amount of work and unrelenting pace (constant flow of visitors)
- Great number of tasks characterized by brevity, variety, and discontinuity
- Favoring action (dislike reflective activities)
- Favoring verbal communication
- Acting between their organization and contact networks (48 % of contact time with subordinates, 44 % with external contacts, and 7 % with superiors)
- Overburdened with obligations (often the rights and obligations are mixed): often the manager can not decide about his own usage of time (Mintzberg, 1980, 109 – 111)

(5.) Farmer (1978) aimed to ascertain how the size of the company influenced managerial usage of time. He categorized managers as owner-operators, typical entrepreneurs, etc. and found that the smaller the company the more the activities of an entrepreneur concentrate on production and selling. When the company grows the entrepreneur's visits to the factory decrease but the time spent getting information increases.

Managers of smaller companies concentrate less on formal and more for production activities and are in contact with a number of activities and their activities were more short-term than those of the managers of bigger companies. Managers of smaller companies also participated less in official meetings and their external network was significantly more constricted (Farmer, 1978, 5-10).

(6.) Kotter (1999, first published 1982) found the following characteristics of the workday of 15 successful general managers in nine companies:

- They spend most of their time with others, with many people in addition to their direct subordinates and their bosses, in short, disjointed conversations
- The breadth of topics in their discussions is extremely wide and during conversations, managers rarely seem to make "big" decisions and rarely give orders in a traditional sense
- They ask many questions during conversations and attempt to influence others
- Their discussions usually contain a fair amount of joking and often concern topics unrelated to work, and the issue discussed is relatively unimportant to the business or organization
- They often react to others' initiatives; much of the typical manager's day is unplanned
- Managers work long hours

Successful managers had developed agendas made up of loosely connected goals and plans and also developed a network of cooperative relationships. Kotter points out the importance of conversations that look like a waste of time while he found that such conversations prevent burn out and promote long-term competitive advantage. (Kotter, 1999, 145- 159)

(7.) According to Stewart (1988) work hours varied from 35 to 60 hours per week. The managers spent 43 % on unstructured conversations, 36 % on paperwork, 7 % on committees, 6 % on control, 6 % on telephone calls, and 4 % on other social activities. The internal contacts (foremen, subordinates, colleagues) took much more time than external contacts (customers, suppliers, others). Workdays were fragmented and full of interruptions. Long hours burn off, usage of time was at the mercy of other people, and decisions were often superficial.

To sum up the work of entrepreneurs is quite fragmented, with the time taken to concentrate on a single task being often only a matter of minutes. According to many other studies (Fisher, 1992; Hochschild, 1997; Jacobs & Gerson, 1998; Maume & Bellas, 2001; Kvassov, 2002; Tetard, 2002; Brett & Stroh 2003) managers and entrepreneurs (Federation of Finnish Companies, 2005) work about 50- 60 hours per week, which is 10 – 12 hours per workday. The workload is very demanding and the pace is unrelenting, much time is spent on face-to-face communication, discussion topics are in a wider context and often not work-related and the managers ask many questions. A manager functions in different roles (in interpersonal-, disseminator-, and decision-making roles). Managers spent much time in their own office and work unit. Travel and transportation and meetings take up much time.

## One Finnish Study Comparing the Usage of Time of an Entrepreneur to Other Professions

Next a Finnish survey of usage of time of all professions (male and female), and especially examining the usage of time of entrepreneurs (male and female). (Niemi & Pääkkönen 2001)

According to the survey, male farmers have the longest work hours of all professions, and the shortest is female higher employee. Entrepreneurs work 228 hours per year more than other professions, that is, more than 28 eight-hour workdays per year (Table 3, Niemi & Pääkkönen 2001, p. 21).

TABLE 3: ANNUAL WORK HOURS OF DIFFERENT PROFESSIONS

Annual work hours 1999 – 2000 (hours/year)					
<i>Men</i>	<i>Profession</i>	<i>Women</i>	<i>mean</i>		
2.409	farmer	1.722			
1.965	higher employee	1.442			
1.849	lower employee	1.563			
<u>1.904</u>	worker	<u>1.478</u>			
2.032	<i>mean of other professions</i>		1.551		1.792
2.287	entrepreneurs	1.752	2.020		

The data for Table 4 has been taken from the study "Usage of time of working men 1999 – 2000" and from "Usage of time of working women 1999 – 2000" (Niemi & Pääkkönen 2001, pp. 67 and 69). Figures include all seven days of the week.

TABLE 4: USAGE OF TIME OF DIFFERENT PROFESSIONS

USAGE OF TIME 1999 – 2000 Men (women)						
	<b>Farmer</b>	<b>Higher employee</b>	<b>Lower employee</b>	<b>Worker</b>	<b>Entrepreneur</b>	
<b>*Working</b>	6.43 (4.48)	5.54 (4.23)	5.32 (4.45)	5.43 (4.26)	6.38	(5.10)
<b>Housework</b>	2.03 (5.08)	2.26 (3.40)	2.19 (3.38)	2.25 (3.47)	1.58	(3.17)
<b>Personal needs</b>	9.55 (9.44)	10.04 (10.23)	10.22 (10.27)	10.07 (10.29)	10.15	(10.34)
<b>Studying</b>	0.03 (0.00)	0.07 (0.08)	0.07 (0.05)	0.03 (0.04)	0.10	(0.09)
<b>Leisure</b>	5.02 (4.11)	5.22 (5.22)	5.34 (5.00)	5.33 (5.06)	4.49	(4.43)
<b>Miscellaneous</b>	0.14 (0.09)	0.07 (0.04)	0.06 (0.05)	0.09 (0.08)	0.09	(0.07)
<b>Total</b>	<b>24</b>	<b>24</b>	<b>24</b>	<b>24</b>	<b>24</b>	<b>24</b>

\*Working includes commuting; Housework includes household work, maintenance, taking care of children, shopping, and transactions; Personal needs include sleeping (mean of gender 8 h 20 min), eating, get washed and dressed; Studying includes transportation

**Working:** male farmers work the longest (47 h 1 min during the week/seven days) and second longest male entrepreneurs (46 h 26 min/seven days). Female higher employees work the shortest hours (30 h 41 min/seven days) as mentioned earlier. The biggest difference between genders is found among farmers: males work 1 h 55 min longer than females. (See Housework) The difference between entrepreneurs by gender is 1 h 28 min in favor of men.

**Housework:** Female farmers work the longest hours (35 h 56/seven days). Male entrepreneurs spend the least time on housework (14 h 21 min/seven days). The difference between genders is approximately the same in all professions being about 1 h 20 min in favor of women. Female entrepreneurs spend the least time on housework of women in all professions. Taking care of children took 10 min from male and 11 min from female entrepreneurs.

Personal needs: Female entrepreneurs spend the longest time on personal needs 10 h 34 min (→ they spent 8 h 33 min sleeping), female farmers spent the least time (9 h 44 min). Biggest difference between genders is by worker. Male entrepreneur slept 8 h 7 min and female 8 h 33 min which was the most of all professions.

Studying: Hardly any time was spent studying among all professions. Male entrepreneur spent 1 h 10 min/seven days studying and female farmers spent none.

Leisure: Male lower profile employees have the most leisure time (38 h 58 min/seven days) and female farmers the least (29 h 17 min) and female entrepreneur (33 h 1 min) the second least. The biggest difference between genders is by lower employees (3 h 58 min/seven days). The difference by entrepreneurs is 6 minutes in favor of men. (TABLE 4)

Consultants have developed many systems for time management. Their aim is to spend time more effectively. They often include recommendations to make lists of priorities, restrict the number of contacts, etc. According to Kotter (1982) successful managers did not follow these instructions (see earlier).

It has been said that the people, who work independently and who have power, seem to have the biggest problems mastering usage of time. A tremendous amount of self-discipline is needed to effectively spend time because people easily forget plans and begin to do something nice.

## Study Findings-Present and Future States

The median respondent is male, aged 43, married with 2–3 children, ‘O’-level to college-level education and has worked for 12 years as an entrepreneur. The entrepreneur profile is in Appendix 1.

The usage of time was charted according to “Demands for the vocational qualification of an entrepreneur” and it was presumed that entrepreneurs spend their time *Planning and management operations* (4 statements), *Development of customer- and market-oriented functions* (5 statements), *Development of human resources* (5 statements), and *Development of financial administration* (9 statements). The time spent on *personal development* (6), in *different roles* (4), with *different people* (6), and in *different places/ equipment* (5) was also charted.

The respondents were asked to judge their usage of time (present state) using four grades: I spend my work time 1= almost not at all; 2 = some; 3 = moderately much, and 4 = very much. The future state: my usage of time is OK = 0; I would like to spend a little more time =+1; moderately more =+2; much more =+3.

The scale of the future state has been transferred to the same as present state, that is

<u>future</u> state: I would like to spend time	<u>present</u> state: I spend my work time
much more = + 3 → 1	= almost not at all
moderately more = + 2 → 2	= some
a little more = + 1 → 3	= quite much
my usage of time is OK = 0 → 4	= very much

Tables 5 – 12 in Appendix 3 (pp. 15 - 17) show the means and standard deviation (SD) of the present and future states of all eight elements examined.

Planning and managing operations element

Present state. Differences between statements among the *Planning and management operations* element are very small. Time was spent on all statements *quite much*. *Some* time was spent only on Forecasting functions, mapping out risks. Table 5 shows the order of four statements.

Future state. The answers show that most of the extra time the respondents wanted was for ‘Forecasting functions, mapping out risks’ in *Planning and management operations* element corresponding to the Present state. (Table 5, page 15)

Development of Customer and Market-oriented Functions

Present state. The most time was spent on the *Development of customer- and market-oriented functions* element in the statement ‘Interactive, productive salesmanship and customer service’ and the second most on ‘Customer satisfaction’ function. The least time was spent on ‘Interpreting market research and competitor analyses’.

Future state. The least extra time in the *Development of customer- and market-oriented functions* element was for ‘Interpreting market research and competitor analyses’ so it was considered unimportant or felt to be in order.

Respondents wanted to spend most extra time on 'Customer satisfaction'. In 'Free word' they emphasized the meaning of old networks, even those from college days. Some criticized the whole idea of segmenting customers by their profitability. (Table 6, page 16)

#### Development of Human Resources

Present state. The most time was spent on *Development of human resources* elements' statement 'Attending to the wellbeing of the personnel' and second most on 'Enhancement of team spirit'. The least time was spent on 'Using human resources development discussions in personnel management' and the second least on 'Eliminating resistance to change'.

Future state. Most of the desired possible extra time was for 'Attending to the wellbeing of the personnel' and 'Enhancement of team spirit' so the ample time already spent on those was considered insufficient. The least extra time was for 'Eliminating resistance to change'. Probably the resistance to change was not a problem for respondents. The differences between the present and future state are big. In 'Free word', the relationship between work and rest and good taking care of oneself was considered very important and a prerequisite for taking care of other people. Resistance to change was eliminated by careful listening and reasoning. (Table 7, page 16)

#### Development of Financial Administration

Present state. Most time was spent on *Development of financial administration* element in statement 'Working with profitability, liquidity, financial stability, and productivity matters in company operations'. The least time was spent on 'Working with regulations, company forms, company reorganization, and contract regulations' and second least on 'Defining indicators for surveying the business'.

Future state. Respondents wanted to use most extra time on 'Planning, controlling, and directing the company economy'. The present showed that most of the time was already spent on this so it was considered very important. The least extra time was wanted for 'Using the services of accountants, accounting companies, or such when planning, controlling, and directing the company economy'. In "Free word" 'Using ,the services of accountants, accounting companies, or such when planning, controlling, and directing the company economy' was considered important, if one cannot do something or have no time it is better to buy the service. It was also stated that it is easy to analyze but not easy to fulfill or react to analyses. (Table 8, page 16)

#### Personal development

Present state. In *Personal development* most of the time was spent on 'Maintenance of family-/friendship relationships' and the second most on 'Studying the skills needed in work' (like public appearance, communication skills, information technology skills, foreign languages, knowledge of one's own field, analyzing skills). The least time was spent on 'Taking care of affairs connected to confidential post (outside work life)'

Future state. The respondents wanted most extra time for 'Maintenance of family-/friendship relationships' and secondly to 'Physical hobbies'. Least extra time was wanted for 'Taking care of affairs connecting to confidential post (outside work life)'. (Table 9, pages 17)

#### Usage of time in different roles

Present state. Most of the time spent on *in different roles* went on actually completing the production/services, that is functioning in 'Technical role'. Most respondents were small entrepreneurs so the input of the owner is essential. The least time was spent on 'Dissemination role'.

Future state. Most extra time was wanted for 'Dissemination role' and least for 'Technical role'. (Table 10, page 17)

#### Usage of time with different people

Present state. Most time in the *Usage of time with different people* element was spent on 'Customers' and second most of 'Employees'. The least time was spent on 'the other owners of company (which perhaps do not even exist) and second least on 'Fellow entrepreneurs'.

Future state. Most of the extra time wanted was for 'Customers' and surprisingly the second was for 'Private individuals'. The least extra time was spent on 'Other owners of the company and the second least on 'Employees'. (Table 11, page 17)

*Usage of time in different places/equipment*

**Present state.** When charting the *Usage of time in different places/equipment*, most of the work time occurs in ‘Own office’ and the second most ‘On the telephone’. The least is for ‘Lunch hour’ and the second least ‘Transportation’.

**Future state.** The respondents wanted most extra time firstly for ‘Own office’ and secondly for ‘Handling emails’. The least extra time was wanted for ‘Lunch’ (Table 12, page 17).

Table 13 deals with the data of the means of present and future states, the numeral differences between them, the mean of the means, orders of present and future states of the eight elements for spending time. (TABLE 13)

TABLE 13: ORDER OF FUTURE STATES AND MEANS VS. ORDER OF PRESENT STATES AND MEANS

n = 656

	Order	Future state	Present state	Order	Difference
Planning and managing operations	1.	2.96	2.48	<u>2.</u>	0.48
Customer- and market-oriented fu	2.	3.00	2.33	<u>3.</u>	0.67
Personal development	3.	3.03	2.13	7.	0.90
Financial administration	4.	3.15	2.21	5.	0.94
Human resources	5.	3.23	2.09	8.	1.14
Different roles	6.	3.34	2.52	<u>1.</u>	0.82
Different people	7.	3.39	2.26	4.	1.13
Different places/equipment	8.	3.69	2.19	6.	<b>1.50</b>
Mean of means		<b>3.22</b>	<b>2.28</b>		0.94

According to respondents most of their time should be spent on *Planning and managing operations* but they actually spent second most time on it, – so the actual usage of time and wishes are almost balanced (difference of one place). The same situation is in the *Customer and market-oriented function* and *Financial administration* elements, which also have a difference of one place. The third important function on which time was spent (future state) was the *Personal development* element. According to actual usage it was only in seventh place, a difference of four places. The usage of time does not correspond to the wishes in the *Personal development* element. The fifth important function how to spend time (future state) was the *Human resources* element. According to actual usage it was in eighth place, a difference of three places. The usage of time does not correspond to the wishes in *Human resources* element either. The biggest difference in orders is, however, in the *Different roles* element, five places (future state sixth place, present state first place). The respondents spend a great deal more time than they would wish on the *Different roles* element. The situation is the same in the *Different people* element, a difference of three places and *Different places/equipment* element, a difference of two places. In both elements the respondents spent more time than they would like. (TABLE 13)

To sum up, in (present state) most of time was spent on ‘Customers’ (*Different people* element), ‘In office’ (*Different places* –element) and in ‘Interactive, productive salesmanship and customer service’ (*Customer- and market-oriented functions* element). In future state, respondents would like to use most of their time on ‘Maintenance of family-/friendship relations, the second most ‘Physical hobbies’ and third most on ‘Taking care of affairs connecting to confidential post (in work life)’ all three belonging to the *Personal development* element.

## The Inner Comparison of Data: Influence of Age, Gender, Education and Parenthood

Is the usage of time different (present and future states) based on different groups? It will be analyzed comparing the data with Mann-Whitney-U-test. The focus is on the influence of age, gender, education and parenthood on eight elements of usage of time. Only the statistically significant differences  $p < 0.05$  will be mentioned.

### The Inner Comparison of Data (Age, Gender, Education and Parenthood) - Present state: Age

The respondents were categorized based on age into four groups: Group 1. = 53 years old or older ( $n=53$ ); group 2. = 43 – 52 years ( $n=237$ ); group 3. = 33 – 42 years ( $n=246$ ), and group 4. = 32 years or younger ( $n= 120$ ). The comparison is between the oldest (53) and youngest (120) respondents. The only significant difference ( $p=.007$ ) was ‘Mental hobbies’ (*Personal development*) in favor of the oldest respondents.

### Gender

Female 163 and male 493  $n= 656$ . A significant difference was found in 14 out of 44 statements; 11 statements in favor of women and 3 in favor of men. (Table 14)

TABLE 14: DIFFERENCES IN USAGE OF TIME: INFLUENCE OF GENDER.

Usage of time	no signif.	statistically significant difference $p < 0.05$
<i>Planning and managing company operation</i>	X	
<i>Development of customer- and market-oriented functions</i>		Interactive, productive salesmanship... (f+) * Customer satisfaction (f+)
<i>Development of human resources</i>	X	
<i>Development of financial administration</i>		Pension, accident and unemployment ins... (f+)
<i>Personal development</i>		Studying the skills needed in work (f+) Mental hobbies (f+) Maintenance of family-/friendship relation.. (f+)
<i>Different roles</i>		Dissemination role (f+) Technical role (f+)
<i>Different people</i>		Employees (f+) Customers (m+)
<i>Different places/equipment</i>		Office (f+); Dealing with email (f+); Lunch (m+); Transportation (m+)

\* f+ in favor of women, m+ in favor of men

Only the *Planning and managing operations* and *Human resources* elements had no significant differences influenced by gender Table 14.

### Education

Does education influence the actual usage of time? The respondents were categorized into four groups: group 1. = no degree or vocational; group 2= college-level training or O-level; group 3.= lower academic, and group 4.= higher academic degree. 94 respondents were in group 1, 294 in group 2, group 100 in group 3, and 61 in group 4, with 107 unaccounted for. In a comparison of groups 2 and 4, the only significant difference ( $p=.016$ ) was in favor of group 4 ‘Other owners of the company’ (*Different people* element).

### Parenthood

Does parenthood influence the actual usage of time? 79 of the 605 respondents had no children and 526 had one or more children. No statistically significant differences were found.

### The Inner Comparison of Data (Age, Gender, Education and Parenthood) -Future State:

#### Age

Comparison is between oldest (53) and youngest (120) respondents. No statistically significant differences.

#### Gender

Comparison between 163 female and 493 male respondents showed significant differences in favor of women were found in 10 statements, none in favor of men. Women would like to have extra time significantly more than men in three statements belonging to *Human resources*. Women are more people-oriented so this result was predictable like

the result that women also wanted to spend extra time in five statements belonging to *Different people* element. Women also wanted to be able to use significantly more time on ‘Taking care of affairs connecting to confidential post (outside work life)’ (*Personal development* element) and handling in ‘Interpersonal role’ (*Different roles* element).

#### Education

Comparison between groups 2 and 4 showed that differences in 17 statements were all in favor of respondents having a higher academic degree. See Table 15.

TABLE 15: DIFFERENCES IN USAGE OF TIME: INFLUENCE OF EDUCATION

Usage of time	No Significance	statistically significant difference $p < 0.05$
<i>Planning and managing company operation</i>		Follow transactions, critical evaluation of state Planning, developing production/services Executing plans, using org. and manage. skills Forecasting functions, mapping out risks
<i>Development of customer- and market-oriented functions</i>		Segmenting customers by profitability Customer satisfaction Interpreting market research, competit analyses
<i>Development of human resources</i>		Enhancement of team spirit Eliminating resistance to change Attending to the wellbeing of the personnel
<i>Development of financial administration</i>		Planning, controlling, directing economy Profitability, liquidity, financial stability.... Profit + loss accounts, balance sheets, budgets Interpret annual accounts, reports, and key f... Using accountants, when planning, controlling? Defining indicators for surveying the business Accounting and taxation
<i>Personal development</i>	X	
<i>Different roles</i>	X	
<i>Different people</i>	X	
<i>Different places/equipment</i>	X	

#### Parenthood

605 parents were with children and 79 without. The only significant difference ( $p = .040$ ) was working in ‘Office’ (*Different places/equipment* element) in favor of parents. Dividing 24 hours of day and night on work, making housework, and taking care of children, studying, having free time and sleeping show present and future states as well as the length of workday.

#### Work (including transportation) n= 310.

The work time spent on work was based on workdays (five days). Niemi & Pääkkönen, 2002 study used seven days. The mean time spent on work (present state) is 11 hours, median 10 hours; 130 respondents spent 10 hours and 80 12 hours. The future state part got only 30 answers. Few answers do not provide reliable information.

#### Housework (Including Cooking, Cleaning, Repairs, Maintenance, Gardening, Paying Bills, etc.) n=305.

The mean time spent on housework (present state) is 1.7 and the median 2 hours, but 125 respondents (41 %) spent 2 hours and 116 (39 %) 1 hour. Future state n= 267. 118 (44 %) respondents wanted to spend *moderately more* and 107 (40 %) a *little more* time on housework.

#### Taking Care of Children (Including Transportation) n= 218

Mean time spent taking care of children (present state) is 1.1 and median 1 hour, but 85 (36 %) respondents spent no time taking care of children. Future state n= 218. 85 (39 %) respondents were satisfied with time spent taking

care of children, 70 (32 %) wished to be able to use a *little more*, 47 (22 %) *moderately more* and 16 (7 %) *much more* time for taking care of children.

**Studying (Including Transportation) n = 217**

The mean and median time spent studying is 1 hour. 69 (32%) respondents spent no time, 102 (47 %) 1 hour, 35 (21 %) two hours, 5 (2 %) three hours and 2 even six hours a day. Future state n= 197. 89 (45 %) respondents wished to spend a *little more*, 69 (35 %) were satisfied, 34 (17 %) wished to spend *moderately more* and 5 (3 %) *much more* time studying.

**Leisure, n=300**

Both mean and median for leisure was 3 hours. 76 (25 %) respondents had two hours, 68 (23 %) three, 46 (15 %) four, 45 (15 %) one, 31 (10 %) had five, 12 (4 %) six and 12 (4 %) even seven hours leisure. Future state n= 186. 74 (40 %) wanted *moderately more*, 63 (34 %) *much more* and 43 (23 %) a *little more* free-time. 6 (3 %) of respondents were satisfied with their leisure.

**Sleeping, n= 307**

Mean is 6.9 and median 7 hours for sleeping. 133 (43 %) reported sleeping eight hours, 84 (27 %) seven, 44 (15 %) six, 14 (5 %) nine and 10 (3 %) only one hour. 11 respondents reported not sleeping at all. Without those that did not sleep the mean would be 8.6 hours and median 8 hours.

Future State n=20

So few answers did not provided reliable information.

To sum up, the day and night of the median respondents is as follows: 10 hours for work, 2 housework, 1 taking care of children, 1 studying, 3 leisure and sleep 7 hours.

According to the means the day and night are spent as follows:

Work (incl. transportation)	11.00
Housework (incl. cooking, cleaning, maintenance, gardening, paying bills)	1.42
Taking care of children (incl. transportation)	1.06
Studying (incl. transportation)	1.00
Leisure	3.00
Sleeping	6.52
Total	24.00

Present state. This part of the study attempts to give a picture of an actual workday of an entrepreneur. Converted to weekly work hours (according to means) work hours will be 55 hours (according to medians 50 hours). According to the earlier study of Niemi & Pääkkönen, 2001, entrepreneurs (mean of male and female) worked 5 h 54 min/seven days, converted to 5 days' weekly hours it would be 41 h 18 min. So the entrepreneurs in this study have about a 2 hour 43 min longer workday ( $11 - 8.17 = 2.43$ ) the respondents of this study spent 55 min less time for housework ( $2.37 - 1.42 = 55$  min), 32 min less ( $1.38 - 1.06 = 32$ ) for taking care of children and 3 min less ( $1.03 - 1 = 3$  min) for studying, 1 hour 46 min ( $4.46 - 3 = 1.46$ ) less for leisure, and 1 h 28 min less ( $8.20 - 6.52 = 1.28$ ) for sleeping

Future state. Only a few respondents expressed their wishes concerning the amount of work. Evidently they are content with the amount of time spent working. 118 (44 %) respondents wanted *moderately more* time for housework (n=267) and 107 (40 %) a *little more* time. 74 (40 %) (n= 186) respondents wanted *moderately more* for leisure, 63 (34 %) *much more*, and 43 (23 %) a *little more* leisure. Six entrepreneurs (3 %) were content with the amount of leisure.

**Conclusions**

This paper aimed at shedding more light on the profile of a Finnish SM entrepreneur and increasing the amount of research by emphasizing the themes and elements which become evident as usage of time. This paper aims at answering the following questions:

- 1. How does the workday of an entrepreneur divide between different elements and how does one want it to divide? As a sub question: Are there any differences based on age, gender, education or parenthood?

- 2. How are the 24 hours divided and how one wants them to be divided? As a sub question: What is a length of the workday?

In answer to the first question it can be seen that according to their own opinions the respondents spend most of their time handling and functioning in *different roles* and of the roles the 'technical role' was emphasized. Entrepreneurs must spend plenty of time actually working (for instance in manufacturing or selling). This is because the responding companies are small in size. According to Mintzberg's (1982) research results, the managers in the smaller companies spend their time more on manufacturing. The decision-making role was also emphasized. Particularly in small companies, the entrepreneur is often the only decision maker. The second biggest time consumer was the *Planning and managing operations* element, again due to the small size of the companies. In Tengblad, 2002 most of the time was spent on financial and administrative affairs and the dissemination role.) The least time in this study was spent on *Human resources* and the second least on functioning in the *Personal development* element. Evidently these two are elements where time can be most easily deducted without immediately disturbing the normal functions and operations of a company. Most of the time was spent equally on single statements: 'With customers', 'Office', 'Selling/customer service'.

SM entrepreneurs are closer to their customers than the managers of big companies. But the amount of time working in the office is about the same as in the other studies. Most extra time was wanted for the *Planning and managing operations* element. This understandably is very important for the company and also one that entrepreneur can not delegate. Time is very easily spent on routines, but for planning one must deliberately find time and allocate more than just a few minutes. The second most extra time was wanted for work in the *Development of customer- and market-oriented function*. In a small company the customer cannot be forgotten even for a moment. Entrepreneurs wanted to spend least time on *Different places/equipment*. The difference between the present and future states was greatest in this element. Eating and transportation take time, which was a worry. According to other studies these obligatory breaks are important and entrepreneurs ought to try to relax and enjoy these breaks worrying just uses up energy and creates negativity. The second least extra time respondents wished to have to spend was on *Different people*. According to public discussion managers and entrepreneurs must always have their door open to employees to come, but this study shows that entrepreneurs do not want to spend more time with their employees (future state: the eight last place). The 'Maintenance of family-/friendship relationships', 'Physical hobbies', and 'Taking care of affairs connecting to confidential post (work)' all in the *Personal development* element were emphasized and at the top of the list for extra time. Additionally, 'Mental hobbies' work was emphasized. The most important value (Valjakka, 2005 "Life values and company work"... ) of these very same entrepreneurs was 'The family, its safety and taking care of family members', so it is evident they would like to have more time to spend with the family. Also the 'Physical state' of these respondents (Valjakka, 2006 "Is Modesty attractive?") had the mean of 2.63 which meant *hardly well* (the lowest figures in its category). A good physical state also helps in mental pressures and, on the other hand, Finnish society places a high value on good physical condition.

To answer to the question: 'Are there any differences based on age, gender, education or parenthood concerning usage of time, in both the present and future state?' it can be seen that the influence of age is insignificant, at least compared to that of gender and education. The only statistically significant difference (present state) was in 'Mental hobbies' where the oldest respondents spent more time ( $p=.007$ ).

Gender, on the other hand, had a lot of influence. In the present state women spent more time on three statements belonging to the *Personal development* element. These were 'Studying the skills needed in work', 'Mental hobbies', and 'Maintenance of family-/friendship relationships'. Additionally more of women's time was spent on two of the statements in *Development of customer- and market-oriented functions*: 'Interactive, productive salesmanship and customer service' and 'Customer satisfaction'. Additionally women spent more time on four other statements. Male respondents spent more time than women on 'Customers', 'Lunch', and 'Transportation'. See Table 14 on page 9.

Gender. Future state. In the summary of 44 statements examined, women wanted extra time in ten statements, men in none. What does this say about women? Respond the usage of time of women worse their wishes than men's? Are women slow and ineffective workers compared to men? Or do women have a higher standard concerning their performance? Or do women have lower self-esteem than men?

Parenthood, or actually non-parenthood only influenced work in 'Office'; non-parents wanted to work significantly more in their own office than parents.

The influence of education (present state) can be seen in the statement 'Other owners of the company' belonging to *Different people* –element. The most highly educated spent significantly more time with other owners than those having college-level education. In the future state, education significantly influenced 17 statements in favor of those having a higher academic degree. See Table 15 on page 10. Higher education seems to add to the feeling of inadequate skills especially in financial affairs. The old Finnish proverb (Mikä tietoa lisää, se tuskaa lisää) "What adds knowledge, adds distress" seems to be true with regard to the results of this study concerning education. Or those having higher education have a higher standard concerning their performance.

In answer to the question: 'How are the 24 hours divided and how one want them to be divided?', the division is as follows: work takes 11 hours, housework more than one and a half hours, taking care of children about one hour, studying one hour, leisure three hours and sleeping almost seven hours. The entrepreneurs in this study clearly spend more time working than other professions, excluding male farmers (Niemi & Pääkkönen, 2001). According to several studies concerning usage of time, the length of the workday is 11 hours, so the evidence of this study supports the result of other studies. The respondents were not satisfied with the division of the 24 hours, wanting more time for housework and leisure.

# The Development of Thai Entrepreneurs

John Walsh, [jcwalsh@shinawatra.ac.th](mailto:jcwalsh@shinawatra.ac.th)  
Shinawatra University, Thailand

## Abstract

Entrepreneurialism in Thailand has been hampered throughout known history by the segregation of the labour market, the lack of governmental and institutional support for local firms and the low level of emphasis placed upon value-adding activities. The result has been that the bulk of entrepreneurial activity has been organised and controlled by people from other countries. This situation has persisted into the modern age and it was not until the inauguration of the systematically pro-business Thai Rak Thai government that significant, Kingdom-wide efforts were made to encourage high quality entrepreneurial activity in the wake of the 1997 financial crisis, which had already flourished in terms of numbers as many industrial, urban jobs were lost. It is not yet clear whether these efforts have been sufficient to embed desirable types of activity thoroughly into the bedrock of the economy.

## Introduction

The renowned Thai historian Chatthip Nartsupha wrote in his seminal work *The Thai Village Economy in the Past*: “The Thai village economy in the past was a subsistence economy. Production for food and for own use persisted and could be reproduced without reliance on the outside world. Bonds within the village were strong. Control of land was mediated by membership of the community. Cooperative exchange labour was used in production. Individual families were self-sufficient. Agriculture and artisan work – that is, rice cultivation and weaving – were combined in the same household ... Production relations were similar to those of the primordial socialist community – a small community in which people help one another in a spirit of common humanity” (Chatthip, 1999, p.73).

This very influential viewpoint concerns the heart of what it means to be a Thai: to live in a village free from external control and to grow rice. The concept of the village seems almost to be one of paradise. As a consequence, anything that challenges the ways that the traditional villagers live and the way they try to change their lives will always be seen to be antithetical to Thai-ness and, consequently, wrong. As village life has become monetized and the villagers themselves have attained levels of personal mobility and transportation that has freed them from isolation, they have sought out cash paying income for periods when their labour is not needed in agricultural pursuits. Now, villages throughout Thailand boast at least some houses with air conditioning, satellite TV and other emblems of twenty first century consumerism. As people are able to achieve their dreams of personal wealth, they also become estranged from their roots and the moral values attached to those roots. This is not a phenomenon that is restricted to Thailand, of course, although it is held strongly in the Kingdom, which retains many very powerful and conservative social institutions. The concept of an entrepreneur, therefore, which is wholly lacking of Chatthip’s conception of village life, is an alien one to the Thai way of life, no matter how well and avidly many Thai people have taken to it. As trade in its various forms has, throughout recorded history, been controlled and conducted by people from other countries, the correlation between trade and the non-Thai has become more firmly established. Entry into the world of commerce has become primarily the preserve of ethnic Chinese, while those who consider themselves more purely Thai prefer government service or the professions, if possible. Of course, this concept of ‘ethnic purity’ is next to meaningless (or, more accurately, highly susceptible to manipulation of social perceptions and expectations) in a land in which waves of migration have led to the thorough intermixing of dozens of different ethnic groups (Evans, 1997).

Resulting from some ambivalence about the role and importance of entrepreneurial activity, therefore, the growth in the number of entrepreneurs required by the modern age has led to some social concern. Efficiency in all forms of agricultural production has yet to penetrate all sectors of the industry in Thailand but it has achieved enough that it would no longer be feasible to argue that, overall, farmers are now primarily involved in subsistence

agriculture. Consequently, more people are freed to work in other forms of activity and, at least in the closing decades of the twentieth century, the long-term blight of the Thai economy, under-population, has been largely resolved and so urban populations have grown. The urban environment has never been described as a 'primordial socialist community' and has always been regarded as a place where commerce has sovereignty over many other forms of non-feudal activity; that is, activities which came under the jurisdiction of the crown and the feudal system which supported it remained their supremacy, even though agencies of the crown used commercial institutions to transact the state's business. Ultimately, support for business and the entrepreneurs who are an important part of creating it came into direct conflict with socially conservative elements in Thai society in the form of organised street demonstrations against the Thaksin Shinawatra government which achieved their aim of restoring military dictatorship to the country. However, in the twenty-first century, business has become such an important part of a sophisticated modern society that it would be almost impossible to try to suppress it without serious damage to the economy overall.

This paper investigates the ways in which entrepreneurs and attitude towards entrepreneurs in Thailand have changed through history and pays particular attention to the ways in which entrepreneurs have been supported since the 1990s and what the future prospects for these issues are likely to be for the future.

#### **Entrepreneurialism in Premodern Thailand**

Throughout recorded history until the modern age, the majority of Thais were subsistence rice farmers who owed the monarch a period of *corvée* labour which could last for several months per year. The *corvée* labour period was generally spent in civil engineering projects or else military service. Men, therefore, found their lives to be circumscribed by the seasonal needs of agriculture and the need to serve the state. Women were more likely to enter into petty trading, using barter to exchange home made food or handicraft items. This was necessary since men were unavailable. The history of the great cities such as Ayutthaya and Angkor Wat in Cambodia, abound in accounts of women rowing small boats through the many canals which were the main urban thoroughfares and selling their produce. Most of these women entered the city to trade and returned to their rural homes subsequently. Urban areas were the homes of government and its religious and military apparatus. They were also the homes of artisans, who made items that brought status to rulers and which were also of intrinsic economic value. Since the non-elite Thais were restricted to rice farming, most artisans had to be imported from other areas, either voluntarily or involuntarily. The warfare that was endemic throughout mainland Southeast Asia for most of known history was largely motivated by the desire to increase manpower and, so, capture slaves. For example, The Chiang Mai Chronicle records King Mangrai the Great travelling to Phukam-Ava in the last decade of the thirteenth century because he had heard of the famous god, silver and bronzesmiths living there. Accompanied by his army, the mighty Mangrai obviously made a powerful impression because the Burmese king of Ava granted him 500 artisan families to take with him back to his capital of Chiang Mai (Wyatt and Aroonrut, 1998, p.39).

After the establishment of Ayutthaya as a great city, many forms of trade were conducted both domestically and with overseas traders. Indians, Persians and Chinese were very important in organizing the trade of the nation. Most Thai people had no role in the trade, even though their home villages might already have been converted to economic specialties. For example, the Chronicles of Ayutthaya describe villages known as, among others, Hamlet of the Shrimps, Village of the Gong Shed and Village of Sweet Mango (Cushman, 2000, *passim*). The movement of peoples around the country, it would seem, had already reached the level by which specializations had been achieved. Since these villages had been placed under the ownership of one of the elite classes of nobility or privileged Chinese merchants, it would be inaccurate to describe the individuals involved as entrepreneurs. However, as the owners of the artisans were unlikely to have a high level of technical knowledge of the crafts involved, it was the workers themselves who would have been involved in innovation and new product development, albeit at not a very rapid pace in most examples. Although, not many of all the associations have been retained through the centuries until the present.

Vietnamese were important early entrepreneurs in the country. As foreigners, they were exempt from *corvée* labour and poll tax and, so long as they could put up with occasional harassment, they could establish their small businesses wherever they could find an empty patch of land and a market. This was particularly common in the northeastern part of the country known as Isan. Étienne Aymonier, who traveled the region in 1883-4, observed that:

“ ... my travelers saw some tens of huts of other Annamese [Vietnamese] who had lived there for five or six years. They burned patches of the forest to plant rice and they distilled alcohol. Being foreigners, they had no poll tax to pay. And because they had come from the border areas of Annam, they knew nothing about their country” (Aymonier, 2000, p.100).

Foreign entrepreneurs have remained important in Thailand, since many of the Thai people lack the education and experience to create lucrative new businesses themselves. It has been observed that Thais are naturally entrepreneurial in nature and a trip to any town or city would reveal the diligence with which so many try to create some profit. However, it has often been necessary for outsiders to show how a new and unknown form of skill or knowledge may be exploited to create a surplus. In recent years, Dr Harvey Ludwig established Seatec International as an environmental engineering consulting firm, which was the first such business in Thailand. Many Thai engineers received training and experience from the company and then subsequently left to establish their own consultancies (Ludwig, 2006).

The rural-urban system had already become established during the period of Ayutthayan ascendancy. When that city was razed to the ground by the invading Burmese army in 1767, the founder of the new (and continuing) Chakri Dynasty established a new capital at Bangkok, albeit initially on the Thonburi side of the river. Goods were grown or created in rural areas under the control of merchants or elites and then sold in urban markets. This is clear from the description of entrepreneurial activity by Fournereau who, visiting the capital in 1892, observed the vibrant Talat Noi (ironically, ‘little market’) and the entrepreneurial activity therein:

“This market is the greatest of Bangkok one finds anything one desires here and naturally, by preference, things from English or German origin. Like in France, in the Middle Ages, each type of business has its special quarter here: in the first part, called Talat Noi, one finds the carpenters, the coopers, the basket makers, the bottle merchants, haberdashers, a few government operated pawnshops, Chinese restaurants and, finally, small stalls in which low quality silks, cloths with flower patterns used for making sarongs, Indian cloths, cotton threads, hats, etc., are sold. The majority of these stalls belong to Chinese (Fournereau, 1998, p.51).

The entrepreneurial activities available for the majority of the common people, therefore, were strictly limited to marketing and petty retail activities. There was no leadership in promoting entrepreneurial activities or in fostering conditions in which high value-adding activities can take place (Ayal, 1966). Public sector activities to foster entrepreneurialism were hampered by lack of resources and understanding (Marsden, 1984).

A similar system has persisted in modern Bangkok, in which large numbers of market traders work hard to earn small amounts of commission from trading goods which belong to a larger scale entrepreneur, who acts in the form of a landlord. This can provide opportunities for small-scale traders to come into contact with much larger economic actors and to enter into relations with them:

“The interaction between micro-entrepreneurs and the volatile real estate market as mediated through relations with landowners’ points to spatial transformations of selling environments vis-à-vis inputs of capital. This results in both opportunities for and marginalization of small-scale cooked-food sellers. Some small food-shop owners have relocated within the growing number of food centres in the city, most situated in department stores and shopping plazas” (Yasmeen, 2006, p.183).

The economic history of Thailand, in short, reveals a series of connected characteristics which are features of entrepreneurialism in the country: most activities are micro-scale in size (i.e. fewer than 10 employees and usually just single-person), retail and service sectors are dominant and women are over-represented numerically. The margins on which the businesses operate are also generally very thin and a sudden economic shock can leave many thousands in a negative cash flow position. A survey of small-scale entrepreneurs in Bangkok and Phetchaburi in 1999 found that most were aged 30-40, with a few older and very few younger. Their education level was lower than average and most had completed only the elementary level of education. Women predominate in the micro-enterprise category, either because of lack of access to suitable resources or because of a long-standing attitude towards gender-suitable work (Maitree, 1999). There are, certainly, larger-scale entrepreneurs and many of these are able to prosper because of already existing connections established by family and relatives. Thailand is a generally low-trust society in which family connections are often significantly more important than economically-based relations. This makes members of influential family-based networks particularly attractive as business partners.

Panthongthae Shinawatra, the son of former Prime Minister Thaksin, was able rapidly to attract capital and success to his media import company in large part because of the willingness of partners to establish a relationship with him. The history of Thai entrepreneurialism, therefore, demonstrates the low level of value-added activities that have been permitted to those Thai people able to participate in entrepreneurial activity. More economically advanced activities have traditionally been entrusted to or controlled by nationals of other countries. Thai entrepreneurs with good ideas for new business activities have often found their inspiration from an overseas partner or educational institution, although there have of course been some natural born geniuses who have personally created new businesses and industries, although this has been rare. Research among entrepreneurs in the Isan region has demonstrated that, up until the 1990s at least, these issues remained relevant to Thai entrepreneurialism. It was dominated by people of ethnic Chinese origin and the activities they pursued were clustered into a comparatively small number of sectors. Personal networking through professional organizations was also a powerful tool (Ueda, 2000). Subsequent research has failed to find tangible links between the possession of network connections and information and subsequently superior performance (Butler, Brown and Wai, 2003).

Research among the Vietnamese migrant community in Thailand also demonstrated the importance of personal connections in establishing a successful business and the clustering of entrepreneurs into a restricted list of industrial activities. After the migration of Vietnamese across the Mekong in 1945, for example, a secret committee established an unofficial machine repair training facility and, as a result, many young Vietnamese men opened businesses in this field subsequently (Walsh and Nguyen, 2005).

### **The 1997 Financial Crisis**

In the years leading up to 1997, the Thai economy was hurtling along at a rapid and seemingly accelerating pace. As subsequent events demonstrated, this progress was hiding a number of structural problems which were revealed with, for many, disastrous results. The closing of many industrial facilities led to the large-scale movement of people out of regular employment and into semi-employment or unemployment. Some people in these categories also started their own businesses. The impact on people in different business sectors was very varied and the ability to cope depended considerably on internal resources such as resilience and determination. Many people faced the prospect of returning from Bangkok to provincial homes where they might be able to find partial or full employment in the agricultural sector, which was benefiting from higher cash prices for some agricultural products. However, most such people had already rejected the agricultural life and preferred to live in the urban environment. To do so, a number of people resorted to petty trading entrepreneurialism and related trades. Food vending and market stall management were popular and available choices. Between 1997-8, the number of people employed in the private sector declined by nearly a million (8.2%) and the number of people in the unpaid sector by more than 300,000 (5.5%) and, while some of these losses were countered by increases in the 'employed' and 'own account' categories (National Statistical Office figures, 1998). However, the total size of the active labour market declined by more than 850,000, which represented a 2.8% decrease overall. Those who were most vulnerable were generally those with lowest levels of education and income (hence savings). When members of the affected population enter entrepreneurial activities, therefore, they are most likely to do so in sectors which offer low margins and few opportunities for improvement.

The 1997 crisis revealed, among many other things, the lack of a coherent, integrated and overarching labour market policy in Thailand.

There are certainly elements of labour market policy objectives which are principally enacted by public sector agencies with diligence and determination but these are not part of a wider whole infused by a vision of what is required for future economic growth. Many other countries share a similar situation, of course, although that does not make the situation any better. A labour market policy for modern Thai society should integrate at least the following elements:

- Active labour market elements: policies and agencies to assist people move into new work opportunities through vocational training, job matching and database management schemes;
- Passive labour market elements: social security payments for the unemployed or those unable to work;
- Migration management policies: thousands of Thais go overseas to work temporarily or permanently, while more than one million overseas migrants are in Thailand in a variety of officially and

- unofficially registered activities. Policies are needed to identify a vision for managing these situations and ensuring that individuals and skills meet current and future jobs;
- Education: there is a need to identify future skills and competency needs and to provide schools and colleges with the resources to enable willing students to obtain those skills and competencies.
  - Business support for entrepreneurs, including research and training facilities, micro-credit support schemes, credit facilities and similar activities.

Currently, these various functions are divided among a host of different and often overlapping government agencies. Coverage of the entire Kingdom is not always assured and long-term funding is rarely guaranteed. Research has indicated that a number of entrepreneurs are not satisfied with the complexity of the search for specialist support that they need, especially when considering the often very limited resources of time and money that they have and on which there are numerous other calls. The quality of support is also not consistently high and this exacerbates the often incipient problems of mistrust between the private and public sectors.

Maitree (1999) found that a sample of SME executives had the following constraints in improving their business prospects:

- Lack of or limited access to credit financing
- Lack of access to wider markets
- Lack of capability for business planning
- Lack of or limited skills of workers
- Lack of knowledge or information on technology
- Lack of skills in financial management and simple accounting
- Lack of knowledge or information on other markets and on business opportunities
- Lack of knowledge or information on tax laws and other commercial laws and regulations.

The next government of Thailand, which was a broad-reaching coalition of political interests under the banner of Thai Rak Thai (Thais Love Thais) led by Thaksin Shinawatra, aimed to address some of these issues. Of course, there had been initial examination of the conditions in which entrepreneurs might flourish prior to Thai Rak Thai, with a number of politicians sponsoring and supporting schemes of differing levels of success. These included the promotion of technology development and business incubation (Swierczek, 1992). However, these attempts were rarely if ever systematically deployed or deeply embedded in the commercial system of the country.

#### **The Thaksin Administration**

The Thai Rak Thai party was elected under a pro-business manifesto and the intention to develop regional Thailand from which it drew most of its support. It also included support from labour unions and activists and a number of radical thinkers who had, in previous decades, been categorized as and excoriated for being Communists. Some of these coalition partners broke with the government in power.

A variety of new institutions was created to support small and medium-sized enterprises (SMEs) as part of a policy programme that came to be known, sometimes vituperatively, as ‘Thaksinomics,’ which was based on the concept of reducing dependence on external demand (export industries) fed by manufacturing industries in urban areas and on unproductive asset speculation (i.e. the property bubble), through developing domestic demand and traditional sectors of the economy. This has led to a dual track form of economic development and it had five main policy areas:

- Revitalizing growth at the grassroots level
- Jump-starting key sectors
- Enhancing economic efficiency and long-term competitiveness
- Providing a stable and supportive macroeconomic environment to facilitate growth while maintaining overall policy discipline
- Promoting the external sector through market expansion and fostering financial stability through regional and global cooperation (ADB, 2005).

Clearly, this policy set required considerable stimulation of the entrepreneurial segment of society and institutions and agencies were established in order to support it. One of the principal forms of support was the creation of the SME Bank<sup>1</sup>. The Bank describes its mission as being “... the leading bank for developing and strengthening

competitiveness of Thai SME entrepreneurs, in the drive towards a strong and sustainable growth of the Thai economy, with high-quality services, good governance, efficiency, and financial stability.” The services that they provide include multi-stage funding such as: general credit; factoring credit; packing credit; leasing and hire-purchase credits; joint venture; L/G (letter of guarantee); and Aval (a guarantee added to a debt obligation by a third party who ensures payment should the issuing person default). Numerous types of loans are also advertised under a variety of schemes, as well as a number of networking activities, newsletters and counseling services. Additionally, many training services are provided, including: New Entrepreneur Creation scheme; accounting system and software application; POS system training for small retail businesses; tax laws and planning training for SME entrepreneurs; market research and new product development training; product distribution and public relations strategic training for SMEs; intellectual property management training; modern financial management training; techniques for capital reduction in SMEs and training for early-retired government officers.

In addition to the SME Bank, there is the Department of Business Development, the One Tambon One Product (OTOP) scheme, the Institute for SME Development and the National Food Institute. It is not clear to what extent these services will survive the military government. OTOP is a scheme aimed at promoting local knowledge and products and selling them in both the domestic and international markets. As of the end of 2006, the 7,405 tambons (sub-districts) of Thailand produced more than 23,000 OTOP items (ThaiTambon.com, <http://www.thaitambon.com/English/TTBPRIA.htm>). The government has assisted the scheme by providing extensive trade fairs and marketing and distribution support which had not previously been available to local people. The purpose of the scheme was not just to promote local products but to enhance rural development while retarding the growth of internal migration. Inevitably, many products have been found to be uncompetitive because of lack of demand or, more importantly, lack of consistent supply and quality control. In a number of cases, government agencies through the Ministry of Labour (especially the Department of Employment) have been able to intervene to provide training and education to help remedy the shortfall in quality control and supply chain management. Once people have the incentive of being able to sell products they themselves have understanding of and to the improvement of which they might be able to contribute, then they are generally more receptive to receiving such training.

It is difficult to evaluate the success or the sustainability of the OTOP scheme overall because of the lack of comprehensive statistics and because many issues are shrouded in political complications. However, it is certainly true that domestic and to a lesser extent some international demand has been created and OTOP items have been integrated into the distribution systems of some large multiple retail stores. Ironically, these foreign-owned retail multiples have sporadically received criticism and demonstrations accusing them of destroying the regional economies of Thailand.

The bankruptcy law of 1940 was amended and enacted in 2004. It represented a modernization of some stipulations relating to the bankruptcy laws and restructuring of various fees and procedures. In bringing the bankruptcy provisions somewhat more closely into line with international norms, as represented by the International Association of Insolvency Regulators (IAIR), the Thai government promoted entrepreneurialism to some extent by reducing the negative implications of bankruptcy.

Figures from the Board of Investment suggest that the various measures were moving in the right direction; the Private Investment Index, which took a baseline of 1995 = 100, fell dramatically in 1997 and had only reached 81.6 in 2004, 87.9 in 2005 and 91.5 in August of 2006, before tailing away again after the military coup of September 2006 (BOI, 2007, [http://www.boi.go.th/english/how/private\\_investment\\_indicators.asp](http://www.boi.go.th/english/how/private_investment_indicators.asp)). Up to date indicators of business registrations are difficult to obtain, although the Department of Business Development figures suggest an initial rise in the number of new businesses. The labour market expanded from 2002 to 2004 by 5.0%, with the majority of this increase led by the private employee classification (15.3% increase). However, the situation remains very volatile with high churn rate of entrepreneurs – besides which, the technical capacity of the Thai civil service to record accurate, comprehensive and timely statistics is limited, especially given how many firms are part of the unofficial or black market sector. Some evidence suggests that the number of household-based businesses in semi-urban and rural Thailand as much as tripled in the wake of the financial crisis but it is not clear how many of these have ever been viable (Paulsen and Townsend, 2005).

## **The Current Agenda**

The military government has sought to differentiate itself from the previous, ousted government by declaring many of the previous policies inappropriate or improper as a result of being 'populist' in nature. It has promoted the concept of the Sufficiency Economy, which is closely related with the ideas of HM the King and, hence, beyond criticism of any sort within the country. The Sufficiency Economy has been summarised by the UNDP in the following way:

“The Sufficiency Economy is an approach to life and conduct which is applicable at every level from the individual through the family and community to the management and development of the nation. It promotes a middle path, especially in developing the economy to keep up with the world in the era of globalization. Sufficiency has three key principles: moderation; wisdom or insight; and the need for built-in resilience against the risks which arise from internal or external change. In addition, those applying these principles must value knowledge, integrity, and honesty, and conduct their lives with perseverance, toleration, wisdom, and insight.

Sufficiency in this sense should not be confused with self-sufficiency, turning inward, rejecting globalization, or retreating towards the mirage of a simpler world. Rather, this approach offers a way to cope with the unavoidable realities of the market and globalization in the contemporary world. The Sufficiency approach stresses that individuals need a certain measure of self-reliance to deal best with the market, and countries need a certain measure of self-reliance to deal with globalization. Sufficiency has the dual meaning of 'not too little' and 'not too much.' The principle of moderation or the middle way is a guide for finding the right balance between internal resources and external pressures, between the needs of society at the grassroots, and the imperatives of the global economy” (UNDP, 2007, p.XV)

It is noticeable that, throughout the whole length of this book length report, the word 'entrepreneur' is used only twice and, on both occasions, to describe events that happened prior to 1997. It may be assumed, therefore, that while the Sufficiency Economy is not necessarily antithetical to the concept of entrepreneurialism, it accords no particular value or virtue to the concept and, hence, little if any support will be provided for those involved in such activities. In this sense, therefore, the Sufficiency Economy may be seen as a return to the traditional, conservative view of Thai-ness and the proper role of people in the Thai economy. However, exactly how that view will be enacted in the future, with its endless bustle of events and external shock, remains to be seen. The 10<sup>th</sup> National Plan, for example, specifies the role of social entrepreneur in the development of the country, particularly with respect to the role of women. Indeed, much of the language of the military-appointed prime minister General Surayud Chulanont and his office in discussing the economy remains very similar to that of the previous, democratically-elected government, although most regional development policies have been scrapped. It is also not clear whether the military government will feel itself bound to follow the 10<sup>th</sup> National Plan, since it was approved in early September, 2006, a few weeks prior to the armed coup. If the junta has an alternative plan by which it intends to guide the development of the economy, then it has not yet shared this with the public.

## **Policy Recommendations**

In considering what might be done to strengthen the role of entrepreneurs in the Thai economy, it is impossible not to have to consider what is practical and will be considered acceptable as well as what is desirable. Even so, there are clearly some areas which must be addressed, popular or not:

- the OTOP programme is a success and should receive further funding and support. Of course, not all areas have been able to develop successful products and those in such tambons may be offered training to work on different products;
- continue to work with innovative free trade agreements such as the Japanese-Thai Economic Partnership Agreement which includes a private sector initiative by Japanese firms to provide apprenticeships in Japan for Thai workers;
- reassert the importance of lifelong learning in Thai society and encourage people to continue to invest in their own skills and competencies. Thailand currently enjoys something of a demographic dividend arising

from minimal payments in support for non-members of the labour market and now is the time to use that dividend to create a more skilled workforce;

- maintain existing provision of government services and be aware of response among customer groups and stakeholders and adjust the provision and nature of services in response to changes of demand;
- work with and within international organizations such as ASEAN and the ILO to obtain better training for the labour market and help in identifying new opportunities for entrepreneurs to consider.

The continuing and probably irreversible internationalization of the Thai economy will lead to the wider identification of possible entrepreneurial opportunities and products by potential or existing entrepreneurs. The introduction of mechanisms by which such innovation and creativity may be transmitted more widely throughout society would be very welcome.

## **End Note**

<sup>i</sup> SME is Small and Medium Sized Enterprises, which are conventionally categorized as firms with fewer than 250 employees. In Thailand, the great majority of SMEs are much smaller than this.

# Psychic Distance and the Market Entry of Finnish Software Firms to the Japanese Market

*Arto Ojala, Arto.K.Ojala@jyu.fi  
University of Jyväskylä, Finland*

## Abstract

**This paper investigates the concept of psychic distance in the Uppsala internationalization model by analyzing the market and entry mode choice of eight small and medium-sized Finnish software firms. The case findings in this study reveal that, despite of the psychic distance between Finland and Japan, most of the firms entered Japan at a very early stage of their internationalization process by using direct entry modes. This could be interpreted as a sign of the Uppsala internationalization model being non-valid or outdated in the present global business environment. Findings also imply that highly segmented product offering forced the case firms enter into countries which provide a large customer base. In addition, high requirements for close cooperation with customers in sales and after-sales processes increased the need for direct business operations. However, firms were able to overcome psychic distance by hiring local employees and western managers who already had working experience in the Japanese market.**

## Introduction

Several internationalization theories [5, 11, 14, 18, among others] describe internationalization as a gradually developing process through various “stages” where a firm enter first nearby countries using indirect entry modes, such as exporting, which require less commitment to the market. Once the firm has gathered more experience on the market, it starts to develop operations which require more commitment to the market and establish direct business operations such as subsidiaries or joint ventures. One of the best known and most cited internationalization theory is the Uppsala internationalization model [11, 14], which includes the idea that when firms start to expand their operations to foreign markets, they first enter countries with a low psychic distance to theirs and then gradually move on to countries with a greater psychic distance. Although the arguments in the Uppsala internationalization model seem reasonable, it should kept in mind that the model was developed from the viewpoint of large, well established multinational firms. For these reasons, several studies related to international entrepreneurship [2, 3, 6, 20] have investigated the applicability of the model to small and medium-sized high-technology firms. These studies propose that SMEs in the field of international entrepreneurship do not commonly follow incremental step-wise progress in internationalization [11, 14]. Although findings in these studies [2, 3, 6, 20] give support to the conception that high-technology intensive SMEs first internationalize their operations to countries with a low psychic distance to theirs, they have not found evidence supporting the incremental internationalization process viewpoint. On the contrary, SMEs in the high-technology sector tend to internationalize their operations simultaneously to several countries within short time period and using various entry modes.

The conceptual model of Bell et al. [4] suggests that high-technology intensive firms start to internationalize their operations to leading markets, such as the USA and Japan, soon after their establishment. A limited domestic market, niche market segments, and high research and development costs in high-technology sectors can function as drivers for entering markets with a large customer base and purchasing power [4]. For these reasons, this study focuses on small and medium-sized Finnish software firms’ internationalization to the Japanese market. Japan is among the leading markets in the world, and it is a very important market for foreign software firms. Japan is ranked as the world’s second largest software market after the U.S. [9], and the overall software market size in Japan was 131,773 million U.S. dollars in 2004 [23]. However, the Japanese market has commonly been cited as a difficult one to enter for foreign firms [e.g. 7]. Japan can also be characterized as a psychically distant country from Finland due to cultural and language differences [15].

## Literature Review

The concept of psychic distance came popular after Nordic studies by Johanson and Vahlne [11] and Johanson and Wiedersheim-Paul [14], known as the Uppsala internationalization model, were published. In the model, the factors that determine psychic distance between countries were defined as differences in language, culture, political system, level of education, level of industrial development etc. [14]. These factors affect a firm's capability to learn and acquire knowledge from the target country. Thus, the lack of knowledge of foreign markets and operations have proved to be the main obstacle for internationalization. Lack of knowledge relates to the differences between the home and target country. According to the model, firms are expected to enter first into familiar markets with a low psychic distance, but once they have acquired more knowledge about how to operate internationally they start to enter countries with a greater psychic distance. International experience is also connected to the choice of entry mode: a firm first starts irregular exporting to the target country and, while gathering more experience, it starts exporting via independent representatives, may establish a sales subsidiary, and may finally start its own production in the target country. The choice of entry mode is conceptualized as a learning process and increasing commitment to the market [11, 14].

In the Uppsala internationalization model, knowledge of foreign markets is divided into general knowledge and market-specific knowledge. General knowledge includes marketing methods of a product, operation modes, and typical customers in a global scale. It is mainly objective and transferable from previous countries entered to the target country [11, 12]. Market-specific knowledge is experiential knowledge about the target country environment, such as culture, the market structure, customers in the market etc. This knowledge is mainly acquired through operating in the target country [11] and it is highly tacit. Due to this tacitness it is difficult to acquire and transfer from country to country [17]. However, a firm can, to a certain extent, use their experiences and knowledge from earlier foreign operations when entering into a new country. Through their experiences in the market, the firm can learn the general characteristics of markets, such as how to act with customers, suppliers, competitors and public organizations [13].

## Psychic Distance in the International Entrepreneurship Literature

Several studies related to international entrepreneurship [2, 3, 6, 20, among others] have tested the suitability of the Uppsala internationalization model to explain internationalization behavior of small and medium-sized high-technology firms. These studies propose that SMEs involved with international entrepreneurship enter first to geographically close countries, which gives support to the concept of psychic distance. However, these studies have commonly found some additional factors, which explain internationalization of high-technology SMEs better than psychic distance between countries.

The study of Coviello and Munro [6] related to New Zealand-based small software firms implies that entry mode and market choice depend on firms' formal and informal network relationships which evolve over time. The firms' network relationships first give access to countries with a low psychic distance and, in time, these relationships enable market entry to countries with a greater psychic distance [6]. This is somewhat in line with the Uppsala internationalization model [11, 14], with the exception that the internationalization process of small software firms was very rapid, included less stages, and used a number of alternative entry modes simultaneously.

Findings in the study of Moen et al. [20] are consistent with the study of Coviello and Munro [6]. They found very little support to the Uppsala internationalization model related to the market and entry mode choice of small software firms. The entry mode choice of small software firms is more dependent on available network relationships than on the firms' international experience. Initial market selections were related to psychic distance whereas in later choices the psychic distance is less visible. However, their [20] findings suggest that firms prefer countries where English is commonly spoken, because it facilitates communication and networking. This finding gives some support to the concept of psychic distance.

In his study, Bell [2, 3] investigated the internationalization of small software firms in Finland, Ireland, and Norway by validating the applicability of incremental internationalization models in explaining the

internationalization behavior of software firms. Findings of the study suggest that software firms internationalize their operations first to countries with a low psychic distance, but there are other explanatory factors with more explanatory power than the concept of psychic distance. Bell [2] found that internationalization behavior of firms is more related to customers' followership, niche markets, and industry-specific characteristics than to systematic steps or stages as suggested in the Uppsala internationalization model.

## Summary and Research Questions

Altogether, earlier studies propose that the concept of psychic distance is valid, to some extent, in the internationalization process of both large multinational firms and SMEs in the high-technology sector. However, these studies have commonly taken a cross-national viewpoint without focusing on any specific country. For this reason, this study investigates the market entry and entry mode choice of eight Finnish software firms in the Japanese market. According to the concept of psychic distance, Japan can be ranked as a country relatively distant from Finland. Thus, in line with the concept of psychic distance, Finnish firms are supposed to enter the Japanese market only after operating directly in several less distant countries. This helps to validate the applicability of the traditional internationalization theories regarding the present global business environment. Therefore, the following questions are of particular interest in this study:

1. To what extent does psychic distance influence market entry to the Japanese market?
2. To what extent does psychic distance influence entry mode choice in the Japanese market?
3. What are the particular reasons for market entry to the Japanese market?
4. How are firms able to overcome psychic distance in the Japanese market?

## Research Method

The multiple case-study method was selected for this study due to the explanatory nature of the research question. Eisenhardt [8] holds the view that multiple case-study enables studying patterns that are common to the cases and theory under investigation. The case-study method also makes it possible to explain the significance and cause-and-effect relationships of the examined phenomena [24].

The case firms were selected for this study for theoretical reasons and not by random sampling [8]. The selected firms complied with the following criteria: a) they have their headquarters in Finland, b) they have direct business operations in the Japanese market, c) they do business in the field of software, and d) they have a maximum of 500 employees worldwide. Focusing on one single sector in this study helps to complement existing studies related to the software industry [2, 3, 6, 20] and reduces the potential for confusing results [22]. In addition, it allows comparing research results to earlier findings in the software industry, especially to those related to international entrepreneurship. Internationalization process of the case firms in this study was limited only to direct business operations in the target countries (excluding Japan) due to the fact that software products are easily delivered through Internet or firms' file transfer protocol (FTP) server making traditional exporting activities less important than was the case previously.

In this study, Finland was chosen as the country of origin due to its small and open economy with a very limited domestic market. Due to its small domestic market, internationalization is generally a common growth strategy for Finnish software firms. Japan was chosen as the target country for the following reasons: firstly, Japan has the second largest market for software products. Thus, it is among the leading markets for software firms. Secondly, as recognized in several studies [e.g. 7], Japan is a very challenging country to enter and conduct successful business with. Thirdly, due to language and cultural differences between Finland and Japan, Japan can be characterized as being a psychically distant country from Finland [15, 18]. Finally, choosing Finnish software firms in Japan enabled addressing the target group, to a large extent, by using a qualitative case-study method.

Suitable firms for this study were identified from the websites of the Finnish Chamber of Commerce in Japan and Finnish Software Business Clusters, as well as from a list of firms in the publication "Software Product Business Cluster in Finland 2005". By using these sources a total of nine suitable firms were identified. These firms

were contacted with an e-mail request to attend the research. Eight of the nine firms answered and were willing to share their knowledge and their experience of the Japanese market.

Altogether 16 semi-structured open-ended interviews were conducted with managers in each firm's headquarters in Finland and their units in Japan. All executives (with titles: CTO, Director, Executive Vice President, President, Managing Director, and Sales Administrator) that were interviewed had an in-depth knowledge of their firms' international operations and the entry to the Japanese market. The 60-90 minute-long interviews were digitally recorded, carefully listened to, and transcribed verbatim with the help of a word processor. A second listening was arranged to ensure correspondence between the recorded and transcribed data. Complete case reports were sent back to the persons interviewed to ensure the validity and authenticity of the collected data. If interviewees in the case firms found some inaccuracies in the text, these were corrected based on their comments. In addition, some telephone and email interviews were used to collect further information from the interviewees. The collected data was also compared with other sources, such as websites and annual reports of the case firms.

In the data analysis, guidelines suggested by Eisenhardt [8] and Yin [24] were followed. All eight individual cases were written out as stand-alone case histories. After that, the unique patterns of each case were identified and similar patterns were categorized under common themes. This helped to organize and summarize the collected data. In addition, analytical tools were applied within and across the cases as proposed by Miles and Huberman [19]. For instance, checklists and event listings were used to identify critical events related to market entry process of each case firm.

## **Research Findings and Analysis**

This section presents the empirical findings of this study and compares the findings to the theoretical background of this study. Firstly, the internationalization history of case firms is presented from the establishment of a firm until the market entry to the Japanese market in terms of direct business operations. Secondly, development of business operations of the case firms in Japan is described and discussed. Thirdly, the main reasons for the market entry of the case firms are presented. Finally, some strategies to overcome psychic distance in the Japanese market are discussed.

### **Internationalization Activities of the Case Firms before Entering the Japanese Market**

All the case firms had been established between 1990 and 2000, except firm C that had been established already in 1966. The number of overall employees varied from 12 to 300, the average being 127 employees. Fig. 1 demonstrates the internationalization history of the case firms in terms of direct business operations until the establishment of direct business operations in Japan.

FIG. 1: DIRECT BUSINESS OPERATIONS OF THE CASE FIRMS UNTIL THEIR MARKET ENTRY TO JAPAN

As it can be observed from the Fig. 1, almost all the firms started their foreign direct business operations in countries with large markets for their products and only two in a country with a low psychic distance. Four of the firms started their foreign direct business operations by entering into the USA market, one selected the UK as the first target country, and one firm entered straight into the Japanese market. Only firms C and F started their foreign direct operations by entering Sweden, which represents a psychically close market to Finland. However, pretty soon after entering the Swedish market, they started direct business operations in more distant markets such as Hong Kong and Malaysia. Firm C was the only firm that had direct business operations in more than two countries before entering the Japanese market. Four of the firms (B, D, E, and H) selected the Japan as the second target country and as noted earlier, firm G started their direct business operations first in Japan. These findings demonstrates that firms' internationalization process before entering Japan did not generally follow the concept of psychic distance of the Uppsala internationalization model [11, 14], which proposes that firms first enter countries in a psychical proximity. Six case firms out of eight entered first countries which offer a large market for their products, namely the USA, Japan, and the UK. Only two of the firms started their foreign business operations in a nearby country. However, the internationalization processes of the case firms give support to the conceptual framework of Bell et al. (2003), which affirms that knowledge-based firms tend to internationalize their operations to the leading markets. This is also in line with Bell (1995) in that software firms enter to markets which are assumed to offer growth possibilities to their niche products.

#### Entry Mode Choice of the Case Firms

All in all, the case firms used six different entry modes in their market entry (Fig. 2). Firms C and F started their business operations by using Japanese distributors and firm E by direct sales. Other firms entered the market through direct business operations. Three of the case firms (A, B, and D) used representatives as their first entry mode. Firm G established a joint venture and firm H entered into the Japanese market by selling their shareholding to a Japanese corporation; the firm still had headquarters in Finland and operated as an independent unit of the corporation.

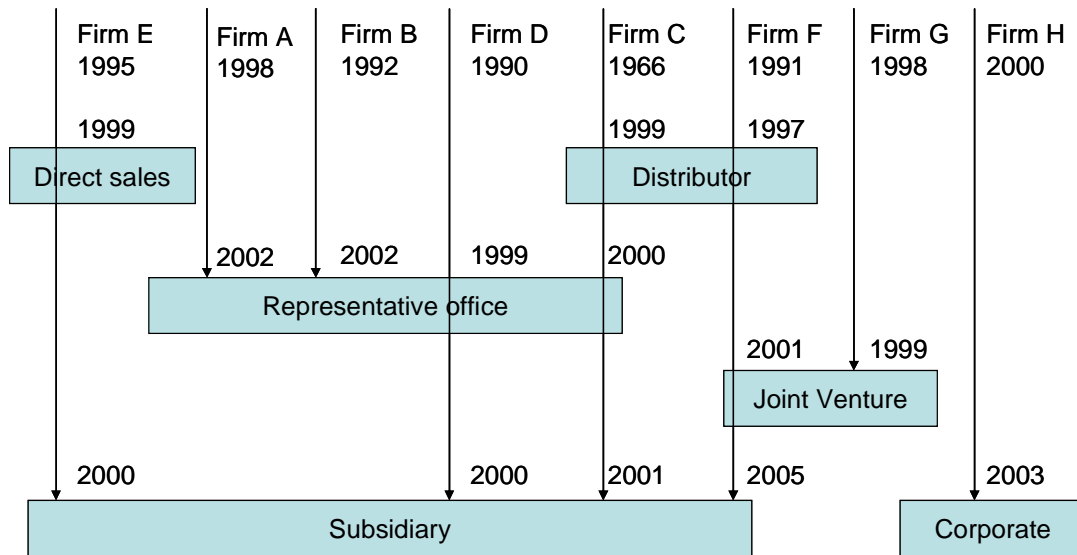

FIG. 2: CASE FIRMS' ENTRY MODES IN THE JAPANESE MARKET

Firms A and B used a representative as their current entry mode. Firm A was established in 1998 as a spin-off from a large Finnish software corporation and they had a representative in Japan from 2002 onwards. Firm A's initially thought handling the market through a distribution channel, but due to the complex nature of the products using a sole distributor proved impractical. Their representative in Japan worked within the distribution channel in technical sales support. Firm B was established in 1992, and they started developing their current products in 1998. In 2002, firm B established a representative office in Japan for two reasons. Firstly, a representative in the market enabled close cooperation with customers in both pre and after sales phases. One informant at firm B commented on this in the following way:

“Keeping regular contacts with our customer is much more difficult if we have to do it from here [Finland], it is the same with visits to potential customers [in Japan]. Regular appointments are required for these types of products... Anyway, physical presence is a must in our business”.

They also contemplated the possibility of handling the market with the help of a distributor. However, product sales would have required deep technical knowledge not possessed by the distributor. Secondly, a representative office enabled a cost-effective market entry and, compared to a subsidiary, required less bureaucracy in the establishment phase.

Four of the firms (C, D, E, and F) used a subsidiary as their current entry mode. In all of these cases, the subsidiary was established mainly for sales and marketing activities although firms C, E, and F had some minor product development activities in Japan. Firm C was established already in 1966, and they entered the Japanese market in 1999 with the help of two distributors. However, quite soon the other of the distributors closed its business and firm C found itself in a situation where they needed to find a new distributor or establish a unit for the Japanese market. They thought that handling the Japanese market with the help of single distributor was too risky. In 2000 they established a representative office, and in 2001 changed it to a subsidiary mode. This enabled better marketing and after-sales support for their customers in the Japanese market. Firm D that was established in 1990 entered into the Japanese market in 1999 by establishing a representative office. The purpose of the representative office was to provide support to their distributor who started to sell their products in Japan at the same year. The representative office also gave good opportunities to find and recruit local employees for their subsidiary that was established one year later (in 2000). The subsidiary enabled better support services to local distributors who handled the sales of their products. Firm E was established in 1995 and they entered into the Japanese market in 1999 with direct sales

from Finland to Japanese customers. However, after half of year they decided to establish a subsidiary. The subsidiary was needed for keeping regular contacts with the distributor and for technical support. Another reason for establishing the subsidiary was the requirement to hire an employee able to speak Japanese. One informant at firm E explained this in the following manner:

”There were many potential customers in Japan, but the market was very difficult to handle without knowledge of the Japanese language. Those negotiations where I was involved were really difficult, because Japanese customers spoke only Japanese and we always needed an interpreter”.

Firm F was established in 1991, and they entered into the Japanese market in 1997 with the help of a distributor. That time they had only few customers in Japan due to the mobile network structure in Japan than was different from those elsewhere, and they were able to handle the market through the distributor. However, when Japanese launched the third generation (3G) mobile network, firm F established a joint venture (in 2001) for the Japanese market, which now offered large market potential for 3G network analyzers. A joint venture with Japanese partners provides better opportunities to network with customers and to give better after-sales support. However, firm F changed their operation mode to sales subsidiary in 2005 to achieve a better control of the market.

Firm G was established in 1998 and they entered into the Japanese market only one year after the start-up establishing a joint venture with their Japanese partners in 1999. Earlier, in their former jobs, the firm’s employees had created personal relationships their Japanese partners who were interested in launching firm G’s products to the Japanese market. Helped by their local partners, the firm was able to get access to Japanese telecom operators. Firm G’s unit in Japan gave maintenance support to the distributors who delivered their mobile games to the consumers.

Firm H was established in 2000, and they got access into the Japanese market by incorporating with a large Japanese corporation. Firm H noticed that successful market entry into the Japanese market required a great deal of financial resources and local knowledge. They decided to sell their shareholding to this Japanese corporation and corporate with them in 2003. This strategy facilitated a successful market entry, and one unit of the Japanese corporation started to sell and market firm H’s products in Japan and in other East and Southeast Asian markets.

As the case descriptions demonstrate, firms C, E, and F followed stepwise entry routes in line with the Uppsala internationalization model, starting their operations in Japan with ‘export’ activities without their own presence. Firms C and E however changed their entry modes to the subsidiary mode within a very short period of time. Five of the firms started their operations in Japan with integrated entry modes. The main reason for using integrated entry modes were the requirements for close cooperation with customers in the sales and after sales process. Thus, the overall development of entry modes of the firms discussed here does not fully support the conception of stepwise extension of operations as suggested in the Uppsala internationalization model [11, 14]. However, the findings are consistent with Coviello and Munro [6] implying that firms are simultaneously using several entry modes in the market. In this study, all firms (excluding firms B and H) used distributors in addition to their own units in the market.

#### **Reasons for the Market Entry to the Japanese Market**

Five of the firms (A, C, D, E, and F) mentioned that the main reason for their market entry was the large size of the target industry in Japan. Firms G and H entered the Japanese market attracted by the sophisticated industry structure for their products, and firm B chose the market for the reason that their important customer was located in Japan (see TABLE 1).

TABLE 1: THE MAIN REASONS FOR THE MARKET ENTRY TO THE JAPANESE MARKET

Main reason for the market entry	Firm A	Firm B	Firm C	Firm D	Firm E	Firm F	Firm G	Firm H
Size of the target industry in Japan	X		X	X	X	X		
Sophisticated target industry							X	X
Important customer located in Japan		X						

Firm A produced virtual designing and modeling tools for mobile phone manufacturers, telecom operators, and electronics industry. The large size of these industries in Japan made the market very important for firm A. Firm C's core business in Japan focused on modeling software for steel and concrete construction industries, which are large industries in Japan and offer good opportunities for selling products to the local construction firms. Firms D and E produced enterprise level security software solutions mainly for banks, financial institutions, and network operators. The Japanese market offered a large customer base for these highly specialized data security solutions. Firm F produced analyzers for telecom networks and, in Japan, sold their products to telecom operators and research and development units which developed mobile networks. Although all these four firms were doing business in very narrow industry segments, the Japanese market offered a large customer base for their products. The market entry of these four firms occurred at the time of the so-called "IT-boom". One informant at firm D explained this in the following way:

"It was really crazy times at the end of 1990s; although our products were based on software, we were not able to deliver as many licenses of our software as we got orders in Japan"

Firm B developed software components for handheld devices such as mobile phones. The market entry of firm B was thought necessary, because they got an important customer from Japan. The negotiations with the customer and product specifications required so much time and traveling between Finland and Japan that firm B decided to establish their own unit in the market. Other reasons for the market entry were attractive markets in Japan that might generate more sales later on to other mobile phone and semiconductor manufacturers.

The main reason for the market entry of firms G and H was the sophisticated target industry in Japan. Firm G sold mobile phone games to consumers through telecom operators which distributed games to end users. Value added services in mobile networks in Japan were well developed and consumers were used to use these services. Another reason for the market entry was based on the idea that sophisticated Japanese telecom markets might teach them something that would be useful later on in other markets. Firm H developed gaming-on-demand solutions and content for broadband networks. Use of their products requires highly developed broadband networks, and in this respect the Japanese market offered the most sophisticated markets for their products.

The above case descriptions underline the fact that almost all of the case firms produced their software for areas such as mobile phones, telecom networks, and data security, that were regarded as very attractive markets for foreign firms in Japan [10]. These findings parallel those of Bell et al. [4] and Rothaermel et al. [21], which indicate that technology intensive firms tend to favor countries with attractive markets. However, the size and sophisticated industry structure in vertical markets seemed to be more important, as a determinant of the country choice, than the overall market size. This became evident in that none of the firms based their choice of the market on the number of consumers, instead the market choice was based mainly on the size of the target industry. Apart from firms G and H, all the other case firms sold their products to other firms in Japan. This finding gives support to Bell [2] in that software firms enter to markets which offer growth possibilities to their narrow product segments.

### **Ways to Overcome Psychic Distance in the Japanese Market**

According to the Uppsala model, experience of foreign markets and operations there lower the uncertainty to invest into more psychically distant markets [11, 12]. However, all the firms expect firm C, entered the Japanese market at a notably early phase in their life-cycle. Four of the firms (A, E, G, and H) entered into Japan within five years after their establishment and three (B, D, and F) within ten years after their establishment. In addition, the case firms' international experience before establishing direct business operations in Japan were relative exiguous (from one year to five years). In addition, the case firms started to use entry modes which require high commitment (such as subsidiary, joint venture, own representative) in the market quite soon after the establishment. However, all the case firms which had international experience in terms of direct business operations reported that those experiences helped them when they started their operations in Japan. The experience gained facilitated mainly in operational level activities such as cost estimations, choice of entry mode, and location choice in the target country, i.e. in issues to be dealt with in the market entry process. This knowledge was reported to be mainly in the headquarters and not facilitated in practical issues in Japan, which required more knowledge related business environment. One informant at firm E highlighted this as follows:

“In the headquarters, they knew how to evaluate cost and time [of establishment] to make everything to work and what steps are required...but so far, the experience is still always personalized...person who established our subsidiary in the USA, he know how to do it, but he was not at all involved [in the establishment process of the subsidiary in Japan], he was managing our subsidiary in the USA...some parts of this process was known in the headquarters, but the knowledge about what we needed on the spot [Japan] was missing”.

These findings are in line with Johanson and Vahlne [13] which indicate that, to a certain extent, a firm can resort to their experiences and knowledge from earlier foreign operations when they are entering into a new country. This also supports the concept of knowledge in the Uppsala model suggesting that general knowledge about markets is mainly objective and transferable from one country to another, whereas market-specific knowledge is tacit and based on experiences of individuals [11, 12, 13]. This tacitness makes it difficult to transfer market-specific knowledge between different countries [17]. All the case firms, except firm A, acquired local knowledge either by recruiting local employees for their unit in Japan or for the headquarters or by partnering with a Japanese firm (firms G and H). This facilitated fast market entry and commitment to the market. Because knowledge of both business practices and technology were critical for the case firms, most of their employees in Japan were recruited from competitors or customers. These employees already knew the products and players in the market. This decreased their training needs and enabled the use of their already existing business connections. In addition, firms C, D, E, and F recruited a western manager with a long working experience in the Japanese market for their subsidiaries in Japan. These managers were able to act as “cultural mediators” between the western culture and the Japanese culture.

### **Conclusions**

This paper investigated the market entry and entry mode choice of eight small and medium-sized Finnish software firms to the Japanese market. In addition, this study analyzed reasons for the market entry and how firms were able to overcome psychic distance between Finland and Japan. The findings in this study show that six of the eight firms started their foreign direct operations by entering into a country that would provide large markets for their products. In addition, the firms started developing their foreign direct business operations relatively early on by establishing foreign units to the main market areas for their products. These findings support the conceptual model of Bell et al. [4] suggesting that high-technology intensive firms start to internationalize their operations to leading markets soon after their establishment. However, these findings give very little support to the internationalization process described in the Uppsala internationalization model [11, 14]. Many of the firms entered Japan at an early stage of their internationalization; one of the firms even selected Japan as the location for their first direct operation abroad. This could be interpreted as a sign of the traditional internationalization or “stage” theories being non-valid or outdated in the present global business environment.

In their entry mode choice, only three firms out of eight followed the traditional stepwise entry route in the Japanese market by starting their operations using indirect entry modes. However, these firms established their own units in the market quite soon after starting these indirect operations. Other five firms started their operations using direct entry modes. Thus, the findings in this study do not fully support the entry route suggested in the Uppsala internationalization model [11, 14], where a firm first acquires knowledge about the market by using indirect operations and then gradually starts to favour direct business operations. The findings in this study highlight that the choice of the entry mode was based on the complexity of the firms' products, which required intensive cooperation with the customers in the sales process, implementation phase, and also made it possible to offer after-sales services near the customers. This gives a less obvious role to the network relationships in the entry mode choice compared to the findings of Coviello and Munro [6] and Moen et al. [20], because only in three cases (G, H, and F), the entry mode choice was related to the firms' available networks.

The findings of this study are in line with the earlier studies in the field of international entrepreneurship [2, 3, 6, 20] in suggesting that high-technology firms select their target countries for other reasons than those related to psychic distance. This study found that most of the firms selected the Japanese market for the reason that it provided a large customer base for the firms' niche products, which were commonly targeted to telecommunication industry or for dealing with large corporations' telecommunication networks' security. The limited local market in Finland was also one reason why the firms started to search market opportunities in major markets, such as Japan and the USA, for their products. Thus, the case firms were forced to enter into these major markets despite of the psychic distance to them. Only this enabled the firms to conduct profitable business in their niche market segments. This is consistent with Lindqvist [16] findings indicating that due to niche product offering, firms in high-technology sectors are forced to internationalize into markets where their target customers are located. Because the firms were actively targeting their products to the Japanese market, this might be the reason why network relationships had a less obvious role in the market selection compared to findings in Coviello and Munro [6] and Moen et al. [20].

Although all the case firms entered the Japanese market quite early on in their internationalization process and with limited international knowledge, they were able to overcome the psychic distance between Finland and Japan. For instance, almost all the case firms hired local employees to handle sales processes in Japan where the Japanese language is an important skill. In addition, each firm with a subsidiary in the market recruited a western manager with a long working experience in the Japanese market to overcome the cultural differences there. These managers had experiential knowledge about business practices in the Japanese market, which helped them to develop their firm's operations in the market. As highlighted in the study of Barney [1], experiential 'tacit' knowledge is a valuable competitive resource for a firm. This finding suggest also that the perception of cultural differences by managers in firms seems to be more important than the actual variation in cultures. From a practical perspective, this is an important managerial implication suggesting that a firm can significantly reduce psychic distance between home and the target country by hiring managers with relevant experiential knowledge. This facilitates the market entry, makes it faster, and helps integrate firms operations to the culture of the target country.

#### **Limitations and Further Research**

This study is not without its limitations. Firstly, it focuses only on direct business operations of the case firms, thus its findings are not fully comparable to earlier studies related to internationalization of small and medium-sized software firms [2, 3, 6, 20]. Secondly, the concept of psychic distance is a wide concept and there are several alternative definitions for it. This study used the definition of psychic distance based on the Uppsala internationalization model [11, 14]. However, further study is needed to investigate the psychic distance concept more deeply, especially on an individual level, because it seems to help firms overcome differences between home and target country. Thirdly, although network relationships had less obvious role in this study compared to earlier findings in the field of international entrepreneurship [2, 6, 20], the supportive role of network relationships in internationalization process requires further study. Network relationships in the internationalization process have been commonly studied using cross-national perspective. Further network relationship studies could benefit from investigations dealing with impacts of network relationships where a firm is targeting their operations to a certain country. Finally, although the sample of this study covered almost all Finnish small and medium-sized software firms having direct business operations in the Japanese market, the sample can be generalized only to some extent and further study is needed to validate these findings.

## Acknowledgements

The author would like to thank Merja Karppinen for her valuable insights and suggestions for an earlier draft of this paper and Pasi Tyrväinen for his assistance with figures. Financial support from the Foundation for Economic Education in Finland for this study is also gratefully acknowledged.

# Early Prediction of Employee Attrition in Software Companies-Application of Data Mining Techniques

Vishnuprasad Nagadevara, [nagadev@iimb.ernet.in](mailto:nagadev@iimb.ernet.in)  
Vasanthi Srinivasan, [Vasanthi@iimb.ernet.in](mailto:Vasanthi@iimb.ernet.in)

## Abstract

Employee retention is one of the biggest challenges in IT companies all over the world. Different companies adopt different strategies to retain the employees. These strategies include large increases in compensation, liberal perks, frequent job rotations, as well as travel and stay abroad. However, literature on turnover indicates that a person's intention to quit is a function of demographic characteristics, job characteristics and organizational characteristics. Individual who have an intention to quit are also likely to engage in other withdrawal behaviors like absenteeism and late-coming. This paper uses data on demographics and the withdrawal behaviors like absenteeism and late-coming to predict turnover. It applies various data mining techniques to identify turnover in organizations. This exploratory study identifies four variables which could enhance the accuracy of prediction of turnover. Further research on the variables needs to be done to contribute to prediction and also identify the possible reasons for attrition.

## Introduction

India has emerged as a major exporter of software services in the international economy in the past decade and a half. India's software sales grew at a compound rate of over 50% between 1995 and 2000. Despite fears that the market for Indian software would surely collapse with the recession in the US, the growth of the software services industry continued and the industry diversified into other geographical and related markets. According to NASSCOM Mc Kinsey report, 2005, the number of people required in the IT industry alone would be 0.8 million in 2010 (Nasscom, 2005).

The initial growth of the Indian software industry could be attributed to the fortunate circumstance of an excess supply of engineers and scientific labour (Arora and Athreye 2002). As the demand for software professionals increased, wages in the software industry started to grow and attrition rates started increasing. More than half of all firms covered in the study by Arora selected manpower shortage and employee attrition as the most serious problems affecting them.

Attrition creates different kinds of threats and problems. When IT professionals leave an organization, not only is the number of them available for assignment to projects decreased, the professionals themselves often take specialized skills, tacit knowledge, and understanding of specific business operations and information systems with them (Moore & Burke, 2002). When attrition is at senior levels then it is also likely that a firm loses some of its customer base to the competitor. "Many of the firms saw employee attrition as an important problem. Several clients commented on the delays due to entire project teams leaving in the midst of the project in response to a more lucrative offer. Such delays were particularly troubling for smaller clients and for product focused clients with a need to shorten product development cycles. In both cases attrition threatened to open up the credibility gap which earlier firms had strived so hard to close" (Athreye 2003).

With increasing competition for human resources, the ability to attract, develop, and retain high-quality employees is becoming the main concern for the industry. Companies are adopting a number of strategies such as market hiring (hiring experienced people from other companies), advertisements, job portals, campus recruitment, headhunters, joint industry-academia programs, employee referrals, and support for higher education, flexi working schedules and retaining freelance headhunters to work exclusively for a particular company. Still, no single approach adequately meets the need.

## **Turnover in Software Industry-Global Scenario**

Turnover of software professionals appears to be a global phenomenon. Some of the studies from US report that the knowledge and skills of IT professionals are needed by a multitude of industries globally. This results in them being more able and willing to change employers than workers in other industries (Freeman & Aspray, 1999). Many IT professionals engage in frequent job-hopping, which provides a greater scope of experience and training rather than remaining in the same position (Summer, 2001 as cited in Snyder et al, 2006). A recent survey indicates that the average time that managers consider acceptable to retain IT workers decreased from an average of 33 months in 2001 to an average of 30 months in 2004 (ITAA, 2004 as cited in Snyder et al, 2006) Capelli (2001) found a particularly high level of turnover among programmers. In a National survey of college graduates done by him, only 19% of computer science graduates remained in the field 20 years later while 52% of the civil engineering graduates did so. A study by George Mason University similarly found that career change among IT workers was double that of workers in other fields (Mandell, 1998). It is increasingly being recognized that the relatively short tenure of IT professionals may be due to the focus by the organizations on hiring workers who have the technical skills needed to deliver on the project immediately, but may realize after the project is completed that the formerly valuable skills are no longer beneficial (Snyder et al, 2006). Providing additional training to the workers creates a contradictory process. While training may increase the ability of the workers to perform better on current and future projects, it also enhances their attractiveness in the market and they become targets for poaching by competitors. Therefore, organizations appear to have chosen the “buy” strategy of seeking necessary skills in new workers rather than retraining (Capelli 2001). However, IT professionals tend to rate career development and a challenging job as greater than monetary compensation in determining their job satisfaction. (Meares & Sargeant, 1999 as cited in Snyder, et al, 2006). This inconsistency makes it difficult for organizations to balance between hiring and training to achieve the balance of skills that are required. In the Indian context, with rising internal competition and continued overseas demand for talent, the average industry attrition ranges between 12 and 35 percent (as reported in popular press), leading to a very high cost of hiring and employee development. For knowledge-intensive activities such as high-tech product development, attrition means not only losing people to competitors but also knowledge walking out of the organization (Moitra, 2001).

The competitiveness of the Indian IT industry rests on its labour pool and therefore, employee turnover is a source of great concern to the industry as a whole. The cost of attrition to the company can be broadly classified in to five categories: the cost of recruiting the new person, the cost of training, the cost of loss productivity, the cost of lost knowledge and the cost of the position remaining vacant till a suitable replacement is found (Sharma, 2007). All these costs would significantly take away the profitability of the firms. Presently cost and quality of personnel are the two sources of competitive advantage for the Indian IT industry.

## **Research on Turnover, Absenteeism and Lateness**

The three dimensions namely turnover, absenteeism and lateness have been grouped together as withdrawal behaviors and have been studied by work psychologists since they impact cost, production and productivity directly. Adler and Golan (1981) define lateness as “the tendency of an employee to arrive at work after the scheduled starting time” Johns (1985) defines absenteeism as the “failure to report for scheduled work” Others define absenteeism as “an individual’s lack of physical presence at a given location and time when there is a social expectation for him or her to be there (Martocchio & Harrison, 1993). The definition of turnover is “the termination of an individual’s formal membership with an organization (Lee, 1997). The connections between the three kinds of withdrawal behaviors have been of interest to researchers.

In particular, the progression perspective has been of particular interest in recent years. It can be conjectured that withdrawal will progress from minor, less salient acts, such as occasional lateness, to more salient acts, such as absence and finally turnover (Johns 2001). Longitudinal studies by Clegg (1983), Wolphin, Burke, Krausz and Freibach (1988) and Rosse (1988) found a lateness-absence progression although Adler & Golan (1981) and Krausz, Koslowsky and Eiser (1998) did not. Blau (1994) found a pattern of increasing chronic lateness that was

associated with elevated absence within the same 18 month period. Several studies reveal a progression from absence to turnover (Krausz et. Al, 1998, Crosby & Brandt, 1988; Rosse 1988). If the progression was indeed existent, then statistically we would expect the relationship between lateness and absenteeism, absenteeism and turnover to be stronger than the relationship between lateness and turnover. The meta-analysis studies support this connection. Koslowsky et al (1997) reported a corrected correlation of 0.40 between lateness and absence and Mitra et al (1992) reported a corrected correlation of .33 between absence and turnover. Koslowsky et al estimated the mean correlation between lateness and actual turnover to be .07 and that between lateness and an apparent composite of actual turnover and turnover intentions to be .27 (Johns, 2001).

The linearity of the progression of withdrawal behaviors is still under scrutiny. However, some studies (Somers, 1999; Sheridan 1985) have found a nonlinear, discontinuous relationship between these behaviors and their relationship with some attitudinal constructs. The review of literature presented above indicates that any study of attrition would need to consider the history related to absence and late-coming.

## **Demographic Variables and the Impact on Withdrawal Behaviors**

The literature on the impact of demographic variables on withdrawal behaviors has been ambivalent. Research has reported ambivalent findings on age, tenure, gender and education. Some studies have reported positive relationship between absenteeism and educational level and gender (Steel & Rentsch, 1995). In a review of literature on turnover among sales professionals, Lucas et al (1987) report that , among all personal characteristics , the most studied and the most consistent in its relationship to turnover is the employee age. Older employees were less likely to leave the organization than younger employees. The role of Tenure and education was unclear; however other researchers (Mobley 1982) consider tenure to be the best single predictor of turnover.

In the research done on IT, Ahuja et al (2007) found age had a modest but significant effect on turnover intention, but tenure did not affect turnover intention. Gender and marital status also did not affect turnover intention. While the database search on turnover and IT/MIS professionals yielded significant results, a similar search on absenteeism and lateness and IT/MIS professionals did not yield any articles. It is therefore, assumed that such a study exploring the relationship between turnover, absenteeism and lateness may not have been explored in the context of software professionals. .

This study attempts to understand attrition by using the demographic variables like age, sex, tenure, nature of the project and martial status along with the withdrawal measures like lateness and absenteeism. This would enable organizations in identifying individual employees who are likely to leave. Application of data mining techniques can help these companies in addressing this problem.

## **Objectives of the Study**

The objectives of the study are as follows:

1. To evaluate the effectiveness of different models with respect to their predictive accuracy.
2. To identify the factors that influence employee attrition
3. To develop a predictive models for employee attrition

## **Methodology**

The methodology adopted involves application of various data mining techniques to predict employee attrition. The models used are artificial neural networks, logistic regression, classification trees (C5.0), classification and regression trees and discriminant analysis. The data on employee attrition was obtained from a software company. The data was extracted from a sample taken from the records of the company. The names of the employees as well as all other such identifiers were first removed from the data. In order to facilitate validation of the models, each employee record was given a unique identification number. The sample consisted of employees who had left the company during the past 3 years as well as those who are still with the company at the time of selecting the sample.

This variable was taken as the dependent variable for the purpose of prediction of attrition. The following data was obtained from the employee records:

- Date of birth
- Gender
- Marital status
- Total years of work experience (binned into 3 categories)
- Months of experience in the present company (binned into 3 categories)
- Months of in the current team (binned into 3 categories)
- Months of experience in the current position (binned into 3 categories)
- Type of position occupied currently in the company (binned into 6 categories)
- Type of software domain expertise
- Number of job changes till joining the present company (binned into 3 categories)
- Month-wise use of casual leave (binned into 3 categories)
- Month-wise use of privilege leave (binned into 3 categories)
- Month-wise data on arrival time at work (binned into 3 categories)

Most of the literature concerning lateness, absence and turnover uses data from employee personnel files to measure the behavior. This study uses the same basis to collect information. The age of the employee was derived from the date of birth. All the experience related variables were binned into categories. The binning was generally based on equi-depth binning. The month-wise data on casual leave, privilege leave and daily arrival times were analyzed to identify changes in the patterns during the past 6 months. The analysis was primarily aimed at isolating cases where the usage was similar, or increasing or decreasing over the past 6 months. When an employee had left the company, the data for 6 months prior to leaving the company was analyzed. Similar analysis was done to identify changes in patterns in arrival times at work.

The normal practice while applying data mining techniques is to divide the data into training and testing data sets. Such division is usually done on random basis. The models are trained using the training data set and then the model thus developed is tested using the testing dataset. The main objective of such separation of training and testing datasets is to make sure that the models developed will not be specific to the special patterns in a particular dataset. Such a separation would be possible where the number of observations is large enough to allow such a luxury. In the present case, the same dataset was used for training as well as for testing because of the dataset contained only a limited number of observations. It is proposed that the models developed and tested could be used with data on other employees in the company for cross validating the model.

## **Sample Profile**

Among all the employees in the sample, 28 percent had left the company where as the remaining 72 percent are still with the company as on the date of sample selection. The sample is predominantly male accounting for 70 percent. Only one-third of the sample employees were married. The group was relatively young with only 30 percent aged above 28 years. The average experience (total experience) was slightly less than 5 years. At the same time, only one-third of the sample employees had more than 6 years of total experience in the industry. The average experience within the company was slightly more than 2 years. More than two-thirds of the sample employees had experience of less than 30 months in the present company. The average experience within the current team was slightly more than 18 months, which is somewhat longer than the usual norm in the industry. The sample employees have spent even less time on average in their current position. The average time in the current position was less than 18 months indicating that the promotions were rather fast and early? Another interesting aspect of the sample was that the average number of job changes was just about one. This was the very first job for about one-third of the sample employees.

In summary, it appears that the employees in the sample are young, with fast growth in the company and continuing in the same team for a fairly long time. They are predominantly male and single.

## Development of Prediction Models

As mentioned earlier, five different types of models were trained and tested. These models are:

- Artificial Neural Networks (ANN)
- Logistic Regression
- Classification Trees (C5.0)
- Classification and Regression Trees (CART)
- Discriminant Analysis

The following section describes each of the models and presents the results with respect to the training and testing of these models. The variables that are significant in each of the models and their relative importance are also discussed in this section.

### Artificial Neural Networks

The artificial neural networks (ANN) are generally based on the concepts of the human (or biological) neural network consisting of neurons, which are interconnected by the processing elements. The ANNs are composed of two main structures namely the nodes and the links. The nodes correspond to the neurons and the links correspond to the links between neurons. The ANN accepts the values of inputs into what are called input nodes. This set of nodes is also referred to as the input layer. These input values are then multiplied by a set of numbers (also called as weights) that are stored in the links. These values, after multiplication, are added together to become inputs to the set of nodes that are to the right of the input nodes. This layer of nodes is usually referred to as the hidden layer. Many ANNs contain multiple hidden layers, each feeding into the next layer. Finally, the values from last hidden layer are fed into an output node, where a special mapping or thresholding function is applied and the resulting number is mapped to the prediction. The ANN is created by presenting the network with inputs from many records whose outcome is already known. For example, the data on age, income and occupation of the first employee (first record) are inputted into the input layer. These values are fed into the hidden layer and after processing (by combining these values using appropriate weights) the prediction is made at the output layer. If the prediction made by the ANN matches with the actual known status of the employee (say either left the company or not), then the prediction is good and the ANN proceeds to the next record. If the prediction is wrong, then the extent of error (expressed in numerical values) is apportioned back into the links and the hidden nodes. In other words, the values of the weights at each link are modified based on the extent of error in prediction. This process is referred to as the backward propagation. The artificial neural networks are found to be effective in detecting unknown relationships. ANNs have been applied in many service industries such as health (to identify the length of stay and hospital expenses) (Nagadevara, 2004), air lines (Chatfield, 1998) and ANNs are used in this paper for predicting the categories of the members of the loyalty programmes (Nagadevara 2005).

A total of 14 variables are used to build the ANNs for predicting the employee attrition. These are in addition to the dependent variable, which is a nominal variable indicating whether the employee is still with the company or had left the company. Most often the mathematical relationships or equations developed by the ANNs are complex and not available to the user. As a result, these are treated as black boxes, only to be used to obtain the prediction results. Nevertheless, it is important to know the relative importance of each of the variables in predicting the categories. The software used provides the sensitivity of the prediction with respect to each of the variables and this can be viewed as an indicator of the relative importance of the variables in question. Table 1 summarizes this information with respect to each of the 14 variables used for building the ANNs.

TABLE 1: RELATIVE IMPORTANCE OF THE INPUTS USED IN THE CONSTRUCTION OF ANNs

Variable	Relative importance
Privilege Leave Used (Binned)	0.148577
Current Position in the Company (Binned)	0.146736
Current Technical Expertise	0.146736
Late Arrival at the office (Binned)	0.144292
Experience in the company (Binned)	0.082996
Total Experience (Binned)	0.078281
Domain Experience	0.071921
Casual Leave Used (Binned)	0.069042
Total number of job hops	0.034097
Marital Status	0.025611
Gender	0.014790
Age (Binned)	0.010350
Experience in the current position (Binned)	0.004343
Experience in the current team (Binned)	0.003620

The prediction accuracy obtained using the ANNs is 81.63 percent. The prediction percentages are presented in Table 6 at the end of this section. While the ANNs are able to predict those who remained with the company with an accuracy level of more than 90 percent, the accuracy level of prediction is only 59 percent with respect to those who left the company. In other words, the ANNs are excellent in their predictions with respect to those who remain with the company. The most important indicator for prediction is the pattern of use of Privilege leave. This is followed by the current position in the company, current technical expertise and the pattern of late arrival at the office. It is not surprising that two of the four most important indicators are the changes in the behavioral patterns of the employees.

#### **Logistic Regression**

Logistic regression is a specialized form of regression used to predict and explain a categorical dependent variable. It works best when the dependent variable is a binary categorical variable. The regression equation developed is very similar to a multiple regression equation with “regression-like” coefficients which explains the impact of each of the independent variable in predicting the category of the dependent variable. One special advantage of logistic regression is that it is not restricted by the normality assumption which is a basic assumption in the regression analysis. It can also accommodate non-metric variables such as nominal or categorical variables by coding them into dummy variables. Another advantage of logistic regression is that it directly predicts the probability of an event occurring. In order to make sure that the dependent variable, which is the probability, is bounded between zero and one, the logistic regression defines a relationship between the dependent and independent variables that resembles an S-shaped curve. It uses an iterative process to estimate the “most likely” values of the coefficients. This results in the use of a “likelihood” function in fitting the equation rather than using the sum of squares approach of the regression analysis. The dependent variable is considered as the “odds-ratio” of a specific observation belonging to a particular group or category. In that sense, logistic regression estimates the probability directly.

In order to get the best prediction results from the logistic regression, it is important to have continuous variables as independent variables. It is also important to define the nominal variables appropriately, so that they are converted into the required number of dummy variables. Thus, the use of binned variables is kept to the minimum possible in the case of logistic regression. The variables used in building the logistic regression and the corresponding coefficients are presented in Table 2.

TABLE 2: VARIABLES IN THE EQUATION

Variable	B	Exp(B)
Age (in years)	.762	2.142
Gender	-.770	.463
Marital Status	1.699	5.470
Total Experience in Years	-.984	.374
Experience at the Company	.263	1.300
Experience in the Current Team	-.461	.631
Experience in the Current Position	-.334	.716
Total number of Job Hops	-.459	.632
Casual leave used	.410	1.506
Privilege Leave used	-.119	.888
Late arrival at the office	-.262	.769
Current Position (Binned)		
Current Position Binned(1)	-.828	.437
Current Position Binned(2)	.623	1.865
Current Position Binned(3)	-.409	.664
Current Position Binned(4)	-2.318	.098
Current Position Binned(5)	3.612	37.035
Constant	-14.489	.000

TABLE 3: OMNIBUS TESTS OF MODEL COEFFICIENTS

		Chi-square	df	Sig.
Step 1	Step	60.179	16	.000
	Block	60.179	16	.000
	Model	60.179	16	.000

The prediction accuracy obtained by the logistic regression is 79.58 percent. In logistic regression, interpretation of the regression coefficient is not as that of the regular regression equation. The exponential value of the coefficient is considered to be the measure of the impact of the corresponding independent variable on the “odds-ratio”. Hence, Table 2 presents not only the regression coefficients, but also its exponential value. The relative importance of different variables on the “odds-ratio” can be obtained directly from Table 2.

**Classification and Regression Trees (CART)**

Classification and Regression Trees (CART) is one of the popular methods of building classification trees. CART always builds a binary tree by splitting the observations at each node based on a single attribute or variable. CART uses gini index for identifying the best split. If no split that could significantly reduce the diversity of a given node could be found, the process of splitting is stopped and the node is labeled as a leaf node. When all the nodes become leaf nodes, the tree is fully grown. At the end of the construction of the tree, each and every observation has been assigned to a leaf node. Each leaf can now be assigned to a particular class and a corresponding error rate. The error rate at the leaf node is nothing but the percentage of misclassifications at the leaf node. The error rate for the entire tree is the weighted sum of the error rates of all the leaf nodes.

The classification and regression trees work best with nominal or binned variables. Hence, the data used to build the classification and regression tree is either in the form of binned data or nominal data. The resultant tree is presented in Figure 1. It can be seen from the tree that experience in the current team is one of the important determinants. Not only it appears at the top of the tree, but it also results in a pure node on one of the branches.

Similarly, the relative importance of different variables could be seen from the tree. As shown in Table 6, the prediction accuracy of the Classification and Regression Tree is 89.80 percent. Here also, the predictions are much better with respect to those who have not left the company.

#### **Classification Trees (C5.0)**

In the case of C5.0 classification trees, the splitting of the records at each node is done based on the information gain. Entropy is used to measure the information gain at each node. This method can generate trees with variable number of branches at each node. For example, when a discrete variable is selected as an attribute for splitting, there would be one branch for each value of the attribute. The construction of the tree, creation of leaf nodes and labeling of the leaf nodes as well as the estimation of error rates are very similar to the CART methodology.

As it is in the case of Classification and Regression Trees, nominal or binned variables are best suited for the Classification Trees. The tree constructed using the classification tree (C5.0) method is presented in Figure 2. One major difference between the CART and the classification trees is that classification trees allow multiple branches at any given node where as CART allows only binary splits. This is evident at Node 4 (Level 3) of the classification tree. In the case of classification trees also, experience in the current team appears to be one of the important factors in predicting attrition. The pattern of late arrival at the office appears to be one of the important determinants under classification trees. The prediction accuracy of the classification trees is 88.44 percent, which is very similar to that of the CART. The prediction accuracy of the classification tree is marginally better with respect to those who had left the company (as compared to CART).

The prediction accuracies of both CART and Classification Trees are very similar. This is not unexpected, considering that both the techniques work on similar principles, but differ only in terms of methodologies and splitting criteria adopted.

#### **Discriminant Analysis**

Discriminant analysis is one of the commonly used statistical techniques where the dependent variable is categorical or nominal in nature and the independent variables are metric or ratio variables. It involves deriving a variate or “z-score” which is a linear combination of two or more independent variables that will discriminate best between two (or more) different categories or groups. The discriminant analysis involves creating one or more discriminant functions so as to maximize the variance between the categories relative to the variance within the categories. The z-scores calculated using the discriminant functions could be used to estimate the probabilities that a particular member or observation belongs to a particular category.

It is important that the independent variables used in discriminant analysis are continuous or metric in nature. Accordingly, the variables used in estimating the discriminant function are the original variables. The coefficients of the standardized discriminant function are presented in Table 4. In addition to the coefficients, the Chi-square statistic as well as Wilks’ Lambda, which indicates the goodness of fit are also presented in Table 5.

The prediction accuracy of employee attrition based on discriminant analysis was 82.09 percent. The predictions are more accurate with respect to the employees who had left the organization. It can be seen from Table 4 that the standardized coefficients with respect to four variables namely, age, experience in the company, casual leave used and late arrival at the office are negative. The dependent variable, which is categorical, is coded as “0” for those who left the company and as “1” for those who remained in the company. Thus it can be concluded that these variable with a negative coefficient have a positive relationship with attrition (employees likely to leave the company)

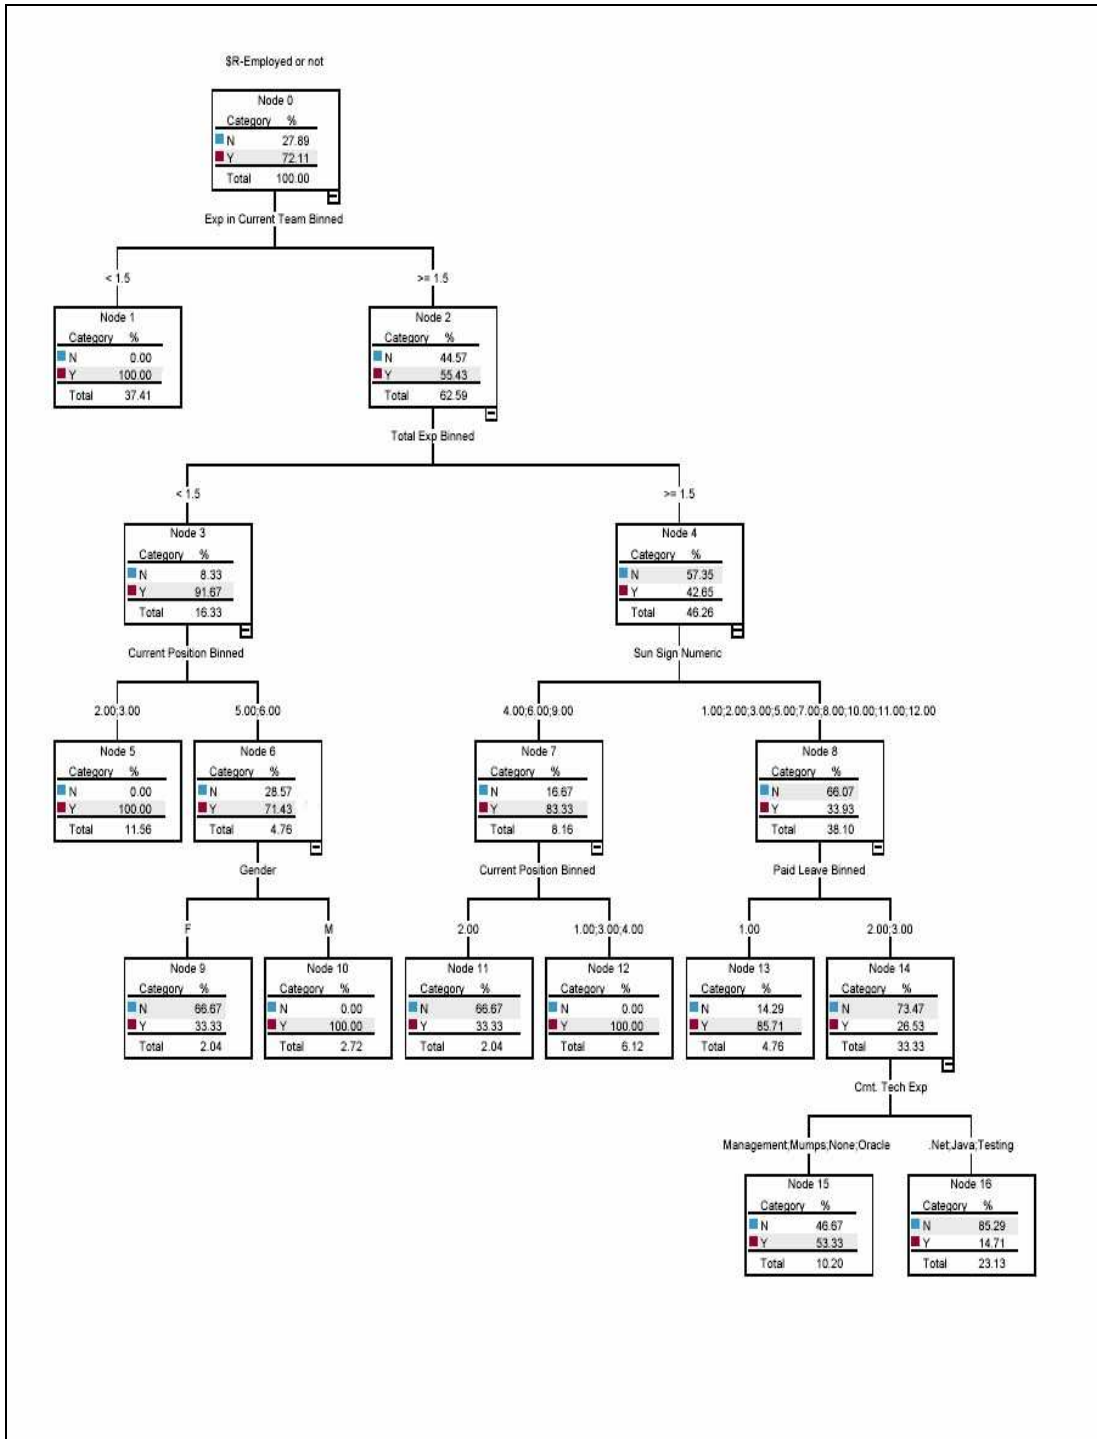

FIG.1 CLASSIFICATION AND REGRESSION TREE DIAGRAM

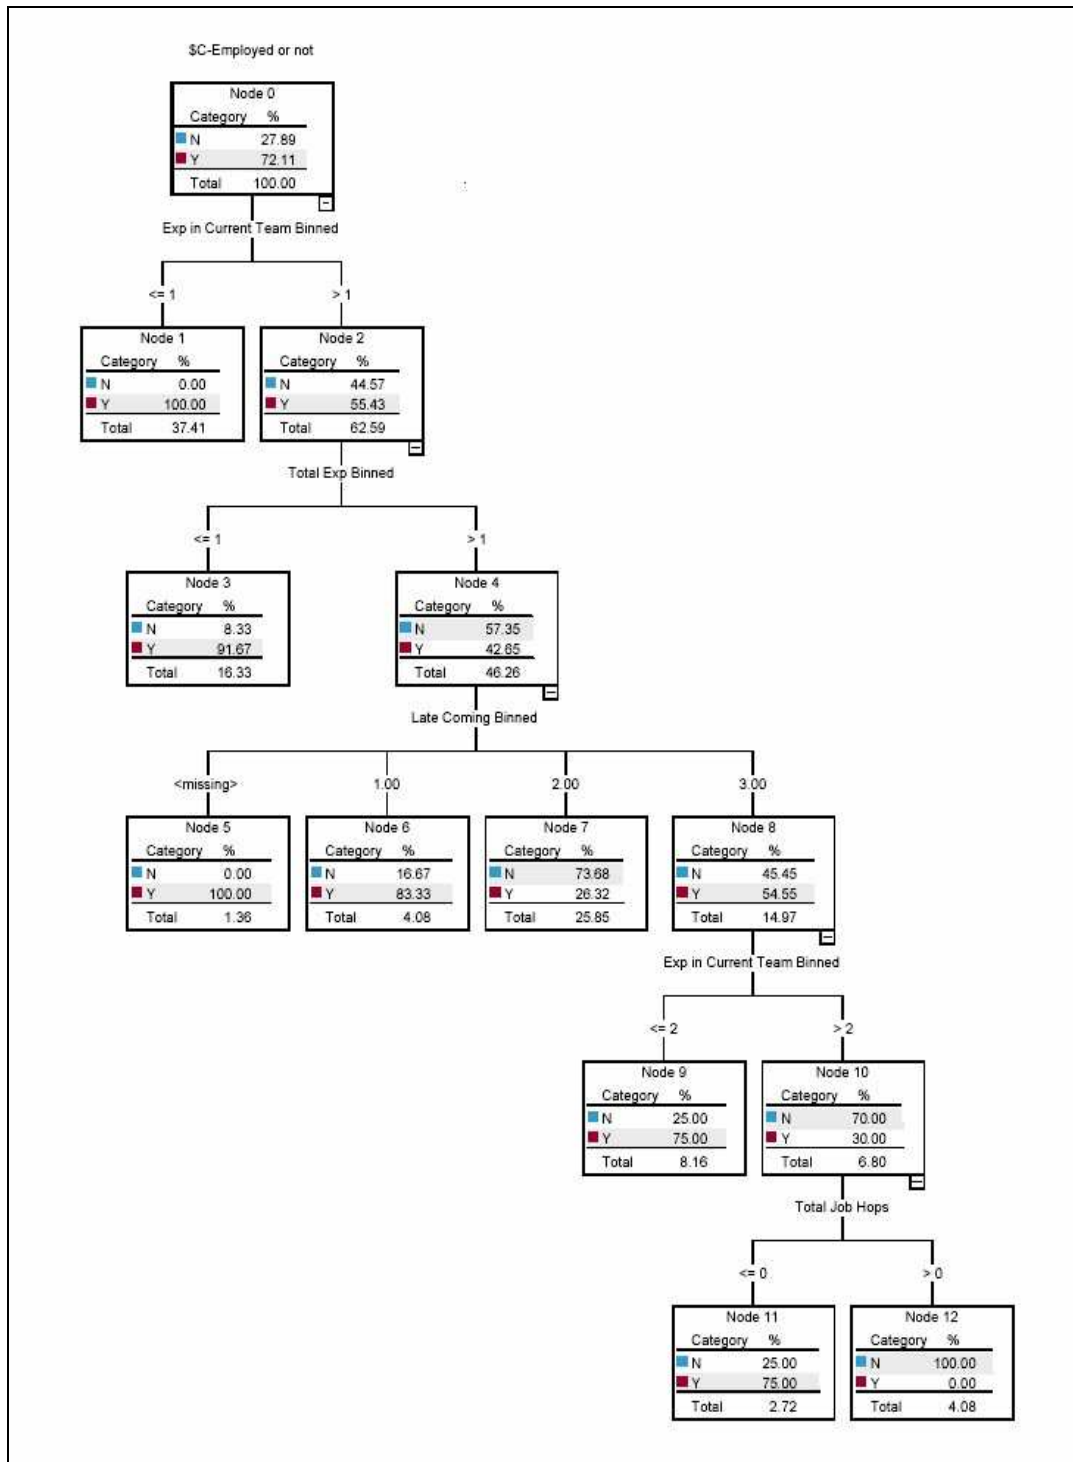

FIG. 2 CLASSIFICATION TREE DIAGRAM

TABLE 4: STANDARDIZED CANONICAL DISCRIMINANT FUNCTION COEFFICIENTS

Variable	Coefficient
Age (in years)	-1.437
Total Experience in Years	1.815
Experience at the Company	-.832
Experience in the Current Team	.629
Experience in the Current Position	.615
Current Technical Expertise	.002
Total number of Job Hops	.197
Casual leave used	-.306
Privilege Leave used	.204
Late arrival at the office	-.073

TABLE 5: CHI-SQUARE STATISTIC AND WILKS' LAMBDA CORRESPONDING TO THE DISCRIMINANT FUNCTION

Test of Function(s)	Wilks' Lambda	Chi-square	df	Sig.
1	.742	37.873	10	.000

Table 6 summarizes the prediction accuracies of all the five techniques used for prediction of attrition. Interestingly, all the five prediction techniques have shown reasonable accuracy levels with respect to those employees who remained with the company. On the other hand, discriminant analysis had given the highest accuracy level with respect to those who had left the company. Artificial neural networks are the lowest on predictive accuracy with respect to those who had left the company. From the company's perspective, it is important to predict those who are likely to leave the company more accurately so that pro-active strategies could be initiated to minimize the attrition levels. The company would be in a position to engage those who are predicted as likely to be leaving the company to identify the possible reasons even before the employees have made the final decision. On the whole the classification trees and CART appear to give the best results in terms of prediction accuracy. Both these techniques are able to predict the attrition with an accuracy level of above 80 percent. At the same time the accuracy levels of these techniques with respect to those who remained with the company are above 90 percent.

TABLE 6: PREDICTION ACCURACIES OF DIFFERENT TECHNIQUES USED

Actual	Prediction		
	Left the Company	Not Left the Company	Total
C 5.0			
Left the Company	82.93%	17.07%	100.00%
Not Left the Company	9.43%	90.57%	100.00%
CART			
Left the Company	80.49%	19.51%	100.00%
Not Left the Company	6.60%	93.40%	100.00%
Logistic Regression			
Left the Company	75.00%	25.00%	100.00%
Not Left the Company	18.63%	81.37%	100.00%
<i>The cut value is 0.700</i>			
Artificial Neural Networks			
Left the Company	58.54%	41.46%	100.00%
Not Left the Company	9.43%	90.57%	100.00%
Discriminant Analysis			
Left the Company	86.84%	13.16%	100.00%
Not Left the Company	19.79%	80.21%	100.00%

## Summary and Conclusions

This paper applies various data mining techniques to identify such individuals. Five different techniques namely, artificial neural networks, classification and regression trees, logistic regression, classification trees (C5.0) and discriminant analysis were applied to predict the employee attrition. The overall predictive accuracy was between 79.57 percent and 89.80 percent. The companies would be more interested in the prediction accuracies of those who are likely to leave the company. The prediction accuracies have shown a wide variation in this respect. The ANNs appear to lowest predictive accuracy at only 58.54 percent where as the best prediction was possible with discriminant analysis. The identification of the four variables age, experience in the organization, late coming and casual leave in their relationship to turnover is significant from a research perspective. The role of age as a variable in the Indian context is particularly significant. The IT industry has been hiring in large numbers from the campus. Most of these graduates are first time workforce entrants who appear to have unrealistic expectations from the job and the organization. This unrealistic expectation coupled with scarcity of employable skills, and soaring salaries make them particularly vulnerable for turnover. It is also likely that many employees engage in a process of career exploration in their first few jobs. Therefore, the relationship between age and turnover has to be examined in the Indian context. Existing research on careers also suggests that older employees given their career and life stage, may not be able to move as easily. The role of lateness and absenteeism in predicting turnover requires further examination.

While these predictive accuracies are specific to the data used in the analysis and to the specific company in question, the study has shown that it is possible to predict the employee attrition, and identify those who are likely to leave the company even before they had made their final decision to leave. Such predictive abilities could help the company to initiate proactive measure to minimize the attrition. It is important for the company to try out different models and techniques and identify important variables before finalizing on a specific technique or model. It is also possible to adopt a hybrid methodology rather than depending on a single technique alone to improve predictive accuracies.

# Technological Knowledge Transfer from Foreign Partners to Uganda's International Joint Ventures: A Case of the Manufacturing Industries

*Mary Basaasa Muhenda, mbmuhenda@umi.ac.ug*

*Universiti Sains Malaysia*

## Abstract

The study investigates the extent of and factors that affect technological knowledge transfer from foreign partners to IJV in Uganda's manufacturing sector. Government's policy that encourages local firms to acquire and adopt technological knowledge to foster industrialization prompted the study. A total of 103 IJV's were surveyed using a self administered questionnaire. Data was analysed using factor and reliability analysis and multiple regressions. Findings confirm a fairly low incidence of transfer of technological knowledge from foreign partners to IJV and also indicate that learning and development and structural attachment have a positive significant effect on the extent of technological knowledge transfer. This is in line with Blau's (1964) social exchange theory which recognizes the importance of investing in irrecoverable resources in a relationship to create ties that set an expectation of reciprocity. Future research could be directed to conducting a longitudinal study to investigate other types of knowledge preferably in service industries.

## Background of the Study

The application of knowledge is now recognized to be one of the key sources of growth in the global economy (World Bank, 2006). Countries especially those in the developed world are at the forefront of harnessing employer's knowledge as a strategy to increase competitiveness, growth and wealth and to improve performance. And as global competition that has resulted in an increasingly complex and unpredictable business environment intensifies, access to and application of knowledge become decisive factors in determining economic growth (Dahlan, Ramayah, Karia, Fun & Asaari, 2005; Hoeg & Schulze, 2005; World Bank, 2006). Developing countries in general and Uganda in particular who wish to effectively participate in globalization and benefit from it and yet their knowledge bases are insufficient must focus on facilitating knowledge worker productivity for survival more than ever before. In response to these challenges, governments around the world are adjusting their development strategies within a new framework in which accumulation of knowledge by way of knowledge transfer is occupying a central place.

The Government of Uganda in its effort to promote high economic growth and compete globally is committed to building local technological capabilities in-order to propel the country towards the status of an industrialized nation (UNCTAD, 2004). This fundamental national economic move is articulated in Uganda's National Vision 2025 emphasizing macro economic stability through an enterprising, innovative and industrious society. Industrial development is linked with the existing national policies, programs and strategies that regard technology and knowledge among the key factors of production (World Bank, 2006). The expansion or establishment of new industries whose goal is wealth creation and improvement of people's welfare and poverty reduction is expected to increase the value of the county's natural resources, ensure job creation, guarantee enhanced household incomes, raise foreign exchange earnings and facilitate the transfer of technical know-how.

Aware of its insufficient levels of scientific and technological knowledge (UNCTAD, 2004; World Bank, 1995), the Government of Uganda has embarked on several strategies aimed at acquiring and adopting new scientific and technological knowledge from foreign partners. Through its numerous economic reforms, the government has since 1986 attracted many foreign investors, encouraged local firms to form joint ventures in business partnerships with foreign investors in the hope that firms in Uganda could gain knowledge and expertise from such consortia and partnerships and apply it in their own operations and enacted the 1991 Investment Code that delineates the policy that promotes the transfer of technological knowledge from foreign partners. In spite of all

these efforts on the part of Government to accumulate technological knowledge from foreign partners, there is no indication of the extent of transfer of technological knowledge from foreign partners as a result of joint partnerships.

Though there are few existing studies in form of case studies and donor commissioned surveys that provide an insight on the transferability of technological skills in Uganda, we are not aware of any empirical studies that have particularly investigated the transfer of technological knowledge from foreign partners to IJV in Uganda. The few studies revealed that the soft side of technology transfer, absorption of organization and management practices as well as tacit knowledge that refer to the kind of instinct values, personal beliefs, individual actions and experience that resides in people's minds (Nonaka, 1994; Nonaka & Takeuchi, 1995; Polanyi, 1967) was neglected (UNCST, 2000, 2001). The studies further suggest that technologies that were transferred were embodied in new equipment or in patents, blueprint technical drawings and manuals that brought direct outcomes of innovation rather than mechanisms, which facilitate learning about the innovation process itself (UNCTAD, 2002; UNIDO, 2000). Since there is ample literature to show that knowledge transfer in organizations occurs through alliances and other forms of inter-organizational relationships, this study complements literature by investigating technological knowledge transfer from foreign partners to IJV in Uganda's manufacturing sector. The choice for the manufacturing sector cannot be underscored since technological knowledge comprises the knowledge base that manufacturing industries apply in the development, design, production and application of processes, procedures, systems and services.

## **Literature Review**

Starting from Polanyi's (1967) assertion that knowledge comprises of tacit and explicit dimensions that are mutually complementary, several other scholars have also defined knowledge by categorizing it into different forms (Bloodgood & Salisbury, 2001; Edvinson & Sullivan, 1996; Nonaka & Takeuchi, 1995). Nonaka (1994) has categorized tacit knowledge into two dimensions. The technical dimension encompasses skills, crafts, and the cognitive dimension that resides in people's heads in the form of instinct values, experience and personal beliefs that shape the way individuals perceive the world around them. The importance of technical know-how in Uganda cannot be underscored considering that it is such type of knowledge that is required to transform the available resources and to produce direct outcomes of innovation that spur industrial growth (Fernandize, Montes, Gullermo, Bustamante & Vazquez 1999; Shrivastava & Souder, 1987). We consider such technical know-how as technological knowledge, which is defined as a body of experience, contextual information and techniques used in the development, design, production and application of processes, procedures, systems and services (Shrivastava & Souder, 1987).

### **Knowledge Transfer in International Joint Ventures**

Earlier research on International joint venture literature dwelt on three interconnected theoretical dimensions of primary emphasis (Luo, 2000; McFashion & Sweeney, 2003; Parke, 1996; Wong & Ellis, 2002). The dimensions are antecedents, which include JV formation and partner selection; specific management issues pertaining to control and conflict; outcomes that encompass JV stability and performance. The traditional approaches however omitted the concept of learning, which are now the trend of current research and the focus of this study. The concept of learning as a current phenomenon has gained popularity at unprecedented levels in the last century (Bochel et al., 1998; Lyles & Dhanaraj, 2004). The organizational learning perspective focuses on how value is created through the enhancement of partner skills (Inkpen, 2000; Lyles & Dhanaraj, 2004). There are two distinct values on alliance learning (Peridis, 2000), co-specialization and capability enhancement and conduits for skills accessibility. The opportunity for co-specialization and enhancement of capabilities that are associated with new business opportunities arise from the integration of partner capabilities (Griffith et al., 2002; Mimbaeva & Pedersen, 2003). The second value coined "the race to learn" (Hamel, 1991) views alliances as conduits for accessing partners' strategic resources and embedded knowledge (Inkpen & Beamish, 1997; Tiemessen et al., 1997). The second value is considered as a win-win situation because the benefits of learning are transferable to the partners other business hence resulting in a multiplier effect and increasing the incentive to co-operate (Peridis, 2000). The race to learn on the other hand is considered unstable because a faster mastery of skills on the part of a partner that is quicker to learn is likely to lead to alliance instability (Inkpen, 1998). Organizations capable of integrating and utilizing

knowledge according to Griffith et al. (2002) have been linked to improved manufacturing productivity, alliance efficiency and adaptability, supporting international expansion strategies and developing a sustainable competitive advantage.

#### **Factors Affecting Technological Knowledge Transfer**

Some studies have analyzed barriers of knowledge transfer and replication, which include features of knowledge or causal ambiguity (Inkpen & Dinur, 1998; Simonin, 1999; Zander & Kogut, 1995). Other studies explored the effect of social contexts in terms of social distance and organizational culture on the transfer of knowledge (Inkpen, 2001; Inkpen & Dinur, 1998; Kostova, 1999). Gupta and Guvindarajan (2000) also investigated perceived value of the source unit's knowledge, the transferors' willingness to share knowledge, the existence and richness of transmission channels and transferee's willingness to share knowledge. Tsang (2002) also investigated the effect of previous experience in forming and managing alliances or having collaborated with the same partner on knowledge transfer. Yet other studies investigated the characteristics of the transfer process (Argote, 1998; Argote et al., 1990; Baum & Ingram, 1999; Darr et al., 1995). Literature suggests that research on knowledge transfer in joint ventures does not seem to converge as evidenced by a proliferation of constructs and models (Lyles & Dhanaraj, 2004). From our discussion on the various frameworks above, it is evident that several factors affect the transfer of knowledge in Joint Ventures. However some studies on technological acquisitions and innovation emphasize the importance of similar external environments, technological similarity, geographical proximity and comparable internal structures in facilitating effective inter-firm technological knowledge transfers (Rosenkopf & Almeida, 2003; Stern & Henderson, 2004).

#### **External Environment**

External environment refers to anything outside the typical boundaries of an organization that create opportunities and threats to the organization, but over which the organization has little control (Hall, 2002; Robbins, 2001). Five organizational environmental domains include social, political, ecological, economic and technological (Hall, 2003). The different environmental domains have varying impacts on organizations according to Hall (2003). Whereas some organizations face relatively static environments like absence of new competitors, unavailability of new technological breakthroughs, less consumer demands others face very dynamic environments. Erratic government policies and regulations, sophisticated consumer demands, insufficient raw materials and numerous competitors are some of the characteristics of dynamic environments. The relatedness of external environment is an important determinant of where an IJV will search for and acquire competencies (Hansen & Lovas, 2004). Empirical studies of patent data posit that firms continue to seek and draw upon knowledge bases of firms most technologically similar to theirs (Mowery, et al., 1996) and from those in geographically proximate locations (Rosenkopf & Almeida, 2003; Song et al., 2003).

#### **Technological Similarity**

The extent to which firms can internalize new skills and techniques may be partially dependent on the recipients' knowledge bases (Hamel, 1991). Hamel (1991) further observed that if organizations' learning has to be effective, the knowledge bases have to be almost similar or else there will be many learning steps that make learning almost impossible. A partner firm possesses a related technological competence as long as its technological and technical expertise has similarities with what an IJV requires. This implies that elements of similar technological knowledge facilitate the integration of the acquired knowledge base (Hamel, 1991; Kogut & Zander, 1992). The proposition of technological similarity is anchored on Cohen and Levinthal's (1990) notion of absorptive capacity. It is posited that common skills, shared languages and similar cognitive structures enable technical communication and learning (Lane & Lubatkin, 1998). Likewise, technologies that are particularly foreign and unfamiliar to the firm in relation to its technical competency base are difficult to comprehend (Steensma, 1996).

#### **Geographical Proximity**

Studies investigating technology transfer have pointed out that most technological knowledge that accompanies hard technology is highly firm specific, tacit, personal and less transferable across boundaries (Kogut & Zander, 1992; Mowery et al., 1996). To transfer such technological knowledge, the recipient firms would usually need to establish a much closer and more interactive relationship with the knowledge providers (Roberts, 2000). Studies investigating the impact of physical distance have posited that intense interactions often required in R&D demand close proximity (Almeida, 1996). That this is important because the parties need to go through alliterations of trying and testing and

doing some more in order to develop R& D capability (Cummings & Teng, 2003). These studies suggest that geographical proximity reduce the cost and time of communicating and increases the frequency of personal contacts that build social relations thereby facilitating knowledge flow (Rosenkopf & Almeida, 2003).

#### **Comparable Internal Structures**

Technological knowledge is often embedded in a firm's problem-solving techniques, communication channels that with time become taken for granted. These core structural features of an organization where technological knowledge is embedded become implicit, durable and difficult to change (Nelson & Winter, 1982) and as such learning about complex technologies becomes context-dependent. As a result of this, the effective transfer of technological competencies across businesses with less compatible internal structures is highly unlikely for in the absence of such similarities, the recipient firms would lack the following (Stern & Henderson, 2004): The communication channels needed to evaluate, receive and filter rich information; The organization routines and structures for effective storage and maintenance; The implicit problem-solving strategies needed to interpret information and apply it to solve organizational problems and apply it to commercial ethos.

#### **Conceptual Framework and Hypotheses**

Though recent research emphasizes the ease of technological knowledge flow between technologically and geographically proximate firms, we support Rosenkopf and Almeida's (2003) suggestion that the formation of strategic alliances as in case of joint ventures can enable firms overcome geographical and technological constraints. We also posit that even when partners undertake to collaborate with the intention of exploiting external knowledge, certain requirements must be in place for the successful completion of the whole process. One is that partners must be confident that the relaters can be relied upon to behave in such a manner that the long term interest of the partners will be served, they must be committed to the relationship long-term maintenance and willing to have earnest dialogues. Another is that, there must be norms or routines that provide a formal structure to a relationship. Luo (2002) described such ties that manifest at an organizational level as structural attachments that bind parties to a relationship and make it difficult to consider other exchange partners (De Wulf et al., 2003). Lastly, the partner must have the necessary capacity to learn. This capacity includes an ability to internalize within its core organization the knowledge that it acquires through an alliance and the ease with which an organization allows its staff to generate new ideas. Our choice of variables is guided by theories that underpin the model, by previous literature on technological knowledge and by the Ugandan context in which IJV operate. Although some of these factors have been examined extensively in developing economies, to the best of our knowledge, these are yet to be extensively researched in the underdeveloped economies.

The importance of establishing very close and more interactive relations with knowledge providers and the essence of technological similarities is cited in technological transfer literature (Ahuja & Katila, 2001; Hansen & Lovas, 2004; Rosenkopf & Almeida, 2003; Steensma, 1996; Stern & Henderson, 2004). The inclusion of relationship quality factors was based on Uganda's past history. With the expulsion of the Asian community most of who owned the industries and were the custodians of the technical know-how, we believe that investigating trust between IJV and foreign partners and communication behavior cannot be underscored. We drew relationship quality and firm-level learning capabilities' variables from Argote (1999) model and incorporated inter-party attachment from Luo (2002) model. We have not come across any previous research that considered Argote's and Luo's constructs simultaneously. By combining Argote's and Luo's constructs into one integrated model, we have been able to enrich the model further. We can therefore assess the differential impact of these factors in a more reliable way as opposed to testing their effect separately. We integrate this conceptualization with the social exchange theory on the premise that partners will only continue to exchange valuable resources if they perceive the exchange relationship attractive and likely to yield a pattern of reciprocal obligations (Blau, 1964; Demirgarg & Mirza, 2000). The affection that develops motivates partners to share strategic resources like know-how that enhance a firm's ability to recognize and evaluate new knowledge (Cohen & Levinthal, 1990). Such a framework will contribute to theory, contribute to the aforementioned existing gaps in literature and expand research that could significantly impact on emerging economies that will propose solutions to narrow the technological gap between them and advanced nations.

From the review of literature and from our conceptual perspective, we believe that the main motive behind joint venture formation in Uganda is their importance as conduits through which firms can access and learn each

other's critical skills and capabilities (Inkpen, 2000, 2001). We thus seek to investigate the extent to which technological knowledge has transferred from foreign partners to IJV in Uganda's manufacturing sector. The transference of technological knowledge is particularly imperative because technological knowledge constitutes an important phase for industrialization on which developing countries anchor their economic growth. The study assesses how factors such as relationship quality, inter-party attachment, and firm-level learning capabilities affect the extent of technological knowledge transfer in Uganda's IJV.

#### **Trust and Communication Behavior**

The quality of a relationship between IJV and its partners is very important because a firm is able to learn more easily from alliance partners when the degree of trust, transparency and openness between them is high (Doz & Hamel, 1998; Hamel, 1991). Since the cost of developing, deploying capabilities and of sharing know-how in inter-organizational relationships is high, effective mechanisms must be in place to discourage free riding and allow knowledge exchange (Dyer & Singh, 1998). Equally important is the quality of information and know-how exchanged in terms of accuracy, comprehensiveness and timeliness and participation in goal formulation and joint planning referred to as communication behavior.

Existing research suggests that mutual trust between partners reduces the fear of free riding and opportunistic behavior often associated with the exchange and accessibility of assets such as knowledge that create value, are not available on open market and require time to build up (Ahuja, 2000; Gulati; 1995 Zaheer et al. 1998). Building upon this extent literature, that improved relationship quality can contribute to a freer and greater information exchange and expertise between committed exchange partners. Overall, we believe that the amount of knowledge transferred from foreign partners to the IJV will be influenced by the degree of trust between the foreign partner and the IJV. More trust in the partners' competence will result in higher intent to acquire and adopt knowledge on the part of the IJV because higher levels of transparency and openness are often associated with the ease to learn (Inkpen, 1998) and will most probably affect the amount of knowledge transferred. Second, partners who trust each other are likely to lower the level of protectiveness towards each other thus increasing transparency. This nevertheless leads to accuracy, comprehensiveness and timeliness of information provided. Information is a necessary medium in organizational learning for knowledge exploitation (Nonaka, 1994). Individuals obtain and interpret information and learn by updating their mental models (Von Hippel, 1994). As individuals' mental modes are enhanced, organizations ability to search, identify, acquire and adapt external knowledge is also enhanced. We therefore conclude that improved communication behavior will result in greater extents of technological knowledge transfer. Thus, we hypothesized that:

*H1. The higher the quality of the relationship between partners in terms of trust, the greater the extent of technological knowledge transfer.*

*H2. The higher the quality of the relationship between partners in terms of communication behavior, the greater the extent of technological knowledge transfer.*

#### **Structural Attachment**

Cross organizational boundaries aimed at establishing social ties (Luo, 2001) at either individual or organizational level play an important role in knowledge transfer. When the partners have developed a strong attachment that is manifested at organizational level, it's more likely that they will have a basic understanding about each other's skills and competencies (Inkpen & Beamish, 1997). Effective attachments reduce risk by carrying expectations of trust and abstention from opportunism and encourage resource exchange (Luo, 2000; Seabright et al., 1992) of which technological knowledge transfer is part. More so, social ties lubricate the workings of the relationship by supporting the existence of shared values, non-opportunistic behavior (Morgan & Hunt, 1994) and timely communication. We follow Luo (2002) argument that attachments in IJV create a favorable climate for knowledge exchange because increased trust and commitment that develops between exchange partners facilitate the transfer of especially embedded knowledge. Both parties develop a common culture that nourishes mutual learning which when coupled with increased familiarity of policies and procedures with greater understanding of the nuances of each other's knowledge, ease the ability to transfer. We thus hypothesized that:

*H3. The greater the structural attachment between partners, the greater the extent of technological knowledge transfer.*

### **Learning & Development and Creativity & Flexibility**

A transferee's learning capability is reported to be a major influence of knowledge transfer (Gupta & Govindarajan, 2000; Lane et al., 2001; Simonin, 1999). An IJV learning capacity requires that firms have considerable in-house expertise that complements the technology activities of its alliance partners. Organizations that have clear strategies for learning and staff development acquire knowledge more effectively from their foreign parents (Inkpen & Crossan, 1995). Learning and development will enhance individual absorptive capacity and cumulatively improve overall learning of the IJV. Since possession of prior related knowledge is necessary for the effective assimilation of new knowledge (Cohen & Levinthal, 1990) we anticipate that IJV that encourage their employees to learn by formal training and development are more likely to exploit any critical external knowledge opportunities. Likewise, Amabile et al., (1996) posits that the creation of new knowledge depends upon a person's expertise, thinking skills and motivation. She argues that whatever an individual's expertise and creative thinking skills, the environment under which one operates can either enhance or inhibits the level of creativity. This line of argument is also supported by Rice (2003) who argues that employees can engage in creative problem-solving and exploitation of new knowledge as long as the working conditions within which an IJV are operating are flexible enough and conducive to allow for individual and group creativity. We hypothesized that:

*H4. There is a positive relationship between IJV degree of competency in training and development and the extent of technological knowledge transfer.*

*H5. There is a positive relationship between IJV flexibility and creativity and the extent of technological knowledge transfer.*

### **Methodology**

This study focuses on the extent of technological knowledge transfer in Uganda's IJV. The conceptualization is underpinned by three fundamental principles: First, the quality of the relationship in terms of trust and communication behavior helps partners to share strategic resources like knowledge without fear of opportunistic behavior. Second, the strength of the relationship emerging as a result of organizational ties sets an organizational climate where there is more interdependency in the relationship and a more likelihood of sharing information and communicating tacit knowledge. This breeds trust, reciprocity, receptivity and transparency (Lyles & Dhanaraj, 2004) that counteract opportunistic hazards and enhances inter-organizational exchanges of strategic resources thereby increasing a firm's prior related knowledge. Third, firm-level learning capabilities as reflected in the way in which an organization encourages training and development of its staff in addition to supporting creativity and providing a flexible work environment enhances IJV absorptive capacity to recognize, evaluate and utilize foreign technological. Below we present the relationship among variables namely relationship quality, inter-party attachment and firm-level learning capabilities and extent of knowledge transfer as envisaged in our conceptualization that integrates Argote's (1999) and Luo's (2002) framework as depicted in Fig. 1.

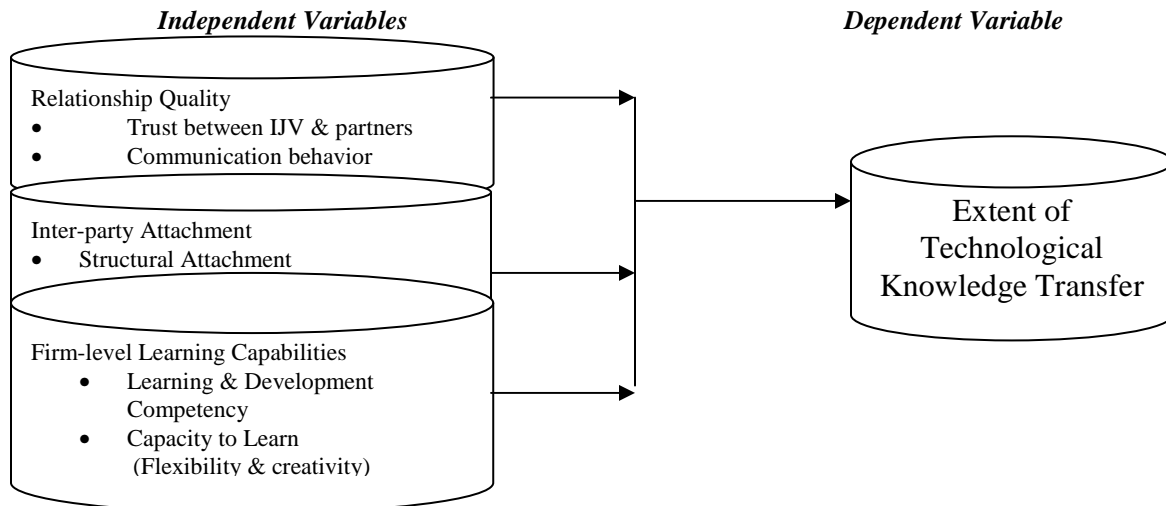

FIG. 1: THEORETICAL FRAMEWORK (Adapted from Muhenda, 2006)

The study was conducted in all the districts of Uganda that had IJV and a total of two hundred and fifty six (256) IJV registered with the Uganda Investment Authority between 1995 and 2003 were purposively selected and their CEO interviewed. The IJV being the key decision making entity among alliance partners and where the technological knowledge outcomes could easily be observable and appraised is the main unit of analysis. The instrument used in the questionnaire was adapted from various authors as indicated in Table 1 below. To ensure goodness of measure, the cronbach alpha coefficient was computed for all the variables where all the coefficients indicated values above 0.50 which strengthened the reliability of the instruments used in the study.

TABLE 1: SUMMARY OF VARIABLES

Variable	Number of items	Cronbach's alpha	Source
Communication Behaviour	5	0.95	Mohr & Spekman (1994) Selnes & Sallies (2003)
Trust between IJV & Dominant Partner	2	0.83	Moorman et al.(1992); Selnes & Sallies (2003)
Structural Attachment	3	0.67	Luo (2001)
Learning & Development	4	0.85	Hurley & Hult (1998)
Creativity & Flexibility	2	0.64	Amabile et al. (1996)
Management Support	2	0.57	Amabile et al. (1996)
Knowledge Transfer Extent	3	0.80	

## Results

A total of 103 respondents were used for the purpose of this study that accounts for 62.5% of the response rate. A total of ninety respondents were male 86.4 % whereas female CEO were only fourteen and accounted for 13.6 %. Only 13.6 % of the respondents were expatriate staff as compared to 86.4 % of local staff. Of these managers, the majority 58.3% had worked in the IJV for periods ranging from one to five years and only 3.9 % of the respondents had worked for less than one year in the IJV. Based on the responses from the managers interviewed, majority of the IJV's in Uganda started their operations from 1990 and account for 58.3%. A total of twenty three or 22.3% of the IJV are Tobacco and Beverages processing industries followed by Chemicals and Chemical Works industries

(19.4%) whereas food processing industries account for (18.4%). The higher percentage of Agro Industries is attributed to Uganda being largely an agricultural country. The smallest group of industries deals in Timber, Paper and Printing and account for 4.9% of the manufacturing industries. Such a low percentage could be attributed to many local firms being involved in the sectors that do not require complex technological knowledge that would have attracted joint partnerships. Majority of the companies earn over 500 million Uganda Shillings (61.2%), which is equivalent to United States dollars \$ 300,000. The Uganda Manufacturers' Association categorizes these as large-scale industries. Majority of IJV employ more than 200 employees, which account for 45.6 %. In our hypothesis generation, we postulated relationships between some factors of relationship quality, inter-party attachment and absorptive capacity on the extent of technological knowledge transfer. Using factor analysis, we were able to identify six dominant factors under each of the three variables namely communication behavior and trust constituting relationship quality; inter-party attachment as a single factor under structural attachment, creativity and flexibility, learning and development and management support factors under firm level learning capabilities. The results of the factor analysis are presented in Table 2 below.

TABLE 2: FACTOR AND RELIABILITY ANALYSIS OF RELATIONSHIP QUALITY, STRUCTURAL ATTACHMENT & FIRM-LEVEL LEARNING CAPABILITIES VARIABLES

### Multiple Regression Analysis

To test the simultaneous effects of several independent variables on the extent of technological knowledge transfer, multiple regression was carried out to determine the variance of the effect of the factors mentioned above on the extent of technological knowledge transfer. Table 3 summarizes the results:

TABLE 3: SUMMARY OF REGRESSION ANALYSIS RESULTS

Step	Variables	R square	Adjusted R	Sig F	$\beta$
1.	Controls	0.09	-0.02	0.70

### Discussion

Communication behavior, trust between IJV and foreign partners, structural attachment, learning and development and creativity and flexibility have a positive effect on the extent of technological knowledge transfer. Management support is negatively related to the extent of transfer implying that an increase in the degree of management support leads to a decline in the extent of technological knowledge transfer which finding is contrary to our hypotheses. Structural attachment and learning and development have a positive significant relationship with the extent of technological knowledge transfer in Uganda's IJV. The two variables explain 0.63 of the variance in OBP ( $R^2 = .63$ ). The following results are obtained: structural attachment ( $\beta = .46$  at 1% level of confidence) and learning and development ( $\beta = .32$  at 5% level of confidence). The results imply that IJV that offer more learning and development opportunities to their employees and whose degree of structural attachment is higher are likely to, experience higher extents of technological knowledge transfer from foreign partners. Structural attachment and learning and development have a greater impact on the transfer extent than communication behavior.

#### Extent of Transfer of Technological Knowledge in Uganda's IJV

We sought to find out the extent of technological knowledge transfer in IJV in Uganda. Taking 5.0 as the highest extent of knowledge transfer on our scale and 3.0 as average transfer extent, we can conclude that the extent of knowledge transfer from foreign partners to IJV in Uganda is fairly low. Transfer extent recorded a mean score of 2.97, which is slightly below average level of incidence of transfer performance.

#### Relationship between Independent Variables and Extent of Transfer

We attempted to find out how factors such as relationship quality, inter-party attachment and firm level learning capabilities influence transfer of technological knowledge in Uganda's IJV. The findings are consistent with the

dominant factors that were derived from the factor analysis which include communication behavior, trust between IJV and foreign partners (relationship quality), structural attachment (inter-party attachment), learning and development, creativity and flexibility and management support (firm level learning capabilities).

### **Communication Behavior**

Contrary to our hypotheses, communication behavior was not significantly associated with the extent of technological knowledge transfer. The results of our study are inconsistent with several other studies that emphasize the importance of sharing high quality information in exploiting knowledge opportunities in alliances (Dyer & Singh, 1998; Child, 2003; Inkpen, 2001; Nonaka, 1994). The studies cited above confirm that availability of information stimulates an awareness of needs and concepts and is also a means by which behavior is modified, change is effected, information made productive and goals achieved (Cole, 2001). The inconsistency in our findings could possibly be attributed to five (four) major reasons, namely underlying national and organizational cultural differences, information overload, failure to adopt adequate institutional mechanism, and level of technicality. **Underlying national and organizational** cultural differences arise as a result of different cultural orientations of partners and may result in sharing of poor quality information which may have negative impact on the extent of technological knowledge transfer. **Information Overload** refers to overloading users with unnecessary vast amounts of data may lead to situations where useful information is discarded or ignored and not put to effective use. The failure on the part of the IJV to adopt **adequate institutional mechanisms** to ensure effective communication behavior in terms of sharing relevant knowledge among employees including those who may not need it immediately. **Level of Technicality** suggests that a larger component of technological knowledge comprises of tacit elements and finding proper language to articulate what they know and share expertise with novices may often be difficult for the partners to communicate with the IJVs.

### **Trust between IJV and Foreign Partners**

The contrary results that found no positive and significant relationship between trust and knowledge transfer are similar to earlier findings by Lane et al.(2001) and Lyles et al. (2000). Lane et al. (2001) did not find trust to be directly associated with learning. An earlier study done by Lyles et al. (2000) in Vietnam found that changes in learning structures like parent assistance accounted more for changes in IJV knowledge acquisition than they found for trust. The prevailing logic of why trust does not significantly affect the extent of technological knowledge transfer from foreign partners to IJV in Uganda could be justified by the fact that successful knowledge distribution depends on the amount of explicit knowledge available in the IJV (Davenport & Long, 1998). Technological knowledge comprising largely tacit elements, is difficult to convert to explicit knowledge and therefore difficult to share and adopt even in the presence of a strong relationship commitment. Another possible reason could be due to earlier history experiences that brought anew dictatorial regime to power that summarily expelled the Asian community, thus seriously undermining investor confidence. Though succeeding governments sought to attract foreign investors to Uganda, the confidence of potential Asian investors in particular could not be readily rekindled (UNIDO, 2000). This could partly explain why trust between IJV and foreign partners is not significantly associated with the extent of technological knowledge transfer in Uganda's IJV given that the most dominant foreign partners are of Indian nationality and account for 49%.

### **Structural Attachment**

Structural attachment was shown to be positively and significantly related to extent of technological knowledge transfer. Luo (2001) urges that attachments in JV create conducive climate for knowledge exchange because increased trust and commitment that develops between exchange partners facilitates the transfer of embedded knowledge. As a source of enduring commitment from each party over time, attachment helps create a repository of reliable information from exchange partners (Inkpen and Beamesh, 1997). Research on attachment has also investigated the relationship between personal and structural attachment and how they interactively influence performance. Luo (2002) reported that both personal and structural attachments exert a strong positive influence on IJV performance. Luo's (2002) study further posits that such attachments stimulate IJV sales and profits. Due to increased acquaintance with policies and procedures between exchange partners along with greater understanding of the nuances of each other's knowledge, the ability to transfer is enhanced. This underlies the positive association between structural attachment and technological knowledge transfer extent in this study.

### **Learning and Development**

Learning and development was shown to have a positive significant effect on the extent of technological knowledge transfer as earlier predicted. As already discussed, absorptive capacity requires that a firm develops considerable in-house expertise that complements the technology activities of its alliance partner. Organizations that have clear strategies for learning and staff development acquire knowledge more effectively from their foreign parents (Inkpen & Crossan, 1995). Absorptive capacity of the transferee is reported to be a major influence of knowledge transfer (Gupta & Govindarajan, 2000; Lane et al., 2001). The results from this study are also consistent with Lyles and Salke (1996) who demonstrated empirical support for the linkage between training of local employees by foreign parents and knowledge acquisition. The findings of Hathaivaseawang (2004) also showed that formal training was an important predictor of acquired marketing knowledge. It is thus true to presuppose that IJV in Uganda that support employees' learning and development initiatives are more likely to exploit any critical external knowledge opportunities.

### **Creativity and Flexibility**

Surprisingly, creativity and flexibility were found to be positively but not significantly related to enhanced technological knowledge transfer. The inconsistency in our findings could possibly be attributed to some of the following factors. One key influence on the success of any creative enterprise is the acquisition of requisite resources particularly necessary financial support (Damarpour, 1996). **Lack of adequate resources** that is characteristic of many developing economies could be a major hindrance to creativity and flexibility given that forty percent (40%) of the IJV in Uganda earn less than 300,000 US dollars in gross annual revenue. With insufficient resources, the chances of trying out new ideas and rewarding employees for their innovations are severely curtailed. The situation is further compounded by lack of supervisory and managerial support crucial to the process of ensuring supply of the necessary resources. Interviews with the shop floor staff confirmed inadequate resources and restrictions as being setbacks in the bid to trying out new ideas. For the majority of staff interviewed, experimenting and trying to solve same problems in different ways is considered a waste of resources and is not acceptable in the majority of IJV. Other possible reasons could include some of the following. **Conflict of opinion** because of diverse professional backgrounds and cultural backgrounds of team players. . In addition, **inability to share creative** ideas across units and or even within teams could inhibit the extent of technological knowledge transfer. **Inherent socio-psychological dynamics** also feature. Knowledge that is always considered a source of power which if lost could undermine the experts' spheres of influence and peer recognition could also be responsible for the inconsistency in our findings. On the other hand, **hierarchal extrinsic rewards that breed conformity** and conservatism and skill specialization may discourage creativity among IJV staff.

### **Management Support**

Management support, however, does not affect the extent of technological knowledge transfer in this study yet earlier studies reported significant association between management support and knowledge management product (Davenport & Long, 1998; Rice, 2003). The only prevailing logic as to why executive support does not positively influence the extent of knowledge transfer could be that since knowledge would already be acquired, applied and disseminated, with time it becomes automatically integrated with or without any support. Hence the contrary results.

### **Policy Implications**

The results confirm a low incidence of the transfer of technological knowledge from foreign partners to IJV in Uganda which findings could guide policy makers. The Uganda Government could encourage, support and strengthen the existing policy on investment in general and IJV in particular. There is need to enforce the policy, which encourages the transfer of foreign technology and expertise and lays out all conditions which limit the ways in which technical know how may be used. The Government could institute punitive measures for non-compliance like refusal of license renewal and denial of investment incentives like tax holidays. In addition, the overall findings also suggest that IJV resources also influence the extent of knowledge transfer, hence the need to emphasize IJV earnings in technological knowledge transfer. Government could moderate the erratic high levels of taxation, lower

interest rates on business loans and restrict importation of competing products. The findings of the study also suggest that relationship characteristics among organizations in an alliance may facilitate or inhibit the extent of technological knowledge transfer. Therefore, the government should illustrate to participating firms how the process of technological knowledge transfer could be enhanced and improved to facilitate the transfer of knowledge from foreign partners to IJV. This could be accomplished through seminars and workshops where dissemination of research results could be discussed and stakeholders encouraged to share experiences. Government could also fund or solicit funding for research in technological knowledge transfer fields and ensure that the types of skills that are needed by local industries are generated in adequate numbers through policies that promote firm-level learning and that encourage interaction between educational institutions and industries. Strengthening technology support institutions and establishing new relevant institutions in addition to enforcing science subjects in schools could also be appropriate options.

## **Recommendations for Future Research**

This study has contributed to the body of knowledge in the area of knowledge management especially in supporting theory development. Further empirical research could explore other variables like technical and organizational infrastructure that has been cited in knowledge management studies (Davenport et al., 1998; Davenport & Marchand, 2000; Shyrme, 1999). The convergence of telecommunications and computing that allow the exchange of knowledge across firms regardless of geographical boundaries could warrant future research. Technologies that support communication building, people networks and on the job learning are considered crucial for organizational learning and knowledge transfer whose influence on technological knowledge transfer could be investigated further. This study confined itself to IJV in the manufacturing sector omitting service industries because it investigated the extent of technological knowledge. More empirical research could be extended to service industries to investigate the transfer of other forms of knowledge. A longitudinal study is recommended for this type of research to address the continual process that takes place during the transfer of technological knowledge.

## **Limitations**

Several limitations were experienced in research design and methodology, the nature of data collected and the population size. Such limitations have a bearing on result interpretations and generalizations. The first limitation is due to the population size. The IJV were identified from the Uganda Investment Register only. Collecting data from listed and non-listed IJV could strengthen the findings of this research. Another limitation is that one CEO responded to the questionnaire on behalf of the IJV, which makes the responses not fully representative of the views of all employees.

Secondly, some methodological problems were encountered. Some data collection methods adopted for the study have inherent disadvantages: questionnaire retrieving requires frequent reminders; and some participants require long distance travels to access them. Another problem could have resulted in the directive from Uganda Investment Authority requesting the CEO's to fill the questionnaire which directive may have been unwelcome and hence the incomplete 56 questionnaires were returned but could not be used. Lack of understanding of some terminology in the instrument might also have interfered with the interviewees understanding of some questions in the instrument because 58% of the items were discarded after factor analysis. The other problem is that this study was a cross-sectional study where data collected at one point in time might not convey a true picture of the facts on the ground.

## **Conclusion**

This study investigated the extent to which technological knowledge from foreign partners has transferred to IJV in Uganda. We first examined the extent of technological knowledge transfer from foreign partners to IJV in the Ugandan manufacturing study. The results confirmed a low incidence of extent of transfer of technological

knowledge from foreign partners to IJV in the Ugandan manufacturing sector. This is divergent from government's effort to encourage joint partnerships aimed at tapping into foreign partners technological bases. Secondly, we examined the relationship between a set of factors and the extent of transfer of technological knowledge. Results revealed that learning and development and structural attachment significantly impact the extent of technological knowledge transfer from foreign partners to IJV in Uganda. Results also indicate a non significant relationship between communication behavior, structural attachment, creativity and flexibility and management support and the extent of technological knowledge transfer. Based on the findings, this study calls for concerted efforts on the part of the Government of Uganda to provide a policy and legal framework that will guide the acquisition and adaptation (our term for knowledge transfer) of technological knowledge from foreign partners. The study is very useful because it brings out differences in current thinking, contributes to current discussions, arouses interest to the broader audience and proposes solutions for remedying alleged deficiencies that are in line with current theories.

## Abstract

The study attempts to elucidate the determinants of multi-layer platform strategies along the vertical interfirm division of labor for product development drawing on the cases of the Chinese and Japanese mobile handset industries. Firms could devise and exploit their proprietary platform designs in pursuit of both product development efficiency and product diversification. Yet, the global surge of product modularization encourages the product development in open interfirm networks. Particularly semiconductor vendors, which integrate product functions on chipsets, are reported to drive the transition. Meanwhile, the study highlights the vertical interfirm division of labor due to the difference in required development capabilities between core chipsets and circuit board designs. The vertical interfirm process is not sufficiently open until the chipsets and/or boards each are arranged in the form of technological and/or product platforms. These findings designate that effective product platform strategies resides in the management of vertical interfirm process: vertical architecture.

## Introduction

In the past decade, the vertical disintegration of product development and manufacturing activities has drawn our attention to interfirm modularity (e.g., Chesbrough, 2003; Christensen, Verlinden, and Westerman, 2002; Sturgeon, 2002). Product modularity, which is based on standardized product design rules and elements, enables manufacturers to decompose complex problem-solving into a set of localized problem-solving steps (Baldwin and Clark, 2000). The shift to modular product architecture has even enhanced interfirm modularity. Specialized vendors each cover specific component/technology development activities while manufacturers focus on product design and manufacturing activities.

The vertical disintegration of product development has shaped the global open interfirm product development networks, so that even emergent firms could rapidly develop products at a relatively low cost by adopting element technologies from specialized vendors. For instance, wireless handset manufacturers in China make use of the interfirm modularity in which specialized vendors provide element technologies (i.e., wireless cores/platforms, components, handset designs, software, etc.) to help handset manufacturers quickly release a variety of new models.

Amongst a variety of element technologies, a technology platform, which consists of the wireless chipset, software, reference product design, and related technological supports for the product concerned, plays a critical role to shape the open interfirm networks (Iansiti, 2003; von Hippel, 2005). The technology platform provides a standardized product design to realize a set of core product functions. Manufacturers may easily develop products by using the platform in open product development networks.

However, standardized element technologies such as a technology platform could be transferable and/or shared between firms, so that these technologies would not necessarily secure firms' competitiveness (Pil and Cohen, 2006). The availability of a technology platform in open product development networks is liable to cause harsh competition, which requires firms to pursue product variety. Thus, assembly product firm relying on interfirm modularity is further required to struggle to both quickly develop a variety of products and distinctive products in the competition (e.g., the Chinese industries).

In carries on both product variety and distinctiveness, a firm attempts to design proprietary product platforms. A product platform is a set of subsystems and interfaces that forms a common structure from which a firm

can efficiently develop a stream of derivative products (Meyer and Lehnerd, 1997). For automobiles, a product platform is generally defined by a combination of chassis, engine, drive train, transmission, and other major subsystems upon which a variety of different models can be based (Nobeoka and Cusumano, 1997). Product platform development requires the architectural knowledge to properly arrange various elements on a platform design particularly when new technologies are introduced into the product platform. Thus, even in interfirm open networks, firms for themselves need to integrate various technologies into products paying sufficient attention to both the uneven changes of various components and the interdependencies between them (Brusoni & Prencipe, 2001; Staudenmayer, Tripas, and Tucci, 2005).

The industrial shift toward interfirm modularity seems to blur the role of close coordination within and between firms, which were once regarded as one of the most critical factors of effective product development (e.g., Japanese automobile firms, Clark and Fujimoto, 1991; Yasumoto and Fujimoto, 2005). In digital electronics industries, open interfirm networks have threatened assembly product manufacturers, which have accumulated both the architectural and component knowledge on their products in close coordination within and between firms. Yet, even in the open interfirm networks of the vertical interfirm division of labor, it would be difficult to develop a novel technology platform into a distinctive proprietary product platform without interfirm collaborations.

Many of past researches discuss product platform designs in terms of the intrafirm perspective view. Meanwhile, we attempt to explore how to design product platforms in the interfirm context of the vertical interfirm division of labor. More specifically, the study will examine how assembly product manufacturers develop external new technology platforms into proprietary product platforms in the collaborative relationships with technology platform vendors. The study would contribute to not only elucidating the role of the interfirm collaborations in open interfirm networks but also drawing the competitive product development strategies in the era of vertical disintegration.

In the section 2, we will review past researches to propose our perspectives. In the section 3, we attempt to consider the generality of successful designing of product platform drawing on three cases: a mobile phone handset manufacturer in Japan, an ODM in Taiwan and a design house in China. In the section 4, we will discuss the results of the comparative study between these cases. Finally, in the section 5, we will present some implications for product platform design of electronic products and show future research issues.

## **Research Perspective**

The standardized knowledge of product technologies (i.e., open technology platforms), which is independent of firm/product-specific contexts, enhances the open interfirm division of labors for assembly product development. In spite of the openness of technology platforms, each specific product development is context-dependent. Product developers need to not only develop distinctive products but also quickly yield a variety of products in the harsh competition according to open interfirm product development networks (Christensen, Verlinden, and Westerman, 2002). These conflicting requirements encourage product developers to establish proprietary product platforms to achieve both product distinctiveness and variety.

A product platform design needs to cope with both market and technological changes. For instance, the lifecycle of software products are short, software firms need to redesign the product platforms for the next generation of software product development (Cusumano, 2004; MacCormack and Verganti, 2003). The successful product platform development needs a proper organizational coordination within and between firms (Robertson and Ulrich, 1998).

The perspective of “product architecture” explicates the necessity of organizational coordination. Product architecture is characterized in a spectrum from the “modular” to the “integral” according to the “interdependency of functions and components (Ulrich, 1995).” The development activities for integral architecture products are hardly decomposable into independent element development activities as the interdependency of functions and components is relatively high. In contrast, modular architecture products are characterized with the lower technology interdependency of functions and components, so that product designers can easily divide the development activities into relatively independent element development activities. Thus, the coordination between the development

activities of product platforms depends upon the architectural attributes of the platforms (Meyer and Lehnerd, 1997; Sanderson and Uzumeri, 1997).

Modularity is attributed to the architectural stability. The stability enables firms to refurbish modular products by realigning or replacing a part of element technologies without changing the architectural configurations of elements. Yet, even the product development based on interfirm modularity is accompanied by the coordination between product elements (Staudenmayer, Tripas, and Tucci, 2005). Particularly drastic element technology change may cause architectural instability to erode the decomposability between product designs and elements, and thus would enhance collaborative problem-solving within and between firms (Iansiti, 1997; Takeishi, 2002).

High technological uncertainty with new technology introduction sometimes causes the lack of architectural knowledge (Yasumoto and Fujimoto, 2005). Novel core technologies cause high technological uncertainty as the introduction of such technologies may lead to the interdependent changes of functions and components. The technological change will force firms to abandon their accumulated architectural knowledge which defines the interdependency between functions and components.

When technological system is static, open transactions between related firms could serve as a forum for product development. Yet, the cost of creating and maintaining interface standards will be prohibitively high as technological systems are rapidly changing. The logic makes us infer that when adopting novel core technologies, product developers should build information channels to monitor technological changes and have intensive contacts with external specialized vendors. The product development capabilities based on the close collaboration foster the knowledge exchange/sharing (Clark and Fujimoto, 1991; Iansiti, 1997; Takeishi, 2002), which shapes architectural knowledge. Thus, a product platform development accompanied by novel technology platform introduction will necessitate close interfirm coordination even in the vertical interfirm division of product development.

In electronic product industries, a firm attempts to integrate many functions into a product. The continuous improvement of the advanced technology of semiconductor process enhances the innovation for the convergence of functions. On the other hand, specialized chipset vendors (i.e., technology platform vendors) offer technology platforms as nearly total solutions that encapsulate many of product functions into a chip. The progress of function encapsulation built inside System on Chip (SOC) continuously redefines the architectural interdependencies of functions and components. Product developers should pay attention to the changes of the interdependencies in order to effectively renew their product platforms. Such changes resulting from technology platform renewals should call for close interfirm collaborations between technology platform vendors and product developers even in open interfirm product development networks.

## **Case Study**

### **Research Focuses and Data Collection**

The study focuses on the proprietary product platform development in the mobile phone handset industries in Japan, Taiwan, and China. Handset developers in any of these countries have increasingly exploited external technology platforms from vendors though the level of the vertical disintegration of handset development may differ by countries. Any of handset developers may shape proprietary product platforms based on standardized technology platforms. Yet, several prominent handset developers collaborate with technology platform vendors in both technology and product platform developments even in the open interfirm networks.

According to Funk (2002; 2004), in the period from 1994 to 1998, mobile phone handset manufacturers focused on not only product quality but also the variety. He indicated that by offering a variety of mobile phone handsets more than Ericsson and Motorola, Nokia acquired the biggest market share among them. In the initial time of the 2G mobile phone handset industry, manufacturers internally developed mobile phone handsets including core components. However, in the end of the 1990s, many specialized vendors started to offer core components or solutions to mobile phone handset manufacturers. The vertical disintegration occurs in the mobile phone handset industry according to the change raised a new issue to mobile phone handset manufacturers: how to effectively cooperate with external specialized vendors into mobile phone handset development.

The perspective in the previous section makes us infer that the interdependency of technology platform and product platform designs have critical impacts on the coordination between handset developers and vendors. The

interdependency technologies interact with each other. Handset developers' product platform development would rely on the coordination. The interdependency may often occur in handset platform development even though vendors provide standardized technology platforms to define the interrelations between handset components.

After product functions are defined, product designers translate them into specifications and start to decide which function can be implemented by particular component. Sometimes a function should be implemented by various components. For instance, in the development of the MP3 music function, designers should consider the memory size for storing, the alternative technologies for playing (i.e., software or hardware), the modification of the play settings during calling-in, and other usages of user. These problems require handset developers to consider the NAND memory (hardware), Base Band chip (hardware), Operating System (software), User Interface (software) and other related components so that the MP3 function is achieved by the compatibility between these components. Technology platforms which may relate these elements to the MP3 function could be redeveloped or modified in the process. Such interdependency will encourage the coordination between handset developers and technology platform vendors.

The study sheds lights on how handset developers collaborate with technology platform vendors in handset product platform development. At first, the case attempts to outline the interfirm handset development networks. Following the description, we examine the critical product development capabilities in the networks, which are common to relatively competitive handset development firms, drawing on the cases of handset developers in these regions.

The data of handset development was collected by semi-structured interviews from 2005 to 2007 in China, Japan, and Taiwan. More than 50 firms, which included handset manufacturers, mobile service carriers, wireless core chip vendors, software vendors, component vendors, and design houses, were involved in the study. We focus on a relatively competitive handset developers in each country, who develop proprietary handsets exploiting the close collaborations with technology platform vendors. We also make use of the information appeared in published journals and reports.

#### **Technological Structure of Mobile Phone Handset and Vertical Interfirm Division of Labor**

The technological structure of mobile phone handset is divided roughly into 'communication part', 'signal processing part', and 'External I/O part'. 'Communication part' implement telecommunication function received from electric wave by antenna etc. and cover the signal to digital data to 'signal processing part'. 'Signal processing part' has its own CPU for controlling all the system which liked INTEL in PC. Finally, 'External I/O part' controls each inputs and outputs of source of information from every components, liked display panel, key pad, and others. Finally, these parts are laid out to be a Printed Circuit Board (PCB), which is a terminal main body of mobile phone handset. The display, the key, and the digital camera, etc. are main devices in the circuit of the terminal main body.

In our concern, we choose the 'signal processing part' to be mainly analysis, because this part plays the role as the center of the mobile phone handset. In this part, there is a Base Band chip(BB chip) that controls signal and the communication processing. However, recently, the multimedia function has come to be valued in the mobile phone handset. Therefore, the BB chip become not only process the telephone calling function but also executes the multimedia function, liked MP3, high quality of camera imaging, games, video playing, touch panel screen, Global Position System(GPS) and so on. These value added GSM mobile phone handsets have been called feature phone, smartphone, and PDA phone and to fit each market segment. As the various functions required in a mobile phone handset, the development man-hour of software also has been rapidly increasing. These applications, firmware, operating system (OS) software should be designed and assured according to hardware components. Smartphones and PDA phones often use Windows, Linux, and Symbian OS to control the entire system including hardware component drivers, communication, application, and others. Feature phones use the Real Time Operation System (RTOS) that has real time of switching each task at several ten-micro second for controlling the entire system. Usually, these OS are offered to mobile phone handset manufacturers by IC chipset vendors together with chipsets.

As multimedia functions have increased in a mobile phone handset, BB chip vendors should consider the product architecture for designing mobile phone handset. Because of advanced semiconductor process technology, BB chip vendors can design powerful BB chips to execute multimedia functions. Furthermore, between BB chip vendor and mobile phone handset developer, there is not a simple buyer-supplier relationship, but a closed relationship with each other. Otherwise, because a BB chip is not a passive component, which received signal and

reactive only, and these passive components are almost standard, that can be purchased from the IC catalogue list of chip vendor.

On the contrary, the design of a BB chip will need system-level knowledge of mobile phone handset, and sometimes need to cooperate with operator if the telecommunication technology is advanced. For instance, Qualcomm cooperates with Japanese Operator 'au by KDDI' closely to implement its own telecommunication standard and advanced service based on their advanced technology of BB chips (Inagawa,2006). Because the BB chip can implement the various functions, the developer of mobile phone handset will need to understand the interdependencies of the chip with other components. Learning the interdependencies will become more difficult if BB chip vendor change their design of BB chip that will cause interdependence of other components. According to Clark (1985), we can consider that such innovations in core component design represent a movement 'up the system hierarchy' and, sometimes, represent revolutionary changes where system foundations are built afresh.

As we described before, when 2G started booming, Nokia and other major manufacturers tended to handle BB chip and software(RTOS, protocol stack, power management, wireless interface, and UI, etc.) and combine them with other devices for designing product platforms. On the contrary, the Japanese manufacturers also develop these components for themselves but did not design product platforms. While specialized chip vendors(TI, ADI, Philips (present NXP), Qualcomm, etc.) started to offer BB chips from the end of 1990's, both in 2G and 3G, most of Japanese manufacturers adopted BB chip from outside. Nowadays, most of the mobile phone handsets are using advanced 3G telecommunication technology and developing mobile phone handset based on operators' services requirement. In Asia, especially in Taiwan, PC manufacturers started duplicate their successful ODM business model for mobile phone handset. They follow the specifications from Motorola, Sony Ericsson, and so on, and develop the detail specifications of their mobile phone handsets. Otherwise, they also elaborate their procurement capability of components and advantage of economies of scale for that Ultra Low Cost (ULC) mobile phone handset outsourced from Motorola, Sony Ericsson and so on.

Finally, China mobile phone handset industry can be regarded as a divergent path of upgrading which is while export growth has been overwhelmingly led by multi-national corporations, increasingly fierce competition in the domestic market ignited by the advent of local mobile phone handset manufacturers have induced unique industrial evolution in the manner of backward linkage effects : (1)outgrowth of design houses specialized in mobile phone handset development and (2)emergence of IC fabless ventures that design core ICs for mobile phone handset. The emergence and evolution of China's mobile phone handset industry is likely to have international implications as the growth of the global demand for low-cost and multi-function mobile phone handsets is expected to accelerate(Imai and Shiu,2006). There are several types of mobile phone handset development in vertical interfirm division of China mobile phone handset industry, in the case of design house, they only focus on design and rely on the EMS's volume production(Marukawa, Yasumoto, Imai, and Shiu,2007). Here we choose the design house as analysis because of their benefits of sales are higher than local mobile phone handset manufacturers. The benefits of design house roughly come from design fee which follow customers'(mobile phone handset manufacturers) requirements or specifications. Another benefits come from the PCBA(Printed Circuit Board Assembly) which means design house offer a PCB which components has been mounted on, and this part of benefits have been increasing for design house compared to design fee. In the case of PCBA business model, design house licensed BB chip from external BB chip vendor and provide a list of product functions for their customers. After their customer decide which functions are necessary, design house started to select their pre-verified components to develop a PCBA. Compared to design service by customer's specifications, PCBA business model needs to do some market research by themselves for their understanding what are the functions will be required in future. In the fast changing market, shorten product life cycle, design house will face the high uncertainty in the PCBA business model. So, in our research, we will take PCBA business model as analysis to find out what is the successful factor for designing product architecture.

In sum, although in the following 3 cases, they implement the same procedure of mobile phone handset development including (1) product definitions, (2) product design, (3) pilot production and review, (4) testing, acquisition of compulsory certification, (5) preparation for volume production (FIG. 1), however, there are different levels of uncertainty from market when they define their product functions and design their product architecture. At PCB level, we can distinguish different levels of market uncertainty influence between Japan, Taiwan, and China.

Although, Japanese manufacturers and Taiwanese ODMs follow the specifications from operator and major companies respectively, Japanese manufacturers have to reach many advanced service which has been offering by operators, on the contrary, Taiwanese ODMs design the low-end and middle-end of mobile phone handsets outsourced by major companies, and which have been exported to BRICs. Therefore, it shows that high market uncertainty influenced on product design in Japan compared to low market uncertainty influenced in Taiwan. China mobile handset design houses also face a high uncertainty for product functions definition in their PCBA business model as we describe before. At the followings, we will analyze three different business models for different levels of uncertainty they are facing, and also consider what to do with technology uncertainty from BB chip vendors next.

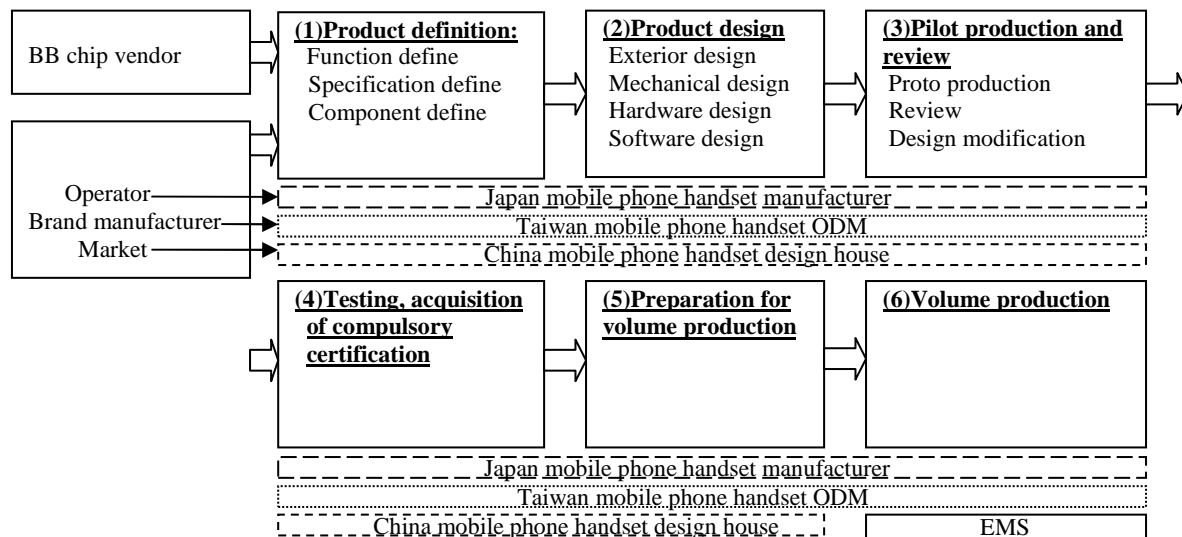

FIG. 1 : VERTICAL INTERFIRM DIVISION OF MOBILE PHONE HANDSET DEVELOPMENT IN JAPAN, TAIWAN, AND CHINA

#### Japanese Mobile Phone Handset Manufacturer

Ever since NTT DoCoMo operator introduced i-mode service in 1999 and 3G service (W-CDMA) in 2001, mobile phone handsets have become not just a communication tool but also a multimedia terminal product. There are a total of three operators competing in the service area while eleven mobile phone handset manufacturers are competing in product differentiation. Firm A was a late-entrant manufacturer in 1998. However, it provided more products compared to others, therefore, it has the highest market share amongst its competitors at the present.

Firm A has 6 Business Units: (1) 1st Personal Communication Business Unit (for NTT DoCoMo operator), (2) 2nd Personal Communication Business Unit (for Softbank operator), (3) 3rd Personal Communication Business Unit (for overseas market, mainly for Vodafone operator), (4) 4th Personal Communication Business Unit (for au by KDDI operator), (5) IP Communication Business Unit (for fax machine, cordless phone handset, etc.), and (6) Platform Development Center. 1st, 2nd, and 4th Personal Communication Business Units receive service requirements from three different operators respectively, and develop mobile phone handsets for them tailored to the domestic market. Moreover, they are not allowed to exchange customer information with other business units.

Although the service requirements of these three domestic operators are different from each other, some components of a handset model are similar to and are shared within its handset lineup at Firm A. For instance, most parts of an user interface application software do not have feature characters, so these can be regarded as common software platform and can be shared with different mobile phone handsets. To give an actual example, model number 904, 905, and 705 mobile phone handsets have the same PCB design; but 904 model has VGA, 3 mega camera pixels, and other functions. Whereas 905 model adds extra mobile television function, while 705 abandons

high performance in exchange for a slimmer body. However, in order to share these common components with other various mobile phone handsets developed by the business units, Firm A has established 'Platform Development Center'. This 'Platform Development Center' develops common software (the basics of protocol stack, user interface, mailer, browser, etc.) and hardware (display panel, camera module, etc.) that are to be shared, and also manages these common components as libraries with clear specifications and definitions.

The 1st, 2nd, and 4th Personal Communication Business Units also use three different technology platforms respectively for developing mobile phone handsets. When adopting a technology platform for developing mobile phone handsets, technological uncertainty constantly rises. Because technological uncertainty causes unexpected yet unclear software bugs, a long debug process is always required. Without practical usage experiences, a new technology platform includes various unexpected bugs during the development stage of a chipset. Moreover, a technology platform which performs advanced multimedia functions also has compatibility problems with software and hardware components. For example, when Firm A began to use a technology platform that is composed of an NEC-Panasonic BB chip and a TI OMPA application processor to design 900i series mobile phone handsets, they made an effort to debug. Even though Firm A referred to the development board and product design offered by NEC, Panasonic, and TI, it did not secure the right information on the condition of the technology platform. From this experience, they concluded that it was necessary to cooperate with technology platform vendors closely in order to put the required knowledge on the core chipset.

Afterward, Firm A joined the core chipset development project with DoCoMo, Renesas, Fujitsu, and Mitsubishi in 2006. In this project, they developed a comprehensive mobile phone handset platform combining a single-chip LSI for dual mode mobile phone handsets supporting HSDPA/W-CDMA and GSM/GPRS/EDGE. They also developed core software such as operating systems. The new technology platform will help DoCoMo to accelerate their global adoption of W-CDMA services, and to lower the cost of these handsets for mobile phone handset manufacturers at the same time.

This technology platform is built on the previously developed single-chip LSI technology, which is a combination of a BB chip and an application processor; a processor for dual-mode W-CDMA and GSM/GPRS phones from DoCoMo and Renesas since July of 2004. The jointly developed technology platform adds new functions, such as support for HSPDA and EDGE technologies, and full development support including OS, middleware, and drivers. This technology platform also can serve directly as a base system for W-CDMA handsets, and eliminates the need for mobile phone handset manufacturers such as Fujitsu and Mitsubishi to develop separate systems for common handset functions, thus significantly reducing time and cost of development. If the technology platform is further spread and adopted, a further cost reduction of the mobile phone handsets will also be expected.

By joining this cooperation, Firm A can propose their IP (Intellectual Property) into the core chipset and receive royalty fees. Moreover, Firm A also has the benefits of time-to-market compared to its competitors. Usually, a technology platform vendor offers development board and reference design as technical support for saving product development lead time. However, on the contrary, Firm A used to believe that relying on these development supports deeply would not help them understand the interactivity among components. Furthermore Firm A also mentioned that in the past, they did not have such experience in designing core chips while other competitors had, so it was difficult for them to find out problems or to create something new by themselves. As a result, '1st Personal Communication Business Unit' and 'Platform Development Center' are mainly responsible for the core chip development project. 'Platform Development Center' also verifies the compatibility of components related to the core chipset.

#### **Taiwanese Mobile Phone Handset ODM**

The starting point of Taiwanese mobile phone handset industry was approximately 1994 when BenQ began developing mobile phone handsets. In 2000, PC ODM such as Quanta Computer, Compal Electronics, Inventec, and Arima computer simultaneously began production of mobile phone handsets by investing in their mobile phone handset subsidiaries or in-house divisions. Between 2001 and 2004, Chi-Mei group, Hon Hai Precision Ind., High Tech Computer, Asustek Computer, Mitac International, Wistron, and Gigabyte Technology also entered the market actively. Some companies developed their own brand mobile phone handsets while some duplicated the ODM business model of PC to mobile phone handset business.

Firm B entered the mobile phone handset industry in 1999 and has become the biggest ODM of mobile

phone handset in Taiwan. It receives specifications from Motorola and Sony Ericsson, and then shape detailed mobile phone handset designs and manufacture them. Nowadays, Firm B has 7 product development teams for developing 2G, 2.5G and 3G handsets. In 2006, mobile phone handset models were developed under several different technology platforms including 2G chipset such as, Calypso and LoCosto from TI; and 3G chipset from Qualcomm. In 2006, Firm B used Calypso and Locosto to develop 2~3 product models and 6 derivative models. In its R&D division, 'New Product Development Team' keeps surveying on several different technology platforms and propose to their customers to replace present core chips if these technology platforms perform better and show cost advantage.

Firm B develops software (i.e., device drivers, firmware, games, melody, phone address book, file management, MP3 drivers, etc.) for executing multimedia functions or for integrating some other IC chips (i.e., Bluetooth, NAND memory, melody IC, image sensor, etc.) from 3rd parties. However, when they adopt a new TI's chip for developing mobile phone handsets, they face high technological uncertainty. For instance, at the initial time of adopting one technology platform, they found that there were more than 10,000 software bugs and 1,000 hardware bugs. The reason was that TI could not expect the usage of customers, such as mobile phone running out of battery if it were used to take pictures. Firm B emphasized that in order to overcome these problems, it enhanced their debugging capability by hiring more Quality Assurance Engineers 3 years ago. Furthermore, Firm B also cooperates with TI and became a *α* site customer of TI. Since the release of LoCosto' engineering samples in 2005 by TI, Firm B have exerted an effort on debugging capability for their new core chip. Firm B has system-level experience that is similar to the usage of customers, so TI can get feedbacks and continuously upgrades their version of the core chip. On the other hand, through this cooperation Firm B also acquired knowledge regarding the core chip faster than other competitors did, and this also contributed to the saving of the lead time for its mobile phone handset development.

#### **Chinese Mobile Phone Handset Design House**

Beginning in the 90's, mobile telecommunication service industry started a worldwide full-fledged growth. The trend soon spread to China. Driven by the surge demand both from the world and from its domestic market, China's mobile phone handset industry has exhibited a spectacular growth since the late 90's. Export and domestic consumption rose almost parallel until 2003, after which the latter became more or less flat. In 2005, around 75 percent of handsets produced in China were exported. Although local mobile phone handset manufacturers turn increasingly outward-looking recently, multi-national companies altogether still contribute to close to 95 percent of its total export. When we turn our eyes to the domestic market, however, a strikingly distinct picture could be seen. Stating from just around 5 percent in 1999, local brands' shares increased radically until 2003, when China's official media triumphantly announced that Chinese mobile phone handset makers had captured more than 50 percent of the domestic market; then almost all of a sudden came the reversal. Since 2004, a majority of local mobile phone handset manufacturers slid into a retreat, which continued until early 2006.

Because of the increasingly heated competition in the domestic market, the advent of local mobile phone handset manufacturers to induce organizational or technological innovations where strong cost sensitivity and enduring quests for novelty coexist has been ignited. These domestic-competition-induced innovations, as we call them, may have international implications as global demand for low-cost and multi-function mobile phone handsets is expected to grow in coming years. According to (Marukawa, Yasumoto, Imai, and Shiu, 2006), there are many phone models in the market, but the number of sales for each model is small. For instance, it is necessary to aim at one million units by the number of sales of one model in Japan, but in China, if 200,000 units were sold, profit would be paid. Therefore, it is thought that the development cost put on one model is far greater in China than in Japan.. In Japan, the life cycle of a model is 6 months, but in China there is no rule on the life cycle of a model. On average, the life cycle of a model is 9 months, but sometimes there would be a model that keeps selling for two years. Recently, a phenomenon can be observed is that if a manufacturer can not release derivative models every month, a fall in its market share would shortly follows.

The domestic market share of a local mobile phone handset manufacturer reaches approximately 50% in 2003. Despite that, its market share has changed radically that it is experiencing a descent. In 2006, even with the achievement on financial affairs, the improvement is still lesser in market share compared to major foreign companies such as Nokia and Motorola. However, the design house industry has not fallen in as extremely as the

local mobile phone handset manufacturers. According to a U.S. research company, iSuppli's investigation, there are about 50~60 design house companies in China, and it is expected that the products that the design house design will account for 50 percent or more for the volume of shipment of the local mobile phone handset manufacturers. In addition, the top 5 design house companies account for 70 percent of the mobile phone handset design market. The major design house has the ability to implement all processes of the mobile phone handset design composed of the circuit, software, the mechanism, and externals (i.e., case). Moreover, this major PCBA business model is based on its own independent marketing research and then provides solutions to the customers. However, this type of business model has been gradually adopted by other design houses.

It is a conformational change of the chipset market to be changing the business environment for design house companies in China greatly in recent years. Design house companies mainly procured chipset from Europe and America vendors such as TI and Phillips until 2004. However, the Taiwanese IC chipset vendor Mediatek suppressed the license fee at about the end of the same year and started to release their new chipset. The adoption with the design house began to extend. As a result, the market share of Mediatek has been increasing radically that it exceeded TI's market share, and reached about 40% in 2006 (Merrill Lynch, 2006).

Compared to the TI's technology platforms, Mediatek's technology platforms had more powerful performance on executing multimedia functions. In other words, Mediatek's technology platforms integrated various multimedia functions such as Bluetooth, camera, etc. more than TI chipset did. However, their new technology platform contained a lot of technological uncertainty. Design house companies did not adopt it except that of Firm C. Firm C believed that Mediatek's technology platforms would fit the requirements of the market, and began to adopt it since the end of 2004.

Firm C emphasized that a successful mobile phone handset development should match the needs of the market concerned with available related technologies. Firm C mentioned that when they observed a selling point in the market, various divisions including sales division and R&D division would be organized to form a 'Project Research Committee.' In other words, these members from each division can give different technology perspectives, market perspectives, or operator perspectives into the discussion on the possibility of commercialization. If the possibility were high, they would start to develop. Unlike other major mobile phone handset manufacturers, 'Project Research Committee' in Firm C was not a permanent organization for deepening technology and researches, but mainly for analyzing technical trend and market requirement.

Developing a chipset takes 10 months or more. Firm C cooperates with Mediatek for 6th months. At the time, the chipsets are developed though did not arrive for the mass production test. At this stage, Firm C gives market information to Mediatek on what the architecture of the product would be. Afterward, Mediatek and Firm C decide the interdependencies of other components at system level. Because Firm C has much experiences in contacting customers, they became an important  $\alpha$  site customer for Mediatek. The  $\alpha$  site customer of Mediatek's 6217, 6218, and 6219 chipset in Taiwan was a design house Darts that was invested by Mediatek before 2004. However, two development teams of Darts have been pulled out to ARIMA and Foxconn respectively. After 2004, Mediatek started to work with Firm C closely to develop 6226, 6228, and 6229 chipsets.

In the close cooperation with Mediatek, Firm C has encountered various problems and managed to solve them in early stages since the kick off of the project. In the early problem-solving stage, they verified compatibility and debug not only Mediatek's chipset but also other components or devices in a laboratory test. The problems of compatibility might be unexpectedly brought up, so it was necessary to fine-tune the settings between Mediatek's chipset and the components or devices such as image sensors, Flash memory, software drivers, etc. Firm C emphasized that by cooperating with Mediatek, they would acquire knowledge on the interdependencies among components. Moreover, they also pointed out that this cooperation saved the product development lead time and accumulated knowledge on product platform design. As a result, in 2006, Firm C successfully developed nearly 50 types of product platforms, which each used several Mediatek technology platforms. To this date, the amount of mobile phone handsets (i.e., customers) which have been developed by their product platform has exceeded 100 types.

## Discussion

The communication standards, national factors, and business models may differ between Japan, Taiwan and China. Nevertheless, we observed that the Japanese firm A, Taiwanese firm B and Chinese firm C all faced high technological uncertainty when they adopted new core chipsets. According to our interviews, they also emphasized that the technological uncertainty could be reduced by close cooperation with core chip vendors.

The firm A collaborated with DoCoMo, Fujitsu, Mitsubishi and Renesas to develop a technology platform based on a highly integrated core chipset. DoCoMo intended to establish a common technology platform to accelerate its services. In the past, DoCoMo only cooperated with the chip vendor: Renesas. Recently Fujitsu, Mitsubishi and the firm A are enrolled in the project. The common technology platform will enhance the benefits of economies of scale. However, the firm A also pointed out that they can learn the characters of core chip and interdependencies among components through the project.

In the case of the firm B and C, they all collaborated with core chip vendors exchanging information with each other. They also emphasized that they solved problems earlier than other competitors by testing their core chipsets and related components and debugging software problems through the collaborative processes with these vendors.

The firm A, B and C represent the leading position in each country's mobile phone industry respectively, so that the cooperation with core chip vendors is considered as a natural result. However, when we turn our eyes to the Chinese local mobile phone handset manufacturers and design houses, they also show the same perspective, "the cooperation with core chip vendors will contribute to their product development." Some of them attempt to be an  $\alpha$  site customer while others want deeper cooperation with core chip vendors. For instance, one of the major design houses, Techfaith, established in 2002, mentioned that the firm established a joint venture with a core chip vendor, Qualcomm, in 2006 as the multimedia will be more value-added in the future. A local mobile phone handset manufacturer, AMOI, provides another emblematic case. The firm has been in cooperation with a local IC core chip vendor, Spreadtrum, to develop the Chinese 3G standard TD-SCDMA mobile phone handsets. Moreover, AMOI also worked with Spreadtrum to design GSM/GPRS mobile phone handset, and thereby took the biggest market share in the local made mobile phone handset market in the beginning of 2007. These cases show that, in general, a simple buyer-seller relationship is not proper to related firms especially when technological uncertainty is high.

However, the limited technical support resources encourage core chip vendors to concentrate on a handful of main customers. Our interviews with the Chinese local mobile phone manufacturers and design houses since 2005 provide some evidences. The interviewees all emphasized that, in their handset development projects, sometimes it is difficult to identify where the problems come from and cannot solve them without technical support from core chip vendors. As a result, these problems always delay their product development. A design house, established in 2005, pointed out that it is necessary to be an  $\alpha$  site customer of Mediatek not only because the firm can receive lower sell prices but also because the firm could develop their handsets with the latest core chipsets quicker than competitors. However, the firm also emphasized that design capabilities and customer experiences are indispensable for the cooperation with Mediatek.

Past researches indicated that interfirm modularity seems to blur the role of close coordination within and between firms, which were once regarded as one of the most critical factors of effective product development (Clark and Fujimoto, 1991; Yasumoto and Fujimoto, 2005). Takeishi (2002) suggested that boundary spanners or gatekeepers enable intra-firm product developers to acquire external complementary knowledge. Yet, our cases show that bilateral close communication channels between handset developers and technology vendors should be also indispensable when technologies change rapidly. Technologies have the attribute of a "system" in nature (Winter, 1987): technologies are embodied in multi-components and interrelated to each other. A set of components together is integrated to provide utilities for customers. The system performance is dependent not only on the performances of individual components but also on the extent of the mutual compatibilities between them (Henderson and Clark, 1990).

In our research, we found that a firm which designs product platforms can be regarded as a system integrator plays the role to deal with the interrelationships between technologies at the product system level. In the

case of the firm A, the specialized platform development center examines components in order to secure high compatibilities between specific core chipsets and common components shared between handset development units. The firm C closely cooperated with core chipset vendor, Mediatek, so that the firm pre-verifies the compatibilities between core chipsets and components.

These cases show that system integrators execute two functions in interfirm product development networks. First, the integrators provide solutions to support product development activities. These solutions reduce technological uncertainty which product developers face in the process of aligning a variety of components from core chip vendors and different 3rd parties. Second, these integrators play the role to maintain the integrity of the systems concerned in case that the systems' performance slippages (Garud and Kumaraswamy, 1995) could occur due to the incompatibilities created by the technological change of core component.

In the vertical interfirm division of labor, any single firm, even a system integrator, can hardly invest in all complementary technologies. Thus, the close cooperation with complementary vendor is a vehicle to acquire such complementary technologies. Nevertheless, sometimes, it is hard to maintain long term cooperation in the interfirm division of labors. Firms in a strategic alliance are liable to preserve their knowledge within them while always attempting to learn from competitors. Yet, we could scarcely find such tensions between mobile phone handset manufacturers and core chip vendors in our cases.

In contrast, some of the China local mobile phone handset manufacturers emphasized that Mediatek's total solutions make it difficult to develop distinguished handsets. This situation is also the case in the DVD player industry in China. Mediatek's total solutions can shorten product development leadtime to market. Yet, companies hardly differentiate their products as Mediatek encapsulates the most of product functions into their chipsets or bundle other components with their solutions. As a result, handset manufacturers could hardly balance the tension between cooperation and competition in the vertical interfirm division of labor. The fact shows that manufacturers can take the most of the values of products only when manufacturers for themselves nurture and hold the capabilities to define and develop the functions or components of the products.

## **Conclusion**

Nowadays, the industrial structures of many electronics industries have been shifted to the vertical interfirm division of labors. Product developers use even core technologies from specialized vendors. Drawing on the cases of a Chinese, Japanese and Taiwanese handset developers, and the study attempts to elucidate how product developers develop product platforms adopting novel technology platforms from vendors. The cooperation with technology platform vendors in the early stage of product platform development helps shaping architectural knowledge, which is insufficient in the technology uncertainty of novel technology platform application. The collaboration between product developers and vendors enhances effective product platform development even in the vertical division of labors for product development. These finding would contribute to not only explicating the dynamics of the product development in open interfirm networks but also revealing the managerial issues of product platform development in the vertical division labors of product development.

Product developers in the vertical interfirm division should learn how to acquire knowledge from core component or complementary vendors. Cooperation with these complementary vendors also can be regarded as knowledge sharing or exchanging. Past researches indicated that core component vendors have component knowledge while manufacturers have architectural knowledge. Manufacturers and vendors exchange complementary knowledge (i.e., component and architectural knowledge) between them in the collaboration.

However, IC chip vendors will have more possibility to put various functions into their chip in the continuous improvement of the semiconductor process. In this case, bilateral mutual learning will become more difficult. In order to have the chance of mutual learning with core component vendors, manufacturers should make more investment into system level architectural knowledge (Takeishi, 2002). In the future researches, we need to explore whether more architectural knowledge can contribute to the earlier reduction of technological uncertainty to the extent that both technology and product platform design activities are advanced.

Furthermore, the mutual learning is competency-enhancing in the long term. The knowledge of

competency-enhancing is derived from accumulated experiences as both of collaborative firms continuously gain a deeper appreciation of (1) which aspects of platforms will drive future improvements, (2) how core chip and the other components are interdependent, and (3) how complementary component vendors are integrated together to develop or improve product platforms. These management issues of product platform development are also left to the future researches.

## End Notes

- [1] Design House in the context of the mobile phone handset industry is a firm that is specialized in the development

of mobile phone handsets. Design Houses specialized in the development of electronic devices were born in the US in the trend of design outsourcing beginning in the 1990s. Cellon, a San-Jose-based venture established in 1999 by Chinese and US engineers claims to be the first Design House specialized in mobile phone handset development. For more detailed information about Design House, please refer the Ken and Shiu(2006).

### **Abstract**

**A society of the future is the society of knowledge, in which the capability of knowledge concentration and transformation into innovative and applicative solutions are important and respected values. Knowledge has become the central resource of the new society where knowledge workers are key elements of its work force. There is no limit for knowledge society. Knowledge can be gained faster than ever because it moves faster than any other production factor. Modern communication and information technologies made it easier to get to the information. Yet it is still hard to gain applicable knowledge in this jungle of information. The basic strategy for achieving the knowledge society in Europe was set with the Lisbon strategy (European Commission, 2000). The Lisbon Strategy is focused on investing in people and enhancing their knowledge. The aims of the paper are: to analyze new profile of managers; to identify the new managerial role; to identify changes in education and sustainable development of managers.**

### **Introduction**

Knowledge as a key element of future society differs from all other classical production factors. The resources of knowledge are endless. The use of knowledge does not destroy them; on the contrary, it makes them even more valuable. The knowledge gained in the past sticks around. The Romans would say: *Omnia mea mecum porto* (I carry everything with me). We can sell it but we still own it. The same knowledge can be shared with many people. The only limitation to it is the human ability. The main objective for the European Union is to find a way to face the challenges of the global economy. Creating a knowledge society is the best and probably the only way how to achieve this. Innovations, technological modernization, applicative use of knowledge and top design will benefit to the European society and all its inhabitants. The basic strategy for achieving the knowledge society was set with the so-called Lisbon goals (European Commission, 2000). At the Lisbon summit in March 2000, Europe's heads of state declared their ambition to make the European Union *"the most competitive and dynamic knowledge-based economy in the world by 2010, capable of sustainable economic growth, with more and better jobs and greater social cohesion"*.

### **Knowledge Society and Human Capital**

Knowledge is an idiosyncratic feature of a human being. Knowledge society thus cannot be built without sufficient and adequate human capital. Human capital refers by definition to the knowledge and skills accumulated by people in the process of their education and training. The pioneer in the field who published "Human capital" in 1964 is professor Gary S. Becker, a Nobel Laureate (1992) from the University of Chicago (Becker, 1993). In his opinion, *the new economy has increased the value of education and returns for investment on education*. The macroeconomic aspect of education and investment in human capital contribute to economic growth.

Economically, human capital can be measured as "stock" or "flow" type of indicator, where the first one represents the level of education and knowledge of people and the second reflects the process of education. Highly educated and skilled people have an economic advantage on the labor market earning more, which is a return on their investment in education. The income level is a function of education and experience; highly educated people

have a higher price of their skills, thus earning higher income while entering the labour market and experience a more rapid growth during the working life cycle (Samuelson, 1995).

Human capital has become the most important factor and can be effectively used in the economic process only by well-educated and skilled workers.

Economic development is connected to the absorption capability that is defined by the quality of the human capital. Growth conflict is a psychological process in which people due to the lack of knowledge begin to appose the process. Therefore the investment into technology must be necessarily accompanied by investment into human capital. The investment into human capital means education and training of employed people.

The econometric studies (OECD, 2001a) confirm a significant positive impact of human capital accumulation on the productivity (output per employee) and economic growth. Although the human capital theory is clearly defined, some dimensions are more difficult to quantify empirically. The human capital defined as capacity for work has five categories: individual knowledge, experience, skills, capability for work (health), willingness and readiness to work (personality). Some of them can be measured, while others have to be estimated.

Human capital stock is most often measured by the educational attainment of people according to the personal characteristics like age, gender etc. Another method of human capital stock measurement is observation of labor income paid in a year, assessment of the future income for each group of people according to their educational attainment, to sum the estimated aggregate value of human capital. The static model-based estimate origins from current level of education, while the dynamic model takes into account also the education in process (work-study stage and work stage). Education is a foundation of economic and social development, thus the role of human capital is discussed among researchers, economists and politicians.

The new European employment strategy sets ten policy priorities (Commission of the European Communities, 2003):

1. active and preventative measures for the unemployed and inactive,
2. job creation and entrepreneurship,
3. adaptability and mobility,
4. promotion of the development of human capital and lifelong learning,
5. increased labour supply and active ageing,
6. gender equality,
7. combating discrimination,
8. making work pay,
9. transformation of undeclared work,
10. addressing regional employment disparities.

The concept of lifelong learning is an objective of the European employment policy within the fourth policy priority "Promote development of human capital and lifelong learning" that states: "Member states will implement lifelong learning strategies, including the quality and efficiency of education and training systems, in order to equip all individuals with the skills required for a modern workforce in a knowledge-based society, to permit their career development and to reduce skills mismatch and bottlenecks in the labour market." (Commission of the European Communities, 2003).

A recently adopted EC document "Education and Training 2010" (Commission of the European Communities, 2003) is focused on quality, access and openness of education and training systems. EC DG, Employment "Study on human capital in a global and knowledge based society" (De la Fuente and Ciccone, 2003) claims that average level of education by one year represents a 5% increase in economic growth in the short-term and another 2.5% in the long-term. In addition, the positive impact of education on employment, health, and social inclusion has been shown.

Several factors: economic, social and technological – account for the growing emphasis on the human capital (Commission of the European Communities, 2003):

- a) Firstly, in any modern economy today, the **production** of goods and services increasingly relies on human, rather than physical, capital, i. e. on its workers' **individual** and collective endowment of knowledge and skills. For example, Germany's endowment of human capital is today more than twice the value of its physical capital.

- b) Secondly, in the knowledge and information society the quality of education is increasing and directed towards more active and innovative gaining of knowledge and skills.
- c) Thirdly, growth of the “new economy” is also seen as a reason for the expansion of knowledge-based jobs. The idea of a “new economy” focuses attention on the role of ICT and its impact on technological progress.

## **Human Capital for Knowledge Society in Slovakia**

In the new economy - the information society accompanied by the globalization process - education and training are important not only for individuals, who due to their knowledge and skills become more successful and competitive on a more and more open labour market, but also for enterprises, for which human capital has become an important factor of production. The basic principle is intellectual flexibility and life long learning of adults. The main reasons for lifelong learning can be summarized by the following interrelated functions:

- individual function - individual development and career opportunities,
- economic function - productivity and competitiveness of enterprises,
- social function - higher living standard, social inclusion, decreasing unemployment, cultural progress,
- national function - competitiveness of the national economy.

Individual benefits from education and training through better employability, higher productivity, increased earnings, increased mobility in the labour market and by widening their career opportunities. By investing in the human resources enterprises improve their productivity and competitiveness not only on local markets but also on the global markets. “The economic performance of 62 world wide car assembly plants around 1990, measured in terms of labour productivity and product quality (assembly-related defects per vehicle), proved to be closely associated with the presence of three dimensions of business strategy, lean production, team working and innovative human resource management (HRM) practices. Economic growth and social development of countries are invariably associated with large and sustained investments in education and training; countries with the highest incomes are also those where workers are most educated” (ILO, 2003).

The available data from the employment register that we analyzed for Slovakia include people employed by enterprises, small businesses and institutions. The analysis of the data on employed people by the educational institutions shows that 36 % of them have secondary specialized and secondary general education, 38.7 % are skilled or unskilled workers.

Based on the UNDP report on human resource development in 2004 Slovakia went down at the 42<sup>nd</sup> position in HDI (from the 39<sup>th</sup> in 2001). Education that is taken for the top priority in any economy is not recognized in Slovakia. The proof can be seen in the percentage of the GDP invested into the sector. While in the most developed countries it accounts for approx 1.33% (1998) in average and the trends show its growth, in Slovakia the GDP percentage invested into education fell from 1.05% in 1990 to 0.64% in 2001. Slovakia thus stood at the last position of the OECD member countries.

The similar situation is characteristic for research in Slovakia. The GDP percentage invested in research fell down from 1.45% in 1993 to 0.59% in 2002 and contribution from state budget went down from 0.46% to 0.26% in the same period. The average in the EU countries accounts for 1.9% of GDP with the highest investment being in Sweden (3.78%), Finland (3.37%), Germany (2.48%), USA (2.27%), France (2.15%) in 2002.

Following the EU education priorities the most important issue is to increase investment into education. Thus it is particularly important to increase investment in human capital from public funds, the business sector and individuals. The secondary priority is the introduction of lifelong strategies that is the education and training of adults. Education of adults is not only an investment by the individuals, but also by enterprises with a view to promote productivity, competitiveness and a more active ageing. The management in progressive companies that is aware that competitiveness can be only achieved with well-educated people, will strive to encourage employees to continue education and training – by entering the long-life learning.

Human capital development – the increase in the educational level and flow of highly educated youth on the labor market – does not only lead to welfare and better living standard of individuals and companies, but it

becomes necessity in the knowledge-based society. High-tech intellectual industries need highly educated people. Human (intellectual) capital is a key factor of productivity. Thus in the new economy human capital has become the only real “wealth of nation”.

The solutions to the above mentioned negative trends in Slovakia have become the top priority for the Slovak government. Along the lines of the Lisbon Strategy they are planning to increase the competitiveness of the Slovak enterprises through highly educated workforce. Increased investment into education and research is the subject to numerous reforms in public finance, education systems and enhanced links between research and educational institutions. The changes should be achieved by 2010 (Strategy of the Slovak Republic’s Competitiveness by 2010 - draft).

## **Managerial Competences in the 21th Century**

While thoroughly analyzed managerial competences of the 20th century included the combination of hard and soft skills with the focus on the hard ones, ie were assumed to be mastered during studies and short-term practical training and shifted primarily towards the preparatory phase for the managerial role, the new, transformed managerial role requires the combination of the manager’s qualities and knowledge that will allow for integration of individual experts’ efforts and understanding and respecting of customers’ values for sustainable competitive advantage.

The initial perception of a new managerial role includes the views summarized by Brent, Snow and Miles (1996) and refers to organizational structure. They claim that the shift from the traditional structure (functional, divisional and matrix) towards the structures with higher autonomy, network structures, learning organizations etc. requires new managerial competences including technical specialization based on knowledge, experience in various functional fields including international exposure, collaborative leadership, self-controlling skills, continuous learning, ability to work individually, flexibility, integrity, trustworthiness and the like.

Barlett and Ghoshala (1997) identify different competences for individual managerial echelons. The authors present the change of line managers from operations implementers towards aggressive entrepreneurs characterized by creativity, intuition, persuasiveness, commitment, competitiveness, perseverance, knowledge of company technical characteristics as well as that of competitors and clients, internal and external resources and company operations. In their views, middle managers change from administrative controllers towards supportive coaches. Here, the competences of people-oriented integrator include knowing people, ability to, delegate, develop, empower, enhance relationships, build teams, diminish and resolve conflicts. Top managers are gradually changing from the resource allocators to institutional leaders. Their qualities should include primarily those of an institutionally thinking visionary, ie ability to create interesting (demanding) work environment, enhance trust and belief in the organization, ability to combine conceptual perception with motivational challenges.

Another stream in management theories is represented by the idea of learning organization. For the core competence Bob Garatt (2002) (Figure 1) takes common thinking. This means that managers cannot exercise individualized thinking at the top of the pyramid any more. The new phenomenon could be called a processor of the organization where the information from external and internal sources is processed and becomes part of an efficient information network accessible to all employees. Thus, efficient learning can take place as a basis for strategic decision-making. Employees, participating in the decision-making via contributing and processing information identify with it much more readily. The strategic horizon is shifted towards long-term. The responsibility of individuals is growing and is based on permanent employee development through learning. To be competent under the above conditions, the manager must be equipped with knowledge, skills and other personal qualities, such as ability to attract, educate and retain highly qualified employees, abundant in expert knowledge and skills in the area of his/her field, competences to establish and develop the learning organization (cognitive and behavioral phase followed by results), competences in knowledge management (knowledge as the core competitive advantage) and intercultural managerial competences (communication, listening, empathy, creating atmosphere of trust, efficient feedback and the like).

FIG. 1: MODEL OF LEARNING TOP MANAGEMENT. ADOPTED FROM GARATT (2002)

Burack, Hochwarter and Matys (1997) recommend step-like model of competences consisting of core competences (necessary for managers at all levels), such as flexibility towards change, customer-orientation, stress management, teamwork, ability to collect new knowledge. In addition, they specify the competences for middle management, such as creativity, strategic thinking, cultural heterogeneity, art in creating teams, support for participation. Here, the art to create heterogeneous teams achieving synergic effect is the most important. Top management should consist of good leaders at change implementation, persuasive communicators and strategic initiators.

## Managerial Competences in Slovak Companies and Knowledge Society

Our research focused on identification of managerial competences as envisaged by Slovak managers in the view of the shift towards knowledge society.

### Methodology

A questionnaire consisting of 3 open-ended questions was distributed to 421 managers (university graduates) in 86 organizations regardless the organization's size and field of operations with the return of 283 (67.2 %). Descriptive statistics was used to analyze the responses.

### Discussion

The questions in the questionnaire were intended to identify changes in managerial competences in the recent five years, suggestions for adaptation (completion, change) of curricula for to-be managers and balancing of formal and informal learning in the view of needed future managerial competences.

***Q1: Characterize the change in the profile of a manager (primarily, but not exclusively top and middle management) based on your own experience in the recent 5 years.***

The results presented in Figure 2 show the shift from the traditional managerial role of an information and legitimate locus towards permanently learning and developing visionary able to react to changes, set long-term strategies and understand their impact in short- and medium-term horizons and lead continuous human capital development with the aim to build teams aspiring to synergic effect. The changes are expected to result in the transformation leaders capable to persuade others to follow as well as to identify with the objectives to be pursued jointly.

To summarize the results of the survey is not simple due to different requirements set on different levels of management and the individual, subjective wording and phrasing of the responses because of open-ended questions. However, the common grounds were identified and can be presented as follows:

1. Need to increase customer-orientation and focus on satisfaction of the customer's needs and wants
2. Ability to master various situations and requirements stemming from globalization
3. Continuous attainment and enhancement of skills in ICT applications along with technological progress
4. Ability to persuade and explain
5. Drive for continuous learning and ability to evolve it in one's subordinates
6. Implementation of individual responsibility for permanent staff growth and effective feedback

7. Development of communication skills (including foreign languages)
8. Ability to envisage impacts of one's own decisions and enhancement of conceptual skills
9. Ability to vent constructive criticism
10. Ability to resolve conflicts
11. Flexibility and ability to recruit flexible staff as well as enhance flexibility

FIG. 2: NEW PROFILE OF A MANAGER

***Q2: What do you think is missing in the current profile of a manager? What do you suggest to complete (adjust) current curricula for to-be managers in the view of the lacking managerial competences?***

In a way, all respondents (Figure 3) suggested closer interlink between theory and practice focused on the customer, not individual measurable outcomes of the daily routine. This requires change of learning processes so that the students could see and understand the outcomes of their decisions to be able and ready to undertake full responsibility for their decisions in practice, furthermore, to be able to think in the context of added value. Over half of the respondents suggest including hands-on practical training in fictitious enterprises.

FIG. 3: CHANGE IN CURRICULA IN MANAGEMENT STUDIES

***Q3: Is it feasible for managers to enhance/complete their knowledge and skills in informal education (practice, e-learning, self-study, random courses etc.)?***

Over a quarter of respondents (Figure 4) claim that they continuously learn utilizing all above-mentioned ways. However, and it is critical, 60 % of respondents are unable to grow because their business does not leave any space for their self-education in either of the ways. 32% respondents utilize formal educational opportunities for their growth, many of them (18%) organized by their organizations themselves. Systematic knowledge-exchange events (conferences) are stressed by only 10% of respondents.

FIG. 4: FORMAL AND INFORMAL EDUCATION IN MANAGERIAL DEVELOPMENT

## Conclusion

The research shows that the change in managerial competences in organizations in Slovakia is replicating the global developments as identified by HRM theoreticians. The managers – respondents make it clear that they understand and foresee the changes in their own roles. The brief survey shows also the ‘white areas’ in the perception of the managerial role. Over half of the respondents being unable to develop due to the lack of time signals that the managerial role (in contradiction to the future trends) is still perceived as omni-potent and omni-solving which means that the manager is involved in all activities of the continuum (from strategy to daily routine). If managers are to be leaders (models) for their followers, it is them to start the change in organizations towards continuously growing (learning and developing) human (and humane) entities. Informal education and training provides good opportunities to grow in addition to the formal ones.

## Abstract

Despite the existence of international trade since the time of the earliest civilisations, modern world business activity has celebrated an inordinate intensification with the rapid spread of the free market economy. This phenomenon has been ubiquitously termed globalisation. A hallmark of this condition has been comprehensive reforms in the macro, meso and micro economic environments, such as new levels of foreign direct investment, state corporatisation as well as transformations in the business management culture. It is contended in this paper there are four key forces that are underpinning these changes. These forces are 1) market, 2) cost, 3) government, and 4) competition. Collectively, these forces shape globalisation. The relativity of these forces was examined with data that were obtained from a study with indigenous managers in China (n = 210) and India (n = 239). Employing a pluralist (quantitative and qualitative procedures) design the data reveal market forces were of the most overall importance in both nations, but for different service sectors the principal force varied across communities. An increasing dominance of an open free market ideology will impact all spheres in life, which in turn will compel all levels (macro, meso and micro) to transform mindsets in unique ways to blend values of tradition and modernity.

## Introduction

Globalisation is an encompassing, complex evolutionary phenomenon that affects all spheres of daily life. For instance, globalisation has been viewed as a worldwide phenomenon, but its effects are nevertheless felt at the national (macro), regional/organisational (meso), and the individual (micro) levels (Jeanett, 2000). The roots of globalisation lie in the interaction and integration of economic, social, cultural, technological and political dimensions, and the amalgamation of these multiple layers has forged particular properties during exchange in dialogue or business (Yip, 1989). Arguably, globalisation commenced during the interaction and trade between the earliest civilisations, although history records the more notable contributors, such as Marco Polo or Christopher Columbus as the entities that forged the global forces which were to lead to colonisation, the ultimate spread of capitalism and the beginning of globalisation (Rennen and Martens, 2003; Robertson, 1992). And although the acceleration of globalisation has been linked with particular events or innovations the manifestations of globalisation is more likely to be drawn by government discussions, societal pressures or global governing bodies.

A salient feature of the modern world has been an unprecedented reshaping of national economic frameworks. In fact, many of the former socialist nations of Eastern Europe have undertaken a historic transformation from centrally planned bureaucratic systems to competitive free market economics (Rennen and Martens, 2003). Further, a number of the south east countries that were once British colonies (e.g., Hong Kong, Malaysia, Singapore), and neighbouring states (i.e., Vietnam) have emerged as models of market dominated business practices. In particular India, a nation bound by strong traditions as well as cultural and organisational imperatives liberalised the national economy in the early 1990s. And China, after reopening People's Republic of China to the West in 1978, became a member of the World Trade Organisation (WTO) in 2001. These changes, which were prompted by "...pragmatic interest in terms of enhancing an understanding of differences and similarities so as to facilitate better cross cultural business encounters." (Westwood and Posner, 1997: 31) demonstrate an increasing rate of engagement in the complex global marketplace by national governments.

This ascending of economic liberalisation has highlighted the changing relationship between State and capital. Although governments have found a freedom of economic action by attracting investment for national development, and thereby have created an unprecedented shift in wealth from a 'welfare state' to a region of

'corporate welfare', a new set of dilemmas are being faced by Chinese and Indian managers. On the one hand, they will be obliged to meet the targets of global imperatives, but on the other hand there will be a need for determining a path that will provide a fine balance between tradition and change.

The purpose of this study is to ascertain the viewpoint of indigenous Chinese and Indian managers as to the driving forces of globalisation in the services industry of the two countries. The importance of the forces of globalisation will be initially assessed at the macro level (government/market/cost/competition). Next, from in-depth qualitative based discussions, an elucidation of these forces for specific sectors of these two national communities will be delineated. The implications and likely future challenges will be outlined in the concluding section of the paper.

#### **Macro Level Drivers of Globalisation**

At the *macro* level, many national governments across the globe are seriously considering embracing globalisation. Indeed, the liberalisation of the Indian economy to foreign investment in 1991, China joining the World Trade Organisation in November 2001, and the recent expansion of the European Union from 16 to 25 countries are examples of this trend. Government policies are increasingly moving away from 'introvert' policies and are allowing foreign investment in the indigenous economy (Stiglitz, 2002). Apart from government initiatives towards the liberalisation of trade policies, and the push for deregulation of industries, other supplementary factors including the telecommunications revolution, and the recent trend toward homogeneity in market requirements have all contributed towards the current wave of globalisation and the emergence of a borderless economy that transcends political and geographic boundaries for global trade (Jeanett, 2000; Khandwalla, 2002). In addition to the *government* being one of the driving forces towards globalisation at the *macro* level, industrial organisational theory has identified three other forces enabling global orientation. These forces include *market*, *cost* and *competition* (Levitt, 1993; Morrison, 1990; Yip, 1989; Yip, Johansson, and Roos, 1997). Drawing on seminal work by Yip (1989), the current study employs these four forces of globalisation as the *macro* level drivers within the context of the *macro-meso-micro* framework of the logic of globalisation. The current study defines the four *macro* level forces that impact globalisation:

- *Market forces* enable the extension of industry's market scope beyond national boundaries. They are indicated by new customers from global markets, use of global channels and adoption of techniques and processes from global sources.
- *Cost forces* enable the extension of industry's operation scope beyond national boundaries. They are indicated by global economies of scale, favourable logistics, differences in country costs (including exchange rates), and outsourcing.
- *Government forces* enable the extension of industry's legal and regulatory scope beyond national boundaries. They are indicated by tariff and non-tariff barriers and regulations encouraging an economic climate that fosters global linkages.
- *Competition forces* enable the extension of industry's competitive scope beyond national boundaries by creating well established benchmarks. They are indicated by the matching of structures, processes, systems and strategies employed by competitors.

These four *macro* level forces of globalisation are characterised on the basis of the different roles that each one plays within the *macro* environment (Yip, 1989; Yip, et al. 1997). Specifically, *market* forces act as a customer base, *cost* forces as an organisational base, *government* as a regulator base and *competition* as a competitive base.

In summary, the *macro* level pressures of globalisation are shaped by the four broad forces of *market*, *cost*, *government* and *competition*. These four forces operationalise the *macro* level paradigms that enable the manifestation of globalisation and permeate through the economy providing organisations (*meso* level) with the necessary driving force by constantly revamping their structures and processes to take advantage of the favourable global environment.

#### **Services Industry Dynamics in India and China**

The services industry has been burgeoning across the globe over the past two decades (Nankervis, 2005). The forces of globalization, enabled by the World Trade Organization (WTO), the disappearing geographical trade boundaries, the information technology revolution along with rapidly changing nano-technology and bio-technology initiatives, and the intensified global competition are some of the factors that have enabled the expansion of the services

industry worldwide (Bhattacharjee, 2005; Jeanett, 2000). Nankervis (2005: 1) reports that "...the services industry has now supplanted both the *primary* (agriculture, mining) and the *secondary* (manufacturing) economic sectors, as a predominant *tertiary* sector..." in a number of countries across the globe. Clearly, the services industry can no longer be ignored, due to its primacy in the economies of all developed, and most developing countries in the world. The rapid rise in global services is "...without doubt one of the most challenging social, cultural, political, and especially, economic forces in almost all countries in the world..." (Nankervis 2005: xi).

Specifically, in the Indian and Chinese services industry context, Nankervis (2005) explains that the multifaceted nature of services in the Indian and Chinese economies is a major economic and social influence. In fact, the *macro* level drivers of globalization, supported by a well established services industry with a number of sectors that have now expanded across the globe, contributed 48 percent towards the Indian Gross Domestic Product (GDP) and 33.3 percent towards the Chinese GDP (as per 2005 estimates) (*CIA World Factbook*, 2005). This important burgeoning industry acts as the backbone of this intensification towards globalization in both countries.

While the Indian and Chinese economies continue to embrace global opportunities, their emergence as dominant global economies in the next few decades has been predicted by academics, practitioners and institutions world over. For example, a scenario built on World Bank and Goldman Sachs estimates on the ten largest economies of the world of the future has suggested that between 2051-2100, India would emerge as the largest economy of the world with 16 percent of world income, closely followed by China with 15 percent (Hooke, 2003; Wilson and Purushothaman, 2003; *World Development Report*, 2002). As per 2003 estimates, China ranks second with 12.5 percent world income, India ranks fourth with 5.5 percent share of world income, with USA ranking number one with 21.7 percent world income (Wilson and Purushothamanm 2003; *World Development Report*, 2002). Clearly, the World Bank and Goldman Sachs forecasts, the relative importance of the services industry in India and China (including the current intensification to globalization in the services environment in these two economies) warrant an investigation into the macro level drivers enabling the globalisation of the vast services industry.

#### **Methodology**

##### **Research Design and Site**

The study employed a pluralist research design. Increasingly, scholars (Adler, Campbell and Laurent, 1989; Chaston and Mangles, 2001; Ellis and Watterson, 2001; Hauser, 1998; Hill, Miller, Weiner and Colihan, 1998; Offermann and Spiros, 2001; Teagarden, et al.1995; Wilk, 2001) are applying both quantitative and qualitative approaches to their investigations. The main reason why a pluralist approach is gaining currency is the recognition of a need to complement quantitative studies with qualitative research as a hybrid technique, which provides researchers with a deeper understanding of the pattern of statistical results (De Ruyter, Moorman, and Lemmink, 2001; Pearson and Entrekim, 1998; Sower, Duffy, Kilbourne, Kohers, and Jones, 2001; Trevelyan, 2001; Zotteri and Verganti, 2001). A number of researchers (Foss, 1996; Watson, 1997) have promoted a pluralist approach to research, and Mingers (2001: 240) has even claimed, "...rather than advocating a single paradigm, be interpretive or positivist, or even a plurality of paradigms within the disciplines as a whole, ...research results will be richer and more reliable if different research methods, preferably from different (existing) paradigms, are routinely combined together."

This study was conducted in five phases. In the first phase, the macro level drivers of globalization were defined from theory underpinning the international management literature, and feedback from academic scholars and practitioners across the globe. In the second stage, a draft survey questionnaire was designed on the basis of available literature and inputs from managers in India and China to measure the four macro level drivers. The questionnaire was translated into Mandarin and back translated into English with the assistance of professional bilingual translators. The third phase entailed pilot testing of the questionnaire in three countries, namely, India, China and a neutral context, Indonesia, and refining the questionnaire on the basis of feedback from the results. The subsequent modified questionnaire was administered to Indian (in India – English version) and Chinese (in China – Mandarin version) managers with the assistance of sponsoring institutions, namely, the Indian Institute of Management Calcutta in India and the Consulting Group in China, in the fourth phase. The samples included 239 Indian managers and 210 Chinese managers from various sectors of the vast services industry in India and China. The empirical results were then presented to samples of Indian and Chinese managers (15 managers each) at qualitative one-on-one interviews and focus group sessions in India and China respectively. The managers at these qualitative sessions, who were representative of the respondents in the quantitative phase of the study, were invited

to provide a first hand understanding of the results that were obtained in the various empirical analyses, by providing experiential evidence. A brief description of the demographic characteristics is presented in Table 1.

A prominent feature of the sample was a one third representation of female managers, demonstrating the changing role of women in the corporate scenario in these two traditionally male dominated societies. A second feature of the sample was the dominance of younger managers (less than 40 years of age) represented by 62.4 percent in India, and 76.2 percent in China, respectively. This feature was a characteristic of the importance placed on a young well trained and skilled workforce, and the phasing out of the seniority based promotion system in both countries. A third feature of the sample was that the respondents reported extensive exposure to the services industry, which is illustrated by 65.3 percent of Indian managers and 38.1 percent of the Chinese managers having more than 10 years experience. A final feature of the sample was that all the assessed service sectors were well represented in both countries.

TABLE 1: DEMOGRAPHICS % OF INDIAN (N = 239) AND CHINESE (N = 210) MANAGERS

	India	China		India	China
<b>Managerial Level</b>			<b>Gender</b>		
Executive	35.1	28.6	Female	33.5	38.6
Middle	40.6	45.2	Male	66.5	61.4
Supervisory	24.3	26.2	<b>Service Sector</b>		
<b>Age (in years)</b>			Accounting, Finance,		
Less than 30	24.6	29.5	Banking, Taxation and Legal	24.3	24.8
30 – 39	37.7	46.6	Education	9.2	11.9
40 – 49	28.9	21.0	Insurance	10.0	7.6
50 and above	8.8	2.9	Tourism and Hospitality	9.3	8.6
			Information and	20.1	17.1
			Communications		
<b>Tenure (in years)</b>			Consulting	18.4	11.4
Less than 10	34.7	61.9	Government	5.4	6.7
10 – 19	51.1	28.1	Other	3.3	11.9
20 and above	14.2	10.0			

#### Measures and Analysis

Industrial organisation theory has identified four *macro* level forces impacting global orientation in terms of industry drivers of globalisation; namely *market*, *cost*, *government* and *competition* (Yip, 1989; Yip, et al. 1997). The four industry drivers of globalisation were each defined in two statements. The first statement provided a concise meaning of the driver and the second statement provided some examples of the driver. The definitions were adapted from Yip (1989) and simplified for vocabulary equivalence with first hand feedback from indigenous Indian and Chinese managers in the pilot phase of the study, thereby minimising any loss of meaning from the original definition. The final analysis included the same definition of the industry drivers of globalisation utilised in the pilot study with some additional instructions for respondents.

A non recurring ranking scale was employed to measure the impact of the *macro* level drivers of globalisation. Respondents were asked to read the definitions of the four industry drivers of globalisation and then rank them from one to four to show the level of impact of globalisation each driver had in the services sector in which the respondents were involved. It was explained that number one had the highest impact, number two the second highest impact, number three the third highest impact, and number four the least impact. It was also explained to the respondents that each statement could only attract one rank score, and that each rank could only be utilised once.

## Results

Table 2 shows the means, standard deviations, ranks and bivariate correlations among the *macro* level pressures of globalisation for the Indian and Chinese samples. Given that the *macro* level variables were measured using a non recurring ranking scale, Spearman's rho was used to calculate the nonparametric correlations (SPSS, 2005).

TABLE 2 MEANS AND CORRELATIONS AMONG *MACRO* LEVEL PRESSURES

Drivers of Globalisation	India	China	Market	Government	Cost	Competition
Market	1.88 <sup>1</sup> (1.082)	1.89 <sup>1</sup> (1.092)	N.A.	-.421 ***	-.112	-.330 ***
Government	2.61 <sup>2</sup> (1.083)	2.78 <sup>4</sup> (1.021)	-.484 ***	N.A.	-.346 ***	-.258 ***
Cost	2.69 <sup>3</sup> (0.982)	2.75 <sup>3</sup> (0.986)	-.022	-.368 ***	N.A.	-.387 ***
Competition	2.87 <sup>4</sup> (1.070)	2.58 <sup>2</sup> (1.135)	-.432 ***	-.093	-.543 ***	N.A.

- Notes: a. Superscripts on mean scores are their rankings of the means in ascending order of importance from 1 to 4. 1 is most important.  
 b. Values in parentheses are standard deviations of the means.  
 c. Overall mean score and rankings for total data = Market – 1.88<sup>1</sup>, Government – 2.69<sup>2</sup>, Cost – 2.72<sup>3</sup>, and Competition – 2.74<sup>4</sup>.  
 d. Correlations above the diagonal are for the Indian respondents and correlations below the diagonal are for the Chinese respondents.  
 e. p\*\*\* < 0.001.

The mean scores shown in Table 2 indicate that *market* was the leading driver of globalisation in both the Indian and Chinese services industry. Furthermore, while *government* was rated as the second most influential driver in the Indian services industry, *competition* was seen to be the second most important driver of globalisation in the services industry in China. *Cost* and *competition*, though important *macro* level enablers were ranked third and fourth by the Indian managers. In contrast, the Chinese managers rated *cost* and *government* to be their third and fourth influential *macro* level forces. Explanations for these similarities and differences in the rank scores of these constructs were given by managers at the qualitative feedback sessions whose contentions are elucidated in the next section.

The correlation results presented in Table 2 demonstrate the significant inverse relationships between the four *macro* level pressures in India and China. The first feature of Table 2 was the significant separation between *market* pressures and *government* pressures as well as between *market* pressures and the pressures of *competition* in India and China as evidenced by the significant inverse correlations. A second notable feature of Table 2 was the difference in the relationship between *government* pressures and pressures of *competition* in the Indian and Chinese samples. Thirdly, an insignificant inverse relationship between *market* and cost pressures in both countries was observed. A detailed discussion on the implications of these characteristics in India and China is presented next.

### Discussion

The quantitative results for the ranking of the *macro* level pressures of globalisation, namely market, cost, government and competition, presented some striking similarities and differences for the Indian and Chinese samples (Table 2). These results were presented to the managers at the various focus group and face-to-face interview sessions in India and China during the qualitative phase of the study. The explanations provided by the managers for the study findings were both interesting and purposeful, and are presented after a brief overview of the service industry dynamics in India and China in the following sections.

### The Indian Scenario

While globalisation has been enabled by the *government* acting as a supporter of reform favouring global initiatives such as allowing FDI in a phased manner in various service sectors (Department of Industry Policy and Promotion

of the Ministry of Commerce and Industry of India, 2005), the respondents in the quantitative phase of the current study ranked *market* as the leading driver of globalisation in the Indian services industry closely followed by *government*, *cost* and *competition* in that order (Table 2), which was rather surprising.

At the face-to-face interview sessions in India, the managers were asked to provide some understanding as to whether the rankings of the *macro* level pressures from the quantitative phase of the study were in line with their knowledge and experience. Furthermore, managers were also invited to highlight some of the key *market* and *government* oriented reforms favouring globalisation that had assisted their service sector to tackle the complex challenges associated with globalisation. A summary of the two leading drivers of globalisation in some of the service sectors representative of the feedback sessions in India are presented in Table 3. Table 4 shows that *market* was the leading driver of globalisation in three of the five sectors, namely, the financial services, information technology and public relations/media sectors. *Government* played a leading role towards globalisation in the real estate consultancy, and consumer product/service sectors. A feature of the face-to-face interview sessions in India was the managers' appreciation of a growing importance of a borderless *market*, as being instrumental in extending various services sectors in India, beyond national boundaries (as summarised in Table 3).

TABLE 3: SUMMARY OF THE LEADING DRIVERS OF GLOBALISATION IN VARIOUS SERVICE SECTORS IN INDIA

Services Sector	Leading Drivers of Globalisation	
	# 1	# 2
Financial Services (Banking, Accounting, Auditing, Taxation)	Market	Government
Information Technology	Market	Government
Public Relations/Media	Market	Cost
Consultancy (Real Estate)	Government	Market
Consumer Product and Service	Government	Market

Managers at the qualitative face-to-face interview sessions in India, who were representative of the five sectors featured in Table 3, provided experiential evidence in support of *market* being one of the leading drivers of globalisation in their respective sectors. A marketing executive, from a leading consumer product and service company in India that has set up skin care clinics in India and overseas, provided support for *market* as the leading driver of globalisation in the consumer product and service sector. The manager explained, "...without customers across national boundaries, it would be of no potential benefit for the indigenous organisation to set up/conduct business overseas". Furthermore, the huge expansion of the Indian diaspora to different parts of the globe, due to increased migration opportunities for well educated and skilled Indian migrants, has resulted in India emerging as the "...biggest remittance market with USD 25 billion remitted by Non Resident Indians (NRIs) (out of a total of USD 150 billion global remittance) in 2004", remarked a middle level manager at one of India's emerging remittance gateway and consulting companies. This comment was a further demonstration of the importance of *market* towards the intensification to globalisation in the Indian services scenario. A team leader from a newly set up Business Process Outsourcing (BPO) office for an overseas telecommunications MNC stated, "...the nature of the industry is that we service global clients...support customers from different countries overseas...an innate sense to globalisation..." which highlighted the growing importance of a worldwide borderless market. Adding to this contention, a senior manager at one of India's leading Information Technology (IT) organisations elucidated the importance of market forces towards globalisation initiatives in the Indian IT sector when he stated,

*"...we have clients all over the world...truly everywhere from [North] America to Latin America to Europe to Asia and Australia. [Also], in the IT industry...market is by all means the leading driver because in terms of government, they had deregulated the IT sector a long time ago, that is lesser of an impact compared to market. Competition ahead...now...Indian companies even buying out at times international organisations because it will give them an*

*international exposure...Wipro, Infosys [leading Indian IT organisations] all have had acquisitions abroad, all have been given leapfrogging advantage in globalisation”.*

These comments from the managers at the face-to-face interview sessions in India support the results from the quantitative analysis and provide some understanding as to why *market* was ranked as the leading driver of globalisation in the Indian services industry.

The quantitative results from the Indian sample showed that *government* was the second most important driver of globalisation in the Indian services context (Table 2). This result was surprising, given the important role government played in the ‘opening up’ of the Indian services industry to globalisation, since the reforms of 1991. Nevertheless, managers at the qualitative feedback sessions attributed *government* being ranked second (after *market* forces) to the fact that the government led initiatives, which facilitated the liberalisation of the various service sectors to foreign competition and investment, were only a starting point towards the intensification to globalisation. The managers (of the feedback sessions) explained that the government led initiatives, including the deregulation of various sectors and the allowance of FDI on a sector-wise basis, were the major reform measures enabling the globalisation of a number of service sectors in India. In addition, other government measures including the removal of licensing requirements towards encouraging the private sector to set up operations and compete freely with overseas MNCs, the setting up of excise free zones and tax holidays, the establishing of quality control mechanisms as per international standards (ISO), and the employment of worldwide accounting and auditing standards enabled various foreign companies to operate in the Indian economy. The managers at the feedback sessions further explained that these government led reform measures were a ‘one off’ initiative. Once these regulations were in place, it was imperative that the *market* forces impinge on the various service sectors that had taken advantage of the favourable business environment facilitated by the government initiatives to shape global ventures. As a middle level manager employed with a remittance gateway and consulting company explained, “...*government reforms are initiated once every four to five years...major ones...significant ones...hence, market comes first*”. This statement and other similar comments from the managers at the various interview sessions were consistent with the quantitative results where *market* was rated as a more important *macro* level pressure of globalisation than *government*.

#### **The Chinese Scenario**

While government still continues to play a major role in the development and expansion of the Chinese economy, it has certainly moved away from a ‘command and control’ regime to a more ‘guided capitalism’ approach (Stiglitz, 2002). Under this ‘guided capitalism’ approach, the government intervenes from time to time to ensure that the guiding plans developed to ensure the smooth transition into a globalised Chinese economy are progressing. Given the importance of these government led initiatives towards globalisation in China, it was surprising to note that the study respondents in the Chinese sample from the quantitative analysis suggested that *market* was the leading driver in the Chinese services industry, closely followed by *competition*, *cost* and *government*, in that order (Table 2).

At the face-to-face interview and the focus group sessions in China, the managers were asked to provide some understanding as to why such a ranking order was observed, and whether these rankings, were in line with their knowledge and experience. Furthermore, managers were also invited to highlight some of the key market oriented reforms favouring globalisation that had assisted their service sector to tackle the complex challenges associated with globalisation. A summary of the two leading drivers of globalisation in some of the representative service sectors from the qualitative sessions are presented in Table 4.

TABLE 4: SUMMARY OF THE LEADING DRIVERS OF GLOBALISATION IN VARIOUS SERVICE SECTORS IN CHINA

Services Sector	Leading Drivers of Globalisation	
	# 1	# 2
Information and Communications Technology	Market	Competition
Consumer Product and Service	Market	Competition
Education	Market	Competition
Public Service Agencies	Competition	Government
Retail Service	Competition	Market

Table 4 shows that *market* was the leading driver of globalisation in three of the five representative sectors, namely, information and communications technology, consumer product and service, and education. *Competition* played a leading role in the retail service as well as public service agencies. A key feature of Table 4 was the qualitative session managers expressed the growing importance of *market* towards the globalisation initiative in the Chinese services industry, which was consistent with the quantitative results for the Chinese sample (Table 2). Furthermore, the qualitative results (Table 4) suggested that *competition* was the second most important driver of globalisation in the Chinese services industry which was also consistent with the empirical results (Table 2).

The qualitative face-to-face interviews and focus group sessions with Chinese managers provided support for the patterns observed in the quantitative results. For instance, a senior academic from one of China's premier international universities summarised the impact of *market* as the leading driver of globalisation in the Chinese services industry as a whole when he stated, "...*market is the key force...driving force to deal with globalisation. When people are talking about globalisation, people have to consider whole world as one market...as consumers need products/services...*" Furthermore, the North China Director of a reputed Information and Communications Technology (ICT) organisation, which provides services on a global scale, further elaborated on this viewpoint. He remarked, "...*profit is the leading driver...globalisation's objective is profit...which is related to market...no point globalising without profit.*" This comment highlights the impact of *market* forces and the extensive competition in the ICT sector, which encourages Chinese organisations (in the ICT sector) to engage in business activity overseas in search of international success. To support this view, a senior manager from the telecommunications area of the ICT sector, explained the importance of *competition* in addition to *market* towards the globalisation of the ICT sector in China. He remarked,

*"...the challenge/pressure comes from foreign company that use very international marketing procedures, so internal systems like Enterprise Resource Planning (ERP) gives them lot of pressure...a challenge to traditional Chinese system"*.

In addition, a sales manager from one of China's leading consumer product and service organisations that competes with multinational companies around the world (Samsung, LG and Siemens in particular) illustrated the significance of market and competition as the leading drivers in the consumer product and service sector in China. He remarked,

*"Our organisation applied an international strategy to make it an international brand...hence market is the first driver...customers. Competition comes second...locally in the Chinese market, we don't think national brands can compete with our organisation...so our organisation's competitors come from overseas..."*

These comments provide support for the contention that the *macro* level pressure of *market* was the leading driver of globalisation in a majority of the assessed Chinese service sectors and also support the quantitative findings.

A different view of the impact of four drivers of globalisation was expressed by an audit manager from a multinational retail giant. The audit manager explained the significance of competition in the Chinese retail scenario when she stated, "*Competition comes first...forces our company to obtain more capital and market*". This comment

highlights the intense competition and profit taking in the Chinese retail service sector. In addition, an Associate Professor from one of China's leading international universities remarked on the important role of competitive forces towards globalisation in the public services sector in China when she stated,

*“Especially for government agents, competition will definitely be first followed by government...we do not have full awareness of global competition...and now is really the right time for us to understand international competition...why Premier Zhu Rongji wanted us to join WTO...this was one of the reasons...to face competition globally”.*

In summary, the qualitative feedback sessions provided some degree of consensus on the impact of market and competition as the two leading drivers of globalisation in China. While it was surprising to note that *government* was ranked fourth by the respondent managers (in the quantitative phase of the study), a leading academic from one of China's premier universities explained this puzzling observation at a face-to-face interview, by stating,

*“Ranking of these four factors depends on the degree of openness of industry...if it is widely open, market is the driving force for that industry...if less open industry to outside, don't need market as it is protected by government”.*

This comment highlighted the growing openness of the various service sectors in China to foreign investment. Indeed, the number of Foreign Direct Investment (FDI) projects in various services sectors in China in 2004 providing support to a study conducted by Foreign Investment Department of the Ministry of Commerce in China (2004). However, it should be noted that this remarkable transformation of the Chinese economy, from an insular one to a globally competitive superpower, was made possible by the increased allowances and continuing support provided by the Chinese government to enable the Chinese manufacturing and service organisations to emerge as service providers of international renown across the globe.

## Conclusion

Globalisation can have a considerable influence on the national economic activity. The evidence of this study that was conducted in the two large Asian economies of China and India is that the market forces and phenomenon of globalisation were intimately interrelated within the services industry. For instance, it was demonstrated that market was an important driver of globalisation in the service industry of both countries. Nevertheless, although these market forces appeared to control the destiny of service corporations, it was also evident that when there was a consensual acknowledgement there were considerable benefits to continue certain local industries (i.e, without any influence of foreign competition), government intervention as a 'protection measure' was endorsed. Hence, in some service sectors, government, cost of competition forces were more important drivers of globalisation. A salient observation from the results of this study is that global companies intending to undertake business encounters in China or India need to be mindful of the varying impact of the global dimensions on their industry.

## **Abstract**

The cognitive orientations of managers in processing fast moving global knowledge structures have become critical as corporations around the world make sense of the upheavals of globalisation. As Chinese and Indian firms make unprecedented marks in the global arena, significant reforms and mindset reorientations are emerging as areas of scholarly attention. The capability of intensification of global mindset in terms of synthesising multiple organisational imperatives, structural and technological diversities and entrepreneurial cultures are being impacted by national, organisational and managerial level reforms in these two countries. The study presented in this paper compares some of the identified determinants of global mindsets of managers in the service sector in India and China. Based on a study of 239 Indian and 210 Chinese managers, the results suggest that there is an increasing level of leveraging organisational level reforms evident in both countries as they seek to extend their global visibility and advantage.

## **Introduction**

While globalisation has extended the reach of companies from the developed world, appearance of new players from China and India without the accumulated legacies of their rivals has changed the competitive dynamics of the global game. As barriers to cross-border commerce fall rapidly, creativity in translating global ambitions to reality has become critical to organisations around the world. Global mindset is being viewed as the capability that can strengthen companies in this regard. It is the cognitive capability in processing information emerging dynamically from their competitive landscapes in terms of multiple organisational environments, structural indeterminacy, and cultural heterogeneity (Doz and Prahalad, 1991). This shift in focus from structural, administrative and technical priorities to mindset-based capabilities has become necessary with the increasing complexity of global managers around the world.

Conceptualisation of global mindset highlights two critical elements. Firstly, the cultural and contextual diversity, and secondly, in terms of the ability to integrate imperatives of local and global parameters specific to an industry (Chatterjee, 2005). These conceptualisations lead to meta-competencies in the interpretive world of managers in terms of abilities in developing and interpreting strategic opportunities that transcend national borders. Empirical relationships between global mindset and changing internal and external variables or their reverse impact in an Asian setting are yet to emerge in the literature. Whether global mindset impacts strategy and structure or structural and strategic reforms impact global mindset have not been widely researched. In one of the studies in this area, it was suggested that global mindset was an independent variable driving globalisation (Levy, 2005) while others hold that global mindset is dependent on a firms' attention to strategy, structure and other imperatives (Murtha, Lenway and Bagozzi, 1998).

The paper posits that the intensity of global mindset is dependent on the structural, technological and entrepreneurial reform measures at the organisational level. The hypotheses postulated by this study are tested in the context of the dynamic and burgeoning services industry in India and China. The paper argues that strategic integration achieved through global-local balance, entrepreneurial orientation achieved through economic and learning priorities and technology intensity impacts directly in cultivating and nurturing a global mindset at the managerial level. This empirical study clarifies its conceptual underpinning and contextual divergence in India and China in collecting and disseminating its data. The findings of this study provide some evidence into the linkages between organisational reforms and the development of a managerial global mindset.

**A Conceptual Model of Global Mindset Development**

The question of how multinational organisations cope with the complexities of globalisation pressures has become an important and challenging issue in the field of international management. Scholars have long argued that economic and industrial achievement is context specific and is not achievable by the mere adoption of Western management practices and processes, but rather by work practices and institutional frameworks that blend traditional social values and mores with prevalent structures and emergent technologies (Kao, Sinha and Wilpert 1999). For instance, core competencies of Chinese organisations and employees differ from those of North American ones that differ from those of South African ones. However, increased sharing of information through technological advancements in a borderless economy and subsequent increase in knowledge about different contexts and systems provides organisations (organisational level) and managers (managerial level) with a valuable resource in blending conventional practices with modern ideology. This view is shared by a number of scholars (Evans & Doz 1992; Pucik 1992; Bartlett and Ghosal 1989) who contend that sole reliance on structural changes are not sufficient in responding to the complexities associated with globalisation, and that learning and innovation at the organisational level facilitated by HRD measures at the managerial level is critical to the success of multinational corporations worldwide. Rhinesmith (1995: 36) argues that, “as companies gain a better understanding of the new, global world in which we are competing, they are learning that people are a new competitive edge”.

Some of the key organisational factors which have enabled global linkages at the organisational level include *organisational strategy* (Bartlett & Ghoshal, 1989; McDougall 1989); *technology intensity* (Cavusgil & Knight, 1997; Kohn, 1988) and *entrepreneurial orientation* (Burpitt & Rondinelli, 1998; Covin & Slevin, 1989). Clearly, these are salient features of corporations that are vital for mitigating further change. However, an important caveat is that the organisational level contextual pressures of organisational strategy, technology intensity and entrepreneurial orientation operate simultaneously and this compels managers to develop values, skills, competencies and a culture favourable to compete in the global environment. Recent studies have emphasized managerial level global reform and the cultivation of a global mindset to create an intelligent global organisation (Gupta & Govinarajan, 2002; Jeanett, 2000; Rhinesmith, 1995). A critical success factor for any organisation is the level of global mindset orientation amongst its managers (Harveston, 2000; Murtha, Lenway and Bagozzi, 1998). In this context, a global mindset is defined as the “*The ability and willingness of managers to think, act and transcend boundaries of goals, values and competencies on a global scale*” (Ananthram and Chatterjee, 2004).

FIGURE 1: A CONCEPTUAL MODEL OF GLOBAL MINDSET DEVELOPMENT

Source: Adapted from Ananthram and Chatterjee, 2004

These arguments provides a rationale for a deeper level understanding of the societal, psychological, cultural, economic and individual level parameters shaping the mindsets of managers (Begley & Boyd, 2003; Gupta & Govindarajan 2002; Jeanett, 2000; Beechler, Taylor, Boyacigiller, & Levy, 1999; Murtha, Lenway & Bagozzi, 1998; Rhinesmith, 1995, 1993, 1992; Bartlett & Ghoshal, 1989). Based on these contentions, a conceptual model of

global mindset development linking the organisational level reform measures and managerial global mindset intensity is developed. The linkages hypothesised in Figure 1 are explained in the next section.

#### **‘Organisational’ Level Reform Measures and their Impact on ‘Managerial’ Global Mindset Intensity**

Organisations worldwide are taking advantage of the favourable *macro* environment that supports globalisation initiatives, and are refocusing their schemas to foster global expansion (Boettcher and Welge, 1996; Domzal and Unger, 1987; Svensson, 2001; Yaprak, 2002). Organisations understand the importance of gaining a sustainable competitive advantage given the increased level of competition in the globalised business world and the constant dynamism in the global business environment. Recent trends indicate that this increased level of competition not only impacts major developed Western European and North American economies, but also the newer globally oriented emerging economies in Asia (Bryan, Fraser, Oppenheim, and Rall, 1999; Chen, 2004; Garten, 2000; Lasserre and Schutte, 1995). Researchers are puzzled by the proposition of how organisations across the globe, pressurised by the *macro* level forces of *market*, *cost*, *government* and *competition*, take advantage of the new and complex globalised business environment to develop a sustainable competitive advantage (Bartlett and Ghoshal, 1998; Harveston, Kedia and Davis, 1999; Kidger, 2000; Ohmae, 1994; Porter, 1990; Yip, et al. 1997). These issues have received a great deal of scholarly theoretical and empirical attention in the last decade (Beechler, et al. 1999; Burpitt and Rondinelli, 1998; Makhija, Kim, and Williamson, 1997; Murtha, et al. 1998). A salient contention of this literature is that scholars and practitioners believe that the *organisational* level initiatives impacting the dynamics of the organisation provide a schema for organisations to change their focus and outlook in order to function effectively in the global business environment and build organisational support for global reach (Bartlett and Ghoshal, 1989; Burpitt and Rondinelli, 1998; Cavusgil and Knight, 1997; Covin and Slevin, 1989; Kohn, 1988; McDougall 1989).

The international management literature identifies a number of organisational paradigms that have enabled global linkages at the *organisational* level. These include 1) changing the *organisational structure* (Robbins, Bergman, Stagg and Coulter, 2003) to take advantage of the favourable globalised environment (i.e., altering work specialisation, departmentalisation, chain of command, span of control, centralisation/decentralisation of authority, formalisation, job redesign or actual structural design initiatives), 2) revamping the *organisational strategy* (Hedlund, 1986; Nohria and Ghoshal, 1997) to integrate other global initiatives (i.e., employing international, global, multi-domestic or transnational strategies), 3) rethinking *organisational systems* (Almeida and Bloodgood, 1996; Tesar, 1977) to foster global momentum (i.e., automation and technological advancements, innovation, quality assurance and control, risk management), 4) reshaping *organisational processes* (Burpitt and Rondinelli, 1998; McDougall and Oviatt, 1997) to enable smooth overall functioning (i.e., human resource management initiatives to change workforce attitudes, perceptions and expectations, workplace regulations and overall entrepreneurial orientation change), and 5) restructuring *organisational policies* (Harveston, 2000) that provide an overarching influence to other organisational paradigms to gain a sustainable competitive advantage. The current study explores three *organisational* level variables which have enabled global linkages at the organisational level; namely, *organisational strategy* (Bartlett and Ghoshal, 1989; McDougall 1989), *technology intensity* (Cavusgil and Knight, 1997; Kohn, 1988), and *entrepreneurial orientation* (Burpitt and Rondinelli, 1998; Covin and Slevin, 1989) and tests their impact on the development and nurturing of managerial global mindset intensity. The relationship of these *organisational* level variables and their link with the *managerial* level global mindset intensity is explored next.

#### **Organisational Strategy**

Organisations tend to change their strategies as they globalise. These transformations are undertaken in order to cope with competitive pressures, and eventually, to maintain a sustained competitive advantage (Jeanett, 2000; Kotler and Kartajaya 2002; Porter 1987). This notion has been explored in research by Hedlund (1986; 1993; 1994), Nohria and Ghoshal (1997), and Malnight (2001). These authors suggest that strategies aimed at global dispersion of operations, interdependence of sub-units and emphasis on cross unit learning and structural flexibility enable organisations to successfully operate in the complex marketplace. This viewpoint was explained in detail by Prahalad and Doz (1987). These eminent researchers contended that global competition required organisations to continually balance *global integration* expectations (the attribute and action orientations consistent with centralised production systems that serve a unified world market) and *local responsiveness* expectations (the attribute and action orientations consistent with serving a fragmented world market). Bartlett and Ghoshal (1989) conceptualised this strategising

theory and suggested four types of strategies based on the degree to which *global integration* and *local responsiveness* expectations are important, namely; 1) *international*, 2) *multidomestic*, 3) *global*, and 4) *transnational*.

Successful strategy implementation requires visionary senior management to think and act with a common perspective (Bouquet, 2005; Catoline, 1989; McAlesse and Hargie, 2004). A number of scholars have contended that a global perspective engendered by organisational capabilities to foster global linkages and accept global challenges is vital to the conceptualisation and implementation of organisational strategies (Harveston, 2000; Jeanett, 2000). This notion is shared by Prahalad and Doz (1987) who argued that organisational capabilities to exploit complex strategic perspectives to its full potential depend on managerial mindsets that "...equilibrate integration and responsiveness expectations rather than predispose decisions in favour of one dimension at the expense of the other..." (p. 179-181). This contention is further strengthened by Murtha, et al. (1998) who suggests that "...process theorists have variously specified the direction of relationships between mindsets and business policies that can leverage international strategic change. Mindsets confer insight to design appropriate policies..." (p. 98 – 99). Building on these arguments linking the *global integration* and *local responsiveness* expectations of organisational strategy to *global mindset intensity*, hypothesis 1a and 1b have been developed.

***H1a. Global integration expectations of organisational strategy will positively influence global mindset intensity.***

***H1b. Local responsiveness expectations of organisational strategy will positively influence global mindset intensity.***

#### **Technology Intensity**

The international management literature identifies technology as another source of organisation specific advantage (Dunning, 1988; Hymer, 1976). Consistent with the work of Palvia (1997), and Harveston (2000), *technology intensity* is defined as the extent to which organisations utilise their core technology to gain maximum competitive advantage. In recent times, a great deal of manufacturing and services processes, from the design and development of the products and services, to their delivery, have become technology driven (Maxwell, 2000; McLoughlin and Harris, 1997; Nankervis, 2005). Managers operating in a technologically oriented global marketplace are compelled to endorse the best available technologies (Rosenbloom, 2000). Clearly, being technologically 'savvy' is a competency that managers across different levels need to possess (Rose and Jones, 1985; Smith, 1991; 1992). In this context, Rosenbloom (2000) argues that managers who are willing to employ new technologies that are dynamic and adaptable to changing economic situations and business requirements can successfully compete in the global marketplace. As technological isolation can lead to organisations losing out to competing organisations, which are constantly engaged in making the first pre-emptive strike by taking advantage of their core technological advantage, or, matching rival technologies, it is imperative that managers reorient their global perspective in terms of being sympathetic to technological revolutions (Rosenbloom, 2000). Contemporary managers are encouraged to understand the importance of transcending national boundaries using technology as one of their core organisational paradigms. Based on these arguments, the current study contends that the *organisational* level paradigm of *technology intensity* assists in the development and cultivation of *global mindset intensity* of managers that allows them to think and act globally. Consistent with the *macro-organisational-managerial* contextual model of the logic of globalisation, hypothesis H2 is generated.

***H2. Technology intensity will positively influence global mindset intensity.***

#### **Entrepreneurial Orientation**

*Entrepreneurial orientation* has been the subject of much attention amongst researchers who have linked it to organisational growth (Covin and Slevin, 1988; 1991; Miller and Friesen, 1983). Numerous studies offer different definitions of the term entrepreneurial orientation (Barringer, Macy and Wortman, 1996; Caruna, Morris and Vella, 1998; Covin and Slevin, 1988; 1989; Lumpkin and Dess, 1996; Miller and Friesen, 1983; Smart and Conant, 1994). These studies contend that *entrepreneurial orientation* is an economically oriented mono-dimensional paradigm, encompassing the extent to which organisations engage in risk taking, innovation and proactiveness in international expansion (Harveston, 2000). In addition, it is argued that entrepreneurial orientation has another dimension of *learning*, especially with the growing importance of managing information and knowledge in contemporary times (Burpitt and Rondinelli, 1998; Dutton, 1993). Knowledge as an asset and knowledge management as a process have been of utmost importance to organisations across the world (Naik and Iyengar, 2003). A similar view was shared by

Dutton (1993), and later by Burpitt and Rondinelli (1998) who examined how the organisational paradigm of a two dimensional entrepreneurial orientation (*economic* and *learning*) influenced organisational decision making and ultimately, the overall competitive orientation of the firm. A recent study on work goals of managers across eight divergent Asian contexts revealed the importance managers and organisations are placing on learning (Chatterjee and Pearson, 2002). Arguably, organisations operating on a global scale are forced to apply a dynamic entrepreneurial outlook in order to be able to adapt to the ever changing global business environment.

*Entrepreneurial orientation* at the organisational level is related to *managerial* level managerial orientation, in terms of *global mindset intensity* of managers (Burpitt and Rondinelli, 1998). These researchers contend that the overall *entrepreneurial orientation* of the organisation necessitates the development of a broad global outlook in terms mindset reorientation. In addition, working in an organisational environment which constantly integrates the cross verging global forces of *economic* and *learning* initiatives provides managers with certain skill sets that foster global thought (Jeanett, 2000; Tarabishy, Solomon, Fernald Jr. and Sashkin, 2005). In turn, these skill sets lead to higher *global mindset intensity* (Bouquet, 2005). These arguments provide underpinning for the following two predictions, namely, H3a and H3b.

**H3a. Economic orientation will positively influence global mindset intensity.**

**H3b. Learning orientation will positively influence global mindset intensity.**

#### **Services Industry Dynamics in India and China**

The services industry has been burgeoning across the globe over the past two decades (Nankervis, 2005). The forces of globalization, enabled by the World Trade Organization (WTO), the disappearing geographical trade boundaries, the information technology revolution along with rapidly changing nano-technology and bio-technology initiatives, and the intensified global competition are some of the factors that have enabled the expansion of the services industry worldwide (Bhattacharjee, 2005; Jeanett, 2000). Nankervis (2005: 1) reports that "...the services industry has now supplanted both the *primary* (agriculture, mining) and the *secondary* (manufacturing) economic sectors, as a predominant *tertiary* sector..." in a number of countries across the globe. Clearly, the services industry can no longer be ignored, due to its primacy in the economies of all developed, and most developing countries in the world. The rapid rise in global services is "...without doubt one of the most challenging social, cultural, political, and especially, economic forces in almost all countries in the world..." (Nankervis 2005: xi).

Specifically, in the Indian and Chinese services industry context, Nankervis (2005) explains that the multifaceted nature of services in the Indian and Chinese economies is a major economic and social influence. In fact, the *macro* level drivers of globalization, supported by a well established services industry with a number of sectors that have now expanded across the globe, contributed 48 percent towards the Indian Gross Domestic Product (GDP) and 33.3 percent towards the Chinese GDP (as per 2005 estimates) (*CIA World Factbook*, 2005). This important burgeoning industry acts as the backbone of this intensification towards globalization in both countries.

While the Indian and Chinese economies continue to embrace global opportunities, their emergence as dominant global economies in the next few decades has been predicted by academics, practitioners and institutions world over. For example, a scenario built on World Bank and Goldman Sachs estimates on the ten largest economies of the world of the future has suggested that between 2051-2100, India would emerge as the largest economy of the world with 16 percent of world income, closely followed by China with 15 percent (Hooke, 2003; Wilson and Purushothaman, 2003; *World Development Report*, 2002). As per 2003 estimates, China ranks second with 12.5 percent world income, India ranks fourth with 5.5 percent share of world income, with USA ranking number one with 21.7 percent world income (Wilson and Purushothamanm 2003; *World Development Report*, 2002). Clearly, the World Bank and Goldman Sachs forecasts, the relative importance of the services industry in India and China (including the current intensification to globalization in the services environment in these two economies) warrant an investigation into the dynamics of the workings across the *organisational* and *managerial* levels.

## Methodology

### Research Design and Site

The study employed a pluralist research design. Increasingly, scholars (Adler, Campbell and Laurent, 1989; Chaston and Mangles, 2001; Ellis and Watterson, 2001; Hauser, 1998; Hill, Miller, Weiner and Colihan, 1998; Offermann and Spiros, 2001; Teagarden, et al.1995; Wilk, 2001) are applying both quantitative and qualitative approaches to their investigations. The main reason why a pluralist approach is gaining currency is the recognition of a need to complement quantitative studies with qualitative research as a hybrid technique, which provides researchers with a deeper understanding of the pattern of statistical results (De Ruyter, Moorman, and Lemmink, 2001; Pearson and Entrekin, 1998; Sower, Duffy, Kilbourne, Kohers, and Jones, 2001; Trevelyan, 2001; Zotteri and Verganti, 2001). A number of researchers (Foss, 1996; Watson, 1997) have promoted a pluralist approach to research, and Mingers (2001: 240) has even claimed, "...rather than advocating a single paradigm, be interpretive or positivist, or even a plurality of paradigms within the disciplines as a whole, ...research results will be richer and more reliable if different research methods, preferably from different (existing) paradigms, are routinely combined together."

This study was conducted in five phases. In the first phase, a conceptual model (presented in figure 1) was developed from theory underpinning the international management literature, and feedback from academic scholars and practitioners across the globe. In the second stage, a draft survey questionnaire was designed on the basis of available literature and inputs from managers in India and China to measure the variables. The questionnaire was translated into Mandarin and back translated into English with the assistance of professional bi-lingual translators. The third phase entailed pilot testing of the questionnaire in three countries, namely, India, China and a neutral context, Indonesia, and refining the questionnaire on the basis of feedback from the results. The subsequent modified questionnaire was administered to Indian (in India – English version) and Chinese (in China – Mandarin version) managers with the assistance of sponsoring institutions, namely, the Indian Institute of Management Calcutta in India and the Consulting Group in China, in the fourth phase. The samples included 239 Indian managers and 210 Chinese managers from various sectors of the vast services industry in India and China. The empirical results were then presented to samples of Indian and Chinese managers (15 managers each) at qualitative one-on-one interviews and focus group sessions in India and China respectively. The managers at these qualitative sessions, who were representative of the respondents in the quantitative phase of the study, were invited to provide a first hand understanding of the results that were obtained in the various empirical analyses, by providing experiential evidence. A brief description of the demographic characteristics is presented in Table 1.

A prominent feature of the sample was a one third representation of female managers, demonstrating the changing role of women in the corporate scenario in these two traditionally male dominated societies. A second feature of the sample was the dominance of younger managers (less than 40 years of age) represented by 62.4 percent in India, and 76.2 percent in China, respectively. This feature was a characteristic of the importance placed on a young well trained and skilled workforce, and the phasing out of the seniority based promotion system in both countries. A third feature of the sample was that the respondents reported extensive exposure to the services industry, which is illustrated by 65.3 percent of Indian managers and 38.1 percent of the Chinese managers having more than 10 years experience. A final feature of the sample was that all the assessed service sectors were well represented in both countries.

TABLE 1: DEMOGRAPHICS % OF INDIAN (N = 239) AND CHINESE (N = 210) MANAGERS

	India	China		India	China
<b>Managerial Level</b>			<b>Gender</b>		
Executive	35.1	28.6	Female	33.5	38.6
Middle	40.6	45.2	Male	66.5	61.4
Supervisory	24.3	26.2	<b>Service Sector</b>		
<b>Age (in years)</b>			Accounting, Finance, Banking, Taxation and Legal	24.3	24.8
Less than 30	24.6	29.5	Education	9.2	11.9
30 – 39	37.7	46.7	Insurance	10.0	7.6
40 – 49	28.9	21.0	Tourism and Hospitality	9.3	8.6
50 and above	8.8	2.9	Information and Communications	20.1	17.1
<b>Tenure (in years)</b>			Consulting	18.4	11.4

10 – 19	51.1	28.1	Other	3.3	11.9
20 and above	14.2	10.0			

### Measures

Three key organisational factors that have enabled global linkages at the organisational level were employed as the *organisational* level pressures in this study. These *organisational* level reform initiatives are specified as *organisational strategy* (Bartlett and Ghoshal, 1989; McDougall, 1989); *technology intensity* (Cavusgil and Knight, 1997; Kohn, 1988) and *entrepreneurial orientation* (Burpitt and Rondinelli, 1998; Covin and Slevin, 1989).

### Organisational Strategy

Organisational strategy was assessed by analysing two dimensions, *global integration* expectations and *local responsiveness* expectations. *Global integration* expectations were defined as reflecting the attributes and action orientations consistent with centralised production systems that serve a unified world market, while *local responsiveness* expectations were defined as reflecting the attributes and action orientations consistent with serving a fragmented world market by focusing on country level goals. Murtha, Lenway and Bagozzi (1998) operationalised organisational strategy from the seminal conceptual work by Bartlett and Ghoshal (1989) and Prahalad and Doz (1987), and in this study, an adaptation of the Murtha, et al. (1998) scale was used. *Global integration* and *local responsiveness* expectations were assessed by asking four questions for each construct. The pilot analysis resulted in further adaptation of two items measuring *global integration* expectations and two items measuring *local responsiveness* expectations. Respondents were asked to report their expectations on their organisation's global expansion initiatives on a seven point Likert scale (1 = extremely unlikely to 7 = extremely likely). An arithmetic mean was obtained to measure both the *global integration* and *local responsiveness* scores. Though the individual items employed in this study were adapted to suit the country contexts, two factors were expected, and two factors emerged from a factor analysis with varimax option. A closer inspection, however, revealed significant cross loading of the items suggesting that the dimensionality of the instrument is problematic. Reliability assessments were undertaken to determine the internal consistency of the organisational strategy scale. A Cronbach alpha coefficient of .68 for the global integration expectations and .60 for local responsiveness expectations was obtained. Although lower than the acceptable threshold of .70, the assessments were deemed acceptable, in line with Guildford's assessment (1965, p. 31) who noted that "...an alpha of 0.70 to 0.98 is considered quite reliable, while values as low as 0.35 have been found acceptable when used with other measures." Furthermore, the results of the factor and reliability analyses were shown to the managers at the qualitative feedback sessions in India and China and they were asked to explain the inconsistency in the factor analysis. Managers in both these countries were unsure as to why these patterns were observed, but felt strongly that questionnaire items measuring the two factors did in fact represent the global integration expectations construct and the local responsiveness expectations

construct. Hence, given the acceptable reliability scores and feedback from the managers at the qualitative sessions, it was decided to retain the items as per the original pattern (Burpitt and Rondinelli, 1998).

### **Entrepreneurial Orientation**

Entrepreneurial orientation is defined as the extent to which organisations engage in risk taking, innovation and proactiveness in global expansion, which shapes its overall competitive orientation. Two dimensions of this organisational paradigm have been identified from Burpitt and Rondinelli's (1998) adaptation of Dutton's (1993) entrepreneurial orientation definition, namely, 1) *economic orientation* and 2) *learning orientation*. Both dimensions specifically focus on managerial perceptions of organisational level activities regarding global entrepreneurial orientation. This study adapted a scale originally developed by Burpitt and Rondinelli (1998). *Economic orientation* and *learning orientation* were assessed by asking four questions for each construct. The pilot analysis resulted in further adaptation of three items measuring *economic orientation* and two items measuring *learning orientation*. Respondents were asked to report on items relating to their organisation's economic and learning orientations on a seven point Likert scale (1 = strongly disagree to 7 = strongly agree). An arithmetic mean was obtained to measure both the economic and learning orientation scores. A factor analysis with varimax option revealed

### **Technology Intensity**

Technology intensity is defined as the extent to which organisations utilise their core technology to gain competitive advantage. Several studies have found a relationship between the type of technology employed or the use of technology and globalisation (Almeida and Bloodgood, 1996; Johnston and Czinkota, 1982; Kriplani and MacIntosh, 1980; Tesar, 1977). Palvia (1997) developed an instrument measuring technology intensity which was adapted by Harveston (2000) and in this study; an adaptation of the Harveston (2000) scale was used. The original measure employed four questions. In the current study, however, an original additional item was included. This extra item was designed after a series of discussions and feedback with supervisors, senior academics at Curtin University and across Asia, as well as, with Indian and Chinese managers. Respondents reported on items regarding their primary product or service technology on a seven point Likert scale (1 = strongly disagree to 7 = strongly agree). An arithmetic mean was obtained to measure technology intensity.

### **Global Mindset Intensity**

This variable is defined as the ability and willingness of managers to think, act and transcend boundaries of goals, values and competencies on a global scale. Global mindset has been conceptualised in international management literature as cognitive structure, a set of observable behaviours, individual competencies, leadership traits and strategic maturity (Gupta and Govindarajan, 2002; Murtha, et al. 1998; Rhinesmith, 1992; 1993; 1995). Following the work of Barham (1987), Cateora (1996), Gray (1997) and Kedia and Chhokar (1986), global mindset intensity was assessed by asking managers a series of questions about their attitude towards globalisation. Questions were adapted from Burpitt and Rondinelli (1998). The pilot analysis revealed acceptable internal consistency and external validity scores and the items were not modified for the final analysis. Respondents were asked to report on a seven point Likert scale (1 = strongly disagree to 7 = strongly agree) to indicate their level of agreement/disagreement with each statement. An arithmetic mean was obtained to measure global mindset intensity.

The technology intensity, entrepreneurial orientation and global mindset scales were investigated for their dimensionalities. Previous researchers (Harveston, 2000; Palvia, 1997) have found that the technology intensity and global mindset paradigms were unidimensional, and thus, the five items measuring technology intensity and the four items measuring global mindset were factor analysed with entrepreneurial orientation items, which were expected to form two distinct constructs (Burpitt and Rondinelli, 1998). Hence, four factors were anticipated, but five factors were obtained. A second round of factor analysis was conducted by constraining the factor structure, a priori, to four factors as a result of initial empirical results (Harveston, 2000; Burpitt and Rondinelli, 1998; Palvia, 1997). The technology intensity and global mindset items loaded onto two separate factors, and the entrepreneurial orientation items loaded onto two distinct factors with some cross loadings. Two items measuring economic orientation and two items that were part of the learning orientation scale were deleted because of cross loadings. Hence, economic orientation and learning orientation were each reduced to a two item scale.

Reliability assessments were undertaken to assess the internal consistency of the technology intensity, global mindset and entrepreneurial orientation scales. A Cronbach alpha coefficient of .78 and .84 were obtained for the technology intensity and global mindset scales respectively. Furthermore, an alpha score for economic orientation of .53, and an alpha score for learning orientation of .68 were obtained. Although the reliability score for economic orientation and the reliability assessments for learning orientation were both lower than the acceptable

threshold of .70, the constructs were deemed acceptable, given contentions from Guildford (1965) who has proclaimed that alphas as low as 0.35 can be acceptable for adapted instruments.

## Results

### Means and Correlations

Table 2 shows the means, standard deviations, and bivariate correlations among the *organisational* and *managerial* level variables evaluated for the Indian and Chinese samples. Given that the *organisational* and *managerial* level variables were measured using seven point Likert interval scales, the Pearson coefficient was used to test the correlations (SPSS, 2005). Mean scores that were less than three were considered low; scores of three to five were considered moderate; and scores above five were considered to be high. It is shown in Table 2 that the higher levels of *organisational* reform measures in terms of global integration and local responsiveness expectations, technology intensity as well as economic and learning orientations in the Chinese sample over the Indian sample, highlighted the growing importance that Chinese global organisations placed on *organisational* level reform compared to their Indian counterparts. In addition, the results (of Table 3) also indicated that Indian and Chinese managers possessed a high level of global mindset intensity.

TABLE 2: MEANS AND CORRELATIONS OF ASSESSED CONSTRUCTS FOR INDIAN (N = 239) AND CHINESE SAMPLES (N = 210)

	India	China	strglo	Strloc	Techn	ecoor	lroor	glmin
strglo	4.52 (1.12)	5.12 (0.79)	1	.489**	.380**	.322**	.361**	.376**
strloc	4.56 (1.04)	5.11 (0.65)	.792**	1	.362**	.254**	.279**	.323**
techn	4.35 (0.83)	4.93 (0.77)	.544**	.472**	1	.149**	.210**	.416**
ecoor	5.47 (0.92)	5.66 (0.93)	.369**	.212**	.340**	1	.210**	.230**
Lroor	5.13 (0.99)	5.60 (0.99)	.220*	.207**	.300**	.299*	1	.333**
glmin	5.19 (1.04)	5.01 (0.98)	.378**	.368**	.505**	.333*	.365**	1

- Notes:
- Correlations below the diagonal are for the Indian respondents (n = 239) and correlations above the diagonal are for the Chinese respondents (n = 210).
  - Values in parentheses are standard deviations of the means.
  - Bold values on the diagonal are construct reliabilities for total data (n = 449).
  - Strglo = Global Integration Expectations, Strloc = Local Responsiveness Expectations, Techn = Technology Intensity, Ecoor = Economic Orientation, Lroor = Learning Orientation, and Glmin = Global Mindset Intensity.
  - \*\*p<.01.

Another key feature of Table 3 is that a majority of the examined variables are significantly correlated for both the Indian and Chinese samples. The *organisational* level reform measures of *organisational strategy* (global integration and local responsiveness expectations), *technology intensity* and *entrepreneurial orientation* (economic and learning orientations) are significantly correlated for both the Indian and Chinese samples, indicating the high connectivity between these variables. Also all the organisational level variables were significantly related to global mindset intensity indicating In spite of reasonable support for the study hypotheses, it is widely acknowledged that correlation results provide limited forecasting capacity (as the significant correlations could be influenced by sample

size), and consequently, other statistical techniques are necessary. Hence multiple regression analysis was conducted to confirm the linkages between the assessed variables.

#### Multiple Regression Analysis

Table 3 presents the multiple regression analysis for the constructs of the *organisational* level pressures and the constructs of individual level as well as organisational level *managerial* paradigms with global mindset intensity for the Indian and Chinese samples. All the models presented in Table 3 reflect Adjusted R<sup>2</sup> scores greater than 0.22, thereby providing some degree of confidence in predicting the assessed relationships. The results indicate some similar and dissimilar predictors of global mindset intensity in the two samples. For instance, the *organisational* level constructs of technology intensity and learning orientations had direct impact on the cultivation and nurturing of global mindset intensity for Indian and Chinese respondents. However, while economic oriented entrepreneurial outlook also provided impetus towards the development of a global mindset amongst Indian respondents, the relationship was not supported with the Chinese sample. Interestingly, both the strategic orientation constructs were not contributing to the cultivation of a broader global outlook in both samples.

TABLE 3: RESULTS OF REGRESSION ANALYSIS FOR THE *ORGANISATIONAL* LEVEL REFORM MEASURES PRESSURES ON MANAGERIAL GLOBAL MINDSET INTENSITY FOR INDIA AND CHINA

Variables	Global Mindset Intensity			
	India		China

F	23.617***		15.546***	

Notes: a. b = beta, t = t value, F = F statistic.  
 b. \*p < 0.05, \*\*p < 0.01, and \*\*\*p < 0.001.

#### Discussion: Use of Qualitative Feedback Sessions to Supplement the Quantitative Findings

The multiple regression analysis for the Indian and Chinese samples indicated that three of the five *organisational* level constructs were compelling Indian managers to develop and nurture their global mindset intensity (Table 3). The Chinese sample of the other hand suggested that two *organisational* level constructs significantly contributed to the manager's global mindset intensity (Table 3). The quantitative analysis indicated that while organisational reform measures of changing core and subsidiary technologies as well as rethinking organisational learning orientation perspectives had significant linkages leading to managers developing global thinking in Indian and Chinese respondent service organisations, the organisational strategy constructs of global integration and local responsiveness expectations were not related to the global mindset variable in the both samples. Indeed, earlier discussions on the qualitative feedback responses from the Indian and Chinese samples had indicated that a vast majority of the respondent global service organisations in India and China were constantly changing their technology and global learning orientations at the organisational level as a means to compete in the complex and dynamic global business environment. Most of the core and subsidiary technologies were imported by the Indian and Chinese service organisations from overseas. In addition, managers at the qualitative feedback sessions in India and China explained that indigenous service organisations in both countries that were global players generally installed these globally accepted technologies as cost cutting initiatives, and effective service delivery mechanisms, in order to compete with other organisations within their respective sectors.

Managers at the qualitative sessions in India and China also explained enthusiastically that globally viable technologies were perceived to be vital in order to expand into overseas markets and to compete with global organisations on a worldwide scale. Furthermore, Indian and Chinese managers at the feedback sessions also felt that the possible gains involved on a long term perspective were well worth the investments, and consequently, they required a positive global mindset and outlook in order to perceive such positive notions about globality. In this context, at one of the feedback sessions in India, a senior manager with a leading global IT MNC in India explained the importance of possessing a global mindset in the IT sector. He stated that,

*“Technology is by far the single biggest driver [and] is driving everything right now. Managers have to be technology savvy in order for [them] to know what is the kind of [global] technology demands that [they] would be faced when [their organisation] has to go global.”*

A similar view was shared by a senior academic from one of China’s leading international universities who explained the importance of a broad global outlook engendered by the forces of global technology in the education sector. He explained that, *“Technology is really very important. We encourage all staff to use these [global] technologies.”* The senior academic later added that, *“...you [must] understand the importance of these [global] technologies.”* These global technologies installed in indigenous Indian and Chinese global service organisations thereby necessitated its managers to develop a high global mindset intensity, which facilitated the appreciation of the benefits associated with these global technologies.

In addition to technology reform at the *organisational* level, the entrepreneurial orientation of a global learning philosophy that underpinned organisational policies in the Indian and Chinese respondent organisations was also significantly related to the managerial global mindset intensity in both samples (Table 3). Indeed organisations possessing a global learning philosophy depend on the development of systems, processes and procedures of knowledge and information sharing at a global stage. Consequently, respondents at the feedback sessions in India and China explained that managers employed in global service organisations that valued global learning initiatives in India and China were compelled to develop a mindset that allowed them to strongly believe that their organisations that were engaging in global ventures through these global learning initiatives were being *proactive*. Moreover, managers at the qualitative sessions in both countries agreed that organisations that valued global learning initiatives by providing continuous learning opportunities, and an environment to share knowledge and information, required their managers possess a mindset which facilitates *continuous awareness* of this global learning environment, and thereby continuously engage in expanding their learning horizons. In this context, at one of the qualitative sessions in India, a middle manager in a leading real estate consultancy MNC in India stated that, *“...the essence is in understanding the global market...how foreign clients will be interested in investing in India...what are their risk taking abilities, how the judicial system in India and overseas work.”* This comment was in reference to the impact of global learning initiatives on the mindset of managers. Furthermore, a senior economist and commentator from one of China’s leading international universities elucidated the importance of managers possessing a global mindset espoused by the global learning philosophy of China’s global service organisations. He stated that, *“educational thinking from a broad view – a global perspective and the ability to learn and study about global issues is [vital]...”*

A contrasting result between the Indian and Chinese samples was the impact of the *organisational* level measure of economic orientation pressurising managers to develop a global mindset in the Indian sample (Table 3). The linkage in the Chinese sample was non significant. Indeed, Indian service organisations with a high economic orientation emphasised economic survival and profit making as well as overseas expansion as their underpinning philosophies. Managers at the face-to-face interview sessions in India explained that organisations with these ideologies required its managers to possess an in-depth understanding of the economic, socio-cultural, political and technological scenarios that governed overseas national contexts in order to make prudent business decisions dealing with expansion into foreign locations.

Managers at the face-to-face interview sessions in India further explained that organisations with strong economic pursuits required their managers to appreciate their organisations’ economic goals, and to believe strongly, in the notion that the most attractive opportunities for growth was in overseas ventures. In this regard, at one of the feedback sessions in India, a middle manager with a leading multinational bank in India stated that, *“ [We] need to accept that something that is different is not necessarily bad...need to see the benefit of doing things*

differently.” At another qualitative session, a middle level manager in a multinational IT organisation in India explained the importance of a global mindset in pursuing economic goals. He explained that,

“...the primary competency a manager should possess is a business mindset...the focus is on delivery [of service] itself without making difference to client...should go beyond and create value.”

Moreover, a supervisory manager in a multinational accounting and auditing consultancy firm in India summarised the importance of mindset change in relation to organisation’s economic orientations at an alternative qualitative session. He stated that,

“Awareness of what’s going around...economic related things, new market players, competition...basically information...managers need to be more receptive and adaptive to changing [economic orientation] philosophies, cultures and processes...this mindset has to change to compete.”

These comments from managers at the feedback sessions in India and China provided some support to the assessed significant *organisational* level measures necessitating managers to develop a global mindset.

## Conclusion

In spite of an encouraging development in conceptual area, only little empirical work has been reported in the literature. With the intensification of global competition, global mindset is emerging as the most significant competitive strength. Nothing less than a complete reorientation of global outlook of senior managers can shed the ingrained ethnocentricism inherent in the thinking of global companies. The areas of enduring strengths enjoyed by companies, industries and nations are constantly changing and the advantages of cost, skills, customer service, brand enhancement, knowledge base, and innovation are no longer sufficient in providing global agility to firms.

While strategic, technological and entrepreneurial behaviours are shaped by multitude of factors, they collectively impact upon the cognitive world of managers. The quality of the response from senior managers under conditions of rapid change and complexity involves interpretations and attentions across functions and countries simultaneously. The level of study in this research is primarily at the individual level but its impact at the organisational levels is evident. The study attempts to offer empirical evidence from China and India on constructs drawn largely from Western perspectives. This explicit testing of the universality of the ideas has implications much broader than research on mindsets. The study affirms that organisational level reforms in service organisations across India and China have impacted the cognitive world of their managers. The significance of this research lies in the explanation that motivated forward looking organisations and their leaders need to be able to develop, sustain and enrich their mindset boundaries under diverse contextual settings.

# Tourism and Economic Growth: The Case of China

Sumei Tang, [S.M.Tang@Griffith.Edu.Au](mailto:S.M.Tang@Griffith.Edu.Au)

Griffith University, Australia

## Abstract

**This study investigates the role of tourism in the long-run economic development of China. Towards this purpose, an error correction model (ECM), the cointegration and the Granger causality techniques are used. The results indicate that while there is a two-way directional causality between international tourism and economic growth, there is only single-directional causality from the real exchange rate to economic growth. These findings support the widely believed tourism-led growth hypothesis in the Chinese economy, and suggest that the real exchange rate affects China's economic growth but not tourism.**

## Introduction

China has been ranked as 4<sup>th</sup> of international tourist arrivals (120 million)<sup>1</sup> and 6<sup>th</sup> of international tourism receipts (\$US29 billion) in 2005 according to the statistics of the World Tourism Organization (WTO)<sup>2</sup>. Meanwhile, China has also been experienced the highest economic growth (8%) in the world in 2005. During the period 1978 to 2005, the annual average growth rates of international tourist arrivals and receipts were 19% and 20%, respectively. Tourism plays an important role in the Chinese economy. The direct contribution of tourism accounts for 1.3% of GDP in 2005, while the impact of tourism on the whole economy is much greater. In 2004, tourism generated \$US184 billion worth of economic benefits (11% of GDP) and employment up to 13.6 million (2% of total employment) in 2004<sup>3</sup>. Recently, the WTO predicted that China will become the most favoured international tourism destination in the future. It is expected that in 2020, the number of international tourist arrivals would increase to 145 million and the corresponding tourism receipts would be \$US75 billion representing approximately 8% of China's estimated GDP<sup>4</sup>. China's tourism industry has demonstrated robust growth and is seen as one of the cornerstones of the Chinese economy and a major source of job creation during the period 1978 to 2005. Has the hypothesis of tourism-led growth been held in China? Recognition of the hypothesis of tourism-led growth has been held in China is important because tourism-led growth means that confronting with scarce resources and the increasing competition in the world economy, the rich natural resource of tourism can be exploited becoming a comparative advantage for China competing in the global economy for foreign exchange earnings and economic growth. On the other hand, if the hypothesis of tourism-led growth is not true, tourism promotion may not only be an ineffective strategy for fostering economic development, it may generate adverse externalities on the Chinese economy damaging the natural environment.

Table 1 details China's international tourist arrivals, international tourism receipts, the annual average growth rates of arrivals and receipts, and the percentage share of international tourism receipts in export, economic growth and trade balance deficit over the period 1978 to 2005. International tourism industry in China has been one of the fastest growing sectors of the economy. International tourist arrivals (column 2) and international tourism receipts (column 4) are plotted in Figures 1(a) and 1(b). As can be seen, there was a great increase in international tourist arrivals and tourism receipts in China for the period 1978 to 2005. International tourist arrivals have increased from 1.8 million in 1978 to 120 million in 2005, while the receipts from international tourists arrivals have increased from \$US0.3 billion to \$US29 billion during the same period. During the period 1978 to 2005, the average annual growth rates of international tourist arrivals and tourism receipts are 18.9% (last row of column 3) and 20.4% (last row of column 5). Column 6-8 of the table indicates that international tourism receipts have made an important contribution to China's economy. As can be seen from column 6, tourism receipts as a proportion of export fluctuated between 2.7% (1978) to 7.2% (1999) with an average rate of 4.9% over the period 1978 to 2005. The ratio of tourism receipts to GDP (column 7) has been on the increase with 0.1% in 1978, and gradually reached 1.3% in 2005 with an annual average rate of 0.9% over the sample period. The last column presents the percentage share of international tourism receipts in trade balance deficit which clearly suggests that tourism even plays a greater role than China's export in terms of net foreign exchange earnings.

However, despite the significant contributions of international tourism to China's economic development over the period 1978 to 2005, little attention has been paid to its empirical analysis, so does the role of tourism in economic growth remains controversial. The proponents of tourism-led growth argue that the tourism-led growth hypothesis has been held for many economies (Balaguer and Cantavella-Jorda, 2002; Dritsakis, 2004; Durbarry, 2004; Jackson, 2006; and Wen and Tisdell 1996). Tourism brings foreign exchanges and contributes to government revenues. Tourism spurs local governments to improve infrastructures such as better water and sewerage systems, roads, electricity, telephone and public transport networks. Consequently, it can improve the quality of life for local residents as well as facilitating tourism. Moreover, tourism promotes regional economic development by creating local tourism cluster industries. For example, tour and travel agencies, retailers, accommodation, transportation, telecommunication, banking, education and research institutions etc. Subsequently, these cluster industries contribute to local employment and improve income distribution. Tourism also increases awareness of the country being visited, stimulates international and domestic trade, and generates FDI and domestic investment in tourism industries.

**Table1. The contribution of international tourism to economic growth in China**

Year	Tourist arrivals million persons	Growth in arrivals %	Tourism receipts US \$b	Growth in receipts %	% Share of tourism receipts in export	% Share of tourism receipts in GDP	% Share of tourism receipts in trade balance deficit
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
1978	1.8		0.3		2.7	0.1	-23.1

Notes: 1 and 2. The negative growth in arrivals (column 3) and receipts (column 5) were due to the effects of the Tianmen Square incident and the SARS epidemic in 1989 and 2003, respectively.

FIG. 1 (A): TOURISTS ARRIVALS, CHINA, 1978-2005

FIG. 1(B): TOURISM RECEIPTS, CHINA, 1978-2005

In addition, tourism enhances the efficiency of resource allocation and facilitates the exploration of economies of scale in local firms to remain competitive. It is from this perspective that the tourism-led growth hypothesis is promoted. Empirical studies supporting these arguments include Balaguer and Cantavella-Jorda (2002), Dritsakis (2004), Jackson (2006), and Wen and Tisdell (1996). Balaguer and Cantavella-Jorda (2002) apply the methodology of the Granger cointegration and causality tests to investigate the role of inbound tourism in the Spanish long-run economic development over the period 1975 to 1997. They find that economic growth in Spain has been sensible to persistent expansion of international tourism, and that the tourism-led growth hypothesis is supported in the case of Spain. Dritsakis (2004) uses an error correction model (ECM) to examine the impact of tourism on the long-run economic growth in Greece over the period 1960 to 2000. He shows that international tourism earnings cause economic growth with a strong Granger causal relationship in Greece. In the context of China, Jackson (2006) regards tourism as a regional natural advantage having potential for activating business links in the socialist market economy of China. It means that tourism could form the basis for regional competitive advantage to foster regional economic development and to reduce regional income inequalities. Jackson's study is a qualitative research focusing on the importance of tourism activity to regional economic development. Using cross sectional data and a single-equation regression, Wen and Tisdell (1996) analyse China's spatial distribution of tourism and find that there is a link between tourism and regional economic development. Besides Jackson, and Wen and Tisdell, there are few published studies on China which indirectly study the relationship between international tourism and economic development. For example, Shan and Wilson (2001) in their empirical analysis find a strong reciprocal relationship between international tourism and trade. Also, Tang, Selvanathan and Selvanathan (2007) in their study find there is a causal relationship between international tourism and foreign direct investment.

On the contrary, opponents of tourism led-growth are very skeptical about the hypothesis of tourism-led growth (e.g. Brandon, 1996; Hazari and Ng, 1993; Oh, 2005 and R. N. Batta, 2003). It is argued that tourism may contribute little to the local economy when there are no backward and forward linkages of tourism with the local sectors (R. N. Batta, 2003), and there is absence of effective policies and regulations in the tourism host country. This could be true when the tourism host countries are less developed where tourism is predominantly nature-based, tourism is the major sector of the economy, major accommodations and businesses are owned and operated by foreign investors. Those foreign investors have backward linkages with their home countries and they import almost everything to the tourism host countries for consumption. When tourism occurs, a significant proportion of tourism expenditures (transports, hotels and food) are spent on prepaid tours, and the expenses made by the tourists in the tourism host countries are little. The economic benefits for the tourism host countries include employment opportunities and tax revenues. However, if local people lack the requisite skills, people from outside will grab the employment opportunities arising from tourism development (R. N. Batta, 2003). Moreover, tourism is demand driven and its prices are determined by monopoly power (Hazari and Ng, 1993). In addition, tourism may lead to deforestation and degradation of forest, and depletion of water resources. In this regard, tourism not only contributes

little to the less developed economy, it also generates adverse externalities on less developed economies such as welfare reducing (Hazari and Ng, 1993) and damaging the natural environment. Empirical evidence backing up the views of tourism led-growth opponents can be found in Hazari and Ng (1993), Oh (2005) and R. N. Batta (2003). Hazari and Ng (1993) in their study show that in a monopoly power framework, tourism may be welfare reducing. R. N. Batta (2003) investigates tourism in Fiji and claims that tourism is demand driven, has high environmental impacts, contributes little to the local economy, makes no contribution to conservation and does not elicit local community participation. Oh (2005) uses a vector auto-regression (VAR) model to investigate the causal relationship between tourism growth and economic growth in Korea. Oh claims that the hypothesis of tourism-led economic growth was not held in the case of the Korean economy as the comparable role of tourism in the Korean economy is significantly less than some countries such as Spain.

This study contributes to the existing literature by applying an error correction model (ECM) and time series techniques of cointegration to investigate the role of tourism in the Chinese economy. A real exchange rate variable is included in the system because the role of the real exchange rate in foreign trade (tourism and export/import) and economic growth is well recognised theoretically and empirically. Specifically, we test the hypothesis of tourism-led growth in China's long-run economic development.

In addition, we also investigate the role of the real exchange rate in the Chinese economy, and whether there exists any causal relationship between tourism, economic growth and the real exchange rate. This study differs from earlier studies in a number of aspects. First, it represents the first attempt to directly identify or test the relationship between tourism, the real exchange rate and economic growth in China, offering insights into the disputed tourism led-growth nexus, and exploring the role of the exchange rate in the Chinese economy. Second, relevant quantitative studies in a multivariate framework regarding causal links between tourism and China's economic growth in the long-run are scarce, thus, this study attempts to fill that vacuum by using the ECM model. Using a single equation model (e.g. Wen and Tisdell, 1996) may produce various estimation biases, giving rise to misleading analytical results. Third, we use pure time-series data while previous studies on the Chinese tourism and growth use either cross-sectional or panel data, which are likely to suffer from problems of data comparability and heterogeneity (Atkinson and Brandolini 2001; Srinivasan and Bhagwati 1999).

The remainder of this paper is organised as follows. Section II presents the data sources, unit root and cointegration analyses, ECM modelling and empirical results. The final section III provides conclusions and policy implications.

## Data Source and Analysis

The three variables used in this study are international tourism receipts (TR)<sup>7</sup>, economic growth (GDP) and the real foreign exchange rate (XR)<sup>8</sup>. The data of the three variables are all quarterly time series for the period 1988:1 to 2005:4. The data for the period 1988 to 2004 are compiled from China Monthly Statistics (1987:1- 2005:4), Comprehensive Statistical Data and Materials for 50 years of New China and various issues of China Statistical Yearbook, all published by the National Bureau of Statistics (NBS) of China. The data for the latest year 2005 are obtained from the website of the National Bureau of Statistics (NBS) of China and China National Tourist Office. GDP quarterly time series for the period 1988 to 2000 is constructed on the basis of the monthly gross industrial output (GIO) and the yearly GDP statistics because of the lack of availability of quarterly or monthly GDP statistics<sup>9</sup>.

Figures 2 plot the three original time series in log form, LTR, LGDP and LXR. It is noticeable that there are a few irregular effects appearing in the series of LTR (Figure 2(a)) around 1989:3, 1994:1, 1998:1 and 2003:1. These irregular effects are the 1989 Tianmen Square Massacre, the depreciation of the Chinese currency in terms of US dollars in 1994, the 1998 Asian Financial Crisis and the 2003 SARS epidemic. In Figure 2(c), it is also visible that a sudden large upward shock occurs in LXR series around quarter one of 1994. At the beginning of 1994 the Chinese government depreciated almost 50% of its currency value in terms of US dollars. At the time, China carried out reform of its foreign exchange system and adopted a unified and the centre government managed exchange rate regime based on market supply and demand of foreign exchange. Overall, as can be seen, there is a clear upward

trend in the three time series indicating that the means are changing over time, and hence the three series in level form may not be stationary.

Figure 2(a) The original series of tourism receipts (TR) in natural logs, China 1988:1-2005:4

Figure 2(b) The original series of GDP in natural logs, China 1988:1-2005:4

Figure 2(c) The original series of exchange rates (XR) in natural logs, China 1988:1-2005:4

Figures 3 are the plots of the first difference series of the three time series. They suggest no evidence of changing means indicating that the three series, LTR, LGDP and LXR may be integrated of order one, I(1). To statistically validate these preliminary findings and to ensure the three time series are all stationary, the Augmented Dickey-Fuller (ADF), the Phillips-Perron (PP), and Perron and HEGY tests are used to test the stationarity of the three time series in this study.

### Unit Root Test

The ADF test for unit roots are first performed on the level form of the three series LTR, LGDP and LXR. We follow the testing procedure discussed in Ender (1995) by considering the three models:

Trend and constant model

$$\Delta y_t = \alpha_0 + \alpha_2 t + \gamma y_{t-1} + \sum_{i=1}^k \beta_i \Delta y_{t-i} + \varepsilon_t \quad (1)$$

Constant and no trend model

$$\Delta y_t = \alpha_0 + \gamma y_{t-1} + \sum_{i=1}^k \beta_i \Delta y_{t-i} + \varepsilon_t \quad (2)$$

No trend and no constant model

$$\Delta y_t = \gamma y_{t-1} + \sum_{i=1}^k \beta_i \Delta y_{t-i} + \varepsilon_t \quad (3)$$

Where  $\Delta y_t = y_t - y_{t-1}$  is the first difference of the series  $y_t$ ;  $\Delta y_{t-1} = (y_{t-1} - y_{t-2})$  is the first difference of  $y_{t-1}$  etc.;  $\alpha$ 's,  $\gamma$  and  $\beta$ 's are parameters, and  $\varepsilon_t$  is a stochastic disturbance term. The preliminary estimation suggests that the number of lagged terms to be included is 2, which ensures that the errors are uncorrelated. The sample size used in the three models is 72. The difference among the three regressions is the presence of the deterministic elements  $\alpha_0$  and  $\alpha_2 t$ . Equation (1) includes a drift  $\alpha_0$  and a time trend  $\alpha_2 t$ , equation (2) includes a drift  $\alpha_0$  but no time trend and equation (3) excludes both  $\alpha_0$  and  $\alpha_2 t$ .

The ADF test is applied to the series LTR, LGDP and LXR separately. To reinforce the analysis, the Phillips-Perron (PP) test is also used as Monte Carlo studies have found that the Phillips-Perron test has greater power to reject a false null hypothesis of a unit root (Enders, 1995, p242). Estimation is carried out using the econometric software EVIEWS. The results of the ADF test for stationarity on the original series are reported in Table 2. As can be seen, the level series of LTR and LXR are non-stationary, but the series of LGDP in level form is stationary. The PP test confirmed the ADF test giving a same result.

**Table 2. ADF and PP tests for a unit root on the level series**

Variables	Model (1)		Model (2)		Model (3)	
	Trend & Constant		Constant & No trend		No trend & No constant	
	ADF	PP	ADF	PP	ADF	PP
LTR (2)□	-1.60	-1.86	-0.56	-0.62	-1.40	1.43
LGDP (2)□	-2.56	-5.43**	0.07	-0.58	2.78**	2.14
LXR (2)□	-1.44	-1.28	-2.46	-2.21	1.36	1.47

Notes: \*\* denotes significance at the 1% levels; numbers in brackets are number of lags used in the ADF and PP tests in order to remove serial correlation in the residuals.

As can be seen in Figure 2(c), structural changes may have occurred to the series of LXR around 1994:1. The depreciation of the Chinese currency in terms of US dollars by 50% at the beginning of 1994 induced a one-time rise in the mean of LXR, which was an exogenous shock but likely to have a permanent effect on it. When there are structural breaks, the various Dickey-Fuller and Phillips-Perron test statistics are biased towards the non-rejection of a unit root (Enders, 1995). Thus, it is necessary to use the procedure developed by Perron (1989) to test for a unit root in the presence of a structural change. The following regression equation was considered for the exchange rate variables:

$$y_t = \alpha_0 + \mu_1 DU_t + \mu_2 DT_t + \alpha_1 y_{t-1} + \alpha_2 T + \sum_{i=1}^k \beta_i \Delta y_{t-i} + \varepsilon_t \quad (4)$$

where,  $y_t$  represents LXR<sub>t</sub> in time t;  
 $DU_t$  represents a level dummy variable.  $DU_t = 1$  if  $t \geq \tau + 1$  and 0 otherwise. The structural break of LXR in period 25 (1994:1) occurs so that  $\tau = 24$ ;  
 $DT_t$  represents a slope dummy variable.  $DT_{(25)} = 1, DT_{(26)} = 2, \dots$  if  $t \geq \tau + 1$  and 0 otherwise.  
 $\alpha_0$  an vector of intercept term;  
 $T$  a deterministic trend;  
 $\alpha_i, \mu_i$  and  $\beta_i$  the parameters;  
 $k$  the lag length; and  
 $\varepsilon_t$  the disturbance terms.

The model is generalised to allow a one-time change in the structure occurring at a time. It permits an exogenous change in the level of the series and in the rate of growth. The value of the test statistics of the Perron (1989) test at various lag lengths of LXR are reported in Table 3. The Perron test indicates that the null hypothesis of a unit root is not rejected by the series of LXR in the presence of a structural break at all lag lengths. This confirms the previous finding of the ADF and PP tests that the series of LXR in level form is non-stationary.

**Table 3. Perron test for a unit root in the presence of structural change**

	T	$\lambda$	t-statistic				Critical value
			K=0	K=1	K=3	K=5	
<b>LXR</b>	70	0.36	3.20	2.82	2.26	1.63	<b>-4.22</b>

Notes: T = number of observations,  $\lambda$  = proportion of observations occurring before the structural change, K = lag length. All estimated values of  $\alpha_i$  are significantly different from unity at the 5%.

In general, tourism activities fluctuate strongly with seasons. Besides the natural seasonal fluctuations, China's centrally planned economic regime has also generated a regular pattern of large seasonal fluctuations (Rawski, 2002) in its economy. In Figure 2(a) and 2(b), the seasonality of the both original series of LTR and LGDP seems discernible. In order to investigate the possibility of seasonal unit roots in the series, the commonly used

HEGY (Hylleberg et al, 1990) test is applied to the two series<sup>10</sup>. This test is based on the following auxiliary regression model:

$$y_{4t} = \pi_1 y_{1t-1} + \pi_2 y_{2t-1} + \pi_3 y_{3t-2} + \pi_4 y_{3t-1} + \varepsilon_t \quad (5)$$

Where

$$y_{4t} = y_t - y_{t-4}; \quad y_{1t-1} = y_{t-1} + y_{t-2} + y_{t-3} + y_{t-4};$$

$$y_{2t-1} = -y_{t-1} + y_{t-2} - y_{t-3} + y_{t-4}; \quad y_{3t-2} = -y_{t-2} + y_{t-4};$$

$$y_{3t-1} = -y_{t-1} + y_{t-3};$$

And  $\varepsilon_t$  is a normally and independently distributed error term with zero mean and constant variance. For estimation, we apply the least squares method and include an intercept, three seasonal dummies and a time trend in model (5). The HEGY test involves testing the following three hypotheses:

- (i)  $H_0: \pi_1 = 0$  vs  $H_1: \pi_1 < 0$  ;
- (ii)  $H_0: \pi_2 = 0$  vs  $H_1: \pi_2 < 0$  ;
- (iii)  $H_0: \pi_3 = \pi_4 = 0$  vs  $H_1: \text{at least one } \pi_i \neq 0 \text{ } i=3,4$  .

First two hypotheses (i) and (ii) involve the use of the t-test and the third involves the use of F-test. If null hypothesis (i) is not rejected, it means that there is a unit root at the zero frequency (i.e. a non-seasonal unit root in the series). If null hypothesis (ii) is not rejected, it means that there is a seasonal unit root at the semi-annual frequency only. If null hypothesis (iii) is not rejected, it means that there is a seasonal unit root at the annual frequency only.

Table 4 presents the values of the test statistics and the corresponding critical values at the 5% level for the two time series, LTR and LGDP. The results show that null hypothesis in (i) is not rejected for the two time series, indicating that both series have a non-seasonal unit root. The null hypotheses (ii) and (iii) are not rejected for the LGDP time series indicating that there is a seasonal unit root at the semi-annual and annual frequencies of the series, respectively. For the LTR series, the null hypothesis (ii) is rejected but not the null hypothesis (iii) indicating that the LTR series has a seasonal unit root at the annual frequency but not at the semi-annual and quarterly frequencies.

**Table 4. HEGY test results for seasonal unit roots**

Hypotheses	The test statistics		Critical values
	LGDP	LTR	
(i)	1.51	-1.64	-3.71
(ii)	-2.95	-4.50*	-3.08
(iii)	-5.02	-3.99	6.55

The results so far confirm that the LTR and LXR time series have at least one unit root and hence are non-stationary in level form. For the LGDP time series, the ADF and PP tests indicate that there is no unit root in the series. However, the HEGY test shows that there is, at least, one non-seasonal unit root in the series, which contradicts the result of the ADF and PP tests, and grants that the ADF and PP tests for a unit root on the first difference of the series are required. Moreover, in accordance with the Granger theorem, cointegration necessitates that the variables should be integrated of the same order (Enders, 1995; Engle and Granger, 1987; and Granger, 1986). Thus, in order to ensure LTR, LGDP and LXR are stationary integrated of same order, the ADF and PP tests for a unit root on the first difference of the three series are performed. The results of ADF and PP tests in the three models are presented in Table 5 which confirm that the first difference of the three series LTR, LGDP and LXR are all stationary integrated of order one, I(1).

**Table 5. ADF and PP tests for a unit root on the 1st difference of the three series**

Variables	Model (1)		Model (2)		Model (3)	
	Trend & Constant		Constant & No trend		No trend & No constant	
	ADF	PP	ADF	PP	ADF	PP
LTR (2)□	-5.37**	-8.29**	-5.41**	-8.35**	-4.10**	-7.29**
LGDP (2)□	-8.53**	-26.12**	-8.49**	-26.13**	-6.14**	-20.85**
LXR (2)□	-5.23**	-8.30**	-4.64**	-7.96**	-4.26**	-7.65**

Notes: \*\* denotes significance at the 1% levels; numbers in brackets are number of lags used in the ADF and PP tests in order to remove serial correlation in the residuals.

### Cointegration Test

Even though the three individual series LTR, LGDP and LXR are of non-stationary and of order I (1), it is possible that a liner combination of the three variables may be stationary. Modelling a liner relationship between the three variables, even if each of the variable is non-stationary (that is I (1)), as long as they are cointegrated, the regression involving the three series may not be spurious. Thus, it is necessary to investigate whether the three series LTR, LGDP and LXR are cointegrated having long-run equilibrium relationships. The Johansen methodology is used to perform the cointegration test among the three variables.

To minimize the effect of seasonal fluctuations, a centered seasonal dummy variable is applied when conducting the cointegration test. The reason to use the centered seasonal dummy variable is that a standard 0-1 seasonal dummy variable will affect both the mean and the trend of the level series in a model system, but the centered seasonal dummy variable can shift the mean without contributing to the trend (Johansen, 1995). In addition to the centered seasonal dummy variable, an event dummy variable is also introduced into the cointegration test to capture the combined irregular effects in the cointegration analysis. These irregular effects are reflected in the series and are particular visible in the series of LTR (Figure 2 (a)) around 1989:3, 1994:1, 1998:1 and 2003:1, which are the effects of the Tianmen Square Massacre, the depreciation of the Chinese currency in terms of US dollars, the Asian Financial Crisis and the SARS epidemic, respectively.

A model, which contains 2 lags, a drift and two exogenous dummy variables, is chosen to test cointegration among the three variables after a careful search and test. The result of the Johansen cointegration rank test is summarized in Table 6. It indicates that at least there is a presence of two cointegration vectors at 1% level of significance. In other words, at 1% level of significance, the null hypothesis of no cointegration is rejected for rank of zero, while the alternative hypothesis of one or more cointegration vectors is accepted. Moreover, at 1% level of significance, the null hypothesis of no cointegration is also rejected for rank less than or equal to 1, and the alternative hypothesis of two or more cointegration vectors is accepted. Thus, it is concluded that the three variables of LTR, LGDP and LXR are cointegrated and there exists long-run equilibrium relationships between the three variables, LTR, LGDP and LXR in China.

**Table 6. Johansen cointegration tests**

Null Hypothesis	Alternative Hypothesis	$\lambda_{\max}$ tests	95% CV	99% CV	$\lambda_{\text{trace}}$ tests	95% CV	99% CV
Rank = 0	$r \geq 1$	29.21**	23.78	28.83	52.99**	34.55	40.49
Rank $\leq 1$	$r \geq 2$	21.76**	16.87	21.47	23.78**	18.17	23.46
Rank $\leq 2$	$r \geq 3$	2.02	3.74	6.40	2.02	3.74	6.40

Note: \*\* denotes rejection of the null hypothesis at the 1% significance level.

### The Error Correction Model, Granger Causality Test and the Empirical Results

To test the tourism-led growth hypothesis and the sensitivities of the exchange rate in the Chinese economy, an error correction model (ECM) is developed. The model includes three equations:

$$\Delta \text{LGDP}_t = \alpha_1 + \alpha_{\text{lgdp}} \hat{\epsilon}_{t-1} + \sum_{i=1}^k \alpha_{11}(i) \Delta \text{LGDP}_{t-i} + \sum_{i=1}^k \alpha_{12}(i) \Delta \text{LTR}_{t-i} + \sum_{i=1}^k \alpha_{13}(i) \Delta \text{LXR}_{t-i} + \beta_1 D_{\text{et}} + \rho_1 D_{\text{st}} + \epsilon_{\text{lgdpt}} \quad (6)$$

$$\Delta \text{LTR}_t = \alpha_2 + \alpha_{\text{ltr}} \hat{\epsilon}_{t-1} + \sum_{i=1}^k \alpha_{21}(i) \Delta \text{LGDP}_{t-i} + \sum_{i=1}^k \alpha_{22}(i) \Delta \text{LTR}_{t-i} + \sum_{i=1}^k \alpha_{23}(i) \Delta \text{LXR}_{t-i} + \beta_2 D_{\text{et}} + \rho_2 D_{\text{st}} + \epsilon_{\text{ltrt}} \quad (7)$$

$$\Delta \text{LXR}_t = \alpha_3 + \alpha_{\text{lxr}} \hat{\epsilon}_{t-1} + \sum_{i=1}^k \alpha_{31}(i) \Delta \text{LGDP}_{t-i} + \sum_{i=1}^k \alpha_{32}(i) \Delta \text{LTR}_{t-i} + \sum_{i=1}^k \alpha_{33}(i) \Delta \text{LXR}_{t-i} + \beta_3 D_{\text{et}} + \rho_3 D_{\text{st}} + \epsilon_{\text{lxrt}} \quad (8)$$

After a general-to-specific search in accordance with the Akaike Information Criterion (AIC) and Schwarz Criterion (SC) (Akaike, 1974), 4 lags, a constant, a trend and two exogenous dummy variables are included in the ECM model. A number of lags for each of the three variables have been included to capture the short-run dynamic relationships in the ECM system. In particular, the model includes changes in LGDPt, LTRt, LXRt, and lagged  $\Delta \text{LGDP}_t$ ,  $\Delta \text{LTR}_t$  and  $\Delta \text{LXR}_t$ . De is the event dummy variable for capturing the possible combine effects of the 1989 Tianmen Square Massacre, the 1998 Asian Financial Crisis and the 2003 SARS epidemic. Ds is the centered seasonal dummy variable for minimizing the effect of seasonal fluctuations.  $\hat{\epsilon}_{t-1}$  is the lagged error-correction term.  $\alpha_i$ ,  $\alpha_{ij}(i)$ ,  $\beta_i$  and  $\rho_i$  are the parameters; and  $\epsilon_{\text{lgdpt}}$ ,  $\epsilon_{\text{ltrt}}$  and  $\epsilon_{\text{lxrt}}$  are the white-noise disturbance terms that may be correlated with each other. All the endogenous variables in the model are in real terms in natural logarithm form. The fit of the three equations are best for the data and there are no signs of residual autocorrelations in the model. Table 7 shows the results of the Granger causality test based on the ECM model. The results show that, at the 5% significant level, there is a bi-directional causal relationship between economic growth (LGDP) and tourism (LTR), and only a one-directional causal relationship runs from exchange rate (LXR) to economic growth (LGDP). That is, the empirical results support the widely believed tourism-led growth hypothesis in the Chinese economy, and suggest that the real exchange rate affects China's economic growth but not tourism. The findings are robust and consistent with the results by Jackson (2005), Wen and Tisdell (1996), as same as the conclusions by Balaguer and Cantavella-Jorda (2002) for Spain, and Dritsakis (2004) for Greece.

**Table 7. Granger causality test based on error correction modelling**

Dependent variables	Wald test statistics		
	$\Delta \text{LGDP}_t$	$\Delta \text{LTR}_t$	$\Delta \text{LXR}_t$
$\Delta \text{LGDP}_t$		4.13**	36.46**
$\Delta \text{LTR}_t$	4.33**		1.20
$\Delta \text{LXR}_t$	0.12	0.14	
Conclusion	LGDP $\Rightarrow$ LTR	LTR $\Rightarrow$ LGDP	LXR $\Rightarrow$ LGDP

Note: \*\* denotes rejection of the null hypothesis and the critical value with one degree of freedom is 3.84 at the 5% significance level.

## Conclusions and Policy Implications

Applying quarterly time series data from 1988:1 to 2005:4 to the ECM model and using the Johansen Cointegration method and the Granger causality technique, we have found that the causal links between tourism and economic growth are bi-directional, whereas only a one-way directional causality runs from the real exchange rate to economic growth. That is, the tourism-led growth hypothesis has been held in the Chinese economy, and the real exchange rate has had impact on China's economic growth but not on tourism.

These findings do have some important implications for policy makers in China and elsewhere. Now, globalisation is increasingly testing the ability of China's economy to adapt and maintain its competitive edge. Confronting with the worsening environment issues, income inequality, social frictions, and the increasing cost of investing in China, China must seriously consider its long-run strategies to maintain its economic growth. Since tourism is a natural resource leading growth, the Chinese government ought to emphasise and utilise tourism to form the basis for long-run competitive advantage hence fostering economic growth. In particular, tourism should be used as a long-run effective strategy to promote economic development in its less developed western regions where export of manufacturing goods is disadvantaged while its natural resource of tourism is abundant. Recently, the Chinese government in a five-year plan promised to use foreign direct investment effectively to make the service sector a key area to attract foreign direct investment, and to steer foreign direct investment toward the less developed inland western regions<sup>11</sup>. In this regard, it is strongly recommended that the Chinese Government should be wisely encouraging foreign investors to invest in tourism industry or local infrastructure in the less developed inland western regions to promote tourism. A successful tourism promotion would also activate business links in the region. For example, the demand for other services such as retailers, restaurants and accommodation would increase. Tourism creates local tourism cluster industries. Those cluster industries further contribute to the increase in local employment hence improving income distribution and welfare in the regions. Better tourism, greater economic development should be, and vice versa. In addition, the real exchange rate in the long-run may become a great challenge to China's economic development due to the appreciation of the Chinese currency against other currencies since the middle 2005. Finally, it suggests that in the course of economic development, especially when exploring tourism in the less developed western regions, encouraging participation of the locals to ensure that tourism is effectively linked with the local sectors should be preceded over any participants from outside and good environment protection laws and policies should be formulated and implemented in China.

## Abstract

Recent studies indicate that effective cherry picking entails saving costs through a (1) price search over time or (2) a price search across stores, or both. Many consumers however do not search across stores where considerable store loyalty is present. This does not mean that those consumers do not shop across time at the same store. This study aims to examine the relationship between cherry picking and the distance that consumers travel to do grocery shopping through conducting a survey at 10 different retail outlets across 3 days. The study will enable retailers to benefit from this form of consumer behaviour by taking a proactive approach towards store switching and store location – two of the main influencers of cherry picking behaviour. This study found that there is a highly significant correlation between cherry picking and the distance that consumers travel to do grocery shopping.

## Introduction

Retailers know the cherry picking consumer as a shopper who goes from store-to-store, buying only items that are specially priced. This perception raises various questions for a retailer: who are cherry pickers; how do they behave; and, how does this behaviour impact on retailers? Secondary research conducted by Urbany, Dickson and Sawyer (2000) and Hoch (2004) show that customers are loyal to stores for many different reasons: some are loyal from choice, some are loyal because both parties have invested time and effort in building a relationship, while some are loyal because their needs are met or exceeded, and others because the relationship is profitable to both sides. A number of factors play a part in influencing the loyalty and the commitment of customers, such as the quality and value of your core offering, levels of customer satisfaction, 'elasticity' inherent in the sector or product category, other competitors in the market, and even social, demographic and geographical influences.

The aim of this article is to examine the relationship between cherry picking and the distance that consumers travel to do grocery shopping and whether geographical influences play a role in customer behaviour concerning store switching and location.

Crocker (2005) define cherry picking as “selecting the best or most desirable” The term is used to describe both buyer and seller behaviour. Sometimes the phrase describes sellers who are selective about which customers they serve. The term also describes the behaviour of buyers who are selective about which products or services they purchase at what locations and prices. In both seller and buyer contexts, cherry pickers opportunistically take the best and leave the rest.

This article focuses on the buyer-side of cherry picking in the context of grocery shopping and compares the behaviour of consumers who switches stores and store location and whether geographical influences play a role in customer behaviour concerning store location compared to visiting a single store.

The research article will discuss the literature review, the problem statement and the study's specific research objectives, results of the study and recommendations. The research will also reveal future research needs.

## Reason for the Study

Limited research has been conducted concerning cherry picking, store switching and location in the marketing and retail sector. This is evidence in the limited knowledge available about store switching and location behaviour. This study attempts to clarify certain perceptions concerning store switching and location behaviour to establish whether

a relationship between cherry picking and the distance that consumers travel to do grocery shopping exist. The objectives are important elements in a dissertation, which give direction to the study. These will be discussed next.

## **Objectives of the Study**

Retailers can be severely affected by cherry picking and store switching and need a thorough understanding of what influences and constitutes such behaviour could lead to a substantial competitive advantage in the retailing market. To achieve the objectives of the study, the main aim of this article was to determine whether a relationship between cherry picking and the distance that consumers travel to do grocery shopping exists and whether geographical influences play a role in customer behaviour concerning store location and store switching. To attain the objective of this article, the following hypotheses were drawn:

H<sub>1</sub> There is a correlation between customers who price shop over time and consumers who price shop across stores between cherry picking and the distance that consumers travel to do grocery shopping.

H<sub>2</sub>: There is a significant relationship between store switching and store location.

## **Limitations of the Study**

The demographic profile of the respondents is not representative of the South African context. This could be attributed to the context of the study, the greater Tshwane area, and the specific malls that were targeted.

## **Literature Review**

Cherry picking and customer loyalty, store switching and location, and cherry picking and the distance travel will be briefly discussed.

### **Cherry Picking and Customer Loyalty**

Cherry picking means taking the best and leaving the rest (Fox and Hoch, 2003). Cherry picking is described as a continuum much like a shopper's degree of price sensitivity. A shopping trip is therefore classified as cherry picking if two or more grocery stores are visited on the same day. Customers are loyal for different reasons, namely:

- some are loyal from choice,
- some are loyal because both parties have invested time and effort in building a relationship,
- some are loyal because their needs are met or exceeded, and
- some because the relationship is profitable to both sides.

This paper focuses on buyer-side cherry picking in the context of grocery shopping and compares the behaviour of consumers who cherry pick by switching grocery stores and location of the stores. Consistent with economic theory of search, the propensity to cherry pick is found to be inversely related to shoppers' transaction and inventory holding costs, both due to demographics (e.g., working women, age, income, household size, home ownership) and geography (distance between nearby stores).

### **Store Switching and Location**

Secondary research (Halbritter, 2005, Carter, 2005, Fox and Hoch, 2003) reveals that consumers can cherry pick in at least two related ways. First, each week they can buy their entire market basket at the retailer where they get the best deals. To the extent that competing retailers promote non-identical items, store switching across weeks increases the number of cherry picking opportunities compared to consumers who are store loyal. Moreover, the transaction costs associated with switching stores across weeks do not seem to be much greater than those incurred by store-loyal shoppers, assuming that travel costs to the stores from which they choose are similar and that consumers switch often enough to be adequately familiar with store layouts.

Second, shoppers could engage in a more extreme form of cherry picking where store switching occurs within weeks. In this case, customers split their market basket across stores within a week (potentially on the same

day) to benefit from deals offered by different stores. Gauri, Sudhir and Talukdar (2005:1) observe three types of cherry pickers, namely:

- Those who cherry pick through price searching over time, indicating that these consumers may be store loyal but still price sensitive and thereby delaying their shopping over time, but still doing it at the same store.
- Customers can cherry pick through price searching across stores which implies that customers still do all their shopping on one day but, based on price, shop across different stores.
- Cherry pickers can be customers who shop both across stores and over time. What constitutes cherry picking behaviour is central to this study and our definition of such behaviour will form the foundation for all the findings.

#### **The Distance Travelled by the Shopper**

The cost of shopping also increases with the distance the shopper must travel to the store, reflecting the time and/or direct cost of transportation. We cannot measure travel distance for specific shopping trips, however, because we do not know with certainty where each trip originated and what route the shopper took. Thus, we must treat travel distance as a household trait, rather than a state variable. If we make the simplifying assumptions that (i) all trips originate from home, and (ii) the shopper travels from the first store visited directly to subsequent stores without intermediate stops, then the distance between the closest and next-closest stores reflects the cost of an incremental store visit. We therefore hypothesize that there is a negative relationship between the probability of cherry picking on a given shopping trip and the distance between the closest and next-closest stores to the consumer's home.

Loyalty cards and its influence on store switching and store location seems to be not the prime reason for choosing a particular store, while factors such as price, quality, service, and convenience contribute more to fostering loyal shoppers, according to consumer research food and grocery. A number of factors play a part in influencing the loyalty and the commitment of customers, such as the quality and value of your core offering, levels of customer satisfaction, 'elasticity' inherent in the sector or product category, other competitors in the market, and even social, demographic and geographical influences.

To achieve the objectives of the study, the main aim of this article was to determine whether a relationship between cherry picking and the distance that consumers travel to do grocery shopping store exists and whether geographical influences play a role in customer behaviour concerning store location and store switching. The true definition of cherry pickers needed to be studied. Therefore the following hypotheses were formulated.

H1: There is a significant relationship between store switching and store location.

H2: There is a correlation between customers who price shop over time and consumers who price shop across stores between cherry picking and the distance that consumers travel to do grocery shopping.

Next the research methodology used in this research will be explained.

## **Research Methodology**

Secondary and primary sources were used to gather information. The main secondary sources used were journals, articles, press reports, and books. The main source of primary data was questionnaires. The sampling, data collection methods, measures and inferential statistics of the study will be highlighted.

### **Sampling**

The target population of this study was grocery shoppers where grocery shopping can be defined as shopping for food, toiletries and detergents excluding bread and milk. These sample elements were targeted in the context of shopping malls through the use of mall intercepts and interviewer-administered personal interviews. Mall intercept surveys is a variation of in-house personal interviewing that involves engaging shoppers in a shopping centre, qualifying them and thereafter conducting the interview. This form of survey is more flexible than in-house personal surveys and the interviewer also has full control of the interviewing environment. This form of interviewing is most useful in concept testing like cherry picking (Tustin, Ligthelm, Martins and Van Wyk, 2005:152).

Leedy (2004:18) distinguish between probability samples and non-probability samples, the difference being that in the case of probability sampling, the probability that any member of the population will be included in the sample can be determined, while in non-probability sampling, this probability cannot be specified. In this study

probability sampling was used. A sampling frame was obtained of shopping malls in the greater Tshwane area where specific shopping malls were selected based on convenience and a wide LSM spread. A relatively representative sample was obtained through targeting shopping malls for various LSM groups in different areas of Tshwane.

A realised sample size of 176 was obtained from a target sample size of 250 with 100% of the questionnaires being usable. This could be attributed to the use of personal interviews as a data collection method. The data collection method will be discussed in greater depth in the following section.

#### **Data Collection**

The questionnaire was pre-tested through 10 quasi interviews where respondents were selected based on convenience and respondents were scanned through only allowing the “main family grocery shopper” to participate.

Data was collected over a three day period at 10 different shopping malls through the use of personal interviews as a survey method. A wide spread of respondents were targeted through conducting the survey at different times each day – morning, afternoon and early evening. Personal interviews is generally regarded as the best survey method in testing concepts (Tustin, Ligthelm, Martins & Van Wyk, 2005:155) like cherry picking. In-house knowledgeable interviewers, with an academic background, were used to decrease the likelihood of interviewer bias. No incentives were used to gain a higher response rate.

#### **Measures**

The main construct of this study (location) was measured through the use of Likert-type scales as opposed to the demographic variables, like respondent income and age, whose questions delivered only nominal data. The basic scale design therefore consisted of a Likert-type scale with five scale points (with labels ranging from strongly agree to strongly disagree) and 11 scale items. This scale was found to be highly reliable with a Cronbach’s Alpha of 0.7. The constructs measuring cherry picking behaviour as price searching across time and price searching across stores were measured using similar scales with five scale items. These two scales were also found to be reliable. No items on any of these scales were reverse scored.

#### **Inferential Statistics**

In this study the researchers want not only describe the sample data such as means, standard deviation and proportions but they wish to make inferences about the population based on what was observed in the sample. Inferential statistics allow researchers to make inferences concerning the true differences in the population (Tustin *et. al.*, 2005).

The dataset is further augmented by locations of panel households and grocery stores. These locations allow us to compute travel distances both from shoppers’ homes to stores and between stores in order to assess the relationships between geographic variables and cherry picking. Therefore the following null and alternative hypotheses can be formulated:

H0:  $\mu \neq 10$  km

H2:  $\mu = 10$  km

The research findings of the research will be highlighted next.

## **Research Findings**

Descriptive and inferential statistics were used to test the hypotheses in this study.

#### **Descriptive Statistics**

The sample in this study consisted of 67 percent females and 33 percent males with the average age of between 24 and 28 years. A relatively diverse spread of language across respondents was obtained with most respondent’s preferred language being Afrikaans (40%), English (17%) and North Sotho (15%). This demographic variable is greatly influenced by the province (Gauteng - where North Sotho is a commonly spoken language) and city (Pretoria – where Afrikaans origins date back to the settlers). It is also influenced by the race of the respondents which was distributed as 45 percent African, 52 percent White, 2 percent Coloured and 1 percent Indian.

Two important characteristics are evident from the study. First, 20 percent of the sample does not cherry pick at all. Second, the distribution is heavily skewed with a long right tail. Thus, most households are on the low end of the cherry-picking continuum. The mean and median of the percent cherry-picking distribution are 7.7% and

4.2%, respectively, while households in the top decile cherry pick on 32.0% of shopping trips. Though they may not seem compellingly large, these statistics belie the fact that each cherry-picking trip is made up of multiple store visits. If we consider the distribution of store visits, which reflect retailer traffic counts, we find that the mean and median are 13.2% and 8.2% respectively, while the top decile cherry picks on 49.3% of visits.

**Cherry Picking Behaviour**

As describe earlier cherry picking occurs when a consumer visits two or more grocery stores on the same day. The response of the study is shown below in figure 1.

FIG. 1: CHERRY PICKING BEHAVIOUR

Fig. 1 shows the distribution across households of cherry picking trips as a percentage of all the household’s shopping trips. 20 percent of the sample does not cherry pick while households are less likely to go cherry picking when there is a working adult female in the family only five percent of the sample. Presumably because it is more costly for them to spend time shopping for groceries. Senior citizens ( $\geq 65$  years old) are less likely to be employed outside of the home and so have more time to invest in shopping. Therefore if there is a senior citizen in the household increases cherry picking by 22 percent.

Homeownership also implies greater inventory carrying capability. This further implies that home owning households can take advantage of the greater number of discounts available through cherry picking because they have more opportunity to accelerate purchases by forward buying. As indicated in figure 1 homeownership increases the propensity to cherry pick by about 33 percent.

Wealthy households are assumed to have higher opportunity costs and are less price sensitive. Indeed, household income has a negative impact on percent cherry picking and only three percent of the respondents indicate that they sometimes cherry pick. Whereas larger and low income households are assumed to be more price sensitive and will switch stores, both because they have to spend a greater proportion of their income on groceries (budget constraint) and 15 percent of the respondents indicated cherry pick because they have greater returns to price search by virtue of purchasing scale see figure 1.

Travel distances and times also exert an influence on cherry picking propensity. Although we find no effect for how close the nearest store is to the home, there is a negative effect for the distance from the nearest to next-nearest store. We take this as evidence that the household considers the incremental cost of the extra store visit (which can be very low if nearby stores are close together or more costly if not) against the expected benefit of the additional discounts available if that extra store visit is made. Figure 1 shows that each extra kilometre between stores decreases percent cherry picking by about 5 percent.

**Consumer Loyalty**

As noted in the secondary research customers are loyal for different reasons and some are loyal because they feel they have invested time and effort in building a relationship with the staff of the retailer. In the question 4 of

questionnaire the respondents were asked how loyal they are to their grocery store. The response is indicated in table 1.

TABLE 1: DESCRIPTIVE DATA OF THE CUSTOMER

		Frequency	Valid Percent	Cumulative Percent
Valid	Not loyal	17	10.12	10.12.
	Indifferent	34	25.6.	35.18
	Very loyal	108	64.29	99.47
	Total	168	100.0	100.0
Missing	System	8		
Total		176		

Table 1 indicates that 64.29 percent of the respondents are loyal to their stores while only 10.12 percent reveal that they are not loyal to their stores. This response shows that most of the respondents are loyal to their stores. Next store location will be discussed.

**Store Location**

Most agree respondents (65 percent) agreed that they remain loyal to store conveniently located to them and will not change stores even when a store further from them offers a product cheaper than their regular store. This response indicates that these respondents will not cherry pick even if another store offers lower prices.

**Store Switching**

The respondents were asked whether they would switch from their usual store if lower prices are offered at another store thus price shop across store. Of the respondents, 34.1 percent strongly disagreed that they would switch to another store if that store offers lower prices. While 32 percent of the respondents agreed that they would switch stores if another store offers lower prices. 23.8 percent of the respondents indicated that they are indifferent to lower prices and store switching and will not switch stores.

This question was further analysed to establish whether race has an influence on the respondent's perceptions concerning price shop across stores. The respondents were grouped into African, white, coloured and Indian. More respondents of the African group, 47.4 percent, strongly disagreed that they would price shop across stores than compared to 42.2 percent respondents of the white group strongly disagreed that they would price shop across stores. 33.3 percent of the coloured group respondents strongly disagreed that they would price shop across stores. The response disclosed interesting information as 100 percent of the Indian group respondents strongly agreed that they would price shop across stores compared to 34.4 percent of the African group, 31.1 percent of the white group. None respondents of the coloured group agreed that they would price shop across stores. The 23.8 percent of the respondents who were indifferent to price shop across stores consists of 19.2 percent of the African group, 26.7 percent of the white group, 66.7 percent of the coloured group and none of Indian group.

The study established that respondents of the African group would have less of a tendency to price shop across stores to any of the other groups. This group shows that they are less prepared to cherry pick than any of the other groups.

H<sub>1</sub> = There is a significant correlation between store switching and store location

The response of the hypothesis is shown in table 2.

TABLE 2: THE PEARSON CORRELATION

		(STORE IN Q5) is conveniently located	total: price shop across stores
(STORE IN Q5) is conveniently located	Pearson Correlation	1	.073
	Sig. (2-tailed)	.	.348
	N	167	166
total: price shop across stores	Pearson Correlation	.073	1
	Sig. (2-tailed)	.348	.
	N	166	175

Table 2 shows that the Pearson correlation indicates a perfect correlation of 1 at a significant level of 0.05 2-tailed. When conducting the z-test, H01 was rejected thus accepting Ha1. Therefore, by accepting Ha1, one may conclude that there is a significant correlation between store switching and store location.

The study also seek to establish how far the respondents would be prepared to travel for products on special or offered at lower prices. The respondents who would price shop across store indicated that they would be prepared to travel 10 km for lower priced products.

The study aims to show that there is a significant correlation between cherry picking and the distance that consumers travel to do grocery shopping. The following hypotheses were formulated.

H02:  $\mu \neq 10$  km

Ha2:  $\mu = 10$  km

When conducting the z-test, H02 was rejected thus accepting Ha2. Therefore, by accepting Ha2, one may conclude that there significant correlation between cherry picking and the distance that consumers travel to do grocery shopping.

## Discussion

The study aimed to examine the relationship between cherry picking and the distance that consumers travel to do grocery shopping and whether geographical influences play a role in customer behaviour concerning store switching and location.

Twthane consumers indicated that there is a relationship between cherry picking and the distance that consumers are prepared to travel to do grocery shopping. Geographical influences also play a role in customer behaviour concerning store switching and location.

### Summary of Research Findings

Most respondents indicated an average income of between R 5 000 and R 15 000 (43%), or less than that (39%). The average amount that respondents spend on grocery shopping is R 1 560 stating that, on average, the cherry pickers are prepared to travel 10 km for products on special or offered at lower prices.

### Managerial Implications

Knowledge regarding store switching and store location behaviour will enable retailers to get more sales from its price sensitive shoppers and increasing their market share of the industry. Retailers need to know how cherry picking affects them. Cherry picking and store switching behaviour vary depending upon whether the store is the shopper's primary grocery outlet or a secondary grocery outlet. The reasoning for this analysis is that it is one thing to be a shopper's primary store, where every so often the shopper cherry picks your competition and so spends a bit less money at your store than on a single-store trip. It is another thing to be a secondary store, the one which is actually being cherry picked. Not only does the shopper fail to spend as much in your store, but when she does patronize it, she opportunistically buys more sale items. For each household, we designated as its primary store the

grocery chain at which the household spent the most money over the two-year period. All other stores were designated secondary outlets.

Much of the savings on cherry picking trips is due to the purchase of more promoted items, where this savings is subsidized by manufacturer discounting. Thus, the burden of cherry picking is borne by both retailer and manufacturer, with manufacturers selling more on deal as a result. Also of interest to manufacturers, cherry pickers are not brand loyal. Returning to the retailer's perspective, households that cherry pick more often also have more family members and so consume more goods, suggesting that cherry picking households may generate more retailer revenues. In fact, the cherry picking households spend R1 576/month while households that cherry pick less frequently spend only R1 498/month.

The research indicates that as long as a retailer advertises products, opportunism in the form of cherry picking is inevitable. While retailers must make broad offerings, they can also find ways to embrace this segment. Cherry pickers tend to cherry pick the second store they visit when shopping two stores in a single day. At the second store they are buying less and buy at a higher discount. Cherry pickers are more vigilant shoppers that pay lower prices, but are nevertheless a segment large enough to matter to retailers. Fox (2005) advises the retailer not to marginalize cherry pickers. This is price competition with other retailers; therefore, the retailers want to have the most attractive offers and weekly ads. Retailers should want to offer the things people want and care about, while being competitive in the process. The current study shows that not much research as been done in South Africa about cherry picking.

#### **Recommendations for Future Research**

The research has indicated that insufficient research has been done on the loyalty cards system and its influence on cherry picking and store switching. Future research should focus on furthering the findings of this article. Future research may also include a comparative study between South Africa and the United States of America to determine whether South Africans or Americans are more prone to cherry picking or not.

# **Vulnerability Analysis and Sustainability in Tourism: Lessons from Phuket**

*Alan Nankervis, [alan.nankervis@rmit.edu.au](mailto:alan.nankervis@rmit.edu.au)  
RMIT University, Australia*

## **Abstract**

Much current research in the global tourism industry focuses on its sustainability, within the dynamic and often turbulent environments in which it operates. Sustainability has been variously defined in ecological, socio-cultural, and more recently, economic and commercial, terms, but it has often been falsely assumed that the management of sustainable tourism can occur in the absence of comprehensive analyses of its multiple underlying vulnerabilities. This paper presents a conceptual model for the strategic analysis of vulnerability in tourism, and applies it to the case of a Phuket hotel following the 2004 tsunami.

## **Introduction**

The global tourism sector is estimated to be the largest industry in the world with a growth rate of 25 per cent in the past decade (UNEP & WTO, 2005). The movement of people, and hence foreign currency, as a result of tourism between countries is significant. In 2003, for example, international tourism receipts represented approximately 6 per cent of global exports or US\$525 billion (<http://www.world-tourism.org/facts/eng/economy.htm> 10.16.2005), with the value of international tourism growing to US\$622 billion in 2004 (WTO, 2005a). In 2004 more than 760 million international arrivals were recorded, with the World Tourism Organisation (WTO) predicting that this number could double by 2020 (WTO, 2004).

With such a present and likely future impact on global economics and the ongoing development of individual nations, it is perhaps not surprising that attention has been focused increasingly on the industry's sustainability, as the key to its long-term survival and growth. However, the extension of the notion of sustainability to the management of the industry has been slower to develop than in other industries, due to its inherently complex nature, its multiple stakeholders and constituencies, and its fragmented and often reactive strategies.

This paper explores the development of notions of industry sustainability in global tourism; the consequent linkages between sustainability and crisis management concepts and practices; and argues for the need to utilise vulnerability analysis as a crucial tool in the management of sustainability in tourism. A case study of the hotel sector in Phuket following the 2004 tsunami crisis is used to illustrate the relationships between sustainability, vulnerability analysis and crisis management in tourism.

## **Sustainability in Global Tourism**

The concept of environmental sustainability has been discussed for decades, especially in relation to such issues as beach erosion, air and water pollution, flora and fauna protection, promoted by both scientists and environmental activists, and primarily as a reaction to the damage wrought by industrialisation. Thus, concerns about beach erosion and the destruction of fauna in the wake of tourism and hotel developments (Mangun 2001); the over-development of coastal strips (OAS, 2000); rainforest destruction in Sumatra and Borneo (Kontogeorgopoulos, 1999); and land and water pollution in tourism destinations (Shaw, 2000) dominated the sustainability agenda in the latter part of the twentieth century.

Subsequently, the debate on sustainability in tourism shifted towards the potential (and actual) adverse effects of tourism on endangered ethnic groups and traditional cultures, including hill tribes in Northern Thailand,

and similar communities in Sri Lanka, Indonesia, the Philippines and Pakistan (Richter, 1999), including the impacts of sex tourism in Thailand, the Philippines, Vietnam and Sri Lanka. This broadening of sustainability concepts was also associated inevitably with the deleterious effects of tourism on destinations as a whole, encompassing ecologies, sub-cultures, and locational infrastructures, specifically roads, bridges, water and sewerage facilities. These issues are summarised by Shaw (2000) as competing demands on limited resources, environmental pressures, economic inequity, cultural dislocation, and flawed tourism project management.

A series of composite indices were developed subsequently in an attempt to measure the comparative sustainability of particular tourism destinations. They include the Environmental Sustainability Index, which compares countries and their most popular tourism destinations across a broad range of indicators, grouped into environmental systems, environmental stresses, human vulnerability, societal adaptability, and global stewardship; the Ecological Footprint, which aims to measure the amount of renewable and non-renewable land area required to support given resource demands, and can thus be used as a tourism planning tool; and the Dashboard of Sustainability, which links 100 economic, environmental and social indicators, and examines their interactions on a country-by-country basis (Stevens, 2005). Whilst these indices have been criticised for their accuracy and reliability, particularly in their ability to compare country performance in these broad areas, they represent a serious attempt to evaluate and quantify the multiple impacts of the tourism industry on selected tourist destinations.

Similarly, the articulation of more holistic definitions of sustainability and sustainable development by bodies such as the World Tourism Organisation (WTO), and the International Institute for Sustainable Development (IISD), illustrate the growing maturity of the understanding of sustainability in tourism. Thus the WTO promulgates sustainable tourism development as: *'(meeting) the needs of present tourists and host regions while protecting and enhancing opportunities for the future. It is envisaged as leading to management of all resources in such a way that economic, social and aesthetic needs can be fulfilled while maintaining cultural integrity, essential ecological processes, biological diversity and life support systems'* (Liu, 2003).

The IISD definition is more concise, if similar in tone – 'to be sustainable, development must improve economic efficiency, protect and restore ecological systems, and enhance the well-being of all peoples' (Laimer & Ohlbock, 2004).

Despite these encouraging developments in reframing the notion of sustainability in tourism, their reactive (rather than proactive) and destination-based foci are arguably less than adequate in their applications to the sustainability of the industry as a whole. For instance, whilst there have been some extensions of the concept in reaction to recent natural and human disasters such as 9/11, tsunamis, the Bali bombings and other terrorist acts, SARS and Avian 'flu epidemics, there have been only limited empirical studies and conceptual models which incorporate sustainability and crisis management. As examples, the 2002 'Contribution of the World Tourism Organization to the World Summit on Sustainable Development' ([www.tourismforum.scb.se/Papers](http://www.tourismforum.scb.se/Papers), accessed 16.10.2005), held in Johannesburg, makes no reference to either crisis management or recovery strategies, whilst the World Travel and Tourism Council (WTTC) 'Crisis Guidelines for the Tourism Industry' ([www.wttc.org/publications/pdf/Security](http://www.wttc.org/publications/pdf/Security), accessed 16.10.2005) addresses such issues but primarily as a reactive destination-based strategy, rather than as an opportunity to evaluate the vulnerability propensity of particular destinations, industry sectors and/or the industry as a whole, in order to prepare for likely future crises and their effective management.

Much current generic crisis management literature (Lajtha, 2002; Lagadec and Rosenthal, 2003), suggests that such reactive strategies are inadequate in response to modern types of crisis, and that proactive imperatives such as 'think systemic, be prepared for the unknown, get acquainted with unforeseen complexities, with very high speed shock waves across the boundaries. And prepare leaders for total surprise' are required (Lagadec and Rosenthal, 2003). The United Nations Economic and Social Commission for Asia and the Pacific (UNESCAP, 2002) recommended the development of more comprehensive models for sustainable tourism incorporating the whole range of crisis management strategies from preparation and prevention to recovery.

The incidence of global crises, both natural and man-made, which have had significant impacts on the tourism industry has doubled every ten years since 1960 (Pelling, Ozerdem & Barakat, 2002); and as an illustrative snapshot, the period 2004-2005 witnessed the Asian tsunami; hurricanes Katrina, Rita and Wilma in the Caribbean, the US and the Gulf of Mexico; tropical storms and mud slides in central America; a drought in the Amazon; Avian

'flu in Asia; further bombings in Bali; volcanic eruptions and earthquakes. Many of these, if not entirely predictable, may have been factored in as sustainability components of crisis management strategies.

## **Sustainability and Crisis Management in Tourism**

Crises are generally perceived as unanticipated or unavoidable incidents with the capacity to cause destruction or harm, and the World Tourism Organisation (WTO) defines a tourism crisis as '...any unexpected event that affects traveller confidence in a destination and interferes with the ability to continue operating normally' (WTO, 2005). Whilst useful, these definitions are somewhat limited, as some types of crises (for example, currency fluctuations, growing political unrest, potential terrorist threats, and some natural disasters) may be predicted weeks or even months before their impacts are felt. As examples, regular seasonal crises such as typhoons, and monsoons in the United States, Hong Kong and Southeast Asia, and volcanic eruptions in Indonesia were anticipated long before they devastated their regions and associated tourist destinations. Conversely, whilst general terrorist threats or incidents are expected and feared in all contemporary tourist destinations, specific events are usually impossible to predict precisely.

The WTO definition also links the loss of 'traveller confidence' with 'the ability to continue operating normally'. Whilst it might be expected that a significant crisis will necessarily involve reputational and/or actual harm to affected tourism destinations, there are examples of locations which have suffered only minor collateral damage; of others which have actually benefited from such events; and of other cases in which neighbouring destinations have profited from the misfortune of their competitors. Thus, while the 1997 'Asian financial crisis' devastated the economies of many Southeast Asian nations, including Thailand, Malaysia and Indonesia, the severe weakening of the Thai baht together with its proactive government's 'Amazing Thailand' tourism promotion resulted in increased tourism activity and income, in both the short and longer term.

Simultaneously, the political turmoil in Indonesia (1997-2004) frightened tourists away from Bali and Java, to the benefit of neighbouring tourism rivals such as Penang, Phuket, Australia and Singapore). Sadly, the combination of ongoing political unrest, economic decline, multiple and ongoing terrorist threats and events, and more recent natural disasters throughout Indonesia, have only served to strengthen the competitive tourism industry positions of (at least) Singapore and Australia. Both destinations, and other regional countries such as Malaysia, New Zealand, and Vietnam, experienced additional, arguably shorter term, advantages as a consequence of the '911' incident, due to tourist perceptions of greater personal security in these destinations together with attractive currency exchange rates.

An interesting tourism phenomenon experienced by Bali following the first bombing in 2001, and subsequently by Phuket and Sri Lanka after the 2004 tsunami, which might be described as 'compassionate tourism' or 'defiance tourism', was the flood of tourists from Australia and Europe who returned to those destinations immediately after the events either to demonstrate their ongoing support for the affected communities or to show their objection to terrorism. Evidence from both Bali and Phuket, however, seems to suggest that this may be a short term phenomenon (Israngkura, 2005). Nevertheless, the above examples suggest that tourism crises and their impacts are more complex than such simplistic definitions can explain.

Accordingly, it is suggested that the strategic management of tourism, whether globally, in particular industry sectors, and/or in specific destinations, would benefit from the development and application of more holistic models of sustainability, incorporating crisis management and vulnerability analysis tools, as part of an iterative rather than a linear approach. The concepts of vulnerability and vulnerability analysis are discussed in subsequent sections of this paper, but it is important to realise that the relationship between sustainability and the crisis management components of preparation, prevention and recovery, is not a linear cause-effect one, but rather that crises may precipitate industry or destination-based recovery strategies that in turn become preventative or preparatory stages towards the long-term sustainability of the tourism industry. Thus, the lessons learnt from one crisis are analysed in relation to their contributions to the management of sustainability in future such scenarios. All of these events necessarily take place within a multi-layered canvas, involving complex relationships between economic, socio-cultural, political, geographic, technological and overall industry characteristics.

## **Vulnerability and Vulnerability Analysis**

The significance of vulnerability analysis (VA) lies in its capacity to use evaluative and predictive techniques in order to facilitate the development of proactive and preventative management strategies for the sustainability of the tourism industry, at all its various levels. But what is 'vulnerability' and how might it be analysed?

As with the development of concepts of 'sustainability', research on vulnerability and VA is relatively new, and has been applied in a variety of specific and more generic contexts. Gabor and Griffith (1980), Timmerman (1981), Cutter (1993), and Gillard and Givone (1997), for example, examine the vulnerability of human or natural resources through exposure to hazardous materials. Others (UNDRO 1982, 1991; Blaikie et al., 1994; Green et al., 1994; Weichselgartner & Bertens, 2000) focus on the risks posed by natural phenomena (for example, floods, hurricanes, tsunamis), or the differential risks faced by particular communities or social groups (Susman et al., 1983; Downing, 1991; Dow, 1992; Cutter, 1993; Dow & Downing, 1995).

Over time, the definitions of vulnerability have broadened and deepened to become more holistic and generic. Thus, Bohle et al. (1994) describe vulnerability as:

*...an aggregate measure of human welfare that integrates environmental, social, economic and political exposure to a range of potential harmful perturbations. Vulnerability is a multi-layered and multi-dimensional social space defined by the determinate, political, economic and institutional capabilities of people in specific places at specific times*

Weichselgartner and Bertens (2000), more concisely, suggest that it concerns 'the condition of a given area with respect to hazard, exposure, preparedness, prevention, and response characteristics to cope with specific hazards. It is a measure of capability of this set of elements to withstand events of a certain physical character'. This definition perhaps best encapsulates the complicated relationships between sustainability, crisis management and vulnerability analysis in the global tourism industry. As the definitions imply, vulnerability is a more complex concept than that of risk', which is usually focused on a single hazard in a specific context. Vulnerability has been examined from three particular perspectives – vulnerability as a pre-existing condition; vulnerability as a 'tempered response'; and vulnerability as a 'hazard of place' (Weichselgartner, 2001). The first perspective explores the source(s) of exposure or risk, the second, coping responses, whilst the third is integrative, incorporating 'risk as well as (the) social response, but within a specific area or geographic domain'(ibid. p. 3). Weichselgartner goes on to develop a theoretical model of vulnerability analysis which identifies 'qualities' or 'factors' which may cause actual or potential damage (for example, specific hazard, exposure levels, preparedness, prevention, responses), and then 'maps' the comparative degree of damage over a given area (p.10) Bohle (2001) builds on these earlier definitions to include 'external' and 'internal' sides of vulnerability, in which the former refers to 'the structural dimensions of vulnerability and risk'(p.2) and the latter to 'coping and action to overcome or at least mitigate the negative effects' of the relevant threats, in other words the recovery component of crisis management.

## **An Analytical Model for Vulnerability Analysis in Tourism**

The following model further develops the concept of vulnerability analysis as a practical planning tool to assess the degrees of impact (both positive and negative) of multiple threats on parts of, or whole, tourism industries in particular continents or nations. It is intended to be used in concert with the Delphi technique, rather than as a precise quantitative measure, and its differences from some of the earlier matrices (see Appendix 1: The Washington State Hazard Identification and Vulnerability Assessment, Worksheets 1 and 2; New York University Medical Center Hazard Vulnerability Analysis; WS Hazard and Impact Matrix; and Michigan State University Vulnerability Analysis Chart) rest in its industry or sectoral foci, and its specific applications to tourism

### (\* See the descriptors of the levels of impact in Appendix 1)

The model is based upon the Modified Mercalli Scale (1931) which was developed to assess the relative impacts of earthquakes on different locations, unlike the more widely-known Richter Scale, which measures the intensity of the natural phenomenon. The motif of an earthquake seemed symbolically appropriate for the tourism industry, as it combines both long and short term impacts with differential impacts on areas closer to or further from its epicentre. As the model illustrates, it comprises the multiple vulnerabilities affecting the tourism industry, scaled according to the relative intensity of their impacts (see Appendix 2) on parts of, or the whole, tourism industry in particular continents, regions, nations or destinations; and is intended as a comprehensive strategic planning tool, in the preparation, prevention, or recovery stages of the cyclical crisis management sequence discussed earlier in this paper.

In the model, *industry* vulnerabilities include the relative fragmentation, segmentation, sectoral interface difficulties, dynamic alliances and ownership configurations of the tourism industry in particular regions or destinations, or within specific industry sectors. As examples, whilst natural or man-made disasters may have significant adverse effects on parts of the industry, the cohesiveness of government-private alliances (marketing strategies; well-maintained tourism infrastructures; mutually supportive relationships between hoteliers, restaurateurs, tour operators and travel agents; ‘compassionate’ tourists) may serve to mitigate the intensity of the short or long-term impact. This was certainly the case in Bali following the first terrorist bombing, and in Phuket in the immediate wake of the 2004 tsunami. With respect to the latter, Israngkura (2005) predicts that ‘the tsunami will have small macroeconomic impact, as the incidence did not affect the level of confidence or create negative (stakeholder) expectations as was the case of SARS ..in 2003’(p.18).

*Economic* vulnerabilities encompass global, regional and national economic performance, and may have positive or negative impacts. Severe currency fluctuations, such as occurred in the Asian economic crisis in 1997 or subsequently in Indonesia, actually had positive impacts on both countries’ tourism industries, although Indonesian tourism was soon adversely affected by political and social upheaval, and later terrorism, which together served to effectively destroy its short term tourism hopes.

*Political* factors which are likely to produce more (or less) vulnerability include government policies and marketing strategies for the tourism industry (for example, promotional campaigns such as the successful ‘Amazing Thailand’ programme; taxation incentives or disincentives, for both tourism operators and tourists; visa issues), funding programmes and infrastructure development, inter-regional competition or cooperation, security and safety issues (including terrorist threats and incidents, crime and disease). The intensity of these vulnerabilities may differ from destination to destination, and need to be factored in accordingly. As examples, whilst Australia and Singapore may be perceived as safe and largely free from threats to tourists, Thailand and Indonesia may represent more threats to inexperienced tourists. In the latter cases, analyses of comparative vulnerability may result in the development of more sophisticated infrastructure (for example, higher level security measures at airports, hotels and restaurants, upgraded marketing campaigns or more restrictive tourism routes).

*Social* vulnerabilities derive from the attitudes and current trends in tourist markets, in response to both their perceptions of the safety of regions or destinations as a consequence of natural disasters and terrorist threats, and their view of the novelty (or otherwise) of particular tourism locations. They also encompass the perceived levels of receptiveness and support for tourism, and potential damage to traditional cultures and societies. *Technology* may include the relative effectiveness and efficiency of the provision of services in airports, hotels and restaurants, the difficulties in the technological interfaces between different tourism sectors, or the threats presented by ‘virtual’ tourism or internet booking systems to particular destinations or tourism sectors (for example, travel agencies, linkages between airlines and hotel operators). These factors also have significant impacts, both positive and negative, on the desirability or novelty of various tourism *products and services*, predicated on the dynamic nature of competition and market demands.

The final vulnerability issue concerns *natural* factors, ranging from the impacts of soil erosion and the over-development of tourism in particular destinations, climate changes, and the dramatic effects of natural disasters such as hurricanes, tornadoes, and tsunamis, as earlier discussed.

Whilst the model facilitates the analysis of all these vulnerability issues discretely, it also encourages more holistic interpretations of the overall potential and actual positive and negative impacts of such factors on particular destinations, industry sectors and whole industries, at single and multiple time periods. As such, it represents a useful tool for industry managers to evaluate their own vulnerability parameters, and those of their competitors, as part of their ongoing tourism preparation, prevention, recovery and response (PPRR) planning strategies. The following section depicts an application of the model to a Phuket hotel following the 2004 tsunami, as an illustration of its utility in the iterative recovery and preparedness stages of crisis management in tourism.

## **Vulnerability Analysis and Sustainability in Phuket**

If the Vulnerability Analysis Model (VAM) is applied to the levels of intensity of the impact of the 2004 tsunami on the hotel sector in Phuket, Thailand, with a view to considering the most effective management strategies to adopt in order to both recover in the short term and to ensure the sustainability of individual properties in the longer term, some interesting lessons emerge. The research study was intended to canvas the opinions of a representative sample of hotel managers in Phuket with respect to the effects of the tsunami on future business, and the nature of their strategic management responses, but unfortunately due to circumstances only one hotel manager was interviewed. Accordingly, the following case findings cannot be claimed to represent the experiences of other hotels, but despite this severe limitation, the case (The Seaview Hotel) illustrates the utility of the application of the model.

### **The Seaview Hotel**

The hotel studied is one of four properties in a Thai-owned chain, classified as four star, with more than 400 rooms and employing around 350 staff, predominantly Thais, only 10 percent of whom were originally from Phuket. Prior to the tsunami, occupancy levels ranged from 75 percent in the high season (November-April), to 65 percent in the low season (May-October), with tourist markets primarily from Europe in the high season; from Australia, New Zealand, Korea and China in the low season; and from Japan in both seasons. It should be noted that the tsunami struck Phuket at the beginning of the lucrative high tourist season.

Following the impact of the tsunami, occupancy levels in the short term dropped dramatically, to 15-20 percent. The hotel manager reported that there was a distinct difference in the immediate reaction of its disparate tourist markets. Australians and South Americans tended to be more sympathetic to the plight of Phuket, as compassionate or defiant tourists, whilst its Japanese and Chinese tourism markets appeared to be deterred for superstitious reasons. European tourists appeared more concerned with their perceptions of physical security.

The physical impact of the tsunami on this hotel was apparently minor, as it is located on a hill overlooking Patong Beach (the most popular tourist beach in Phuket), only minimal damage was experienced to the hotel's swimming pools and gardens, and no staff or guests were seriously injured.

An analysis of the Seaview Hotel's vulnerability in the wake of the tsunami would suggest that it rates as a 5 ('medium-term effect on a single tourism agency in a single country or region') on the VAM scale with respect to the level of intensity of the tsunami impact. However, as one of the many accommodation establishments in a devastated tourism region, it undoubtedly rated more highly as a consequence of tourists' perceptions of the entire region (erroneously) and of tourism in Thailand more generally.

### **The Seaview Hotel's Recovery Strategy**

The management immediately took action to remedy the physical damage to the hotel's facilities, in advance of any specific offers of support from Thai government agencies, but with the expectation that such help would be forthcoming, as had been the case in earlier threats to tourism such as the 1997 economic crisis. In a show of good faith, and in contrast to the actions of other Phuket hotel managers, the Seaview Hotel management maintained all staff members on normal salaries, apart from those who wished to take leave or resign (5 percent), despite the fact that for the first three months following the tsunami there were no new guests, and at the time of interview (December 2005) it had not returned to normal occupancy levels.

Whilst the hotel subsequently received no direct government financial assistance, as most of this was directed to infrastructure rebuilding (roads, transport systems, tourism marketing), indirect assistance was provided in relation to delayed payments to government bodies, and moratoria on loan interest and insurance premiums. Taking advantage of the low occupancy rates immediately following the tsunami, the hotel also began retraining its staff in service quality and language issues, added new specific modules on guest safety procedures, linked itself with the emergency monitoring systems of companion hotels located closer to the centre of potential future such events, and is using constant emergency monitoring operators.

The manager reflected that 'the tsunami was a new thing for us. To be honest, I think it is good that it happened. It was a great career experience. We appreciate a (sic) real value of gained knowledge which can be used to educate others in emergency management. This is a good side' (Interview with the General Manager, December 2005). He also identified several crucial issues in the recovery stage of crisis management, including a focus on people rather than property; the maintenance of staff and guest confidence in the ongoing operations of the hotel; the need for government attention to all tourism properties in the region ('It is not good for all of us if on the same street there are some well recovering (sic) hotels looking as new ones and others which are totally smashed'), and its emphasis on the redevelopment of active marketing campaigns, including high-level reassurances of the region's safety for tourists.

## **Discussion & Conclusion**

The Seaview Hotel case suggests that, although a particular hotel may be more (or less) directly impacted by a natural disaster such as the 2004 tsunami, it will be adversely affected by the perceptions of the destination's safety by potential tourist markets. It implies therefore that in such a case, recovery strategies will inevitably involve the combined efforts of private sector operators, the national government and local authorities, in order to address effectively the recovery component of crisis management strategies and thus to restore guest market confidence in the tourism destination. Such multi-faceted and integrated approaches necessarily include attention to the immediate restoration of property damage; the support and maintenance of hotel employees; the rebuilding of essential tourism infrastructure, and temporary relief to private sector hoteliers from taxation and loan repayments burdens; and above all, a comprehensive and proactive marketing campaign focused on traditional and newer guest markets. Fortunately, the Thai government was forthcoming in most of these responsibilities, with the result that Phuket is beginning to regain its status as one of the preferred tourism destinations in South East Asia within two years of the tsunami impact. In contrast, Bali has failed to recover as effectively, due both to the different nature and frequency of its threats, and to the failure of the Indonesian government to act as quickly and as cooperatively as its Thai counterparts.

In applying the VAM to the Phuket experience, recovery has been assisted by the generally positive collaboration of tourism industry stakeholders (private and public sector agencies, compassionate and defiant tourism markets); favourable currency exchange rates for its primarily Western tourist markets; its relatively politically stable environment; attractive Thai social characteristics, which reflect tolerance, friendliness, and careful attention to guest needs; and the consistency and relative quality of the services provided to tourists at all levels of the tourism industry.

In their planning for the longer-term sustainability of the tourism industry in Phuket, both the Thai government and individual hotel managers could benefit from utilisation of the VAM as a predictive tool to identify the destination's and their broader inherent vulnerability (weaknesses and strengths), and thence to factor into their strategies recovery plans to address each of the identified issues. Perhaps the most crucial aspects are that tsunamis occur only in particular seasons, and other potential threats such as regional competition and product life cycles are both predictable and amenable to the careful monitoring of tourist market analyses.

## Appendix 1: VAM Scale for the Tourism Industry

Level of Impact	Impact Descriptors
I	Minor, short-term effect on a single tourism agency in a single country or region
II	Minor, short-term effect on an entire tourism sector, in a single country or region
III	Minor, short-term effect on more than one tourism sector, in a single country or region
IV	Minor, short-term effect on more than one tourism sector, in more than one country or region
V	Medium-term effect on a single tourism agency in a single country or region
VI	Medium-term effect on an entire tourism sector in a single country or region
VII	Medium-term effect on more than one tourism sector, in a single country or region
VIII	Medium-term effect on more than one tourism sector, in more than one country or region
IX	Long-term effect on a single tourism agency in a single country or region
X	Long-term effect on an entire tourism sector, in a single country or region
XI	Long-term effect on more than one tourism sector, in a single country or region
XII	Long-term effect on more than one tourism sector, in more than one country or region

(Adapted from the Modified Mercalli Scale, 1931)

NB. The levels of impact intensity, as in the original Mercalli Scale, are not mathematically based, but a ranking based on observed or anticipated effects, preferably applied by the Delphi Method. There is necessarily a degree of subjectivity, and the impact descriptors may be of positive or negative value. There are, however, quantitative criteria – reduced hotel occupancy levels, decline in profit margins etc. – which should be factored into expert judgements of the impact intensity)

# Community Based Tourism in Global Strategies: A Case of Huai Hee Village in Village

*Bussaba Sitikarn, [bsitikarn@hotmail.com](mailto:bsitikarn@hotmail.com)  
Mae Fah Luang University, Thailand*

## Abstract

Since tourism has become Thailand's economic development strategies. In northern Thailand in particular, a growing number of indigenous communities have been turning to tourism as an alternative to expanding their commercial agriculture. However, while tourism has generated the biggest revenue for the country, most destinations have begun to deteriorate both culturally and environmentally and it caused conflict of interests among stakeholders. This begs the question of how to operate tourism that can really be a sustainable solution to the development of initiatives in the region. Community based tourism (CBT) has therefore become one of alternatives in many communities' development strategies as a means for community development and environmental conservation. The case remains to be made whether or not CBT, as practiced in northern Thailand, is really a sustainable option in practice? To begin to provide an answer, this paper briefly reviews the concept of CBT and then presents the findings of a case-study on perceived impacts of tourism in the CBT destination of Huai Hee village, Mae Hong Son province, which questions the authenticity of this concept in practice and raises concerns of how to operate tourism for a solution to some of the problems of poverty, conflict and socio-cultural and natural resource degradation in the destinations. The paper concluded with key issues for an achievement of sustainable tourism. **Key Words:** Sustainable Tourism, Community-based Tourism, Tourism in Northern Thailand, Natural Resource Management, Socio-cultural Management.

## Introduction to the Research

According to the government's policy on economic development at regional level, tourism is seen as an essential instrument for job generation and income contribution. Development of tourism has taken place in the northern region where has become a popular tourist destination in Thailand because the region has various activities and experiences to offer to visitors such as unique natural beauty, distinctive history, rich cultural heritage, hill tribes, trekking, elephant riding and river rafting (TAT, 1998). In addition, many activities have been created and festivals have been revised in order to support tourism in the region. Thus, NTd has become a destination significantly influenced by tourism development and numbers of visitors visiting the region have recently increased.

Following the general success and growth of tourism in Thailand, many communities in the region have pursued it as their preferred development alternative. Some see tourism as a tool for local income generation and the local community empowerment; others perceive tourism as the solution to conflict of interests towards land use problems as well as to prevent the situation of being evicted from their land (PRLC, 2000). Thus, a diversity of tourist experiences in National Parks and historical sites has been provided. Since 1997 the Royal Forestry Department (RFD) has opened up National Parks to private tourism businesses and worked on a proposal to grant leases to private operators for development of tourist infrastructure. Under promotion of tourism, the RFD has recently implemented large tourism related infrastructure projects, with the construction of roads, parking lots, visitor centres, bungalows, camp sites and nature trails neatly coinciding with the 'RFD's Visit National Park Year 2000'. The project aimed to attract more than 20 million domestic and international visitors to the parks during that year. Most of the annual budget was allocated for constructing building, paving roads, buying vehicles, hiring staff and paying administration costs. This suggested that although tourism has generated the biggest revenue for the country, the country's natural resources would be further sacrificed for short-term economic gain.

As tourism is an agent of changes, tourist activities led northern Thailand to become a mass tourist attraction with impacts on the physical, social, economic and built environment. As a consequence, tourism in the region has faced many problems because of deterioration of most tourism sites both in cultural and environmental aspects. These problems are caused by a lack of: appropriate operation and maintenance of destination; expert interests; involvement of local community in all stages of tourism development process, collaboration among

stakeholders; sufficient funding support from the government (TAT, 1998). As a consequence, CBT has been recognized as a solution to the problems. The case remains to be made whether or not CBT is really a sustainable option in practice. Therefore, this study aimed to investigate perceived impacts of tourism on host destinations in northern Thailand and raises concerns of how to operate tourism for the sustainability and a solution to the problems of poverty, conflicts and socio-cultural and natural resource degradation in the destinations.

## **Defining Community Based Tourism (CBT)**

CBT typically subscribes to a number of broadly defined goals such as economic development, community development and empowerment, resources conservation and social sustainability. It is generally considered to involve host community members in the tourism enterprise. This means that tourism activities are developed and operated, for the most part, by local community members, and certainly with their consent and support. Three types of CBT enterprises have been identified:

- 1) The purest model is the enterprises that are owned and managed by the community, where the community members are employed by using a rotation system. Thus profits are allocated to community members;
- 2) The enterprise involves family or group initiatives within communities and;
- 3) The enterprises are a joint venture between a community or family and NGOs/ an outside business partner.

CBT is recognized as a contributor to the growth of employment opportunities, a reasonable share of the revenues particularly for women, young people and aboriginals. This may include revenue streams which go to co-ops, joint ventures, community associations, businesses that widely employ local people, or to a range of entrepreneurs starting or operating small- and medium-sized enterprises. Another important feature of CBT is its respect for local culture, heritage and traditions as well as concerns for the natural heritage, particularly where the environment is one of the attractions. According to UNEP, CBT does not simply seek to maximize profits for investors. It is rather more concerned with the impacts of tourism on the community and the environment. CBT emerges from a community development strategy and is used as a tool to strengthen community organization through community-wide participation. The Project for Recovery of Life and Culture (PRLC) (2000) define CBT as tourism that contributes to: conservation of natural resource and the local culture, local economic development, local participation and providing socially and environmentally responsible products to visitors. It is essential that the community has substantial control and involvement in the development of initiative. At each stage, awareness and education should be an important element. This will not only keep people interested and supportive, but it will also prepare them to take advantage of opportunities so that the main benefits remain in the community.

Levels of participation by local people are considered critical to the success of CBT. Much of the attention in CBT focuses on concepts and principles actions, incentives natural & cultural resources benefits and communities that live in and around the destination since they have frequently been neglected in the decision-making process. Often the result has been a lack of ownership that has in turn affected the sustainability of conservation and development efforts. If local people have participated in the design of activities, invested resources in implementation, and are able to obtain reasonable returns, then the likelihood of long-term conservation and economic benefits increases. If the distribution of benefits is such that most participants are employees for whom tourism provides an unreliable and poor source of income, the linkage between tourism and the need to conserve resources is potentially weaker, and the long-term benefits more questionable. Not surprisingly, in CBT considerable resources are usually invested in engaging people in bottom-up, small-scale tourism developments that can contribute to CBT objectives. The key elements in the processes of participation are the involvement of people in the decision-making processes, in implementing programmes, their sharing in the benefits of development programmes and their involvement in efforts to evaluate the programmes (Cohen and Upnoff, 1977; Timothy, 1999). Thus, recognition of the value of local knowledge and environmental management practice is crucial for the achievement of local participation (Berger, 1996; Boyd and Ward, 1993). This is to ensure that the benefits include income generation, the enhancement of the local residents' quality of life and economic returns that can be used in maintaining and managing the tourism resources. Furthermore, the local community would participate in supervising

the tourism development of the area and ensuring that it is appropriate. However, Sproule and Suhandi (1998, pp.215-235) argue that though there is increasing recognition of the need to involve communities in participation in general, there is much less agreement about exactly who should participate and to what extent.

Pretty (1995) classified the types of involvement into seven levels of participation which range from 1)manipulative participation, 2)passive participation, 3)participation by consultation, 4)participation for material incentives, 5)functional participation, 6)interactive participation, and 7)self- mobilization. One of the most issues in concerns is about the capability of the local people in tourism planning and its operation. In tourism aspect, how to involve the locals in all stage of development is the key issue.

## **Research Methodology**

To achieve the objectives of the study, Huai Hee destination in Mae Hong Son province was chosen as a case study as tourism at Huai Hee is recognised by many other Community Based Tourism (CBT) proponents in Thailand as a successful model for other communities to follow. In addition, the project was nominated as a finalist for the ‘TO DO! 2000 Contest for Socially Responsible Tourism’, organised by the German organisation Studienkreis Fur Tourismus und Entwicklung. It was also proposed as a ‘model community in forest conservation through CBT activities in the Green Earth Contest’, organised by the Petroleum Authority of Thailand. Tourism has been implemented since 1996 and managed by collaboration between NGO workers and the host community.

The methodologies adopted for data collection were: semi-structured interviews; focus groups and participatory rural appraisal (PRA) with local residents and other stakeholders in both public and private sectors and; participant observation in addition to documentary analysis of records at the case-study location and also other documents which chart the process of tourism development in the area. The stratified random sampling and convenience sampling approach were applied in the research. The population sample frame consisted of all individuals of both sexes, over eighteen years old and had involved in the tourism enterprise in the destination. Descriptive statistics was used for content analysis.

## **A Case Study of Huai Hee Destination**

Mae Hong Son province is located approximately 900 km from Bangkok and can be reached either by Highway No. 108 via Mae Sa Rieng, or by Highway No. 1095 via Pai (see Figure 1). The potential for tourism is based on the natural resource areas and the diversity of population ‘hill tribe cultures’ such as Lawa and Karen. In recent years, Mae Hong Son has become one of the main visitor destinations in northern Thailand, and is based primarily on the living culture of the Long Neck Karen because they live only in the Mae Hong Son area (TAT, 2001).<sup>1</sup> Further, as Mae Hong Son is a borderland to Burma, there has been a great influence on the local tradition and architecture. The Burmese-style temple and Poi Sang Long event are also the main attractions in the area. In addition to the unique characteristic of natural resources of mountain peaks, caves, hot springs and wild sunflower field, alternative activities such as elephant riding and bamboo rafting have been created to support tourism in Mae Hong Son. The Huai Hee village is situated in the Tambon Huai Pu Ling, Muang district, which is about 26 km from the town centre of Mae Hong Son. It takes up to 2 hours to drive the 26 km. on a dirt, rough and winding mountain road to the village. The village is quite isolated from the outside world due to difficult access especially in rainy season.

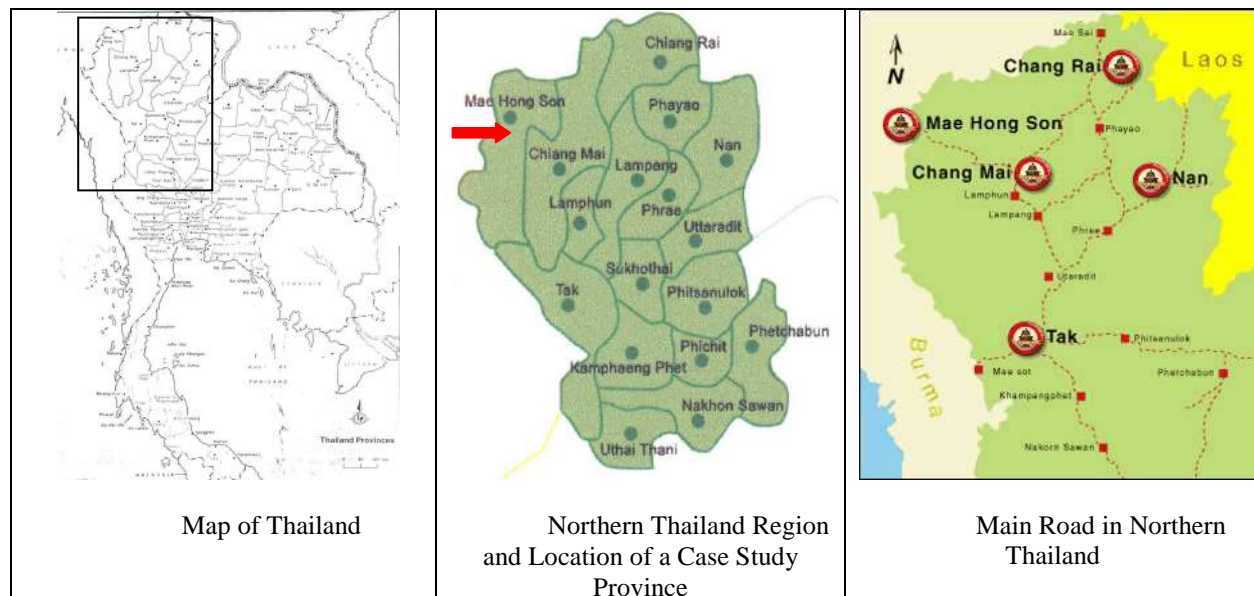

FIG. 1 LOCATION OF HUAI HEE DESTINATION

The people in Huai Hee belong to the Karen ethnic group. They are originally from Burma or from further north, possibly from Tibet. Originally the villagers were Animist but have become Christian during the last 35 years. At present there are 197 inhabitants in the village, represented as 31 families living in 28 households. Huai Hee's economy has traditionally been based on agriculture. Villagers have for the most part been self-sufficient. Like many other highland people in Thailand, the villagers of Huai Hee are blamed for deforestation and the deterioration of highland watersheds. They were threatened with deportation from their traditional living area if they did not change their way of living. As a result, the Project for Recovery of Life and Culture (PRLC) is an NGO organised under the North-Net foundation came in to the village as a mediator to find a sustainable solution for land use rights. Attention to development work is strengthening local communities and stressing a holistic development approach. Through a land classification system, the land area was classified for different purposes such as rice growing, a village dwelling area and land areas to be protected and conserved.

In 1996, community based tourism (CBT) was introduced by PRLC as a tool for conservation of natural resources and local culture of the Karen. It was proposed as a way for negotiation with the authorities and villagers to be involved in tourism management in their village. With an increased awareness of the importance of environmental sustainability, they wanted to involve and control the tourism enterprise in their community. PRLC supported the community by providing the villagers with technical assistance and training while the management of the projects remained in the hands of villagers. Through the implementation of tourism, villagers have had the opportunity to explain and demonstrate to visitors how they protect their forest and at the same time continue to live their lives in accordance with their traditions. Thus, the villagers are slowly being understood by the authorities who earlier accused them of destroying the forest and ruining the watersheds. In recent years, the development of tourism has gradually been recognized. This has been evident in the villagers' interviews:

*'...we are blamed for deforestation and the deterioration of highland watersheds. We are threatened to be evacuated from the village where we have been living for generations. It is our home-land, we don't want to leave. To fight against that...we use CBT to communicate with outsiders that through generations, we as the highland people have supported land use management through our traditional subsistence techniques. If our way of life really causes*

*damages to the natural resources, there would not be any forest left in this area. So far ...our voice could be heard through CBT'*

Recently, villagers are becoming more involved in tourism as accommodation providers in the form of home-stay, tour guides, cooks and selling handicrafts (Fig. 2). In comparison with the income obtained from traditional subsistence that provided people daily basic needs, tourism provides opportunity to earn hard currency.

FIG. 2 ATTRACTIONS AT HUAI HEE DESTINATION

## Tourism Operation and Local People Involvement

In addition to being under the supervision of PRLC, the villagers organize themselves into a ‘tourism club’ to manage tourism through a co-operation among shareholders in the community. The villagers own and manage the enterprise. A rotation system is employed to ensure the members receive fair and equal opportunity to engage and benefit from tourism. In the host family, an adult member of a host family is also appointed as a local guide. Profits are mostly allocated to the villagers (80 per cent of total income each time) and the rest is allocated to the tourism club and community development projects fund. So far, the tourism committee recognized that the input and involvement of the whole community is essential for success. This has been evident through the process of tourism development that has been taken place since 1996. Visitor management is in the hands both of business entrepreneurs in Mae Hong Son as transport providers and of tour operators but equally important, in the hands of the local community as well. The entrepreneurs control the access and transport to the site but the locals manage the visitors on the site.

The general views of villagers and local NGOs indicate that the CBT at Huai Hee faces problems of being dependent on NGOs in terms of marketing. This is because the villagers do not have knowledge or skills in marketing tourism in their area. Therefore, the PRLC staff set up a travel agency to tackle visitors and as a result, most of the benefits go to the travel agency. This has been supported by the data in Fig. 3. However, the villagers in general seem satisfied with income obtained; at least there is no evidence to the contrary.

Tour	No of persons	Travel Agency (price per head)	Locals (Total)	Community (Total)
Karen Culture and Ecology Tour (2days, 1 night)	2	3,280	800	200
	3 or more	2,400	800	200

FIG. 3 TOUR PRICE AND BENEFITS SHARING BETWEEN THE TRAVEL AGENCY AND THE VILLAGERS  
(Figure are presented in Thai Baht)(\$=40 Baht).

Source: The tour leaflet of travel agency in Mae Hong Son and interviews with the villagers of Huai Hee Village

Women in the village tend to have much lower literacy rates, educational opportunities, access to resources, control of assets and decision-making powers than men. For many women, the tasks of caring for visitors add considerably to their daily household duties, especially when husbands are away working as trekking porters and guides. They played a vital role in the transition from trying to meet tourism demand to proactively developing sustainable management and visitor services. This has been evident in the villagers’ interviews:

*‘When tourists are in the village, it is our job to cook and prepare food for them. We use the local materials as much as possible... For example, when we cook, we use vegetable that we have in the garden. When tourists go for trekking, we use leaves for food packing. We want them to appreciate the way we live and they like that...It really gains our pride for what we are. The Karen culture is unique and that is what tourists are interested in...’*

They also have coordinated a cultural revival. Craft cooperatives, traditional dancing and singing are now generating income for the women of the community and promoting pride in their local culture. Although local participation is seen as essential to the strategy of fair benefits sharing in the community, it can be argued that the villagers can also receive unequal opportunity in participating in the enterprise. There is much less agreement about exactly who should participate and to what extent. This is evident in practice in that the participation in home-stay projects at Huai Hee is limited by the condition and size of the house, Thai or English language ability and age. This means that those who are not in the conditions required for the enterprise would be excluded from the project. Moreover, the personal interviews indicate that alongside the positive consequences, the negative side of community involvement could be to add greatly to the cost of tourism planning and development, and to lengthen the period needed to develop plans for the projects.

Alongside tourism management, many attempts were made to determine possibilities for supporting community resource management. The villagers perceive the success of tourism comes from the cooperation among stakeholders in the community and support from outsiders. They think that long-term success of tourism is that the number of visitors is increased so that profit can be made by the local business entrepreneurs. They expect that tourism would not only continue to provide stable income to the local economy but also contribute to the natural resources conservation. Overall expectation from tourism development is that they don't have to evacuate to elsewhere and are able to have control over their land and its surrounding environment and their community's future.

## **Tourism Impacts**

In terms of tourism impacts, the general views of villagers at Huai Hee indicate that the impacts of tourism development on Huai Hee destination were perceived as mostly positive in aspects of physical environment, society, culture, economy and employment. This is probably because the negative consequences are not yet obvious or the impacts are not recognised because the respondents benefit from the enterprise.

So far, development of tourism has been perceived as a contribution to the conservation and preservation of natural resources in the area. Some percentage of the profits are allocated to community development and conservation initiatives, such as the planting of tree seedlings, renovation of the natural trails, waste management and providing loans for women to invest in handicrafts products. The villagers do not perceive there to be negative impact on the natural environment in the area. This is probably because the number of visitors is still relatively small and the locals fully manage the enterprise. Therefore every thing is under their control. This has been evident in the villagers' interviews:

*'...no there are no negative impacts to the natural resources in the area. We have really been taking care of it as it is our lives. For generations, the villagers' lives have been depending on the natural surrounding. But what we are afraid of that may happen in the future is the waste problems. If there are many visitors, there will be more waste. We will discuss the matter with PRLC...'*

In terms of socio-culture, on one hand, tourism development caused positive impacts in the community in terms of standard of living, family life, improvement of housing condition, good relationships among the villagers and improvement in foreign language ability. Besides English, the villagers now tend to be more interested in learning Thai as the majority of visitors are Thai. This has been evident in the villagers' interviews:

*'...We are told that to be home-stay providers, we have to improve our house condition and surroundings and toilet...make sure that they are clean. We also plant some flowers that make the house really nice. We like it too and we hope the visitors also like it... It would be good for us if there are many visitors come to our village. So we can sell handicrafts and earn money from home-stay and guiding. Working in the farm does not give us cash. We want cash, so at least we can buy a pack of instant noodle and a can of sardine, and some biscuit to kids. It is really nice to be able to afford to eat something different. We also want TV. Many of the youth have to migrate to Mae Hong Son for employment...they bought a TV set for a family...'*

On the other hand, tourism has influenced the loss of interest among youth in land stewardship while some older members prefer to maintain their traditional lifestyles of farming and increasing commercialization of local cultural products. Further, it has influenced the drinking habits of the villagers so that they become addicted to coffee drinking. Coffee was not a traditional drink in the community but it was introduced according to the visitors' demand. Moreover, the relationships between locals have improved through tourism management and meetings. For example, the relationship between the older people and young people is well developed as young people work together with their elders to teach visitors about medical plants and other traditional uses of the natural resources. Thus, conflict of interests between them in terms of having different attitudes to life, is mitigated. At the same time, co-operation between the rest of villagers also increases, which has been evident in the villagers' interview:

*'...Although our offspring are keener on working with tourism than maintaining our traditional farming, we like tourism. It brings us together... means that we have meeting among the villagers more often to discuss about the plans, management of tourism resources and its conservation and preservation. Thus we do more activities together such as at the clean-up day and maintenance of the resources, share local knowledge to visitors ...Besides, we have more cash...'*

In economic aspect, tourism development has contributed to positive impacts on the local economy in terms of income generation and employment opportunities. The direct income to the villagers is generated through the provision of accommodation, food and refreshment, souvenirs and through employment as local guides. In comparison to the income from farming, tourism brings 'quick cash' to the community. Further, women in the village are willing to increase their workloads tremendously through the sale of handicrafts 'weaving cotton wares' in order to gain some new measure of financial independence. In terms of benefit sharing, although profits are mostly allocated to travel agency and tourism entrepreneur at down town of Mae Hong Son, the locals are satisfied with income obtained that depending on the degree of involvement in the business 'more they work, more they earn' basis.

## **Discussions and Suggestions**

Based on the outcomes of the study, CBT is perceived as a tool for community development, local income generation and conservation of socio-culture and natural resources. These were conducted through a process of community participation. Additionally, tourism was used as a way for negotiation with the authorities in aspects of natural resources management so that it would be possible for the villagers to have more control over their land and their community development now and in the future. Thus, key successes of CBT seem to be the involvement of the whole community in the tourism enterprise, the cooperation among stakeholders in the community and support from the outsiders. Tourism in Huai Hee destination appears to have had both positive and negative consequences. It has contributed to conservation and preservation of the natural resources, society and culture and has positive impacts on the local economy. On the other hand it has influenced the loss of interest among youth in land stewardship and increasing commercialization of local cultural products and alien consumption. However, it is not seen as a problem now but in the future this could possibly lead to acculturation of the local culture. The identity of the Karen would then be modified. Therefore, whether or not CBT in Huai Hee would contribute to sustainability of the destination in the long term is a subject of some debate.

One of the most issues in concerns is about the capability of the local people in tourism planning and its operation. Based on the study, how to involve the locals in all stage of development is the key issue. However, it is suggested that the successful local participation process could be identified as demonstrated in the Fig. 4.

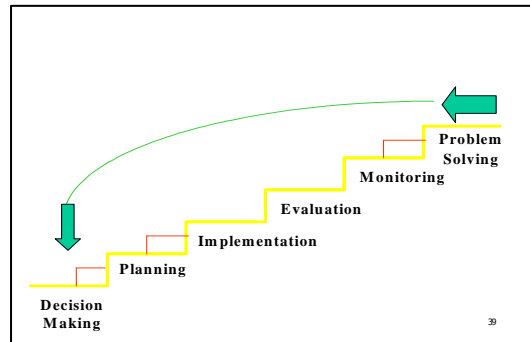

FIG. 4 'PEOPLE PARTICIPATION MODEL' DEVELOPPED FROM CASE STUDY SURVEYS IN NORTHERN THAILAND (2000-2004) and SITIKARN (2004)

In terms of fully participation of the local community in the development process, it could be differently interpreted. Based on this study, it is important that the locals must involve with the process of decision making as they are the one who receive direct affects from the initiative. Therefore they should have an opportunity to express their concerns. The project plans were implemented based on the decision made. Following this, the project plan requires evaluation and monitoring to minimize potential problems. To get through the whole process of development is not easy due to the lack of required knowledge and skills among the locals. Therefore supports from the experts or superior authority are essential for the whole process of initiative development. The supports could be done through the program of training, work shop and study tour.

Further, the economic benefits among the locals is an essential issue that need to be in consideration as it is important to recognize that when communities are earning from their natural resources in order to gain income through the initiative to improve the quality of life of its members. It is assumed that when residents receive benefits, they are more likely to support conservation as well as promotion of cooperation among the members. These could be a path to sustainability.

This study suggested that CBT as practice in Huai Hee village can be seen as a potential force for peace, cross-cultural understanding, wealth, community development and conservation of socio-culture and natural resources of the host destination. This is because an operation of the enterprise engaged with four essential components of sustainability including: 1) Conservation. This involves a contribution to the conservation or preservation of natural environment, social and cultural characteristics of the local community; 2) Local employment and income generation and distribution. This has implications for a range of new business and employment opportunities. Communities are earning from their natural resources in order to gain income through tourism to improve the quality of life of its members. It is assumed that when residents receive benefits, they are more likely to support tourism and conservation, even to the point of protecting the site against poaching or other encroachment; 3) Educational experiences and appreciation about natural environment and local culture. Tourism provides opportunities for visitors to learn through experiences obtained from the activities undertaken to acquire better understanding of the destination, its natural setting, and of its people, including the multilingual interpreters employed at the sites. The local residents have an opportunity to share and exchange knowledge with visitors. Through these educative experiences, there is increasing environmental and cultural awareness among stakeholders and; 4) Local participation and empowerment of host community. This includes involvement of the local residents in participation at all stages of the development process including decision-making, planning, implementation, auditing, evaluation and problem resolution as well as applies to both direct and indirect participants and beneficiaries, and collaboration between stakeholders such as the government sector, private sector and local residents.

Further, the study also demonstrated that in practice, a micro solution provides to a macro solution. Therefore working at community level is essential as success collaboration at community level will also provide collaboration at regional level. This paper does not pretend to offer any formal solutions to the problems occurred from tourism development but high light some issues that need to be considered for an achievement of sustainable tourism such as:

- Promote increased CBT as a means to community development and resources management opportunities;
- Human resources development in tourism and hospitality management skills;
- A better balance (needs to be achieved) between economic development and conservation/protection of environment and socio-culture of the host community;
- Enhance the environmental and socio-cultural awareness amongst stakeholders;
- Continuously build communication channels to enhance the information exchange and cooperation between stakeholders;
- Strengthen local participation in all stages of development (decision making, planning, implementation, evaluation, monitoring and problem solving);
- Tourism development plan and management need to be reformed according to local characteristics and;
- Establishment of CBT networks for marketing contribution channels and other collaboration.

## **Abstract**

Convention tourism has received dedicated interest from both public and private policy makers for its economic opportunities across countries. Unfortunately, however, due to somewhat simultaneous undertakings of such investments, the expected economic gain has been largely conditioned by the marketing and management effectiveness of destinations. More specifically, in the intensified market competition, a fate of the past frenzied public and private investments is left to the hand of convention marketing organisations (CMOs) that markets the destination outside. Building on the inter-firm network literature, this study defines the CMO as a network broker of the destination convention services network and investigates its role and influence in the development of convention organiser's attitude and behavioural intention towards the convention destination. It develops such a model and tests it in a structural equation modelling framework with data collected from convention organisers for the Shizuoka Convention Bureau in Japan.

## **Introduction**

Tourism has gained a growing recognition as the driver of local economic and socio-cultural developments. Convention tourism has developed to claim a distinct research attention within the broad tourism industry. Since 1980s, the development of convention centres has been aggressively promoted as a means of local development and re-development given its associated economic benefits. Nonetheless, the infrastructure development alone does not guarantee any success. The destination has to be promoted as a superior convention host and its capacity has to be managed appropriately through effective demand and supply management. In the tourism literature, it has been recognised that tourism consumers enter a less discrete, more extended series of services episodes consisting of nested, but contingency-bound service encounters and experiences along their journey. This is also the case of convention tourism. However, given the distinctive characteristic of convention tourists who are more restricted in terms of the exposure to contingency-bound service encounters commonly associated with holiday makers with more of luxurious free time in the destination, there is a greater possibility and need for the systematic management of convention tourism services system within the destination. Traditionally, a convention marketing organisation (CMO) has taken the lead in the pursuit of the systematic management of the convention services network in the destination. However, over years, its role had been redefined in response to the evolution in thinking and practice of broader tourism management and marketing management context. Faced with the ever-intensifying market competition, CMOs are expected to play a more active role as a coordinator of the convention services system.

## **Background**

### **Convention Tourism: a driver of local developments**

Organised meetings, conventions, have a long history in civilisation (Montgomery and Strick 1995). Nonetheless, it is rather a recent phenomenon that economic activities derived from conventions as a whole gained recognition as an industry (Spiller 2002). Under the over-arching theme of tourism, convention tourism has evolved to claim its own place in the field and is now regarded as a significant driver of local, national and international developments (Dwyer and Forsyth 1997, Dwyer et al. 2000).

As with consumers in the tourism industry, convention attendees enter a series of interaction episodes with service infrastructure, facilities and providers throughout their journey, purchasing and consuming ranging services. The literature is in agreement as for a positive economic contribution of those convention attendees to local, national and international economies (c.f., Braun 1992, Crouch and Ritchie 1998; Dwyer and Forsyth 1997; Dwyer and Mistilis 1999, Fenich 1992; Rutherford and Kreck 1994). In particular, Kim, Chon and Chung (2003) stress conventions' greater potential of economic contribution along the following five characteristics of convention tourism: 1) conventions' power to draw a larger group of people; 2) a broader supply chain network base of the convention industry which encompass many service sectors; 3) convention attendees' tendency for longer stay when compared to pleasure-seeking tourists; 4) the attendees' tendency to engage in pre- and/or post-convention tourist activities; 5) overseas attendees' dynamic purchasing behaviour. Furthermore, in addition to these direct economic contribution of conventions, Rutherford and Kreck (1994) suggest an indirect, time-lagged economic benefits of the convention tourism to host destinations through convention attendees' re-visits as a holiday-maker and their positive word-of-mouth to induce new visitors. Although the current discourse on host benefits of the convention tourism is dominated by the economic contribution, Dwyer (2002) asserts that other types of host benefits should not be overlooked. For instance, Holcomb and Beauregard (cited in Fenich 1992, p. 186) earlier suggested that the convention centre development lead to an enhanced city image. More recently, McCabe et al. (2000) suggest potential environmental and technological contributions of convention tourism to destination local communities.

Both private and public sectors have been eagerly pursuing economic opportunity embedded in convention tourism. For instance, in the US, this has manifested itself in "a boom in the development of convention centers over the last two decades which is nothing less than remarkable" as a catalyst for local development and renewal (Sanders, 1998, p. 58). On the other hand, on the international front, Australian federal government has been spearheading a nation-wide, collective effort to promote the country as a preferred convention destination against more established world-class convention destinations in the region and the world (McCabe et al. 2000). The country's success, in turn, has stimulated similar concerted promotional efforts in the established convention destination countries (e.g., Japan, Hong Kong and Singapore) as well as the emerging (e.g., Korea). These somewhat concurrent aggressive investments in convention tourism have fuelled intensity of market competition among destinations across different levels of the economic system (i.e., local, national and international). To many convention destinations, Lawson's earlier prophecy has now become a reality that "the greatest challenges facing the industry in the next decade and beyond are likely to be concerned with maintaining growth and sustaining the benefits of investments" (2000, p.200).

#### **Convention Marketing Organisations and New Challenges**

The growing competition among convention destinations underscores the increasing importance of coordinated, industry-wide efforts within each destination, or the system-wide approach. When compared to consumers in the conventional services industry, tourism consumers enter a less discrete, more extended series of services episodes consisting of nested, but contingency-bound service encounters and experiences along their journey. In a word, whole journey experiences come to constitute a tourism services outcome of a tourism consumer. And for this very reason, each consumer's tourism services outcome is idiosyncratic. In this service value chain embedded in the 'web' of services systems along the journey, it is contingencies that pose both challenges and opportunities for effective management of tourism. In this respect, it is logical as well as necessary to manage the tourism services value chain systematically against contingencies in the web. However, in reality, no single tourism service organisation can match resource requirements associated with the systematic value chain management, nor can justify such a pursuit given its limited business opportunities in the broad web of services networks. This is also the case of convention services organisations. However, they should recognise that at least in the destination, convention tourists are more restricted in terms of the exposure to contingency-bound service encounters commonly associated with holiday makers with more of luxurious free time in the destination. And this unique characteristic of convention tourists creates an opportunity for a systematic management of convention tourism services network within the destination. In particular, given convention tourists' preference to efficiency, safety, and elegance and leisure opportunities for their destinations (Buhalis 2000), it is crucial for a convention destination to be able to offer those benefits through such a systematic management. But a question is who is going to spearhead such an effort.

Public policy makers have been active in support of an initiative in systematic destination services network management and creation of a convention marketing organisation (CMO) in destinations. CMOs have come to exist under different labels (i.e., tourism and convention bureau, convention and visitor bureau or simply convention bureau) and under varying ownership structures across countries. Despite these differences, however, all CMOs have traditionally shared the same goal - i.e., the marketing (here focus is on sales) of the destination on behalf of members of the local convention services network, such as hotel, restaurant, transportation, convention centre, tourist attraction and so on (McCabe, Poole, Weeks and Leiper 2000). According to Gartrell (1994, p. 16), the CMO is “the single most important marketing organisation for a community, projecting an image for that destination into the various target markets”. Though the extant literature on CMOs is rather deficient (Yoo and Weber 2005, Weber 2001), it offers some insights into alternative CMOs functions. For instance, Morrison, Bruen, and Anderson (1998) earlier reported the following five functions of CMOs: 1) a driver of local economic development; 2) a coordinator of the industry supply chain network; 3) a marketer of local community; 4) a promoter of community image; and 5) a quasi-public representative.

Yuan, Gretzel and Fesenmaier (2003) more recently stress the growing importance of the CMOs’ coordinator role as an information-intensive boundary spanner of the destination convention tourism industry. They suggest that real opportunities and challenges of the CMOs lie within the system while underscoring the traditionally fragmented nature of the industry and thus, poor coordination efforts within the convention tourism services network (Go, Govers and Vliegthart 2002). Their thesis is also in line with King (2002) who earlier advocated, in a broader tourism context, a need for a paradigm shift in strategic thinking and practice of a destination marketing organisation (DMO). He urges the transformation of DMOs from a mere promoter of the ‘place’ to the designer and facilitator of favourable tourists experiences in the destination. Notably, these recent effort to redefine DMOs’ and CMOs’ function seems to be a direct response to the renewed understanding of the marketing concept and the marketing function among marketing professionals. The former is now more commonly understood in line with Drucker’s original notion as a business philosophy beyond a mere function of sale and promotion of products while the latter is redefined to be “the effective generation, sharing and utilisation of customer and market information and knowledge across the organisation” so as to promote and facilitate an organisation-wide pursuit of superior customer value creation and innovation (Miyamoto 2005, p. 192).

The convention tourism literature is not clear as for a CMO’s coordinator role as a marketing agent for the destination services network. On this, the inter-firm networks literature offers valuable insights as well as a useful framework. In their earlier seminal work (1992), Snow, Miles and Coleman declared the dawn of inter-firm networks era and contended the criticality of ‘network broker’ for a successful network organisation. According to them, there are three network broker roles “especially important to the success of network organizations: architect, lead operator, and caretaker” (1992, 15). In their framework, a network architect and lead operator are defined as those responsible for design and implementation of *radical* improvements in the network operating processes, respectively whereas a network caretaker refers to one who promotes and enables continuous *incremental* network process improvements. Although they did not explicate in their work, the livelihood of network broker is intimate information and knowledge on market and consumers as well as internal operating systems. Drawing from their framework, the aforementioned coordinator role of the CDM can be further refined as an architect, lead operator and caretaker of the destination convention services network. And for its successful operation, the CDM, though the effective management of market intelligence throughout the services system, needs to explore opportunities for superior value creation (e.g., enhanced efficiency, safety, and elegance and leisure opportunities) within the destination convention services network, systematically devise incremental as well as radical improvements in pursuit of the opportunities, and spearhead collective efforts to materialise the opportunities.

In addition, the extant literature also suffers from the following two deficiencies: 1) a poor regional representation (i.e., the domination of North American origin of the articles) and 2) a lack of rigor in statistical analysis (Yoo and Weber 2005). The present study aims to address these short-comings. More specifically, it develops a structural equation model, explores a role and influence of a CDM in the process of client attitude and behavioural intention formation with the data collected from convention organisers for Shizuoka Convention Bureau in Japan.

## The Current Study: Shizuoka Convention Bureau (SCB) in Japan

Shizuoka Prefecture is situated a little eastward off the centre of main island of Japan (see Figure 1). Facing the Pacific Ocean, it sits between Tokyo and Nagoya in an hour distance from the two major cities by a bullet train. In Japan the region is more commonly known for Mt Fuji as well as Tokugawa Ieyasu, the founder of the Tokugawa Bakufu which controlled the country over 250 years prior to the country's rapid modernisation in the Meiji Era. It is also known as a home of Japanese multinational companies like Honda and Yamaha, a producer of green tea and mandarin oranges, and a popular tourist destination for hot springs. A focal convention marketing organisation, Shizuoka Convention Bureau (SCB), resides in Shizuoka City, capital city of the prefecture as well as one of 50 Cities for International Convention Tourism in Japan registered by the Ministry of Land, Infrastructure and Transport.

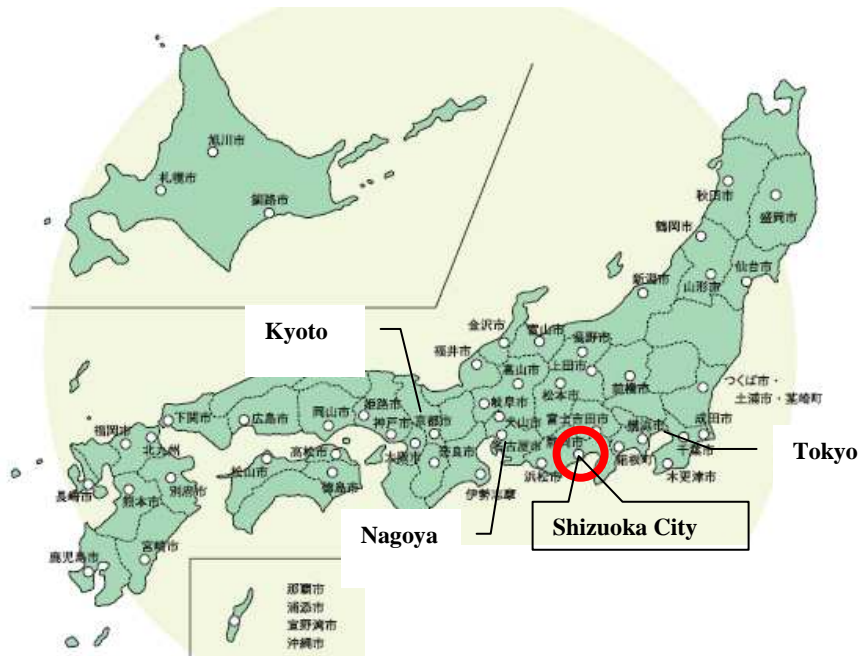

FIG.1: MAP OF JAPAN

Source: Adopted from Shizuoka Convention Bureau 10<sup>th</sup> Anniversary Memories, p.22)

This September the SCB will mark its 12<sup>th</sup> year of operation as a ‘*Zaidan Hojin*’ (i.e., incorporated foundation). According to the SCB 10<sup>th</sup> Anniversary Memoir (n.d.), however, its origin goes back to 1989 when the Sizuoka Chamber of Commerce initiated a vision to transform the city into an attractive host city of international events and conventions. Following a year-long research and discussions, the vision was translated into one of the city strategic plans and led to an establishment of the SCB as a ‘*Nin’i Dantai*’ (i.e., unincorporated association with no legal rights) in 1992. It began operations with three full-time staff and from one of offices in the city municipal building. In 1993 and 1994, the SCB successfully expanded its support base and strategic and operational scope to include the city’s neighbouring cities (4) and towns (2). Following the city’s registration for a City for International Convention Tourism in 1994, the SCB began to prepare its transformation into a ‘*Zaidan Hojin*’ with financial backings from Shizuoka Prefecture government, Shizuoka City municipal, the partner municipals, various non-profit organisations, and business enterprises in the region. And in 1995 it acquired the legal status as an incorporated

foundation. From its humble beginning as an unincorporated association, the SCB has developed itself as a more skilled marketing agent for the region in the ever-intensifying market competition, being supported by on-going developments of convention tourism service facilities and infrastructure in the region. Figure 2 summarise key statistics on the SCB's operations. Although there are year-to-year fluctuations, both the number of conventions, exhibitions, and events supported by the SCB and their participants indicate an upward trend. To provide some insights into the nature of convention tourism, it is worthy exploring reasons for the outstanding increases in the number of visitors in 2001 and 2003. The SCB 10<sup>th</sup> Anniversary Memoir (n.d.) marks 2001 for a hosting of the 'Sekai O'cha Matsuri 2001' (2001 World Green Tea Festival) with 111,227 participants and 2003 for a hosting of 'Kokumin Taiku Taiki' (National Sport Festival) which boosted the number of sport event participants 200,000 more than the previous year. These clearly illustrate highly challenging nature of convention tourism for both demand and supply management.

FIGURE 2: TIME-SERIES DATA ON SCB SUPPORTED CEEs AND THEIR PARTICIPANTS STATISTICS

Source: Compiled from Shizuoka Convention Bureau 10<sup>th</sup> Anniversary Memories

In addition, the SCB has also been active to attract international CEEs. Although there has been some fluctuation in terms of the number of CEEs supported by the SCB, there is a continuing increase as for the number of overseas participants from 643 in 1996 to 7,848 in 2004 throughout the time period (The SCB 10<sup>th</sup> Anniversary Memoir n.d.).

The SCB is fully aware of its role as a marketing agent of the region. It defines its primary role as a facilitator of region-wide cross-sectoral (i.e., public, private and communal sectors), collective efforts to promote the region as an ideal convention. For the purpose, the SCB has actively engaged in generation of customer and market information and knowledge through collaboration with researchers from local universities and commercial consulting companies as well as dissemination of information and knowledge (i.e., current problems and future opportunities) among members of the convention services network and its broader public. In The SCB 10<sup>th</sup> Anniversary Memoir (n.d., p. 30), the SCB defines its key function along the following five areas of activity: 1) marketing promotion of the region as a preferred convention destination and support for convention organisers; 2) public relations for Shizuoka City as a international convention tourism host city and its surrounding region; 3) market research on convention and convention planning; 4) generation and dissemination of information on conventions; and 5) development of and training for convention professionals. In more recent years, the SCB has been trying to establish the region's strategic value proposition as a preferred convention destination through the promotion of a unique Shizuoka-way of hospitality with a variety of local produces and food.

The SCB offers various (free and charged) services to convention organisers as part of its inducement strategy, ranging from a subsidy of up-to 1,000,000 yen (US\$8,700 at the exchange rate of 115 yen to US\$1), the

installation of 'Welcome' display monuments, referrals to convention services providers in the region to commercial services for out-sourced convention related activities. In particular, building on its earlier research findings, the SCB has been spearheading collective efforts in the region to further improve transportation efficiency for convention attendees and opportunity-building of the attendees' encounter with the region's culturally unique attractions (e.g., foods and tourism assets). Now, the construction of a much-debated and controversial regional airport is under way in one of the SCB's constituent regions. This addition to the services infrastructure will surely enhance the SCB's market position and opportunity to host more national and international CEEs. However, at the same time, it has also created a substantial expectation-ridden pressure on the SCB from public given the significant financial investment pouring into the project. The SCB now faces a critical challenge to move up to a next level. Once the airport opens in March 2009 as projected, the SCB's performance will be measured in relation to its economic contribution to the potentially resource-draining airport project. It is now in a great need of knowledge on how to attract more CEEs effectively. Unfortunately, the SCB does not seem to have sufficient knowledge on its role and influence in the process of attitude formation of its clients, convention organisers. The present study aims to explore the important issue in a structural modelling framework based on the data collected from 105 respondents who organised conventions under the support of the SCB during 2004 and 2005.

## Research Methodology

The data was collected from convention organisers who organised conventions under the support of the SCB during 2004 and 2005. The conventions ranged in scope from a prefecture-, regional-, national- and international-level. There were 128 cases of conferences which drew no less than 100 attendees. Here this cut-off number for the case selection for our data analysis was used in line with the SCB's criterion set for its financial support for convention organisers. The questionnaire consisted of six major sections, covering the following areas of inquiry: 1) transportation efficiency and convention centres and accommodation services; 2) performance assessment of different types of convention service providers involved; 3) self-assessment of effectiveness of different aspects of the convention management; 4) self-assessment of effectiveness in entertaining the attendees with host city tourism attractions; 5) assessment of the SCB's service quality across different types of supports; 6) the respondent's attitude to Shizuoka City as a convention host city. Due to more or less idiosyncratic convention organisers' needs (e.g., scope and size of conventions), not many respondents completed all the attribute specific questions in the instrument. Hence we decided to focus only on those questions asking the convention organisers' overall attitude and behavioural intention. More specifically, the study used the following six questions as a single-item scale for their respective construct:

- *Convention bureau support*: 'Overall, how effective was the Shizuoka Convention Bureau in supporting you?';
- *Transportation efficiency*: 'how effectively could you guide the attendees from Shizuoka Station to the convention venue?';
- *Host city tourism attractions*: 'Overall, how satisfactory could you entertain the attendees with Shizuoka's unique tourism attractions?';
- *Convention success*: 'Overall, how well did you manage the convention?';
- *Satisfaction with Shizuoka as a convention destination*: 'To what extent are you satisfied with Shizuoka as a convention destination city?'; and
- *Recommend Host City*: 'To what extent would you likely to recommend Shizuoka as a convention destination?'

As for our model building and testing, there are five issues which warrant some brief discussions. First, our initial model development was driven by the hand-on knowledge of the first author of this paper who has been involved in research projects for the SCB over years. Second, in the model framework, we decided not to include convention organisation's repeat intention (i.e., hold another convention in the destination again). Given the customary practice among convention organisers to rotate convention destinations regularly, it was believed more practical to focus our investigation on the present behavioural intention (i.e., a positive word-of-mouth) rather than

adding another model construct of distanced future repeat intention. Third, for our measurement model which consisted of single-item scale constructs alone, we set a reliability of each scale at .80, assigning 20% of variance of each scale as a measurement error. Fourth, for the model testing and respecification, we used EQS6.1 (Bentler and Wu 2005) and in search of the best fitting model we adopted Anderson and Gerbing's (1988) a nested modelling approach whereby structural sub-models are compared based on a  $\chi^2$  difference test. Finally for our model testing, 105 cases were used instead of 128 for 23 cases had incomplete responses across the six questions concerned. Of the remaining cases, there were 57 conventions with attendees between 100 and 499; 25 conventions with attendees between 500 and 999; 18 conventions with attendees between 1000 and 1999; 4 conventions with attendees between 2000 and 2999 and one convention with attendees of 4,000. Figure 3 depicts our initial model.

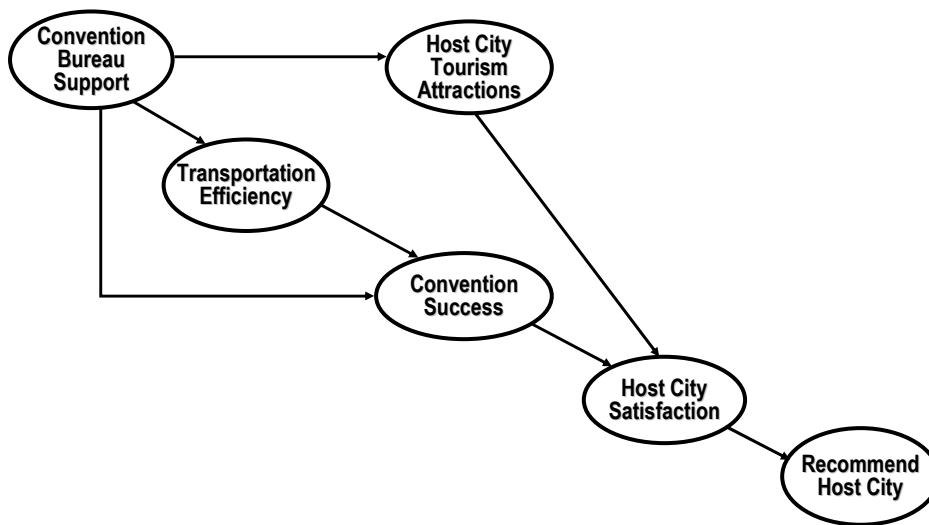

FIG. 3: INITIAL MODEL

Building on the notion of a CMO as a marketing agent and a spearhead of the convention services network presented in the preceding sections, the model aims to capture its role and influence in the development of convention organiser's attitude (i.e., satisfaction) and resultant behavioural intention (i.e., positive word of mouth) towards the host city with three intervening constructs between them. Building on the notion that 'transportation efficiency' and the convention organiser effectiveness in entertaining the attendees with 'host city tourism attractions' are function of 'convention bureau support' effectiveness, the model posits casual paths from the latter to the former. Then the model posits two structural paths from 'convention bureau support' and 'transportation efficiency' to 'convention success', reflecting the criticality of the latter two as the ingredients of a successful management of the convention. As for determinants of the organiser 'host city satisfaction', the model focuses on two dimensions of convention attendees benefits – the functional (i.e., 'convention success') and tourism (i.e., 'host city tourism attractions') needs – and posits their respective paths to the former. Finally the model incorporates the conventional path from customer attitude to behavioural intention. This line of reasoning is also consistent with Buhalis (2000) who stresses the benefits sought after by business travellers as efficiency, safety, and elegance and leisure opportunities. From a convention organiser's perspective, a success in meeting the functional element of the convention depends on the organiser's ability to ensure efficiency in attendee transportation and the management of

the convention program. On the other hand, in their effort to make each convention somewhat more entertaining and memorable, they are under pressure on how to better meet the attendee need for leisure or tourism opportunities unique to each destination (i.e., the leisure element of convention). In a word, the SCB is expected to support the organiser in their design and operations of both functional and leisure value chain. As for the safety issue, it was considered irrelevant in the present study as personal safety in public enjoys a commodity status in the country. As opposed to a convention function which is more or less same, host city attractions, especially tourism attractions, makes each convention.

## Findings & Discussions

Table 1 presents estimated correlation coefficients between the six model constructs and their respective standard errors of estimate in parentheses. All correlation estimates are statistically significant at  $p < .05$ . This measurement model was a just identified model with no degree of freedom ( $\chi^2$  (d.f. = 0) = 0.00; Normed Fit Index = 1.00). Nonetheless, given the model is a base or measurement model, this did not pose any problem to the study. Table 1 presents a summary of the correlation estimates and their respective standard errors of estimate. As for construct validity test of each model construct, it should be stressed again that all model constructs were measured by a single item with the set reliability of .80. Thus, irrelevant was convergent validity test. Furthermore, because of the set reliability for the present study (i.e., a construct explains 80% of variance in the observed variable), it was expected to not to encounter a problem situation whereby discriminant validity is threatened by an unusually high correlation coefficient estimate greater than .90 between model constructs. For testing of discriminant validity, we used a series of  $\chi^2$  difference tests by each time fixing a correlation of a pair of model constructs at 1. For instance, when the model fixed the correlation between 'host city satisfaction' and 'recommend convention host city' (which had the highest correlation estimate of 0.80) at 1, the model  $\chi^2$  deteriorated significantly (i.e.,  $\Delta\chi^2$  (d.f. = 1) = 21.43), supporting their distinctive property from each other.

TABLE 1: ESTIMATED CORRELATION COEFFICIENTS BETWEEN SIX MODEL CONSTRUCTS

	<u>CBS</u>	<u>TC</u>	<u>HCTA</u>	<u>CS</u>	<u>HCS</u>	<u>RCHC</u>
Convention Bureau Support (CBS)	1					
Transportation Efficiency (TE)	.25 (.12)	1				
Host City Tourism Attractions (HCTA)	.42 (.11)	.42 (.11)	1			
Convention Success (CS)	.74 (.07)	.44 (.11)	.35 (.11)	1		
Host City Satisfaction (HCS)	.52 (.10)	.48 (.10)	.56 (.09)	.49 (.10)	1	
Recommend Convention Host City (RCHC)	.55 (.12)	.35 (.11)	.54 (.10)	.44 (.11)	.80 (.10)	1

Testing of our initial model (see Figure 3) did not yield a satisfactory result with the following goodness of fit measures:  $\chi^2$  (d.f. = 8) = 29.25,  $p < 0.01$ , Normed Fit Index (NFI) = .983; Comparative Fit Index (CFI) = .987; Joreskog-Srobom's AGFI = .771; Standardised Root Mean Residual (SRMR) = 0.110; Root Mean Square Error of Approximation (RESEA) = .161). Carefully studying outputs from Lagrangian Multiplier Test and Multivariate Wald test in light of logic, the model was subjected to a series of step-by-step model respecifications.

The final model produced the following satisfactory goodness of fit measures:  $\chi^2$  (d.f. = 7) = 5.89,  $p > 0.55$ ; NFI = .996; CFI = 1.00; Joreskog-Srobom's AGFI = .944; SRMR = 0.032; RMSEA = .00. Figure 4 presents the final model together with key model estimates.

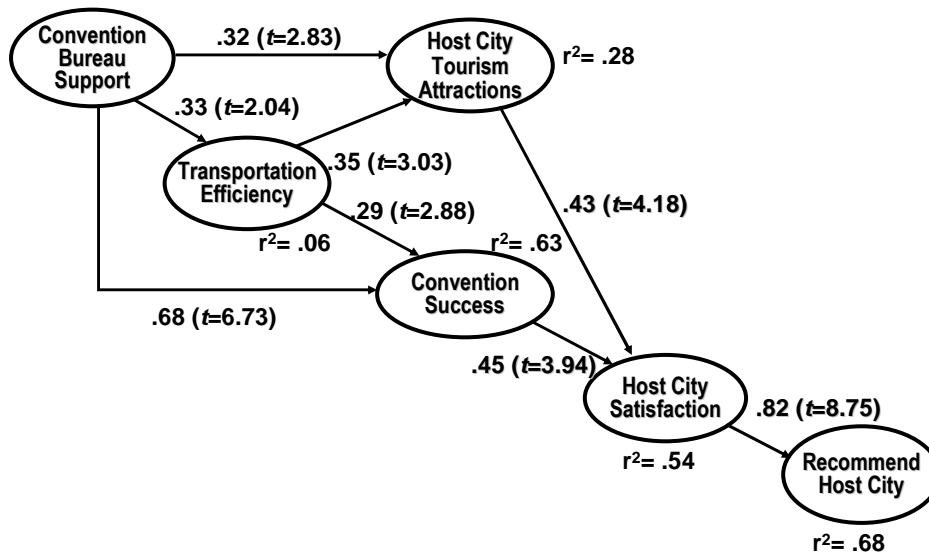

FIG. 4: FINAL MODEL

When this model was compared against a sub-structural model with no path from ‘transportation efficiency’ to ‘host city tourism attraction’ (with one more degree of freedom), the obtained  $\Delta\chi^2$  for the one degree of freedom was 8.85 ( $\chi^2$  (d.f. = 8-7) = 14.74-5.89), supporting a better model fit of the final model. Similar results were obtained when the final model was compared to two sub-structural models with an extra model constraint: one with an additional path from ‘convention bureau support’ to ‘host city satisfaction’ and another with a path from ‘convention bureau support’ to ‘recommend host city’. The obtained  $\Delta\chi^2$  were 0.24 ( $\chi^2$  (d.f. = 7-6) = 5.89-5.65) and 2.21 ( $\chi^2$  (d.f. = 7-6) = 5.89-3.68), respectively.

Results from these model comparisons underscore two important points. First it is suggested that ‘transportation efficiency’ (between the Shizuoka station to the convention venue) influences the convention organiser’s effectiveness in offering host city tourism attractions to the attendees. This seemingly odd structural path will be discussed in the later section. On the other hand, convention bureau support was found to have no direct effect either on the convention organiser’s post-convention ‘host city satisfaction’ nor the organiser’s behavioural intention to ‘recommend host city’. Its influence on them is all through intervening constructs in the model. In addition, it is noteworthy that ‘host city tourism attraction’ does not have a direct path to ‘convention success’. Instead it acts, together with convention success, as an important determinant of ‘host city satisfaction’. These findings underscore the criticality of the availability of the host city tourism attractions and its ease to incorporate them in the convention program for the development of the convention organiser’s satisfaction with the host city as well as the SCB’s competence in supporting convention organisers in their efforts. If the convention organiser’s ability and effectiveness to facilitate the attendee opportunities to encounter host city tourism attractions is further enhanced through the SCB’s support, the organiser’s overall host city satisfaction would also increase.

Table 2 presents a total effect of each of the model constructs on ‘host city satisfaction’ and ‘recommend host city’.

TABLE 2: STANDARDISED TOTAL EFFECTS OF MODEL CONSTRUCTS ON HOST CITY SATISFACTION AND RECOMMEND HOST CITY

	<b>CBS</b>	<b>TC</b>	<b>HCTA</b>	<b>CS</b>	<b>HCS</b>
Total Effect on Host City Satisfaction	.51	.28	.43	.45	-
Total Effect on Recommend Host City	.42	.23	.35	.37	.82

In Table 2, it is noteworthy that ‘convention bureau support’ exerts more influence (i.e., .51) on host city satisfaction than any other antecedents including ‘convention success (.45). And notably more than a half of its total effect derives from its indirect path via ‘convention success’ to ‘host city satisfaction. Similarly, investigation into its total effect on ‘recommend host city’ reveals again its importance (.42) only second to ‘host city satisfaction’ among others. These findings suggest two things. First they underscore the importance of convention bureau support services for functional aspects of convention management other than ‘transportation efficiency’. At the same time, the findings are highly indicative of the importance of the SCB’s (more enhanced) competence at supporting the convention organisers in their opportunity-building effort for the attendee encounter with host city tourism attractions given the observed structural path coefficients from ‘convention bureau support’ to ‘host city tourism attractions’ (.32) and from ‘host city tourism attractions’ to ‘host city satisfaction’ (.43). The following sections explore these issues further.

Table 3 presents summary statistics of responses to specific convention bureau service areas and practices.

TABLE 3: SUMMARY STATISTICS ON SPECIFIC CONVENTION BUREAU SERVICE AREAS AND PRACTICES

<b>Item</b>	<b>Mean (SD)</b>	<b>r (p-value)</b>	<b>N</b>
1. Convention Bureau staff services	6.1 (0.72)	.76 (p<.01)	97
2. Host City subsidy for a national convention	6.1 (0.87)	.54 (p<.01)	39
3. ‘Welcome’ display monument for convention attendees	5.5 (1.07)	.51 (p<.01)	90
4. Convention Bureau web site	5.4 (1.09)	.67 (p<.01)	39
5. Free Host City mini-guide	5.4 (0.99)	.57 (p<.01)	98
6. Referral to various convention support services specialists	5.4 (1.19)	.56 (p<.01)	32
7. Free Host City ‘Dining & Night Life’ map	5.3 (0.99)	.51 (p<.01)	93
8. Free sample photos of Mt. Fuji for convention information kit	5.1 (1.85)	.51 (p<.01)	30
9. Referral to convention centres	5.1 (1.46)	.44 (p<.05)	28
10. Referral to attraction event organisers at a convention party	4.7 (1.48)	.35 (p<.10)	26

As evident in Table, convention bureau staff services plays an important role in the mind of the convention organisers - i.e., a large correlation with the overall convention bureau support effectiveness (i.e.,  $r = .76$ ) together with its observed large mean (i.e., one of the two top ranked attributes together with ‘a subsidy’) and a relatively more stable deviation or smaller standard deviation (i.e., .72) despite its large number of response (97). While indicating the current effective SCB’s relational client-focused approach to its service management, close examination of Table 3 also urges for a further exploration of opportunities for superior value creation and innovation in terms of its referral service from the aforementioned network broker’s perspective. Although it does not seem to be a common problem, given the observed relatively poor assessment of the bureau’s referral service effectiveness (i.e., referral to convention centres and attraction event organisers), it is worthwhile to re-examine the current service process and practices from a more relational services management perspective. When perceived to be appropriate, the bureau staff should get more willingly involved in the convention organiser’s search and selection process of their ideal convention centres as well as attractive event organisers. As a boundary spanner, the SCB staff sits in the best position. They should become a co-designer and co-operator of a convention organiser’s convention value chain by effectively matching the organiser’s needs with talents and skills of the best alternative

service provider building on their local knowledge on the services network. This approach not only enhances the effectiveness of those referral services but also the effectiveness of the bureau staff services. Then they together further enhances the overall effectiveness of the bureau's support service quality.

Lastly this section examines issues surrounding the convention organiser's effectiveness in their pursuit of tourism opportunity-building for the attendees. Table 4 presents summary statistics on responses to the five aspects of host city tourism attractions.

TABLE 4: SUMMARY STATISTICS ON CONVENTION ORGANISER EFFECTIVENESS IN TOURISM OPPORTUNITY-BUILDING FOR THE ATTENDEES ALONG FIVE HOST CITY TOURISM ATTRIBUTES

Item	Mean (SD)	r (p-value)	N
1. Able to introduce unique local souvenirs to the attendees	4.9 (0.95)	.53 (p<.01)	96
2. Able to introduce unique local tourist spots to the attendees	4.8 (1.05)	.52 (p<.01)	89
3. Able to cater unique local food at a convention party	4.8 (1.31)	.47 (p<.01)	95
4. Able to stage tourist attraction event for the attendees	4.8 (1.59)	.36 (p<.01)	79
5. Able to cater a convention lunch based on unique local produces	4.6 (1.22)	.44 (p<.01)	94

On the contrary to responses to convention bureau support service attributes in Table 3, responses to the host city tourism attractions are more converging as for ratings and the numbers of responses. Although all the five questions received higher ratings than the mid scale point of 4, these results As suggested from in Table 4, the convention organiser's effort to stage the attendee opportunity for host city tourism is largely limited to the convention venue (i.e., sale of local souvenirs, catering with unique local foods and produces and staging of tourist attraction event). By comparing the observed standard deviations across the four attributes, it is indicative that the organiser's effectiveness to introduce local souvenirs at the convention venues is rather a well-established practice as opposed to the practice of hosting of local event attractions at the convention. From a practical perspective, however, responses to Item 1, 3, 5 in Table 4 can be explained largely as the product of the convention organiser's choice decisions on more or less pre-configured service modules available at each convention centre.

There seem to be two explanations for the structural path in the final model which was not posited in our initial model. That is, a path from 'transportation efficiency' to 'host city tourism attraction'. The first line of explanation is that some convention venues had both an easier access to Shizuoka station and better convention tourism services network – a services capacity like a greater variety in the aforementioned pre-configured service modules and superior tourism services offering. Or alternatively, it can be argued as that the convention organisers were capable of finding host city tourist destinations along the route between the convention venues and Shizuoka station. Thus the convention organisers could effectively introduce a transportation-convenient tourism sports to the attendees. This is certainly the advantage for the convention tourism of the region. These propositions need to be further researched for clarity as each proposition leads to a different structural model. If the former is found to be the dominant explanation, then the present model needs to be respecified by changing the structural path into mere correlation. On the other hand, if the latter is found to be the case, our model has an important implication to a development of new convention centres and related convention tourism services infrastructure developments.

Finally, in light of its strategic priority on the promotion of convention tourism attractions, the observed mean responses (just under 5 on the 7-point scale) suggest more room for the SCB as a network brokers in their support for the convention organisers as a co-designer of the convention organiser's convention tourism value chain as well as in its effort to promote and support both an incremental and radical improvements of those tourism attraction services in the services network.

## Conclusion

Over the decades, convention tourism has been recognised as one of important economic driver of local development. Accordingly, the sector has received an unprecedented level of support and commitment from both public and private sectors in many countries. However, due to the somewhat concurrent actions taken, the convention destination market has invited ever intensifying competition. Again this background, the convention marketing organisations (CMOs) have been created as a marketing agent of the destination. For a successful development of convention tourism in the destination, the CMOs are now under pressure to transform itself from a mere promoter of the place into a network broker of the convention services system. From the network broker's perspective, this study examined the CMO's role and influence in the development of convention organiser's attitude and behavioural intention to the destination. More specifically, it explores present short-comings and future opportunities of the network broker from the Shizuoka Convention Bureau (SCB) in Japan. While generating empirical evidence for the critical role of convention bureau support to the convention organiser's successful management of convention, the study produced findings which indicate the current shortcoming of the SCB as well as the SCB strategic opportunities and directions. The study supported the notion that the convention organiser's overall satisfaction with the convention host city, the sole determinant of the organiser's behavioural intention, is a function of two elements of convention organiser's need: the functional (i.e., convention success) and the leisure (i.e., the convention organiser's effectiveness in meeting the attendee's need for host city tourism experience). Given the structural paths and their varying magnitudes of influence, it was suggested that the SCB can further improve its effectiveness as a network broker by improving the process and intensity of its involvement as co-designer and co-operator of both the convention organiser's convention value chain (i.e., functional) as well as convention tourism value chain (i.e., leisure).

# **An Empirical Analysis of a Framework on Building Consumer Trust in Mobile Travel and Tourism Contents**

*Hyojae Joun, Hyojae.joun@gmail.com  
Korea Culture and Tourism Institute, Korea  
Namjae Cho  
Hanyang University, Korea*

## **Abstract**

The purpose of this paper is to study building and maintaining consumer trust in mobile travel and tourism contents (M-TTC). Trust development life cycle in e-commerce is a trust building flow of online consumers. Travel information and contents in mobile commerce are in an early and immature stage toward the ubiquitous era. Travel and tourism industry is an information-intensive and network-oriented business. Both bricks and clicks, the public and private, and the virtual and physical aspects of business are involved. A framework of travel and tourism contents under m-commerce context is proposed to identify conceptual components for building information and contents that can draw continuous consumer trust. The results based on the focus group interview methodology highlights a conceptual foundation m-trust model of mobile content in travel and tourism industry. It shows what important factors are and how trustworthiness can be improved.

## **Introduction**

Expansion of internet usage has triggered rapid changes in diverse social groups and industry domains. Jupiter Research forecasts online travel spending to hit from \$85 billion in 2006 to \$128 billion in 2011 [1]. WTO (World Tourism Organization) announces that websites (.travel domain) of travel industry will cast new influences on internet directory [12].

Tourism Industry is rapidly changing as internet usage increases. This trend is observed not only among tourism firms that lead innovation through information technology, but also in public sectors trying to build new channels. Large cities and rural governments try to utilize their diverse tourism resources such as natural scenery, landscape, culture, history etc. to boast up local economy and promote local image. The reliance of them on internet usage for collecting tourist information is increasing everyday.

Korean Ministry of Culture and Tourism (MCT) recently declared the opening of the era of the U-travel. U-Travel focuses on tourists' mobility and the diffusion of mobile phones and PDAs. Korea National Tourism Organization (KNTO) and Jeonrabuk-do province have begun a new service for reservation and the provision of location-based tourism information through mobile system. Public sectors, tourism firms, domestic and international information users, system managers, and communities are all participated in local tourism information portals. As accessibility to information technology infrastructure is constantly increasing, the importance of reliability in contents under limited economic resources is also increasing.

This study discusses a framework on establishing consumer trust from the perspective of mobile consumers, mobile vendor and mobile technology. We will also discuss the role of government.

## **Literature Review**

### **Trust Life Cycle in E-commerce**

As a result of the expansion of e-commerce, the number of participants in various on-line communication and business continue to increase rapidly. Information technology improves accessibility of participants and encourages incessant competition both in quantitative and qualitative improvement in the exchange of information. Research on the concept of trust has been carried in many different areas including business, psychology, and medical science.

Generally, trust is a state involving confident positive expectation about another's motives with respect to one in situations entailing risks [3, 4]. Ambrose and Johnson (2000) suggest three characteristics of the trust [15]. First of all, the relationship between truster and trustee depends on mutual advantage. Secondly, trust includes 'uncertainty' and 'risk'. There is no perfect guarantee but only expectation met between truster and trustee. Thirdly, trust believes trustee's honesty and benevolence also that trustee will not allow the action premised on risk. According to Ratnasingham and Kumar (2000), there are three important considering factors to gain customer trust that are competence trust, predictability trust, and goodwill trust [5].

According to Fung and Lee (1999), customer trust formation in e-commerce can be identified dynamic time-consuming process including initial trust formation and repeating test of transaction until customer royalty toward company is appeared. Siau and Shen (2003) explains initial trust formation to construct customer trust in e-commerce, evaluation on satisfaction, repeat transaction, and customer royalty formation in company as a life cycle (see Figure 1).

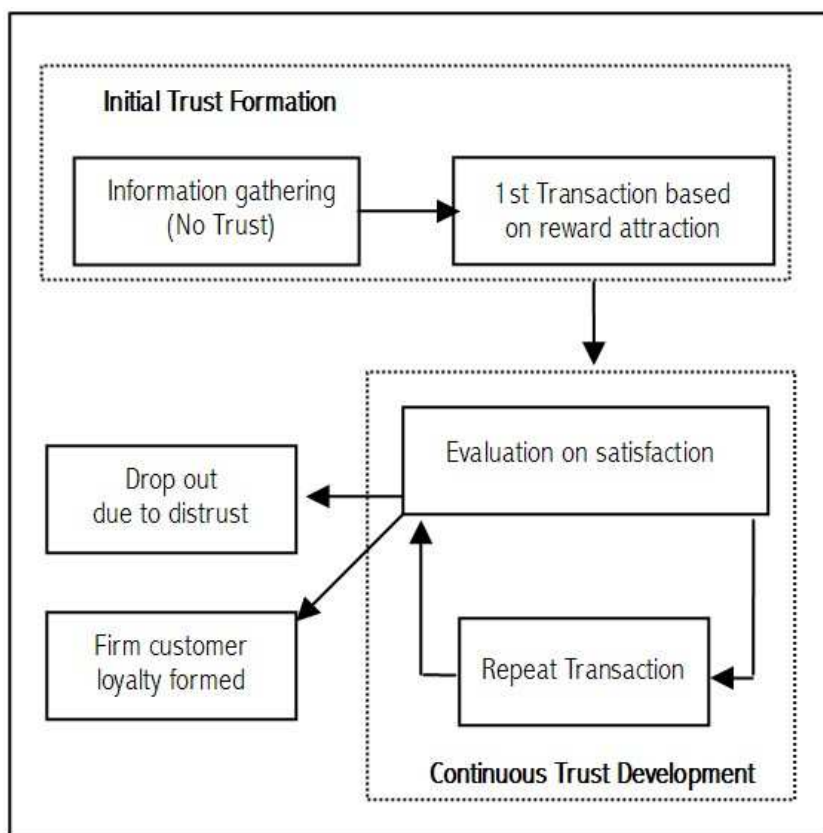

FIG. 1: E-COMMERCE TRUST LIFE CYCLE

### Customer Trust in M-Commerce

Reliability and security is important to construct online trust as much as technology in mobile commerce [7]. There are limit to follow diverse internet contents both in quantity and quality as mobile technology and vendor, the core factors in mobile commerce are technologically dependent in contents formation and the limit in LCD (liquid crystal display) of mobile phone and PDA is raised as an important task in m-commerce growth.

As a traditional concept of city, most crucial factor has been within physical range. However current cities overcome physical limit through development of information technology, enlarged function and scale of new city and evolve it into new conceptual cities that are information cities. Information city fulfills real life into virtual

reality through diverse contents development on industry, market, medical, 119 emergency, transportation, culture and tourism.

Ferguson et al. (2004) suggest construction of information cities at the side of system and web service at the side of open service architecture [8]. For designing and building information cities, they suggest service oriented model of web service. This service-oriented model is based on middleware system and service structure suggests formation of portal information cities.

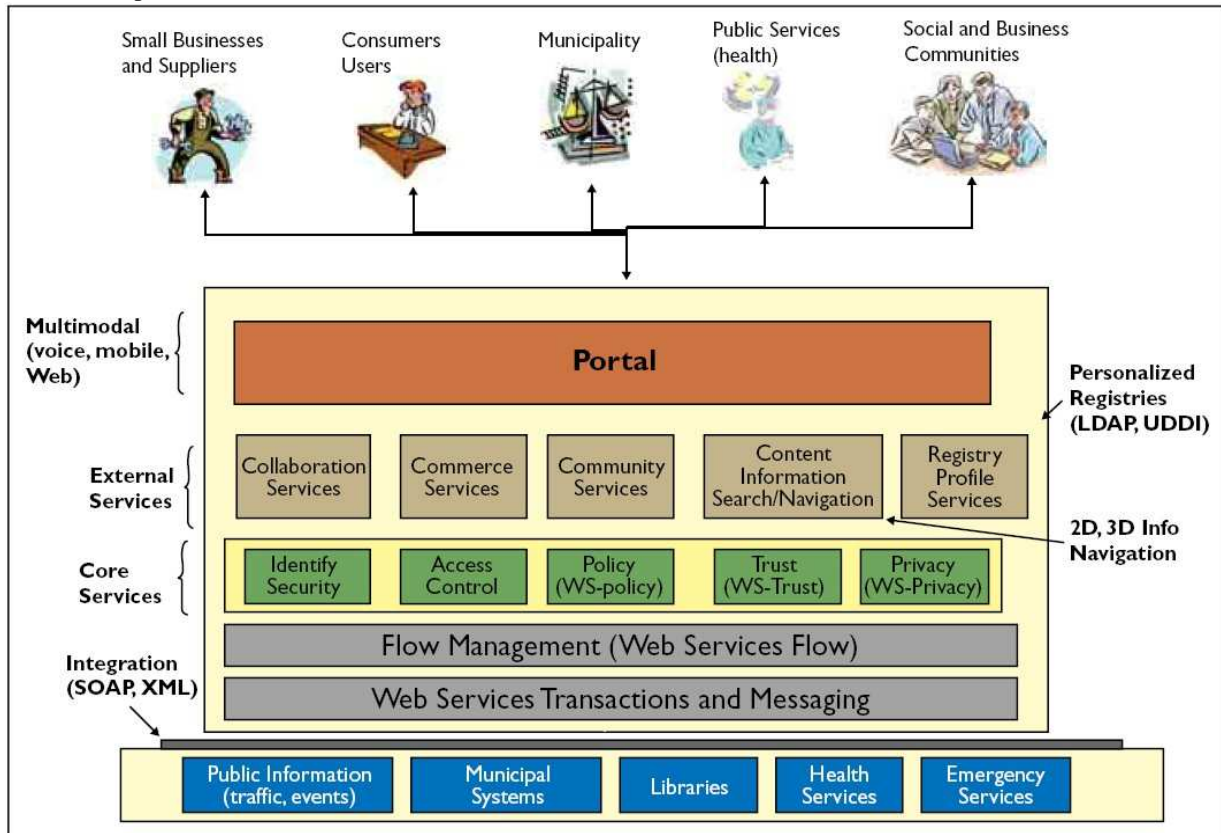

FIG. 2: OPEN SERVICE ARCHITECTURE

Most of domestic mobile service providers provide information service focused on transportation and time however mobile tourist portal service lately is more driven to be verified and expanded such as the case of 'mobile service for outbound travel guide book' by SKT or 'mobile tourist information service' by KNTO.

Customer trust of M-TTC in m-commerce is required to retain diverse and reliable information, and there should be no limit on sharing its information. It is necessary to develop continuous management of information quality and the structure which can secure economical efficiency.

It is not too much say that modern movement of e-commerce has evolved from the travel industry. Travel industry overcame physical limit to handle their business in the market, introduced global distribution systems (GDS), the capable reservation system for flight tickets, hotel and rental reservation services. Mainly GDS such following system, Sabre, Galileo, Amadeus, and Worldspan lead the travel and tourism industry in sharing information and net working of industry. However GDS is mainly focused on large scale of chains, and it is threaten by rapid growth of internet and it accelerates enlargement of 'region-oriented travel and tourism information system'.

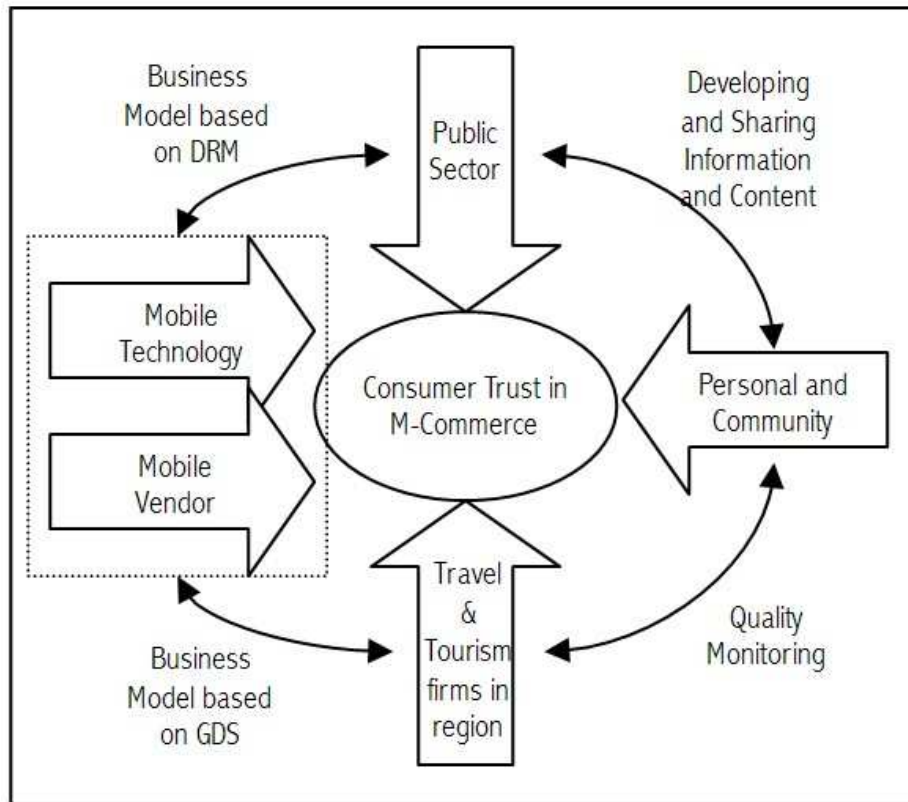

FIG 3: STRUCTURE AND FLOW OF MTTC CONSUMER TRUST IN M-COMMERCE

Figure 3 shows scale of participants to construct continuous customer trust for the region-oriented information of M-TTC and suggests a direction with aspect of mutual interests that contracting parties should pursue. This model is able to aim connectional meaning of M-TTC which improves customer trust in m-commerce based on mutual trust between diverse participants. Public sectors which retain many digital contents of local tourism, should secure the digital copyrights. Provider should search for developing digital contents into products, business model of local reservation system by cooperation with small-and-medium sized tourism firm which adapt technology slowly, enlarge range of information public ownership and develop digital information and contents through locals and community. And locals and community should be able to provide guarantee of product quality to mobile customer which concerns tourist characteristic by monitoring of local tourism products.

## Study model and methodology

### M-TTC Customer Trust Frame Work

According to Siau and Shen (2003), with the aspect of mobile technology, it is important to maintain feasibility at the level of initial trust formation, reliability and consistency during the continuous trust development [4, 16]. And at the side of mobile provider, they suggested familiarity, reputation, information quality, recognition by third-party and attractive awards at the initial trust formation and for the continuous trust development, web-site quality, competence, integrity, privacy policy, security controls, community building, open communication, accessibility, external auditing were suggested as a framework.

FIG. 4: FRAMEWORK FOR BUILDING FOR M-TTC

The M-TTC customer trust framework is an extended version of participants range and their role. Portal local tourism information system has a structure division of public and private sectors [4]. It organizes different sectors on-offline throughout cooperation between central government, local government, national tourism organization as a public sector, tourism firm, mobile service vendor, IT Company as a private sector, and locals and community as a third party. Particularly it has infrastructural characteristic which constructs corporative structure in m-commerce and provides new online contents constantly with internet. This research is to perceive development of M-TTC from the perspective of continuous customer trust development. Continuous customer trust frame work of M-commerce is a model applied with technology, role of provider and time flow. This study attempts to suggest duties of interest parties and technology side applying mobile customer trust development frame work introduced by Siau and Shen (2003) with tourism contents.

**Methodology**

M-TTC model is an integrated model from existing one that are merged with IT, public sector, tourism firm, personal/community, and mobile technology, this study suggests each role of model by focus group interview. Focus group can be used at the preliminary or exploratory stages of a study or during a study, perhaps to evaluate or develop a particular programme of activities or after a programme has been completed, to assess its impact or to generate further avenues of research [9, 10]. A focus group is defined as a group of individuals selected and assembled by researchers to discuss and comment on at the same time, from personal experience, the topic that is the subject of the research [11]. Focus groups are a form of group interviewing but it is important to distinguish between the two. Group interviewing involves interviewing a number of people at the same time, the emphasis being on questions and responses between the researcher and participants. Focus groups however rely on interaction within the group based on topics that are supplied by the researcher [12].

The process of focus group is progress of discussion, data preparation, analysis and reporting utilizing; selection of subject, definition and education of moderator, forming and correcting interview, developing frame, collecting participants, preparation of meeting, interview recording, or systematic recording method and the recommended number of people per group is usually six to ten [13]. Focus group consists of participants already performed regional-oriented tourism information construction business as a demonstration region of Korean MCT in

2004 and business experts and specialists who have experienced mobile contents development project. After introduction of the model by Siau and Shen (2003), participants discussed further about possible components of interest parties in the perspective of initial and continuous level to construct continuous customer trust frame work in M-TTC. Greenbaum (1998) suggested the method for the group and scale for research guideline; full group (8 to 10 persons), minigroup (4 to 6 persons), and telephone group (30 minutes to 2 hours), 10-point likert scale. This applied the minigroup of 6 persons and 10-point likert scale [14]. The subject of discussion was about successful development of M-TTC focused on region-oriented tourism and each responsibility of tourism firm, mobile vendor, mobile technology and local from an aspect of policy to construct continuous customer trust development.

## Results

We were suggested discussed policy issues and further direction to reinforce continuous customer trust for successful management of M-TTC as below. At the initial and continuous level of mobile technology aspect, necessity of developing initial design, network, LBS (location based service), Initial management and operation budgeting, booking/payment service, language pattern and pictogram regarding tourist decision making process are proved and suggested. A policy issue on technology application with aggressive promotion and marketing activities was strongly recommended particularly, due to uncertain visiting period and amount of expenditure from many and unspecified tourists. However technological investments as well as budgeting for initial management and operation (during opening or normalization period) have risen as a very crucial component for the aspect of policy budget support.

TABLE 1: IMPORTANCE BY INITIAL AND CONTINUOUS MOBILE TECHNOLOGY STAGE

Classification	Detail	Mean	Std. deviation
Feasibility	● Mobile user environment similar to user environment of local government tour website (FS1)	8.50	1.61
	● Accessibility of search service by diverse tourist information and itinerary and push massaging service related tourist products(FS2)	8.00	1.73
	● Standard Positioning Service(FS3)	4.83	2.91
Reliability	● Extra cable apart from administrative cable and resources for the opening of initial service and secure mobile service(RL1)	8.33	1.89
	● Confirm message and reservation code by mobile service and reservation /payment notice message from tourism firm based on GDS(RL2)	5.67	1.80
Consistency	● Recognizing limit of Hardware in mobile device and integrating it with appropriate language pattern and tourism information process(CS1)	6.17	2.79
	● Defining information system by mobile tourism pictogram(CS2)	6.67	1.89

Secondly, policy regulation regarding tourism firms (tourism firm authentication), visiting the site, compensation system related M-TTC was risen as important task to develop initial customer trust, logo of local brand and promote M-TTC service before service provide. Especially ensuring human resource in local government is raised as difficult task for managing public sector, technology education although it is more important resources before technology and business plan to maintain customer trust development constantly.

TABLE 2: IMPORTANCE BY INITIAL CONSUMER TRUST FORMATION

Classification	Detail	Mean	Std. deviation
Familiarity	● Local brand development (logo, product, natural scene, human etc.)(FM1)	7.67	2.05
	● Promotion and advertisement on diverse M-TTC information services(FM2)	6.50	1.89
Reputation	● Information provider (RP1)	7.17	2.27
	● Technology provider(RP2)	5.50	2.87
	● Tourism firms(RP3)	3.83	2.19
	● Small-and-medium sized local tourism firm authentication(RP4)	8.67	1.49
Information Quality	● Diverse local news and Tourist information by season (News, Event and festivals) – suited for local characteristic and time(IQ1)	6.67	1.70
	● Story telling service such as e-book, catalogue(IQ2)	5.67	1.11
Third-Party Recognition	● Developing performance evaluation system of M-TTC(TPR1)	7.50	2.22
	● Digital intellectual copyrights(TPR2)	6.33	1.97
	● Information certificates, payment certificates, participating firm certificates(TPR3)	8.17	1.77
Attractive Rewards	● Local tour site certificate services(AR1)	7.50	1.98
	● Developing Mobile seal/ signature(AR2)	5.83	1.86
	● 3+1 credit (bundle of services system) – visit 3 local tourist places a day, issue free mobile coupon for F&B or entrance ticket(AR3)	5.67	2.81
	● Free festival or event card(AR4)	5.33	2.62

Thirdly, for the stage of continuous trust development, function and design oriented mobile service, constant development of locally customized M-TTC based on 3 party-experiences, service publicity maintenance, quality monitoring, cooperation and integration with existing policy, developing evaluation standard of performance and performing system have been emphasized as a core issue to maintain M-TTC business further. Particularly to justify policy security of the business run by public sector, and to visualize business impact under policy, both qualitative and quantitative development (number of visitors, satisfaction rate) is required.

Additionally, each of the stages shows the difference of importance in Figure 5. In detail, mobile technology (MT-Mean 7.11) is more important than participant role (PR\_Mean 6.59) in the initial stage. But, after developing the systems, participant role (PR\_Mean 6.92) is more important than mobile technology (MT-Mean 6.71) in continuous stage. And more, the initial stage (IS\_Mean 6.85) is more important than the continuous stage (CS\_Mean 6.81). But, statistically, this result need more research.

TABLE 3: IMPORTANCE BY CONTINUOUS CONSUMER TRUST DEVELOPMENT

Classification	Detail	Mean	Std. deviation
Site Quality	● Transform into a skill valued quality of site (skills of education, experience, culture and historical facts etc)(SQ1)	6.33	1.37
	● Local brand and design preferred website(SQ2)	5.83	1.21
Competence	● Providing local Top 5 or 10 tourism contents(CP1)	7.17	2.27
	● Constant development and new M-TTC service provide(CP2)	7.17	2.27
	● Accumulation of experimental information based on story telling(CP3)	5.17	2.41
	● Enlargement of referential information such as book, news based on promotion materials(CP4)	5.00	-
Integrity	● Value highly the role and image of public service(IT1)	9.17	1.21
	● Monitoring system of M-TTC(IT2)	8.17	1.67
	● Maximizing participant rate of technology experts at the stage of initial trust formation(IT3)	7.00	3.16
Privacy Policy	● E-commerce standard(PP1)	6.67	1.89
	● M-TTC intellectual copyrights(PP2)	6.50	2.14
Security Controls	● Digital signature, codification, and certificates management(SC1)	6.00	3.61
	● Money transaction based on GDS operation (per tourism firm)(SC2)	7.50	2.50
Open Communication	● Customized travel information (golf course, fishing, pension holiday house etc)(OC1)	6.67	2.49
	● Internet kiosk, 1330 telephone travel information service, mobile service in local tourist information center(OC2)	7.17	2.41
Community Building	● Local community of internet mobile(CB1)	4.83	1.77
	● Local communities and leader training by technology experts and local governments(CB2)	7.67	1.89
External Auditing	● Transparency of Certificate system for excellent tourism firm(EA1)	9.17	0.90
	● Internal, External auditing policy transparency(EA2)	8.83	1.46
	● Business effect (visitor number per day, system performance evaluation etc)(EA3)	7.50	1.71

FIG. 5: TASK IMPORTANCE OF BUILDING CONSUMER TRUST FOR M-TTC

### Conclusions and Future Assignment

FIG. 6: SHIFTING THE ROLE OF IMPACT IN BUILDING CONSUMER TRUST

Shown in figure 6, the importance of role between human and technology shifted according to the time line of developing the mobile tourism information services. This result has shown the importance of maintenance and contents service after developing the initial stage.

M-TTC for the trust should provide harmonized participation and chance to public sector, personals and local communities, business vendor (technology, tourism) and IT. Immature policy for contents management produces uncertainty of tourist information, economical inefficiency as well as low customer satisfaction of tourist and local although local government retains abundant amount of tourism contents of culture, history, event and personal.

Therefore customer trust formation is an important policy indicator to expand aggressive participation of local tourism and promotion from personal to local. However aggressive evaluation about open site of policy in public sector is still insufficient. That is why it is time to develop an integrated M-TTC applying with existing tourist facility and support continuous customer trust development. And the target of continuous customer trust should be virtual citizen and actual tourist who live in attraction of virtual space. And tourism policy should be dealt with actual visitors who visit local area. Targeting on them, developing local tourism contents of game and competition is on demand to create new customer and its trust. Henceforward this is needed to continuous customer trust development of M-TTC, effect of investigation, logical structure of policy affairs, performance barometer such as language pattern, diverse contents, 3D geographical information service of study.

# **Multi-market Contact and Competition Action: A Case Study on China's Domestic Air Flight Market**

*Hu, Ruijuan, huruijuan@uibe.edu.cn  
University of International Business and Economics, Beijing, China*

## **Abstract**

Multi-market contact competition has become one of the most discussed topics during the recent few decades. Many authors have shown that multi-market contact could impact the competition between corporations, or even lead to mutual forbearance result. By following Evans and Kesside (1994) and Singal (1996), this paper firstly calculates the multi-market contact competition (MCC) indices in China's domestic airline market. Using the cross-section data from 244 China's domestic trunk airline routes, the paper does a multi-market regression of route market characteristics measures on the average yield of each airline. The results show that the mutual forbearance hypothesis cannot be rejected significantly by using this sample. Important internal market factors including the price regulation frame and the production technology are also identified. Due to the existence of price regulation and certain barrier on entry, however, concentration cannot be proved as relevant factor in China's domestic airline market, which is contrary to general expectations.

## **Introduction**

One of the most significant institutional developments affecting the organization of the global economy in recent decades has been the trend toward diversification. Many important industries have been restructured as single product firms have been replaced by large conglomerates producing scores of diverse products. A situation where the firms compete against each other simultaneously in several markets (multiple market competition or multiple point competition) is getting ubiquitous. Traditional industrial behavior analyses say that the presence of conglomerate firms in a market will have no impact on competitive rivalry. Since competition in a market is determined solely by internal features such as demand conditions, concentration. Nevertheless, many economists have concerned the external factors such as the potential effects of multiple market contact between firms also play an important role in determining the degree of competitiveness in many industries. Corwin Edwards (1964) firstly raised that the multi-market competition character between conglomerated enterprises might have a unique effect on competition. He stated:

When one large conglomerate enterprise competes with another, the two are likely to encounter each other in a considerable number of markets. The multiplicity of their contacts may blunt the edge of their competition. A prospect of advantage from vigorous competition in one market may be weighted against the danger of retaliatory forays by the competition in other markets. Each conglomerate may develop a live-and-let-live policy designed to stabilize the whole structure of the competitive relationship.<sup>1</sup>

This "mutual forbearance hypothesis" did not receive intensive attention until the late 1970's. On the theoretical aspect, Karnani (1985) developed a conceptual framework for analyzing situations involving multiple point competition and shown that the most frequently observed outcome should be so called mutual foothold (mutual forbearance) equilibrium. Using a repeated Bertrand competition model, Bernheim and Whinston (1990) pointed out that multiple market contact releases the incentive constraints governing the implicit agreements between firms and is likely to improve firms' abilities to sustain collusive outcomes. Phillips and Mason (1992) conducted a series of economic experiments to gauge the level of cooperation between conglomerate rivals, and the results strongly supported Bernheim and Whinston's propositions.

At the same time, "mutual forbearance hypothesis" has been tested statistically by extensive researches. As we can see from TABLE 1, most of these researches show positive proof for the "mutual forbearance hypothesis" (Heggstad and Rhoades, 1978; Evans and Kesside, 1994; Singal, 1996; Gimeno and Woo, 1999; Gimeno, 1999) apart from the result of Scott (1982). Basically, these empirical studies have used the same method which is called

multi-market contact regression. That is, using the company's average fare level or profit/margin level as the dependent variable, and doing regression on both internal market features such as concentration and external market features such as multi-market contact. However, the calculation of multi-market contact index is highly diversified. In general, more influential factors are taken into considerations in the calculation of more recent researches.

While the mutual forbearance hypothesis is relevant to industry in general, many authors have established that the airline industry is rendered as an ideal candidate for empirical test of multi-market competition effects (Evans and Kesside, 1994; Singal, 1996). Airline industry is characterized by relatively well defined local market. Each airline company typically operates on several flight routes which are geographically different from each other. Theoretically, under the condition that the production cost and the demand growth rate differs across the route markets of each competitor, or so-called Bernheim and Whinston condition, the multi-market can impact firms' competitive behaviors by discouraging the competition between the competitors. Since the airline route markets naturally satisfy the above condition, most of the studies (5 researches out of 9 researches in TABLE 1) have used data from airline industry as the sample, particularly from US airlines.

China's airline industry was not commercialized until the middle 1980's. With an annual average growth rate of 18% since the year of 1978, the total output of China's airline industry has increased 85 times to 26.13 billion tonkm in 2005. Although regulation is still strict comparing to that in US, the last two decades has witnessed a gradual evolution of the release of the regulation regime in China's airline industry. In the few studies on the competition in China's airline industry, however, neither internal market factors such as regulation policy and concentration nor external market factors such as multi-market contact are included into the consideration (Cao, 2002; Yang, 2004). Moreover, studies on external influential feature of industrial behavior in any particular industry in China are still left blank. By using the data from 244 domestic airline route markets in China, this paper attempts to reveal a big picture of both the internal market influential factors and the external market influential factors of China's airlines market performance.

The results of this paper show that the external market factor (multi-market contact) can be an important influential factor in China's airline industry. The mutual forbearance hypothesis cannot be rejected significantly by using the sample of China's domestic airline route market. This paper also identifies the important internal market factors including the price regulation frame and the production technology. Whereas, the market concentration cannot be proved as relevant factor in China's domestic airline market, which is contrary to general expectations. This is largely due to the existence of price regulation and certain barrier on entry in China's airline industry.

TABLE 1: RECENT EMPIRICAL STUDIES ON MULTI-MARKET CONTACT AND MUTUAL FORBEARANCE

Author	Sample	Dependent variable	Key independent variable	Key findings	Mutual forbearance hypothesis
Heggestad and Rhoades (1978)	US banking	Interfirm rivalry	Market concentration, multimarket links	Existence of multimarket link is sufficient to reduce rivalry.	support
Scott (1982)	US large manufacturer	Company's profit	Probabilistic multimarket contact measure, market concentration	High multimarket contact alone is associated overall with lower profits.	not support
Hughes and Oughton (1993)	UK Manufacture industries	Price-cost margin and the rate of return to capital	multimarket contact, Berry index of diversification	Multimarket contact has a consistent positive effect on profitability and rate of return on capital	support
Evans and Kessides (1994)	US airline industry	Route fare	multimarket contact, market concentration	External contact has a significant and important effect on price	support
Smith and Wilson (1995)	US airline industry	Firm's response	Sustainable capacity, barriers to entry, market dependency	Market dependency increases the probability of counterattack strategy	
Singal (1996)	US airline industry	Route fare	Multimarket contact, market concentration	For long-distance route, multimarket contact has significantly positive effect on fare	Support for long-distance route
Gimeno and Woo (1999)	US airline industry	Cost efficiency, intensity of rivalry (yield) and profitability	Multimarket contact, interaction effects	Multimarket contact had a significant and positive effect on yield and hence, a negative relationship to rivalry	support
Gimeno (1999)	US airline industry	Yield and market share	Multimarket contact,	Reciprocal multimarket contacts have significantly higher forbearance effects than non-reciprocal contacts	Support for reciprocal MMC
Fuentelsaz and Gomez (2006)	Spanish savings bank industry	Market entry (probability of entry into the market)	Multimarket contact, strategy similarity	Multimarket contact has a U inverted influence on entry rates	Support when MMC is high

Source: edited by author.

The rest of the paper is organized as follows: Section II presents the basic model of the regression and the computation methods of related variables. As mentioned above, although the past researches have taken highly diverse methods in the multi-market contact index, more and more market features are tend to be taken into account. Thus section II highlight the computation of multi-market contact index, where the features including the number of firms in the market, the magnitude of presence, the relative market share, and the size of market are captured. Section III introduces the source and descriptive statistics of the sample. The sample mean of multi-market contact is even higher than that in US airline industry calculated by Singal (1996)<sup>2</sup>. This probably implies that the extent of multi-market contact competition in China's airline industry is even higher. Section IV discusses the regression results and primary findings of this study. Section V concludes and suggests the public policy implications of this study.

## Methodology

### Basic Model

Following Evans and Kessides (1994), this study considers the form expression as below.

$$yield_i = X_i\beta' + Z_i\gamma' + v_i \quad (1)$$

$$\ln(yield_i) = X_i\beta' + \ln(Z_i)\gamma' + \mu_i \quad (2)$$

where  $yield_i$  is the average revenue per passenger-kilometer for all airlines operating schedule passenger service in route market  $i$ , it is the market performance measurement.  $X_i$  is a vector of market characteristics, including the number of competitors, the number of potential competitors, market concentration, and multimarket contact in route market  $i$ .  $Z_i$  is a vector of route technical feature (distance of route, average load factor, average traffic density, annual passenger traffic) and policy factor (guided price, whether or not applies to released pricing policy) in route market  $i$ .  $\beta$  and  $\gamma$  are vectors of coefficients of variables.

### Computation of Variables

#### Dependent Variable: Average Yield

To get the average revenue per passenger-kilometer in route market  $i$ , firstly, we need to calculate the weighted average ticket price in city-pair route market  $i$ , using the price expression (3).

$$P_i = \frac{\sum_{j=1}^{n_i} p_{ij} \times \frac{F_{ij}}{\sum_{j=1}^{n_i} F_{ij}}}{\sum_{j=1}^{n_i} F_{ij}} = \sum_{j=1}^{n_i} p_{ij} \times s_{ij} \quad (3)$$

where  $P_i$  is the average ticket price in route market  $i$  weighted by the market share of each airlines.  $p_{ij}$  is airlines  $j$ 's average ticket price in route market  $i$ .  $F_{ij}$  is airlines  $j$ 's scheduled passenger flights in route market  $i$ , and  $s_{ij}$  is airlines  $j$ 's frequency share in route market  $i$ .  $n_i$  is the number of airlines operating schedules passenger flights in route market  $i$ .

Then the average yield of in route market  $i$ , can be calculated using expression (4).

$$yield_i = \frac{P_i \times lf_i}{Dis_i} \quad (4)$$

where  $yield_i$  is the average revenue per passenger-kilometer in route market  $i$ .  $lf_i$  is the average passenger load factor of all the airlines operating scheduled passenger flights in route market  $i$ .  $Dis_i$  is the distance of route  $i$ .

#### Independent Variables:

**Number of active competitors**  $n_i$  is the number of active airlines in route market  $i$ . Active competitor refer to the company are currently operating scheduled passenger flight on a route market, is also known as incumbent airline.

**Number of potential competitors**  $n_{ip}$  is the number of airlines who are potential entrants of route market  $i$ . Following Morrison and Winston (1990), we define the potential competitor as the airlines that are operating scheduled passenger flight in the origin city, the end point city, or both cities, but not flying the route between the two cities.

Assume that route  $i$  links the city pair  $o$  and  $d$ , and the number of routes between city  $o$  and all other cities and city  $d$  between and all other cities is  $m_o$  and  $m_d$  respectively. Let  $D_{xj}$  be a dummy variable that equals to 1 if airlines  $j$  is operating scheduled passenger flight in route market  $x$ , equals to 0 otherwise. Let  $D_{xyj}$  be a dummy that equals to 1 if airlines  $j$  is operating scheduled passenger flight on both route market  $x$  and route market  $y$ , equals to 0 otherwise. Thus, the number of potential competitors can be calculated using expression (5).

$$n_{ip} = \sum_{x=1}^{m_o+m_d} \sum_{j=1}^{n_x} D_{xj} - \sum_{j=1}^N \sum_{x,y=1}^{m_o+m_d} D_{xyj} - n_i \quad (5)$$

where  $N = \sum_{x=1}^{m_o+m_d} n_x$ ,  $n_{ip}$  is the number of potential competitors in route market  $i$ .  $n_i$  is the number of active competitors in route market  $i$ . On the right side of expression (5), the first term is the total number of airlines operating scheduled passenger flights in city  $o$  and city  $d$  (include repeated calculation), the second term is the number of airlines operating on both route market  $x$  and route market  $y$ . By reducing this term, we delete the repeated calculation and get the number of airlines who are operating on all routes linking city  $o$  and city  $d$ . Reducing the former result by the number of active competitors, we finally get the number of potential competitors in route market  $i$ .

**Market concentration** is Herfindahl-Hirschman Index (HHI) on a route market. Because the route-level output/revenue data of individual airline are not available, we use the weekly frequency of scheduled flights data. Thus HHI can be calculated following expression (6).

$$HHI_i = \sum_{j=1}^{n_i} \left( \frac{F_{ij}}{\sum_{j=1}^{n_i} F_{ij}} \right)^2 \times 10000 = \sum_{j=1}^{n_i} (s_{ij} \times 100)^2 \quad (6)$$

where  $HHI_i$  is HHI in route market  $i$ .  $F_{ij}$  is the weekly frequency of scheduled passenger flights operated by airline  $j$  in route market  $i$ .  $n_i$  is the number of active competitors in route market  $i$ .  $s_{ij}$  is airlines  $j$ 's frequency share in route market  $i$ .

### Multimarket contact (MMC)

Combining the dummy variable presented by Evans and Kessides(1994) and the influential factors presented by Singal (1996), we construct a MMC taking account both company characteristics and route features.

Before the start of calculation, it is worthy to define the market condition and market contact dummy variable for multimarket contact study. Assuming that there are  $n$  individual route markets where  $m$  airlines are operating scheduled passenger flight service. In route market  $i$ , there are  $m_i$  airlines supplying scheduled passenger flight service. However, since most of the airlines operating in more than one route markets, it is easy to know that  $\sum m_i \neq m$ .

Let  $D_{xjk}$  be a dummy variable that equals to 1 if both airline  $j$  and airline  $k$  are operating in route market  $x$ , equals to 0 otherwise. And let  $D_{ijk} = D_{ij} * D_{ik}$ , where  $D_{ij}$  is a dummy variable that equals to 1 if airline  $j$  is operating in route market  $i$ , equals to 0 otherwise.  $D_{ik}$  is a dummy variable that equals to 1 if airline  $k$  is operating in route market  $i$ , equals to 0 otherwise. Thus,  $D_{ijk} = 1$  only if both  $D_{ik}$  and  $D_{ij}$  equals to 1.

Having defined the market condition and contact variable, the multimarket contact index used in this study can be calculated by following three steps:

Firstly, calculate the inter-firm multimarket contact between airline  $j$  and airline  $k$  in route market  $i$  using expression (7).

$$MMC_{ijk} = \frac{D_{ijk}(s_{ij} + s_{ik}) \sqrt{\frac{s_{ij}}{s_{ik}}}}{m_i(m_i - 1) / 2} \times \sqrt{\frac{RP_i \times 100}{RP_{total}}} \quad \text{if } m_i > 1 \quad (7)$$

$$MMC_{ijk} = 0, \quad \text{if } m_i = 1,$$

If  $m_i > 1$ , the contact between two companies in a market  $MMC_{ijk}$  is given by the above expression. On the right side of the expression,  $D_{ijk}$  is the dummy variable discussed earlier. If  $m_i = 1$ , that is, the market is a monopoly, then there

is no contact with another company and therefore multimarket contact  $MMC_{ijk} = 0$ .

In the above expression, this study assume that the importance of multimarket for a market is depend on the following factors presented firstly by Singal(1996): *The number of airlines competing in a route market.* As Singal(1996) mentioned, a contact between two firms in a market with fewer firms is more important than contact between two firms in a market with more firms. Thus, the multimarket contact in route market  $i$  is divided by the number of company-pair in route market  $i$  with  $m_i$  firms  $m_j(m_j - 1)/2$ . *The magnitude of presence of competing companies in a route market.* Since the market contact of two firms with 60% market share is more important than that of two firms with 30% market share, the sum of the two airlines' frequency shares  $(s_{ij} + s_{ik})$  is introduced to take account this effect. *The relative market share of competing airlines in the market.* Contact is more important when the market shares of firms are more dissimilar. This effect is introduced by the square root of the ratio of the frequency share  $\sqrt{\frac{s_{ij}}{s_{ik}}}$  (choose  $j$  and  $k$  such that  $\alpha_j > \alpha_k$ ). *Market size of the route.* Multimarket contact in large markets is likely to be more important to airline than contact in small market. This effect is taken into account by introducing the square root of the percent RPKMs for individual route market  $\sqrt{\frac{RP_i \times 100}{RP_{total}}}$ .

Secondly, by summing the market contact of airline pair  $j$  and  $k$  over all the market the two airlines contact, multimarket contact for an airlines pair, airline  $j$  and airlines  $k$ , is can be calculated. The expression is given by:

$$MMC_{\bullet jk} = \sum_{i=1}^n MMC_{ijk} \quad (8)$$

Thirdly, the multimarket contact of all competing airlines in route market  $i$  is given by:

$$MMC_i = \sum_{jk=1}^{m_i(m_i-1)/2} [MMC_{ijk} (MMC_{\bullet jk} - MMC_{ijk})] \quad (9)$$

The first term in expression (9) represents the multimarket contact between airline  $j$  and  $k$  in route market  $i$ . The second term, in the parentheses, represents the contact between those airlines in all other markets<sup>3</sup>. Summing the total multimarket contact between one airline pair over all airline pair, we get the weighted average airline multimarket contact on route market level.

#### Control Variables

This study concerns two category control variables, route-related control variables and policy-related control variables.

##### Route-Related Control Variables

**Route  $i$ 's distance**  $dis_i$  is introduced to capture the economies of distance in air flight service provision, which is also know as the principle of tapering cost structure.

**Average passenger load factor over route  $i$**   $lf_i$  is introduced to control the effect of plane utilization ratio. The formulation of average passenger load factor in route market  $i$  is given by:

$$lf_i = \frac{T_i}{AS_i} \times 100\% \quad (10)$$

where  $T_i$  is the annual passenger traffic on route  $i$ .  $AS_i$  is the number of total available seats supplied by all competing airlines in route market  $i$ .

**Average density of passenger on a scheduled flight**  $Des_i$  is introduced to capture the cost saving effect of increasing the enplane density of passenger. The formulation of average density is given by:

$$Des_i = \frac{T_i}{Flight_i} \quad (11)$$

where  $T_i$  is the annual passenger traffic on route  $i$ .  $Flight_i$  is the number of annual flights in route market  $i$ .

**Annual passenger traffic on route  $i$**   $T_i$  is introduced to capture the effect of route market size.

##### Policy-Related Control Variables

Currently, China's airlines are subject to a price-ceiling and price floor regulation frame. According to the latest issued price regulation Scheme (SCPC and CAAC, 2004), airlines are allowed to set their fare as low as 55% or as high as 125% of the baseline fare (0.76 per RPKm) set by Civil Aviation Administration of China (CAAC). Aiming at avoiding self-killing price-cut competition, the regulative authority sets and publishes a guided ticket price for the route subject to price limitation. Thus, airlines can set their ticket price in light of the guided price and the market competition.

Besides, the authority has released price regulation on various degrees over some route markets. The first degree is releasing the price floor regulation for 242 routes linking tourist cities and for 225 monopoly routes. The second degree is releasing all the price regulation for 94 regional short-haul routes.

As many researchers have shown that the price regulation in airlines industry can significantly impact the performance and efficiency of the industry (Keeler, 1972; De Vany, 1975; Graham, 1983; Findlay, 1985), this study considers the following regulative policy variable to capture both quantitative and qualitative effect of current regulation policy on China's airlines industry.

**Guided ticket price in route market  $i$**   $Basep_i$  is the price set and published by the regulative authority<sup>4</sup>. This variable is introduced to capture the quantitative effect of price regulation.

**Dummy variable for tourist routes without price floor limitation**  $D_{touri}$  is a dummy variable that equals to 1 if route  $i$  is included in the list of the route that tourists are primary passenger source and implementing released price floor limitation policy (CAAC, ), equals to 0 otherwise. This variable is introduced to capture the qualitative effect of released price floor limitation on tourist routes.

**Dummy variable for monopoly routes without price floor limitation**  $D_{monoi}$  is a dummy variable that equals to 1 if route  $i$  is included in the list of the monopoly routes implementing released price floor limitation policy (CAAC, ), equals to 0 otherwise. This variable is introduced to capture the qualitative effect of released price floor limitation on monopoly routes. Considering the wide differentiation in passenger source and demand pattern between tourist routes and monopoly routes, this study set dummy variable for these two categories of route respectively to capture different effect of released price regulation on different route.

**Dummy variable for regional routes without price limitation**  $D_{freei}$  is a dummy variable that equals to 1 if route  $i$  is included in the list of the route implementing complete market price policy (CAAC, ), equals to 0 otherwise. This variable is introduced to capture the qualitative effect of released price floor limitation on tourist routes.

## The Sample

### Sources of the Sample Data

The sample is obtained from the *Statistical Data on Civil Aviation of China* published by Civil Aviation Administration of China (CAAC) in 2005 (CAAC, 2005, pp59-73). This study chooses 244 routes out of the 248 routes with more than 100 thousands passenger traffic in 2004. 4 routes are excluded from the sample for lack of related fare information<sup>5</sup>.

The ticket price and flight frequency data are obtained from the online ticket inquiry system ([www.airtis.net](http://www.airtis.net)) authorized by CAAC. The ticket data are processed to exclude first-class and business-class ticket. Data used in computation of the dependent variable **average yield**  $yield_i$  and independent variable **Number of active competitors**  $n_i$ , **Number of potential competitors**  $n_{ip}$ , **Market concentration**  $HHI_i$ , **Multimarket contact**  $MMC_i$  are from this data source. The guided ticket price variable  $Basep_i$  is obtained from this data source.

The data used in computation of the control variable **Average passenger load factor over route  $i$**   $lf_i$ , **Annual passenger traffic on route  $i$**   $T_i$  and **Average density of passenger on a scheduled flight**  $Des_i$  are obtained from the *Statistical Data on Civil Aviation of China* published in 2006 (CAAC, 2006, pp59-73). The control variable **Route  $i$ 's distance**  $dis_i$  is obtained from the website of CAAC.

Three dummy variables are set in light of the price regulation policy documents published on CAAC' website ([www.caac.gov.cn](http://www.caac.gov.cn)).

### Descriptive Statistics of the Sample Data

To give an overview understanding of the multimarket contact, market structure and the airline route features, the

paper presents the primary descriptive statistics of the sample in TABLE 2. The sample mean of yield is 0.55CNY/RPKM. Multiplying CAAC's baseline fare (0.76 CNY/RPKM) with the sample mean of passenger load factor (74%) gives a result of 0.564 CNY/RPKM, which is surprisingly close to the sample mean of yield. This coincide author's guess that airlines set price following the guided price. In total, there are 13 airlines competing in the 244 sample route markets. TABLE 2 shows that the number of active competitors ranges from 1 to 6, the HHI ranges from 2229 to 10000. This implies the structure of China's domestics city-pair route market is close to oligopoly and monopoly.

The sample mean of multimarket contact index is 5.77, which is higher than the multi-market contact (ranged from 3.26 to 4.81) in US airline by Signal (1996). This probably implies that the extent of multi-market contact competition in China's airline industry is even more intensive than its counterpart in US. Moreover, among the 244 sample route markets, 226 route markets have non-zero multi-market contact index, which implies that the multimarket contact is exist extensively in China's domestic airline industry.

TABLE 2: THE DESCRIPTIVE STATISTICS OF SAMPLE DATA USED IN MMC REGRESSION

Variables	unit	Sample size	mean	S.D.	minimum	maximum
Average yield	cent/RPKM	244	54.54563	11.07409	35.23231	116.8064
Number of active competitor		244	2.963115	1.123391	1	6
Number of potential competitor		244	5.47541	2.378619	0	10
HHI		244	4724.268	1970.053	2229.081	10000
MMC		244	5.771702	5.714537	0	37.25425
Route distance	km	244	1140.414	594.6387	160	3836
Average load factor	%	244	73.93396	6.00566	47.34734	86.20014
Average traffic density	passenger/flight	244	109.3021	18.61677	39.14576	174.9603
Annual passenger traffic	10 thousand	244	43.27549	45.45944	8.065	434.7942
Guided ticket price	Yuan	244	107.7276	21.41637	43.96848	217.4222

## Results and Findings

Using the sample data, the regression models show in expression (1) and (2) give the results shown in TABLE 3. Model 1 and 2 are in pure linear form, model 3, 4, and 5 are in mixed log-linear form. The  $R^2$  of model 1 and 2 are in the range of 0.60-0.61, which implies about 60% of the effect on average market yield can be interpreted by the pure linear form. The mixed models has slightly better interpretation of 68% to 70%. In terms of the interpretation and F-statistics, all these models can be considered as statistically significant. However, both statistics in mixed log-linear models have higher value (more significant) than those in pure linear models, which might imply that mixed log-linear form interpret the relationship between average market yield and the influential factors better than pure linear form.

The results of the above regression show us the following important points:

### Market structure/concentration is not relevant to higher average market yield

Traditional competition theory presents that high market concentration inclines to foster the market power of firm therefore increase the market price. Many empirical studies also support this theoretical hypothesis (Heggstad and Rhoades, 1978; Scott, 1982; Singal, 1996). This study include 2 variables, the number of active competitors  $n_i$  and  $HHI_i$ , to capture the effect of market structure/concentration on average market yield. As the correlation matrix of sample data in TABLE 4 implies that  $n_i$  and  $HHI_i$  might be highly interdependent with each other<sup>6</sup>, thus should not be included in the regression model simultaneously. The coefficients of  $n_i$  in all models are positive<sup>7</sup>, while the coefficients of  $HHI_i$  are negative, which is contrary to the theoretical expectation. This probably implies that high concentration in China's airline industry do few help to firm's market power, especially under current regulation regime. For instance, airlines are not allowed to give up unprofitable route without the approval of regulative authority, thus some monopoly route market actually have very low average yield (due to low average passenger load factor on these route).

Empirical studies have shown that not only active competitor but also potential competitor can have impact on

market performance (Morrison and Winston, 1990). This study considers the effect of the number of potential competitors  $n_{ip}$ . The coefficients of  $n_{ip}$  are positive, which is also contrary to theoretical expectation, but not significantly in model 1, 2 and 4. This implies that the potential competitor might also be irrelevant currently in China's domestic airline market. As mentioned above, this is largely due to the violations of free market entry and exit assumption.

#### **Multimarket contact might lead to mutual forbearance**

As shown in TABLE 1, most multimarket contact studies have found a negative relationship between multimarket contact and competition rivalry or a positive relationship between MMC and market price or firm's profit. That is, mutual forbearance hypothesis is supported in most researches based on US airlines industry data (Evans and Kessides, 1994; Smith and Wilson, 1995; Singal, 1996; Gimeno and Woo, 1999; Gimeno, 1999). This study include a multimarket contact  $MMC_i$  of route market  $i$ , to capture the effect of multimarket contact. As shown in TABLE 3, the coefficients of  $MMC_i$  are positive and significant at 10% level. Thus, we conclude that multimarket contact can also lead to mutual forbearance in China's domestic airline market. This is also called the "golden rule" conformed by airlines<sup>8</sup>.

#### **Production technology affects average market yield**

As shown in TABLE 3, the route level technology variables are both statistically significant and quantitatively important. The coefficient of route distance  $dis_i$  is significantly negative, which implies that the pricing in China's domestic route market applies the tapering with distance principle. The coefficient of average load factor  $lf_i$  is significantly positive, which implies that increase of load factor does contribute to the increase of average yield. The coefficient of average traffic density  $Des_i$  is significantly positive, which implies that increase of traffic density can lead to increase of average yield. The coefficient of annual passenger traffic  $T_i$  is significantly negative. The annual passenger traffic can be consider as a measure of the demand in a route market, and the average market yield can be consider as a measure of market price, thus, these estimated models can be considered as reverse demand models. Therefore, the negative sign of the coefficient of total consumption quantity implies the air flight service is a "normal good".

It is worthy to mention that, in model 3, 4 and 5, the coefficients of  $ln dis_i$ ,  $ln lf_i$ ,  $ln Des_i$ ,  $ln T_i$  is actually the elasticity of average yield with respect to route distance, average load factor, average traffic density and annual passenger traffic respectively.

#### **Regulation affect average market yield significantly**

The coefficient of quantitative policy variable guided ticket price  $Basep_i$  is significantly positive. This implies that the guided price plays a role of tariff book of leading firm in market competition. Despite of the relatively small net effect in quantity, the published guided price policy did help to restrain sharply price cutting competitions between airlines.

The coefficient of dummy variable for tourist routes without price floor limitation  $D_{touri}$  is significantly negative. This implies that the 52 routes applying to this policy dummy in the sample have lower average yield comparing those route with price floor limitation. These routes are characterized by linking hot tourist city and creating high annual traffic. Released pricing regulation will encourage the airlines take more flexible price policy (more discounted ticket) and increase their revenue.

However, another dummy variable related to 8 monopoly routes applying to released price floor limitation  $D_{monoi}$  is not significant. This implies that released price floor policy hardly impact the monopoly route markets as the monopolist has little motive to cut price, thus this variable is not included in the final regressions.

The coefficient of dummy variable for regional routes without price limitation  $D_{freei}$  is significantly positive. This implies that the 17 routes applying to this policy dummy in the sample have fairly higher average yield comparing those routes with price (ceiling and floor) limitation. Considering that the routes applying to free market policy are characterized by short distance, regional operating, monopoly or few suppliers, it is reasonable that airlines in these route markets generally can increase their revenue by increasing price. Therefore, the effect of totally releasing price regulation (both price floor and price ceiling) increases the average market yield significantly and largely in regional route markets.

The above findings related to the price regulation and deregulation policy in China's domestic airline markets surprisingly coincide with the case in US airline industry. Despite many studies show that deregulation in US airline

have led to fare decrease in trunk routes (Hurdle et al., 1989; Kim and Singal, 1993; Liu and Lynk, 1999), researcher finds that price increased in some small regional routes after the deregulation (Morrison and Winston, 1990).

## **Conclusions and Policy Implications**

By using data from China airlines industry, this paper includes both external market features (multi-market contact) and internal market features such as concentration, production technology factors, and regulation policy factor in the regression models. The results show that mutual forbearance hypothesis can be supported by China's domestic trunk airline route sample. The internal market factors are also identified and found to be consistent with the theoretical expectations. The only exclusion is that the theoretical expectation of concentration can not be supported by this sample.

Based on the above analyses, the paper concludes the following policy implications:

Firstly, as shown in this study, there are observable positive relationship between multimarket contact and higher average yield, though the net effect is relatively low. In real economy, the case that incumbent firms can restrain the price-cutting action by threatening to retaliate in challenger's key market is general. As diversification becoming one of the most significant factors restructuring the global economy, multi-market contact is universal in market competition. Economists have appealed to attention from the antitrust policy authorities (Singal, 1996). Currently, Chinese government is drafting the country's first antitrust law, the study suggest that the multi-market contact effect should be taken into consideration in evaluating effect of firm's competition action (consolidation). However, the negative relationship between the price level and concentration in this study suggests that the concentration (market share) should not be considered as the only measurement in anti-trust practice.

Secondly, this study suggests that regulation have significant and important effect on airlines competition action in China domestic airline route market. The guided price policy is helpful in restraining sharp price cutting competitions between airlines. The net effects of releasing price regulation and totally releasing price regulation will depend on route market characteristics involving supply structure, demand pattern and operating features. For non-monopoly tourist route market, the market average yield can be reduced and consumer welfare can be improved by releasing price floor regulation policy. For monopoly "small route" market, since the average market yield will increase by releasing price ceiling distinctly and might be harmful to the consumer welfare.

## End Notes

<sup>1</sup> as quoted in Heggstad and Rhoades (1978), pp524.

<sup>2</sup> Since this paper takes a similar method in multi-market contact calculation to that of Singal (1996), the comparison of multi-market contact indices between two country can be meaningful.

<sup>3</sup> Only if both terms are non-zero, does this pair of airlines contact contribute to multimarket contact for the route market  $i$ .

<sup>4</sup> Civil Aviation Administration of China is currently the primary regulation authority of China's airlines. The regulation is in two folds, price and market entry. In terms of price regulation, the published guided ticket price is an important measure. The ticket price on a route is calculated according to a generalized formula: Price = minimum price + fare\*distance. The minimum price is currently set at 80 yuan for all scheduled routes. Thus the real ticket price will be decided by the fare and discount applied. For example, the economic class ticket price from Beijing to Shanghai can be calculated from:  $1178(\text{distance}) * 0.76(\text{fare}) + 80(\text{minimum price})$ , that is 975.28. When passenger go to the ticket office, he/she will get a ticket at discounted price plus tax and oil adjust charge.

<sup>5</sup> Those four routes are excluded from the study are Urmuqi-Korla, Chengdu-Panzhihua, Urmuqi-Altay and Kunming-Diqing.

<sup>6</sup> In some case, the number of average firms can be calculated from the HHI, by the equation  $n = \frac{100}{\sqrt{HHI}}$ . where n represents the number of average firms. Thus these two measures are inversely interdependent.

<sup>7</sup> In model 1, we can't reject the coefficient equal to zero significantly.

<sup>8</sup> According to Evans and Kessides (1994), there is a claim that airlines live by the "golden rule", i.e., that airlines refrain from initiating aggressive pricing actions in a given route for fear of what their competitors might do in other jointly contested routes.

# Crisis Risk Management in Transportation Sector: Trends and Framework

Arvinder Loomba, [loomba\\_a@cob.sjsu.edu](mailto:loomba_a@cob.sjsu.edu)  
San José State University, USA

## Abstract

As the business environment in the transportation sector gets more complex, crises risks faced by management are far more frequent, and potentially, more devastating. Globalization, new technologies and economic growth have produced time-space compression: as distances shrink, people and goods travel faster and farther, communication networks become more complex and indispensable, and technological advances spill over from one domain into another almost effortlessly. These developments come at an obvious price tag. Complexity runs amuck and couplings between system components become tighter and tighter, turning the world into error-inducing systems. Not only are the risks of mishaps increasing, they are more likely to become crises and even escalate into full-fledged disasters. In this paper, we investigate risks leading to crises in the transportation sector. We specifically review the trends in the transportation sector around the globe and develop a framework for addressing crises risk in a systematic manner.

## Introduction

As the business environment in travel and transportation industry gets more complex, risks of crises faced by management are far more frequent, and potentially, more devastating. Globalization, new technologies and economic growth have produced time-space compression: as distances shrink, people and goods travel faster and farther, communication networks become more complex and indispensable, and technological advances spill over from one domain into another almost effortlessly. These developments come at an obvious price tag. Complexity runs amuck and couplings between system components become tighter and tighter, turning the world into error-inducing systems. Not only are the risks of mishaps increasing, they are more likely to become crises and even escalate into full-fledged disasters

Much like the marked change the species undergo as posited in the theory of punctuated equilibria, organizational crises have the potential to knock organizations away from their equilibria. This shift can either be attributed to abrupt crises that strike suddenly and catch management off-guard or cumulative crises that accumulate stressors and eventually erupt. Either way, crises are manifested risks with impending negative consequences for the organizations. Over the past several decades, crisis risk management has been gaining recognition as a critical business practice in governments and industries across the globe. In the transportation sector, the overarching objective risk management is to mitigate (or even prevent) accident likelihood and severity. In contrast, the goal of crisis management is the containment of such accidents, disaster recovery, subsequent learning from crises, and business continuation.

Risks in general are idiosyncratic—they can have either a cancelling effect (a risk to one group may present an opportunity to another) or a compounding effect (a risk to one group may lead to a risk to another). The qualification of global risks lies in their systemic nature: their impacts challenge the integrity of the system. The consequences of these risks are harder to predict, frequently disproportionate, difficult to contain and present challenges to us all.

Overall, the Global Risk Network identified 23 core global risks to the international community over the next 10 years in the recently published Global Risks 2007 Report (World Economic Forum, 2007). These core global risks are presented in Table 1. Although it is quite conceivable that some of these risk categories may have cancelling effect with other categories, most of the core risks identified in the report generally have a compounding effect when it comes to impact on transportation sector-related crises risks. For this reason, review of transportation sector related risks that have the potential for becoming full-fledged crises is critical to the long term success of the sector in general and the survival of most of the companies in the transportation industry in particular.

Modern realities of transportation sector usually are quite complex, with many parallel physical and information flows occurring in order to ensure that products are delivered in the right quantities, to the right place in a cost effective manner. Recent business trends like outsourcing, globalization and business fragmentation created the need for tackling the issue from the point of view of the entire transportation industry rather than the limited view of an individual company. On the other hand, advances in information technology have encouraged real time information sharing, coordination and collaborative decision making among companies. Today an emerging and challenging research area, given the importance of crises risk management in practice, focuses on disruptions to transportation from various directions. Transportation crises can arise from many sources, often without warning, exposing the whole transportation network to various types of risks. For example:

- Natural disasters (e.g., the Kobe earthquake in 1995 and, more recently, Hurricane Katrina in 2005 had supply chain impact of global proportions);
- Terrorist incidents (e.g., events of September 11, 2001 in the US);
- Industrial or direct action (e.g., the west coast port strike by ILWU workers in 2002, which severely impacted literally every US supply chain);
- Accidents (e.g., a fire in a component’s sole supplier in Aisin, Japan had a serious impact on Toyota’s operations and supply chain in 1997);
- Operational difficulties (e.g., US flu vaccine shortage in late 2004 due to Chiron, a vaccine maker, that was unable to produce half of U.S. supply of vaccine doses due to problems at its British plant);
- Informational difficulties (e.g., the Cisco failure to process information from its supply chain about the severity and abruptness of the sales slowdown that led to the \$2.5 billion excess inventory charge in 2001);
- Macro-level Transformation in Industry and Competition (e.g., the recent wave of offshoring jobs to China and India, gaining worldwide attention in early 2000, and its resulting changes in organizational supply chain that ensued).

Owing to the close interrelationships between entities operating within a transportation network, the impact of such disruptions can be far reaching.

## **An Ecological View of Transportation-related Crisis Risk**

The fundamental tenet of the theory of punctuated equilibria in biology is that punctuated changes dominating the evolution of life typically come about through shocks that are spontaneous or that occur at the threshold-limit of slowly evolving changes Gould and Eldredge (1977). The risk of breakdown of equilibrium has two specific sources—catastrophic events that appear suddenly and breaks with the past that result from the steady accumulation of stressors. The punctuated equilibrium model has wide implications across disciplines as evidenced by the largely independent emergence of punctuated equilibrium models in biology (Gould, 1989), sociology (Kuhn, 1970) and psychology (Levinson, 1986), and at several levels of organizational theory analysis, such as groups (Gersick, 1991) and organizations (Miller and Friesen, 1984; Tushman and Romanelli, 1985). In the literature of organizational transformation, for example, it emerged as a prominent theoretical explanation for characterizing and investigating fundamental organizational change (Miller and Friesen, 1984; Tushman and Romanelli, 1985; Gersick, 1991).

Much like the marked change the species undergo as posited in the punctuated equilibrium model in biology, transportation sector-related crises risks have the potential to shift industries and transportation networks away from their equilibria. These shifts can either be attributed to risks of abrupt crises that strike suddenly and catch management off-guard or of cumulative crises that accumulate stressors and eventually erupt. Two sources of transportation sector-related crises risks can be identified—abrupt crises that strike suddenly and catch management off-guard versus cumulative crises that accumulate stressors and eventually erupt. For example, a crisis may result from an abrupt event necessitating a corresponding response from the organization (examples: Hurricane Katrina in 2005, the west coast port strike in 2002, the fire at one of the Toyota's sole supplier in 1997, etc.). Alternatively, a crisis may be the consequence of slow changes with little or no response evoked from the organization (examples: US flu vaccine shortage in late 2004, Cisco inventory debacle in 2001; offshoring jobs to China and India, starting in early 2000). Either way, crises are manifested risks with impending negative consequences for transportation networks. Over the past several decades, crisis risk management has been gaining recognition as critical transportation best practices in industries across the globe.

Risk can be viewed as the product of frequency multiplied by consequence. That means a high-frequency/low-consequence event, such as the regular fluctuation of currency exchange rates, can be viewed as similar to a low-frequency/high-consequence event, such as the September 11<sup>th</sup> terrorist attack. A scientific definition of risk was provided by the Royal Society (1992): "The probability that a particular adverse event occurs during a stated period of time, or results from a particular challenge. As a probability in the sense of statistical theory, risk obeys all the formal laws of combining probabilities." Another consideration is the nature of risk mitigation itself, which is illustrated in Figure 1 (Crisis Comprehensive Risk Analysis and Management Network, 2007).

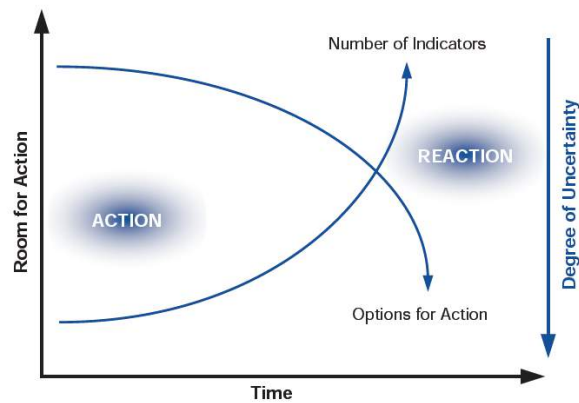

FIG. 1: RISK MITIGATION  
 (Source: Comprehensive Risk Analysis and Management Network)

It is interesting to note that as time progresses, the information surrounding a given risk event may increase. But as it does, the options available for effective mitigation are bound to reduce. Risk mitigation—as with risk itself—involves certain degrees of uncertainty. As illustrated in Figure 1, taking proactive mitigation policies implies operating under considerable uncertainty, with incomplete indicators.

In the transportation sector context, failing to understand the potential vulnerabilities can compromise the transportation networks' ability to handle unexpected and sudden crises. Indeed, it can be argued that transportation sector-related risk is currently greater than ever. A key source of risk is the increasingly turbulent business environment. A further reason for this increased risk has come, paradoxically, from the focus on efficiency and cost reduction, which have been the predominant managerial tendency of recent years. Of course, not all transportation networks are exposed to the same types and magnitude of risks. This is largely dependent on a number of factors, which include industry specific factors (i.e. volatility of demand, product variety etc), as well as characteristics of individual transportation networks (i.e. number of nodes, local vs. global operations, etc).

In order to be able to manage and even take advantage, of internal and external uncertainty, today's firms should understand and quantify transportation sector-related risks. Therefore, there is a need for developing risk management framework that will assess and managing transportation sector-related risks. This is a necessary task before formulating and implementing risk prevention and learning strategies in transportation sector for the future.

The rest of the paper is organized as follows: first, a detailed literature review on best practices on transportation sector-related (and, generally speaking, supply chain) risk assessment and management is presented. Then, a framework for managing transportation sector-related risk is offered. Finally, conclusions and further research issues are mentioned. The purpose of this paper is to introduce this framework and initiate a discussion of several research initiatives among transportation community in an effort to operate recommendations of the risk management framework in organizational strategy making.

## Literature Review

When reviewing the literature on transportation sector-related risk management, it is apparent that two major research streams are dominant. One contains conceptual exploratory research and the other is mathematical modeling. The following literature review is based on that distinction, as well as on the type of risk each research attempts to deal with.

### Sources and Types of Supply Chain Risks: Managerial Tools for Risk Management

A number of articles as well as scientific papers deal with the appropriate identification of supply chain risks, the main sources of uncertainty that lead to risk exposure and the business processes or management tools that can be

used for mitigating those risks. Landeghema and Vanmaele (2002) study the impact of uncertainty on demand and supply chain planning and list a number of potential sources of supply chains/transportation-related risks. This provides the basis for introducing a new tactical planning paradigm, called robust planning.

Chopra and Sodhi (2004) stress the importance of proactively managing supply chain and transportation sector-related risk, taking into account the fact the related difficulty due to the interconnection of individual risks. Companies may mitigate risk by building various forms of reserves including inventory, capacity, extra suppliers transportation contingency planning, and responsiveness.

Hallikas et al. (2004) identify challenges that transportation network cooperation brings to risk management. When the dependency between companies in a transportation network increases, they become more exposed to the risks of other companies. The paper also outlines the general structure of risk management process and presents methods for risk management in a complex transportation network environment. Harland et al. (2002) provide a review of definitions and classifications of types of risk in transportation/supply chain networks and offer a holistic view of risk assessment and management. They also describe a tool to help identify, assess and manage that risk. Finally, Zsidisin et al. (2004) focus on inbound transportation risk. The purpose of their study was to explore, analyze and derive common themes on transportation-related risk assessment techniques in supply chain environment.

#### **Case Studies and Surveys**

Another class of papers / articles uses case studies or surveys from particular industry sectors to analyze risk in supply chains. Wang et al. (2004) use data from the U.S. bicycle industry to examine the relation among product variety, supply chain structure, transportation networks, and firm performance. Johnson (2001) takes the example of toys industry to contribute to risk management in supply chains and transportation networks. Constant product innovation, short life cycles and high cannibalization rates are typical in the toys industry. Based on those types of risks, he proposes strategies to mitigate both demand and transportation-related risks.

#### **Models Dealing with Supply Side Risk in Transportation**

As the degree of reliance on the suppliers is accelerating and the physical supply/transportation cost can easily account for 30% of the total cost of goods sold, efficient management of the supply-side risks may contribute significantly to ultimate supply chain success. Bergera et al. (2004) present a useful way to think about the number of suppliers needed in the presence of risks. They model the decision-making process using a decision tree approach and consider catastrophic, “super-events,” which affect many/all suppliers, as well as “unique events” that affect only a single supplier. Wang et al. (2004) propose a product-driven supply chain selection process using integrated multi-criteria decision-making methodology.

Kamrad and Siddique (2004) use a real options approach to analyze and value supply contracts in a setting characterized by exchange rate uncertainty, supplier-switching options, order quantity flexibility, profit sharing and supplier reaction-options. Finally, Babich (2004) presents a valuation of inventory-reorder options in a competitive environment with suppliers that may default.

#### **Models Dealing with Flexibility in Operations and Processes**

One field of research that is connected to risk management and increased responsiveness to demand side changes/disruptions is the implementation of commonality and postponement in transportation networks. In a manufacturing–distribution system, a considerable portion of the risk and uncertainty costs is due to differentiation in form, place and time. Postponement of the point of differentiation is an important means to reducing or eliminating this risk and uncertainty. Alderson (1950) was the first to analyze the concept of postponement in marketing literature while Dogramaci (1979) provided an early study of component commonality from a risk pooling perspective. Both concepts are now attracting renewed attention as companies are compelled to provide and manage an increasing product variety and to compete in organizational excellence in a global market. Zinn (1990) draws attention to the principle of risk pooling. He states that the number of modules may be smaller than the number of finished products due to commonality, reducing in this way the inventory holding risk. This has interesting implications to transportation networks in terms of cost savings by improved routings.

In that respect, Van Hoek (2001) provides an interesting literature review on postponement research and suggests directions for future research. He identifies postponement opportunities in operations as a respond to uncertainty and as a tool to reduce risk of volume and variety mix by delaying finalization of products. Ma, Wang

and Liu (2002) studied commonality and postponement in multistage assembly systems. They demonstrate analytically whether introducing commonality at a particular stage or delaying the point of differentiation by one more stage can be justified. Finally, Ernst and Kamrad (2000) introduce a conceptual framework for evaluating different supply chain/transportation structures in the context of modularization and postponement.

**Supply Chain Network Models (taking risk into account)**

It is interesting to mention two supply chain/transportation network models that deal with risk management. Nagurney et al. (2004) develop a transportation network model in which both physical and electronic transactions are allowed and in which supply side risk as well as demand side risk are included in the formulation. Blackhurst et al. (2004) propose a network-based methodology to model and analyze transportation systems in supply chains. The methodology represents the operation of a supply chain as an abstracted transportation network. The approach allows for the inclusion of stochastic variables so that uncertainty in transportation networks can be modeled.

**Supply Chain Risk Management Framework**

Based on the transportation sector-related risks classification provided earlier, strategies to manage these risks can be laid out. One way is to company strategies across two dimensions: (i) System Instability and (ii) Network Option Variety.

Instability is the extent to which a supply chain faces rapid, uncontrollable changes or unpredictable conditions that threaten performance and customer fulfillment reliability, i.e., that threaten the task of balancing demand and supply. A clear example of high instability are the times for which a large part of the forecasted demand had not been scheduled in advance, which means that actual supply chain flows are unpredictable and transportation bottlenecks will have to be dealt with at the last minute. Additionally, any loss of transportation capacity can introduce instability into the system.

Options variety is the amount of transportation resources, including strategies, available to the decision makers in the transportation sector to respond to events in the system in order to keep demand and supply balanced at any specific period in time. It includes the available operating reserves and other transportation capacity, and the degree to which the system is capacity constrained. High option variety means, for instance, that the transportation network has available to it a range of resources and can operate well within its control. Low options variety means the resources are outside its control and, ultimately, that very few resources are left and the transportation network must operate close to, or even in violation of its constraints.

These two dimensions together set the conditions under which a transportation network has to pursue its high performance and customer fulfillment reliability. We posit four different performance modes for managing risks and achieving high performance in transportation network, which are termed: just-in-case, just-in-time, just-for-now, and just-this-way. Based on this the proposed transportation-related risk management framework is present in Figure 2. ‘Low’ and ‘high’ are obviously imprecise terms, though they are the terms used and commonly recognized by transportation practitioners. In practice, the system instability and options variety dimensions should be better thought of as continuum without rigid high/low cut-off points.

**Four Performance Modes**

We now provide a brief description of each transportation-related crisis risk management modes that are presented in framework in Figure 2. Similar frameworks have been applied in other industry area such as electrical utility systems (Lawrence Berkeley National Laboratory, 2006).

		<i>System Instability</i>	
		<i>High</i>	<i>Low</i>
<i>Network Option</i>	<i>High</i>	<i>Just-in-Time Performance</i>	<i>Just-in-Case Performance</i>

<i>Variety</i>	<i>Low</i>	<i>Just-for-Now Performance</i>	<i>Just-this-Way Performance</i>
----------------	------------	-------------------------------------	--------------------------------------

FIGURE 2: PROPOSED CRISES RISK MANAGEMENT FRAMEWORK

**Just-in-Case Performance**

When options are high and instability low, just-in-case risk management approach in transportation networks is dominant in the form of high redundancy. Reserves available to the transportation practitioners are large, excess capacity exists at all levels: transportation options are abound throughout the supply chain, and the consumer demand can be as much as forecasted with little or no unpredictability and/or uncontrollability. More formally, redundancy is a state where the number of different but effective options to balance demand and supply is high, relative to the market and technology requirements for balancing demand and supply. There are, in other words, a number of different options and strategies to achieve the same balance. The state of high redundancy is best summed up as one of maximum equifinality, i.e., a multitude of means exist to meet the reliability requirement.

**Just-in-Time Performance**

When options and instability are both high, just-in-time risk management approach in transportation networks is dominant. Option variety to maintain demand and supply remains high, but so is the instability of system variables, in both markets (e.g., rapid product/service price fluctuations leading to unexpected strategic behavior by market entities—refer ‘bullwhip’ effect in supply chain) and technology (e.g., limitations of transportation, and information-related tools).

This risk management approach demands ‘real-time’ flexibility, that is, the ability to utilize and develop different options and strategies quickly in order to balance demand and supply. Since decision makers in transportation networks are in constant communication with each other and others in the supply chain, options are reviewed and updated continually, and informal communications are much more frequent. Flexibility in real-time is the state where the managers are so focused on meeting transportation system performance and customer service reliability requirements and the options to do so that more often than not they customize the match between them, i.e., the transportation network options are just enough and just-in-time. The fact that the instability is high focuses manager’s attention on exactly what needs to be addressed and clarifies the search for adequate transportation network options and strategies. What needs to get done gets done with what is at hand as it is needed.

More formally, the state of real-time flexibility is best summed up as adaptive equifinality: There are effective alternative options, many of which are developed or assembled as required to meet the performance and reliability criteria. The increased instability in system behavior is matched by the flexibility in the focal organization in using network options and strategies for keeping performance within reliability tolerances and bandwidths. An important point to note is that substitutability of options and strategies is high for just-in-time performance.

**Just-for-Now Performance**

When option variety is low but instability is high, just-for-now risk management approach in transportation networks is dominant. Options to maintain demand and supply have become visibly fewer and potentially insufficient relative to what is needed in order to balance demand and supply. This state could result from various reasons related to the behavior of the open transportation network system.

Risks of unexpected shortages can occur, demand may increase to the physical limits of supply capacity; and the use of some options can preclude or exhaust other options, e.g., work overtime to supply chain fulfillment through the transportation network. In this case, unpredictability or uncontrollability has increased while the variety of effective options and strategies is diminished. Here, ‘transportation-related crisis risk management’ begins to come into play, e.g., the transportation network crisis may compel an manager to go outside official channels and call his counterpart at a vendor or a warehouse, who agrees to keep the deliver production unit, just-for-now.

More formally, just-for-now performance is a state summed up as one of maximum potential for ‘deviance amplification’: Even small deviations in elements of the market, technology or other factors in the system can have ramifications throughout the system. Marginal changes can have maximum impact in threatening the transportation networks performance and customer service reliability requirements. From the standpoint of reliability, this state is untenable. Here transportation entities have no delusions that they are in control. They understand how vulnerable

the transportation networks is, how limited the options are and how precarious the balance; they are keeping communication lines open to monitor the state of heightened crisis in the transportation networks; and they are busily engaged in developing options and strategies to move out of this state. They are not panicking and, indeed, by prior design, they still retain the crucial option to reconfigure the transportation networks system itself.

Just-for-now performance is also very fast paced and best summed up as ‘firefighting.’ When options become few and room for maneuverability boxed in (e.g., when demand continues to rise while new supply become much less assured and predictable), transportation managers become even more focused on the big threats to balancing demand and supply. As options become depleted, wraparound managers in the transportation networks come to pitch in and there is less need for lateral, informal relations across the transportation networks.

#### **Just-this-Way Performance**

In this last performance mode for balancing demand and supply, system instability is lowered to match low options variety and just-this-way risk management approach in transportation networks will be dominant. This risk management state occurs as a short-term ‘emergency’ solution. In a critical transportation crisis, the option is to tap down instability directly with the hammer of risk management crisis controls and forced network reconfigurations. The ultimate instrument of crisis management strategy is the declaration of heightened transportation crisis, which requires interruption of firm future orders and capacity allocations in order to bring back the balance of demand and supply from the brink of just-for-now state. The effect of heightened transportation crisis recognition is to reconfigure the transportation networks into a system under command and control management, as much as possible. Options to offset demand can be explored by checking with vendors and competitors, offering rain checks to customers or even turning them away.

More formally, just-this-way performance is a state best summed up as one of zero equifinality: Whatever flexibility could be squeezed through the remaining option and strategies is forgone on behalf of maximum control of a single system variable, in this case load. The effect of heightened transportation crisis recognition has become both a necessary and sufficient condition for balancing demand and supply, again by offsetting the demand directly through alternative supply sources. This contrasts significantly with the other three risk management approaches. There the options and strategies are sufficient, without being necessary. Under “just-this-way” risk management approach, the decision to offset demand has been taken and now information is centered on immediate survival. The vertical relations and hierarchy of an organization are expected to extend across the transportation network—like a *keiretsu*—even to the customer fulfillment entities in form of product shortages, if needed. Formal rules and procedure move centre stage, including the recognition of critical transportation crisis by all entities. Here the entire transportation network ought to perform as one organization.

## **Conclusions and Directions for Future Research**

Today an emerging and challenging research area, given the importance of transportation in practice, focuses on disruptions to transportation networks from various directions. Indeed, it can be argued that transportation-related risk is greater now than ever. Therefore, there is a need for developing standard risk dimensions that will enable a simple and useful process for identifying risks. This is a necessary task before formulating and implementing strategies and developing analytical models for risk management in transportation networks.

After having understood, assessed, and categorized risks in transportation networks, the next research issue emerges from the need to explore how risks are identified and managed in practice and whether flexibility, as proposed by the analytical models presented in the literature review, is the appropriate way to deal with it. Will the framework for transportation-related risk management proposed in this paper be applicable to real-life industry/transportation networks-related environment? It would be interesting as a second step to test and verify the developed framework in practice by conducting an appropriate empirical study. As far as modeling transportation network uncertainty is concerned, deterministic planning models, which do not recognize the uncertainty in the future demand, supply or production yield, can be expected to result in inferior planning decisions as compared to models that explicitly account for this uncertainty. Probability considerations are inherent to risk by definition. Therefore, the majority of analytical models related to transportation risk take into the stochastic nature of the

included variables. Techniques such as multi-criteria optimization or stochastic programming are applicable here. We have also come across stochastic dynamic programming models and use of techniques of stochastic control theory. Decision trees as well as Simulation, such as Scenario Techniques (Comprehensive Risk Analysis and Management Network, 2003), have also been used to model risk in the transportation networks context.

Given the large number of real options associated with transportation networks, quantitative techniques could be used to arrive at optimal exercise (operating) decisions, as well as to assess the overall impact of the option portfolio on the value and risk exposure of the company. Real options can be created and the value of existing options enhanced, by redesigning investment and operating strategies along two dimensions: timing and scope. On the temporal dimension, options are created by postponing investment or operating decisions in order to make them in a more “informed” manner. The scope dimension involves introducing an array of choices, such as different product configurations or suppliers, which creates an option to choose what turns out to be the value-maximizing alternative in the future and in each case<sup>1</sup>.

# HRM Practices and Service Quality in the Hospitality Industry

*Andreas W. Gunawan Putra, putra@hotmail.com;andreas@fe.trisakti.ac.id  
Trisakti University / CV Jasa Utama, Indonesia*

## Abstract

Globalization is preoccupying industry practitioners and scholars in interrelated fields of the tourism and hospitality industry, particularly the hotel sector. Consequently, a number of printed texts that focusing on human resources management (HRM) in the international context of the industry appears growing steadily. The nature of HRM and the extent as to which it is adopted by the industry is examined. The literature concerning HRM and performance in the hotel sector is reviewed and its connection to in the hotel sector is discussed. This paper reviewed a study conducted by Haynes and Fryer (2000) in identifying elements of the HRM practices which best meets the demands of, particularly, the hotel sector operators, which provides more a customized service offer. Further, the paper was using secondary data to explore the application of HRM in the hotel sector. The need for further research is suggested.

## Introduction

People are believed to be one of the greatest costs and also the main assets of many organisations particularly in the hospitality industry. The extent of an organisation' success in terms of its survival and competitive position is determined by employees' qualities, attitudes and behaviour in the workplace. For example, the hospitality industry can no longer gain competitive advantage through technologies, companies' brand image, and physical facilities, but instead must focus on the quality of service provision to customers. It is for this reason, managing of people has become critical and imperative for the hospitality industry as more emphasise has been placed on service quality. As Alleyne, Doherty and Geenidge (2006) pointed out the hospitality industry (e.g., the hotel sector) is labour intensive and this makes it particularly important that it develops effective human resource practices and policies to achieve competitive success.

The hospitality industry particularly the hotel sector is expected to expand rapidly (Foroohar, 2002). For example, between 1991 and 1995, the hospitality industry, particularly, international tourism grew from 450 million international tourists to 567 million (Weaver, 1998 cited in Black, Ham, and Weiler, 2000) and it is estimated that international tourist arrivals will double between 1990 and 2010 (Black et al. 2000). Growing tourist arrivals can assist many nations to develop their economy (Cetron, 2001; Ramirez and Hartel, 2001). The hospitality industry generated US \$445 billion dollars in 1999 (WTO, 1999 cited in Ramirez and Hartel, 2001) and has also enabled many countries to improve their national economy. Consequently, it has become the most important legally conducted business in the world (Ramirez and Hartel, 2001). Indeed, the tourism and the hospitality industry is one of the most important job creators in the world (Cetron, 2001; Ramirez and Hartel, 2001; Affolter, 2001). In addition, the rapid development and widespread international adoption of information technologies has resulted in competition in the hospitality industry particularly the hotel sector being focused on the effectiveness and efficiency of systems and processes (Lazarevic and Terziovski, 2000). Thus, the effective of managing of people in the hospitality industry is imperative to consistently delivery of excellent service. This paper seeks to understand the extent of the adoption of Human Resource Management (HRM) applications and the need of the development of HR functions in order to provide service quality in the hospitality industry.

### Literature Review of HRM

As According to Nankervis, Compton and McCarthy (1999: 4) "early employee specialists were called personnel managers (or personnel administrators) and their main tasks are comprised of a set of activities such as recruitment, selection, training, salary administration and industrial relations". Kelliher and Johnson (1987 cited in Worsfold, 1999), in their original survey of all UK hotels found that in small hotels the responsibility of personnel management

was to recruit and select staff, whereas in larger hotels the situation was expanded to also include wider responsibilities, such as using written contracts, disciplinary procedures and equal opportunity policies.

There has been considerable debate as to whether HRM differs significantly from personnel management (Worsfold: 1999). As Nankervis et al. (1999: 4 - 5) argue personnel management activities (e.g., recruitment, selection, training, salary administration, and industrial relations) are “often performed effectively but with little relationship between the various activities, or with overall organisational objectives”. More recently, the concept of HRM has influenced professional practice which assumes that all personnel management activities are integrated with each other, and strategically with organisational objectives (Nankervis et al., 1999; Nankervis, Compton, and Baird 2002). Nankervis et al. (2002) argue that, in essence, HRM differs from earlier personnel management activities in relation to its focus, its principles, and its applications. Thus, as Nankervis et al (2002: 14) argue “the focus of HRM today is on the effective overall management of an organisation’s workforce in order to contribute to the achievement of desired objectives and goals, thus, all HR functions (e.g., recruitment, HRD, performance appraisal, and remuneration) are seen to be integrated components of overall HRM strategies”. This view is extended by Alleyne *et al* (2006) that HR practices consist of selective hiring, extensive training, employment security, diffusion of information, team working, reduction of status differences, performance related and incentive pay. In recent times, Alleyne *et al* (2006) argue there has been a debate about the differences between Industrial Relations / Personnel Management (IR / PM) and HRM as distinctive approaches to the management of people. Even further, Alleyne *et al* (2006) using the term of “unitarist frame of reference” (closely linked to individual as opposed to collective forms of management), alignment between organisational strategy and the way people are managed, a belief that people are key to competitive advantage which emphasise on flexibility and the utilisation of HR techniques which are intended to engender employee commitment. In addition, Alleyne *et al* (2006) coin the term of “best practice” that tends to be individualistic in terms of national culture, resistance to trade unions, the importance of building employee ability through good recruitment and training, strong role of financial incentives, and the value of enabling the employees to contribute their ideas through work design and employee participation; and “best fit” which seeks to have some *fit* between an organisation’s HRM policies and practices and its overall competitive strategy or position. Furthermore, Schuler and Jackson (1987 cited in Alleyne *et al*, 2006) expanded the term of external fit which is defined as situations where there is an integration of the HR systems with business strategy and the proposition that aligned HR system will perform best. On the contrary, Hoque (1999b cited in Alleyne *et al*, 2006) use the term of internal fit which refers to the synergistic benefits resulting from the introduction of HRM the introduction of HRM as an institutionally supported package of practice that cohere with and mutually reinforce each other. A study conducted by Huselid (1995 cited in Alleyne *et al*, 2006) in the US found a significant relationship between internal fit and employee turnover, productivity and organisational performance but insignificant relationship between external fit and the same performance measures.

#### **HRM in the Hotel Sector**

Increased competition in both national and global arenas has forced managers to reconsider the management of all resources within the organization, paying specific attention to the effective management of the human resource, leading to declarations such as ‘people are our most valuable asset’ (Biswas and Cassell,1996). The shift from traditional personnel management towards a more sophisticated human resource management has been reported extensively in recent years (Storey, 1989; Legge, 1989; Guest, 1989). Guest (1989) identifies the central levers for HRM as selection, training and rewards. As Goss (1994) considers, however, that the main features of a human resource management network include additional features such as welfare, trade unions, assessment, employee involvement and equal opportunities. A further and essential feature of the HR practices is that it is intended to be strategic in nature. Sophisticated human resource management practice stipulates that in order to be effective the HR activities of an organisation must be linked to an overall corporate strategy (Nankervis et al., 1999 and Nankervis et al., 2002) and that the business direction of the organisation must be reflected and supported by the HRM techniques adopted (Biswas and Cassell,1996).

Before discussing human resource strategies in the hotel sector it is useful to offer an insight into the unique characteristics shared by service industries. Sasser, Olsen, Wyckoff (1978 cited in Biswas and Cassell, 1996: 19) describe four main characteristics which render the sector as fundamentally different from manufacturing industries, namely “simultaneity; heterogeneity; intangibility; and perishability”. According to Sasser et al., (1978

cited in Biswas and Cassell, 1996: 19) simultaneity refers to “production and consumption of services; clearly these occur simultaneously”; for example, a meal in a restaurant is consumed as part of the process of the whole event, immediately after it has been prepared and while the consumer and producer are in close proximity, unlike manufacturing where the producer may be thousands of miles from the consumer. As said by Sasser et al., (1978 cited in Biswas and Cassell, 1996: 19) heterogeneity describes “the way in which the hotel sector and restaurants aim to reproduce the same quality of service each time but in actual fact this can vary substantially from establishment to establishment and from day to day because of the variables, e.g. staff attitude, mood, and work atmosphere”. Sasser et al., (1978 cited in Biswas and Cassell, 1996); Hall (1995, 1998); Rowe (1998) argue that services are intangible; therefore the quality of the service is indefinable and will vary from consumer to consumer depending on their experiences, perceptions and expectations. As stated by Sasser et al., (1978 cited in Biswas and Cassell, 1996: 19) perishability indicates that “services have a definite lifespan and cannot be stored”. They gave an example whereby if a hotel has 100 bedrooms and on any given night sells only 90 rooms, those ten bedrooms that remain unsold are ‘lost sales’ as they can never be sold again at a later date. According to Biswas and Cassell (1996), taking these four factors into consideration it becomes clear that the role of the employee in the service process is vital. The employee is the service provider; therefore “the HR strategy is clearly of great importance in terms of securing the operational success of the organisation” (Biswas and Cassell, 1996: 19).

The labour market features of the hotel sector are also significant (Riley, 1991). In addition, Riley (1991: 15) describes such features include “a fairly large proportion of unskilled labour; the transferability of skills between broad ranges of hotel and catering establishments; high levels of labour turnover; absenteeism; and low levels of pay”. Clearly any human resource management strategy must focus on the here and now because of the transient nature of the labour force and indeed the added unpredictability of business within the service sector. As Riley (1991); Whittington (1993); and Legge (1995) identify, the hotel sector relies on employing ‘types’ of associates to ‘fit in’ with the organisation.

As stated earlier, service in the hotel sector can be tangible and intangible. The relationship between tangibles and intangibles as sources of customer satisfaction is an influential factor in determining the employment strategies which a firm uses and the form which HRM takes. As the significance of the intangible element increases, the need to gain employee commitment in ‘delighting the customer’ as a result of training program increases, and the amount of discretion accorded to the employee also increases (Lashley, 1998). Lashley (1998); Storey, Ackers, Bacon, Buchanan, Coates and Preston (1994 cited in Worsfold, 1999); and Worsfold (1999) state that HRM in hospitality organisations stresses the broad choices open to management as being between concerns for controlling labour as a resource (hard) and gaining greater commitment from associates in increasingly competitive situations (soft). The importance of HRM in the hotel sector is thus concerned with control and commitment; for examples, given the nature of most service encounters within hospitality organisations, employee commitment to successful encounters that stress the importance of ‘delighting the customer’ and maintaining the integrity of a branded concept, associates need to provide customer service within controls set by the organisation (Lashley, 1998). In order to ‘delight the customer’ thus HRM persons need to use the skills required of front-line associates provided through training that is in line with organisational business objectives (Kelliher and Johnson, 1997).

An important role of HRM (in the area of service quality) is that HR practices in the hotel sector are integrated with its business strategy (Worsfold, 1999). It is self evident, that in terms of service quality the behaviour of the service provider is of paramount importance (Samenfink, 1994; Sparks, 1994; Mohr and Bitner, 1995) and customer perceptions of satisfactory service have been shown to be directly influenced by the behaviour of service providers which, in turn, appear to be influenced by HRM (Worsfold, 1999). A study by Peccei and Rosenthal (1998: 66 – 86) supports the importance of the HRM role in the hotel sector and states “there is a clear link between commitment to customer service (the hotel sector) and the employee capacity variables of employee knowledge and competence (the behaviour of service provider, e.g. front line staff), thereby suggesting the importance of recruitment, selection, induction, socialisation, and training (HRM function)”. It can said therefore, that given the importance of the customer and employee interaction to the service encounter, HRM has a key role to play in providing service quality where customers engage in a subtle and complex experience which is personal and psychological.

However, It can be argued that regardless of the importance of the HRM role in the hotel sector, particularly in the area of recruiting and training, the hotel sector appears to invest huge amounts of money in training. As Melia (1992: 38) stated, “training for front line associates is necessary in the hospitality industry”, however, questions have been raised as to whether the money is being spent wisely.

It is possible to differentiate customer orientation or service operational types within the service sector (e.g., the hotel sector) in order to identify appropriate management approaches (see Bowen and Basch, 1992 cited in Haynes and Fryer, 2000; Heskett, Sasser and Hart, 1990 cited in Haynes and Fryer, 2000). Reviewing Lashley’s (1998) work in Haynes and Fryer (2000) classifies the most suitable HRM approaches for service operations according to the degree of customization of the service offer and form and the locus of management control of employee performance in which the latter refers to the extent to which control is exercised by management externally (e.g., monitoring, performance pay) as opposed to control strategies reliant on employees internalising organisational objectives. He argues there are four ideal types to ensure service quality such as involvement, professional, participative, command and control. Indeed, he further explains the importance and nature of personalized “service offer” which is at the same time constrained by financial and marketing factors primarily cost considerations and the requirements to maintain brand consistency. Additionally, Lashley (1998 cited in Haynes and Fryer, 2000) argues a new shift of HRM towards service quality from “command and control style” to a more customized in the intangible element of the service offer which reflected in the renewed emphasis on delighting customers as well as standardized in tangible element which reflecting the strong branding of an international hotel chain. Moreover, he emphasizes greater reliance on internal control mechanism that fits involvement style. Studies conducted by Kanji and Asher (1993) stressed the expansion of role of employee to that internal customer and found it is necessary to achieve successful internal working relations in order to be able to satisfy external customers. Johnson (1993) supported this view by saying service quality is driven by the realization that every person in the organisation has internal customers who must be satisfied. It appears that providing service quality to customers depends upon the quality of internal service given to employees. It is expected therefore, the challenge in delivering service to internal customers will be delineated including the culture of organizations (see Cannon, 2002). As explained by Lashley (1998 cited in cited in Haynes and Fryer, 2000) the importance of having management policies and practices in a quality focused hospitality industry strategy is described in FIG. 1 below.

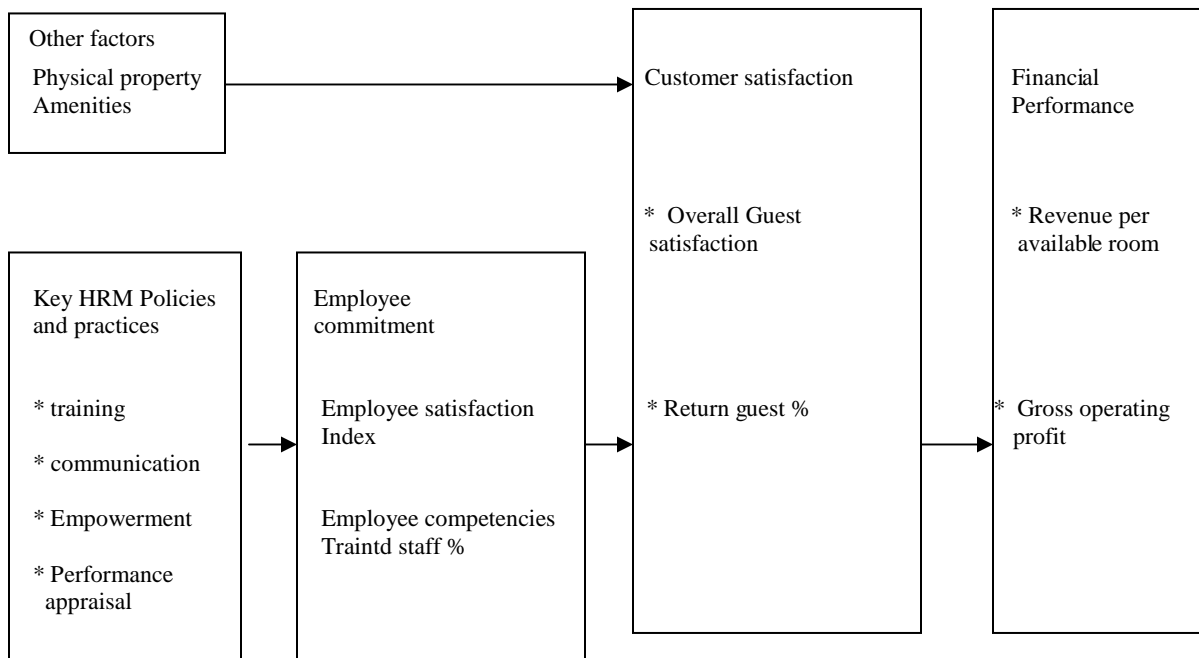

FIGURE 1: MANAGEMENT POLICIES AND PRACTICES IN A QUALITY FOCUSED HOSPITALITY INDUSTRY STRATEGY

Source: Haynes and Fryer (2000) case study in a luxury hotel in Auckland, New Zealand

In order to sustain excellence in customer service thereby increasing customer satisfaction and financial performance is considered necessary to engage employees to provide them with competencies required. The HRM policies and practices are seen critical to the success of the strategy which is referred to Key Performance Indicator. Changes to HRM policies and practices are as follows :

**Training and Career Development**

Given the variety of training types in the hotel sector, however, most organisations appear to be using a ‘traditional approach’ to training activities which consists of the assessment of training needs, the use of training methods to deliver content based on needs, and finally a comprehensive evaluation of the program using several different evaluation criteria and strategies (Tracey and Tews, 1995). The concept of a ‘traditional approach’ to training has now been refined particularly in the area of the assessment of training needs (Putra, 2002b); for example, Nankervis et al., (1999) and Nankervis et al., (2002) state that in order to approach training needs more systematically, three different analyses are required. These are organisational analysis, task analysis, and person analysis. From a thorough needs analysis, then, managers can develop the learning objectives of such programs. After this, managers can select and design the most appropriate methods to deliver training. Once the needs assessment has been completed, the next step is to conduct the training programs and establish criteria which can be achieved via a needs assessment. A thorough assessment also identifies non-training issues that should be addressed before one evaluating the program. After the training program is completed, evaluation is undertaken to determine its effectiveness. This view is supported by Machles (2002) who stated that to ensure success with training, the need for training must be clearly identified and this can be achieved via a needs assessment. A thorough assessment also identifies non-training issues that should be addressed before training is initiated. Once needs are identified, clear objectives must be developed which describe what the learner will do, state the conditions under which they will do it, and establish criteria by which successful performance will be judged.

Smith and Cooper (2000) state that it is now time to shift from concern with the elements of the training programs, i.e., needs assessment, training methods and evaluation, to more concerned with a focus on the delivery of

the training, particularly on relating the training to the program objectives, and closely matching training situations to work situations. They emphasize the interactive relationships between these aspects of training programs.

Haynes and Fryer (2000) found the career structure for operational and managerial staff is linked to employee performance and development review. From Haynes and Fryer study, it was discovered that management training has been emphasised leadership skills (giving power to managers to involve staff and lead changes).

#### **Communication**

Haynes and Fryer (2000) revealed importance of having regular meeting (monthly basis) with staff and HR Director and HR Managers as well as with the General Managers to reinforce the vision and values underpinning the new strategy. In addition, meeting with departmental level which focuses on performance targets for each unit.

#### **Performance Level**

It focuses on employee development and review process and concentrates to job success factors, key performance indicators and competencies.

#### **Job Redesign and Empowerment**

Haynes and Fryer (2000) noticed the worth of redesign the job to allow greater discretion in solving guest's problems. Indeed, staff are empowered to strive for excellence in the service .

Furthermore, Haynes and Fryer (2000) found out positive outcomes such as increasing employee satisfaction, work improvement, reduced labour turn over. In terms of financial performance also improved quite fairly.

## **Conclusion and Managerial Implication**

Even though the paper was a conceptual study, this study provided a useful theoretical approach and demonstrated how HRM can possibly have a link to organisational performance, in this case, to provide the quality of service to people.

For many travellers, what separates one hotel from another is the quality of service. Unfortunately, good service is so intangible a concept that it is difficult to say what the hotel sector can do to improve things. This is one of the toughest challenges for the hotel sector because a guest always has the potential to interact with so many different front line associates at so many times of the day. To accommodate a guest's high expectations of good service, front line associates must be given the tools to do their jobs, and one of these tools is training. As the professional practice of hospitality becomes more widespread, professional hotel managements are likely to play a central role in co-ordinating organisational tasks, structures, people, conducting training and introducing new technology.

The experience of the study done by Haynes and Fryer is expected to assist the hospitality industry scholars and practitioners in identifying elements of the HRM practices which best meets the demands of, particularly, the hotel sector operators, which provides more a customized service offer. The model proposed by Haynes and Fryer depicted a possibility a linkage between HRM and organisational performance.

A research needs to be undertaken to find out whether the model can be applied in hotels in Indonesia to determine the relationship between HRM strategies and organisational performance. Further study also needs to be carried out to find out, if any, other factors which may contribute to organisational performance.

Despite the limitation of this study, a model developed by Haynes and Fryer may be adequate for others who demand a simple which they can understand.

# Key Factors of Internet e-Retailing in the Metropolitan Environment

*Ziqi Liao, victor@hkbu.edu.hk*

## Abstract

This paper explores consumer behavior associated with Internet e-retailing in the metropolitan environment of Hong Kong. It incorporates local market background and social influences to examine the key factors of Internet e-retailing. The empirical results show that consumers might consider Internet e-retail services if the social members in the community have similar interests. However, the easily accessible local retail outlets and individual concern about the risk of virtual business significantly affect consumer behavioral intention to use Internet retail services. The findings have managerial implications for developing Internet-based retail business in mature metropolitan environment.

## Introduction

The Internet together with the implementation of innovative business practices plays a fundamental role in the development of e-commerce. However, it is not uncommon that many virtual business models can not achieve expected outcomes due to the misunderstanding of consumer behavior in a particular market environment and social context. At the early stage, service providers intensively promoted the benefits of e-commerce services, because they assumed that individual consumers might be willing to use the services. Existing studies show that e-commerce would be influenced by many variables in different market environments and social contexts, while individual consumers would rationally explore innovative services (Vijayasathy 2004).

The traditional retail market environment in Hong Kong is characterized by its convenience and a variety of different goods and services. In general, many consumers enjoy shopping individually or with friends and relatives. Individual taste, style, and shopping behavior are influenced by fashion, in-group opinions and shared assumption in such a collective society. Thus, subjective norm might influence consumer perception and shopping behavior. The issue of social context being involved in the process of psychological adoption of technological innovation should not be overlooked in certain circumstances (e.g. Hasan & Ditsa 1999; Venkatesh & Morris 2000). Therefore, it is meaningful to explore the social context associated with consumer perceptions on e-retail storefronts. This paper aims to examine consumer perceptions on e-retailing in the metropolitan environment of Hong Kong. It begins with the descriptions of our research model and hypotheses followed by research methods. It then presents the empirical results and discusses the impact of several factors on consumer attitude towards e-retailing and behavioral intention to use e-retailing. Finally, it highlights the managerial implications and the direction for future research.

## Model and Hypotheses

The theory of reasoned action (TRA) suggests that the immediate antecedent of a behavior is the intention to perform the behavior in question (Fishbein & Ajzen 1975). It specifies two conceptually independent determinants of intention. The first predictor is a personal factor termed attitude towards behavior, it refers to the degree to which an individual has a perception of a particular behavior. The second predictor of intention is subjective norm, which is a social factor referring to the perceived social pressure to perform or not to perform the behavior (Ajzen & Madden 1986). On the basis of the TRA, the technology acceptance model (TAM) was suggested for modeling the end user acceptance of computer-based information systems (Davis 1989; Davis et al. 1989). The TAM is capable of explaining user behavior across a broad range of end-user computing technologies. It asserts that the influence of external variables upon user behavior is mediated through user beliefs and attitude. Perceived usefulness and

perceived ease of use are two major constructs. Numerous studies have sought to expand the TAM by incorporating additional constructs. For example, Taylor and Todd (1995) suggest additional antecedent constructs that underlie the decision of technology adoption. In addition, Szajna (1996) systematically examines the measures of actual system acceptance instead of intended usage. Venkatesh and Davis (1996) test a theoretical extension of the TAM, which explores perceived usefulness and usage intentions in terms of social influence and cognitive instrumental processes using the data regarding four different systems at four organizations. Furthermore, the TAM has been used to examine individual acceptance and usage of websites (van der Heijden 2003). Recently, the TAM has been applied to examine electronic commerce in different contexts (e.g. Gefen et al. 2003; Eriksson et al. 2005). This study applies the TAM and incorporates social constructs to explore consumer behavior in relation to e-retailing in the metropolitan environment of Hong Kong.

#### **Perceived Usefulness**

Perceived usefulness is defined as the prospective user's subjective probability that using a specific application system could enhance job performance within an organizational context (Davis et al. 1989). It refers to the degree to which an individual believes whether the use of a particular information system could enhance a particular performance. It also captures the extent to which a potential user views the innovation as offering value over alternative ways of performing the task (Agarwal & Prasad 1999). In terms of the usefulness of an e-storefront, it is desirable if it has such features as availability, accessibility and personalization. The availability refers to that a website is available so that individual consumers can virtually access information and carry out business transactions with a particular service provider (Liao & Cheung 2001; Liao & Cheung 2002). In addition, individuals should be enabled to customize their personal data, send in requests for services, and purchase product beyond normal opening hours of retail stores. Therefore, Hypothesis 1 is proposed:

H1: Perceived usefulness is positively related to consumer attitude towards e-retailing.

#### **Perceived Ease of Use**

Perceived ease of use refers to the degree to which the prospective user expects the target system to be free of effort (Davis et al. 1989). Existing studies suggest that the perceived ease of use is a determinant for the adoption of innovative services or products. For instance, Cooper (1997) discovers that ease of adoption as an important characteristic for considering innovative services from the consumer's perspective. In terms of virtual storefronts, a website should enable favorable and compelling individual experience (Schenkman & Jonsson 2000). It should also allow easy browsing with a search function dedicated to quickly lead users to the required information (Huizingh 2000). Consumers of technology-based self-services might be concerned about the effort required to use such options and the complexity of the process of service delivery (Dabholkar 1996). Perceived ease of use is generally regarded as an attribute associated with computer-based information systems, because it makes individuals feel enjoyable (Davis 1989). Similarly, Internet-enabled purchase is performed on the screen of a computer-based device, while user-friendly interface should help search information. In particular, perceived ease of use may include intuitive search engine for acquiring information and simple procedure for performing transactions. Therefore, Hypothesis is proposed.

H2: Perceived ease of use is positively related to consumer attitude towards e-retailing.

#### **Perceived Risk**

It seems not uncommon that consumers are concerned about the risk associated with an emerging service. In terms of e-commerce, perceived transactions risk has been shown to strongly influence the business over the Internet (Lee & Clark 1996). It has also been empirically proved that perceived risk is a significant factor affecting consumer behavior (Cunningham et al. 2005). It is essential to ensure security by ensuring that transaction data is kept confidential and that it is not misused (Kiely 1997). The systems must be designed to minimize unauthorized use of e-payments and to maximize the safety of financial information. Privacy over Internet is an issue of increasing concern, with individuals being reluctant to e-business for the fear of unauthorized or illegal duplication and circulation of information (Keeney 1999). To alleviate perceived anxiety, digital platforms must effectively protect users by implementing serious security procedures and systems. Provisions of this nature would help enhance the credibility of service providers (Kienan 2000). Therefore, Hypothesis 3 is proposed:

H3: Perceived risk considerably affects consumer attitude towards e-retailing.

### **Local Retail Environment**

Hong Kong has a highly accessible urban environment around which there are many retail stores and shops. Consumers can easily purchase whatever they need within a reasonable time and travel distance. In addition, due to the limited outdoor facilities, even window-shopping with friends becomes a habit of many residents, especially at weekend. Many local consumers have traditionally adapted the local retail market environments. They might not easily change their shopping habit and purchasing behavior, because individual values and beliefs of individuals that usually develop from childhood and reinforce throughout life might affect individual behavior (Hasan & Ditsa 1999). Moreover, consumers can easily feel, touch and try on fashionable goods in brick-and-mortar stores, which is not available in the virtual environment at this stage. Therefore, Hypothesis 4 is proposed as follows:

H4: The easily accessible local retail market considerably affects consumer attitude towards e-retailing.

### **Consumer Attitude and Intention**

Individual behavioral intention to use a system is determined by one's attitude towards the system, while attitude is a learned response that refers to an individual's evaluation of a concept (Fishbein & Ajzen 1975). In general, attitude towards behavior refers to the degree to which a person has a favorable or unfavorable evaluation of the behavior in question (Ajzen & Madden 1986). The TAM postulates that individual attitude together with perceived usefulness and ease of use is determinants of behavioral intention. Existing studies discover that the impact of attitude on intention to use is significant, while behavioral intention to use a system is directly determined by an individual attitude towards the system (e.g., Agarwal & Prasad 1999; Moon & Kim 2001). Therefore, it should be meaningful to examine the following hypothesis:

H5: Consumer attitude is positively related to behavioral intention to use e-retailing.

### **Social Influence**

The influence of an individual's social group should not be ignored, because perceived social surroundings influence individual to perform an activity in a collective society (e.g. Ajzen & Madden 1986, Hasan & Ditsa 1999, Venkatesh & Morris 2000). Such influences come from parents, family, friends, classmates and relatives and co-workers. Work environment might also affect individual behavior intention of adopting innovative means to accomplish tasks (Morris & Venkatesh 2000). The influence of social groups should be examined, because it is not uncommon that members of a social group usually observe subtle or implicit commitments with the group identity such as fashion, style, taste and consumption behavior, information and even opinion spreading among group members. One might attempt to try if peer friends often use e-retailing. In other words, if the members within a group generally accept e-retailing, an individual associated with the group might be motivated to do so. Therefore, Hypothesis 6 is proposed.

H6: Social group has a positive impact on consumer behavioral intention to use e-retailing.

## **Research Methods**

Our research methods include literature review, questionnaire design, survey and data analysis. The availability of the measures of individual attitude in the existing literatures suggests the importance of empirical analysis. Hence, a questionnaire was design to consist of thirty five questions in relation to perceived usefulness, perceived ease of use, perceived risk, local retail market environment, social influence, consumer attitude and behavioral intention. It was aimed to elucidate the individual perceptions on various variables associated with the concerns mentioned in the previous section and to measure the likelihood of respondents in making purchase decisions through e-retailers. Consumers were requested to indicate perceived importance of different variables and their intention to use e-retailing, based on a seven-point Likert-scale, with "1" scoring the lowest point, not important or strongly disagree, to "7" scoring the highest point, very important or strongly agree. Five hundred questionnaires were randomly circulated to individual consumers. As a result, one hundred and ninety five useful responses were received for data analysis. The response rate is thirty nine percent. The demographics include one hundred and two females and ninety three males, while age ranges from eighteen to over sixty years old.

The Statistical Package for Social Science (SPSS) has been employed to test the data collected. In particular, the following multiple regression models have been used to examine the hypotheses proposed in the previous section. Model I explores whether individual attitude towards e-retailing is attributed to perceived usefulness, perceived ease of use, perceived risk and local retail market environment.

$$\text{Model I: } y_1 = b_0 + b_1x_1 + b_2x_2 + b_3x_3 + b_4x_4 + \varepsilon_1$$

where,  $y_1$ : Attitude towards e-retailing  
 $x_1$ : Perceived usefulness  
 $x_2$ : Perceived ease of use  
 $x_3$ : Perceived risk  
 $x_4$ : Local retail market environment  
 $\varepsilon_1$ : Error term

Model II explores whether consumer behavioral intention to use e-retailing is significantly influenced by individual attitude and social groups.

$$\text{Model II: } y_2 = b_0' + b_1' y_1 + b_2' x_5 + \varepsilon_2$$

where,  $y_2$ : Intention to use e-retailing  
 $y_1$ : Attitude towards e-retailing  
 $x_5$ : Social influence  
 $\varepsilon_2$ : Error term

## Results

The empirical data collected from our survey have been examined using reliability test and regression analysis. Reliability test suggests that the values of Cronbach Alpha are greater than 0.7 (TABLE 1). The results show that the items associated with a particular factor are relatively consistent: perceived usefulness (0.817), perceived ease of use (0.803), perceived risk (0.828), local retail market environment (0.892), social influence (0.902), consumer attitude (0.860), and behavior intention (0.728).

Multiple regression analysis is conducted to articulate the impacts of several factors on consumer attitude towards e-retailing. As shown in TABLE 2, the result of Model I ( $F = 41.038$ ,  $d.f. = 4, 190$ ,  $p < 0.001$ ) together with the adjusted  $R^2$  (0.452) indicates that 45.2% of the variation of the endogenous variable ( $y_1$ ) has been significantly explained by the exogenous variables. It also suggests that H1 is strongly supported, because the perceived usefulness is positively related to consumer attitude towards e-retailing ( $\beta_1 = 0.474$ ,  $t = 8.778$ ,  $p < 0.001$ ). In addition, H2 is supported, because perceived ease of use has a positive impact on consumer attitude ( $\beta_2 = 0.332$ ,  $t = 5.833$ ,  $p < 0.001$ ). H3 is supported, because the perceived risk is negatively related to consumer attitude ( $\beta_3 = -0.110$ ,  $t = -1.987$ ,  $p < 0.05$ ). Moreover, H4 is supported, because the result shows that the highly accessible retail environment is negatively related to consumer attitude ( $\beta_4 = -0.123$ ,  $t = -2.200$ ,  $p < 0.05$ ). Hence, it has a significant effect on individual attitude towards e-retailing.

The result of Model II ( $F = 96.280$ ,  $d.f. = 2, 192$ ,  $p < 0.001$ ) also shows that Model II has a significant explanatory power. The adjusted  $R^2$  (0.497) indicates that 49.7% of the variation of the endogenous variable ( $y_2$ ) can be explained by the exogenous variables. H5 is supported, because consumer attitude is positively related to their behavioral intention ( $\beta_1' = 0.675$ ,  $t = 12.993$ ,  $p < 0.001$ ). Therefore, individual attitude significantly affects individual behavioral intention. Finally, H6 is supported, because social influence is positively related to behavioral intention ( $\beta_2' = 0.118$ ,  $t = 2.263$ ,  $p < 0.05$ ). Therefore, the opinions and behaviors of different social groups significantly affect individual behavioral intention to use e-retailing.

TABLE 1: RELIABILITY TEST

Construct	Number of Items	Cronbach's $\alpha$
Perceived usefulness ( $x_1$ ): competitive price, product variety, special goods, anytime, anywhere, fast delivery, efficiency, customer relationship, personalized service	9	.817
Perceived ease of use ( $x_2$ ): ease of search, product directory, clear classification, presentation, simple procedure, helpful instruction	6	.803
Perceived risk ( $x_3$ ): unauthorized use of credit card, release of private data, inaccurate information, inconsistent product delivered, unpredicted quality, difficult to get refunded, limited maintenance, poor after sale service	8	.828
Local retail market environment ( $x_4$ ): convenient and attractive retail facilities	2	.892
Social influence ( $x_5$ ): suggestions and behaviors of friends, colleagues and relatives	6	.902
Attitude towards e-retailing ( $y_1$ ): positive to e-retailing, interested in e-retailing	2	.860
Intention to use e-retailing ( $y_2$ ): wish to use e-retailing, plan to use e-retailing	2	.728

TABLE 2: MULTIPLE REGRESSION ANALYSIS

		Standardized Coefficients ( $\beta$ )	$t$	Sig.
Model I	Constant		1.335	.183
	$x_1$	.474	8.778	.000
	$x_2$	.332	5.833	.000
	$x_3$	-.110	-1.987	.048
	$x_4$	-.123	-2.200	.029
Model II	Constant		1.408	.161
	$y_1$	.675	12.993	.000
	$x_5$	.118	2.263	.025

## Discussion

The empirical results suggest that perceived usefulness and perceived ease of use significantly influence consumer attitude towards e-retailing. If virtual storefronts can enable individual consumers to purchase products by clicking and selecting various choices on the websites, they are interested in using e-retailing apart from visiting brick-and-mortar stores. As a result, consumers might considerably save time and efforts. In addition, e-retailing might have a cost advantage, because it could eliminate intermediaries through direct sales to individual consumers. If an individual would perceive a cost advantage compared with other retailers, he might be willing to shop in a virtual storefront. In order to compete with traditional brick-and-mortar stores, companies being involved in e-retailing should provide consumers with incentives by promoting products and services at competitive prices. They should also develop competitive marketing strategies to encourage consumers to purchase products, which might not be available in traditional retail outlets. Individual consumers might have unconventional demand and personal preference in different circumstances. Therefore, e-retailers should develop websites enabling tailor-made services for customers.

Perceived risk possesses a relatively negative impact on consumer attitude towards e-retailing, because individuals might worry about the unpredictable risks in the virtual environment. In particular, they are not able to touch and feel the products in the virtual environments. The risk to order a low quality product should be a concern. Therefore, consumers would usually not purchase such goods as clothes and shoes without trying, even if they were

interested in e-retailing. In order to reduce consumer concerns about risk, the explanation of online security should be provided. Detailed information on products and services should also be available. Moreover, consumers should be acknowledged that serious procedures have been implemented to assure the security of credit card payments and to protect personal information and privacy associated with online transactions.

The highly concentrated retail environment significantly discourages consumers to consider e-retailing in Hong Kong. Those who have a habit to purchase in brick-and-mortar stores are unlikely to go for e-retailing, because their habit might not be easily changed for the time being. Actually, the traditional retailing continuously evolves in Hong Kong, although Internet-enabled e-retail business has been developed over the last few years. Therefore, we believe that it would be beneficial if companies could simultaneously operate virtual storefronts in addition to their existing retail business. It would also be beneficial if they could provide consumers with useful information, and match virtual sales with quality products and excellent logistics services based on advanced information and communications technology.

Social groups have a significant impact on consumer behavioral intention to use e-retailing. It is likely a popular phenomenon in a collective society in which one tends to follow if friends, relatives, co-workers, and classmates have a positive attitude to e-retail business. Our empirical findings justify that there is a contextual reality, i.e. social group or so-called word of mouth is important for spreading the image of an e-retailer's brand together with its products and services. Considering the local retail market environment together with the local social context, retailers are suggested to concurrently operate retail business in dual tracks of brick-and-mortar and virtual stores, because the availability of Internet enables individuals to conveniently carry out online services. In particular, if the consumers have extensive computer knowledge and Internet skills, they can easily browse the websites of different e-retailing to search products and services without a request for assistance from others. At this stage, it seems practical if e-retailing focuses on providing information and selling standardized products to encourage repetitive purchases. Therefore, companies should utilize the Internet to facilitate their traditional retail businesses. For instance, it would be useful to use e-advertising to promote products and services and provide consumers with online acknowledgement, order confirmation and other after-sale services.

## **Conclusion**

The empirical examination of consumer perceptions of several factors associated with the existing e-retail services in the context of Hong Kong results in theoretically and practically useful implications. The present work extends the general approaches of technology diffusion (Rogers, 1995), since it explores consumer behavioral intention to adopt e-retailing and explains individual's autonomous intention to adopt the innovative services. It suggests a cross-disciplinary integration of e-commerce and service marketing with strong explanation power.

The present findings reveal that social group has strong impact on one's intention to use e-retailing. Our finding is consistent with information cascading and herding behavior among later users of innovative products and services (Bikhchandani et al. 1992). It seems meaningful to trigger off consumer information cascading and herding behavior and achieve a critical mass of customer base to roll the e-business tide against brick-and-mortar retail rivals, because herding behavior of those later users can be triggered off by early users' action, information spreading, especially word-of-mouth from popular public figures to youth (Ellison, 1995). In addition, the early users usually benefit from being proud of being opinion leaders and their wise selection. They might be more than willing to pass the information to later users and result in asymmetric information cascade. Therefore, in order to encourage more consumers to use e-retailing, incentives can be provided to the existing users for passing on information to different social groups.

It might be assumed that consumers may take reasoned actions in a planned way of purchasing, if they perceive the e-retailing useful and easy to use. However, purchasing decisions can be instantly influenced by emotion and feeling at the buying stage, especially for those fashionable products or services for female consumers, because these products and services can enhance individual visibility and image, and satisfy their psychological desire of success. To offset the consequences of a concentrated local retail market, retailers might consider providing consumers with particular merchandises that are not easily available at the present brick-and-mortar

stores. They are also suggested to capture the concerns and expectations of different consumers, provide information to facilitate them to make purchase decisions, and utilize the Internet to promote high value-added products and services.

Furthermore, the present findings can be practically applicable to other social settings although the present information is derived from a collective social context. In Hong Kong, many consumers are knowledgeable in selection of products and services, because they receive information from different promotions. In order to compete with virtual retailing, many existing brick-and-mortar retailers in Hong Kong concurrently develop both physical and virtual storefronts to accommodate the needs of different consumers. Such experience might be useful for retailers in other regions when operating virtual storefronts and promoting products and services.

The repetitive use of e-retail services by consumers is critical to the sustainable development of e-retailing. As far as this is concerned, though the building of a user friendly and secure service platform is essential, the delivery of quality products and the provision of excellent services are important to generate positive customers' impression and experience. In general, rational consumers might be willing to take certain risk to gain expected benefits, because they understand that nothing is risk free in the world. Therefore, e-retail companies need to guide and accommodate customers, develop their experience and habits in using virtual storefront facilities. It is also the foundation to develop consumers' confidence and enhance their trust in e-retail services. Future research can be carried out along similar venues of contextual dimensions to compare consumer behavior associated with e-retailing across different contexts. It should also be meaningful to incorporate different theories, constructs and variables to explore consumers' attitudes and behavioral intentions to use e-retailing in different market and social environments.

# Internationalization of Retailing: Strategic Overview of Retail Industry in Japan

*Nitin Sanghavi, nitin.sanghavi@mbs.ac.uk*

*Lee Douglas*

*Manchester Business School, University of Manchester, UK*

## Abstract

Japan has become a major destination for foreign retail investment with some of the largest global retailers entering in the last seven years. However, many are finding the Japanese market extremely difficult. Carrefour abandoned its 'go it alone' strategy in 2005 whilst Wal-Mart has operated in deficit since entry in 2002. The relative 'failure' of these global giants is a stark wake up call to retailers planning to internationalise, and an illustration of the unique challenges the Japanese retail sector presents. This paper provides a strategic overview of this recent internationalisation phenomenon. It reviews recent retail change in Japan, the extent of recent foreign entry, and examines the key drivers behind these developments. It goes on to discuss the key challenges facing foreign retailers in this market, and sets out a number of critical success factors to minimise risk. It argues that given the difficulties faced by retailers in Japan, and the unique challenges these present, that these rules for success are perhaps more important in the Japanese market than any other.

## Introduction

Retailing is increasingly an international industry. Although foreign retail expansion dates back to the end of the nineteenth century, in the last ten years the pace and scale of internationalisation has increased dramatically.

A major destination for recent foreign retail investment is Japan. Although the level of internationalisation remains low, recent economic recovery, progressive de-regulation, and its continued position as the world's second largest retail market makes Japan an increasingly attractive proposition for retailers striving to maintain and grow profits.

However, although Japan provides undoubted opportunities for expansion, high operating costs, a complex distribution system, a few remaining regulatory barriers, and the notoriously demanding Japanese consumer present foreign retailers with huge challenges and potential risks.

To maximise the chances of success it is critical that retailers understand the characteristics of this rapidly changing market, and are aware of potential challenges and risks. This paper aims to provide this understanding by presenting a strategic overview of the retail internationalisation phenomenon in Japan. Covering each area in turn, the paper will:

1. Briefly review current trends and processes in retail internationalisation;
2. Review recent consumer and retail market trends in the Japanese market, the extent of internationalisation, and the implications of this foreign investment;
3. Examine the key drives behind this increased foreign entry;
4. Discuss the key opportunities and challenges/risks facing foreign retailers, and;
5. Set out the critical success factors to exploit Japanese retail investment opportunities and minimise risk.

## Retail Internationalisation: Evolution, Drivers & Modes of Entry

To set the context to foreign retail investment in Japan, we first briefly review the broader process and trends in retail internationalisation.

### Current Trends

Retail internationalisation is not a new phenomenon. Alexandra (1997) describes six distinct phases, dating back from the 1880-1945 ‘genesis’ period, characterised by limited expansion of US and European speciality and department stores to select major foreign cities, through to the 1989-2000 ‘regionalisation’ phase, characterised by regional expansion<sup>1</sup> of US and European retailers and initial forays into new eastern European and Asian markets.

Recently however, from the mid to late 1990s, there has been a dramatic increase retail internationalisation and the birth of a new ‘globalisation’ phase (Coe and Lee, 2006). This current globalisation phase - characterised by the rapid global expansion of a small group of large grocery retailers – is distinguished from previous phases in a number of ways (GPN, 2003).

First, after initial forays into Eastern European and Asian markets, these are now the dominant destinations for foreign retail investment. Second, the pace of internationalisation is unprecedented. For example, in 1990, Tesco and Wal-Mart had yet to venture outside their home markets, Ahold was present in just the Netherlands and the US, and Carrefour was represented in five markets outside France. By 2002, Ahold was present in twenty eight countries, Carrefour thirty, Wal-Mart eleven, and Tesco in ten<sup>2</sup>. Third, the scale of investment is unparalleled. This is perhaps best illustrated by Tesco, who had no foreign presence in 1997, yet has planned to achieve fifteen million square feet of operating space by 2007 (GPN, 2003). Fourth, the unprecedented impact of foreign retail investment in the host countries. For example, the food retailing sector in the Czech Republic has been transformed after less than a decade of foreign investment, with all the top ten<sup>3</sup> grocery providers now originating from outside the host country<sup>4</sup>.

### Drivers of Internationalisation

The drivers behind this and past waves of internationalisation are numerous and varied, and are the subject of much debate in the literature (see Wrigley and Lowe 2002, GPN 2003, Coe and Lee, 2006, for critical reviews).

The majority of literature categorises the key drivers into a range of company specific and environmental ‘push’ and ‘pull’ factors. A useful summary is provided by GPN (2003) – set out in table 1. Ultimately, a range of these factors will combine to influence a specific location-investment decision, and, at the individual firm level, will be dependent on the financial/strategic objectives, capabilities and culture of a particular organisation.

TABLE 1: FACTORS INFLUENCING INTERNATIONALISATION

Push Factors	Pull Factors	Facilitating Factors
Perceived/imminent saturation in domestic markets	Unexploited markets	Use of surplus capital/access to cheaper sources of capital
Spreading of risk	Pre-emption of rivals	Entrepreneurial vision
Consolidation of buying power	Higher growth/profit potential	Inducements from suppliers to enter new markets
Public policy constraints	Consumer market segments not yet exploited	Removal of barriers to entry
Economic conditions	Access to new management	Information & communication technologies
Maturity of format	Reaction to manufacturer internationalisation	
Increasing competition	Following existing customers abroad	

Source: GPN (2003) pp18.

A useful explanation for the recent wave of international retail expansion is provided by Wrigley (2000). Wrigley argues that recent internationalisation has been driven, at the individual firm micro level, by the push of overdependence on the home market, and the need to sustain earnings growth and equity valuations. Whilst at the macro level, the social/economic/political characteristics of emerging markets – displaying characteristics such as rapid economic development, rising levels of affluence, rising consumer spending and retail sales, high small independent store retail sales share, and low penetration of western style retail formats – have provided the opportunistic pull (the potential opportunities to secure and grow earnings growth and equity valuation).

As we shall see, this account gives some explanation of the drivers behind recent internationalisation in Japan, though at the same time, the Japanese market is also extremely different (covered below).

#### **Methods and Forms of Internationalisation**

In terms of the 'how's' of foreign retail expansion, there are a number of well documented methods of internationalisation. These include entry through licensing, concessions, equity investments, strategic alliance, franchising, joint venture, merger and acquisition, and self-start/organic growth (see McGoldrick 1995 for a detailed review). These methods are differentiated by extent and time taken to achieve payback on foreign investment, the level of control an organisation has on its overseas interest, cost, and the degree of flexibility to change the investment decision in some way<sup>5</sup>.

The vast majority of recent retail expansion into the emerging markets of Latin America, Eastern Europe and Asia has been through acquisition and joint venture (see Wrigley 2000a, Wrigley and Currah 2003, for a detailed review). It is however, important to point out that the route to internationalisation varies considerably from company to company, market to market and even within the same company in the same market.

It is also important to point out that the internationalisation route is not a static concept of just entry, but a dynamic process of entry and expansion (or rationalisation and/or withdrawal). For example, and as described by GPN (2003), it is common for a foreign retailer to initially enter a market through some kind of joint venture with a local retailer, to then increase its ownership share over time to a controlling interest or complete ownership (acquisition), whilst at the same time pursuing a strategy of new-store openings (organic growth)<sup>6</sup>.

In terms of the form of retail internationalisation, foreign retailers have adopted a number of organisation styles – ranging from the global to the multi-national model. The global operating model (preferred by companies such as Benetton and Gap) is characterised by format standardisation, the pursuit of economies of scale, and the least local market responsiveness. The multi-national model is characterised by multiple formats across international markets and high local responsiveness, but achieves lower benefits/scale economies from integration.

A middle course is usually termed 'transnational' in which organisations attempt to achieve scale economies and respond to local market needs, opportunities and constraints. Developments by companies like Marks & Spencer, Toys 'R' Us, and more recently, Tesco and Carrefour, suggest a trend towards the transnational model, indicating the recognition that even the most successful retail formats within the home market require adaptation to suit the local market needs of the host country.

Ultimately however, the particular form of operation and mode of entry is much dependent on the nature of the market destination. With this in mind, we now turn to the main focus of this paper – the international expansion of retail operations to Japan.

### **Retailing in Japan: Retail Change & Increased Foreign Investment**

Whilst the Japanese manufacturing system has long been characterised as the most efficient in the world, the retail system is often described as inefficient, traditional, and outmoded. It not difficult to see the reasoning behind this unflattering portrayal. For example:

The Japanese retail market is extremely fragmented with the top five retailers accounting for only 10% of total retail sales (value – IDG 2007). Although there are a large number of regional players<sup>7</sup> - particularly in the convenience sector, the market is dominated in numeric terms by small specialist independent retailers. As recently as 2001, Aoyama (2006) estimated that there were over 500,000 independent outlets – more than three times the number in the US, and five times the number in the UK. Indeed, the same report highlights that retailer density is by far the highest of any comparable developed economy<sup>8</sup> (4,232 food, and 6,592 non-food outlets per million inhabitants). Many of these retailers, even some of the largest chains, have been described as technically insolvent - being kept afloat by the banks eager to hold on to their real estate value (Deloitte, 2004).

Another feature of the market is the notoriously complex supply chain system. Unlike in other comparable developed economies, direct supply is limited. Instead, the system is characterised by a large number of multi-layered wholesalers – national, regional and local. These wholesalers, who are heavily influenced by the 'Sogo Shosha' (Trading Houses such as Mitsubishi and Itochu), provide a range of value added services such as financing,

logistics, warehousing, procurement, IT, shipping and consultancy services. Manufacturers hold significant power in these arrangements, including demanding retailers stick to manufacturer recommended retail prices. Although this structure supports the fragmented nature of the market, and many Japanese retailers benefit from the value-added services described above (most notably the fact that many do not own the merchandise they sell, and are protected by 'sale or return' arrangements), on-balance, it is an extremely inefficient, high cost system – for both retailer and consumer.

The Japanese retail market is however something of a paradox. Whilst the above is true, at the same time Japan is home to some of the most successful international retailers in the world. For example, Ito-Yokado (part of the recently formed Seven & I Group) is the largest foreign retailer in the US by number of stores (sixth by turnover), and there are no fewer than 21 Japanese retailers currently operating in China (Larke, 2004). The Japanese retail market is also one of the largest in the world – home to the second largest grocery sector (behind the US), and enjoying the largest sales per capita of clothing and footwear in Asia (Aoyama 2006).

Furthermore, the retail market is currently changing fast. On the demand side, rapidly changing consumer lifestyles have instigated deep changes in consumer behaviour. Most notably, increased working hours and female employment are fuelling increased demand for convenience, whilst recent economic uncertainty has increased the value consciousness of the Japanese consumer. Whilst the latter has not dampened Japan's desire for expensive brand-name goods, consumers are now reacting much more positively to discount formats, and low price products are no longer automatically assumed to be of inferior quality.

On the supply side, the retail sector is undergoing a revolution in structure, dominant formats, merchandising techniques and distribution. The General Merchandising (GMS) and department store formats (and retailers) are in decline, whilst the supercentre/hypermarket formats remain unproven. In contrast, convenience stores (and retailers) are expanding rapidly in response to changing lifestyles, and now account for 32% of total Japanese food sales (value – Euromonitor, 2007). The major beneficiary of this trend has been the 7-Eleven convenience chain, which recently overtook the GMS retailer Daiei to become the leading Japanese retailer with 7% market share (sales value – Euromonitor 2007).

The sector is also undergoing a slow drive towards consolidation, with banks finally releasing previously inaccessible retail assets as property values decline. Distribution and logistical networks are being slowly combined to improve efficiency, and many leading chains are expanding by acquiring smaller regional players. Most notable recent activity includes the merger of Seven-Eleven Japan and Ito-Yokado to create Seven & I Holdings – a new international mixed merchandising 'power house', and the aggressive expansion of Aeon through the recent acquisition of Carrefour's Japanese operations (March 2005), Joy Co supermarkets (June 2004), and the Saty and Posful mass merchandising chains (November 2003)<sup>9</sup>.

Another feature of supply side change is increased investment in new retail concepts, formats, channels and services. Internet retailing and home shopping have shown strong recent growth (total sales values up 512% and 23% respectively between 2000 and 2005 – Euromonitor, 2007) – benefiting from the proliferation in broadband internet services, third generation mobile phones, and satellite and cable TV. Most recently, Japan has seen the development of range of new hybrid formats - including Yen100 convenience stores (combining features of convenience and discount stores), convenience-drugstores, and supermarket-convenience outlets (e.g. Daiei's *Foodium* – launched in 2006). The net result is an increasingly price sensitive, competitive market – as new business models blur the boundaries between different retail formats, and a rapidly modernising retail system.

A key feature and major catalyst behind current consumer and retail market change in Japan is the emergence and recent rise in foreign retail investment. Although foreign retail investment in Japan dates back to the early 1980's with the entrance of luxury brands Louis Vuitton (1981), and Hermes (1983), the last seven years has seen the arrival of the large international grocery chains - Wal-Mart (2002), Costco (1999), Tesco (2003), Carrefour (2000), and Metro (2002). Wal-Mart, with its acquisition of a 34% stake in the Seiyu mass merchandising chain has the largest presence (443 stores), followed by Tesco – the most recent entrant with 116 (80 branded C Two-Network, 18 Frec's, and 19 Tesco).

Many of these entrants have found/are finding the Japanese market extremely difficult. A recent study estimates that 38% of all foreign retailers attempting market entry since between 1981 and 2003 eventually retreated (Toyo Keizai, 2003). High profile withdrawals include Boots from the UK (entered 1999, withdrew 2001), and

OfficeMax from the US (entered 1997, withdrew 2001). More recently, Carrefour abandoned its 'go it alone' strategy in 2005<sup>10</sup>, Costco has failed to meet initial sales targets for five years running, whilst Wal-Mart has operated in deficit since entry in 2002.

There are a number of reasons cited for these failures – depending on the retailer involved. For example JETRO (2003) report that Boots made the strategic blunder of choosing locations that didn't fit its store concept and failed to market its private brands effectively. A common theme amongst all however, is the difficulties in satisfying the 'unique' Japanese consumer. This is particularly relevant to the difficulties encountered by the large foreign grocers who have entered with large store/hypermarket discount formats. Given Japanese consumers have historically displayed three broad characteristics – a preference for quality, an expectation of high levels of customer service and extremely frequent shopping frequency, it is no surprise that they have found it difficult to accept large store formats and discount concepts with minimal service.

As outlined above however, this is slowly changing. Recent economic uncertainty and consumer lifestyle changes are driving a more positive reaction to discount formats, and low price products are no longer automatically assumed to be of inferior quality (though a high level of customer service is still expected in all circumstances). Some retailers are responding to this more positive reaction. For example, Tesco have begun expanding its supermarket-convenience concept. It opened its first store under its own Tesco Express banner in April 2007, and plans to roll-out a further 35 new stores before April 2008.

As Tesco and other foreign retailers expand, they will further drive change in the Japanese retail sector. Indeed, the recent increase in merger and acquisition activity (described above) is partly in response to the recent arrival of these powerful and efficient grocers. They are introducing new ways of doing things (e.g. new retail operational practices, technological systems, formats, etc). As these are absorbed into domestic market (through imitation and innovation/further modernisation), and adapted to the particular needs of the local market, a new hybrid or even more modern retail system will emerge, that is different from both the domestic home market of the foreign retailers, and the original system in the host market.

## **Drivers behind Increased Foreign Investment in Japan**

There are a range of political, economic, social, technological, legal and cultural factors driving foreign retail investment in Japan. Many of these have already been covered or are self-evident given the review above. For example:

- The Japanese retail market is one of the largest in the world by value, and so is an attractive proposition for any retailer planning international expansion. As described above, Japan is home to the second largest grocery sector (behind the US), and enjoys the largest sales per capita of clothing and footwear in Asia (double that of Singapore, the next largest - Aoyama (2006)).
- The current nature of the Japanese distribution system provides opportunities to improve supply chain efficiency (and ultimately price competitiveness) through exporting supply chain expertise and systems.
- The current fragmented nature of the market – particularly the large number of small independent chains, the recent property market downturn (which makes these chains more affordable), and the apparent growing willingness of banks to release their retail assets, provides opportunities to achieve significant presence and penetration relatively quickly through acquisition.
- Finally, Japanese consumers appear to be increasingly willing to accept new/foreign retail formats, practices, and merchandise – particularly discounting concepts given increased consumer price consciousness.

There are however a number of other drivers that require attention. These include:

- The size and recent growth of the Japanese economy which provides the broader backdrop for retail growth and positive investment conditions. For example, despite almost a decade of economic stagnation, Japan remains the second largest GDP in the world. Recent GDP growth – 2.8% in 2005 – also surpassed that achieved in both the US and the European Union.

- The wealthy Japanese consumer. Although average disposable income fell slightly between 2000 and 2005 (by 0.6% - Euromonitor 2007) Japanese consumers remain some of the richest in the world. In addition, mean disposable income is forecast to rise by 12% over the next five years (2005 to 2010 – Euromonitor 2007).
- Progressive legislation which has levelled the playing field between foreign and domestic companies – and has made it easier to enter. Most notably, the recent revision of Japan’s commercial code (June 2005), makes it easier for foreign retailers to enter through merger and acquisition. As well as removing payment restrictions, the new code created provisions whereby a foreign company can set up a Japanese subsidiary, let the subsidiary have its shares, and then use the arrangement to gain leverage in merging with a separate Japanese firm.
- The proliferation of communication channels that raise awareness of foreign retailers and brands. That is, the increasing number, openness and sophistication of business-to-consumer and consumer-to-consumer channels increasingly allows real-time awareness of different retailers, their brands, and changing product fashions on a global scale.
- Finally, internationalisation itself is key driver behind further foreign investment as leading domestic retailers fear being left behind. That is, any retailer with global aspirations may feel it has to be present in one of the key global retail markets.

## **Issues, Challenges and Risks Facing Foreign Retailers in Japan**

The Japanese market provides undoubted opportunities to foreign retailers. As we can deduce from the above analysis, the market displays some of opportunistic pull factors (and key facilitators) that characterise the ‘new’ global phase of retail internationalisation. For example, it is characterised by a high number of small independent retailers with high market shares (combined shares), and benefits from both the recent removal of entry barriers, and a modern information and communications technology infrastructure.

However, Japan is also quite different from other markets in this new internationalisation phase. Most obviously, it is a developed, as opposed to an emerging market, and as such, does not present the same level of consumer spending and retail growth potential as other less developed retail economies (recall the review of Wrigley 2000, GPN 2003, and Coe and Lee 2006, above). At the same time, the market also presents foreign retailers with the same kinds of challenges and potential risks present in other markets. Given these two facets – lower levels of spending and sales growth than in emerging markets, yet the same level of risk, the Japanese market perhaps one of the most difficult markets for foreign retailers to succeed. Indeed, as outlined above, there have been a number of recent high profile failures/withdrawals.

Many of the challenges/risks/issues have been covered above. For example:

- Despite recent economic recovery, overall consumer spending and total retail sales value growth remains relatively low (the latter grew by just 1% in the financial year 2005-2006 (Euromonitor 2007));
- The notoriously demanding nature of the Japanese consumer and their slow acceptance of foreign retail formats and practices – particularly the one-stop shopping concept and hypermarket format (although as described above, this is changing slowly), and;
- Increasingly strong domestic competition – particularly the recent trend towards consolidation of large domestic operators. Given the amendments to the Japanese commercial code (described above), we can expect more acquisition activity, and thus the emergence of even larger/stronger domestic players.

Again however, there are a number of other key issues that require further attention:

### **The Distribution System**

Although eventually, the distribution system described above will consolidate, and larger wholesalers will offer integrated logistical services, this will take time. In the mean time, foreign retailers will be forced to use the current extremely costly systems, and/or develop their own. Modernising the system will however prove extremely difficult as many of the existing contracts are based on long-standing historical business as well as personal relationships. As such, in the short-term at least, foreign retailers will be faced with extremely high operating costs.

### **Recent Legislative Changes**

Despite recent progressive legislation, the Japanese government is reportedly considering new legislation that would make it harder for large retailers to set up in the country. The Ministry of the Economy, Trade and Industry (METI) and the Ministry of Land are discussing regulations to discourage large retailers from building on agricultural land close to the outskirts of cities. This is in addition to the Large Store Location Law, introduced in 2000 to replace the existing Large Retail Store Law. The law aims to enforce environmental, noise pollution, and traffic control standards on new retail developments. Note however, the proposed new legislation will also affect domestic operators - limiting the ability to expand both existing and new operations.

### **Changing demographics – Particularly a Shrinking, Ageing Population**

Japan is expected to suffer a population decline of over 10 million people between 2005 and 2020. Furthermore, the population is aging fast – with the number of people in the 15 to 64 age groups declining continuously between 1996 and 2005. As such, in volume terms, foreign (and domestic) retailers will be faced with a reduced level of demand and a shift in the nature of that demand. Boosting per-capita purchases and/or developing new market niches will therefore become more important.

### **Critical Success Factors**

There is no such thing as a guaranteed formula for success in the Japanese market. We believe however, that there are a number of critical factors to consider in order to maximise the chances of success and minimise risk. The most important are:

1. Establish whether sufficient demand exists in the target market – now and in the future – for your products/services/formats to create a viable business.
2. Carry out entry/trading cost evaluation to identify “true” costs, key cost drivers and likely returns.
3. Review competitive conditions; what is the competition, how does it operate and how is it changing?
4. Learn from partners and competitors who have done it well.
5. Determine the method of entry; what is the preferred and/or most appropriate method? Carry out cost/benefit/control analysis.
6. Where entry involves partnerships and/or company combinations focus very carefully on management of cultural integration.
7. Establish “realistic” sales/profit/growth targets over, say, a five year time-line.
8. Decide operational requirements.
9. Think carefully about supply chain and logistics issues.
10. Adapt to local market conditions – strategic localisation versus general localisation.
11. Focus on product lines strategically – select items to match home market culture.
12. Establish/nurture local links with local governments and communities.
13. Determine the “cost of doing business the local way.”
14. Think carefully about two variables: (a) market position of the retail offer in the host country – which can be very different from the home country; and (b) the format of the retailing offer – particularly given the recent experiences of foreign entrants in Japan (recall the trend towards hybrid formats).
15. Draw up a comprehensive plan but also remember that too much analysis can bring paralysis. You must learn when to “freeze” the frame and then go – cautiously, carefully. Remember, retailing of goods and services is as much an art as a science. You can only minimise the uncertainty, not eliminate it. Whatever you do, do it professionally. Do not be afraid to ask for deals.
16. Start now – start the international culture in your organisation before you actually go overseas.

## Summary & Conclusions

Japan is somewhat of a paradox for international retailers. On the one hand, it is characterised by high operating costs, a complex distribution system, and thousands of inaccessible, technically insolvent retailers. On top of this, the notoriously demanding Japanese consumer presents a huge challenge to foreign retailers.

On the other hand, the wind of change is blowing through the Japanese retail market. Recent economic recovery, progressive deregulation, increasingly value conscious consumers appearing willing to accept change, and its continued position as the world's second largest retail market makes Japan a more attractive proposition for foreign retailers.

This attractiveness has persuaded many of the largest foreign retailers to begin to invest in Japan. Although the level of overseas retail investment is still relatively low by international standards (particularly given the size of the market), Wal-Mart, Costco, Tesco, Carrefour, and Metro have all taken the plunge in the last seven years, to join a host of niche and luxury brands that entered throughout the 1980's and 1990's. Through their attempts to introduce efficient supply chain management, new merchandising practices and discounting concepts, they are providing the catalyst for consumer and retail market change.

However, many are finding the Japanese market extremely difficult. Carrefour abandoned its 'go it alone' strategy in 2005, whilst Wal-mart has operated in deficit since entry in 2002. Major reasons cited for these difficulties include strong domestic competition and the difficulty in satisfying the Japanese consumer. The relative 'failure' of these global giants is perhaps a stark wake up call to retailers planning to internationalise, and a graphic illustration of the unique challenges and risks the Japanese retail sector presents.

We have set out a number of critical rules to address these challenges – to maximise the chances of success and minimise risk. These success factors emphasise the importance of understanding the unique demand, supply, and competitive characteristics of the host market at the local scale, and finely tuning the retail offer to reflect these. Given the difficulties/challenges set out above, these are perhaps more important in the Japanese market than others.

Finally, a prophesy; given the positive consumer and retail market changes set out above, combined with recent falls in property prices (and consequently the abundance of relatively cheap retail assets), we expect many more foreign retailers to follow. We believe the tipping point will occur when the country resolves its banking crisis. Then many existing retail assets will become available to foreigners and the floodgates will open. It is then however, that the critical success factors set out in this paper will become more important than ever.

### End Notes

<sup>1</sup> Further expansion into foreign regions they had already entered.

<sup>2</sup> Tesco is now (2006) present in twelve countries.

<sup>3</sup> Ranked by sales value (GPN, 2003).

<sup>4</sup> There are many other examples of this unprecedented structural impact. For example, in Thailand, where Tesco has become the clear grocery market leader after just nine years, since entry in 1997 (see GNS 2003 for other examples).

<sup>5</sup> Note the above list of market entry methods is ordered according to the relative cost and control of each strategy. For example, the first in the list – licensing, offers the least capital investment and risk, but the least control, whereas the last in the list – acquisition and self start, offer the most control but are the most costly strategies.

<sup>6</sup> GNS (2003), pp16.

<sup>7</sup> There is currently no 'true' national chain in Japan – with a major urban and rural presence in all 47 prefectures (IDG 2007).

<sup>8</sup> France, Germany, United Kingdom and United States.

<sup>9</sup> Aeon is also in the process of acquiring a 15% stake in Daiei with the aim of combining sourcing, NPD, and sharing information and distribution. At the time of writing this deal is yet to be finalised (June 2007).

<sup>10</sup> In March 2005 Carrefour announced a strategic partnership with Aeon. Carrefour sold its 8 Japanese hypermarkets to Aeon, whilst Aeon will use the Carrefour brand in Japan and sell Carrefour private label products.

# The Role of the Cash and Carry Wholesaler in the South African Distribution Channel

*University of South Africa*

## Abstract

The traditional South African cash and carry wholesaler has survived for more than twenty years in its present form but is showing signs of being influenced by a strong innovative process. Factors such as smaller packaging, credit, delivery and consumer marketing, which go against the principles of the traditional cash and carry wholesaler, are taking root. Innovation is being spurred on by changes in the target market, specifically as a result of the inclusion of the spaza shop target market. The research shows that the spaza shop is a vital future market of the cash and carry wholesaler. Intensive competition forces the cash and carry wholesaler to modify its marketing functions. It can be concluded that the cash and carry wholesaler definitely fulfils a vital role in the South African distribution channel.

## Introduction

The wholesale sector of the economy is often known as the invisible industry because the final consumer<sup>1</sup> does not usually purchase directly from the wholesaler and therefore has little contact with it. The cash and carry wholesaler is a typical wholesaler that performs essential marketing functions between the manufacturer and the retailer, and therefore provides a link between the two. The retailer, in turn, is the link between the cash and carry wholesaler and the consumer in the distribution channel. Therefore, the retailer can be regarded as the cash and carry wholesaler's primary target market.

This article aims to determine the role of the cash and carry wholesaler in the South African distribution channel. The cash and carry wholesaler's place in the South African distribution channel will now be outlined under the following headings: definition, origin, development, future, competitive position, right of existence and target markets.

## Definition of the Cash and Carry Wholesaler

A cash and carry wholesaler is a typical wholesaler that sells a limited range of products, and according to Skinner (2005:405), does not perform all the wholesale functions. The clients of cash and carry wholesalers must themselves perform specific marketing functions such as delivery and provision of credit in exchange for cheaper products.

Kotler and Armstrong (2005:372) and Etzel, Walker and Stanton (2004:363) emphasise the fact that the cash and carry wholesaler markets a limited range of products with a fast turnover. It concentrates primarily on a limited range of products in order to obtain the competitive advantages of purchasing in bulk. These advantages give the cash and carry wholesaler the edge as far as price competition is concerned and ensure its survival in the distribution channel.

Schoell and Guiltinan (2004:342) define the cash and carry wholesaler as "... a limited-service wholesaler whose customers are willing to give up services such as credit and delivery for lower wholesale prices. These wholesalers usually stock a limited line of products, mostly staples and fast-turnover items. Their customers tend to buy frequently and in small quantities." This definition emphasises the fact that retailers who tend to purchase from the cash and carry wholesaler are small and purchase products on a regular basis.

These definitions show that the cash and carry wholesaler's existence in the distribution channel is definitely justified because the retailer is willing to perform the particular market functions usually carried out by the full-service wholesaler in an effort to save costs. The retailer is thus prepared to perform specific wholesale functions

itself which has led to the development of the cash and carry wholesaler. The rise of the cash and carry wholesaler will now be briefly outlined.

## **The Rise of the Cash and Carry Wholesaler**

The cash and carry wholesaler developed in the 1950s and in spite of an impressive start, initially did not make a great contribution to the wholesale sector. In the USA, where the concept originated, in 1954 there were only 922 cash and carry wholesalers with joint annual sales of \$300 million. According to Beckman, Engle and Buzzell (2004:169) at that stage, the US cash and carry wholesaler sold mainly food products. However, the scope of the cash and carry wholesaler market grew dramatically over the years (Makro's method 1991:31).

In South Africa, the cash and carry wholesaler concept, only developed about 20 years later (in 1971), with the establishment of Makro in the then Pretoria/Witwatersrand/Vereeniging (PWV) area. During the 20th century, the wholesale sector was ravaged by increasing competition from the manufacturers and retailers. The manufacturers contended that the cash and carry wholesalers unnecessarily increased distribution costs in the distribution channel, and attempted to perform the wholesale function themselves. The upshot was that the manufacturers eliminated the cash and carry wholesaler from the distribution channel and began marketing directly to the retailer.

However, the rise of the large retailer further reduced the involvement of the wholesaler in the distribution channel. The larger retailers were in a position to perform the wholesale functions themselves. Consequently, the manufacturers own marketing endeavours and the development of retail led to intense competition. This competition resulted in the cash and carry wholesaler's removal from the distribution channel.

Besides the competition between the larger retail and the cash and carry wholesaler, competition between the larger retail and independent retailers also developed (*The Cape Times* 1995:19). Because the large retailer was in a position to market products more cheaply, it posed a threat to the retailer (Pride & Ferrell, 2005:377).

The cash and carry wholesaler gradually began to realise that its survival was linked to that of the smaller retailer because the latter was compelled to support the cash and carry wholesaler. Owing to the fact that the retailer purchases smaller quantities, it is unable to buy from the traditional full-service wholesaler. The cash and carry wholesaler and its involvement with the retailer is the focus of this chapter, but it first necessary to outline the development of the cash and carry wholesaler in the distribution channel.

## **The Development of the Cash and Carry Wholesaler**

The development of the cash and carry wholesaler in the South African distribution channel from 1960 to 1997 will now be highlighted.

### **The Period, 1960 to 1970**

During this period, there were no cash and carry wholesalers in South Africa. According to secondary sources consulted, the cash and carry wholesaler concept was unknown in the distribution channel in this country. During this period, the full-service wholesaler was primarily responsible for distributing products to retailers.

### **The Period, 1971 to 1985**

It was during this period that the cash and carry wholesaler was introduced in South Africa. Makro was one of the first cash and carry wholesalers in the country, and in 1971, the Dutch group Nederlandse Steenkolen Handelsvereniging (NSHV) (Makro's method 1991:31) established the first Makro in the then PWV area. In 1987, owing to anti-apartheid pressure on the Dutch enterprise, Makro was taken over by the Wooltru Group.

The second cash and carry wholesaler to be established in South Africa was Metro. According to a report in *The Citizen* (1990:11), Metro came into being in 1979 when the former Kliptown Wholesalers started taking over competitive wholesale groups such as Leiserowitz Brothers, Savex and Kirsh. Metro grew so rapidly that in the same year, it was listed on the Johannesburg Securities Exchange. In the period from 1971 to 1984, only Makro and Metro developed from the cash and carry wholesalers.

### **The Period, 1986 to 1990**

The period from 1986 to 1990 was characterised mainly by the growth of Makro and Metro as well as the establishment of new cash and carry wholesalers in the country. The latter development increased intratype competition between Makro, Metro and the other smaller cash and carry wholesalers in South Africa. Increased competition resulted in further takeovers, which resulted in the race to acquire a greater share of the cash and carry wholesale market.

In 1987, Makro changed owners because the Dutch Group was compelled by political pressure to withdraw from South Africa. The group sold its interests to the Wooltru Group. Makro went from strength to strength over the years, and in 1987 already boasted five outlets in the densely populated urban areas of South Africa. Makro's unprecedented growth emphasised the importance of the cash and carry wholesaler in the distribution channel. If there had been no room for the cash and carry wholesaler in the distribution channel, this market would not have grown so rapidly. Makro is pursuing even higher growth as expressed in the following objective: "Our objective is to be considered by retailers as the most desirable alternative to purchasing direct from a manufacturer or importer" (Wooltru 1996:23). Makro's existence in the distribution channel is possibly justified by the fact that it renders a specific and unique service to the retailer. The retailer contends that this service can only be rendered by the cash and carry wholesaler --- hence its right of existence (*Financial Mail* 1993:21).

Metro also expanded its interests and by 1987 already had more than 250 wholesale outlets. It concentrated on the specific needs of builders as well as the formal retailers and spaza shops in the black residential areas. In March 1987, Metro took over the Frasers Group, comprising mainly 41 cash and carry wholesale outlets in Lesotho, for R21 million. The upshot of this new takeover was that the Metro group had become a formidable competitor, and in 1987 was already the largest group in the country.

During this period, the Metro group operated three different kinds of cash and carry wholesalers, namely Metro, Bingo and Trade Centre. A report in *Finansies en Tegniek* (Stryd om verskaffing aan spaza's 1994:27) explained the difference as follows: "Trade Centre has a wider product composition than the other wholesale groups and sells groceries, building products and household fittings, while Bingo markets household fittings only and Metro groceries only" (my translation). Through the retailer, Metro concentrates on the consumer who comprises mainly the C and D income groups. This means that Metro is in direct competition with the large retailer Pick 'n Pay (*Finance Week* 1991:10).

Owing to this competition between the cash and carry wholesaler and the large retailer, Pick 'n Pay established its own cash and carry wholesale outlet, Price Club. According to a report in *The Cape Times* (Wooltru R173,4 m Capex 1990:18), the first Price Club was opened in October 1986 and concentrates on the black retail market which purchases products on a cash and carry basis.

In 1983, another cash and carry wholesaler, Success was established by the Shield Trading Corporation. Success grew rapidly, and five years later already had seven outlets. In July 1987, the Shield Trading Corporation established another cash and carry wholesaler, namely Shield Cash and Carry. The Shield Trading Corporation now had 150 cash and carry wholesale outlets and marketed to approximately 22 000 retailers. During this period, the cash and carry wholesaler was therefore meeting the needs of the retailer, thus justifying its existence in the distribution channel.

### **The Period, 1991 to 1997**

During this period, the cash and carry wholesale industry was characterised by a large number of cash and carry wholesalers such as Metro and Makro, which were all subsidiaries of large listed groups. During this period, the Wooltru Group controlled the cash and carry wholesalers, Makro and Shield, while die Premier group, controlled, Trador, Bingo and Trade Centre. Furthermore, Pick 'n Pay, had its own cash and carry wholesaler outlets, namely Price Club.

According to the McGregor list, an additional 25 smaller cash and carry wholesalers were established in South Africa during these years. However, in the secondary sources consulted, the starting dates of these smaller cash and carry wholesalers could not be determined. They were relatively unknown --- hence the lack of information on them. In this study, an effort will be made to acquire more information on the establishment of the smaller cash and carry wholesalers.

The merger of Metro and Score Foods under the Premier Group in 1991 gave rise to the largest cash and carry wholesale industry in South Africa. This group owns about 28 percent of the cash and carry wholesale market with a turnover of approximately R6 billion per annum (Premier Groep 1996:3 According to a report in *Finance Week* (1991:6-12), Metro, Trador and Trade Centre follow a niche marketing strategy<sup>2</sup>. These cash and carry wholesalers are enjoying exceptional success in implementing a niche marketing strategy. This possibly shows that the marketing strategies of these cash and carry wholesalers have been altered --- hence another reason to justify the continued existence of the cash and carry wholesaler in the distribution channel.

Owing to stiff competition between Metro and Makro, in 1992, the latter in collaboration with Makroffice, Shield and Drop Inn, formed a new wholesale group known as Massmart. Massmart is a competitive cash and carry wholesale group that owns approximately 18 percent of the cash and carry wholesale market in South Africa (*Finansies & Tegniek* 1993:26). This study focuses mainly on the development of cash and carry wholesaler in the South African distribution channel during the 10-year period from 1987 to 1997. The classification system of the cash and carry wholesaler will now be briefly discussed.

## **Competitive Position of the Cash and Carry Wholesaler**

The origin and development of the cash and carry wholesaler increased competition in the South African distribution channel. The cash and carry wholesaler experiences competition primarily from the following distribution channel members:

- the large retailer
- the manufacturer

The competitive position between the cash and carry wholesaler and the above-mentioned members of the distribution channel will now be discussed.

### **The Large Retailer**

In South Africa, the three main groups of large retailers, OK Bazaars/Shoprite & Checkers, Spar and Pick 'n Pay are responsible for 63 percent of all food purchases in retail (*Insig* 1988:21). According to Schoell and Gultinan (1993:316), this type of retailer is a large enterprise that purchases directly from the manufacturer and is therefore in direct competition with the cash and carry wholesaler. According to McCarthy and Perreault (1995:318), increased growth in the retail sector exacerbates this competitive situation.

From the definition of a wholesaler --- an enterprise that obtains 50 percent or of its gross sales from wholesale sales --- one can deduce that wholesalers, like retailers, also market to consumers. Their target markets thus overlap and they are involved in a competitive struggle.

According a report in *Marketing Mix* (Pick 'n Pay's tills ring the changes 1995:63), the spaza shops also buy products from the large retailers --- hence the cash and carry wholesaler cannot lay claim to the total spaza shop target market. The spaza shop market increases the competitive situation between the large retailer and the cash and carry wholesaler even further.

Kotler and Armstrong (2005:376) contend that the distinction between the large retailer and the cash and carry wholesaler is in the process of blurring, and they go on to say that, some retailers are being operated as wholesale clubs and hypermarkets that perform wholesale functions. This is possibly another reason why the target markets of the cash and carry wholesaler and the large retailer overlap and cause stiff competition.

Another reason for the increasing competition is the establishment of larger cash and carry wholesale groups such as the Premier Group, which is increasingly encroaching on the target market of the large retailer. However, the latter is also not innocent and endeavours to take over part of the cash and carry wholesale market by sending large trucks with low-priced products into black residential areas (*Weekly Mail & Guardian* 1995:3). This new trend is not only causing competition for the cash and carry wholesaler but also threatening the very survival of the spaza shop. One of the secondary aims of this study is to determine the exact position of the competition between the cash and carry wholesaler and the large retailer. According to Boyd, Walker and Larreche (1995:321), the ever-growing retailer poses a fundamental and relatively serious threat to the continued existence of the cash and carry wholesaler.

### **The Manufacturer**

McCarthy and Perreault (2005:336) maintain that the large retailer and the cooperative retailer purchase directly from the manufacturer. The negotiating power of these types of retailers is seemingly so strong that the cash and carry wholesaler is being eliminated from the distribution channel.

The manufacturer further strengthens the competitive position of the cash and carry wholesaler with the formation of depots (forward vertical integration) in the black residential areas (*Financial Mail* 1993:21). These depots supply products directly to the spaza shops and are possibly also eliminating the cash and carry wholesaler from the distribution channel.

### **The Cash and Carry Wholesaler's Right of Existence**

According to Morris (2004:79), justification for the existence of the cash and carry wholesaler in the distribution channel is twofold. On the one hand, the manufacturer is confronted with increased distribution costs such as delivery costs and the high risk of supplying credit. As a result, the manufacturer tends to pass these marketing functions on to the cash and carry wholesaler, which can perform them more cheaply. The smaller retailers, on the other hand, experience problems purchasing products from the full-service wholesalers because the latter do not sell small consignments.

The cash and carry wholesaler's right of existence can be partly ascribed to the fact that it supplies small amounts of products to the retail sector. Hence, the cash and carry wholesaler meets the needs of the manufacturer as well as the retailer and so fills a gap in the distribution channel. The cash and carry wholesaler's existence in the distribution channel is thus justified because the manufacturer and the retailer need it in the distribution channel.

Justification for the cash and carry's existence in the distribution channel can possibly also be attributed to the rise of the spaza shop, which in fact constitutes one of its target markets. The rise in the number of spaza shops because of increased population growth, low levels of economic growth and unemployment, has possibly led to a shift in emphasis in the cash and carry wholesaler's target market (*Weekly Mail & Guardian* 1995:3). The increased growth of the spaza shop encourages the cash and carry wholesaler to exploit this target market.

The history of cash and carry wholesalers in South Africa indicates that they definitely have a right to exist in the South African distribution channel but need to adapt timeously to changes in the target market. The target markets of the cash and carry wholesaler will be briefly discussed below.

### **The Cash and Carry Wholesaler's Target Markets**

The place of the cash and carry wholesaler in the South African distribution channel is determined by its target markets, which, because of developments in the target market, are undergoing changes. From the literature sources consulted, it would appear that the cash and carry wholesaler can select a target market according to three different requirements --- the size, type and geographical location of retailers. However, little research has been conducted into the target markets of the cash and carry wholesaler --- hence the aim of this study to try and determine its precise target markets.

The target market of the cash and carry wholesaler can be defined as a specific group or a potential retailer served by a cash and carry wholesaler. Kotler and Armstrong (2005:374) explain the cash and carry wholesaler's choice of a suitable target market as follows "The cash and carry wholesaler can choose a target group by size of customer, type of customer or need for service." The execution of marketing functions is central to this definition and suggests that the cash and carry wholesaler is prepared to change its marketing functions if so required by the target market.

Schoell and Gultinan (2004:342) define the target market of the cash and carry wholesaler as follows: "Small grocers and small building contractors are their customers who tend to buy frequently and in small quantities." It is essential for the cash and carry wholesaler to harmonise its abilities and resources with the needs of its target markets in order to identify suitable target markets. By carefully determining its target markets, the cash and carry wholesaler can use its resources optimally so that it can position itself more effectively in the market. It can thus gain a differentiated advantage over its competitors.

According to Morris (2005:79), the cash and carry wholesaler's target market comprises retailers from the informal sector such as spaza shops and hawkers. He puts it as follows: "Hawkers, spaza shops and unlicensed or illegal traders from the informal sector have utilised the cash and carry concept to the maximum effect." This definition confirms that because of its limited functions (no deliveries or credit) the cash and carry wholesaler is an ideal position to meet the specific needs of the spaza shop. It therefore forms a vital link in the distribution of the products to spaza shops (Van Scheers 1992:154). From the above definitions, the following target markets of the cash and carry wholesaler can be identified:

- formal retailers
- spaza shops
- quasi-retailers

Each of these will now be outlined.

#### **Retailers in the Formal Sector**

Kotler and Armstrong (2005:355) define the retailers in the formal sector as retailers that are managed independently, own a relatively small share of the total market and are operated independently of other enterprises. According to Etzel et al (2004:374), there are about 53 644 retailers in the South African formal sector. Retailers form a stable market and are the cornerstone of the continued existence of the cash and carry wholesaler.

The formal retailer is the retail institution that is most prevalent in South Africa. Initially this type of retailer traded in the coastal towns, but it was only in the densely populated Witwatersrand area where it increased in both size and power, that it became independent of the wholesaler in certain areas. The upshot was that the formal retailer became a strong competitive factor in the distribution channel. The growth of the large independent retailer was the cornerstone of the retail revolution in South Africa.

The retail revolution as the emancipation of the retailer, the wholesaler and the manufacturer. There was unprecedented growth in the retail sector during the 1960s, which surprised the manufacturers and the larger retailers (currently the large retailers) and caught the smaller retailers on the back foot. The smaller formal retailers had difficulty adjusting to the rapid and radical changes in the distribution structure. It is this group of retailers that currently constitute the target market of the cash and carry wholesaler. During the period 1971 to 1989, the number of formal retailers rose by an average of 4,9 percent per annum, which consequently increased the marketing potential of the cash and carry wholesaler substantially.

Ntsika Enterprise Promotion Agency (1997:1) defines the formal retailer as "... a business with a turnover of less than the value added tax registration limit of R150 000, and which employs no more than five people".

Skinner (1994:243) adds an additional characteristic to the above definition, namely that the operating area is centred locally. The retailer as an enterprise that obtains more than 50 percent of its gross sales revenue from sales to the general public (the consumer) for personal and domestic use. Pride and Ferrell (2005:398) emphasise the fact that some retailers also sell to other retailers.

Dalrymple and Parsons (2005:559) state the following: "Retailers perform a variety of useful functions for the producer, including the carrying of inventory, advertising, promotion, credit, delivery and shopping convenience." One can infer from this definition that the retailer also supplies credit and delivers products, which are usually regarded as typical full-service functions. It would appear from the definitions that the formal retailer undoubtedly plays a role in the cash and carry wholesaler's target market. The latter's involvement with formal retailers will now be cursorily discussed.

Retailers in the formal retail community are an important segment of the South African free-market system. Formal retailers contribute approximately 29 percent to South Africa's gross national product and form a vital target market of the cash and carry wholesaler (Etzel et al 2004:374).

Economic trends such as unemployment and limited job opportunities in the formal sector generate increasingly more retailers. Although the formal retailer generally showed a small increase during the period from 1988 to 1994, the urban retailer grew by 34 percent (Pick 'n Pay's tills ring the changes 1995:63-64). This explains why the cash and carry wholesaler endeavours to be situated in close geographic proximity to these retailers.

A study undertaken by *Die Transvaler* (KSOK help smouse 1992:14), found that the active promotion of retailers is one of the most effective methods of solving South Africa's unemployment problem since 95 percent of all new job opportunities in the world are created by small and medium retailers.

In South Africa, retailers in the formal sector are responsible for about 75 percent of new job opportunities (Southern Africa 1992:16). The Reconstruction and Development Programme (1994:76) encourage the development of retailers in South Africa, and the stimulation thereof is seen as a possible solution to the unemployment problem. The formal retailer is an key target market of the cash and carry wholesaler and justifies its existence in the distribution channel. On the other hand, the retailers (spaza shops) in the informal sector constitute only a small part of the cash and carry wholesaler's target market, but because of the tremendous growth opportunities, this target market will also be elucidated.

#### **The Spaza Shops in the Informal Sector**

The spaza shop or informal retailer is part of the informal sector. The latter can be defined as the sector in which enterprises are not regulated according to the normal, conventional prescribed methods. The term "informal sector" is used to define an economic phenomenon that is widespread in the rural and urban areas of Third World countries (Pick 'n Pays tills ring the changes 1995:63-64).

The right of existence and feasibility of the spaza concept can be ascribed to the convenience-shopping trend of black consumers (Black Enterprise 1989:15-70). It is important for the cash and carry wholesaler to determine precisely how large the spaza shop target market is in order to justify its own existence in this distribution channel.

However, it is impossible to establish the exact size of the spaza shop market. According to an estimate by Black Enterprise (1989:32), on the East Rand alone, there are about 4,000 to 20,000 spaza shops. Scott-Wilson and Mailoane (1990:10) estimate that there are approximately 20,000 spaza shops in the whole of South Africa. These estimates are probably too conservative. Van Zuydam-Reynolds (Pick 'n Pay tills ring the changes 2005:63-64) painted a more realistic picture in his estimate of about 66,000 spaza shops in 1995. These estimates are further complicated by the fact that new spaza shops are continually entering the market, while others again are going under almost daily.

The joint spaza shop purchasing power of about 16 billion per annum is indeed extremely high and therefore constitutes a promising market for the cash and carry wholesaler (Black Market Report 1991:2-3). The joint retail purchasing power of motivates the cash and carry wholesaler to exploit the spaza shop target market. According to a report in *Finansies en Tegniek* (Stryd om die verskaffing aan spaza's 1994:27), the cash and carry wholesaler regards this target market as an important outlet for marketing to the black consumer. Preston-Whyte (Pick 'n Pay's tills ring the changes 1995:63-64) is of the opinion that through the spaza shop, the cash and carry wholesaler can market a part of the black consumer market, which was previously not possible.

#### **The Involvement of Spaza Shops**

According to an article in *Marketing Mix* (Pick 'n Pay's tills ring the changes 1995:63-64), the cash and carry wholesaler is a significant supplier of products to spaza shops. The spaza shop concept is a promising new concept, and Mantle, Harrod and Nel (1992:19) contend that the spaza shop market is growing by about 10 percent per annum. If this growth trend is linked to the cash and carry wholesaler, its existence in the distribution channel is possibly justified (Stryd om verskaffing aan spaza's 1994:27).

Themba (Pick 'n Pay's tills ring the changes 1995:63-64), however, holds that too much emphasis is being placed on the spaza shop market and that this concept does not have a future. He goes on to say that, it is not a solution to South Africa's unemployment problems and merely offers a temporary solution. Sithole (1989:34) concurs with Themba and poses the following question: "Are home-based enterprises (spaza shops) worthwhile?" He is convinced that they are not the solution to the country's long-term economic problems.

The chances of survival of the smaller spaza shops that are not strategically located are slim. A possible reason for this is too little client traffic. However, according to Rogerson (Pick 'n Pay's tills ring the changes 1995:63-64), the larger spaza shops situated near to the highways, definitely have a better chance of survival. New urban areas are continually being developed, and in places where there are no formal retailers, new spaza shops that will purchase from the cash and carry wholesaler, will undoubtedly develop.

According to an article in *The Cape Times* (Wooltru R173,4 m capex 1990:18), the growth of the spaza shop definitely confirms Makro's right of existence in the distribution channel. *The Star* (1997:1) also underlines the importance of the spaza shop and indicates that this industry realises a joint turnover of R107 million per annum. If one considers the incredible growth of the spaza shop target market and the fact that the cash and carry wholesaler

supplies most of the products to this target market, the spaza shop can undoubtedly be regarded as a factor that justifies the existence of the cash and carry wholesaler in the distribution channel.

It is also important to note that the spaza shop target market alone cannot possibly justify the existence of the cash and carry wholesaler in the distribution channel. This could be because the spaza shop market is still too small. However, there is a possibility that the increase in unemployment in South Africa, and the resultant growth of the informal sector will in the future create a greater marketing potential for the cash and carry wholesaler. However, retailers also buy from the cash and carry wholesaler for their own use, these purchases being known as quasi-retail. Quasi-retail as a target market will now be discussed.

#### **Quasi-Retail**

Quasi-retail is also a target market of the cash and carry wholesaler because the formal retailers and the spaza shops purchase for their own private use. However, it is important to note that the primary target market of the cash and carry wholesaler is the formal retailer and the spaza shop. Hence quasi-retail actually constitutes a random as opposed to a primary target market of the cash and carry wholesaler. Makro, however, contends that 25 percent of its turnover comprises quasi-retail (Strydom *verskaffing aan spaza's* 1994:27).

Most cash and carry wholesalers do not appear to have any objections when clients who satisfy the criteria for resellers, purchase products for their own use. However, no special provision is made for consumers who purchase small amounts at a time.

Lamberti from Makro (*Finansies & Tegniek*, Augustus 1991:9) explains that their price and product mix is determined on a wholesale basis, which as a rule, does not satisfy the specific needs of quasi-retail. Trador and Price Club's product mix, however, does not make any provision for quasi-retail, because pressure from their retail client forbids this (Makro's method 1991:31). There appear to be different opinions about the importance of the quasi-retail market and one of the aims of this study is to clarify this matter.

### **Changes in the Target Market**

The target markets of the cash and carry wholesaler really seem to be in a state of flux. The inclusion of the spaza shop target market could be advanced as a reason for this. There was strong sentiment among the respondents that the continued existence of the cash and carry lies in the further exploitation of the spaza shop target market. It is recommended that this target market should be exploited more rapidly to enable the cash and carry wholesaler to obtain a competitive advantage over the large retailer.

### **Future Trends for Cash and Carry Wholesalers**

Greater involvement in spaza shops, marketing aimed at the consumer and adjustments to the credit and delivery functions appear to be the future trends that can be expected in the wholesale sector. The cash and carry wholesaler is currently undergoing structural changes, is performing increasingly more retail functions of the large retailer and is marketing to the consumer to a greater degree, all of which are impacting on the basic characteristics of the cash and carry wholesaler.

The cash and carry wholesaler itself is also even willing to give credit and deliver products, and is thus increasingly impinging on the terrain of the full-service wholesaler. Innovation is unavoidable. Fortunately, a new kind of wholesaler is being formed, that can optimally satisfy the needs of the target market. In the process, cooperation with the full-service wholesaler will be of inestimable value. The function of the cash and carry wholesaler in the South African distribution channel will be briefly highlighted below.

### **The Function of the Cash and Carry Wholesaler**

Traditionally, the cash and carry wholesaler operates between the manufacturer and retailer to supply products to the consumer. The transfer of products generates marketing functions that are performed by the cash and carry

wholesaler. The latter should carry out these functions in such a way that there is a saving for both the manufacturer and the retailer. The efficient performance of marketing functions justifies the cash and carry wholesaler's existence in the distribution channel. The marketing functions of the cash and carry wholesaler will be touched on in the next section.

#### **The Marketing Functions of the Cash and Carry Wholesaler**

According to Schoell (2005:338), the primary marketing function of the cash and carry wholesaler is to organise the market for the manufacturer. The cash and carry wholesaler renders a specialised, indispensable and essential service to the manufacturer and the retailer and therefore forms a vital link in the distribution channel.

Restructuring and repackaging are additional marketing functions performed by the cash and carry wholesaler for the manufacturer and the retailer. The cash and carry wholesaler purchases products in bulk, which enables the manufacturer to produce in bulk so that economies of scale, can be utilised (Kotler & Armstrong 2005:370). The cash and carry wholesaler is also in a position to combine small orders from retailers into one large order. These wholesale functions save both the manufacturer and the retailer distribution costs and therefore justify the cash and carry wholesaler's existence.

Furthermore, the cash and carry wholesaler provides the manufacturer with inventory-holding facilities so that it can carry less stock. The upshot is that the manufacturer requires less capital that is used unproductively. The cash and carry wholesaler therefore bears the risks of fire damage, price fluctuations and changes in fashion or damaged goods (Skinner 2005:400).

However, cash and carry wholesalers give no credit to retailers. The latter are also compelled to make their own delivery arrangements because the cash and carry wholesaler does not deliver products. The retailer is prepared to perform these functions itself in an effort to keep costs low. The wholesale functions are therefore passed on to the retailer (Schoell & Guiltinan 2005:342).

#### **Changes in Specific Marketing Functions**

As indicated earlier, changes to the marketing functions because of the inclusion of the spaza shop target market impact on the role of cash and carry wholesaler in the distribution channel. It would appear that some of the respondents have already made changes to their packaging, sales representatives, credit and delivery functions. Each marketing function will now be discussed in turn.

#### **Changes in the Packaging Functions**

As indicated earlier, the spaza shop purchases products mainly in small quantities. According to Van Scheers (1998:279), it would seem that 77,8 percent of the cash and carry wholesalers have already adjusted their packaging functions to accommodate the spaza shop. This response is regarded as significant because it shows that most cash and carry wholesalers already regard the spaza shop as an vital target market and have therefore made changes to accommodate the specific target market.

#### **Changes in the Function of Sales Representatives**

Traditionally, the cash and carry wholesaler does not employ sales representatives to visit retailers. The study shows that one-third of the respondents in fact send out sales representatives (Van Scheers 1998:279). Further changes are also anticipated since retailers would welcome contact that is more personal with the cash and carry wholesalers, which would give them a competitive advantage.

#### **Changes in the Credit Functions**

Granting credit is traditionally regarded as a full-service function and definitely not one of the functions of the cash and carry wholesaler. If the respondents do in fact grant credit to their clients, this could be a sign that the cash and carry wholesaler's marketing functions are indeed changing drastically. The study shows that 27,8 percent of the respondents have already changed their credit function (Van Scheers 1998:279). The respondents concurred that the purpose of the changes they have made to their credit functions are to improve their service to better meet the needs of the spaza shop, and that further changes are anticipated. This opinion ties in with the discussion in section 1.3 which indicated that the cash and carry wholesaler does not traditionally grant credit, but that in the interests of new target market development, is willing to consider doing so.

#### **Changes in the Delivery Function**

Traditionally the cash and carry wholesaler does not deliver products. This marketing function is regarded as a typical function of the full-service wholesaler. Changes in the delivery functions can be regarded as further evidence

of the fact that there is innovation. The study by (Scheers 1998:279) shows that 22.2 percent of the cash and carry wholesalers are already delivering products. This implies that although most cash and carry wholesalers do not deliver products some are already adapting their delivery functions to meet the needs of the spaza shop target market. Changes have been introduced because of stiff competition in the target market.

## **Conclusion**

In conclusion, there is no doubt that the cash and carry wholesaler is playing a vital and active role in the South African distribution channel, but that there also are signs of drastic innovations. The inclusion of the spaza shop as target market guarantees the cash and carry wholesaler a definite place in the distribution channel. However, structural changes and innovation have resulted which goes against the basic principles of the industry. The driving force behind innovation has been changed in the target market. The cash and carry wholesaler is in the process of changing into a new type of wholesaler that manifests characteristics of the larger retailer and the full-service wholesaler, and is better able to satisfy the needs of the target market. The successes that have already been achieved and will be achieved in time will depend largely on the cash and carry wholesaler's ability to make timely adjustments to its marketing functions.

## **Recommendations**

According to the discussion of the main findings regarding the place and function of the cash and carry wholesaler, it is clear that the latter does in fact deserve a place in the distribution channel. However, the findings show that the cash and carry wholesaler is going to be eliminated from the distribution channel if it does not make timely adjustments to its target markets. To assist the cash and carry wholesaler with these adjustments, the following recommendations are made:

- The main recommendation is that the cash and carry wholesaler needs to make additional drastic changes to the spaza shop as target market to increase its own chances of survival.
- This study shows that the large retailer is the cash and carry wholesaler's main competitor. The large retailer also has a competitive advantage because it is already firmly entrenched in the consumer target market. It is recommended that the cash and carry wholesaler position itself in such a way that the consumer target market can be optimally marketed.
- It is further recommended that the cash and carry wholesaler should pursue an intensive price competition strategy in an effort to be more competitive towards the large retailers.
- Intratype competition was also identified as a problem in the industry and the South African cash and carry wholesaler has been labelled as over-concentrated. From this perspective, it is recommended that a mechanism be developed in collaboration with government to ensure orderly competition. A possibility that could be investigated is the Robinson-Patman legislation used in the USA to control the power position of the distribution channel members.
- It is also recommended that the smaller cash and carry wholesalers join forces or conclude agreements to be more competitive in the distribution channel.
- The target markets of the cash and carry wholesaler are extremely sensitive to price changes --- hence direct competition with the large retailer is inevitable. It is recommended that the cash and carry wholesaler compete directly for price in so doing to capture a greater part of the target market.
- It is also recommended that the cash and carry wholesaler become actively involved in the consumer target market so that it is less vulnerable to changes in the distribution channel.
- It is generally accepted that innovation in the cash and carry wholesale sector has occurred in response to the changing needs of the target market. Because of these changes, the cash and carry wholesaler began marketing to the spaza shop. However, the inclusion of the spaza shop as target market effected drastic changes in the credit

function. Adjustments were made to the credit function in particular. It is recommended that the cash and carry wholesaler introduce a credit card system to give spaza shops easier access to credit.

- Further changes need to be made to the delivery function. It is recommended that the cash and carry wholesaler acquire delivery vehicles so that it can deliver more efficiently to spaza shops. It is also recommended that the cash and carry send trucks with products into black residential areas to ensure that they and the spaza shops are not forced out of the distribution channel.

## Conclusion

In conclusion, there is no doubt that the cash and carry wholesaler is playing a vital and active role in the South African distribution channel, but that there are also signs of drastic innovations. The inclusion of the spaza shop as target market guarantees the cash and carry wholesaler a definite place in the distribution channel. However, structural changes and innovation have resulted which goes against the basic principles of the industry. The driving force behind innovation has been changed in the target market. The cash and carry wholesaler is in the process of changing into a new type of wholesaler that manifests characteristics of the larger retailer and the full-service wholesaler, and is better able to satisfy the needs of the target market. The successes that have already been achieved and will be achieved in time, will depend

## End Notes

<sup>1</sup> In this study, the final consumer or consumer refers to the general public who purchase products for personal or domestic use.

<sup>2</sup> The niche marketing strategy involves specialization in a limited or unique product range (Bowersox & Cooper 1992:45)

# Comparative Advantages of China's Ocean Shipping Industry

Xiaodong Wang, wangxd@uibe.edu.cn

University of International Business and Economics, China

## Abstract

Logistics is always considered as a derived demand for trade. As economic globalization becomes a very important feature of the 21<sup>st</sup> century, international logistics is increasingly drawing more and more attention. Meanwhile, China's booming export and ever growing fleet seems to be a quite good footnote for the above theory. However, this research studied market performance of China's ocean shipping industry (especially container transport sector) and found out that China's ocean shipping industry is lack of advantages over its foreign competitors.

## Introduction<sup>1</sup>

The past twenty years has been the best years for Chinese exporters. Since 1990s, average increase rate for Chinese exports has always been over 20%. Except for the unusual years, balance of payment for commodity trade has always been enjoying surplus. China's access to WTO in the year 2001 encouraged the nation to apply even more open policies, thus Chinese companies' fastened their already hasty steps toward the global market. From the year 2002-2005, annual increase rate of commodity export was about 30%, which is much higher than average level. At the meantime, service export, which was playing an ever important role in the global market, suffered constant deficit. In the year 2005, surplus of commodity export was \$134 billion, while deficit in service trade was \$ 9.4 billion.

As a supporting power of China's export-oriented economy, the ocean shipping industry developed dramatically during the last 20 years. In 2005, the scale of China's fleet in terms of deadweight tonnage accounted for 6.8% of the world's total quantity and ranked 4<sup>th</sup> among maritime powers. Moreover, China's main ports such as Hong Kong, Shanghai, Shenzhen, Qingdao, Ningbo, Tianjin and Guangzhou are among the top 20 container ports around the world. Two leading players, COSCO (China Ocean Shipping Company) and China Shipping are ranked as 7<sup>th</sup> and 8<sup>th</sup> biggest container carriers in freight market. In the meantime, the national railway and highroad, which served as links to hub ports, also developed very fast. In a word, logistics infrastructure, which is supporting import & export business, has made full growth.

## Literature Review

Quantifying international difference in comparative advantage has always been a significant task. The reason behind it is not difficult to understand: economic conditions in various trading countries determined their international comparative advantages and trading patterns. Trading patterns, in turn, determined each nation's patterns of production and consumption which may affect it's future economic condition as well. Thus, economists are eager to appraisal international comparative advantage to study its impacts on economic development. Li and Guisinger (1992) used international comparative advantage to explain MNC's strategic location decisions. Siew-Yean (2001) assessed comparative advantage of China manufacturing industry over Malaysia and predicted that China's impending accession in WTO would enhance her competitiveness while affecting negatively on her competitors' exports. Kalafsky (2001) measured comparative advantage of US machine tool companies and held that despite of steady decline of US MT industry, it would experience commercial recovery in the long term.

However, due to the complexity and variety of service industry, few studies have been made on comparative advantages of service trade, even less focusing on the competitiveness' of transportation sector. Nevertheless, due to its significant role in service import & export, most studies on service trade have included discussions on transportation service trade. Zheng (2000) held the opinion that while China's service sector was lagging behind in export, labor intensive sectors as travel service and ocean shipping industry possessed factor

endowment and enjoyed comparative advantage. Ding (2000) pointed out that development of China's service sector is quite unbalanced. Yet, he concluded that ocean shipping industry and travel service industry did have certain competitiveness. Yang (1999) further illustrated that China's ocean and air transport sector had tremendous potential for development. Meanwhile, Zhang (2004) concluded even in labor-intensive industry, such as ocean shipping industry, China did not have comparative advantage. Chen and Yang (2001) argued though China's shipping service export had made some progress, it didn't enjoy international comparative advantages yet. Wan (2005) assessed China's ocean shipping industry, travel service and banking sector and drew quite negative conclusion of their competitive advantage.

It is quite clear that there's no consensus on market performance of China's ocean shipping industry. On the contrary, existing findings are quite contradicting. The objective of this research is to make a thorough study on China ocean shipping industry and decide its international competitiveness.

Methodology is quite important to economic study as it has always been. Balassa (1965) defined Revealed Comparative Advantage index 30 years ago. Peterson and Barras (1987) studies measurements available for judging international comparative advantage and concluded that RCA index is a reliable indicator of trade performance. Till now, RCA index has been widely used in similar studies. Li and Guisinger (1992), Ling(1996), Siew-Yean (2001), Kalafsky, (2001) used RCA index to provide insights into export performance of selected exporting products in global markets. Wang etc. uses RCA index as an explanatory variable representing importing country's comparative advantage to model effect of logistics on trade of agriculture products. Malley and Moutos (2002) developed an import demand function which involved RCA index to indicate comparative advantage of the products. Though researchers such as Li and Guisinger (1992) developed new index (International Competitiveness Index) as an alternative tool to measure international specialization, it makes no substantially distinction between the new one and RCA index.

As a result, NTB and RCA index will be used as important measurements to reveal China's international comparative advantage in this sector. To compare, the researcher selects top 39 nations and regions which are ranked as top 30 exporters in either goods or services trade. Among them, mainland China, Hong Kong and Macao are considered as 3 regions.

## **Comparative Advantage of China Ocean Shipping Industry**

### **Current status**

In 2005, commodity trade kept playing a key role in global import & export market. Among the 39 nations and regions selected, commodity exports accounted for 79.9% of the total exports (sum of service export and commodity export) whereas the service export was about one fifth of the total. With regard to service trade, transport service export made up only 4.3% of total exports, which was lower than that of the travel service export (5.1%). Except the nations and regions which failed to provide complete data, ocean and air service export held 31.4% and 24.4% of total transport service exports respectively.

As to mainland China, it is the 3<sup>rd</sup> largest commodity exporter, 12<sup>th</sup> largest transport service exporter. Its commodity exports amounted to \$762, 484 in 2005, accounting for 91.1% of the total exports while transport service exports represented only 1.8% of the total. Among transport service exports, ocean and air service exports occupied 57% and 25% respectively whereas cargo, passenger and auxiliary service trade accounted for 69%, 17% and 14% of transport service exports. Hence, it is no doubt that commodity export is crucial for China exports while ocean transport service constitutes the main part of transport service sector.

### **Analysis with NTB index**

NTB Index is quite commonly used for measuring international comparative advantage. It is defined as the ratio of the difference between the exports and imports and the total amount of the two, i.e.

$$NTB = \frac{\text{Exports of transport service} - \text{Imports of transport service}}{\text{Exports of transport service} + \text{Imports of transport service}}$$

The NTB Index is between -1 and 1. As a nation's NTB Index approaches 1, its trade comparative advantage is regarded as stronger.

Table 1 shows that in 2005 except for the slender advantage, which commodity exports had taken on, China suffered negative NTB Index of service export, transport service export as well as ocean shipping and air service export. Although ocean shipping service held a largest share of the transport service export, its NTB Indexes presented apparent disadvantages over the other nations. All at once, NTB index shows that Greece, Sweden and Russia possessed highest trade advantages in the global market.

However, NTB Index can only contrast balance of imports and exports. Negative NTB index can only mean that a nation is a net importer in the global market. It gives no clue on competitive position of China ocean shipping industry in the world market. Next RCA Index will offer a good supplement.

#### Analysis with RCA index

RCA is defined as export specialization in terms of country j's share of group exports of product i relative to its corresponding share of group exports of all products and services, i.e.

$$RCA_{ij} = \frac{\text{Export of Country } j\text{'s Service } i}{\text{Country } j\text{'s Total Export}} / \frac{\text{World Export of Service } i}{\text{World Total Export}}$$

Since developed, RCA Index has been widely used to measure competitiveness of a nation's tradeable goods and services. With higher RCA Index, a nation or region is regarded as more competitive in the sector compared with the world's average level.

TABLE 2: RCA INDEX OF THE 15 TOP TRANSPORT SERVICE EXPORTERS

	Transport Service	Ocean Shipping	Air Service	Other Services	Comodity	Service Trade
USA	3.22	2.77	25.45	47.20	2.21	10.10
Germany	1.94	9.04	12.07	10.83	2.39	4.15
Japan	1.82	13.18	8.77	0.00	1.40	2.96
UK	1.67	8.83	11.07	4.45	0.94	5.42
France	1.38	n.a.	n.a.	n.a.	1.08	3.11
Korea,	1.22	n.a.	n.a.	n.a.	0.71	1.22
Netherlands	1.08	n.a.	n.a.	n.a.	0.85	2.11
Singapore	0.91	n.a.	n.a.	n.a.	0.57	1.38
Greece	0.88	8.34	0.66	0.62	0.04	0.92
Italy	0.80	3.31	5.16	5.41	0.92	2.41
Norway	0.79	6.21	0.39	5.18	0.26	0.77
China PR	0.79	4.58	3.32	4.51	1.88	2.00
Spain	0.78	1.08	7.52	7.50	0.48	2.51
Belgium	0.71	3.68	1.69	8.04	0.65	1.49
Austria	0.54	n.a.	n.a.	n.a.	0.29	1.45

As Table 2 indicates, mainland China exhibited comparative advantages to a certain extent in both commodity and service trade. China's RCA Index for commodity exports ranked the 3<sup>rd</sup>, falling behind US and Germany only. But, China merely ranked 8<sup>th</sup> for service trade, 12<sup>th</sup> for transport service export and 6<sup>th</sup> for ocean shipping export. Particularly, RCA index demonstrates that China ocean shipping industry was far behind that of Japan, Germany, UK, Italy etc<sup>2</sup>. Besides, disadvantages of other transport service sector were much more apparent. Thus, RCA analysis supports findings we have got with NTB analysis.

To sum up, NTB and RCA indexes indicate that China's ocean shipping sector is still in disadvantage compared with those of strong trading powers. The result is different from the understandings formed during the early years (Zheng 2000; Ding, 2000; Yang, 1999), whereas similar to the results of more recent studies (Zhang , 2004; Wan , 2005).

### Discussion on Competitiveness of China's Ocean Shipping Industry

It is generally agreed that transport service (especially cargo transport service) is derivative demand. Subsequently, it is predicted that expansion of commodity trade will motivate growth of transport service export. Regression result in Table 3<sup>3</sup> supports the above conclusion and confirms that transport service export is closely related to either commodity trade volume (import plus export) or export volume. Furthermore, as more than 2/3 of commodity trade will use sea transport service to support overseas market, it is likely that ocean shipping sector might expand together with China's dramatic increased exports. Surprisingly, while China's commodity trade is booming, relative scale and market share of China ocean shipping sector are declining. Not only that, China is one of most competitive commodity exporters around the world. But the competitiveness of China's ocean shipping industry in terms of NTB and RCA indexes lags far behind theoretical expectations. The above observation seems contrasting against

economic theory. Further studies on China shipping industry exposed that following reasons may answer for the paradox.

TABLE3: RELATIONSHIP BETWEEN TRANSPORT SERVICE EXPORTS AND COMMODITY EXPORTS

	Export of Transport Service	Export Of Shipping Service	Export Of Air Service
Commodity Export	0.852* ( 77%** )	0.906* ( 59%** )	0.849* ( 64%** )
Sum of Commodity Import and Export	0.978* ( 81%** )	1.012* ( 61%** )	0.949* ( 68%** )

\*Be significant at the level of 0.5%      \*\* Adjusted R<sup>2</sup>

As a whole, mainland China is taken as a transitional economy while her shipping market is a one of the most open market in the world. Its shipping market was open to the outside world as early as 1980s. Since then, China required no cargo reservation for domestic carriers. Foreign companies can easily start their business in China and serve local import & export market. As a result, the grown cargo volume are shared by both Chinese and foreign carriers.

Competition is fierce. Around the world, ocean shipping industry, especially liner industry is traditionally regarded as a highly international and oligopoly market. Shipping companies used to form cartel (for example shipping conference or a certain kind of alliances) to deal with cargo owners. Consequently, independent carriers do not have too much room to rival. Evidence from Li's research (2006) proved that Shipping Conferences or Shipping Alliances are decisive players in the market (see Table 4). Although US applied New Shipping Act (1998) and EU committee declared to exempt Shipping Conference of any rights for anti-cartel regulations, Shipping Conference or Strategic Allies such as New World or Asia Australia Discussion Agreement still keeps significant market share. Meanwhile, with more mergers and acquisitions independent carriers like Maesk successfully take about 21% of world's container shipping capacity<sup>4</sup>. Unfortunately, leading goats among China shipping companies such as COSCO and China Shipping are definitely one of the few independent carriers within the industry. Even though they started certain co-operations with other shipping companies these years, they are not famous for being involved in any coalitions or cartels. In consequence, though the two companies have developed rapidly in the past decade, they are still not strong enough in the market resulting in unsatisfied market performance of China shipping industry.

TABLE 4: MARKET CONCENTRATION OF CONTAINER SHIPPING INDUSTRY

	Market Share (Herfindahl-Hirschman Index)		
	Shipping Conference	Strategic Alliances	Independent Carrier
Far east – North Europe	77.8% (6187.0)	69.9% (1447.1)	30.1%
Around Pacific Ocean	67.8% (4736.2)	72.7% (1363.5)	17.4%
Far east – Mediterranean	74.1% (5722.9)	47.7% (1278.9)	52.3%
Far east - Australia	96.1% (9246.1)	96.1% (1653.0)	3.3%

Source: Na Li etc. “Empirical Study on Market Concentration in Global Container Line Industry”, *Shipping Management*, 2006.12, 10-13

Last but not least important, productivity of China’s ocean shipping industry is still quite low. Productivity of an industry is closely related to its international competitiveness. In ocean shipping industry, up-to-date facility and high level service (including Customs Clearance, Cargo Handling, and Warehousing Service etc) will surely impact its efficiency or productivity. However, facility infrastructure and service are still not satisfactory in China even now (Wang 2006). Table 5 shows that there is big gap between productivity of China shipping industry and that of the other countries’.

TABLE 5: PRODUCTIVITY OF TRANSPORTATION SECTOR IN VARIOUS COUNTRIES<sup>5</sup>

	China	Israel	Japan	Korea	Singapore	Thailand	US	Germany	UK
Home Currency	293	2253	79021	290480	759	4044	793	569	350
SDR*	28.7	409.2	477.5	174.3	326.3	72.8	631.6	399.4	403.4

## Conclusion

All in all, dramatically increasing commodity trade offers great potential for the development of China shipping industry. However, as productivity of the industry is rather low compared to its foreign counterpart, its international competitiveness in terms of NTB and RCA index is not satisfactory. In the meantime, China’ open market encourages more foreign carriers to come in for a share who compete more severely against local players. With more production capacity concentrated to few giant market powers like Maesk or MSC, Chinese shipping industry will inevitably encounter more challenging environment in the future.

Fortunate enough, we see certain improvement already shown in the industry. As Figure1 presented, despite huge commodity exports, the RCA Indexes of both the commodity and service trades have exhibited great fluctuation since late 1990s. Good news is though RCA index for China shipping sector fell during 1996 to 1999, it increased steadily and gradually since 1999. The trend may not guarantee a promising future for Chinese carriers. Still it is encouraging enough for more progress.

FIGURE 1: RCA INDEX FOR CHINA'S EXPORT DURING 1996-2005

### End Notes

<sup>1</sup> Except for sources mentioned, data in this research are from or calculated based on data provided by *IMF Balance of Payment Statistics: (2002-2005)*.

<sup>2</sup> Information from ocean shipping market showed that Korea, France and Singapore are also famous for their fleets and ocean shipping carriers. Then, though detailed data is not available, we still take them as comparatively competitive players...

<sup>3</sup> The model is expressed as:

$\ln(\text{exports of transport service}) = a + b \ln(\text{exports of commodity trade})$

in which the coefficient tells the elasticity of transport service export to commodity exports. Export volume data are from Balance of Payment of 165 nations.

<sup>4</sup> *The 2005 Report on China's Shipping Development*, China Communications Press, 2006

<sup>5</sup> Productivity is defined as total GDP of shipping industry divided by number of employees. The two groups of data are from "Statistical Yearbook of World Economy", Figure 4-13 and 6-4. Exchange rate is provided by IMF.

## Abstract

The research objective of this paper is to seek the suitable way to solve the problems of environmental and labor protection, based on the analyses the phenomenon that the ship breaking / recycling industry transferred globally in the past 50 years. The paper also analyzes the uneven social responsibilities among the shipping, ship building and shipbreaking industries, based on the fact of production values of them. The paper discusses the situation and problems faced by IMO, ILO and Basel Convention Regulation that are currently discussed for solving the environmental and labor protection problems and dealing with the transition of wastes across boundaries internationally, and the concerning points of related parties. Paper finally discusses the future trends of dismantling obsolete ships and prices, suggests the topic that shipping and ship building sectors should undertake more social responsibilities to environment and labor protection, appreciates the solution model developed by Holland and China companies in this field, and predicts the potential development trend of the shipbreaking clustering.

## Literature Review

### Shipbreaking is part of the underbelly of globalization

Shipbreaking industry is part of global industry set, which has been the hot topic in international media. After the reporting team won a Pulitzer Prize, the story gained additional momentum due to European interest. In 1998, Greenpeace published its own report on Alang (India), making the explosive claim that there were approximately 365 deaths a year from shipbreaking accidents, resulting in the slogan: "Every day one ship, everyday one dead."<sup>1</sup>

Based on the view of some experts in the world, such as Rune Larsen, he pointed that, in the early 1970s ship breaking was a highly mechanized industrial operation carried out in the shipyards of Great Britain, Taiwan, Mexico, Spain and Brazil. As the cost of upholding environmental, health and safety standards in developed countries has risen, ship breaking has increasingly shifted to poorer Asian states.<sup>2</sup> To maximum profits, ship owners send their vessels to the scrap yards of those relative poor countries.

From the research done by Commission of the European Communities, each year between 200 and 600 sea-going ships of over 2,000 dead weight tons (dwt) are dismantled worldwide. A peak is expected in 2010 when around 800 single-hull tankers will have to be phased out.<sup>3</sup> Nowadays, two thirds or more of these ships are dismantled on beaches and river banks on the Indian sub-continent, with Bangladesh currently holding the largest share of the market.<sup>4</sup> At present there is "green" ship recycling capacity, i.e. conforming to environmental and safety standards, to handle at most 2 million LDT/year worldwide, which is around 30% of predicted total scrapping

demand in normal years. Most of these facilities are in China, but and in some EU Member States, which find it is difficult to operate, as they cannot offer the same scrap prices and have much higher costs than their competitors in South Asia.<sup>5</sup>

Ship breaking industry's development do need the research from technical and economical fields, Mr. Yan Hemin, the chairman of China National Ship Breaking Association, remarked that as one part of economic chain cycle set, to develop ship breaking is indispensable. Meanwhile he pointed that ship breaking can reduce the pollution to environment as the scrapped steel is much better than row ores to produce steel, concerning the energy consumption. In this case, ship breaking is beneficial to the development of economy, especially for developing countries.<sup>6</sup>

#### **Problems Faced by International Communities**

Last year (2006), international media reported the news of le Clemenceau, the French Aircraft Carrier first navigating to Alang, India, to be scrapped, but on December 31, 2005, Indian Administrative Court cleared the way for the redundant aircraft carrier to depart for the scrap yards in Alang, India via the Suez Canal.<sup>7</sup> The members of an NGO Platform for Clean Ship-breaking believed that French efforts to side-step international protocols and global agreements preventing countries from exporting hazardous waste have been frustrated by the campaigning efforts of Ban Asbestos France and Greenpeace. They blamed that some ship owners of advanced countries violated the Basel Convention, which prohibits the transition of wastes internationally.<sup>8</sup> The similar story was also presented about the SS Norway in international medias.

Some environmental protection experts even regarded the ship breaking industry as one of the world's dirtiest industries. The 1998 Pulitzer Prizes winner's pictures showed the poor situations regarding to environmental and labor protection in ship breaking yard in a south Asian country. The title of the pictures is as "A Third World Dump for America's Ships?"<sup>9</sup> The pictures reflect that the working condition in ship breaking industry in some Asian countries seems to be the situation in 18<sup>th</sup> century. Whereas at present ship building industry is developed very quickly and technologies in this industry have been developed as very modern. The shipping industry in the world is also developed very rapidly. Concerning whole economic chain of ship building, shipping and ship breaking, it is obvious that ship breaking industry is developed far behind other two industries in the technological fields in the chain.

The issue of ship recycling was first brought to the attention of the IMO (international Maritime Organization) Marine Environment Protection Committee at its forty-second session (MEPC 42) in 1998 and at the following sessions of the Committee it was generally agreed that IMO had an important role to play in ship recycling, including preparation of a ship before recycling commences, and a coordinating role towards the ILO and the Basel Convention in recycling matters.<sup>10</sup>

Expert Roy Watkinson developed a list of key international activities taken by IMO, ILO, Basel Convention and so on, which is listed in the Table 1

TABLE1 KEY INTERNATIONAL ACTIVITIES ( 1998-2008 )

Basel Convention COP-5	December 1999
Industry Ship Recycling Code of Practice	2001

Source: Roy Watkinson. ENVIRONMENTALLY SOUND MANAGEMENT OF SHIP RECYCLING WASTES. The presentation in the IMO Regional Seminar of Ship Recycling, Zhuhai, China, February 7, 2007.

From the table1 above, it is apparently that IMO has devoted a lot of efforts to hold seminars to discuss the IMO Guidelines on Ship Recycling, which hopes to issue an accepted international regulation in 2008 or 2009 and be implemented in 2010.<sup>11</sup> About the guidelines, Japanese scholar Koichi Kato, Class NK, pointed that IMO guidelines should take gradual phase-in approach. If the facility standard were set too high, there would be little ratification. Support from recycling states is essential. Avoid regional regulation that will distort competitive conditions of the industries.<sup>12</sup> IMO is facing the challenge to find the balance to the interests of various types of countries, ship breaking yard's countries and ship owners' countries and to balance economic development and environmental protection. Meanwhile, Basel Convention faced the challenge to the avoidance of responsibility of transferring waste crossing country's bound carried by ship owners, which sold their ships in the last life period as used ships to some companies and than passed to ship breaking companies that mostly are located in South Asian countries, where environmental and safety issues are really tough.

## The Transitions of Clustering Centers of Shipbreaking

### Phenomenon of transition of ship breaking clustering centers in past decades globally

In past 50 years, the clustering center of ship breaking industry in Asia transferred from Japan, Korea, and Taiwan region to Mainland China, India, Pakistan and Bangladesh. The times that indicate the peak stages of the ship breaking clustering in those countries are summarized in Table 2.

TABLE2: THE TRANSITION OF CLUSTERING CENTERS OF SHIP BREAKING (1953-2006)

Year	1953	1964-	1969-	1989	1992-	1994	1995	2003	2004-
	-	1987	1988	-	1993		-		2005

	1963			1991			2002		
Clustering Centers	Japan	Japan Taiwan Region	Taiwan Region	India	Mainland China	Mainland China India	India	Mainland China India	Bangladesh

Note: above presentation is based on the reference [13] to [18].

During 1953 to 1963, Japan was in the most prosperous period and the quantity of ship breaking took 70%<sup>13</sup> of the world shares. In 1976, owing to the recession of ship building industry, Japanese government set the funds to set up the Ship Breaking Promoting Association. But the result of the funding was not positive, Japanese shipbreaking industry lost its leading position as the economy grew to high level, the costs of labor of shipbreaking and environmental protection were too high to survive for those shipbreaking firms. So, the transition of the industry is the necessity.

Taiwan and Korea accepted the clustering transition from Japan in 1960s. Taiwan enjoyed the largest share in 20 years from 1969 to 1988 which led to the name as “Ship Breaking Realm”, and the number of shipbreaking companies reached to 202.<sup>14</sup> The technology of shipbreaking in Taiwan was also developed soundly, especially in its clustering center, Kaohsiung.

India was the later star in shipbreaking industry in world, the government of which loosened control power for purchasing obsolete ships that led to the booming of ship breaking industry. In 1990, while the world’s ship breaking industry began to decline, India’s ship breaking quantity still had 1,091,590DWT per year<sup>15</sup> and became the first in the world.

Shipbreaking in mainland China started in 1950s and occupied as the leading position first time in 1992 which took about 50% of the world shares, which only lasted for two years. From 1994 to 2002, India took placement as the world’s largest shareholder of shipbreaking. With the quick development of Chinese economy, China returned to the leading position again as the largest shareholder of shipbreaking in the world.

Since 2004, Bangladesh’s shipbreaking has jumped to the first position in the world. Furthermore, according to the report published by the IMO in 1999, the largest ship breaking countries in proper order are: India, Bangladesh, Pakistan and China. Their total dismantling ton takes the 90% of the world.

**Reason for transition of ship breaking clustering centers**

The reasons for transition of ship breaking clustering centers are complex. Following analyses may serve as the references for digging the reasons for further research.

To begin with, it is highly related to the GDP per year of ship breaking countries. From Table3 it can be found that the clustering center of ship breaking industry has transferred clearly from the countries with higher per capita GDP to the countries with lower one.

TABLE3: THE GDP PER CAPITA OF SEVRAL SHIP BREAKING COUNTRIES IN THE PAST DECADES (UNIT: USD)

Region Years	Japan	Taiwan, Region	Korea	Turkey	China	Bangladesh	India	Pakistan
1950s	1555★	170						
1960s	2949★	★	★					
1970s	4080★	1127★	279.9	363	32.8	97.8	106.8	
1980s	5699	4813★	1670★	1281★	305.5★	146.2★	259.7	330
1990s	24604	11355	5917.2	2686★	339.2★	207.1★	357.7★	450★

------	-------	-------	-------	-------	-------	--	------	------

Source: China statistics bureau, <http://www.stats.gov.cn>

Note: “★” = the clustering centers of ship breaking industries.

It can be learned from the above table that when the GDP per capita of Japan reached to USD5, 699, ship breaking clustering centers was difficult to survival. As same, Taiwan Region, when the GDP per capita reached to USD4, 813, ship breaking clustering centers remained existing. But with the further economical development, the industry phased out. It seemed to be that ship breaking industry in Japan, Taiwan Region, and Korea boomed when GDP per capital of these country are lower than USD5, 000, its ship breaking industry can still exists. Now, the GDP per capita of China, India, and Pakistan are, respectively, USD2, 003, USD727, USD748 in 2006, all of which are far less than USD5, 000, so there is still large space for these countries to develop their ship breaking industries.

Secondly, the tax rates of ship breaking countries play an important role in this industry. Generally speaking, when the tax rate increases, the total volume of ships dismantled trends to decline, whereas, when the tax rate decreases, that volume will ascend again. Take China for example, the relationship between the whole tax rate and LDT of the shipbreaking during the period of 1993 to 2006 is described in the Figure 1. It is apparent that the tax rate is the key inference to the fluctuations of ship breaking industry in China.

FIGURE1: THE RELATIONSHIP BETWEEN TAX RATE AND TOTAL VOLUME OF SHIPS DISMANTLED IN CHINA

Source: 1. China National Ship breaking Association.

2. Feasibility research of setting up green ship breaking yard in China, the web of metal recycling in China.

Thirdly, steel requirements of ship breaking countries are also an important factor in affecting transitions of ship breaking clustering centers. As the “Green Paper on Better Ship Dismantling” conducted by Commission of The European Communities reported, ship scrapping is an important source of raw materials in South Asia. Bangladesh derives 80-90% of its steel from end-of-life ships. The prices paid for them by ship-breaking companies are now well in excess of \$400 per light displacement ton (LDT) in Bangladesh and thus considerably higher than in other countries. And another paper of ‘the ship breaking industry in Turkey: environmental, safety and health issues’ also pointed that, according to 2005 figures. The steel industry of Turkey is mainly dependent on scrap iron.

Finally, but not the least, the difference in economy and labor costs between different countries is another critical factor for the transitions. In South Asia, some countries are still suffering from hungry, cold, and out of work, so labor costs in these countries are extremely low workers earn 1-2 USD/day and employer’s expenses for safety and health are negligible. So in these countries, ship breaking is welcomed with job position.

#### The environmental and safety issues with the transition

The environmental and safety issues are critical resulted from the transitions. In the process of shipbreaking industry transitions, the technologies and management know how for dealing with environmental, safety and health did not

accompany. As the firms in new clusters of shipbreaking usually lacked of capitals to investment, few heavy machines are used in the breaking processes; therefore, these firms are truly labor-intensive. For the reason, the hazardous waste can not be disposed in shipbreaking properly, which pollutes the environment. Meanwhile, because of this reason, there is a high risk of dangerous accidents. According to a 2004 government report in India, there were 434 incidents at the Alang yards between 1996 and 2003, killing 209 laborers. In Bangladesh, according to media reports, more than 400 workers have been killed and 6,000 seriously injured over the last 20 years. While faced with the problem of the environmental and safety, the treatment of waste rarely conforms to even minimum environmental standards. The transitions of shipbreaking clusters are only for location changes, pollution is moved from previous center to new ones without bring advancement technologies accompanied. This issue should be solved by international communities in the future.

## Present situation of shipbreaking and the problems

### Abnormal high prices of obsolete ships

During the past decades, the prices of obsolete ship increased greatly. From the data of MSR-Consult, Clarkson Research Services & LR-Fair Play, in the period 1977 to 1997, the average price of obsolete ships was approximately USD111.9 per LDT. From the IMO second ship breaking seminar held Zhuhai, February 7, 2007, Bangladesh ship breaking yards offered USD 490, which is the highest price in the world. The Asian shipbreaking amount and prices are presented in Table 4.

TABLE4: THE ASIAN SHIP BREAKING AMOUNT AND PRICES (2006.9-2007.3)

Country	The amount of scrap ship (LDT)	The highest price (US\$/LDT)	The lowest price (US\$/LDT)	Average price (US\$/LDT)
Bangladesh	369,787	490	380	444
India	115,209	459	139	392
Pakistan	75,215	465	375	433
China	20,735	296.5	269	286

Sources: China Ship Technology Research and Economy Development Institute

- Note:
1. this statistics does not contain the scrapped ships which be soled with high value metals such as stainless steel and so on.
  2. This statistics does not contain the scrapped ships which the data such as scrap country name, price and weight were not specified clearly.

In above Figure 1, the data of 2005-2007(April) is collected by us. It is very clearly that the price of obsolete ship has been the increasing tendency since 1970s.

It is also clearly that the highest price to purchase obsolete ships is all appeared in South Asian countries. The average purchase price of obsolete ship in South Asian is about USD 390 to 440 per LDT, which is about USD 130 difference higher than the price in China. In this case, most ship owners sold their obsolete ships to the ship breaking yards in South Asian Region, this is why the booming of ship breaking appeared in there. It reflected the abnormal competition in ship breaking industry, which reduced the margin of those yards. Why such situation existed? That competition only focused in price is main reason. Concerning market mechanism this situation is fare, but only care of price without thinking of environmental and safety issues is remaining for the challenges to international communities.

TABLE5: NUMBER OF RECYCLERS OF 5 MAIN SHIPBREAKING COUNTRIES

Countries	INDIA	CHINA	BANGLADESH	PAKISTAN	TURKEY
Number of recyclers	173 plots	Approx. 10	32 plots	Approx. 30	20
Locations	Alang, Gujarat, WC India	Shanghai and Xinhui areas	Chittagong, Bay of Bengal	Gadani Beach, near Karachi	Aliaga, north of Izmir

Source: Presentation of Carsten Melchior, Secretary General, CPM of BIMCO, IMO Tokyo Seminar of Ship Breaking,

September 2006.

**Advanced vs. laggard**

According to the report of European communities, there are about dismantling capacity of 780,000 LDT that are identified as green recyclers in the world. As obsolete ships usually are sold in international bidding, at present, most ships flew to South Asian countries, where the highest bid often appeared. In this case there is such situation that advanced ship breaking yards with sound facilities of environmental and labor protections have very few shares of ship breaking in the markets, whereas that laggard ship breaking yards with poor measures to care of environment and labors get most shares in the markets.

In the year of 2006, Bangladesh became the number one in the global ship breaking industry, totally 1,181,160 LDT of ships were dismantled in this country. India, Bangladesh and Pakistan, from 1994 to 2002, the ship breaking yards in these countries took part of 77 percents of world total. In these countries, usually ship breaking firms are small size, which have few capabilities to treat with the hazardous materials from ship breaking processes, therefore just these many small ship breaking firms are blamed as the reason of the pollution.

**The concerns and attitudes of related parties of shipbreaking**

There are at least four categories of shipbreaking related parties, shipbreaking firms, ship owners, governments and international organizations such as IMO, ILO and Basel Convention and so on. Their concerning points and behaviors are put into the Table6.

TABLE6 THE CONCERNING POINTS AND TYPICAL ATTITUDES OF RELATED PARTIES OF SHIPBREAKING

Related parties	Concerning points	The category with typical attitudes
Ship breaking firms	The profits. The price of ships. Sustainable channel to get ships. More recyclable materials with high value from ships. Technology innovation. Environmental and labor protection standards.	<ol style="list-style-type: none"> <li>1. Pay attention only to profits, less or even no attention to environmental and safety issues.</li> <li>2. Pay short term efforts to investment in environmental and labor protection, less modern equipments used in the processes of breaking.</li> <li>3. Regarded that safety and environmental protection are more important than economic benefits, pursue long term success in the industry, to invest in advanced equipments and dock facilities.</li> </ol>
Ship owners	Higher bidding and cash flow. Legislation and international convention. Reputation in the society. Safety and capacity and efficiency of fleets, repair costs. Decision of buying new ships or repairing old one. Decision of timely sell its old ships with good prices. Decision of maintaining crew or reducing the numbers.	<ol style="list-style-type: none"> <li>1. Only care about the highest bidding, regardless of environmental reputation of shipbreaking firms.</li> <li>2. Dependent on the enforcement of regulations, make the decision of balance to see the benefits, say some shipbreaking firm pay much higher prices, then sell their ship, say the difference of prices not being very high, so may decide to sell their ships to firms with advanced facilities of environmental and labor protection.</li> <li>3. Pay more attention to environmental and labor protection, even get lower payment for selling their ships</li> </ol>

Governments	<p>Tax income.  Economic development.  Employment.  Environmental and labor protection.  Political relationship with other countries and international communities.</p>	<ol style="list-style-type: none"> <li>1. Developed countries, pay more attention to environmental and labor protection, pay allowance to shipbreaking firms.</li> <li>2. Some developed countries encourage international cooperation to dismantling, pay positive attitudes to develop new convention of shipbreaking.</li> <li>3. Some developing countries, pay little attention to environment and labor protection, and pay more attention to economic development and employment, encourage developing shipbreaking industry and charge less custom duty to import ships.</li> <li>4. Some developing countries, pay common attention to environmental and labor protection, and sometimes regarding shipbreaking industry as pollution one, and sometimes regarding it as sustainable one, so the custom duty and tax rates fluctuating.</li> </ol>
International organizations	<p>Ship safety.  Environmental protection.  Labor's working condition and health.  International cooperation to favor economic development and harmonious relationship.</p>	<ol style="list-style-type: none"> <li>1. IMO: Ship safety, environmental protection.</li> <li>2. ILO: Labor condition and health, employment and the lowest wages.</li> <li>3. Basel Convention: Transition of hazardous waste materials across boundary.</li> <li>4. ## Discussions of potential development of ship breaking

### The demand of ship breaking will increase globally in future.

Now, approx 50,000 ocean ships are running in the world. The ship's average life is approx 25 years. World total commercial ships are about 850 Million tons of weight loading of displacement, each year retires 30 million tons of weight loading of displacement, and about 6 million of light displacement tons need to be dismantled each year. The ship recycling market is a certain growth market. At the end of this decade (2010) some 4,000 ships with an aggregate gross tonnage of 24 million should be recycled. As the shipping has been the most economic means of transportation, in the expectable future, shipping will exist without any doubt. Therefore, it is obviously that ship breaking is an ever existing industry in the international economy. The following Figure 2 illustrates the amount of ships breaking in the past 30 years in the world, the data of 2005 is only one thirds of the period of 2001 to 2003, the reason of which is ship owners postponing the ship retiring because of the huge demand of international transportation with global economic growing in that period. As the regulation of IMO urges that all ship should be out of work no longer than 30 years, international ship breaking industry will see the huge demand for dismantling those ships that enlarged their life in near coming years. Therefore, the environmental and labor protection will be even tougher than ever before.

### The future price trend of obsolete ships

In order to predict future trend of world prices of obsolete ships, the price data are collected from extensive sources. The following figure2 indicates scrapped ship prices globally in recent three decades, and the regressive analyses are carried out for deep probing.

FIGURE2: THE WORLD PRICES OF SCRAPPED SHIPS FROM 1977-2007

Note: The latest data in the above table is from April 4, 2007.

Sources: 1.Clarkson Research Services (1970s to 2004)

2. <http://www.cotzias.gr/>

3. Zhu Rujing, Bao Zhangjing. "The international ships market review". SHIP ECONOMY & TRADE, 2006.4, P3-8.

4. China Ship Technology Research and Economy Development Institute

From the figure2, the blue curve is the data line standing for the fluctuation of each year prices of scrapped ships, and the black curve is the linear regression line.

Regressive formula is  $Y=6.5196X+40.187$  (US\$/LDT).

And the red curve is average movement line standing for the tendency every five years during last 31 years.

The finding is that the prices of scrapped ships are steady during the period of 1977 to 2001. While from 2002 to 2007, the obsolete ships' prices were keeping sharply rising globally. The price of scrapped ships increases highly since 2002, whose climax is \$430 in 2007 and the major price-acceptable region was South Asian area such as Bangladesh and so on.

FIGURE3: THE PRICE (USD PER LDT) FLUCTUATION OF THE OBSOLETE SHIPS IN THE WORLD 2002-2007

TABLE7: STATISTIC THE PRICES OF OBSOLETE SHIPS WORLDWIDE (1977-2007)

Prices and slope ratio	1977-2001	2002-2007
The average price USD/LDT	110.34	286.8
Slope ratio	1.3423	67.8
The highest price USD/LDT	172.5 ( 1989 )	430 ( 2007 )

On the whole, the prices of the scrapped ships in the world were kept in a steady state generally from 1977 to 2001, the regression slope of which is only 1.3 degrees. In the last 31 years, the most sudden change has happened during 2002 to 2007, the regression slope of which is high as 68 degrees, much higher than previous 24 years, which is extremely abnormal. As the prices of obsolete ships have been reaching to those of new steel products, for example, the price of ship plates made in China is only USD 480 per ton, the profits of shipbreaking in normal situation are rare, and such high prices could be the historical peak of obsolete ships. As large quantity of single hull oil tankers will be soon phased out shipping markets, the prices of obsolete ships could be predicted in dropping case in near future.

**Which industry sectors should take main responsibilities for the environmental and labor protection issues of ship breaking?**

Clearly, the turnovers of shipping industry and ship building industry are far exceeding that of ship breaking industry, following Figure4 indicates globally the production values of these three industry sectors along the whole chain of ship life in 2006.

FIGURE 4: THE PRODUCTION VALUE OF GLOBAL SHIPBREAKING, SHIPBUILDING AND SHIPPING INDUSTRY (2006)

- Source: 1. <http://www.cotzias.gr/index1.htm>  
 2. The report of the national shipping industry economy in 2005 and in 2006, China Association of the National Ship building Industry.  
 3. The development of marine in China, Shipping transaction paper , 2006-8  
 4. China National Ship breaking Association  
 5. Clarkson Research Studies

According to Figure4 above, shipping and shipbuilding got huge product value, especially the shipping industry. However, ship breaking occupies only a minor figure, the ratio of which is 100: 28.5: 0.45 and the profits should be in similar situation for these three sectors. So reasonably shipping and ship building industries should undertake more social responsibilities than ship breaking industry do. But nowadays, it seems that ship breaking industry in the world undertake the main blames from international society, meanwhile ship owners of shipping industry sold their ships to those yards with poor environmental and labor protection facilities, instead of those with sound environmental facilities at lower prices. If those ship owners undertake more social responsibilities, the environmental and labor protection situation would be greatly improved. As the ship building industry, how to reduce hazardous materials and consider advanced in designing and manufacturing stages are extremely appreciated for favoring the shipbreaking industry as well.

#### **The solution model to meet the requirement of sustainable development**

The cooperation between Holland P&O Nedlloyd and Chinese Changjiang Ship Breaking Yard is the model solution to resolve the issues raised from shipbreaking. This cooperation began in the year of 2000. Before the cooperation, P&O Nedlloyd broke ships in the yards of Netherlands with tough problems concerning to deal with pollutions, and the costs to dismantle those ships were very high. So P&O Nedlloyd started in 1997 to search for some capable ship breaking service providers in the world, which should have sound capabilities of environmental protection and with high intentions to take care workers health. In the 2000, P&O Nedlloyd signed letter of intent (L.O.I.) with Jiangyin Changjiang Ship Breaking Yard in China. P&O Nedlloyd offered also the ship breaking service provider with advanced equipments and the trainings. In the late of 2000, the first ship MV “Texas” of P&O Nedlloyd was broken in the Changjiang Ship Breaking Yard. After that, from 2000 to 2006, there are totally 21 retired ships from P&O Nedlloyd were broken in the yard in the green manner, the level of pollution is greatly reduced and the workers were in the good working conditions. During the cooperation, the two parties do their best to improve the environmental and healthy technology, in order to support the investment in upgrading the technologies, P&O Nedlloyd returned some portion of the purchasing revenues to Jiangyin Changjiang Ship Breaking Yard. Both Chinese authority and Netherland authority appreciated very much for this kind of cooperation. Mr. Tom Peter Blankestijn, one of the managers of Dutch Shipowners’ Association, remarked that “Is this still a challenge to ship owners? In our opinion not. They just need to do it.” If main international ship owners can follow the model created by the P&O Nedlloyd,

which is now a part of MAERSK, the largest container shipping company in the world, the tough problems of environmental and labor protection faced by international communities could be solved quite soundly.

#### **Further transition of ship breaking clustering**

In past 50 years, the clustering center of ship breaking industry in Asia transferred from the developed regions to the developing regions, followed in direction from East to West, and now the clustering centers are in South Asian region. Where will be the further transition for the clustering in the future? Based on the Table 2, the transition of clustering centers of shipbreaking, it could be predicted that China will get more shares of shipbreaking after the dropping (2003 -2006). Coincidentally, 2013 could be the year China return the position as it took as the largest share of ship breaking in the world both in 1993 and 2003 previously. Because firstly, compare with the five main ship breaking industries, shipbreaking firms in China are mostly carried out strictly measures to reduce hazards to environment and occupational safety and health. With more international regulations and legislations of environmental protection and labor protection are issued, Chinese companies could get more chances of shipbreaking. Secondly, with the development of Chinese economy, China has built a lot of new ships. In 2003, the sea transportation increases 92 million ton, China increases 74 million ton, which is nearly 80% of the world total. If Chinese government issues the legislations to forbid the behavior of Chinese ship owners just to get cash flow regardless of environmental protection, more Chinese ships will be dismantled in China, therefore it will be favor for the booming of Chinese shipbreaking again.

## **Conclusions**

Based on above analyses, the following conclusions could be raised for favoring ship breaking industry.

Firstly, advanced technology and management did not transfer with the transitions of cluster centers of shipbreaking. The global transitions of clustering centers of shipbreaking is with the direction from East to West, from Japan to Taiwan Region and Korea, then to mainland China, and finally to India and Bangladesh. The transitions did not bring the technology and management for dealing with environmental and labor protection issues, so it is only the location changes and pollution transformation from previous centers to new ones. As obsolete ship will be increased with huge quantity in near future, environmental and labor protection will be even tougher than ever before.

Secondly, USD 5,000 GDP par capita is the deciding line of transition of shipbreaking industry center. Shipping industry is indispensable part of international economy, as the ship breaking is the final chain of the shipping, therefore ship breaking industry will be ever existing in the world. As the labor costs increase, shipbreaking industry in developed regions tend to transfer into other region, usually USD 5,000 GDP par capita is the transition line illustrated by Japan in 1960s and Taiwan in 1970s. According to the analysis about GDP above, the current GDP of China, India, Bangladesh are far lower than those of Japan in 1960s and Taiwan in 1970s, therefore, the ship breaking industry in those countries will develop further without doubt.

Thirdly, at present, total capacities of green ship recyclers in the world is far less than need, even though is the problem that these advance facilities are in vain, as their environmental and labor protection costs are much higher than those competitors in South Asian countries, where they took the main shares of international obsolete ships. Just as these laggard shipbreaking firms offering the highest bidding, their low level operations of shipbreaking caused seriously pollution and labor protection problems. The deep reason of this situation is some shipping firms pursuing cash flows, without taking the social responsibilities of environmental and labor protection. It is still a hot topic for international communities and researchers to optimize the collocation of resources in world wide in order to guide the industry transition on healthy way.

Fourthly, shipping and shipbuilding industries took much larger production values than shipbreaking, which is only the 0.5% of shipping industry. So reasonably shipping and ship building industries should undertake more social responsibilities than ship breaking industry do. However, currently concerning environmental and labor protection, ship breaking yards in the world undertake the main blames from international communities, meanwhile the ship owners seems less responsible, which is unfair.

Finally, at present, the cooperation between shipping and shipbreaking in company level is practically the

best solution to reduce pollution and take care of labor's safety and health. Since it will be a long time before current new convention being enforced, the pollution is the continuous problems existing, which should not be waited too much time to be solved. To better protect the environment and labors' safety and health, the cooperation case of P&O Nedlloyd (now belonged to MAERSK) and the Jiangyin Changjiang Ship Breaking Yard China should be greatly appreciated, which deserves to duplicated by other responsible firms both in shipping and ship breaking industry. How to enhance this model internationally? The further research is waiting for us.

Thanks to: Mr. Yan Heming, Mr. Xie Dehua and Ms. Pan Xia, from China National Ship Breaking Association, for offering helpful data for this research.

Thanks to: Mr. Tan Zemin, Vice General Manager, Zhongxin Ship Breaking and Steel Co., Ltd. China, and Mr. Koichi Kato, Class NK, Japan, for the valuable opinions.

# Factors of Success in Network Industries: The Case of Videogames.

Paola Scorrano, *p.scorrano@economia.unile.it*  
University of Salento, Italy

## Abstract

In the group of sectors that develop and use advanced technologies, the videogame sector has emerged in the last thirty years as one of the most interesting. The objective of the task herewith introduced consists in analysing the peculiarities and the perspectives of the videogames sector within the network industries. The task examines the factors that lead to the creation of a market winner-take-all following the affirmation of a dominant standard, the effects of the net, the importance of the dimension of the installed base and the factors that influence its constitution (pricing policy, promotional policy, switching costs and connected lock-in effects, economies of scale in the production and in the demand). Finally, the supply chains in the home video game industry and the external relations of Nintendo have been analysed.

## Introduction

The origin of network industries is wide and variable, comprising a multitude of enterprises operating in different sectors (one thinks of, for instance, the telecommunications sector, the producers of hardware and software for computers, the music industry, that of video players or video movies, of videogames, etc.)<sup>1</sup>.

The characteristics that define businesses that offer “network products” are complementarity, compatibility and standards, switching costs and lock in, significant economy of scale in production, network externalities. The latest peculiarity assumes an exceptional importance for the competitiveness of enterprises herewith analysed because the value (and thus the purchasing motivation) that the single customer gives to the product utilized increases with the number of users of the very same product. The consumer’s main benefit in using a product that generates the network effects, apart from deriving from the “physical” affiliation of the consumer towards the network (direct network effects, typical of the telecommunications market), can also be generated from the *market-mediated effect*, that is, it can be expressed as a major product low-pricing, major speed in its recruitment (even in secondary markets), availability of a major selection of complementary products, better maintenance services and more. The indirect network effects usually appear in network industries characterized by the hardware/software paradigm where the decision of a single consumer to adopt a specific type of technology is reflected on the future availability or future prices of the complementary products compatible with the very same above-mentioned decision. The need to generate the network externalities and to take an economic advantage over its effects calls for, therefore, the creation and consolidation of a vast and well-spread customer base from enterprises operating in such sectors, more than in others. It is however obvious how the relationship enterprise-customer in this business model is characterized by the existence of switching costs and lock-ins that, in actual fact, stabilize the above-mentioned relationship, making the admission of new potential customers particularly difficult.

## The Nature of the Videogame Product

High-tech products are generally characterized by a series of factors that contribute towards increasing difficulties in management of these products. Amongst these difficulties, the unpredictability of the market, the high level of technological insecurity, the high level of volatile competition, high investments in research and development, the rapid obsolescence of products, the presence of network externalisation, need to be considered.

The above-mentioned factors, typical of high-tech products, are also present in videogames which, not only are classical examples of composite products, because, in order to use them, two complementary elements are needed, hardware and software, but they also display particularly interesting network externalities. Moreover,

videogames include, in hardware as well as in software, technologies that require continuous investment in R&D so as to pursue a continuous improvement of the product that the market evolution, from the position of offer and demand, may impose for the survival of the sector within the enterprise<sup>2</sup>. This involves a progressive reduction of the life cycle of the product and, in many cases, the adoption of a strategy of planned obsolescence as a means of defence of personal market shares<sup>3</sup>.

In the course of time, it is important to remember, amongst the main reasons contributing to the expulsion of numerous enterprises from the market, their incapacity to innovate their product portfolio as well as errors in the choice of introduction periods of innovation in the market, and the adoption of incorrect distribution policies that have not allowed for the creation of an adequate customer base. This shows that in videogames, traditional elements of competition (quality of the product and his price) aren't sufficient to guide the choice of acquisition of the consumer because other different factors of evaluation intervene that represent a link between the features of real economy and that of information economy (Gallagher and Park, 2002).

Within this context, different studies have shown that in order to create a dominant position, innovating continuously is not enough nor is the first mover necessary, although the important role assumed by these support elements that allow for the attainment of a leadership cannot be denied. In each console generation, the strategy that has allowed for the predominance over competitors has been the creation of a vast customer base and a network of complementary products that have allowed each enterprise to establish switching costs. The possibility that an enterprise may be expelled from the market (Schilling, 2000) highly exists if it does not possess a sufficiently vast customer base and if it cannot rely on a high number of complementary products (such conditions are linked to each other), if an error takes place in the choice of entrance in the market (either too early or too late), if it doesn't invest sufficiently in uninterrupted learning processes.

In a "resource based" vision, the realization of a new generation of consoles, thus innovated technology, establishes its origins in typical enterprise capacity and in its learning process. The introduction of new technology in the market is subsequently adjusted by the choices relative to the launching period, to the presence of obstacles when introduced, to the pricing policy and to the plausibility of the brand. After the introduction in the market, the elements of competition move from the innovation of technology to the creation of an adequate customer base and a vast network of complementary products; when these elements, in actual fact, increase the value that each consumer gives to the product, they grant the cut of switching costs that the potential customer may sustain for the abandonment of the technology used and the adoption of his own technology. Taken from another point of view, the vast customer base and the availability of a consistent number of complementary products can allow for the creation of transition costs that keep the customer tied to the use of his product avoiding the adoption of a technological competitor; this provokes an ulterior expansion of the customer base and of the number of complementary products that, as mentioned beforehand, are the true elements of competition in a network market.

Some typical features of the above-mentioned network industries will be further analysed and the means through which such factors are introduced in the videogame sector will be identified, as well as the effects of each one on the competitiveness of the enterprises operating there.

## **The Hardware-Software Paradigm and the Formation of a Winner-Take-All Market**

The so-called hardware-software paradigm (Katz and Shapiro, 1994) is typically found in the markets of complementary products and establishes its characteristics, other than on the concept of complementarity (the need for the consumer to use both products in order to gain a benefit from their use), also on that of compatibility/incompatibility within technological standards. Generally, it is stated that two machines are compatible if they can work together (Shy, 2001). There are many different reasons leading to compatibility; amongst these reasons, two machines can operate according to the same standard (that is using the same operational system) or using the same software; besides, reverse-compatibility is the possibility of a machine being compatible with a preceding model.

Irrespective of the numerous options available, it seems that a single technology emerges as a dominant one. This comes as a result of pressure towards the adoption of one single standard technology that then becomes the

dominant one (notwithstanding the fact that in many cases it is not the more technologically advanced). This is motivated by the benefits that producers, distributors and clients derive from the compatibility. The lifecycle of technology tends to be extremely *path-dependent* and for this reason, random events that occur in the first phases of the cycle are able to provoke enormous impact on the final outcome (Williamson, 1998). One observes, however, that the factors on which the aforementioned “unpredictable outcomes” exert their influence (that they claim that their design is the dominant one) can, at the same time, submit enormous pressure caused from the strategies adopted by businesses. As such they can take control of a certain level of the process involved in the adoption of technologies (in this way it would not be considered a mere coincidence).

The principle motivations originating from the convergence of enterprises towards a unique technological option, especially in high-tech sectors that consequently lead to the establishment of a dominant layout are herewith picked out (Suarez and Utterback, 1995)<sup>4</sup>.

The main reason that leads to the spread of a technological standard is made up of a growing performance in its adoption which represents associated benefits in terms of the spread and use of a technological product enjoyed by both the creator of the product as well as its consumers. From the point of view of the producers, the growing performance is seen from the learning process, whereas from the point of view of the consumers, such benefits are picked out through the so-called network externalisation which will be analysed further on.

The learning effects are brought about from a greater knowledge in the use of technology that improves it as well as its devices. A direct relationship exists between the spread of a given technology and its development, its effectiveness and efficiency. Such a relationship is defined by the so-called experience curve where the cumulated volume of production is placed together with cost and productivity. Such an effect is represented by the following formula (Schilling, 2005):

$$Y = ax - b \quad (1)$$

Where  $y$  = average unitary production cost,  $a$  = average unitary production cost of the first unit,  $x$  = cumulated value of the units produced,  $b$  = learning process.

The preceding formula which tends to be standard, differs from one enterprise to another and from one sector to another in its  $b$  parameter, which, in actual fact, is the benefit obtained by the enterprise in terms of average unitary cost reduction when the growth of cumulative production takes place.

The growing performance of adoption, together with the introduction of market innovation and the promotion policies chosen to sustain this adoption, can lead to the creation of a *winner-take-all* market. In such markets there can be one or very few enterprises that, by acknowledging the technology previously defined or acknowledging the control over an essential component (for example the operational system) (Gilbert and Riordan, 2003), can potentially enjoy the short-term monopoly, and, besides can manage to establish development features of the entire sector in which they belong.

## The Videogame Sector as a Winner-Take-All Market

The videogame sector is a classical example of a winner-take-all market because with the passing of time and during the console generations there has been a dominant technology which has become a market leader reducing competitors to becoming marginal operators (see the following chart).

It can be seen that the first mover enterprise does not necessarily coincide with the enterprise owning the major widespread plant in the market and with the one possessing dominant technology. It is possible to see, for example what happened in the first generation of consoles where Fairchild entered before anyone else in the Channel F market (the first console with interchangeable cartridges) but it was then the Atari VCS to become the dominant feature conquering the largest market share. A similar situation took place in the second and fifth generations of consoles where Mattel and the 3DO had to render their leadership respectively to Coleco and Sony<sup>5</sup> (Williams, 1992). Such a phenomenon shows how the introduction period is only one of the variables that determines the dimension of the customer base and confirms the importance of elements like the availability of complementary products, compatibility choices and patent relationships, more generally, the characteristics of the technological environment.

TABLE 1: CONSOLE GENERATION AND DOMINANT DESIGNS

Generation (Time Period)	Rival Platforms (Manufacturers)	Introduction Date	Operating Performance		
			CPU	Bit	ROM
1st (1976-1982)	Channel FDD (Fairchild)*	Aug. 1976	2 MHz	8	
	VCS** <sup>DD</sup> (Atari)	Oct. 1977	1.19MHz	8	4K
	RCA (Studio)	Jan. 1977		8	2K
	Odyssey <sup>2</sup> (Magnavox)	1978	1.78	8

## The Hardware-Software Paradigm and the Network Externalities in Videogames

As previously mentioned, a videogame is a product composed of a main element, a console and accessories, a device and, they are all used together.

Establishing which element is more important to achieve total sales, is not at all easy because the demand for both components are strongly linked to each other. Besides, videogames enjoy the network effects that are a consequence of the demand-side economies of scale. This phenomenon is based on the idea that the value that the consumer gains from the utilization of a specific technology grows according to the number of its users<sup>6</sup> (Downes and Mui, 1998). In particular, the network effects in the videogame sector can be classified as *market mediated effect* because the demand for consoles (main component) is influenced by the availability of complementary products, mainly games (accessories).

Therefore, video players gain major utility from using a game in a growing market where such a game becomes compatible; this is because the widespread use of the video machine amongst the consumers guarantees a greater range in terms of amplitude and intensity of games available for that machine, or, generally speaking, a higher quality of the product and a major availability of the services connected to it (for example, maintenance, after sales services, etc). Besides, it can be seen that once a specific degree of the diffusion of the main product in the market is reached, that is the hardware platform, its ulterior spread is made easier owing to major quality and the numerical availability of compatible games with that machine, therefore the presence of a great number of attractive games in the market that are compatible with a specific technology will entice the consumer to buy that very same machine and not a rival machine with fewer perks. Consequently, video players particularly appreciate a hardware platform with a higher availability of compatible games. It is important to note however that the availability and the quality of compatible games with a console in a market depend on the diffusion that the very same console manages

to have amongst the public; however, even the availability of complementary products depends on how vast the customer based console is. A circuit of self-supply is created in such a way so as to involve hardware producers, the creators of software and the consumers. Such an effect is represented in the following figure where the elements determining the amplitude of the customer base is summed up<sup>7</sup> (Gandal, Kende and Rob, 2000), highlighting the strong link that exists between the hardware and the software component in a videogame:

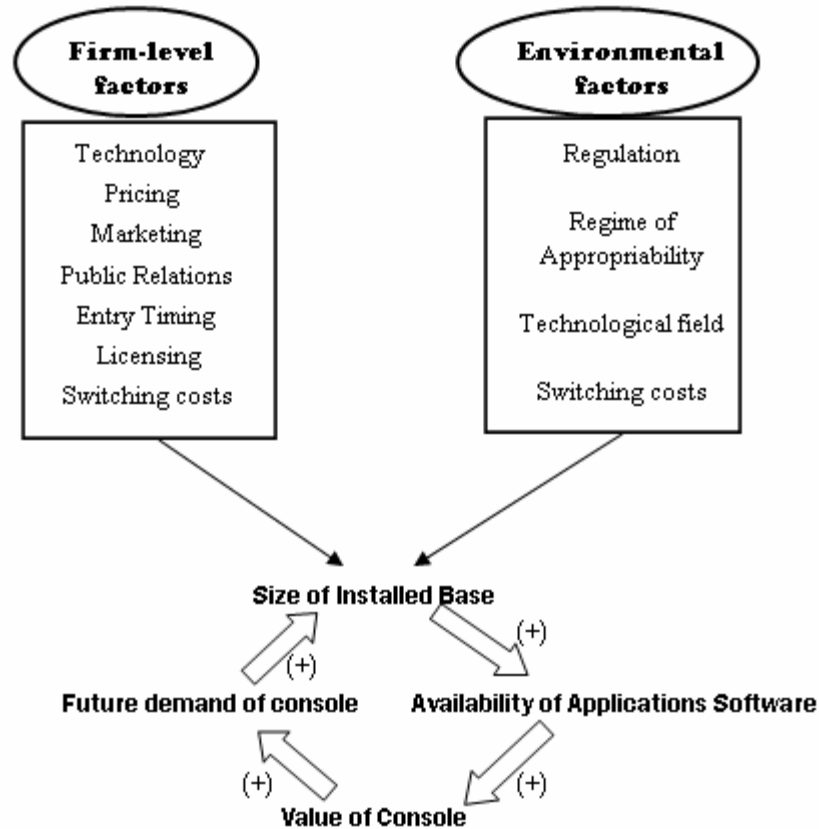

FIG. 1: THE VIDEOGAME VIRTUOUS CIRCLE

Source: our adaptation from Hill, C.H. (1987). Establishing a standard: competitive strategy and technological standards in winner-take-all industries. *Academy of Management Executive*, 11, 2, pag. 9 and from Suarez, F.F. (2004). Battles for technological dominance: an integrative framework. *Research Policy*, 33, pag. 275.

Obviously, the main aim of an enterprise that operates in a market characterized by the network externalisation is to create a sufficiently high range of consumers (critical mass) that allow it to create a network. When this takes place, the enterprise is able to trigger off the economies of scale in production and demand which will allow it to gain adoption cost benefits and start off the virtuous circle of network self-supply.

We confirm in fact that the main motivation is that it pushes upgrades them consumer to adopt one determined technology is proportional to the usefulness that attends to gain from its uses. The quantification of such advantage is based on the historical sales of the good (therefore on the base of customers already constituted) and on the expectations approximately the future adoption of the same technology (therefore on upgrades them widening of the installed base).The dimension of the base installed hardware is influenced from numerous variable, some of which depend on the strategic choices operated from the enterprise, others, instead, like already said, they derive from taken place accidental events in first is made of the cycle of life of the technology that are demonstrated in a

position to provoking of the remarkable impacts on its final performance (*path dependency* and *lock-in*) (Arthur, 1989) and that then they lead to the birth of a “dominant design”.

In this paper, the variables that the enterprise may influence in trying to build up its customer base will be analysed.

## Promotion Policies

A relevant variable in the process of creating a network of consumers is the policy of promotions adopted by business that gives weight, above all, to first stages in the lifecycle of a new technology. Such an assertion is derived, beyond the observations previously made with respect to the probability of adoption of a new technology (that does not depend exclusively on its technical potential, but mainly from the numbers of customers that have already made a choice and the expectations of adoption by most of the users), also from the analysis of current theories in the literature in respect to the path of growth (or depth of diffusion) of a new technology. Graphically it can be described by a sigmoid curve with a base axis of time against the number of acquired customers. Such a curve is symmetrical when the technology attains its maximum speed of spread exactly in the middle of its path of growth, and it is asymmetric when the maximum speed of spread is attained before the middle of the same process (Malerba, 2000).

Generally the introductory step, quite long, is followed by a faster growth encouraged by the increasing number of users. One of the causes accounting for slowing down the process of adopting a new technology by the users is contained in the ‘critical mass’ models of diffusion based on the assumption that a new technology is always able to bring about for those who adopt it, a number of benefits superior to the existing technological expectations. If the adoption occurs slowly this is due to the lack of information about the new technology both in terms of its existence and of its performance. According to this model, the necessary and sufficient condition for adopting the technological innovation is thus the diffusion, among the potential adopters, of the information related to it.

In the videogame sector the development of innovation can be brought back to the mixed model because in the introduction phase, the spread of information on new technology is triggered off by sources external to the potential adoptive community, that is, it comes from the very same producers or from promotional agencies commissioned by production firms; at a later stage, when the new technology was adopted by a minimum threshold of customers, the circulation process of information amongst consumers that had already adopted the new videogame and the group of potential users, is supplied as an effect of the network externalities. For all that, all the actions aiming at influencing the expectations of the potential adopters about the technical characteristics of the new technology and especially about its range of diffusion among the users will probably lead the product to be successful as dominant standard; moreover, such process will be much faster as more optimistic are these expectations (Loch and Huberman, 1999). Therefore, a common attitude adopted in high-tech sectors subject to network externalisation consists in the imminent commercialisation of a new product (that in many cases is far from being introduced in the market) in order to influence the consumers’ perception on the dimension of the actual customer base (*vaporware*) (Dranove and Gandal, 2000); this takes place in order to hamper rivals thus building the buyers’ hopes (Shapiro and Varian, 1999). The above-mentioned statement generates two types of effects in favour of new technology (Farrell and Saloner, 1986):

1) If some consumers decide to wait for the previously-announced introduction of new technology in the market, the moment it really gets introduced and, even more so, adopted by such consumers, the network will gain greater advantages in contrast to the hypothesis whereby no consumer may opt to wait;

2) The customer base of the old technology will be reduced to the number of consumers that wait for the launching of the new one.

It is however important to note the possible negative effect deriving from the adoption of such a strategy that is represented by the “cannibalization” of products that the very same enterprise announces.

## The Availability of Complementary Products

One of the two essential elements of a videogame (besides the hardware) is thus the software, which represents a strong competitive element for enterprises in this sector not only because it directly influences the dimension of the customer base but also because the profit margin obtained from the sale of devices is greater than the sale of the material element of the videogame<sup>8</sup> (Gallagher and Park, 2002). This phenomenon is due to the typical cost structure of enterprises in this sector that permit the pursuance of economies of scale in the production process. What practically happens is that the creators of software products acknowledge that platform producers possess a royalty for each compatible game sold, obviously, with the very same platform (Coughlan, 2004). Seeing that different games can be used on the same console, as a consequence, the producer of hard components obtains an important business opportunity in the sales of these devices<sup>9</sup> (Consoli, 2004).

It is important, however, not to disregard that the number of games compatible with a specific hardware platform derives from the diffusion that the very same product has reached the people that, on their behalf, rely on their personal technical performance and sale price. Consequently, one of the main reasons why the producers of machines encourage the spread of their technology amongst the people, aim at obtaining the market standard and thus managing to attract the top creators of software. But the existence of attractive software, compatible with a specific machine, will encourage consumers to buy the very same machine, triggering off a viscous circle and the beneficial effects will reach the individuals involved, that is, the hardware producer, the software creator and the final consumer (indirect network externalities<sup>10</sup>). In the meantime, the enterprises, through the pursuance of a suitable growth strategy, will try to reach the critical mass of clients that will allow them to cooperate, perhaps exclusively, with the best game creators. Such strategies plunge into the analysis of pricing leadership as well as into product differentiation. Once they have reached the minimum number of clients necessary to be able to cooperate with competent creators, the enterprises will also try to act on the consumer's degree of addiction through the so-called *lock-in* that generates *switching costs* for the consumer.

## Choices of Compatibility and Switching Costs

The switching costs or transition costs create burdens<sup>11</sup> for the individual (or a business) that should be able to be sustained by abandoning the technology in use and taking up a new one. The costs involved measure the degree of dependency the supplier of the technology has on the consumer, thus constituting a barrier to the release of the product and slowing take-up where the competitor's technology is not compatible. For the owners of new technology start-ups, the transition costs, instead, represent a hurdle when the release of their product incorporates an incompatible technology compared to one already available in the market, even if it is more technically advanced. The customers, in fact, often remain "stuck" with the network from their current company for the sake of the switching costs<sup>12</sup> (Farrell and Saloner, 1986). For this reason, one of the instruments of defence against the appearance of new competitors that manufacturers of old technology more frequently use, are with the various typologies of *lock-in*<sup>13</sup> there is at least one associated typology of switching cost<sup>14</sup> (Shapiro and Varian, 1999). For their part, the suppliers of new technology, in order not to endure the presence of the transition costs and in order to render the own offer more attractive, would have to be in a position to guarantee a benefit that is greater than the costs that the customers would suffer for transferring. Such benefit could come from the technological superiority of the new machine<sup>15</sup> associated with an adequate promotional strategy and appropriating pricing policy. In particular, the switching costs can reflect on the pricing policies in two ways:

a) If the consumer is already locked-in on the network, the company can increase the price up to a limit represented by the transition cost,

b) If the consumer is not yet locked-in because there is no network in existence yet, the business will head for a policy of pricing for market penetration with the aim to create a critical mass of customers who, once it locked-in to the network, could be subjected to pay a higher price.

The aspects tied to compatibility and incompatibilities amongst different technological standards are particularly important in the production of consoles for games because from these choices, switching costs are

reached and the mutual lock-in effects. In particular, such an aspect is reflected on the use of devices so that it is difficult to find the same title for different consoles in that, usually, console producers try to have the exclusive product from the creators<sup>16</sup> (Brandenburger, 1995). A common transmission model of the lock-in sector of videogames exists, in fact, when the consumer, having bought the long lasting product (the console), is forced to buy the complementary products (software devices for games) in order to make use of the machine owned.

The profitability deriving from the technological standards goes, therefore, through the solution of the trade-off between two options: the *acceptability*, that is to facilitate the use of the new technology in order to make the number of the adopters grow, being content with a weaker control on the property rights (for example, IBM Personal Computer); the possibility to be *ownership*, that implies a careful control on the property rights, but it can also delay or impede the attainment of one critical mass of users of the same technology (for example, Apple Macintosh) (Grant, 1999). The choice between the two alternatives is conditioned, therefore, by the necessity of the marketers to constitute the network among the consumers that will be able to foster by itself.

## The “war” of Prices

A strategy often adopted by enterprises operating in high-tech sectors subject to network externalities consists in the establishment of price penetration in the launching phase of new technology so as to attract potential adopters and rapidly develop an adequate customer base in order to consequently enjoy the benefits deriving from the viscous circle of network supply. The analysis of the pricing strategy adopted by enterprises operating in the videogame sector has allowed for the analysis of how a pricing policy adopted by them does not correspond however to the theoretical rules to be respected. From a historical analysis, it was possible to see that, in actual fact, the enterprises operating in the videogame sector have a general tendency to enter the market with prices that tend to be high followed by a successive drop. This usually happens when a rival’s new console is about to enter the market and the enterprises concerned want to hamper the launch making their personal machine more accessible by reducing the price in favour of a specific sector of consumers. Further on, pricing strategies adopted by major competitors of the personal top console will be analysed:

FIG. 2: PRICING ( EUROPE)

By analysing the pricing dynamic of the three major competitors in this sector a typical “strategic behaviour” comes to mind. It is referred to the hypothesis whereby an enterprise takes a decision based on the forecast of the competitors’ possible reaction (Tirole, 1991). Such a decisional process presupposes interdependence amongst enterprises that operate in a given sector because the strategic behaviour has reason to exist when the choices made by enterprises influence the decisions and, thus, have an effect on the profits of other enterprises. This happens mainly in markets as the one herewith examined with an oligopoly-type structure. From the

analysis in the graph it can be deduced that the various price reductions represent the reaction of the different competitors towards the action carried out by one of the enterprises and, in actual fact, it can be seen that the modification of prices take place with the approach of the launch of a new console from a competitor and besides, they appear to be concentrated in a restricted temporal span. Finally, it is important to note that at the end of the price fixing, all the enterprises converge towards a unique level therefore, at that point, the challenge (and it is important to remember that it is aimed at the creation of a vast customer base) moves towards other competitive elements previously highlighted (please see the graph on the circle).

## The Supply Chain in the Home Videogame Industry

In the supply chain of the home videogame industry, with reference to the hardware production as well as the software

FIG. 3: THE SUPPLY CHAIN IN THE HOME VIDEO GAME INDUSTRY

Source: Coughlan, P.J. (2004, November 5). Note on home video game technology and industry structure (abridged). *Case n. 9-704-488 Harvard Business School*, pag. 7.

1) *Content Provider*: lead by the intellectual propriety of the game, that is, the idea, the names used, the characters, the plots and any other content linked to the game. The Content Providers require rewards for concessions for the utilization of the contents owned, generally in the form of *royalties* on the sale price of each software. The content providers in Italy are Electronic Arts (EA) and Ubisoft.

2) *Software House*: are those who develop videogames and can be classified as:

- *Software house* owned by the software editors (for example Activision, Ubisoft, Electronic Arts, Konami);
- *Software house* owned by *platform providers* (for example Sony Computer Entertainment, Microsoft, Nintendo);
- *Independent software house* (for example Milestone and Trecision).

With the growth of complexity of the systems and the technology associated with the console (as well as the growing expectations of the consumer), the development costs of a videogame has grown considerably with respect to the first generation console and can vary considerably from title to title<sup>17</sup> (Olhava, 2003).

From 1987 to 1997 the number of studios dedicated to the development of software has grown considerably. The aim is that of reducing this mechanism and consequently increasing those of major success. There are very few independent software houses able to self finance their own projects, therefore many resort to publishers or directly to the platform producers to obtain external funds in exchange for publishing and distribution copyrights. In the following table there are the software percentages developed directly by the hardware producer; it is clear that (apart from the games developed by Nintendo for N64 in 1996), the quotations are very much reduced with relationship to games available, all in all, for each console.

TABLE 2: GAMES DEVELOPED IN HOUSE (USA)

Platform	Platform Provider	% of software developed in house				
		1994	1996	1998	2000	2002
Playstation	Sony		19,04	20,45	18,2	15,08
N64 (Cartridge)	Nintendo		80	26,16	18,99	20,74
Genesis	Sega	28,63	29,88	34,94	26,56	19,4
Playstation2	Sony				2,22	8,37
Super Nintendo Entertainment System	Nintendo	11,16	10,36	16,67	25,44	17,46
Dreamcast	Sega				19,59	22,09
Saturn	Sega		31,45	30,07	35,64	0
Nintendo Entertainment System	Nintendo	11,5	25,6	35,29		

Source: our adaptation from Clements, M.T., & Ohashi, H. (2005). Indirect network effects and product cycle: video games in the U.S.. 1994-2002. *The journal of industrial economics*, 4.

3) *Publishers*: apart from financing the creation of videogames, they develop relationships with the *platform providers*, carry out market research, and negotiate with retailers or with distributors and, usually, they deal with the packaging and marketing of the games.

Already in the mid nineties, practically all the publishers had created or purchased their very own studios for the creation of entertainment software. In some cases, even if not often, the very same publishers saw to the creation of videogames. The more important publishers deal directly with the distribution of titles amongst retailers, others rely, totally or partially, on distributors.

One of the most important aspects of the publishing of a videogame activity is the management of relationships with the producers of this activity. The *platform provider* that chooses to control its own technology needs a *licensing* contract from the publishers before creating software for its platform. The publishers must thus pay a *royalty* to the console producer for each copy sold; they generally try to commercialise the same game for different rival platforms so as to soften the high prices for their creation but such a strategy is often in conflict with that of the console producers that, vice versa, try to have exclusive titles for their platform.

4) *Platform providers (or format owners)*: they carry out business activities in 3 main areas:

- The design, manufacturing and marketing of hardware,
- The creation and publishing of software for their system,
- The management of relationships with independent software houses.

The main distinction between a title developed directly by the console producer and that developed by an external creator is that the former is available exclusively for that platform, while the latter can act with rival platforms. The platform producers determine the related market and establish the norms: they decide, in actual fact, if a game for their platform can be published or not, they grant authorizations and development kits and they evaluate the standards of quality. Besides, at times, the production of games takes place at the platform providers; in the end, they establish the selling price zone for software according to their royalty level. The business model for console producers foresees three types of returns: those from the sales of the personal consoles, those from the sales of software created in house, royalties from sales of software created by external developers, compatible with their platform. The large console producers are Sony Computer Entertainment (PS1, PS2, and PSP), Nintendo (GBA, GC, and GBC), and Microsoft (XBOX).

5) *Retailers*: they try to optimise agreements taken with suppliers, whether publishers or distributors, so as to guarantee a vast and intense range of pc or console games that allow them to maximize their profits. Amongst the retailers' responsibilities, there is the setting of the final price of the game. The retailers choose or agree to place in evidence each game with the publisher/distributor and, as a consequence, there are key figures that determine the success of a game – the fundamental role of the consumer in the supply chain of the videogame has already been dealt with in detail in the previous chapters-. With the development process previously described, the software houses (also thanks to the contributions of programmers and independent technicians) ought to be able to prepare a game that publishers consider worthwhile to be published and that, with the help of distributors and different

accessible sale channels, may reach the final customer. Each actor involved in the different phases of the circuit has a turnover which is proportional to the contract power and can allow him to carry out potential investments in the original creation and the subsequent development/publication of a new game triggering off, in this way, a new value circuit. At times, therefore, it is in truth the lack of funds for innovation that impedes the growth in the videogame sector within some economic contexts and that force the creators in these countries, that have reduced contract power, to address foreign publishers or, at least, venture capitalists.

It is important to highlight, however, the crucial aspects of relationships amongst different individuals involved in the supply chain industry of domestic videogames for the success of the consoles and, consequently for the compatible complementary products. As already mentioned, such an importance comes from the need for hardware producers to rapidly create a sufficiently high customer base to allow for the self-supply of the network through the externalities generated. This brings about major returns for the hardware producer but also for the software creators compatible, creating, in this way, the potential development of ulterior investments in Research and Development, and, through these means, growth in this sector.

### External Relationships: the Nintendo Case

The market structure of the videogame sector is of an oligopoly-type nature because it is characterized by the presence of few large enterprises that control the market. In particular, this is referred to the winner-take-all market because the very few enterprises that possess a dominating technology (Sony, Microsoft and Nintendo) not only are in a condition of enjoying, in the short term, the returns of a monopoly but, even more so, they can define future developments in the sector herewith referred to. Within this context, please see the graph which represents the concentration discussed in this analysis with reference to the European market.

FIG. 4: THE CONCENTRATION OF THE SECTOR (EUROPE, 2004)  
Source: Banca dati Amadeus Bureau van Dijk

The major market shares concentrated in few enterprises are herewith highlighted; in particular, only 9 of these possess almost half of the European market's videogames. Amongst the world videogame market leaders there is the presence of Nintendo<sup>18</sup> who, amongst the major competitors in this sector, is the one that operates in the game

market since it originated; besides, Nintendo was the first to enter the world of electronic games and that, today, still has the more *traditional* vision of videogames that, according to Nintendo's philosophy, must primarily "entertain" (the use of domestic consoles for aims other than games, such as listening to music, watching films, etc. is a typical prerogative of other two leaders in this sector, that is, Sony and Microsoft while they are less important for Nintendo). The circumstance which gets Nintendo to deal with the production of videogames (hardware and software)<sup>19</sup> allows the enterprise to analyse its business choices knowing that they are geared only towards the videogame business. In this study, major attention has been given to the relationships that link Nintendo to external economic individuals through the analysis of the list of partner enterprises present on the official website of the company on the 31/12/2006<sup>20</sup>.

It is important to specify that in the above-mentioned list the legally authorized enterprises are included by Nintendo for the production of games and accessories compatible with its consoles as well as other merchandising products. A written text follows, taken from the Nintendo website regarding relationships with authorized partners: "**Licensee Game and Accessory Companies**"

*Below, you will find a list of companies that are licensed to create games, accessories, and other licensed merchandise for Nintendo systems and characters. ... Unlicensed games and accessories are not recommended for use with Nintendo systems. If the item appears to be licensed, but the company's name does not appear on this list, it is possible that the company is either no longer licensed or is no longer in business. If the product is no longer working, it may be appropriate to consider replacing the product."*

In order to avoid counterfeiting, Nintendo has also created brands that guarantee the quality and the originality of complementary products compatible with the consoles. A text referring to the above-mentioned guaranteed brands follows<sup>21</sup>:

#### **"LICENSED PRODUCTS & MERCHANDISE**

*All licensed merchandise, software, hardware and accessory packaging, worldwide, displays Nintendo's "Official Seal" (pictured below). This symbol is your assurance that the product has been approved by Nintendo, and is recommended for purchase.*

*Products that display this symbol have been approved by Nintendo, and are recommended for use with its systems. Licensed merchandise -- such as bed sheets, trading cards, or clothing for example -- will also display this symbol*

*Prior to the summer of 2003, these seals were found on the packaging of licensed products sold in North America. The seal on the left was used for licensed products such as software, hardware, and accessories. The seal on the right was used for licensed merchandise such as toys and clothing".*

In order to facilitate the interpretation and use of this research, of the information deduced from the above-mentioned list, it is important to elaborate statistically the data referred to the partner enterprises. The statistic analysis is based on the following hypothesis:

- A coincidence of the sample universe with the list of Nintendo's enterprise partners taken from the company's website;
- The creation of a non-casual samples made up of partner enterprises where their Internet website is also included<sup>22</sup>;

- The elimination of the sample of enterprises having an Internet website if inaccessible for technical reasons, although well-known the moment they were being consulted.

In the following scheme, there are briefly different numbers and types of relationships carried out by Nintendo with partner enterprises.

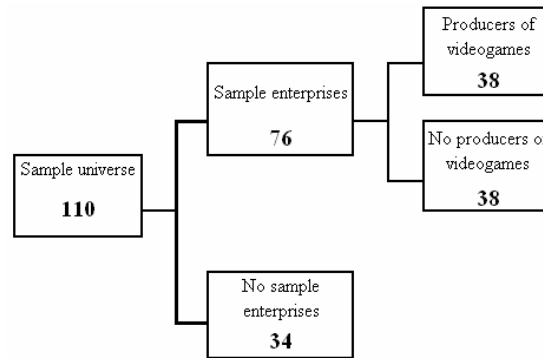

FIG 5: NINTENDO'S PARTNERS

The sample examined include 69% of the enterprises authorized by Nintendo to use the company brand on complementary products available because, such enterprises, as already stated beforehand, have an accessible Internet website at the moment it is consulted; as a consequence 31% of the enterprises at the start were excluded from the sample. 50% of the sample enterprises use the Nintendo brand to produce and commercialise products which are different from the core business of the parent company (that is games); the range of such products is vast and full of variety and it includes household linen (like sheets, duvets, curtains, etc), t-shirts, boxes of sweets and other. This shows the large diffusion reached in the years of the Nintendo brand and the positive contribution of this “non-core” business at the setting of the company’s economic standard through the royalties obtained.

Another interesting aspect is the geographic location of the partner enterprises<sup>23</sup>. From the respective websites 96% of the sample enterprises furnish an American mail; the other 4% of the sample enterprises publish a Canadian mail on their Internet website.

In almost all the cases studied the producers and/or distributors of videogames do not have an exclusive relationship with Nintendo because they also produce titles for other competing enterprises<sup>24</sup>. In actual fact, the technical characteristics, the 3D scenes and the settings are so different as to render each game unique. Finally, in this analysis the importance of the relationships in pursuing the competitive advantage of the enterprises studied has been highlighted; at the same time, it has been possible to observe how the traditional competitive elements in network industries (and therefore also videogames), also recognized by the quality and pricing of their products, are not sufficient to guide the consumer’s purchasing choice because other different evaluation factors intervene (the role of the dominating scheme, switching costs and innovated technology, entrance period, complementary products and customer base) that are the link between a true economy and that typical of an information economy.

## End Notes

<sup>1</sup> Shy, O. (2001). The economics of network industries. *Cambridge University Press*.

<sup>2</sup> Within this context, one must bear in mind how, in the first half of the Eighties, the entire American videogame industry disappeared due to the introduction of the personal computer on the market that was technologically more advanced than the console. More recently, one must remember Sega that in 2001 announced its abandonment of the hardware production (its last console was Dreamcast that, although technological competitive with its rivals at a 128 bit, didn't manage to express its potential due to commercial errors within the company) in order to dedicate itself exclusively to software production.

<sup>3</sup> About the rapid and endless innovation that characterizes the videogame sector in the more general high-tech environment, the Moore Law needs to be quoted according to which "the density" of the transistor in integrated circuits doubled every 18 months ; please see the article published by Gordon Moore in "Electronics" the 19 April 1965. Besides ' the number of game devices will increase from 215 million units today ( mainly Playstation, Playstation 2 and Gameboy) to over 2 billion 600 million devices in 2010! In addition to this frightening number, there will be 450 million people with a vast access to Internet that will nourish a market of downloads of games, new levels, music, etc. as never in the past...In less than ten years, the electronics game sector has developed into a small, powerfully global niche and this trend is expected to continue until at least 2010. Guided by the inexhaustible Moore law, the electronic games linked to high technology will generate intensive movements that will spread well beyond electronic games – not distinguishing divisions amongst different industries. Those who acted previously like Sony and Microsoft, have already been spending billions of dollars to position themselves as market leaders, and many others are getting ready to launch. It's risky, but the risk of not accomplishing is a lot higher – just as premium benefits are considered to be high'. Published on the website [www.playreview.it](http://www.playreview.it) 4 June 2004

<sup>4</sup> <<We think that the emergence of a dominant design is the result of a fortunate combination of technology, economic and organizational factors>>.

<sup>5</sup> For years Sony has been able to enjoy the advantages of being a *first mover* thanks to the Playstation even without being the first real console to be launched on the market possessing such specific characteristics. Naturally, the

possibility of sustaining this competitive acquisition advantage is reduced whenever the environment in which the enterprise is found is turbulent. For a classification of sector bases to the sustainability of competitive advantages please see Williams, J.R., (1992). How sustainable is your competitive advantage?. *California Management Review*, 34, 3.

<sup>6</sup> Such an effect can be measured with the Metcalfe Law according to which “the use that a network presents for a single consumer is equal to the square number of consumers in the very same network”.

<sup>7</sup> It is interesting to note how in the compact disk industry, characterized too by the network externalisation and hardware-software paradigm, the diffusion of CDs and the increase of CD shares have been caused by two factors: direct, that is the decrease of prices in CDs and the costs to increase their potency, and those defined as cross-breads, that is the increased tendency of consumers to buy CDs due to the increase of CD shares and vice versa.

<sup>8</sup> <<Profit margins on software, historically cartridges, but more recently CD-ROMs, have been higher than on the hardware, i.e., game consoles>>.

<sup>9</sup> In this regard, what comes to mind is that the Korean Game Park introduced the console GP32 in the market that, with respect to the other competitors present on the market, it possesses the absolutely innovative characteristic that gives everyone the opportunity to gain access to the development instruments with which software can be installed. Therefore the uncertainty linked to the availability of games created for the console, main factor on which the commercial appetite for any new product depends, is reduced owing to the possibility given to the community of fans and to enterprises to develop and adapt entertainment software (and not only) to the new video machine.

<sup>10</sup> Due to the existence of virtual networks of consumers of hardware/software systems based on partial technical standards or totally incompatible with other systems.

<sup>11</sup> Measured not only in economic terms, but also as loss of time and, more generally, uneasiness.

<sup>12</sup> The QWERTY keyboard is exemplary here; although once inferior in the market it has succeeded in preventing the adoption of faster and more ergonomic keyboard alternatives because of the habits already developed by numerous typists who ‘touch-type’ (“battitura alla cieca”). *Excess inertia* can be defined as <<a socially excessive reluctance to switch to a superior new standard when important network externalities are present in the current one>>.

<sup>13</sup> Situations of lock-in derive from contractual agreements; from the purchase of durable goods, from specific training, from the complementarity between hardware and software, from the established supply of specific goods, from the support of research costs, and from customer loyalty programs.

<sup>14</sup> “I ricavi provenienti dai clienti soggetti a lock-in altro non sono che il rendimento degli investimenti effettuati sui clienti”.

<sup>15</sup> The technological superiority of an enterprise can derive from the combined presence of a highly specialized field of work, of a particularly competent management and adequate financial resources.

<sup>16</sup> When Nintendo entered the videogame market in 1985 with NES it obtained from independent creators of software not only copyright payment but also exclusive rights for at least two years on the games created for NES.

<sup>17</sup> The estimated development cost of the new game is about 10 million dollars.

<sup>18</sup> Nintendo Europa with a 13,33% turnover is the European market leader in videogames.

<sup>19</sup> The brief description of Nintendo’s activity present in the budget is the following “Nintendo was originally a manufacturer of playing cards which early in 1980 started the manufacture of electronic games”. Taken from the website: <https://osiris.bvdep.com>.

<sup>20</sup> In this regard, please see : [http://www.nintendo.com/corp/licensees.jsp#accessory\\_network](http://www.nintendo.com/corp/licensees.jsp#accessory_network).

<sup>21</sup> Taken from the website: <http://www.nintendo.com/consumer/licensed.jsp>

<sup>22</sup> Such a choice was made necessary because of the lack of availability of information sources alternative to the internet network from where news is obtained regarding relationships between Nintendo and its partners.

<sup>23</sup> It is important to specify that not all the addresses regard central offices but at times Customer Care or Sales.

<sup>24</sup> Amongst the Nintendo partners only one enterprise, Blizzard Entertainment, has dealt with the creation of console games (in the past they created games for PCs) and works exclusively for the enterprise in the portable videogame sector (Game Boy).

## Old and New Paradigms for IT Services Offshoring

### Abstract

This paper presents some new conceptual and interpretative paradigms concerning offshoring Information Technology services, in the light of the most recent market trends. In the current competitive scenario, IT structures are increasingly asked to “participate” in the development and innovation of business, rather than being merely a “support” for the value chain activities, managed merely on the basis of technical and economic efficiency. We start by confuting two traditional concepts: first, those only activities which are quite distinct from the core-business can be candidates for outsourcing, and secondly that the advantage to be derived from offshore outsourcing is above all a matter of costs. What is meant by “success” in this new perspective? We analyse the main critical factors in an offshoring contract enhancing value creation and business strategy. Particular attention is paid to analysis of the main drivers of solution design and ongoing management in IT offshoring strategies.

### IT Outsourcing

In the past, the decision to outsource information technology (IT) activities and processes responded above all to the need to call in specific competences, reduce management costs and free up financial and human resources to be concentrated in the core-business processes and reinforcement of distinctive skills (Quinn and Hilmer, 1994). Companies turned to IT outsourcing to take advantage of the competences of third parties, the investments they have made and the related scale economies provided by a multiclient offer.

In the competitive scenario of today, there is an increasing demand on IT structures to contribute to making management processes not only more efficient and economical but also flexible in both operative and strategic terms. In other words, the IT structures are proving crucial factors in the implementation of business plans. They affect the efficacy and efficiency of the firm’s value creation processes, rather than being merely supporting factors for the activities of the value chain. In this context they must show themselves to be amenable to the dynamics and requisites of business, provide tools to raise the quality level of both material and immaterial components of the company’s offer, and contribute to increasing the strategic and operative flexibility of the management processes.

Recent empirical analyses have highlighted some interesting phenomena. Dissatisfaction with the services offered by IT providers is increasing with the growing demand for quality and levels of innovation with respect to expectations of savings on costs; IT outsourcing is becoming increasingly selective, related to certain components of the information system, and no longer responds merely to full outsourcing, involving the entire IT system of the company; providers of IT services are specialising more and more, basing their pursuit of competitive advantage on differentiation rather than cost leadership relying on a standardization approach. These are all phenomena which show how the paradigm of outsourcing in the IT sector is changing, moving from motivations of economy and efficiency to strategic developmental business innovation. The company system is being opened up to the contribution of knowledge possessed by third parties, seen as owners of integrative and complementary resources with respect to those in-house.

On the basis of these brief considerations we investigate outsourcing in the IT sector, going beyond the axioms of a traditional approach to view it as the vector for developing the firm’s capacity for innovation and hence competitive edge. We respond by citing the principles and contents of *strategic outsourcing*, analysed with specific reference to IT offshoring.

## The Scenario for Decisions Regarding IT Services Offshoring

In the current global competitive scenario IT services offshoring represents a strategic choice, in constant expansion since the early 1990s, pursuing the optimal economic and organizational conditions for implementing activities or processes which had previously been taken care of in-house, and entrusted to specialised operators in foreign countries, by means of outsourcing contracts.

The development of high levels of IT competence globally has seen countries with emerging economies taking the lead in offering IT services, thanks to a considerable level of investment in research and development and in training human resources in the IT sector, as a deliberate strategy for developing their economies and increasing their competitive edge with respect to Europe and the USA (Leonard, 2006). The domain of IT is part of the industrial sector identified by many countries in Eastern Europe, India, Philippines, China, Canada, Brazil and Ireland for attracting foreign investments and increasing GNP<sup>1</sup>. They can base their competitive standing in the global arena on significant and objective cost advantages in productive factors, notably human resources<sup>2</sup>.

The increasing recourse to offshoring has also been due to the traditional approach to choices of *make or buy*. Outsourcing activities or processes was a valid option for companies seeking to increase their levels of efficiency and productivity, maintaining in-house the more strategic areas of activities ensuring their competitive advantage.

The considerations we have outlined are valid in general for any process of IT services outsourcing, including on-shoring and near-shoring. They are however all the more relevant to offshoring, on account of the significantly greater economic advantage obtainable and the extraordinary diffusion of knowledge and competence in the IT domain seen in recent years in the emerging countries.

In terms of the economic advantages, there is no doubt that for European and American companies these countries represent a significant opportunity for improving efficiency and productivity. One has only to think of the significant cost differentials of professional resources which still obtain between Europe and America and the emerging countries.

Considering the diffusion on the global scale of IT expertise, it must be noted that the emerging countries can now count on high levels of professionalism and specialization which, in several cases, are clearly superior to those to be found in the traditional European and American leader companies. To cite just a few examples, we can mention companies such as Tata Consultancy, Infosys, Wipro Technologies and HCL Technologies, all operating in the Electronics City<sup>3</sup> of Bangalore, India, Flextronics in Singapore, Celestina in Canada, all numbering among the leaders as highly qualified IT providers.

In fact these are companies which have established themselves in the global panorama with the requisites of international certification that can indeed fuel preoccupation in Europe and America as to the future evolution of the market in IT services (Garner, 2004). In particular the Indian companies can claim a position of excellence concerning one of the most important systems of international certification for the quality of IT services offered, namely the "CMMI - Capability Maturity Model Integration for Software". According to the five levels featured in the CMMI system<sup>4</sup>, 50-60% of companies to have obtained the certification at the highest levels (4th & 5th) are Indian.

The CMMI system starts from the assumption that mature organizations produce quality services or products efficiently and constantly; in a mature organization the managers monitor the quality of the software products and processes they produce. There is an objective quantitative base for assessing the quality of the product and analysing the problems related to the product itself and the productive process. The business plans and budgeting are based on past performance and are realistic; the expected results, in terms of cost, timing, functionality and quality of the products are generally achieved. In general, mature organizations follow a disciplined process in a consistent way since all the participants are aware of the importance of doing so, but there is also the necessary infrastructure in place for supporting this process.

In conclusion, what once constituted the undisputed domain of European and American companies is no longer theirs "by right". The new geography on a global scale of the leading competences in IT is at the basis not only of the widespread recourse to offshoring but also of a change in its nature, which today goes well beyond the

pursuit of mere cost advantage and includes vectors of development of the business system based on relations of partnership in the mid-long terms with IT services providers.

## **The Traditional Approach and Beyond**

The traditional paradigm for making decisions on outsourcing in the IT sector was based on the imperative of cost saving and the possibility of dedicating more organizational, financial and human resources to core-business activities.

In terms of the first vector, analysis of *make or buy* based on the comparative evaluation of alternative solutions viewed in economic terms led to large-scale processes of outsourcing of activities, processes and services towards specialised operators able to offer lower costs than the hierarchy. The theoretical framework guiding these decisions was that of *transaction-cost economics theory* formulated by Williamson (1986), which took up and developed the older propositions of Coase (1937), according to which the choice between market, hierarchy and intermediate solutions must be made so as to minimise the total costs due to production and transaction.

It is quite clear that the industrialization of processes which characterises the offer of the largest and most qualified providers makes it possible to obtain scale economies in terms of production and management which significantly reduce the cost of buying IT services on the market.

Such a choice was based on the dual premise of being able to maintain control, free of operative and financial risks, by means of a detailed specification of the levels of performance required, and at the same time maintaining an adequate monitoring of the activities being outsourced.

As for the second vector, the outsourcing of non-core activities, it makes it possible both to streamline the organizational structure and make it more flexible, and also facilitates the development of competences related to the core-business activities. These can then benefit from the transfer of whatever, in terms of financial, organizational and human resources, is saved by means of the outsourcing of the functions and activities in support of the core of the value chain.

In this context it should be borne in mind that virtually all the economic and business literature on the topic seemed for a long time to endorse the restriction of outsourcing to activities quite distinct from the core-business, with few dissenting voices (Accabi and Lopez, 1995; Hinterhuber and Stuhec, 1996; Quinn and Hilmer, 1994). It is only recently that different opinions have begun to emerge concerning the objectives, contents and nature (tactical or strategic) of outsourcing, attributing to the relative decisions considerable potential to contribute to business development and innovation. The new orthodoxy to emerge from the theories of the *resource-based view*, *knowledge management*, and *distinctive competences* and *networks*, take a strategic approach to the processes of outsourcing. They also extend the scope of outsourcing from simple commodities to processes which participate in value creation (*Business Process Outsourcing*<sup>5</sup> and *Transformational Outsourcing*<sup>6</sup>).

These are the two premises on which the traditional paradigm for outsourcing in the IT sector has been founded, dominating the scene from the beginning of the 1990s up until very recently. What is more, changes in the approach to outsourcing activities and processes in the domain of IT can also be ascribed to a significant number of failures and a growing incidence of in-house reintegration of activities and processes.

The main causes for failure in outsourcing in the IT domain are the following: unsatisfactory customer service, higher costs for outsourcing than forecast<sup>7</sup>, failure to understand the business implications on the part of the provider, limited adaptability and flexibility for the IT services on offer with respect to the company's requirements, greater difficulties with the technological changeover than forecast, failure on the part of the provider to honour the established service levels and, to a lesser degree, a loss on the part of the client company of competent and qualified human resources.

In order to map out the evolution of the decisions concerning outsourcing in the IT sector we can identify three main historical phases which correspond to changes in the objectives and contents of this strategic choice:

- I phase: IT *on-shore* and *near-shore* outsourcing for “*commodities*”;
- II phase: IT offshoring for “*cost saving*”;
- III phase: IT offshoring for “*value creation*”.

In the first phase, corresponding to the 1980s, companies resorted to IT outsourcing in order to improve their economic efficiency and productivity, calling on specialised operators first in their own countries (on-shoring) and then slightly further afield but still in countries with cultural and institutional affinities (near-shoring).

The second phase, typical of the 1990s, saw the emergence of *offshoring*, meaning the outsourcing of activities and informatic systems to companies operating in far distant countries, above all with emerging economies<sup>8</sup> (Mol, van Tulder and Beije, 2005). This phase featured the pursuit of cost advantages offered by countries known as *low cost*, as the basis for competitive differentials (Jilovec, 2005). Such countries were just beginning to reap the benefits of their investments in computer technology, setting up as providers of an ever increasing range of services and closing the gap with respect to American and European-based firms. In this phase the phenomenon of offshoring involved above all medium/large-sized companies which were more interested in internationalization processes, and for whom IT activities represented support for their value chain. The economic advantages of outsourcing IT functions and services, already put to the test in local (on-shoring) and nearby (near-shoring) markets, led companies to look further and further afield for offers which were satisfactory from the point of view of quality but offering considerable savings with respect to previous solutions. The imperative of “cost saving” still dominated the decisions concerning outsourcing, but in the light of a significant increase in efficiency and the related possibility of modifying cost structures by means of “variabilising” previously fixed costs.

In this second phase, outsourcing towards low cost countries became possible because it proved clients could count on the same level of quality for services, technology and professionalism available in Europe and America at considerably reduced costs. In terms of offer of outsourcing services, the providers developed business by relying above all on standardization, meeting the need for basic services which could be supplied even over a great distance without the need for face-to-face management processes, offering clients something which the latter merely considered as back-up to the processes and activities of their core-business.

The passage from the second to the third, current, phase involved the progressive erosion of cost advantages and the ensuing quest for higher levels of quality for services and greater participation on the part of providers in business development and innovation (Kotabe and Murray, 2004). The perceived advantages lay in the new competitive challenges brought about by globalization and the incessant technological progress in the IT domain, leading to the loss of a firm’s “self-sufficiency”. Once the Fordist paradigm and vertical integration had been superseded in a profoundly altered environment (in both general and competitive terms) (Di Bernardo and Rullani, 1990), merely internal control of material and immaterial resources proved inadequate and prompted the concept of their “availability” for business processes rather than their “propriety”. In this context, among the various approaches elaborated in the 1990s the *resource-based theory* and *core-competence theory* showed that the pursuit of competitive advantage must be based on possession of distinctive competences (Prahalad and Hamel, 1990) which are difficult for competitors to imitate (Teece, Pisano and Shuen, 1990), leading to competitive differentials. In the current economic context, distinctive competences are constructed with the contribution of knowledge and skills of third parties, and no longer merely drawing on what is available in-house.

At the same time the geographical dispersion of competences in the IT domain is beginning to show the limits of its qualitative growth, giving rise to a demand for planned knowledge development which not all countries have been able to ensure. Furthermore this development requires forms of coordination and finalization of investments in IT which some countries have promoted and deliberately pursued, creating networks of cognitive exchange and the organizational premises for the birth of true innovative “poles”.

This passage from expectations centred solely on cost to a higher quality of services and the request to the provider to participate in value creation also explains the growing phenomena of back-sourcing, of the interruption of contracts and selective outsourcing<sup>9</sup>. These failures are also the result of an over enthusiastic initial adoption of offshoring (to an even greater degree than was the case for near-shoring and on-shoring), not always supported by an adequate strategic appraisal, either beforehand, through a careful identification and evaluation of the global costs of outsourcing, or during, by correct management of relations with the provider (Brandes, Lilliecreutz and Brege, 1997). The latter aspect was still viewed above all as a contractual exchange rather than a partnership. Thus it comes as no surprise that many client companies experienced dissatisfaction with respect to the quality levels of the services obtained from their providers and the numerous problems of organizational and cultural coordination between client and provider (Ventricelli, 2004). Such problems of offshoring were frequently underestimated, and

led to greater expenses than had been forecast (“hidden costs”), to which one must add those deriving from geographical distance (difficulties of face-to-face interaction, problems of time zone) and environmental differences (language, varying regimes of labour jurisdiction, political stability).

Moreover, in the mid- to long-term perspective it must be borne in mind that globalization, acting in all directions, will lead in future to convergence also of salary levels, according to professional classes, which is bound to reduce the gaps that still characterise the global scenario. One factor which will contribute to this levelling off of salaries in the future relates to the growing expectations of all stakeholders concerning the ethical and moral aspects of the company’s activities. For behind the low salary levels there are all too often circumstances of dubious ethics and morality, and social control over these aspects is likely to assume more and more importance in the future. We are already seeing a drop in the salaries of IT professionals worldwide with respect to the boom years of the net-economy (Jilovec, 2005).

The third phase, which has got under way in the first years of the 21st century, features the diminishing importance of cost differentials as the source of competitive advantage, accompanied by the quest for differentiated IT services of high quality<sup>10</sup>, closely linked to the client company’s specific needs.

We also see in economic and business literature an increasing awareness that analyses carried out on the basis of *make or buy* involving transactional costs “ignore other possible variables which can lead to a more dynamic vision of the pros and cons of in-sourcing as against out-sourcing” (Calvelli, 1998: p. 251).

In the IT sector the increasing difficulty for firms to dominate the variability and variety of the technological and market environment makes it necessary to find partners able to offer integrative and complementary cognitive and technological resources with whom to enter into partnership and set up a *competence building strategy* (Cantone, 2003).

Thus nowadays even core-business activities are moved out on the basis of collaboration agreements and partnership relations (Sicca, 2003), in order to have access to technological knowhow and new competences, fostering innovation and value creation processes. Moreover the all-pervasive nature of IT in the value chain makes it difficult to distinguish between mere support activities and those involving participation in the processes of value creation (Venkatraman, 1997).

One other factor characterising this third phase of the evolution of IT services markets is the “polarization” of computer knowledge and competences. These have become increasingly specialised and able to propose a differentiated offer of IT services, offering client companies solutions of business development and not merely support at low cost based on standardization.

The emerging phenomenon of *selective outsourcing*<sup>11</sup> represents the concrete effect of the polarization of knowledge and the differentiation of specialised services for the solution of specific problems encountered by the companies. In fact selective outsourcing involves outsourcing parts of the informatic system or specific segments of the company’s activities. Whatever the specific focus of selective outsourcing, the primary aim is to gain direct access to particular resources (Aiea and Clusit, 2006): specific professional competences, tailor-made applicative solutions, or niche and particularly innovative technologies.

Moreover, the evolution of the market for “*utilities on demand*”<sup>12</sup> also responds to the logic of going to whoever can best meet the company’s needs, according to changing and real requisites, not necessarily available from a single provider. The request for “*managed services*” in a selective outsourcing approach is linked to the need for companies to be able to count on the latest technologies, increase their own ability to react to the surrounding context (greater flexibility), and have the highest level of security and calculus capacity for their computer systems. The differentiated and changing requisites of the companies, especially those operating on a global scale, make the choice of *full outsourcing* in many cases no longer adequate when it is a question of providing IT activities and processes *in toto*, with contracts which bind the company to the technological partner for a number of years.

In addition, the acquisition in offshoring of these competences can avoid having to transfer abroad parts of company activities to acquire specializations scattered worldwide (Al Najjari, 2003): in this sense this type of company model has been defined “meta-national” (Doz, Santos and Williamson, 2004).

## A New Approach to Business Development and Innovation

Building a new approach to offshore strategies must start from the realisation that cost advantages cannot always be obtained by moving IT functions and activities abroad. We noted above that management frequently underestimates a whole series of additional costs involved in the choice to offshore, which are ignored in the economic evaluations of “make or buy” that lead to opt for outsourcing. These “*hidden costs*” involve numerous factors which cannot always be accurately measured at the outset, since they may arise during the outsourcing process (Barthelemy, 2001). In practice they can be summed up as follows (Gilotto and Cali, 2004):

- cost of identifying partner and negotiations;
- cost of start-up inefficiency and reaching quality regime;
- cost of monitoring and coordinating;
- cost of accessory operations and modifications during the contract period;
- cost and risk of losing in-house competences.

There are also other factors to be taken into account as sources of additional costs in the choice to offshore. One is the political instability of some countries involved in offshore projects, a by no means secondary consideration. When some operations are transferred abroad, insurance premiums may well be higher on account of the greater risk factors.

A second aspect concerns the lesser degree of control exercised over the productive processes when interacting with people and structures at a great distance. To cope with the problems deriving from geographical distance there are bound to be higher management costs. For example, one or more management experts employed in the home country may be used as the link between internal and external operations. When one adds to such a resource the costs of special infrastructures and travel expenses, it is hardly surprising that the hourly cost is considerably higher than what had been budgeted at the outset.

It must also be taken into consideration that the agile methodologies of coordination based on physical proximity (face-to-face), such as stand-up meetings and sharing of the same workspace, are much more difficult to reproduce. This problem is affected by both geographical distance and time zones.

A third aspect concerns data protection, software piracy and intellectual property. National legislation is not applicable in other countries, and even when the contract stipulated with the provider includes relevant provisions, some contracts cannot be taken to court in foreign countries. In spite of the prominence given recently to questions of privacy and data protection, this continues to be a grey area subject to different interpretations in different countries. There is thus the need for a legal consultant expert in international law, and so costs deriving from legal activities may also prove higher than budgeted. The problem of the protection of intellectual property is particularly significant when one considers how efficient low cost countries are at assimilating new knowledge. The phenomenon of appropriation by foreign operators of knowledge and skills is critical not only in view of the different juridical regimes that regulate this subject but also because the confidentiality clauses inserted in contracts do not always ensure full protection of intellectual property (Renard, 2003).

Further elements to be considered in the choice of offshoring which generate additional costs, concern differences in culture, not least managerial culture, between the country of the client firm and that of the provider, as well as the language gap, which still constitutes a barrier to efficient communication at all operative levels.

Thus having seen the limits of offshoring based on cost advantage, we can turn to the contents and objectives of this strategic approach. The two premises for such an approach are the availability worldwide of resources of highly qualified competences and the difficulty for companies to dominate markets and technologies relying exclusively on their own efforts. The paradigm that dominated the choices of outsourcing in the past is becoming outdated, not least in view of the fact that the emerging distinctive capacity which nowadays may result in a competitive advantage is the ability to manage relations with other companies, with a view to sharing and reciprocally increasing knowledge (Quinn, 1999), setting up learning processes not only in-house, and embracing the innovative contribution of external partners, placing their specialistic competences at the service of the client company.

From this point of view we can say that the risks perceived by the companies, which often preclude choices of outsourcing, namely “loss of control over strategic activities”, “cognitive dependence on the provider”, and “impoverishment of internal innovative capacity”, actually represent merely the incapacity or reluctance to accept that one’s own business system and the sources of one’s competitive advantage lie outside the firm, out of the hierarchy’s control, and thus, almost by definition or ineluctable destiny, are bound to create dangerous conditions of dispersion of one’s own capacity for survival and the strategical impoverishment of the firm.

Moreover, according to a survey carried out in 2004 by Sirmi S.p.A., an Italian company responsible for research, market analysis and consultancy in ICT, in a cross-section of some 250 companies, the fears of “dependence on the provider” and “loss of technological knowhow” were real to companies which had never tried solutions of outsourcing but were practically non-existent among those which had (Fig. 1).

FIG.1: THE “FEARS TO BE OVERCOME”

As can be seen from the data in Fig. 1, the gap between companies which rely on outsourcing and those which do not is very significant. “Dependence on the provider” is feared by 35.1% of companies which do not use outsourcing, and only 15.1% of those which do; the “loss of technological knowhow” is feared by 21.7% of companies which do not use outsourcing and only 9.6% of those which do. We can also note that the “problems relating to information security” are the main source of preoccupation for those companies which use outsourcing (26%), exceeding those which do not (24.6%).

These empirical indications also go to confirm the fact that the emerging distinctive competence consisting in the capacity to coordinate and manage the “innovation network” presupposes acceptance of the fragmentation of one’s own business system, the participation of third parties in the development of one’s own innovative capacity, and hence competitiveness, meaning in practical terms an approach which seeks out the “best competences” available worldwide.

If one accepts the idea that the key new competence for achieving competitive advantage is the ability to manage and coordinate the network of relations which the firm is able to put in place, and which can become “distinctive” with respect to competitors, then one must also be prepared to go beyond the traditional distinction between core and non-core activities in deciding which activities can be outsourced.

In other words, limiting outsourcing to non-core activities or processes while maintaining the core counterparts in-house is based on two apparently axiomatic elements which must be called into question.

The first concerns the possibility of clearly separating what is “core” from what is not, and this is by no means always straightforward; the second concerns the restriction of distinctive competences, based on the traditional evaluation of *make or buy*, to the management of activities which are critical for the value chain, meaning those which generate the competitive differentials characterising the company.

Concerning the latter aspect, the identification of the distinctive capacities with reference to the management of the value chain, comprising in a functional perspective activities linked to one other in order to produce an output, does not include any consideration of the most important distinctive competence, meaning the management of the network of inter-organizational relations and, more concretely, the coordination and control of the cognitive and functional input of external operators specialised in certain activities or processes.

Thus the problem is not identifying possibilities of outsourcing according to the “degree of proximity to core-business” activities, but rather evaluating whether the competences possessed by a certain company are superior to those available on the market (Fig. 2).

		TECHNOLOGICAL AND INFORMATIC COMPETENCES	
		Inferior to market	Superior to market
QUALIFICATION OF ACTIVITY	“core”	OUTSOURCING	INSOURCING
	“non core”	OUTSOURCING	INSOURCING

FIG. 2: A CRITERION FOR IDENTIFYING WHAT TO OUTSOURCE

One factor that used to make outsourcing appear unsuitable for managing activities close to the core-business was the difficulty of finding qualified competences on the market capable of grasping the business requisites of the client company and coming up with appropriate informatic solutions which could be fully integrated in the specific processes involved in the competitive capacity of each firm.

This difficulty was also due to the standardization approach which characterised the provider’s traditional offer, the basis for the development of the business, so as to achieve scale economies and orient competitive strategies according to cost effectiveness.

Recently providers have realised that the requirements of the client firms are no longer connected merely with obtaining cost advantages, but are increasingly associated with improving the quality of performances and the acquisition of differentiated services, calibrated according to their needs. Thus also the competitive strategies of provider firms, from being predominantly based on cost leadership, have gradually switched to differentiation. This has become possible thanks to the extraordinary development of technological and informatic competences and an increasingly *marketing oriented* approach. For example, one of the striking aspects of the offer of many Indian

providers is the strong sense of *commitment* and the marked operative flexibility they display towards the business requirements of the client company, with a *client satisfaction* approach which in essence involves a great willingness to enter into long-term partnership relationships.

Thus the problem consists in the evaluation of the contribution which the external provider of IT services can make to the improvement of the company system in its entirety, and identifying “how” this potential contribution can be implemented reducing the risks (loss of control, impoverishment of resources and innovative capacities, strategic dependence on the provider, etc.) traditionally associated with outsourcing those activities which are strategic and/or close to the “core-business”. From this point of view there has to be a change of approach, going beyond the rationale of exchange or contract and ensuring the adoption of true “sharing” and “reciprocal integration” (Gubitta, 2005).

If the aim of the relationship is the co-generation of new common knowledge, it is no longer enough to define contractual rules to coordinate the action of the parties; it is necessary to create the organizational conditions for facilitating the sharing of knowledge and the integration of the respective value chains: of the client firm and of the provider firm. Thus we can say that at the basis of the new paradigm for offshoring there is the passage from the rationale of *transaction-based outsourcing* to that of *relationship-based or partnership-based outsourcing* (Lee, 2001).

The relational dimension of the outsourcing of activities or processes also modifies the parameters and criteria for selecting the provider. The latter’s value chain has to be evaluated in terms of structural and strategic compatibility with respect to the client company. There is also a change in the organizational tools for managing the relationship. They will no longer be based merely on contractual obligations but will involve coordination mechanisms, both formal and informal, to facilitate the joint undertaking of programming and operative activities. In practice the rationale of networking, which for some time could be seen as modifying exchanges between client and provider (Calvelli, 1998), in strategical decisions regarding offshoring reaches its full affirmation in a sector, like IT, in which the knowledge factor dominates the production processes.

## **Conditions for Successful Offshoring in a Value Creation Perspective**

We have shown how the broad and composite panorama of outsourcing is characterised by new tendencies, imposing new interpretations of the phenomenon in terms of both strategy and management. We pointed out that the traditional approach in which only those company activities and processes removed from the so-called “core business” could be considered for outsourcing is outdated. This is in fact due to several factors:

- the ever greater difficulty in identifying what can be considered “core business” in companies which are increasingly seen as unitary organisms;
- the growing centrality and specialisation of competences;
- the enormous, rapid evolution of many technologies;
- the globalization of the market.

To this list of factors, which is by no means complete, we can add the consideration that in many sectors of the market these elements are not only present but also highly inter-dependent. In the telecommunications market alone, the continuous introduction of new services based on the availability of broadband networks, the need for convergence between land and mobile systems involving service orchestration, the increasing importance of content management and digital asset management, and the recent launch of IP television services, are just some examples of areas representing challenges and requirements for operators that are quite new with respect to the past:

- the need for multi-layer competences, at various levels of technical expertise: management of the new generation of network infrastructures, personalisation of packages, system building, service assurance, network protocols, etc.;
- the problem of the rapid obsolescence of such skills and the corresponding need for new competences;
- the impossibility of finding all the requisite competences in a single partner/provider.

These new requirements have in fact already generated new relations of IT outsourcing aiming at guaranteeing essential market elements: availability of state-of-the-art technology skills, possibility of up-grading

resources at short notice, stability of operating costs (and not necessarily, it must be stressed, reduction of such costs). In these cases it is quite difficult to regard the activities featuring in such contracts as “non core”.

Moreover, the change in perspective we have illustrated does not simply refer to the objectives that companies are constantly extending and differentiating with respect to the past, but also to the growing awareness that sourcing strategy must be viewed as a whole – i.e. not limited to a single sector or project, but as a choice and integrated management of a system of trusted alliances and providers – and also as a dynamic feature, deriving from the evolution of the required skills, volumes of activity, change in the priority of goals, etc.

In other words, for outsourcing to be viewed as a strategic choice which conditions, and does not merely support, value creation processes, it must be grounded in a partnership between client company and provider company which goes well beyond the simple commercial supply agreement (partnership-based outsourcing).

Furthermore, outsourcing encompasses a variegated galaxy of relations which vary significantly in terms of context, modalities and objectives. This is reflected both in the strong growth characterising outsourcing over the last twenty years in all sectors, and in the significant number of failures (about 50% of contracts stipulated between 2000 and 2004 did not achieve their intended objectives in one way or another), often due precisely to the fact that this articulation was undervalued in one or more of its complexity factors (“compulsive outsourcing”).

The “compulsive” approach to offshore outsourcing involves the generation of risks concerning aspects which are crucial for the success of an initiative. Although many considerations have a general validity, offshoring IT services presents peculiar features which cannot be extended to other typologies of outsourcing.

An important starting-point is to clarify what the various parties consider as “success”. This may seem obvious, but in fact it is often actually spelt out only when the contract goes live. The main reason lies in the frequent gap between company strategy and choices of sourcing or, in other words, between top and middle management. This gap not only leads to a muddled definition of expectations in terms of final results but is often the main limitation that makes it extremely difficult to outsource activities considered as “core business”.

Defining and characterising the expected success of the outsourcing initiative in terms of business results is, on the contrary, indispensable for identifying the main critical factors of success. The traditional conceptual model which qualifies the success of an outsourcing contract in terms of the measurable achievement of predetermined levels of service is ineffectual in the current economic scenario, as well as being problematic within the traditional approach. However, this consideration does not hold only for the client company. As we said above in connection with the centrality of the contract, the partner/vendor is also a vector of needs and requisites which change over time concerning both the market and competitors and its own changes in strategy.

Keeping our focus on contracts concerning Information Technology which contemplate offshoring, it is clear how what we have just said takes on even greater importance, for two main reasons:

- the onus of governance and ongoing management in offshore contracts is significantly greater compared to onshore contracts: geographical dislocation, time zones, language, cultural and methodological differences, and greater need to formalise requisites, are some of the factors which can lead to greater management overheads and hidden costs;
- the multinational dimension introduces the problem of the various juridical systems regulating important aspects of an outsourcing contract: labour legislation, safeguarding of intellectual property, differences in financial regulation, etc.

A second point we feel to be fundamental is the central role that the contract should occupy, both while it is being negotiated and drawn up and during the phase of contract management. It must be said first of all that an outsourcing contract may take on different characteristics according to the combination of at least three dimensions – or classification criteria – which may in turn have differing degrees of inter-dependence:

- *Scope*: the typology of activity featured in the outsourcing contract. In this context the standard subdivision between BPO, Business Process Outsourcing, AO, Application Outsourcing, and ITO, Infrastructure Technology Outsourcing, can be maintained, although each typology has to be classified in greater detail. For example, in the context of Application Outsourcing alone there is a variety of services – here too variously classified – such as Application Maintenance, Application Development, Applicative Help Desk, Operation Services, etc.;

- *Operating Model*: the modality of provision of the services covered by outsourcing. In this context various classifications are possible, but here we shall merely point out the fundamental distinction between *onshore*, *near-shore* and *off-shore*;
- *Contract Framework*: the typology of contract stipulated with the partner/vendor. In this context the classification is even less standardised, in view of the fact that the juridical systems of each country often feature substantial differences in concept and instrument regulating the discipline. A possible classification valid above all in countries subject to common law consists in identifying certain standard contract schemes: a) *contract-out strategy*, b) *preferred contractor strategy*, c) *buy-in strategy*, d) *preferred supplier strategy*.

We do not intend here to go further into the classification profiles or list all the typologies occurring in the various dimensions. We merely wish to point out how even classifying outsourcing contracts shows up the need to view the phenomenon as comprising a vast and articulated universe of relations which cannot be encompassed in an excessively schematic approach. In the light of this, it emerges that the centrality of the contractual aspects can be essential for:

- ratifying the expectations of both parties;
- providing instruments able to guarantee operative flexibility.

Although it does respond to the concept of juridical negotiation, in practice the predominant approach sees the negotiating phase as the pursuit of an equilibrium between terms and conditions designed to safeguard and guarantee the two parties against negative events or the occurrence of antagonism.

In actual fact the business of defining and formalising the contract often only comes about after a business agreement is considered to have been entered into by buyer and vendor. Thus the phase of drawing up the contract becomes merely a negotiation concerning general terms and conditions which all too often introduce elements of extreme rigidity into the relationship.

The thesis we are advancing here is, on the contrary, to consider the given contractual framework as a critical factor in the success of any outsourcing contract, as a means of linking up company strategies.

There are several reasons for this:

- a) the contract has legal validity between the parties, which makes it not *a priori* adaptable to changes in scenario and requirements. Thus it is essential for it to envisage explicitly the possibility of modifications and integrations, as well as the procedures of change management enabling it to be modified while in course;
- b) it must envisage service level agreements which are genuinely linked to the company's business aims, avoiding the need to respect the numerous indicators which all too often involve rapidity and quality which not only are not required but which are not even useful. The definition of SLAs drawn up only on the basis of technical/operative criteria or parameters introduces not only the risk of an excessive rigidity for the provider but also the impossibility of being able to overcome this<sup>13</sup>;
- c) it is fairly clear that a contract should meet (or seek to meet) the needs and expectations of the client. It is less obvious or usual for the needs and expectations of the provider to be examined in detail. Making the contract central helps to focus attention on the provider's standpoint, laying the foundations for a genuine partnership rather than leaving this to be only a declaration of intent or a purely commercial matter.

Of course, as in any outsourcing contract, the choice of provider is an essential factor for success. Nowadays there are many competitors on the market who can claim a rich portfolio of services and aggressive pricing policies. What is more, many of the players from emerging countries – if this term makes sense any more – have opened branches in Europe, for not only commercial but also traditional on-site consulting purposes.

At the same time, the main players in the global market such as IT, Accenture, IBM, HP and EDS have long included in their offer *delivery centres of excellence* in countries such as India, Brazil, Russia, China and the Philippines, with highly qualified personnel dealing with all the most innovative platforms and technologies. In this way the major holdings can resist global competition since they are able to combine the best of their more traditional onsite activities with the need for industrialization and efficiency offered by the delivery centres of excellence.

This leads to a third factor important for success in offshore IT initiatives: the mix of on-shore/off-shore activities. For each service there are standard combinations, but it is important to resist the two compulsive

temptations: a) maximum outsourcing of activities to reduce costs as much as possible, b) minimum outsourcing for fear of losing control over activities.

Experience in the field shows that both temptations are in fact illusory, and that a careful evaluation of the mix must be carried out according to rational, measurable factors such as:

- the competences actually available from the outsourcee;
- the end-to-end productive process and the number of interlocutors involved (from end users to operation demand);
- real requisites of timing and quality for delivery;
- the structure and requirements of customer service and help desk.

We have highlighted some of the key factors in success, but there are many others that could be considered. Nonetheless we wish to end by focusing on one aspect which is all too often neglected or undervalued, and which on the contrary often proves decisive in practice: communications. It should be borne in mind that an outsourcing contract involves an operation which often seems to “invade” the organism of a company. If this awareness is patent in cases in which a branch of the company is to be ceded, above all in the light of the union impositions, the same does not hold for cases in which frequently innovative activities are taken away from the internal IT structures. We pointed out above that it is fundamental for strategic objectives to constitute the basis both for the definition of the contract and for ongoing management. Here we wish to recall this aspect in relation to communications to stress that an important premise for the success of the contract is awareness at all levels of objectives and goals. The absence of communication or a communication which is insufficient, leaving middle management on the sidelines, can be a pre-eminent negative factor, for there is no doubt that “hidden strategy yields hidden costs”. This risk derives not only, as can be imagined, from the operative structures operating without criteria for identifying risks and priorities, but also for what concerns the motivation of the staff in the internal IT structure, often leading to obstructionist attitudes or indeed the loss of the best resources, who cannot be retained.

In conclusion, we have sought to show how the outsourcing of IT applications constitutes a very powerful tool in the hands of companies, and how as time goes on this tool has become ever more sophisticated, thanks to the increasingly rich offering by the market players. However, power and sophistication have also led to increasing complexity of management which can only be properly matched by a model of governance featuring dynamism and flexibility (the systemic approach). In other words, the success of an outsourcing contract does not depend merely on a correct operative management by the business unit involved but, increasingly, by its efficient integration in the company strategies.

## End Notes

Although this paper is the result of a joint effort, sections 2, 3 and 4 were written by Paolo Popoli, section 5 by Arturo Popoli, and section 1 by the two authors together.

<sup>1</sup> The services sector accounts for more than 50% of the GNP of India; in particular, in the decade 1991-2001 the exportation of IT services grew by 50%, reaching in 2002 the figure of 8 billion dollars, and by 2008 is forecast to rise to 50 billions.

<sup>2</sup> Average salaries are at much lower levels than in the developed countries, since labour supply in the IT sector is much higher than demand; in India more than a million people work in the IT domain, and this figure is expected to rise to about 2 million in the next two years.

<sup>3</sup> Electronic City, Bangalore, and other technological poles in India are often referred to as “cathedrals in the desert” since they are much more closely connected to the economic and technological centres of the developed countries benefiting from delocalisation of services (not least thanks to the presence of branches or joint ventures of large international groups such as IBM, Microsoft, General Electric) than with their local territory, which continue to be geographical areas characterised by great poverty and very low standards of living. It is not difficult to understand why the major technological firms delocalise and create branches in low cost countries in view of the fact that the cost of an Indian employee is approximately 1/9 that of an American or British counterpart.

<sup>4</sup> The CMMI, developed by the Software Engineering Institute (SEI) of Carnegie Mellon University, is a system of rigorous standards for the evaluation of the “degree of maturity” demonstrated by companies in the organization and management of their software processes. It gives the following description of organizational evolution:

Level 1: *Initial*. Software development processes are usually ad hoc and chaotic. Most often a stable environment does not exist. Success depends on the competence and heroics of individuals;

Level 2: *Managed*. Elementary management processes are adopted to monitor costs, programme activities and define functionality. The discipline is in some way available for repeating initial successes in similar projects;

Level 3: *Defined*. The process is characterised in terms of both managerial and technical activities. Moreover it is based on recognised standards. All projects use an approved and (where necessary) personalised version of the standard company model for developing and maintaining software;

Level 4: *Quantitatively Managed*. Detailed reports are captured on software process and product quality. Both elements (process and product) are evaluated and controlled in quantitative terms;

Level 5: *Optimizing*. Continually improving process performance is achieved using quantitative feedback from the evaluation applied to the process itself and initiatives of technological and process innovation associated with critical areas kept monitored.

<sup>5</sup> *Business Process Outsourcing* involves outsourcing management processes in their entirety, such as human resources, supply chain, logistics, training, financial services, and also R&D.

<sup>6</sup> *Transformational Outsourcing* involves engaging a provider to operate a radical transformation of the company’s whole informatic system, and manage the associated changeover both of organizational and managerial processes and of business characteristics and rationale.

<sup>7</sup> The leading exponent of the *transaction-cost economics theory* himself, Williamson (1996), was aware that an analysis of transactional costs was possible, *ex ante*, only for certain typologies of cost, while for others only forecasts could be made. In particular, these transaction costs *ex post* concerned monitoring the activities and performance of the provider, revising the contractual agreements in the light of unforeseen events, settling disagreements and dealing with opportunistic behaviour on the part of the provider.

<sup>8</sup> Offshore projects can be divided up into two main categories: “fixed-price projects”, in which the client does not participate in the developmental phase but merely outlines the requisite aims; “collaborative projects”, in which the offshore team participates in developing the project together with the insite team, in a *co-sourced* approach, requiring adequate processes of communication and interaction between client company and provider.

<sup>9</sup> The “2005 Global IT Outsourcing Study” carried out by the American agency Diamond Cluster shows that the number of clients which have broken off contracts of outsourcing in the last 12 months has more than doubled, arriving at 51 per cent today as against 21 per cent a year ago.

<sup>10</sup> A phenomenon which has contributed massively to offshoring has been the boom of Internet and the net-economy, on account of the limited availability of resources and specialised competences at home, available abroad at much reduced costs. These benefits became all the more significant in the subsequent period of recession in the net-economy.

<sup>11</sup> In *full outsourcing* the management and maintenance activities, including applications development, assigned to a specialised provider feature the *entire system* of the company’s IT facilities, while in *selective outsourcing* only one or more *components*. In the context of selective outsourcing there are various typologies (Aiea and Clusit, 2006): *Vertical outsourcing*, covering one or more functional areas of the company application portfolio; *System Management*, covering the area of elaboration and software systems; *Network Management*, covering communications infrastructure components; *Desktop Management*, covering work stations *End User Computing*, covering the management of elaborative and distributive areas; *Application Management*, covering the maintenance, implementation and development of the client’s software applications; *Outsourcing of IT functions*, such as quality or other specific services, including professional and consultancy.

<sup>12</sup> The added value which now characterises the offers of “outsourcing on demand” is flexibility, thanks to the ability of the provider to offer personalised solutions and increase or diminish the calculating capacity of computer systems according to the client’s business needs (e.g. for phenomena of seasonal variation or concerning new, specific initiatives), on the basis of “*sense and respond*”, feasible only in the presence of a strong partnership.

<sup>13</sup> It may be helpful to give an example. A standard indicator in services of bug fixing in the context of Application Outsourcing contracts is *resolution time*, meaning the time taken to solve an application error measured from when it was reported to its release in the operative environment. An SLA which required for all errors a very short resolution time would mean a continuous and onerous installation activity in production, with a consequent interruption in operative availability for end users. A more suitable solution, frequently adopted nowadays, can instead be to base the resolution time on a classification of errors according to severity and priority, leaving less serious errors to be dealt with in production and programmed “patches”.

# Knowledge & the Dynamic Evolution of Co-operative Alliance

Dharma Deo Sharma, *deo.sharma@hhs.se*  
Stockholm School of Economics, Stockholm, Sweden

## Abstract

The number of international cooperative alliance has been increasing. Research in the field of cooperative alliance is also increasing. The major portion of this research is based on the traditional approaches of game theory and the transaction costs theory. Process based investigations are few. In this paper, alliances are investigated from a process perspective. It is argued that cooperative alliance result from a long period of interaction between firms. Based on two European cases, it is argued that it takes time to lean about the alliance counterpart. Based on this knowledge, commitments are made, and solidarity and flexibility between the alliance partners develop.

## Introduction

Research on inter-firm co-operative alliances is growing (Dollinger and Golden, 1992; Parkhe, 1993; Hamel, Doz & Prahalad, 1989; Nielsen, 1988; Gulati, 1995). Co-operative alliance have been studied under a variety of different headings, such as symbiotic marketing, strategic alliances, strategic partnerships, strategic networks, interorganizational linkages, interfirm cooperation, cooperative strategies, collective strategies, buyer-seller relationships, and corporate linkages etc. In this paper, *cooperative alliance* are defined as 'relatively enduring interfirm cooperative arrangements, involving flows and linkages that utilise resources and/or governance structures from autonomous organisations, for the joint accomplishment of individual goals linked to the corporate mission of each sponsoring firm'<sup>1</sup>. *Cooperative alliances* are forged with the aim of exchanging strategic resources between two or more firms, directed towards a given purpose with strategic significance. Alliances are 'a bilateral relationship characterized by the commitment of two or more partner firms to reach a common goal, and which entails the pooling of specialized assets and capabilities' (Jorde, and Teece, 1989).

In the literature much attention has been paid to initial design issues (Parkhe, 1993). This is, however, not enough as 'some adjustments in the alliance's governance structure may be necessary yet unanticipated for parent firms, perhaps due to inexperience with a particular collaborative task, mistakes made during the ex. ante design stage, or emerging opportunities' (Reuer, Zollo, and Singh, 2002). The need to study alliance as dynamic process is emphasized (Arino, and de la Torre, 1998; Doz and Hamel, 1998). Doz (1996) and Kumar and Nti (1998) proposed dynamic model in which initial conditions for alliance generate learning, and dynamic in the alliance. Arino and de la Torre (1998) added new aspects to the above model. Other process based studies have been produced by Gulati, Khanna, and Nohria (1994, 1998), Inkpen and Beamish (1997), Koza and Lewin (1998). Researchers have shown that inter-firm relations pass through phases (Dwyer, Schurr, and Oh, 1987; Van de Ven, 1994), and aspects of exchange may change over time (Koza and Lewin, 1998; Jap and Ganeshan, 2000; Zajac and Olsen, 1993; Bowman and Faulkner, 1997; Ring and Van de Van, 1994). Doz (1996) stated that strategic alliances pass through a cycle of learning, re-evaluation and readjustment stages.

Our knowledge on the process aspects of alliances and their dynamic evolution is still limited and deficient, as evident from the vast number of alliance failures. There is, thus, a need to improve our knowledge of dynamics of alliance. This is the purpose of this paper. I present a process based model for the dynamic evolution of alliances. It is argued that co-operative alliance are organic structures that evolving over time. They have a past, a present and a future. It is argued that alliances are not necessarily strategic from the very beginning. Indeed, some inter-firm relationships overtime evolve into strategic alliances. In this evolutionary process alliance partners accumulate knowledge and make commitment, and the governance structure is modified. I base my arguments on two interrelated theoretical schools, namely, knowledge literature and the relational view of marketing.

## **A Model for Dynamic in Co-operative Alliance**

Firms, in order to survive, require resources. These resources may be acquired either by market based arms-length transaction, or by non-market based domesticated exchange (Arndt, 1979). Market-based exchanges are characterized by non-idiosyncratic investments, the transaction costs are low, and information exchange between partners is minimal. Under these conditions, it is easy for companies to change partners. Cooperative alliances evolve as the environment in which companies operate is uncertain and involve dependence power relations between firms (Pfeffer and Salancik, 1978). The advantage of cooperative alliance lie in that (a) there is substantial knowledge exchange between the co-operating firms, (b) partners invest in relation-specific assets, (c) pooling of complementary, but scarce, resources and capabilities, and (d) lower transaction costs than competitor alliances, due to more effective governance mechanisms.

The argument made in this paper is depicted in figure 1. It is argued that at any point in time, based on the current and past operations, alliance partners possess specific stock of knowledge. This guides their resources commitment in an alliance. As resources are committed, firms accumulate more knowledge and their knowledge base is altered which effects influences their future resource commitment in the alliance. This is a dynamic, evolutionary process, a process in which there exists a temporal inter-connectedness among seemingly discrete events or episodes in alliance. This process may be non-linear, occasionally non-planned, and unfolding over time. This is a learning process in which even seemingly minor changes in the environment may produce significant, often unanticipated changes in the alliance. The model does not explicitly incorporate trust. I do not deny that alliance partners may develop trust, but dynamics in strategic alliance is not necessarily dependent upon trust (Zollo, Reuer, and Singh, 2000).

## **Knowledge & Absorptive Capacity of Firms**

Partners in a cooperative alliance trade resources based on their current stock of their own resources and knowledge of the resources of companies with whom they are co-operating. Although all knowledge is accumulated by individuals, in this paper we focus on organization knowledge. By knowledge is implied 'the process within the organization by which knowledge about action-outcome relationships and the effect of the environment on these relationships is developed' (Duncan and Weiss, 1979, p. 84). Knowledge is stored in the routines and standard operating procedures in firms. By routines is implied 'the way in which a firm typically addresses aspects of organizing its business activities' (Morsini, Shane, and Singh, 1998; p. 139). These routines and processes include procedures for scanning the environment, interacting with and managing customers and suppliers. Organizational routines and processes vary significantly between firms and nations (Lincoln, Hand, and Olson, 1981), evolve in interaction with a firm's history and institutional environment (Collis, 1991), and, consequently difficult to replicate by other firms (Barney, 1991). These define the context for new knowledge development and exchange within firms. Zahara and Georg (2002) conceptualise this as a 'dynamic capability pertaining to knowledge creation and utilization that enhance a firm's ability to gain and sustain a competitive advantage' (p. 185). These are unique, rare, valuable, and imperfectly imitable resources embedded in organizational processes and directed to-wards enabling organizational change and evolution. Routines and processes shape a firm's absorptive capacity (Cohen and Levinthal, 1990) or 'receptivity' (Hamel, 1999) to new knowledge, and define the repertoire of available alternatives that a company has in a decision- the experiential knowledge of firms. The absorptive capacity also defines a firm's ability to absorb new, related knowledge and the direction of its search and noticing activities. As firms operate in markets, they extract cues on cause-effect relations and learn. Over time, some of these cues are encoded and stocked in the routines and operating systems in firms. The absorptive capacity of firms defines a firm's capacity to (i) understand/learn new external knowledge. This includes what is learnt and the speed of the learning, (ii) codify and assimilate this new knowledge, and (iii) apply new knowledge to solve business problems (Lane and Lubatkin, 1998). These three dimensions are combinative in nature and build upon each other to offer a dynamic capability. We distinguish between technological knowledge and managerial, including marketing knowledge. An organizations capacity to learn is relative.

Routines and processes shape a firm's absorptive capacity (Cohen and Levinthal, 1990) and its receptivity (Hamel, 1999) to new knowledge. This, in turn, defines the repertoire of available alternatives that a company has in a decision making situation. The absorptive capacity of firms is bi-product of the actual experience of problem solving or learning a new external knowledge is made easy when two firms have similar knowledge base and possess similar cues in the routines and decision making processes in the firm. The absorptive capacity of firms defines the speed and reliability with which alliance partners learn about each other's actions. The current alliance partners receive early signals regarding what the other partner is doing, why, and when. As suggested by Gavetti (2005) distance from action reduces ability to interpret the experience. Also, the speed with which the signals travel from one alliance partner to the other is important, as the strength of the signals decay with the passing of time. The wider the differences between the decisions making routines, and consequently the encoded knowledge in the firm the more limited the understanding of the external knowledge. A number of factors seems to influence learning, including prior knowledge of the foreign partner, transparency of alliance partners (Hamel, 1991), cultural similarity between the alliance partners (Mowery, Oxley and Silverman, 1996), and difference in partners nationality (Parkhe, 1993). Codifying and assimilating new knowledge requires openness on the part of the alliance partners. Socialization is important (Nonaka, 1994). Through socialization individual in alliance partners interact, engage in face-to-face communications, and exchanging experiential knowledge. In international alliance this is important and the knowledge developed in one environment may not be applicable in other environments (Boyacigiller and Adler, 1991). Parts of this knowledge are deposited in the current routines. Finally, the acquired knowledge and the history of alliance partnership supply a firm with knowledge about a counterpart, its complex internal and external exchange relationships and social network. The use of knowledge is important, which reflects an organization's ability to employ and incorporate knowledge into its business operations. This depends upon the ability of firms to retrieve knowledge that exists in its routines and processes.

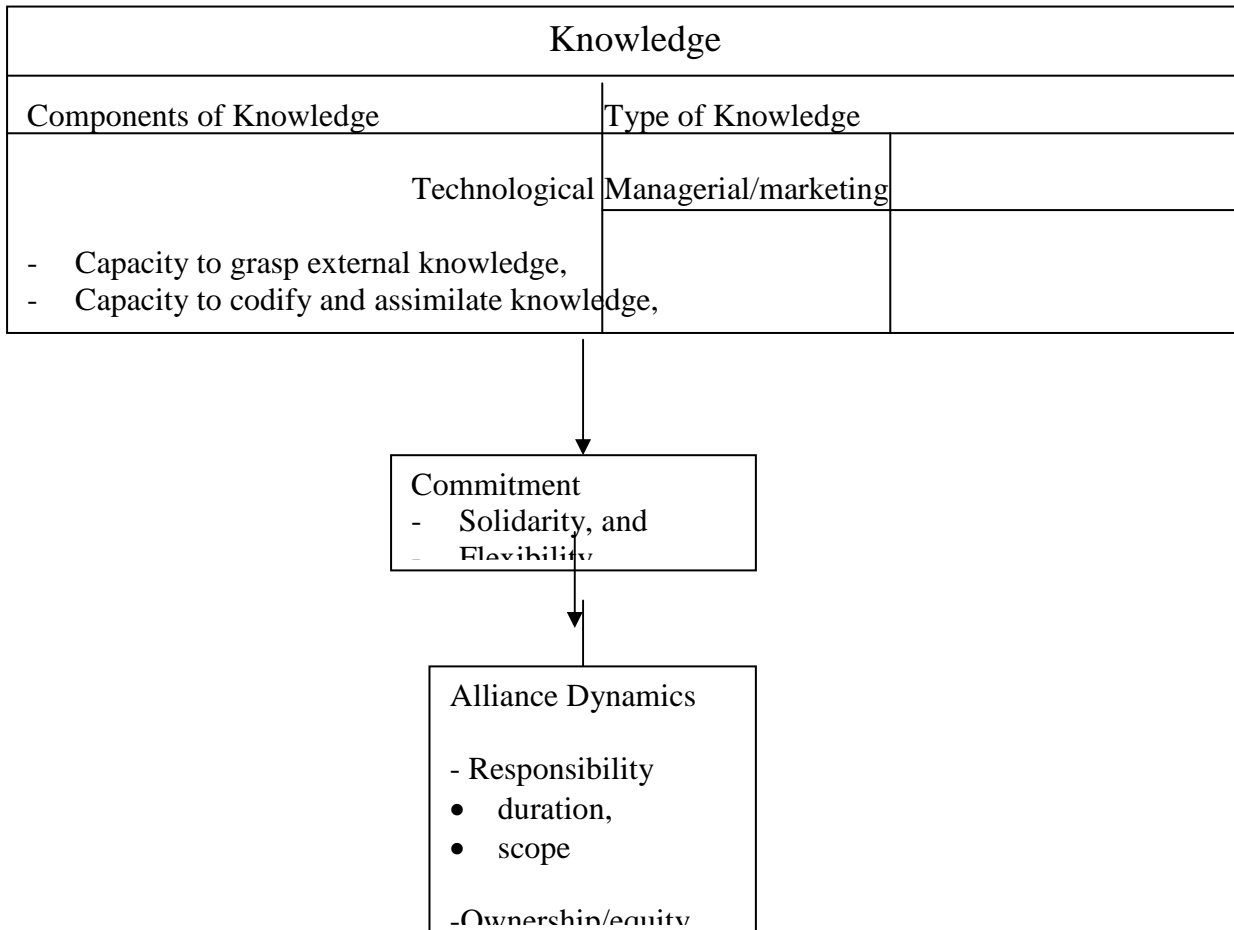

FIG. 1: DYNAMIC PROCESS OF CO-OPERATIVE ALLIANCE

Accumulating knowledge and resources is path dependent, and the absorptive capacity of firms is “partner specific”, that is, “the ability to recognize and assimilate valuable knowledge from particular alliance partners” (Dyer and Singh, 1998, p. 665). Partner specific absorptive capacity develops as partners repeatedly engage in exchange. The partner specific absorptive capacity may result in installation and refinement of routines, guides their future investment decisions. This may allow partners to develop specific capabilities to assess, combine, utilize, and exploit an specific counterparts knowledge resources. The partner specific abortive capacity is also important in order to properly and timely detect the feeling of dissatisfaction in the alliance counterpart. This is important as there are significant ambiguities in what the alliance partners do and why. The partner specific knowledge is helpful in differentiating between the causes why an alliance is (not) performing well. But, routines in firms are heterogenous. An important consequence is that this, and may isolate a firm from other potential co-operative partners. Also, knowledge extracted by each alliance partner may differ in quality and quantity. Firms are ‘locked out’ of certain types of knowledge. They ignore opportunities for initiating co-operation with new partners. This may be because, as pointed out by Leonard-Barton (1992, 1995), that a firm’s existing knowledge may also be a firms core rigidity.

The initial stock of knowledge and the absorptive capacity of the counterparts in an alliance are different, and consequently, what the counterparts learn and the speed with which they learn will be different. This may also happen as the alliance partners seek to learn different things and at different times (Makhija and Ganesh, 1997).

## **Commitment in Cooperative Alliance**

Based on their knowledge alliance partners make commitment. Commitment implies that, “an actor is committed to another actor in the network to the extent that choice of current exchange partner, can be predicted from previous partnership” (Cook and Emerson, 1978, p. 728)<sup>3</sup>. Commitment induces inertia due to (1) a lack of pressure for change, for example, to change the source of a particular resource, and (2) the pressure to change is blocked (Blau, 1964). Commitment is, consequently, a “binding force between exchange partners that can lead to the maintenance of an existing relationship to the exclusion of alternatives” (Seabright, Levinthal, & Fichman, 1992, p. 122). Extant research shows the importance of commitment in co-operative exchange. Macauley (1963) pointed out that businessmen often use non-contract mechanisms to govern their transaction. Ring (1997) detected that commitment-based, non-contractual governance improves exchange efficiency as well as results in a more equitable out-come for exchange partners.

Commitment is forward looking, and refers to a desire by the alliance partners to maintain the exchange. This is a willingness to make short term sacrifices, but it goes beyond a simple positive evaluation of a counterpart. Commitment implies ‘...adoption of a long term orientation towards the relationship’ (Anderson and Weitz, 1992, p. 19). Commitment is a willingness to be exposed to vulnerability and a degree of confidence in the counterpart and that the counterpart will refrain from exploiting the alliance and the vulnerability of the partner (Barney and Hansen, 1994). Commitment implies investing idiosyncratic tangible and intangible resources in an alliance. Idiosyncratic investments create credibility with the counterpart (Ganesan, 1994) and facilitate the formation and development of psychological contract between the alliance partners (Ring, and Ven, 1984). Commitment generates higher rents than the sum of those obtained from the individual endowments of each partner.

Commitment in alliances implies a willingness to show (a) solidarity, and (b) flexibility in attitude and in behaviour. Solidarity is a sense of unity among members of the network (Achrol, 1997). It is the ‘common conscience’, a norm of stability, preservation, some sacrifice, and to act for the joint solution and benefits. Solidarity shows a feeling of mutuality and an expectation that the counterpart will act to maintain the exchange between alliance partners. Flexibility is the bilateral expectations that the substance and terms of exchange are subject to good-faith modification and adaptation if environmental changes so require (Heidi & Johan, 1992). That is, opt for a change in the relationship as circumstances change, resulting in an atmosphere of co-operation. Solidarity stabilizes an alliance relationship, flexibility, at the same time, allow alliance partners to incorporate in their exchange future contingencies and future discoveries. These together allow alliance partners to share tacit and confidential information with respect to future goals and plans of firms. Co-operative alliance supported by a high degree of solidarity and flexibility are stable, and better performing. Alliances lacking solidarity and flexibility may compel partners to devise additional mechanisms, for example, third party arbitration, to monitor the counterpart. This is expensive and may reduce the value of the cooperation. As commitment increasing, exchange is evaluated within a long-term perspective and future casts a shadow on present behaviour of firms.

Developing commitment is a gradual process. Individuals that are in contacts with each other accumulate knowledge on the counterpart and their resources. They uncover potentials as well as problems in the alliance. This, in turn, may trigger idiosyncratic resources to benefit from the opportunities or remedy the problems. Idiosyncratic commitment can not be moved over from one alliance to another without a loss in value. The same resources are of little or no use in alternative alliances. The more specific resource commitments alliance partners accept the more difficult and costly it becomes to defect from the alliance. Heidi and Johan (1988), thus, found that idiosyncratic investments create exit barriers in exchange relations. Also, there is a positive co-relation between commitment in an exchange and joint action by parties (Zaheer, and Venkatraman, 1995). Kersi and Frazier (2001) found that commitment in exchange relations reduce contract enforcement severity. This may also reduce perceptions of conflict between partners. By conflict is implied a feeling by an alliance partner that its goals are being impeded or

opposed by the counterpart. Committed alliance partners focus on a positive behaviour and give each other the benefit of doubt and disregard negative behaviour. In such alliances negative outcome may be explained as temporary aberration or being caused by factors external, such as increased competition in the market, changing economic conditions in the market, or resulting from the inability of the partners to correctly forecast the market. Alternatively, the standard applied in assessing success in the alliance may be altered. An alliance may be assessed in comparison with (i) other alliance by the same firm, (ii) other alliances with the same counterpart, (iii) other alliances in the same industry etc.

### **Alliance Dynamics**

As partners accumulate knowledge the counterpart, norms of solidarity and flexibility evolve, the exchange may deepen. Alliance dynamic evolves as committed partners respond in kind (Emerson, 1962; Homan, 1961), and the attitude and behaviour of the alliance partners may change and alliance partners may reshape or modify the goals or its implementation. As new potentials are detected the framework within which knowledge is accumulated and assimilated are modified. A dynamic evolves. This implies an exploration based double-loop learning, that is, '.....search for and exploration of alternative routines, rules, technologies, goals, and purposes rather than merely learning how to perform current routines and more effectively, (Lant and Mezias, 1992, pp. 49). New aspects of cooperation are detected and incorporated into the alliance. This dynamics is seen in as the partners may alter (a) the distribution of responsibility in the alliance, and (b) the incentive structure (for example, equity/ownership structure) of the alliance. The former incorporate changing the scope or the functions covered by the alliance. The scope of an alliance may vary from being narrow to wide. Alliance between firms may include one or many function, such as, product development, manufacturing, marketing of products and services. Alliance scope may also vary in its geographical coverage. Alliances could be limited to a national market or could cover international market as well. Alternatively, the duration or the timing for which the alliance is valid may change. In this process a dynamics evolves as the alliance may incorporate new governance mechanisms to continue with the exchange. Many of these changes are un-planned, and may even be un-intentional. Thus, an alliance may enlarged or shrink.

### **Two Cases**

The arguments produced in the preceding pages are illustrated with the help of two case examples. The aim is not to produce a comprehensive analysis of the two cases, but only to illustrate the points argued on the preceding pages. However, the two cases are rather typical and do serve to illustrate the manner in which cooperative alliance evolve and grow. Over the years, the author has investigated in detail, more than a dozen cooperative alliances between companies. In each case the European partner in the alliance was interviewed a number of times. Structured questions were put to the executives in the European firms. In each company, a minimum of six hours of interviews was conducted. In one company, the interviews totalled over twenty hours. A minimum of three people was interviewed. Moreover, the interviews with each company were conducted at different occasions and scattered over time. In at least one case there was a gap of around seven years between the first and second series of interviews. In this manner, we covered a long lifetime of the alliances under study. Consequently, we interviewed a number of people in each company. We interviewed those executives who were directly responsible for, and engaged in, the implementation of the alliance. In five of the alliances, the author was allowed to read the legal, formal contract between the alliance partners. In two cases, the author was given a copy of the formal, legal contract between the alliance partners.

#### **The Fishing Company**

The European Entertainment Co. is a small, independent European Co. with sales of around 30 million dollars (1981-82). In the closing years of the 1970s its international operations were confined to exporting to the European nations and North America. These sales were managed with the help of foreign sales subsidiaries, but often through a network of foreign agents. The company did not own any production units abroad. The company was purchasing most of its input requirements from the other European countries. The company, thus, controlled a highly efficient production, marketing and purchasing organization.

The European Entertainment Company participated in a cooperative alliance in an African country. The venture started in the last years of the 1970s as an official aid project. The local company, The Fishing Company, was a part of the Ministry of Industry of the country. The country itself pursued a socialistic ideology and private investment was limited. Investment by foreign firms was strictly regulated, and the rules and regulation for foreign

investment were cumbersome. At this time, the company employed around 50-60 people. Its main product was fishing boats.

In the proceeding years the local company had not produced satisfactory results. Both maintenance and new investments were neglected and production had dropped. Its manufacturing process was out-dated. The company was incurring huge losses. In order to remedy the situation, The European Entertainment Company was hired as a technical consultant. An official aid agency agreed to finance the project. Two consultants from the European Entertainment Company studied the local firm and gave suggestions. It was pointed out that the local company lacked proper operations and maintenance routines. However, the local management, failed to implement the suggestions made by the consultants. The local company continued to languish and suffered heavy losses. Finally, the company's local owners offered a management contract, whereby all the managerial responsibilities of the local company were delegated to The European Entertainment Company. The goal was to develop a commercially successful company, managed by local staff. To this end, the formal contract between the firms stated that the foreign firm shall 'initiate and implement training programmes that will allow...counterpart staff to gradually take over responsibilities for management and operations. The objective of this transfer of skills should be that at the end of the two years assignment the factory will be to a large extent managed independently of expatriate technical assistance'. The European firm accepted to export a part of the output from the local firm.

In order to achieve the above goals, the European firm supplied three categories of experts, (i) long term personnel in executive and technical positions, (ii) short term personnel, and (iii) head-office personnel for general backstopping. The European firm deployed a number of expatriates in the local firms, these included, managing director, financial manager, production and planning managers, marketing manager, manager procurement and material handling, and quality control manager. These expatriate managers together spent 152 man months in the local firm. In order to transfer skills to local managers, to each of these managers was assigned a local (trainee) manager. In addition, a number of European technicians carried out short term assignments in the local firm. The European firms received extra, tax free payments for these services. The managing director of the firm was also a member of the board of directors.

The first such cooperative agreement lasted two years. It was realized that the current legal status for the local firm was hampering its commercial development. Expatriates suggested that the local firms should be converted into an independent company. This suggestion was accepted shortly thereafter, and the local company was converted into '...(a) government owned autonomous company for the main purpose of manufacturing boats and other products....'. A new Board of Directors took over.

The expatriate management installed various administrative, operational and technical routines in the local company. Throughout these years, The European Entertainment Company procured input resources on behalf of the local company. Most of these procurements were made from the international market. The Fishing Co. paid a commission to the European Co.. These include procurements to replace the rusting and out-dated production equipment, spares and components. The expatriate managers were also responsible for marketing operations of the firm, managing financial affairs (contacts with banks and other financial bodies, for example). In addition, expatriates introduced management tools for production planning, financial reporting, and procurement routines and inventory management. Earlier, lack of these routines was a permanent source of difficulty for the local firm. The expatriates supplied management training to locals. In the marketing side expatriates, for example, expatriate management identified and initiated contacts with potential customers, such as, the self-employed people and cooperative societies. They also contacted local banks and helped in arranging loans and financing for clients. Expatriate managers developed management tools to assess costs of operations and manufacturing boats, and repair requirements. They also developed tools to estimate the potential fish catch using these costs further assistance was also supplied in the technical fields.

The production record of the company improved. At the termination of the first contract, the parties agreed to prolong the contract for one more year. The management contract was thereafter repeatedly prolonged. However, during the extensions, no significant changes were introduced in the provisions of the formal written contract, the responsibilities carried out by the expatriate managers, and the modes of fee payments. Through out these years the local partners agreed not to distribute the profits earned by the local company and to seek consent from the The European Entertainment Company in the case of large investments (sums exceeding 200,000 SEK) etc.

The local company did well over these years and the production results were goods. In 1987, the company earned its first ever profit. In addition, the expatriate managers arranged for hard currency loans. In 1989, The Fishing Co. introduced larger boats into its production program (10-12 meters long).

The cooperative agreement worked well. In the final years of the 1980s, as the agreement was ending, The European Entertainment Company was offered an option to purchase equity shares in the local company. The European Entertainment Company acquired 25% of the equity shares in the local company. A further 25% of the equity shares were bought by another European organisation. However, in order to make this possible, the local industrial laws were amended. Previously, as stated earlier, the local laws did not allow for the equity participation of foreign companies in the local industries. By the end of the 1980s, this law was changed and foreign participation became possible.

#### **The European Housing & Cement Co**

The European Housing & Cement Co is a large diversified international company. In the beginning of the 1970s the company was earning more than half of its revenue from exports. The firm had production facilities in countries such as Australia, Denmark, Egypt, Mexico, and the US. The overwhelming share of its production are (was) sold on the international market. From the point of view of marketing and production, the domestic market was of limited importance to the company. In the African continent, the company was represented, but only to a limited extent. Moreover, the company could not export to these markets. The European Co. was interested in expanding their international operations, including selling its management and technological skills. To manage its operations, the firm had developed a highly efficient and geographically diversified marketing and procurement network of foreign sales subsidiaries and agents.

In the second half of the 1960s a cement factory was established in an African nation. This was an official assistance project and in the beginning years experts from the European aid donor country managed the plant. Gradually the plant, consisting of three production units of 100, 125, and 250 thousand tons a year, was handed over to the local managers. However, the production record of the local company, Africa Cement, started to deteriorate. In 1983, the production was down to around 120 thousand tons as the local managers did not pay proper attention to servicing and maintenance.

In the second half of the 1970s, an official aid agency contacted the European Housing & Cement Company. The purpose was to seek assistance on behalf of Africa Cement. The assignment was to seek technical assistance to improve the production record of Africa Cement and to modernise the cement factory. This was a period of high oil prices. The local firm wanted to replace its oil based production process with coal based production process. Coal was less expensive.

The European Housing & Cement Co was hired as a technical consultant to the African company. After investigations, the European Co. produced several recommendations. The local company did not implement these recommendations. Shortly after, the European Co. was hired to provide more technical assistance. The European Co. was also requested to deploy engineers in the local firm to implement the recommendations. The European firm obliged. After completing the assignment, the expatriates left the local firm. In 1983, the largest cement unit of the local company was damaged, and production stopped. Without a competitive bidding, the European Co. was hired to investigate and suggest measures to rehabilitate and modernise the unit. The European experts assessed the damage and planned the rehabilitation. A sum of around 2 million dollars was invested to rehabilitate the plant and a team of seven technical experts from the European Housing & Cement Co was deployed in the local company. The expatriates worked with the local staff and the local managers. To co-ordinate the rehabilitation program, a separate position was constituted at the head office of the European Co.. The European expatriates also suggested that a sum of around 2 million dollars a year be set aside for purchasing spares and components. This recommendation was accepted by the local firm. Hardly, any of these spare parts and components were available on the local market.

As the initial group of seven expatriates commenced the rehabilitation work, they realised that more expatriate technical personnel were required. More expatriates were deployed. Gradually, in the middle of 1984 a five year long cooperative agreement (a management contract) was signed through which the European Co. took over the entire responsibility to manage the technical operations of the local company. In so doing, the European Co. also supplied production guarantees. For example, the European Co. guaranteed that the capacity utilisation in the terminal year of the contract will be no less than 80% of the installed capacity. In case of a failure, the European Co.

agreed to pay a penalty. It was agreed that a short fall of more than 10% in production will result in a penalty of around 4 US dollars/ton. On the other hand, if the production exceeded more than 10% of the target, the European firm shall receive a bonus payment of around 3 dollars/ton. From the very first year of the agreement, the local company improved its production record.

The European firm deployed a group of seven technical experts in the local firm. But, this was not enough, and five more experts were deployed in the local firm. The position of a project coordinator was created. During their stay in the local company, the expatriates detected deficiencies in the managerial and administrative sides of the local company. The local company lacked proper and rational administrative structure and routines. For this reason, for example, the parts and components needed to keep the production process running were frequently in short supply. The expatriates informally made several suggestions to the local owners to improve the matter.

After several meetings and deliberations between the local government (who owned the local company) and the European Co., the recommendations produced by the expatriate team were accepted. It was proposed that to improve the management practices in the local company, the local team of managers should be exposed to the best managerial practices in the industry. Thereafter, the scope of the cooperative agreement was widened and the entire management responsibility in the local company was delegated to the European firm. In so doing, the local company did not look for alternative sources of management in the international market.

A team of 13 expatriates was permanently deployed in the local company, all in the top technical and managerial positions, for example, the managing director, operations managers, production manager, manager material supply, and manager finance. This agreement continued until 1989. In 1988-89, the terminal year of the management contract the production level of the local company had improved dramatically and exceeded 80% of the installed capacity. In addition, during these years, the expatriates suggested, planned and implemented a massive investment plan to modernise the local cement factory. The hard currency part of these investments was around half a billion SEK. To complete the modernisation program, additional technical personnel were deployed in the local company. These were not covered by the management contract. They supplied specialised technical skills.

As the management contract was approaching termination, the local owners initiated inquiries with the European Housing & Cement Co to investigate their interest in prolonging the management contract. The European Co. was willing. In 1989, the contract was prolonged for another two years. The team of European managers remained in the local company. During the period of the management contract, the local company continued to perform well. The company was very profitable.

As the second period of the management contract was approaching its end, the local owners were uncertain and felt the need for continued external managerial support. Indeed, they were impressed by the good performance of the local company. The local managers had improved their performance, but this was not considered enough. The local owners wanted a more permanent presence of the European Co.. They wanted to avoid a repetition of the past failures. The European Co. was willing to prolong its presence in the local company.

However, the European Co. taking a more permanent presence in the local company was problematic as the local laws prohibited the equity participation of foreign companies in local industries. At around the same time, the industrial regime of the country was changed and foreign participation in the local industries was welcomed. This opened new opportunities for the European Co.. In the deliberations that followed, the European company was offered equity participation in the local company. The European Co. accepted the offer.

Since the European Co. had managed the local company for some time, the expatriate managers were aware of the problems and opportunities the local company faced. They realised that the state ownership in the local company was problematic, and not in the best commercial interest of the local company. The European Co. suggested, in fact, insisted, that the state ownership in the local company be diluted to below 50%. In addition, to avoid future difficulties with the local bureaucracy and politicians, the European Co. decided only to invest in the local company if an official agency from European would also acquire a portion of the local company's equity shares. The European Co. was unwilling to go it alone.

Initially, the local owners were unwilling to accept either suggestion, but gradually, they agreed. In less than five years, the public sector ownership in Africa Cement would be reduced to below 50%. In the following months the equity base of the local company was enlarged. The European Co. acquired 13% of the equity shares in the local company. Another 13% of the equities shares went to an official Swedish agency. This cost the European

Co. four million dollars in hard currency. The European Co. and the official agency was both allotted one seat each in the Board of Directors.

In 1991, the cooperative agreement was extended for another five years. No major changes were introduced into the agreement. However, the need for expatriate managers was declining. In December 1992, the number of expatriate managers in the local company had declined to five (from 13 in the past). More locals were placed in the top-level managerial positions.

## **Discussion**

The two cases illustrate the dynamic process of how alliance evolve and change over time. For the two European firms, the alliances were a means of strengthening their positions in the international market. The local owners of the firms wanted to improve their management practices by introducing new and modern management techniques. The aims entertained by the respective parties in the alliances were non-conflicting.

The knowledge base and the absorptive capacity of the two European firms were vastly superior to the knowledge base and the absorptive capacity of the two local firms. But, the two European firms were also different from each other with respect to knowledge and their absorptive capacity. The boat firm was small with little experience of foreign production or international alliances. But, their knowledge of and routines for serving international clients, and managing international procurement was high. The building material firm was successfully operating in the competitive, international market. They developed and refined their production and management routines, had a huge pool of qualified and experiential technicians and managers, and had developed routines for international production, marketing, management, and procurement. The knowledge base of both the European firms was relevant for a modern competitive market economy. The absorptive capacity of the two firms was significant.

The two local firms were very different. Both were small, government owned, and inefficient. Their organizational structure, reporting and accounting systems were very underdeveloped. At the time signing the cooperative agreement, neither the local managers nor the local owners of the firms had a proper idea of the financial position of the firm, its staff, and its production record, or inventories. Indeed, these hardly existed. Their manpower pool was limited. Moreover, these were state owned monopolies, and their operations were restricted within the domestic market. On the whole, their knowledge base and absorptive capacity with regard to technological and managerial knowledge was very limited, and not very relevant for a competitive market economy.

Initially, the local partners viewed the association with the European companies as a temporary, isolated business transaction, of limited duration. The local companies viewed the association as a means to acquire some minor resources, for example, better technology. Gradually this changed. Neither of the firms had worked with each other. At the time of the initial formal contract their partner specific knowledge and absorptive capacity was more or less nil.

In both cases, the cooperative alliance evolved gradually over time. Both began as a discrete and limited (in time as well as scope) technical assignment, leading to the accumulation of experiential knowledge, and the alliance partners learned about the systems and procedures their partner companies. Commitments gradually deepened, and the scope as well as the duration of the alliance changed. Finally, the two European firms became co-owners of the local firms. The solidarity and flexibility shown by the European firms is indicated by their willingness to alter the scope of the cooperation to suit the needs of the local firm.

In both the cases the co-operation started with an assignment that was limited in duration and scope. The initial technical assignments rather unintentionally supplied the two European companies and their respective local partners, with a platform to accumulate knowledge. The two European firms detected the opportunities and deficiencies, as well as the resources available, in the two local companies. This happened, as two European firms deploy technical and other managerial personnel. They installed management routines and procedures in the local firms. The expatriate managers deployed in the local firms daily interacted with the local managers and employees. They accumulated knowledge on the local owners of the firms, their local counterpart, their network contacts, the local clients, and the local business climate. As the performance of the local companies improved, the European companies realised the commercial potential of the local partners. The presence of foreign expatriates in local firms

improved communication and the uncertainty concerning each other's motives, goals and resources was reduced. The European firms realized that the two local companies had good commercial potential, both enjoying a monopoly in the local market. If run efficiently, the two local companies were sound business investments. This cast a positive shadow on the behaviour of the two European firms.

The expatriates carried out the managerial and top level technical functions in the local companies, installed management, marketing and technical routines and systems. They had full insight into the resources of the local companies, the on-going investments and projects, the plans, clients, and government contacts. A partner specific knowledge developed. The local managers were exposed to their foreign partners. The European firms showed solidarity and flexibility in their exchange with the local counterparts. The European firms did what was needed to develop a commercially viable local firm. Over time, thus, the two European firms widened the scope of their engagement in the local firms. By agreeing to take over the management functions in the two local companies, for example, the two European companies showed solidarity as well as flexibility to the local firms. By agreeing to carry out the management responsibilities in the two local companies, the two European companies were able to prove their managerial and technical expertise to the local owners of the companies, who both happened to be national governments. The highly visible penalty clauses in the agreement, moreover, proved their credibility in the alliances. This demonstrated how the European companies command the resources to operate and manage the local ventures. For these reasons, the two local firms did not search for alternative sources of technology and management skills.

One member of the national government occupied a position on the board of directors of the local companies. Through these connections, the European companies were able to develop relationships and reputation in the concerned ministries of the host country. This happened, for three reasons, firstly, that during the period of the management contract the production recorded a marked improvement. This brought the local company, as well as the European managers into limelight of the local press, local media, and the local debate. Secondly, as stated earlier, the financial performance of the two local companies improved. The two local companies were no longer depending on the state's subsidy for their survival. The above success, and the improved performance of the local companies, was recognized and the European management could claim the credit for the success.

During these years a number of expatriates were deployed in the two local companies. They stayed in the respective local companies for years and daily met the local managers, the technical personnel and the local owners. They were not visible to out-siders, but these helped develop individual level contact and a means of strengthening the commitment to the local companies. Supplying technological knowledge was less problematic than supplying managerial and marketing knowledge. As long as the relationships were contract based, this was difficult and time consuming to achieve. But, the prevailing national laws made this impossible. Thus, discussions were initiated to seek equity participation by the two European firms. This too was highly visible to out-siders.

Once the local laws were amended, and a foreign participation in the local industry was allowed, the formal shape of the alliance changed, and the commitment made by the European companies escalated. The above transformation in the alliance occurred at a time when the requirement for the European managers in the respective local companies was on a decline. For example, as stated in the Africa Cement case, by 1992, the number of European managers had dropped from thirteen to five.

The two European companies deployed several experts and managers in the two local companies. The expatriates had full access to the information on the operations of their local partners, their client structure, and the local government. There was a large area of interaction between the locals and the expatriates. The interaction area and contact frequency was high. The presence of expatriates was a source of accurate, timely, and reliable information to the European companies regarding the local partner and their resources. This strengthened the alliance.

## **Final Remarks**

In this paper shows that co-operative alliance has a past, present, and a future. Two cases are presented. It is argued that some business exchanges evolve into long term business alliances. Our study illustrates that the evolutionary

process of alliances is based on learning and commitment in alliances. The process by which small and discrete exchanges evolve into cooperative alliance is discussed. The above transition from a more limited exchange to a cooperative alliance is incremental during which the responsibilities carried out by the alliance partners may change. Initially, due to the limited cognition, the alliance partners may hardly understand the strategic implication of their co-operation. As firms accumulate knowledge commitment is evolved, solidarity and flexibility in the relationship develops. This is a process of trial and error, only parts of which are planned and visible to the outsiders. The more visible aspects of the alliance (for example, changing the equity share holding in the local firms) change, but less frequently. Indeed, changes in the visible aspects of alliance may only manifest parts of the overall exchange between the alliance partners. The less visible parts of alliance change frequently. Indeed, each inter-face has an impact of the knowledge accumulated and commitment made by alliance partners. These aspects are less visible to out-siders. Our cases show that, in each case, the time gap between the first business exchange between the alliance partners and the acquisition of equity shares in the local firm was large. During this period the scope, as well as, the duration of the alliance changed. More and more aspects were covered in the exchange. The key to understanding alliances lie in uncovering the not so visible aspects of an alliance.

# Determining the Antecedents of Customer Loyalty in Banks for Managing Services in a Global Economy: A Case in South Thailand

*Nik Kamariah Nik Mat, drnik@uum.edu.my*  
*Nattakarn Eakuru, dnattakarn@yahoo.com*

## Abstract

This study attempts to determine and validate the antecedents of customer loyalty in the banking sector in South Thailand. Customer loyalty is crucial in bringing long term profitability and managing services in tandem with the development of the global sector. From the literature, six antecedents of customer loyalty were identified. Each variable is measured using 7-point Likert-scale: perceived service quality (13 items), perceived value (11 items), trust (5 items), image (15 items), customer satisfaction (7 items) and commitment (6 items). Using survey method, 120 questionnaires were distributed to customers of four bank branches. The responses collected were 102 questionnaires representing 85 percent response rate. Confirmatory factor analysis using maximum likelihood and oblimin rotation method performed on the data produces six underlying components consisting of perceived service quality (10 items), perceived value (2 items), customer satisfaction (8 items), commitment (2 items), trust (3 items) and image (3 items). Thus, the antecedents of customer loyalty were substantiated and its construct validated in this study. The finding is discussed in the light of managing services in the global economy.

## Introduction

With the increasing importance of relationship marketing in recent years, particularly in the service industries, the emphasis now is on customer loyalty. Several authors emphasize the positive relationship existing between customer loyalty and business performance (Reichheld and Sasser, 1990; Reichheld, 1993; Sheth and Parvatiyar, 1995). Consumer loyalty is considered an important key to organizational success and profit (Oliver, 1997). Selin et al. (1987) stated that, "those consumers that demonstrate the greatest levels of loyalty toward the product, or service activity, tend to repurchase more often, and spend more money". As a result, a great deal of research attention has focused on the identification of effective methods of actively enhancing loyalty, including loyalty programs such as point reward schemes (Lach, 2000). Loyalty programs "create a reluctance to defect" by rewarding the customer for repurchasing from the organization (Duffy, 1998). Loyal customers not only increase the value of the business, but also enable it to maintain costs lower than those associated with attracting new customers (Basky 1994, Barroso and Martin, 1999). Moreover, loyalty rather than satisfaction is becoming the number one strategic goal in today's competitive business environment (Oliver, 1999).

With a growing focus on offering excellent services and meeting the needs of customer, banks need to have a good understanding of their customer behavior so that appropriate marketing strategies directed towards relationship building and retention can be developed. Past research on loyalty in the banking sector has been limited, and has tended to focus on retail banking, with an emphasis on the positive effects of customer satisfaction (Colgate and Hedge, 2001; Loveman, 1998; Jamal and Naser, 2002).

Much of the original work on loyalty defined it in behavioral terms (repurchase or purchase frequency), and then later admitted an attitudinal component (Jacoby and Chestnut, 1978). Ganesh et al. (2000) found two factors in their loyalty items, active loyalty (word – of mouth and intention to use) and passive loyalty (not switching even under less positive conditions). Other authors have considered loyalty as a process rather than an outcome. Oliver (1997a), for example, distinguishes among four stages of loyalty: cognitive, affective, cognitive, and action loyalty. Clearly, loyalty is a rich concept with many possible definitions.

A common approach is to distinguish between a consumer's attitudinal loyalty and behavioral loyalty (Dick and Basu, 1994; Zeithaml, 2000; Chaudhuri and Holbrook, 2001). Behavioral loyalty is repeated transactions (or

percentage of total transactions in the category, or total expenditures in the category) and can sometimes be measured quite simply with observational techniques. Attitudinal loyalty is sometime defined equivalently with relationship commitment (Morgan and Hunt, 1994).

Behavioral loyalty is highly prized, because it means sales. Attitudinal loyalty is also highly prized, because as Oliver, (1997a and 1999) argues, behavioral and attitudinal loyalty are highly intertwined, repeated purchases lead to positive affect which leads to cognitive loyalty, high levels of involvement and intention to continue repurchase. We may consider both affective and cognitive loyalty to be kinds of attitudinal loyalty. Strong attitudinal loyalty makes customers more resistant to attempts by other marketers to steal them away (Gundlach et al., 1995) and more resistant to counter – persuasion and search for alternatives (Dick and Basu, 1994). However, the extent to which these findings explain business customer behavior in banking is unclear.

Thus, the objective of this study is to identify the antecedents of customer loyalty in the context of retail banking in South Thailand and to validate the internal consistency of each antecedent construct. This paper is structured as follows. First, we review the marketing literature on the antecedents of customer loyalty: customer satisfaction, commitment, trust, image, perceived service quality and perceived value. Next, we present the research framework, methods, measures and findings. Finally, the results were discussed in terms of its contribution to global banking business and recommendations for future research.

## **Literature Review: Antecedents of Customer Loyalty**

Bank customers could become loyal due to a myriad of reasons. From our readings we have identified six main antecedents vis-à-vis customer satisfaction (Oliver, 1997, 1999; Kotler and Clarke, 1987; Ehrenberg and Scriven, 1999; Bloemer et al. 1998; Berrli et al. 2004, Hallowell, 1996; Strauss and Neuhaus, 1997; Cassel and Eklof, 2001), commitment (Oliver, 1997; Beatty et al. 1988; Luarn and Lin, 2003), trust (Moorman et al., 1993; Morgan and Hunt, 1994; Deutsch, 1960; Luarn and Lin, 2003; Ball et al, 2004), image (Keller, 1993; Fornell, 1992; Sirgy and Samli, 1985; Bloemer et al, 1998; Kandampully and Suhartanto, 2000; Heung et al, 1996), perceived service quality (Zeithaml, 1988; Juran, 1988); Bloemer, 1998), and perceived value (Zeithaml, 1988; Roig et al., 2006; Luarn and Lin, 2003; Parasuraman and Grewal, 2000; Dodds et al., 1991; Grewal et al., 1998; Reichheld, 1996; Dodds et al., 1991; Buzzel and Gale, 1987; Patterson and Spreng, 1997; Rokeach, 1973; Sheth et al., 1991a & 1991b; Bolton and Drew, 1991).

### **Customer Satisfaction and Loyalty**

Oliver (1999) points out that satisfaction and loyalty are related. Customer satisfaction is defined as a judgment that a product or service feature, or the product or service itself, provides a pleasurable level of consumption related fulfillment including the level of under or over fulfillment (Oliver, 1997). Satisfaction is thus a function of relative level of expectation and perceived performance. Expectations are formed on the basis of past experience with the same or similar situations, statements made by friends or other associates (Kotler and Clarke, 1987). Ehrenberg and Scriven (1999) define loyalty as “an ongoing propensity to buy the brand, usually as one of several”. A customer is said to be loyal to a brand that provides a satisfactory experience. Hence, satisfaction has been shown to have its influence on customer loyalty in past studies (Bloemer et al 1998; Berrli et al., 2004, Hallowell, 1996; Strauss and Neuhaus, 1997; Cassel and Eklof, 2001). For example, Berrli et al. (2004) conclude that satisfaction together with personal switching costs are antecedents of loyalty.

### **Commitment and Loyalty**

Customer commitment is another factor affecting loyalty by which Oliver (1997) defines loyalty as: “A deeply held commitment to rebuy or repatronize a preferred product/service consistently in the future, thereby causing repetitive same-brand or same brand set purchasing despite situational influences and marketing efforts having the potential to cause switching behavior”.

Beatty et al., (1988) define consumer commitment as the psychological attachment to a service that develops. A customer would be able to determine that their purchase behavior was derived from a sense of loyalty. Luarn and Lin (2003) establish significant relationship between commitment and loyalty.

### **Trust and Loyalty**

Trust is defined as “the willingness to rely on an exchange partner in whom one has confidence” (Moorman et al., 1993). Morgan and Hunt (1994) felt trust exists “when one party has confidence in an exchange partner’s reliability and integrity”. According to Deutsch (1960), trust consists of two components: confidence in ability and intention. Past studies investigating the relationship between trust and loyalty has found significant relationships in e-service (Luarn and Lin (2003) and banking sector (Ball et al, 2004).

### **Image and Loyalty**

Image has been defined as “the perceptions of an organization reflected in the associations held in consumer memory” (Keller, 1993). This is similar to corporate image which is assumed to influence the customer’s choice of service company when it is difficult to distinguish between service attributes. Corporate image is established or developed in the consumer’s mind through communication and experience (Fornell, 1992).

Past studies had found equivocal results regarding the relationships between image and loyalty. While some past studies has found image to have no significant impact on loyalty (Sirgy and Samli, 1985; Bloemer et al, 1998), some researchers has reported positive significant relationships (Kandampully and Suhartanto, 2000; Heung et al, 1996).

### **Perceived Service Quality and Loyalty**

Perceived service quality is defined as “the consumer’s judgment about a product’s overall excellence or superiority” (Zeithaml, 1988). According to Juran (1988), quality consists of two primary elements: (1) to what degree a product or service meets to needs of the consumers; and (2) to what degree a product or service is free from deficiencies. Service quality is believed to depend on the gap between expected and perceived performance (Anderson et al., 1994). In past studies, perceived service quality is hypothesized to have an indirect positive effect on loyalty via satisfaction (Bloemer, 1998).

### **Perceived Value and Loyalty**

There is a multifacet meanings of value which vary according to different functional context –economics – (utility and monetary costs), social science (human values) (Rokeach 1973); industrial settings (processes and costs), and marketing (consumers’ perspective on tradeoffs between benefits and sacrifices or costs)- Zeithaml, 1988, Dodds et al., 1991; Buzzel and Gale, 1987; Roig et al., 2006; Patterson and Spreng, 1997) The meaning is not limited to these functional definitions but also include cognitive and affective aspects of value such as social, emotional and epistemic value (Sheth et. al., 1991a &1991b). Drawing from the vast literature on value, the definition employed in this study is from the marketing perspective whereby Bolton and Drew (1991) define perceived value as a “richer measure of customers’ overall evaluation of a service than perceived service quality. Luarn and Lin (2003) define perceived value from economic perspective which is the customers’ perceived service utility relative to its monetary and non-monetary costs. Prior studies support the general notion that perceived value contributes to customer loyalty (Luarn and Lin, 2003; Parasuraman and Grewal, 2000; Dodds et al., 1991; Grewal et al., 1998; Reichheld’s (1996). For example, Luarn and Lin (2003) have found significant relationship between perceived value and loyalty as well as perceived value and commitment. Roig et al (2006) approach perceived value from six multidimensional formative construct (GLOVAL scale) and test the study on bank customers. They found that perceived value is indeed multi-dimensional.

## **Research Framework**

Figure 1 shows the research framework of the study. The literature indicates that customer satisfaction, commitment, trust and image are direct antecedents of customer loyalty. Perceived service quality is an indirect antecedent of customer loyalty through customer satisfaction. Perceived value is an indirect antecedent of customer loyalty through customer satisfaction and commitment.

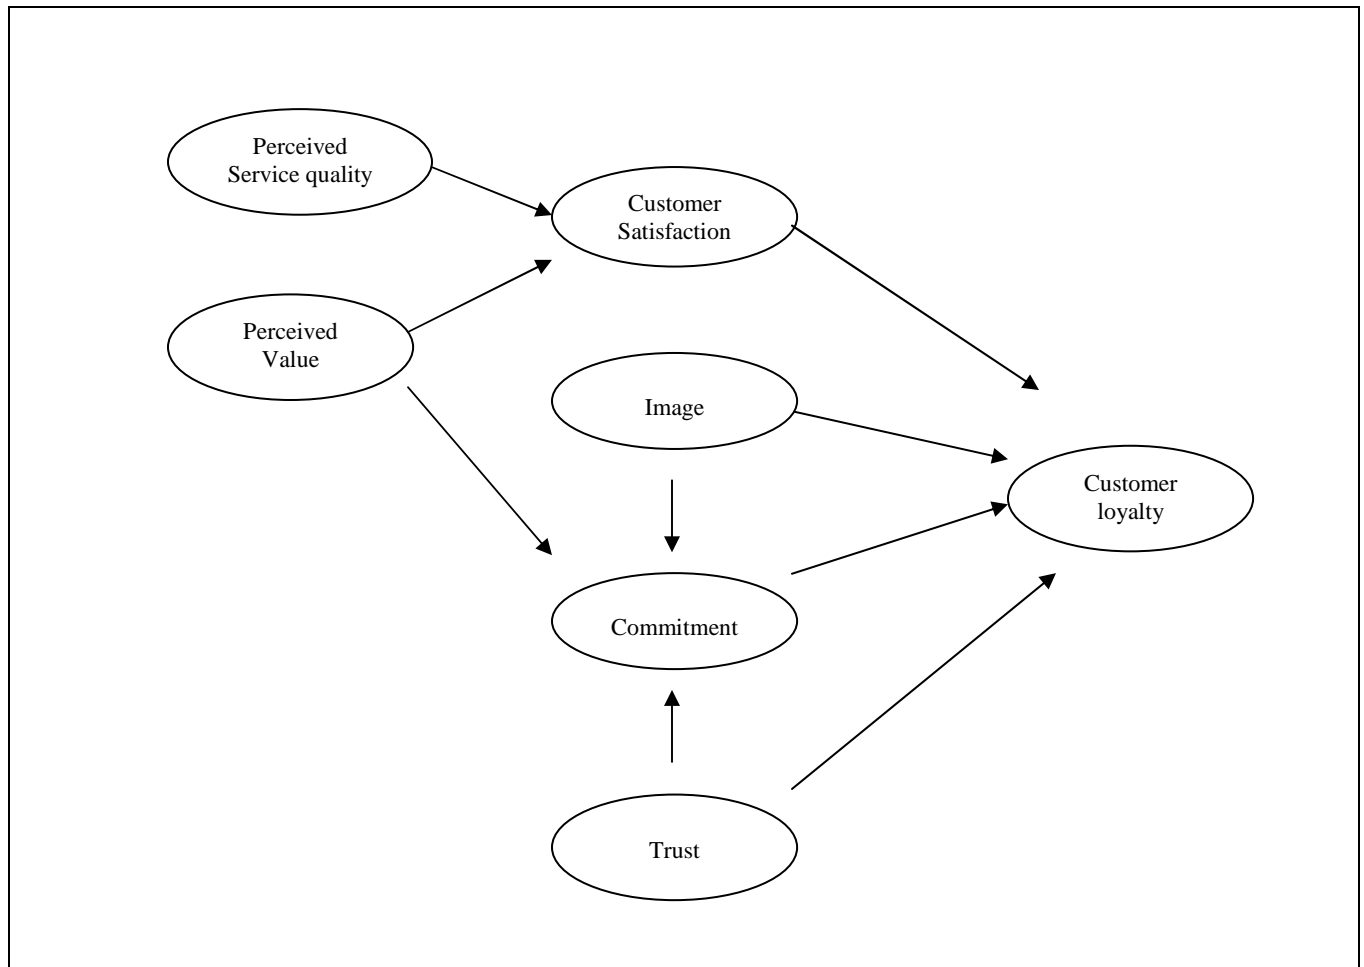

FIG. 1: RESEARCH FRAMEWORK

## Methodology

A total of 120 respondents from four branches of a bank in South Thailand was randomly selected for the survey. The responses collected were 102 questionnaires representing 85 percent response rate. Each variable is measured using 7-point Likert-scale: perceived service quality measure was adopted from Gouneris et al., (2003) and Arasli et al., (2005)-(13 items), perceived value was adopted from Roig et al., (2006)- (11 items), trust was adopted from Ball et al., (2004)-(5 items), image was adopted from Yavas and Shemwell, (1996) and Flavian et al., (2004)- (15 items), customer satisfaction was adopted from Patterson and Spreng (1997); Bloemer et al., (1998); Caruana (2002) and two self-developed items-(total 7 items) and commitment was adopted from Luarn and Lin (2003) and Hunt et al., (1985) (6 items). The data collected was analyzed using SPSS software mainly utilizing factor analysis, descriptive statistics and reliability test. The cronbach alpha readings of all measures are presented in Table 1. All alpha readings are above .70 indicating a high internal consistency in all measures utilized.

TABLE 1: RELIABILITY COEFFICIENT

Variable Name	N	No. of Items	Alpha Coefficient
Customer satisfaction	102	7	.891
Image	102	15	.960
Perceived Value	102	11	.832
Perceived service quality	102	13	.957
Trust	102	5	.920
Commitments	102	6	.836
Customer loyalty	102	9	.932

## Findings

An exploratory factor analysis using principal component extraction method with varimax rotation was applied in the first instance to test for sample adequacy in running this method of analysis. The KMO or Measure of Sampling Adequacy (MSA) reading is .889 (>.5) and Bartlett's test of sphericity stands at significant level of .000 (sig<.05), thus making the following factor analysis permissible (Hair.et al.2006). Next, a confirmatory factor analysis (CFA) using maximum likelihood extraction method with oblimin rotation method was duly conducted. The KMO has increased to .922 and Bartlett's test of sphericity shows a significantly high reading (sig at .000). Table 2 illustrates the result of the confirmatory factor analysis. The final results produced 6 components with eigenvalues above 1 and explaining a total of 70.412 percent of variance cumulatively. Factor 1 which represents perceived service quality contains 10 items remaining from 13 items proposed originally. Factor loadings above .50 were selected and it explains 29.609 percent of variance in factor one. Factor two which is perceived value now consists of two items reduced from 11 items initially. Only one item of the original perceive value with factor loading above .5 was retrieved and one image item was regroup in this component. There was a mixed regrouping of the customer satisfaction and image items. However, 8 items with factor loadings above .5 were secured in this group of component. Customer satisfaction measure indicates a 3.969 percent variance. The fourth factor produced by the CFA is commitment consisting two items with factor loading above .5 and percentage of variance explained is 3.042. Trust forms the fifth factor consisting of 3 items with factor loadings readings above .5 and percentage of variance of 2.929. The sixth component is image which consists of 3 items with factor loadings of above .5 and percentage of variance is 1.936. To conclude, the CFA conducted indicates that all six factors are likely constructs of each measure. The internal consistency of each construct are somewhat substantiated.

TABLE 2: FACTOR ANALYSIS RESULT

Factor/Variance explained	Label	Attributes	Factor Loadings
Factor 1 Perceived service Quality  Variance 29.609 %	Psq9	1.If there is a problem, the bank is willing to discuss it with me.	.789
	Psq8	2.The bank offers a wide variety of product.	.701
	Psq10	3.You do not have to visit your bank many times to solve a particular problem.	.700
	Psq13	4.You receive prompt service from the bank's employees.	.667
	Psq01	5.This bank's reception desk employees are neat in appearance.	.661
	Psq02	6.The employees of this bank understand your specific needs.	.650
	Psq06	7.This bank has employees who give you personal attention.	.645
	Psq07	8.Employees of the bank are well dressed and appear neat.	.641
	Psq03	9. This bank physical facilities are visually appealing.	.617
	Psq05	10. This bank performs the service right at the first time.	.574
Factor 2 Perceived Value  Variance 28.926%	Pv5	1. The service as a whole is good?	.514
	I14	2. The bank and its employees explain their services and fees clearly and completely.	.506
Factor 3 Customer satisfaction Variance 3.969%	I04	1. I believe that the reputation of this bank or savings bank is better than that of the rest of the companies.	.852

		2. This bank or savings bank has a good reputation.	
	IO3	3. I am very satisfied with my decision to deal with this bank.	.763
	Cs01	4. The bank and its employees are trustworthy.	.737
	I05	5.I am very satisfied with the Bank services provided.	.717
	Cs02	6. Security in transactions.	.648
	I01	7. Provides a comfortable environment to do business.	.637
	I07	8. I believe that this bank does what it promises for its clients.	.555
	I02		.537
Commitment Variance 3.042%	Co2	1. I am very satisfied with the bank services provided.	-1.007
	Co1	2.I am very satisfied with my Decision to deal with this bank.	-.578
Trust Variance 2.929%	T04	1. The bank will keep my own account secretly confidentially.	.777
	T05	2. The bank will not let other people know my account balance.	.741
	T03	3. The bank will not inform my cash flow account to other people.	.727
Image Variance 2.929%	I09	1. Offers convenient branch locations.	.640
	I08	2.Pays high interest rates	.619
	I12	3. Does a lot of advertising.	.522

Extraction Method: Maximum Likelihood.

Rotation Method: Oblimin with Kaiser Normalization.

Kaiser-Meyer-Olkin (KMO) Measure of Sampling Adequacy .922, Bartlett's test of Sphericity: Chi-Square= 3759.672, df = 946, Sig= .000.

## Discussion

The objective of this research is to determine and validate the antecedent factor constructs of customer loyalty. Six factors were subjected to confirmatory factor analysis shows a promising result of internal consistency. The CFA include all the six factors as possible antecedents of customer loyalty. Bearing in mind that the measurements has been usually applied in a western culture, the construct validity gives some indications of its applicability in an Eastern culture such as Thailand in general and banking in specific.

## Contribution and Recommendation for Future Research

The findings could be applied for utilization in research regarding customer loyalty for the banking sector in other Asian countries. Furthermore, the analysis of this study could be extended to the confirmatory factor analysis using structural equation modeling (SEM).

## Conclusion

This study has achieved its objective in determining and validating the internal consistency of six constructs or the antecedents of customer loyalty in the banking sector. The six factors in sequence of importance are perceived service quality (10 items), perceived value (2 items), customer satisfaction (8 items), commitment (2 items), trust (3 items) and image (3 items).

## Preventive Measures of Transactions Data in Internet e-Banking

*Ziqi Liao, victor@hkbu.edu.hk*

### Abstract

This paper examines preventive measures of transactions data and consumer concerns about individual privacy associated with Internet e-banking services. The empirical results indicate that the minimization of transactions error, the control of unauthorized use of customer data, the restriction of offensive access, and the maintenance of transactions data are critical to the enhancement of perceived privacy of Internet e-banking services. The commercial banks and financial institutions are suggested to implement rigorous administrative procedures and measures to protect customer transactions data. The present findings have implications for formulating security policies and managing trusted Internet e-banking services in different contexts.

### Introduction

As one of the popular e-commerce activities, the Internet-enabled e-banking provides an effective electronic channel for delivering banking and financial services and enables individuals to access their bank accounts anytime and anywhere. However, the spread of e-commerce increasingly raises a great concern about the protection of individual privacy (e.g. Eileen 2000; Dhillon and Moores 2001; Liao and Cheung 2002). For instance, many consumers feel that they lost controls over how personal information is being used and circulated among different companies (Eileen, 2000). The provision of personal data and the subsequent misuse without permission raise privacy concerns (Dhillon and Moores, 2001). In the case of Internet e-banking service, consumers are usually not aware of the administrative procedures and privacy policies implemented by the service providers, while the access of the Internet banking requires the submission of personal and sensitive data. Perceived privacy is a key factor influencing user acceptance of Internet e-banking (Liao and Cheung, 2002). Therefore, it is strategically critical for Internet e-banking service providers to understand the individual concerns about perceived privacy and formulate a series of preventive measures from the consumer perspective. As far as this is concerned, this paper aims to explore the determinants and preventive measures of perceived privacy of Internet banking service. A survey has been conducted to collect empirical data from individual consumers. In particular, it examines the impact of several prevent measures on perceived privacy and consumer acceptance of the Internet banking. Furthermore, it discusses the strategic measures for securing consumer privacy associated with Internet banking service.

### Background and Hypotheses

Information privacy can be defined as a condition of limited access to identifiable information about individuals (Smith 1993). Numerous studies have examined the protection of privacy in different contexts (e.g. Culnan 1993; Milberg, Burke, Smith and Kallman 1995; Dutta and McCrohan 2002; Fulkerson, Gonsoulin and Dianne 2002; Liao and Cheung 2002; Smith, Milberg and Sandra 1996). Smith, Milberg and Burke (1996) suggests four dimensions of individuals concerns about organizational practices in managing information privacy, which include collection, unauthorized secondary use, improper access, and errors. In the e-business environment, for instance, consumers might worry about the release of personal data collected by different companies. Therefore, protecting the privacy of consumers on the Internet is a critical issue (Udo 2001). If the firm's practice raises privacy concerns resulting from the perception that personal data is unfairly used, this may make consumers be unwilling to disclose additional

personal information (Culnan and Armstrong 1999). Information privacy has an impact on business-to-consumer e-commerce (Belanger, Hiler and Smith 2002). On the basis of previous work, this study explores several variables possibly relate to perceived privacy in operational environments of Internet e-banking. The hypotheses proposed below will test the impacts of preventive measures in relation to personal data collection, data errors, unauthorized use of personal data, offensive access control, and data loss and their impacts on consumer perceived privacy, attitude and behavioral intention to use the Internet e-banking service.

Firstly, it is not uncommon that individuals might be concerned about extensive amounts of personally identifiable data collected by firms (Smith, Milberg and Burke 1996). Individuals would resent that a large amount of data regarding their personalities, background, and actions are being accumulated (Milberg, Smith and Burke 2000). According to Culnan and Armstrong (1999), individuals are less likely to perceive data collection procedures that invade individual's privacy if the data collected is relevant to the transaction. Eileen (2000) argues that the nature and amount of data collected from consumers should be limited to relevant data that is necessary. Similar to traditional banking and financial service, commercial banks need to request customers to provide personal data when opening an Internet bank account. In this circumstance, some customers may feel offended by the request of providing personal data. Therefore, Hypothesis 1 is proposed:

Hypothesis 1: The collection of customer personal data has a positive impact on perceived privacy.

Secondly, the protection against deliberate and accidental errors in personal data might be inadequate, because some firms are not able to eliminate errors in data processing (Smith, Milberg and Burke 1996). Many individuals believe that some organizations do not take enough steps to minimize problems from errors in personal data (Milberg, Smith and Burke 2000). As far as this is concerned, it is practically difficult to completely eliminate deliberate and accidental errors in business transactions. The assurance of data correctness and data integrity remains an important issue (Fulkerson, Gonsoulin and Dianne 2002). The concern about transaction errors in banking environment may considerably affect individual perceptions of privacy. Therefore, Hypothesis 2 is proposed:

Hypothesis 2: The minimization of transactions errors has a positive impact on perceived privacy.

Thirdly, data collected from individuals might be circulated internally within an organization, or used for another purpose, or disclosed to an external party without authorization from individuals (Smith, Milberg and Burke 1996). Because computerized information is easily duplicated and shared, there is a risk that information provided for one purpose may be reused for unrelated purposes without authorization from individual (Culnan and Armstrong 1999). The sale of current or prospective customer names, addresses, phone numbers, purchase histories, categorizations are not uncommon, while the information is often transferred between the organizational entities as digital files (Milberg, Smith and Burke 2000). The data collected from individuals can be used for unusual purposes without permission. Even within a company, for example, the data collected for research purpose may be used for marketing promotions (Cespedes and Smith 1993). For instance, the data collected from loan applications may be used to classify customers into different categories for different service promotion. In terms of unauthorized use of personal data, it may include secondary use of customer data and share of customer contacts with other firms (Culnan 1993; Smith, Milberg and Burke 1996). Therefore, Hypothesis 3 is proposed.

Hypothesis 3: The control of unauthorized use of personal data has a positive impact on perceived privacy.

Improper access refers to the concern that data about individuals are readily available to people not properly authorized to view or work with the data (Smith, Milberg and Burke 1996). How to effectively control unauthorized access is a critical administrative issue of an organization (Smith, Milberg and Burke 1996). An individual's privacy could be invaded, if unauthorized access to personal information occurred due to security breach or inappropriate internal controls (Culnan and Armstrong 1999). Because some who are not authorized may be able to view or work with a particular data, the offensive access to individuals account is especially sensitive in e-banking environment. Therefore, Hypothesis 4 is proposed:

Hypothesis 4: The restriction of offensive access has a positive impact on perceived privacy.

Furthermore, the storage and data maintenance of individual data remains an important task especially for bank operations management. Customer data and transactions records may be lost while it is processed. They might also be accidentally erased in a database. If an individual assumed that there would be a loss of personal data when

using an information system, little privacy of the application would be perceived (Fulkerson, Gonsoulin and Dianne 2002). Therefore, Hypothesis 5 is proposed.

Hypothesis 5: The maintenance of transactions data has a positive impact on perceived privacy.

## Research Methods

The research methods of this study include survey and statistical data analysis. The questionnaire was designed to elucidate consumer concerns about privacy and individual attitude and behavior intention to use Internet banking service. In order to ensure content validity of the scales adopted, the items within the questionnaire were developed with reference to the existing literatures. Questionnaires were randomly distributed to individual consumers. The respondents were asked to indicate whether they have experience on the use of Internet banking. Individuals were requested to rate their perceptions in relation to a particular item based on the seven-point Likert-scale ranging from 1 to 7. The survey questions were coded such that a higher value indicates a greater perceived importance. They were also requested to provide demographic data such as gender, education, income and occupation. As a result, two hundred and twenty useful responses were received. The Statistical Package for Social Science (SPSS) was used to analyze the data collected and explore the major concerns in relation to perceived privacy of e-banking services. The regression model below includes the endogenous variable  $y_1$ : perceived privacy and the exogenous variables ( $x_1$  to  $x_5$ ) in relation to the five hypotheses proposed in the previous section.

$$y_1 = a_1 + b_1x_1 + b_2 x_2 + b_3 x_3 + b_4 x_4 + b_5 x_5 + \epsilon_1$$

Where,  $y_1$  Perceived privacy of e-banking

$x_1$  Collection of personal data

$x_2$  Minimization of transactions errors

$x_3$  Control of unauthorized use of personal data

$x_4$  Restriction of offensive access

$x_5$  Maintenance of transactions data

$\epsilon_1$  error term

## Results and Managerial Implications

As shown in TABLE 1, the result of the multiple regression analysis indicates that the research model is significant, because several exogenous variables have significant impacts on the endogenous variable ( $F = 28.057$ ,  $d.f. = 5,214$ ,  $Sig. < 0.001$ ,  $Adjusted R^2 = .382$ ). It also suggests that H2, H3, H4 and H5 are strongly supported, though H1 receives limited support. In other words, the minimization of transactions errors, the control of unauthorized use of personal data, the restriction of offensive access and the elimination of transactions data significantly determine the perceived privacy of Internet banking.

TABLE 1: RESULT OF REGRESSION ANALYSIS

	Standardized Coefficients $\beta$	$t$	$Sig.$
(Constant)		4.518	.000
$x_1$	.035	.636	.525
$x_2$	.166	2.566	.011
$x_3$	.231	3.363	.001
$x_4$	.138	2.000	.047
$x_5$	.259	3.689	.000

It has been found that consumers usually understand that they need to provide necessary personal data when opening an account in a financial institution. Therefore, the collection of consumer data has limited impact on

perceived privacy in the case of Internet banking. The banks have little problem on collecting the personal data of a customer when opening a bank account. However, it is desirable that the banks are able to identify any data problems and transaction errors and make prompt corrections during data processing. In addition, the elimination of unauthorized use of customer personal data is critical to the protection of customer privacy. It is not uncommon that some banks might intensively analyze the personal data of customers in order to appreciate customer preferences. The data mining might help customer relationship management. Although the banks usually have particular administrative procedures and regulations for data analysis, consumers are still concerned about the use of personal data. As far as this is concerned, the banks should ask the customers whether they are allowed to use the information for future service promotions.

In order to effectively protect the privacy of customers, commercial banks should strictly restrict offensive access to Internet e-banking systems. A consistent investment in the most advanced security technology is critical because it can enable the banks to immediately identify any unusual attempt to access an e-banking account and to restrict different offensive attacks to the banking information systems. The implementation of a series of rigorous security measures such as the identification of unauthorized access, the control of transactions, and the protection of confidentiality are essential to assure the continuity of e-banking service. The elimination of security risk is essential for enhancing individual confidence. In order to protect financial transactions and look after the assets of customers, the banks should continuously strengthen information systems management and implement the latest security technologies.

Commercial banks should also pay attention to consumer education in relation to the operations of Internet e-banking systems and the use of e-banking service. Consumers might be not aware of the security procedures and technologies actually adopted by the banks, although the banks had implemented the advanced technologies to secure Internet operations. Some worry about uncertainties of Internet e-banking in terms of disclosure of private data and release of transactions information. As far as this is concerned, commercial banks should consistently tell the consumers about security measures and privacy policies when promoting the use of the e-banking and financial service. Customers should also be regularly informed of how to update anti-virus software, change passwords and not to respond to any suspicious e-mail messages.

The empirical results show that the consumers are concerned about the possible loss of transactions data, because the actual transactions through e-banking systems are beyond their control. The banks must be responsible for maintaining all transactions records. The effective elimination of data loss should greatly enhance the customer confidence in e-banking services. The empirical findings suggest that it is necessary to effectively minimize transactional errors, eliminate unauthorized use of personal data, prevent any offensive access, and maintain the transactions records of the customers. Preventive measures should help enhance the perceived level of privacy protection. In order to encourage more consumers to use e-banking, banks must consistently formulate privacy policy and implement a series of security measures to manage e-banking service operations.

## **Concluding Remarks**

This study empirically explores several preventive measures in relation to the protection of privacy from consumer perspective. The results indicate that preventive measures in relation to the control of transactional errors, unauthorized use of personal data, offensive access and transactions data are vital to the enhancement of perceived privacy, which also significantly affect individual attitude and behavioral intention to use e-banking. As a matter of fact, the understanding of consumer concerns and expectations is especially important in the service industry. The findings have managerial implications for improving the existing e-banking systems and managing sustainable e-banking service. Accordingly, the commercial banks and financial institutions should implement a series of consistent administrative policies in order to protect privacy and enhance consumer confidence in e-banking services. Practically, there are various variables associated with the protection of individual privacy in different social and cultural environments. The present study can be extended to explore the determinants of trusted e-banking in different contexts.

# **Insurance Business in Japan from Corporate Value Perspective**

*Yasuhiro Iwase, iwase505@fpu.ac.jp  
Fukui Prefectural University, JAPAN*

## **Abstract**

The corporate value of insurance business should be evaluated from two standpoints, the corporate value creation by underwriting and that by investment. In this report, the minimum requisite capital, which was paradoxically determined based on the ROE when EVA -based stockholder value was zero, was used in various analyses. The corporate value creation by underwriting has a close correlation with underwriting income, but no such close correlation with increase ratio and loss ratio. In the comparison between the theoretical values and actual values of liability reserves, it was revealed that the decrease in the theoretical values was larger than that in the actual values. On the other hand, the corporate value creation by investment strategy has a negative correlation with the ratio of securities for assets. This shows that the return generated when an insurance business entity bears a high finance market risk will not confer benefits on stockholders regarding their value creation.

## **Introduction**

Amid increasing demand for shareholder-oriented management in recent years, the words such as corporate value and business value have been often used. In the corporate and business values, a focus is put on how much cash flow will be produced by the present main business (business and investment/loan) and other businesses. Then, can the corporate value of the insurance business be measured by the same scale? This study was performed basically to clarify the ideal corporate value of the insurance business.

## **Evaluation Markers of Corporate Value**

### **Types of Evaluation Markers**

Corporate value evaluation is a relatively new concept in business management, and various approaches and ideas are now being produced. The followings are major evaluation markers.

Abbreviation	Marker	Details
PER	Price Earnings Ratio	Share price ÷ Earnings per share
PBR	Price Book-value Ratio	Share price ÷ Net assets per share
EPS	Earnings Per Share	Current income ÷ Number of shares authorized
ROE	Return On Equity	Current income ÷ Shareholders' equity
ROA	Return On Assets	Current profits before deduction of interest ÷ Net assets
TRS	Total Returns to Shareholders	Return of shareholders during a certain period (increase of share price and dividend)
DCF Model	Discounted Cash Flow Model	Corporate value is determined by adding the value of investment/loan to the business value determined based on forecasted cash flow.
EVA	Economic Value Added	After-tax operating income - Capital cost (Capital cost is considered to be weighted average of the cost of shareholders' equity and the cost of interest-bearing liabilities.)
MVA	Market Value Added	Total of present value of forecasted EVA value
REVA	Refined Economic Value Added (Refined EVA)	A refined type of EVA in which actual value is used as the cost of shareholders' equity

FIG 1: TYPES OF CORPORATE VALUE EVALUATION MARKER

#### Reasons why we put a Focus on EVA

Although many Japanese companies set ROE as their management goal, there are many problems including the risk of unstable equilibrium in corporate management since ROE is a ratio-based marker<sup>1</sup>. On the other hand, EVA has the following advantages.

##### (1) A marker involving risks

For analysis on the insurance business, a marker involving risks is required. Different from ROE, EVA includes risks because the capital cost determined taking risks into consideration is deducted.

##### (2) A marker that enables cumulative evaluation as an absolute value

Since EVA is a marker for absolute values, cumulative calculation can be performed. This is a feature that cannot be observed in ROE and other markers. For example, when EVA were 10 billion yen, ▲3 billion yen, and 8 billion yen in past three years, respectively, the cumulative value of EVA will be 15 billion yen (10 billion - 3 billion + 8 billion yen). For businesses with long tail like the insurance business, cumulative calculation of management markers is essential.

##### (3) A marker with a concept of economic profit

The economic profit is determined by deducting capital cost from current income of a company. This is distinguished from accounting profit.

Capital cost is the return expected to be obtained when investment is made for a company with similar risks, in other words, the opportunity cost. When a surplus is lower than capital cost, it cannot be said that the company produced economic profits. When determining capital cost, not only dividend but retained earnings should be taken into account. Since the retained earnings are generally paid after distribution of dividends, it is considered that the cost will be zero, and the earnings can be freely used by the company, but this is incorrect. Actually, the profits produced by a company should be returned to shareholders, in addition to the retained earnings. Thus, retained earnings are the profits that are not distributed as dividends and are stocked in a company when shareholders agree with reinvestment of the profits. In this meaning, retained earnings are same with the capital or capital reserves that are paid by shareholders.

It is also inappropriate that only dividends are considered to be the costs for shareholders. Investors expect not only dividends but also capital gain by increase of share values as their return. Since investors make

investment, expecting minimum return on investment by both dividends and increase of share values, corporate executives should consider these as the costs for shareholders.

(4) A simple and clear marker

EVA is a simple and clear marker. EVA higher than zero means that shareholder values are created, while EVA lower than zero means decrease of shareholder values.

Since first introduction of EVA by US companies in early 1990s, EVA has been widely used by academic conferences, security analysts, investors, etc. In recent years, many Japanese companies are interested in EVA<sup>2</sup>.

## Value Creation in Insurance Business

Insurance business is a business category with a unique feature in which underwriting and finance are intricately intertwined with each other. Therefore, the corporate value should be evaluated from two standpoints, the corporate value creation by underwriting and that by investment.

### Share price and EVA, Share price and MVA<sup>3</sup>

Firstly, correlation between share price and EVA/MVA in the insurance business was investigated.

Figure 2 shows changes in share price and EVA during a period from FY1996 to FY2004. Figure 3 shows the correlation between share price and EVA (horizontal axis and longitudinal axis show accounting periods and Pearson's product-moment correlation coefficient, respectively).

The disordered correlation observed in FY2002 or later was caused by the EVA decreased due to decreased current income, which was caused by the fact that the reverse for extraordinary casualties were transferred due to successive large-scale typhoons in FY2004. The correlation coefficient when excluding FY2004 (sum total from FY1996 to FY2003) was 0.58, showing a relatively high correlation.

FIG3: CORRELATION BETWEEN SHARE PRICE AND EVA

Figure 4 shows changes in share price and MVA during a period from FY1996 to FY2004. Figure 5 shows correlation between share price and MVA (horizontal axis and longitudinal axis show accounting periods and

Pearson's product-moment correlation coefficient, respectively).

Since FY1996, the correlation between share price and MVA has become higher year by year. This is supposed to be caused by corporate efforts of the insurance business to increase the shareholder value.

From FY2000 to FY2002, decrease of MVA was observed. Since MVA is expressed as the difference between total market price of shares and shareholders' equity, MVA is decreased by increase of shareholders' equity. In FY2002, many companies decreased shareholders' equity by payback because ROE was required to be improved for investors. To inhibit decrease of MVA due to falling share price, decrease of shareholders' equity is effective.

Because of increase in share price in FY2003 and later, shareholders' equity was increased, contributing increase of MVA. This shows the original mechanism in which increase of shareholders' equity works as a factor for increase of share price.

\* FIG. 2 - 5 were prepared by the author based on "earning statement" and "balance sheet" of individual insurance companies, "Insurance -Non-life Insurance Statistics-," and "IIC Partners' yields of government bonds."

**Value Creation by Underwriting**

To correctly observe the actual situation in the insurance business, minimum requisite capital, which is determined paradoxically based on target ROE with zero (0) of EVA, is used instead of economic capital<sup>4</sup>.

Value creation by underwriting may be examined by confirming correlation between total market share price and representative markers of insurance business, such as economic underwriting income<sup>5</sup>, increase ratio, loss ratio, and liability reserves.

(1) Economic insurance income and increase ratio

Figures 6 and 7 show changes and correlation of “total current share price/minimum requisite capital” and “economic underwriting income/minimum requisite capital,” respectively. Figures 8 and 9 show changes and correlation of “total current share price/minimum requisite capital” and “increase ratio,” respectively.

Extremely high correlation was observed between “total current share price/minimum requisite capital” and “economic underwriting income/minimum requisite capital” in any fiscal year, while no such high correlation was confirmed between “total current share price/minimum requisite capital” and “increase ratio.” This means that investors tend to put a focus on profitability rather than growth potential represented by “increase ratio.”

FIG.7: CORRELATION BETWEEN “TOTAL CURRENT SHARE PRICE/MINIMUM REQUISITE CAPITAL” AND “ECONOMIC UNDERWRITING INCOME/MINIMUM REQUISITE CAPITAL”

FIG.8: CHANGES IN “TOTAL CURRENT SHARE PRICE/MINIMUM REQUISITE CAPITAL” AND “INCREASE RATIO”

(2) Loss ratio

Figures 10 and 11 show changes and correlation of “total current share price/minimum requisite capital” and “loss ratio.”

It was revealed that such correlation was not so high, although decrease of “loss ratio” may have an impact on the shareholder value. The impact of changes in “loss ratio” on total current share price is limited, and that on entire capital cost is small. When paradoxically considered, it can be said that no large impact is placed on total current share price even at the expense of underwriting in the insurance business. However, this may lead to the possibility that underwriting is considered less serious.

(3) Liability reserves

Figure 12 shows comparison of the current values in FY1996, which were determined by dividing actual value and theoretical value of liability reserves by individual risk-free rates (ten-year yields of government bonds). Theoretical value means the difference between premium paid-in and claim paid in the relevant fiscal year.

In recent years in the insurance business, minimum requisite capital has been rapidly increased, while liability reserves have been decreased year by year<sup>6</sup>. An especially problematic fact is that theoretical value of liability reserves has been decreased drastically since FY1996, compared with actual value.

(4) Total current share price and economic underwriting income

Figures 13 and 14 show changes and correlation of total current share price and economic underwriting income, respectively, showing almost no correlation. This means that absolute value of total current share price has no relationship with economic underwriting income.

In general, share price performance is affected by the scale of an issuing organization, but this is not observed in the insurance business. This means that the economy determined by the scale of an issuing organization in the financial market may not be applied to the insurance business.

FIG.13: CHANGES IN TOTAL CURRENT SHARE PRICE AND ECONOMIC UNDERWRITING INCOME

FIG.14: CORRELATION BETWEEN TOTAL CURRENT SHARE PRICE AND ECONOMIC UNDERWRITING INCOME

\* Figures 6 - 14 were prepared by the author based on "earning statement" and "balance sheet" of individual insurance companies, "Insurance -Non-life Insurance Statistics-," and "IIC Partners' yields of government bonds."

### Value Creation by Investment

#### (1) Risk taking of the insurance business in the financial market

Figures 15 and 16 show changes and correlation of "total current share price/minimum requisite capital" and "ratio of securities for total assets" in the insurance business during a period from FY1996 to FY2004, respectively. In the insurance business, the "ratio of securities for total assets" has been increasing in recent years, and this has negative correlation with "total current share price/minimum requisite capital." The return generated when an insurance company takes high risk in the financial market will not create the value for shareholders. However, evaluation on share price is not always decreased when investment risks are taken. It can be expected that high investment income and ROE are ensured by investment strategy with high risk. However, since there are various limitations such as solvency and requests from the rating organization in the insurance business, the investment risks cannot be covered by underwriting income.

In addition, the impact of asset scale on the value for shareholders is small in the insurance business<sup>7</sup>. Discussion should be made on the risk in the total assets, not the scale of total assets, and whether an insurance company has shareholders' equity for the risks. In other words, the assets with high risk should be reduced.

\* Figures 15 - 16 were prepared by the author based on “earning statement” and “balance sheet” of individual insurance companies, “Insurance -Non-life Insurance Statistics-,” and “IIC Partners’ yields of government bonds.”

## Characteristics of Capital Cost in Insurance Business

### Insurance Underwriting Risk and Financial Market Risk

In all business entities, capital cost is related to the quantity and quality of the risk to be taken by the companies. The business activity of insurance business includes insurance underwriting contracts and investment in the capital market, and the capital is related to both insurance underwriting risk and financial market risk. Therefore, for evaluation on the capital cost of insurance business, insurance underwriting risk and financial market risk should be examined separately.

In such examination, liability reserves should be discussed. In calculation of minimum requisite capital based on EVA, liabilities were appropriately adjusted in accordance with the actual situation in the insurance business. In the adjustment, the reserves for extraordinary casualties were included in the shareholders’ equity because the reserves for extraordinary casualties are considered to be pseudo shareholders’ equity as the reserves can be accounted for debts for a long period with no interests<sup>8</sup>.

On the other hand, from a standpoint of Basel II, ordinary liability reserves are considered to be the costs to cover average loss, while the reserves for extraordinary casualties are considered to be the risk to cover the difference from average loss. In other words, ordinary liability reserves are the cost in which loss is forecasted in advance (EL: Expected Loss) and the reserves for extraordinary casualties are the resource to cover the risk of unexpected loss (UL: Unexpected Loss)<sup>9</sup>.

### Problems Regarding Liability Reserves

The insurance business can obtain benefits through investment of liability reserves. This means that the insurance business has resource for reinvestment in the capital market. Thus, the investment risk of the insurance business at the capital market is affected by leverage effect of insurance underwriting risk.

In addition, B/S in the insurance business includes the items such as reinsurance with no liquid market, in addition to liability reserves. Many of financial assets in the insurance business are non-liquid financial assets. When

the financial assets are liquid, the market price can be considered as the economic value, but this is not applied to the insurance business.

In addition, capital investment in the insurance business has greater tax-related demerits and agency costs<sup>10</sup> than direct investment by investors. Therefore, the net cost of liability reserves is determined by taking investment income from capital cost.

**Problems Regarding Additional Capital**

When new capital is added in line with increase of foreign investors, the funding costs, such as commission cost and communication cost are generated.

(1) Commission cost

When new shares are issued, commission fee must be paid for the additional capital to investment bank.

(2) Communication cost

Communication cost is required for communication with new investors, including disclosure of present situations and past achievements in the capital market upon the issue of new shares. When appropriate information is not disclosed, the shares of existing shareholders will be diluted.

IR activity is well known as a method to decrease communication costs. Although IR activity does not contribute to benefits in P/L directly, the activity can decrease capital costs when performed effectively. The role of IR is to absorb the shock at market, and provide investors with timely information. When the shock of market can be absorbed, changes in share price (volatility) will become small, resulting in decrease in capital costs.

**Limit of Shareholders' Capital Cost Rate**

In this report, "target ROE (%)," which is determined subjectively by business managers themselves as shareholders' capital cost rate, was used. This is because the use of popular CAPM (Capital Asset Pricing Model) is not realistic, since expected return on investment is determined based only on statistics of shares of shareholders.

In addition, it is known that allocation for individual insurance types cannot be performed and beta values are unstable in using CAPM<sup>11</sup>.

**Existence of Frictional Costs**

As mentioned above, the insurance business takes insurance underwriting risks in addition to financial market risks, and thus additional costs named frictional costs are generated. Frictional costs are the opportunity costs which shareholders receive when they invest through insurance business, not direct investment at the financial market. The following three costs are the frictional costs in the insurance business.

Type of frictional cost	Promotion factors
(1) Financial cost	Franchise values, capital adequacy
(2) Agency cost/uncertainty cost	Transparency, rumor, incentive
(3) Illiquidity cost (capital regulation, capital rating)	Regulation environment, rating environment (capital regulation)

FIG.17: FRICTIONAL COSTS IN INSURANCE BUSINESS (Reference: SWISS RE (2005) ,13.)

**Conclusion**

Insurance business is a business category with a unique feature in which underwriting and finance are intricately intertwined with each other. Therefore, the corporate value should be evaluated from two standpoints, the corporate value creation by underwriting and that by investment.

For analysis, the minimum requisite capital, which was paradoxically determined based on the ROE when EVA-based stockholder value was zero, was used. Regarding insurance underwriting strategy, correlation of total current share price with insurance underwriting benefits, increase rate of revenue, and rate of fractional damage was examined. As a result, it was revealed that insurance underwriting benefits had extremely close correlation in any fiscal year, while no such close correlation was confirmed with increase rate of revenue and rate of fractional damage. In addition, liability reserves have been decreasing year by year. When comparing theoretical values and actual values, it was revealed that decrease in theoretical values was greater than that of actual values. Although stock price performance is generally affected by the scale of issuing organizations, this is not confirmed in the insurance business.

Regarding investment strategy, negative correlation was confirmed between “total current share price/minimum requisite capital” and “securities/total asset.” The return generated when insurance business takes high finance market risks will not create the value for shareholders. This is because investment risks cannot be covered by insurance underwriting benefits in the insurance business due to various regulations such as solvency and requests from rating organizations.

From a viewpoint of investors, investment through insurance companies accompanies more tax-related demerits, agency costs, and frictional costs caused by uncertainty, compared to direct investment. On the other hand, business managers have various problems, for example, CAPM to be used for calculation of shareholders’ capital cost cannot be allocated for individual types of insurance, and it is difficult to take risks at financial/capital market for many illiquid assets due to capital regulations. This means that the insurance business has more limitation on corporate value creation than other general companies and financial institutions.

## End Notes

<sup>1</sup>Iwase Y. (2006).Corporate Valuation based on EVA, *Journal of Insurance Science*, 594, 23.

<sup>2</sup>Many companies including Asahi Kasei, Kao, Coca-Cola, Kirin Brewery, and Sony use EVA. In addition, more than 50 companies including Kawasaki Steel, Sumitomo, Matsushita Electric Industrial, Mitsubishi, HOYA, and Orix use practically same management method to EVA.

<sup>3</sup>Iwase Y. (2004).An Analysis of Japanese Non-Life Insurance Business Based on EVA, *Journal of Insurance Science*, 587,163.

<sup>4</sup>Determined by taking current debt from current asset

<sup>5</sup>In “An Analysis of Japanese Non-Life Insurance Business Based on EVA” presented in *Journal of Insurance Science*, 587, I adjusted EVA in accordance with actual situations of the insurance business. Economic underwriting income is determined by taking asset management-related items from income and cost in the process of the adjustment. Pre-tax values were used because actual situations were supposed to be confirmed more correctly when frictional cost was counted out.

<sup>6</sup>Iwase Y. (2006).Corporate Valuation based on EVA, *Journal of Insurance Science*, 594,30.

<sup>7</sup>Iwase Y. (2006).Corporate Valuation based on EVA, *Journal of Insurance Science*, 594,32-33.

<sup>8</sup>Iwase Y. (2006).Corporate Valuation based on EVA, *Journal of Insurance Science*, 594,35.

<sup>9</sup>In Basel II, bad debt loss caused from credit portfolio of financial institutions is divided into EL (Expected Loss) and UL (Unexpected Loss). EL is considered to be average loss or the cost accompanied with loans, while UL is considered to be the difference from the average or the risk. The risk does not mean all of the loss, but the part of loss that shows unexpected changes. EL (cost) is imputed to interest rate on loans in the same way with funding cost and expenses. It is required for the loan department to control UL (risk) within the range of shareholders' equity, which is allocated in the frame of comprehensive risk management. (Miyachi A. (2004).Characteristics of new BIS proposed regulation and its impact on financial system, *Japan Bank Working Paper Series,Economic Seminar*, 598.2.)

<sup>10</sup>Iwase Y. (2006).Corporate Valuation based on EVA, *Journal of Insurance Science*, 594, 35-36.

<sup>11</sup>For insurance companies with item portfolio that is different from the average in the insurance business (for example, insurance companies that deal only with accident insurance), CAPM is not an appropriate calculation method of shareholders' capital costs, and beta values of all insurance companies are not always equal to the average of insurance business. Therefore, it is difficult to estimate entire insurance business using beta values that vary depending on individual insurance companies. (Swiss Re (2005).*Capital cost and creation of economic value in insurance companies,Theory and operational problems*, sigma 2005,Vol. 3.28.)

# International “Constraints” on the Life Insurance Markets and Risk Management for Life Insurance Companies

*Hideya Kubo, kubo22533@nissay.co.jp  
Kobe University, Japan*

## Abstract

The purpose of this paper is to analyze the linkage and common factors of the life insurance markets worldwide by using a concept called the “Face amount ratio” (hereinafter called the “FA ratio”).

The FA ratio is a very simple index which is obtained by dividing the personal insurance amount by the nominal GDP, but is one of the international “constraints”. In addition, the market structure in a country and the future expansion can be learned from structures of the other countries’ FA ratios in certain periods.

And the FA ratio is effective to notify us of unusual changes in the markets. Large deviation of this index means that the insurers’ strategy achieved an overly successful outcome, which implies a phase where the risk control is insufficient as seen in Japan and U.S.. FA ratios play an important role in managing or supervising the soundness of life insurance companies.

## Factors to determine the level of insurance amount

The life insurance markets have country-specific characteristics. For example, in the Japanese market, the life insurance amount (of personal insurance only) is four times as much as GDP; and in the U.S. market, the premium income from personal pension accounts for more than 60% of the total premium income. As with other goods and services, however, the purchase of life insurance (including personal pension) depends on the consumers’ expenditure preference based on their satisfaction, subject to a limitation of personal income. Therefore, the international life insurance markets are assumed to have common factors because of people’s common needs for risk aversion.

The differences of life insurance from other goods and services are the facts that: (1) life insurance is a regulated industry; and (2) that the suppliers’ action significantly influences the market formation. The regulations to ensure the soundness – such as entry of new competitors and product development – also restrict free competition. Survivorship insurance products (hereinafter called the “Security-oriented Products” and the market for the Security-oriented Products is referred to as the “Security-oriented Market”), which support the livelihood of surviving families if the head of household is dead, yield a relatively higher profit margin than other products without competition with other businesses. Therefore, the insurers have incentive to mainly sell the Security-oriented Products if such action is acceptable in the market. Since the sale of the Security-oriented Products requires highly functional sale channels that offer consulting and other services in order to bring out the potential needs, insurers do not easily change or abolish the products. Accordingly, the starting point of analyzing life insurance markets is the Security-oriented Market in which insurers’ action is reflected.

First of all, we look at the Security-oriented Market in key countries. To adjust the difference of economic scale, the international comparison is made with the MS ratio, which is obtained by dividing the insurance amount (of personal insurance only) by the nominal GDP, both of them denominated in each country’s currency. Figure 1 shows the MS ratios in bar graph (unit: times). Three values are shown for Japan approx. every 15 years and the latest available values are shown for other countries in order to clarify the time- and area differences. In Japan which has the highest MS ratios, the life insurance amount underwritten only by the private life insurance companies is 2.1 times as much as the nominal GDP in 2004; and it becomes 2.9 times when the amount by Japan Post and Japan Agricultural Cooperatives is included. In Thailand, on the contrary, the insurance amount is equivalent to 20% (one fifth) of the GDP. In the U.S. and U.K., countries most advanced in insurance, the insurance amount is almost same as the nominal GDP – that is, the MS ratio of about 1.

For international comparison of purchase ability, which is often needed for other goods and services, the lines of the GDP per capita (in U.S. dollars) are added to Figure 1. It is presumed that the insurance market expands in accordance with the increase in national income. This is the case in Asia, but negatively correlated in the U.S. and Europe, which suggests that there are factors other than the national income that have an effect on the MS ratio.

FIG.1: INTERNATIONAL COMPARISON OF MS RATIO

When we reconsider the needs for life insurance, the Security-oriented Products are intended for supporting the livelihood of surviving families in case the head of household is dead. The cost of living for surviving families depends on the income level at the particular time, which means that higher level of living requires greater amount of benefits. This is called the “Income Factor.” Also, in the countries where division of domestic roles is dominant – i.e. husbands earn income and their wives keep house, the higher insurance amount is required for their husbands’ death. In other words, the insurance amount is deemed to decrease if more women advance into society and enter the workforce. This is called the “Female Financial Independence Factor.”

And consumers choose the financial product containing insurance and pension in order to fulfill their needs. The rate which Consumers choose insurances and pensions is called "Preference for Life Insurance." ( See, Section 2 )

Although many other factors exist, these simple parameters are used in this research paper in attempting to explain the differences of the MS ratios in various countries.

The explanatory variables consist of the aforesaid GDP per capita in U.S. dollars as the “Income Factor” and the gender difference in labor force participation rate as the “Female Financial Independence Factor” and “Preference for Life Insurance” The cross-sectional analysis based on country factor and time-series factor was performed for (1) eight countries, that is, Japan, the U.S., U.K., Canada, Korea, Taiwan, Singapore and Thailand for (2) seven years starting from 1999 to 2005 in (3) the life insurance market consisting of personal insurance and personal pension.

Figure 2 shows the results of analysis. Although not all cases are fully explained, t-statistics of three predictor variables are high enough (5.933, 5.504 and 2.127 respectively) to indicate a relationship of the basic structure. Therefore, the relation between Japan (with the MS ratios of more than 3) and Thailand (the MS ratios of around 0.2) is consistent. Also, there are common factors in the Asian market and the European market which significantly vary in the economic and social structures and in the development stage of insurance market.

The deviation between actual values (solid line) and estimate values (dotted line), which could not be

explained in this structural formula, contains each country's market characteristics and standard error of the estimate. The deviation has a considerable significance as discussed in the next section. In Japan, Canada and Taiwan, the actual values exceed the theoretical values, showing that the Security-oriented Market is excessively large, whereas, in the U.S. and Singapore, the actual values are below the theoretical values, showing that the insurers' managerial decision to bring out the potential market needs could expand the Security-oriented Market. Note that the level of theoretical values may vary according to changes in national income and the labor force participation rate of men and women.

FIG.2: ESTIMATE OF MS RATIO ( 1999 - 2005: 8 COUNTRIES )

## Breakdown of the MS ratio

The portion, equivalent to the MS ratio of approx. 0.5, still remains unexplainable with the aforesaid simplified estimate formula containing two variables. To explain this portion, further analysis is conducted for the MS ratio from another angle.

The MS ratio can be broken down into the following formula.

$$\begin{aligned}
 \text{MS ratio} = & \frac{\text{Personal Life Insurance Amount}}{\text{Nominal GDP (in home)}} \times \frac{\text{Personal Life Insurance Amount}}{\text{Personal Life Insurance Premium}} \times \frac{\text{Personal Disposable Income}}{\text{Personal Life Insurance Premium + Personal Pension Premium}} \\
 & \times \frac{\text{Personal Disposable Income}}{\text{Nominal GDP}}
 \end{aligned}$$

The first, second, third and fourth terms on the right side of the equation are called “Preference for Life Insurance,” “Ratio of security to premium,” “Preference for Insurance over Pension” and “Ratio of Household Budget.” The first term represents the household budget tendency toward life insurance: how much consumers paid for purchase of life insurance from disposable income. The second term represents the product strategy: how far the life insurance companies increase the security component of life insurance products. The third term represents the ratio of personal insurance premium to the sum of personal insurance premium and personal pension premium. Personal insurance emphasizes a security component, while personal pension does savings and investment components. Thus, this ratio indicates preference for security over pension. The fourth term represents the ratio of household budget to the entire economy.

Table 1 shows a breakdown of this equation in three major countries. The comparison between Japan and the U.S. for these 30 years shows that the MS ratios in Japan nearly double those in the U.S. at the moment but they were almost at the same level until 1970, as well as the percentages of four elements described above. The main factors that the disparity of the MS ratios between the both countries rapidly expanded subsequently are the changes in the “Preference for Life Insurance” and “Preference for Insurance over Pension.” The former factor was presumably caused by the difference of circumstances in Japanese and the U.S. life insurance industries. The highly regulated Japanese life insurance industry was able to steadily take in the household budget and personal financial assets, whereas the U.S. life insurance industry failed to do so under the continuous fierce competition with banks, securities companies, and investment trusts.

TABLE 1: STRUCTURE OF THE MS RATIO

	Items	1970 or before	1981	1990	1995	2000	2005
Japan	MS ratio	0.73 (1967)	1.65	2.57	3.14	2.75	2.28
	1. Preference for Life Insurance	3.4%	4.4	6.9	7.0	6.1	7.8
	2. Ratio of Security to Premium	32.5%	58.5	68.1	84.7	85.7	76.4
	3. Preference for Insurance over Pension	98.6%	98.3	91.2	86.2	88.1	66.5
	4. Ratio of Household Budget	68.0%	64.7	60.0	61.5	59.2	57.5
U.S.	MS ratio	0.74 (1970)	0.64	0.92	0.93	0.95	0.80
	1. Preference for Life Insurance	2.4%	2.0	2.7	2.9	3.4	3.1
	2. Ratio of Security to Premium	45.4%	56.4	89.0	87.8	91.5	89.1
	3. Preference for Insurance over Pension	94.7%	77.6	53.0	50.4	42.3	40.1
	4. Ratio of Household Budget	70.8%	71.8	73.9	73.1	73.3	72.3
U.K.	MS ratio	—	0.8 (1985)	0.95	0.99	1.08	0.97
	1. Preference for Life Insurance	—	2.9	5.1	6.2	9.0	6.9
	2. Ratio of Security to Premium	—	61.8	41.3	34.2	26.5	32.6
	3. Preference for Insurance over Pension	—	71.3	69.4	67.1	66.9	64.8
	4. Ratio of Household Budget	—	63.3	64.8	69.5	67.8	66.3

Source: ACLI "Life Insurers Fact Book 2005," ABI "Long-term Business 2006/11" on the website of Life Insurance Association of Japan

Note 1: Figures in Japan represent only those of private life insurance, excluding postal insurance and JA.

Note 2:

- 1) MS ratio is obtained by dividing the personal life insurance amount by nominal GDP.
- 2) Preference for Life Insurance is obtained by adding the personal life insurance premium to the personal pension premium and then dividing the sum by the personal disposable income.
- 3) Ratio of Security to Premium is obtained by dividing the personal life insurance amount by the personal insurance premium.
- 4) Preference for Insurance over Pension is obtained by dividing the personal insurance premium by the sum of personal life insurance premium and personal pension premium.
- 5) Ratio of Household Budget is obtained by dividing the personal disposable income by the nominal GDP.

The latter was caused by two factors. First, in the U.S., the female financial independence actively promoted the sale of personal pension, while in Japan, the slow participation rate of female labor force allowed the insurers to pursue security-oriented products. According to the OECD statistics, the gender difference of labor force participation rate in Japan was 22.7% in 2005, almost twice as high as that in the U.S. (12.0%). The second factor is the difference in the role of the public pension as source of income after retirement. In the U.S., the personal pension premium exceeded the personal insurance premium in the late 1990's to cover the low level of public pension, thus decreasing the "Preference for Insurance over Pension" to 40.1% in 2005. On the other hand, in Japan, despite its aging society, generous public pension system maintained the high level of the "Preference for Insurance over Pension" at 80% in the late 1990's and 66.5% in 2005, almost twice as high as that in the U.S.

As described above, such large Security-oriented Market in Japan was maintained by the slow financial deregulation, low female participation in the labor force, and generous public pension system. Therefore, any change in these three conditions may considerably alter the Security-oriented Market in Japan.

## Interest Rate Fluctuation and Preference for Life Insurance

Interest rates are one of the competitive conditions between banks and life insurance companies. Banks offer a “variable rate under short-term fund management,” whereas insurance companies offer a “fixed rate under long-term fund management.” Interest rates remain an important factor for consumers to select products even though the deregulation in the financial market makes it difficult to clearly differentiate business categories on the basis of interests due to the increase in sales of investment trust or variable insurance. Especially in the U.S. life insurance market, where competition among financial institutions is intense, the interest rate of treasury bonds maturing in ten years and the “Preference for Life Insurance” are highly linked as shown in Figure 3.

FIG.3: U.S. INTEREST RATE AND PREFERENCE FOR LIFE INSURANCE

However, this relation has been less clear since 2000. Although, life insurance companies compete with banks in the Individual financial assets market intensely, insurance companies accelerated to use banks as one of pension-sales channels. In 2005, the sales channels of banks have 30 percent of the share by a fixed amount pension, and it has about ten percent of the share by a variable annuity on the U.S. individual annuity. In Europe, The share of the insurance sales share by the bank exceeded 60 percent in Spain, France, and Italy. And the sales share around twenty percent is occupied even in Britain, Germany where other channels are strong.

The above direct relation between the fluctuation of interest rates and the “Preference for Life Insurance” is not only seen in the U.S. where the financial deregulation has made progress and thus the MS ratio is low, but also in Asian countries whose MS ratios are still high.

In Taiwan, as with Japan, security-oriented products dominate the life insurance market in which the MS ratios exceed 2.5. Figure 4 shows a structural change of the MS ratios in Taiwan, indicating that the “Preference for Life Insurance” had largely increased in the decline of interest rates since 1997, especially during the period between 2001 and 2003 when interest rates had sharply dropped. Both the “Ratio of Security to Premium” and the

“Preference for Insurance over Pension” had decreased during this period, which means that the personal pension had significantly increased. In 2005, although personal pension kept high level maintained, “Preference for Insurance over Pension” has been increasing.

FIG4: MS RATIO (YEAR-ON-YEAR RATE) IN TAIWAN

The MS ratios are also high in Korea, which overcame the currency crises in Asia and the adversity under the control of IMF. The insurance companies in Korea reviewed their products and sales channels, for example by increasing the sales of personal pension plans at bank counters since 2002 to make up for the decrease of their sales staff since 1997. Consequently, the percentage of premium income at bank counters increased to 12.3% in the first half of 2004, while the actual MS ratio value remained below the theoretical value, which shows the potential for large Security-oriented Market in Korea.

As shown in Figure 5, even though long-term interest rates in Korea had rapidly fallen since 2001, the “Preference for Life Insurance” had dropped in 2005 to 80% of the highest record in 1998. In the phase of low interest rates that are favorable to life insurance companies, they did not attempt to earn excessive premium income and instead employed the strategy to increase profitability by enhancing the security components, presumably because Korea had learned a lesson about running the risk of competition with high assumed rate of return, judging from the experiences in insolvency of life insurance companies.

Personal pension increased in Korea, too, as in other countries, but was exceeded by the personal insurance premium and Life Insurance companies in Korea have had the strategy to increase the MS ratios through increase of the “Ratio of Security to Premium.”

FIG.5: MS RATIO (YEAR-ON-YEAR RATE) IN KOREA

In summary, Taiwan adopted a strategy to increase the premium income, considering the change in interest rates as a good opportunity because of the excessive Security-oriented Market from a view of the MS ratio, while Korea adopted a strategy to increase the long-term profitability without taking advantage of the change in short-term interest rates from a view of risk control. Korea was able to use the strategy since it has the potential for large Security-oriented Market indicated by the MS ratios. This strategy is deemed sustainable because the MS ratio increased to 1.67 in 2005, but still under the theoretical value of 1.84 in 2005.

### International Linkage of the MS ratio

The analysis above shows that life insurance markets do not rely on a single factor, but on multiple factors, such as national income, changes in the MS ratios and interest rates, as well as insurer's managerial strategies. Since the MS ratios vary with the times, two countries, which have different market structures at present, may have similar structures at a different point of time. Moreover, the past structure of the MS ratios in the countries advanced in insurance may imply the future insurance market of those developing in insurance.

For this reason, the international linkage of those structures was studied from the long-term transition of the MS ratios in Japan. Figure 6 shows the variation of Japan's MS ratios from 1982 to 2005. At that time, daring policy was taken to ease monetary supply in Japan so as to address the rapid tendency toward a strong yen and recession since the Plaza Agreement; and thus interest rates of the long-term government bond fell to around 4% from more than 7%. At the same time, the MS ratio had significantly risen. As the Security-oriented Products account for a large portion of life insurance products, the Japanese market is claimed to be less influenced by interest rates; however, that is not the case. In the phase of such declining interest rates, life insurance companies were forced to take a risk in future interest fluctuation, for example through selling savings-oriented single premium life insurance products on a massive scale in order to meet the action of consumers with high liquidity. As a result, the absence of risk control in this period caused the insolvency of many life insurance companies in the late 1990's.

For the past several years, Taiwan has been in a financial environment similar to that of Japan in the mid 1980's: their official discount rate was lowered to 1% range in 2003 from the middle of 5% range in 1997 as a measure to counter IT recession and due to worldwide low interest rates. Under such similar circumstances, the structure of the MS ratios between 2000 and 2005 in Taiwan (see Figure 4) and that between 1982 and 1988 in Japan (see Figure 6) followed the same pattern.

FIG.6: MS RATIO IN JAPAN AND LINKAGE WITH OTHER COUNTRIES

In the 1990's after the collapse of its bubble economy, Japanese life insurance companies drastically shifted their managerial strategy to increasing total amount of insurance in force through raising the "Ratio of Security to Premium." This shift followed the same path as the strategy employed by Korea which placed emphasis on a security component of life insurance products after currency crises in Asia. There is a similarity between the structure of the MS ratios in Japan from 1990 to 1994 and that of Korea from 2001 to 2005. However, since Japan, unlike Korea, had the excessively large Security-oriented Market where the MS ratios largely exceeded the theoretical value, it presumably cost tremendous expenses and heavy burdens on distribution channels to pursue this strategy. As a result, Japan experienced the subsequent decrease in the MS ratios, large-scaled reduction in sales staff and manifestation of insolvency risk. Consumers had lost their confidence in life insurance companies and the "Ratio of Security to Premium" and the "Preference for Life Insurance" continued to decline until 2001.

This situation changed in 2002. The sales of personal pension surged after the deregulation that permitted sale of personal pension plans at bank counters. High premium income obtained by personal pension plans raised the "Preference for Life Insurance" while inducing consumers to purchase personal pension instead of Security-oriented Products, which further lowered the "Ratio of Security to Premium." Such pattern in Japan from 2002 to 2005 bears a striking resemblance to that happened in the U.S. from 1999 to 2002 when the sales of personal pension increased dramatically.

The fluctuation and structure the MS ratios in Japan followed the same patterns that occurred at certain

periods of Taiwan and Korea, as well as of the U.S. and Europe. It can be said that the structures of life insurance markets, which look different between countries at a certain point of time, have common factors in the long view.

Namely, the MS ratio is one of the international “constraints” on the life insurance markets by which market structures are determined according to the change of long-term interest rates and the sales strategy of suppliers (i.e. insurers) who utilize such change. In addition, the market structure in a country and the future expansion can be learned from structures of the other countries’ MS ratios in certain periods.

### **Estimation of the Insolvent ratio in U.S. by MS ratio**

In Japan, the structure of MS ratio where we saw just before the aspect which seven life insurance companies became insolvent indicate a high possibility of something unusual of the soundness risk.. The signs which insolvent of life insurance companies are generated are the following three. (1) The continuous fall of MS ratio, (2) The big rise of the “Preference for Life insurance” and subsequent nose dive. And a sudden rise of the “Ratio of Security to Premium,” (3) Continuous falls of “Preference for Life insurance” in the phase of downside of interest rate.

If three insolvent signs where saw in Japan with few examples (seven examples) are applied also to the insolvent phase of the U.S. life insurance markets with exceeding 500 insolvent companies, these insolvent signs of MS ratio can apply internationally.

AM Best, credit rating agency in U.S., has given “E” ranks (a ranking rank means failure) to the life insurance company of 547 from 1976 to 2002.

The aspects of the Insolvent ratio which is obtained by dividing the number of insolvent companies by the number of companies belonging to ACLI exceeded 1% in 1983, 1988-1993, 1997-1999. The Insolvent ratio rose by the breakdown of the health insurance company accompanying the rise of medical cost in 1983 and by breakdown of ten affiliated companies of General American Life, in 1999. They are slightly special cases.

On the other hand, the insolvent risk increased on the whole industry in 1988-1993. In 1991, the number of collapsing life insurance companies amounted to 55 companies and the Insolvent ratio rose to 3.7%. The long-term interest rate is located in the long fall phases from 1984 (12.5%) to 1993 (5.9%).

As for the rate of change of MS ratio hit the peak, and had been falling for seven years. Moreover, the “Preference for Life Insurance” changed to falling from a big rise, and the “Ratio of Security to Premium” carried out a reverse motion simultaneously. Three insolvent sign in Japan also showed up in U.S.

As shown in Figure 7, the Insolvent ratio in U.S. is estimated roughly from both the rate of deviation ((actual value-theoretical value: Fig. 2)/actual value) and “Preference for Life insurance” of MS ratio. When MS ratio goes up and approaches to the theoretical value, the market will be overheated and the Insolvent ratio will increase. On the other hand, the rise of “Preference for Life insurance” depresses the Insolvent ratio.

Thus, the market structures which MS ratio shows link to the insolvent risk closely. And MS ratio contributes to strengthen the risk management of life insurance companies by finding the insolvent signs early.

# Customer Expectations of Service Quality in Financial Services Sector

*Bhim Rao Ghodeswar, ghodeswar@nitie.edu*  
*National Institute of Industrial Engineering, Mumbai, India*

## Abstract

Capital markets in India have evolved and are offering many new products and services for the benefit of individual and institutional investors. Technological developments are changing the way how services are delivered enabling customers and contact employees to provide better, efficient and customized services. Service providers need to develop and provide service offerings that satisfy customer needs and service expectations. The author examines the service quality literature and delineates the important dimensions of service quality in financial services sector. This paper provides an understanding of the customer expectations in financial services sector, viz. investor services, depository services, etc. The study examines the perceptions of managers about customer expectations on different service quality parameters and provides support for a better understanding of the service mechanisms that lead to consumer satisfaction in financial services.

## Introduction

With growing competition in many service sectors, it is imperative for service providers to develop service systems that help them to gain strategic competitive advantage. Zeithaml and Bitner (2003, p.14) noted that technology is profoundly changing how services are delivered, enabling both customers and employees to get and provide better, more efficient, customized services. The service providers have the major objective to develop and provide service offerings that satisfy customer needs and service expectations. It is imperative for the service marketers to close the gap between consumer's expectations and perceived performance.

Capital markets in India have evolved in recent decade and led to a growth with increasing focus on new services, market information, innovative product offerings, improved relationship with clients/ investors, and financial intermediaries. The Depository Act 1996 in India changed the way the capital markets, specifically the stock exchanges, investors and related organizations would function, setting a framework for changing over capital market investing and trading from paper to electronic mode. This set of financial services are fairly new in the country and need to be studied for understanding the consumer expectations that would enable service providers to design their service systems to offer superior performance/experience to the consumers. While it is useful to generalize about the characteristics of services and service businesses, it appears to be equally important to recognize that differences exist among various services and among the firms that market them (Zeithaml, Parasuraman and Berry, 1985). Hence, research was conducted to study the service quality dimensions of one major national financial service provider.

## Understanding Service Quality

Because services are performances, rather than objects, they cannot be seen, felt or tasted or touched in the same manner in which goods can be sensed (Zeithaml, Parasuraman and Berry, 1985). Service organizations create value for consumers through performances (Berry, Seiders and Grewal, 2002). According to Brady and Cronin Jr. (2001), the service quality is defined by either or all of a customer's perception regarding (1) an organization's technical and functional quality; (2) the service product, service delivery, and service environment; or (3) the responsiveness, empathy, assurances, and tangibles associated with a service experience. The five dimensions of SERVQUAL are terms that might be used to refine some aspect of service quality. The SERVQUAL scale operationalizes and measures service quality along five distinct dimensions: tangibles, reliability, responsiveness, assurance, and

empathy. SERVQUAL scores along these dimensions can be viewed as indicators of the construct of perceived service quality (Zeithaml, Berry and Parasuraman, 1988).

Price, Arnould and Tierney (1995) revealed through their research in service relationship that when the customer interacts with the service provider, three dimensions of service encounter shaping service provider are: temporal duration, affective or emotional content, and the spatial proximity of service provider and customer. According to Zeithaml, Berry and Parasuraman (1996), customers perceiving service performance to be inferior are likely to exhibit behaviors signaling they are poised to leave the company or spend less with the company. These behaviors include complaining, which is viewed by many researchers as a combination of negative responses that stem from dissatisfaction and predict or accompany defection.

The service quality is an antecedent of consumer satisfaction and that consumer satisfaction exerts a stronger influence on purchase intentions than does service quality (Cronin Jr. and Taylor, 1992). Service firm executives may not always understand what features connote high quality to consumers, what attributes a service must have in order to meet consumer needs, and what levels of performance on those features are necessary to deliver high quality service (Zeithaml, Berry and Parasuraman, 1988). There is a strong need to identify the attributes that influence the customers' perceptions of service quality.

#### **Consumer Expectations and Satisfaction**

Expectations are beliefs about a product's attributes or performance at some time in the future (Spreng, MacKenzie and Olshavsky, 1996). Parasuraman, Berry and Zeithaml (1990, p. 12) noted that the service expectations concept is "intended to measure customers' normative expectations," and that these expectations represent an "ideal standard" of performance. More evaluative definition of the expectations construct confounds a person's judgment of some event with his or her expectation of the likelihood of its occurrence (Spreng, MacKenzie and Olshavsky, 1996). Teas (1993) revealed the causal link between perceived quality and consumer satisfaction.

Bolton and Drew (1991) relate customer satisfaction to a customer's evaluation of a specific transaction, while a customer's attitude corresponds to a global evaluation of the product/ service, rather than to an evaluation of a specific transaction. Feelings of satisfaction arise when consumers compare their perceptions of a product's performance to their expectations (Spreng, MacKenzie and Olshavsky, 1996). Satisfaction is a customer's post purchase evaluation of a product / service offering. A customer is satisfied when an offering performs better than expected and is dissatisfied when expectations exceed performance. Customer satisfaction/ dissatisfaction (CS/D) typically is modeled as a function of disconfirmation arising from discrepancies between prior expectations and actual performance (Bolton and Drew 1991). Attitude is the customer's global evaluation of a product/ service offering. Recent research in services marketing has centered on customer evaluations of the overall excellence or superiority of a service – that is, evaluations of service quality (Parasuraman, Zeithaml and Berry, 1985, 1988; Zeithaml, 1988).

Overall (or cumulative) satisfaction is "an overall evaluation based on the total purchase and consumption experience with a good or service over time". Rather than capturing the transient and encounter-specific evaluations and emotions, applied market research tends to measure customer satisfaction as the consumer's general level of satisfaction based on all experiences with the firm (Garbarino and Johnson, 1999). Spreng, MacKenzie and Olshavsky (1996) in their study of determinants of customer satisfaction revealed that feelings of satisfaction arise when consumers compare their perceptions of the performance of a product or service to both their desires and expectations. Dissatisfaction leads to consumer-complaining behavior that is manifested in voice responses (such as seeking redress from the seller), private responses (negative word-of-mouth communication), or third party responses (taking legal action) (Singh, 1988). Affective commitment is an antecedent of both customer retention and customer share development (Verhoef, 2003).

In addition to the theoretical support for performance-based measures of service quality, practitioners often measure the determinants of overall satisfaction / perceived quality by having customers simply assess the performance of the company's business processes. Furthermore, performance-based approach may actually be more in line with an antecedent/ consequent conceptualization: that is, judgments of service quality and satisfaction appear to follow the evaluation of a service provider performance (Cronin Jr. and Taylor, 1992).

## Methodology

Literature survey in services marketing reveals qualitative research being used for identifying dimensions of service quality (Parasuraman, Zeithaml and Berry, 1985) and to study customer interactions and service complaint handling (Tax, Brown and Chandrasekharan, 1998). Qualitative research was used to identify the dimensions the customers consider while evaluating service quality. The research was conducted in one major financial services organization offering investor services such as services relating to market operations (receiving the order to receiving/ delivering the securities from the clearing house to facilitate purchase and/or sale transactions); scrutiny, lodgement, and follow up of securities with Registrars of Issues and /or companies; custody of physical receipt of securities; collection, compilation, and maintaining information about the capital market; reporting market updates; and depository services.

The responses to unstructured, open-ended questionnaires were obtained from 120 executives of a financial services company. Respondents were asked to complete an open-ended questionnaire about the specific attributes they perceived as influences on the interactions, environments, and outcomes encountered during recent service experiences. The respondents were encouraged to list all factors that influenced customers' perceptions of service quality.

## Discussion

The results presented here are an attempt to understand the service quality dimensions that are important from viewpoint of managers' perceptions about customer expectations. The study provides evidence that consumers form service quality perceptions on the basis of their evaluations of service performance. The major dimensions that emerged through the study are discussed below.

### **Employee Capability**

In a research study of customer satisfaction with the individual aspects of the banking service, Ganesh, Arnold and Reynolds (2000) revealed that satisfaction with the people factor of the service will be a stronger discriminant of customers than satisfaction with other aspects of service. The employee capability comprises of three dimensions as employee attitude, employee knowledge and competence, and responsiveness can affect the service delivery positively or negatively.

**Employee Attitude:** The attitudinal and behavioral responses of customer-contact employees are important in delivering the service and they can affect customers' perceptions of the service quality. Keaveney (1995) revealed that service encounter failures were all attributed to some aspect of service employees' behaviors or attitudes, and if employees were uncaring, impolite, unresponsive or unknowledgeable, customers switched service providers. According to Hartline and Ferrell (1996), the five attitudinal and behavioral responses of customer-contact employees, viz. self-efficacy, job satisfaction, adaptability, role conflict, and role ambiguity affect the ability of contact employees to serve customers in a manner that enhances service quality. Empathy, which is identified as another focused emotion (as opposed to an ego-focused emotion), involves feeling compassion for others in a social or interpersonal context. With greater empathy, perceived time and energy costs will be lower (Berry, Seiders and Grewal, 2002). Extended, Affective, Intimate Service Encounter (EAI encounters) demand a service provider role that incorporates empathic sharing, communication of caring, evolving intimacy, and exchange more characteristic of friendship than commercial service provision (Price, Arnould and Tierney, 1995).

**Knowledge:** Customer contact employees need to have knowledge about the consumer need, their buying pattern, usage pattern and knowledge about the company offerings that match the consumer expectations. Consumer insight is increasingly emerging as the key success factor for frontline employees in understanding and meeting consumers' needs. This is dependent on the skill and competence of the customer contact employee. Being knowledgeable and being well versed in state-of-the-art techniques is viewed by service consumers as important benefit. Sharing information reaffirms (Schneider and Bowen, 1999) customer feelings of competency, whereas being condescending to customers clearly challenges their self-perceived level of intelligence.

**Responsiveness:** In many cases, customer contact employees are the first and only representation of a service firm. Customers often base their impressions of the firm largely on the service received from customer contact employees (Hartline, Maxham III and McKee, 2000). A sample of service executives claimed that frontline employees are pivotal in forming a customer's level of perceived service quality (Parasuraman, Zeithaml and Berry, 1985). The "employee responses to service failures" were grouped into three subcategories that range from bad to worse: (1) reluctant responses, (2) failure to respond, and (3) patently negative responses (Keaveney, 1995). Frontline employees' quality is sensitive to burnout tendencies that emerge from self-regulation failures as they try to cope with increasing role demands, ambiguity, and conflict (Singh, 2000). Contact employees who share the customer-oriented values of the firm are more likely to exhibit behaviors that are consistent with those values and the firm's strategy (Hartline, Maxham III and McKee, 2000).

### **Product Configuration**

The product configuration deals with three dimensions, viz. product range, price, and additional services.

**Product Range:** The depository and custodial services address the individual investor's needs. The service provider designed financial products keeping in mind the investment psyche of the clients/investors. The product range consisted of financial products such as pledging of shares, dematerialization, purchase and selling of securities, and value added products.

**Price:** When price and performance are consistent, expectations have an assimilation effect on performance and satisfaction judgments; when price and performance are inconsistent, expectations have no effect on performance and satisfaction judgments (Voss, Parasuraman and Grewal, 1998). The pricing category included all critical switching behaviors that involved prices, rates, fees, charges, surcharges, service charges, penalties, price deals, coupons, or price promotions. Pricing subcategories included (1) high prices, (2) price increases, (3) unfair pricing practices, and (4) deceptive pricing practices. In the "high price" subcategory, customers switched services when service prices were exceeded internal reference prices. Prices were deemed too high relative to some internal normative price, too high relative to the value of the services received, or too high relative to competitor's prices (Keaveney, 1995).

**Additional Services:** Additional services such as advisory services, expert advice, providing analytical reports to facilitate decision making by the consumer, delivering products as per consumer convenience, etc. are valued and desired by the consumers. These services also facilitate other associated/complimentary services making the purchase/ use easier and offer convenience to the consumer.

### **Service Recovery**

While timeliness focuses on provision of information and service delivery at right time, complaint handling refers to solving the problem faced by consumers by establishing appropriate resolution procedures, interpersonal communication, and delivery of desired outcomes.

**Timeliness:** Information – the product of communication – is the tie that binds in any relationship, including commercial relationships with customers and other stakeholders. Information is something that makes decision making easier by reducing uncertainty. Information processing has dominated most approaches to marketing communication, which suggests that communication can be managed or controlled (Duncan and Moriarty, 1998).

**Complaint Handling:** A complaint is viewed as a conflict between the customer and the organization in which the fairness of (1) the resolution procedures, (2) the interpersonal communications and behaviors, and (3) the outcome are given the principal evaluative criteria of the customer (Tax, Brown and Chandrasekharan, 1998). Consumer complaints are highly symbolic; they might imply failure or inadequacies of previous marketing decisions, and constitute criticism of the individuals responsible for the problematic policies or programs (Fornell and Westbrook, 1984).

Complaint handling refers to the strategies firms use to resolve and learn from service failures in order to (re)establish the organization's reliability in the eyes of the customer (Hart, Heskett and Sasser, 1990). Complaint data, are key in quality management efforts because they can be used to correct problems with service design and delivery, which makes it more likely that performance will be done right the first time (Lovelock, 1994). In general, the less time and effort required of consumers to effectively deal with a failed service, the better is the recovery service. Service system design is instrumental in managing the time and effort costs required for consumers to use a

service (Berry, Seiders and Grewal, 2002). Justice involves the propriety of decisions. A three-dimensional view of the concept has evolved over time to include *distributive justice* (dealing with decision outcomes), *procedural justice* (dealing with decision making procedures), and *interactional justice* (dealing with interpersonal behavior in the enactment of procedures and delivery of outcomes) (Tax, Brown and Chandrasekharan, 1998, Schneider and Bowen, 1999).

### **Convenience**

Convenience of buying and using the services is viewed in terms of reliability of services, process simplicity and technology, and accessibility.

**Reliability of Service:** All types of convenience that reduce consumers' time and effort in shopping, such as operating hours or credit availability, belong to the domain of service convenience (Berry, Seiders and Grewal, 2002). Consumers' energy expenditures, or effort, are acknowledged to be a distinct type of no monetary cost that, like time, influences perceived convenience (Seiders, Berry and Gresham, 2000) and satisfaction (Lovelock, 1994). The factors that influence consumers' perceptions of waiting are service, facility, and customer characteristics; perceived fairness of the wait; and information provided by the firm (Berry, Seiders and Grewal, 2002). Consumers, on average, significantly overestimate time spent waiting (Hornik, 1984). The consumers may perceive the service provider's location, hours of operation, waiting time for service, or waiting time to get an appointment as convenience. They also perceive minimizing or eliminating mistakes, billing errors, etc. as other sub dimensions of convenience.

**Process Simplicity and Technology:** Technology is a key adjunct to service system design (Meuter, Ostrom, Roundtree and Bitner, 2000). Self-service technologies (SSTs) are technological interfaces that enable customers to produce a service independent of direct service employee involvement. Technologies specifically designed to improve service convenience can affect each type of service convenience. Berry, Seiders and Grewal (2002) have identified five defining types of convenience, viz. decision, access, transaction, benefit, and post benefit convenience. According to them, 'decision convenience' refers to making it easier for consumers to take decisions about intangible and variable services; 'access convenience' refers to consumers' participation in using services; 'transaction convenience' relates to waiting time; 'benefit convenience' refers to a service's benefit what consumers invest resources to receive; and 'post benefit convenience' refers to allocating additional time and effort resources to reinitiate contact with a firm after a service encounter. Post benefit inconvenience is exacerbated by regency effects; it comes at the end of the consumer's service experience.

**Accessibility:** Offering service through several outlets increases the convenience of access for customers but may start to raise problems of quality control as convenience of access relates to the consistency of the service product delivered (Lovelock, 1983). Identification of ideal service locations is critical to achieving better facility utilization since the demand for customer service is based on convenience. With ATMs in place, serving a customer need such as financial transactions processing does not have to be limited to the regular banking hours and the service can be made available for 24 hours a day, 365 days a year. The transactions can be processed through ATMs placed at strategic locations off the bank premises (Bharadwaj, Varadarajan and Fahy, 1993). Self-service technologies usually have wider availability and longer, more flexible hours of operation and help customers to immediately solve a problem (Meuter, Ostrom, Roundtree and Bitner, 2000).

Because service encounter environments are purposeful environments (i.e., they exist to fulfill specific needs of consumers, often through the successful completion of employee actions), spatial layout and functionality of the physical surroundings are particularly important (Bitner, 1992). An effective way to reaffirm a customer's feeling of confidence and competency is to arrange environments in ways that permit them to feel in control (Schneider and Bowen, 1999). Ambient conditions include background characteristics of the environment such as temperature, lighting, noise, music, and scent. As a general rule, ambient conditions affect the five senses (Bitner, 1992). A service provider can maintain and enhance esteem in services by making the environment knowable and predictable; by creating a customer-friendly environment in which people feel smart, competent, important, and comfortable; and by offering them choices (Schneider and Bowen, 1999).

### **Assurance**

Assurance is viewed in relation to the trust and commitment processes.

**Trust:** Moorman, Deshpande and Zaltman (1993) define *trust* as a willingness to rely on an exchange partner in whom one has confidence and that an expectation of trustworthiness results from the ability to perform (expertise), reliability, and intentionality. Morgan and Hunt (1994) define *trust* as the perception of “confidence in the exchange partner’s reliability and integrity.” Doney and Cannon (1997) define trust as the perceived credibility and benevolence of a target of trust. According to them, trust primarily involves a *calculative process* (when one party calculates the costs and/or rewards of another party cheating or staying in the relationship), the *prediction process* (relies on one party’s ability to forecast another party’s behavior), the *capability process* (determining another party’s ability to meet its obligations), the *intentionality process* (the trustor interprets the target’s words and behaviors and attempts to determine its intentions in exchange), and a *transference process* which suggests that trust can be transferred from one trusted “proof source” to another person or group with which the trustor has little or no direct experience.

Commitment is recognized as an essential ingredient for successful long-term relationships (Morgan and Hunt, 1994) and refers to an enduring desire to maintain a valued relationship (Garbarino and Johnson, 1999). According to Schneider and Bowen (1999), security refers to the need to feel unthreatened by physical or economic harm. In a volatile stock market era, financial advisers establish investment portfolios suited to their clients’ risk limits and thus fulfill their security needs. Upholding a customer’s need for security involves the basic mental and emotional security concerns of the consumer.

Central to the development and maintenance of relationships is the establishment of norms of conduct that allow for future exchange and increased risk taking in the relationship. The most fundamental norm is trust, which provides the foundation for understanding expectations and for cooperation in the relationship. Relational trust facilitates joint learning activities. With relational trust, it is more likely that the parties share information they otherwise would consider sensitive and that they create constructive, creative dialogues around making sense of information they share, to the benefit of both parties. It also follows that as the parties build mutual trust, they are more likely to develop a shared memory with access across company borders (Selnes and Sallis, 2003).

## **Managerial Implications**

The competitive climate has changed rapidly in the last one decade in Indian financial market. At the same time, technological innovations in service delivery and changing expectations of consumers in this sector have induced offering of many new financial products and services. Since service providers have a primary objective to achieve consumer satisfaction, this research helps in identifying important dimensions for their service consumers.

Study has revealed that the twelve dimensions of service performance are valued by the customers. Three dimensions viz. employee attitude, employee knowledge and competence, and responsiveness can affect the service delivery. Managers have to focus on front line employees/ consumer contact employees by providing them training and education, job clarity, minimizing the role conflict. Employees need to be empathic to their consumers, skillful and competent, well versed in state-of-the art techniques, caring for the consumers, intimate and friendly with consumers, flexible to accommodate consumer requests, responding to consumers’ queries, and to be proactively communicative.

Product range that offers better choice is valued by the consumers as an important dimension of performance in financial services ranging from depository services to value added products. Consumers are also sensitive to price levels and expect price levels that are not high, deceptive, and/ or unfair. Additional services such as advisory services, providing expert knowledge to the consumers to enable them to take faster decisions is also viewed as performance criterion from the viewpoint of consumers.

While timeliness focuses on provision of information and service delivery at right time, complaint handling refers to solving the problem faced by consumers by establishing appropriate resolution procedures, interpersonal communication, and delivery of desired outcomes. The convenience related factor consists of three dimensions, viz. reliability, process simplicity including self-service technologies, and accessibility. Decisions relate to service system design, physical service environment, self-service technologies, technology facilitated transactions, reduced effort and waiting time, streamlining service performance and easy accessibility including locational convenience

and flexible hours of operations. The service managers have to formulate the trust development processes which are in line with the expectations of the consumers.

Thus, service managers need to identify the gaps in actual performance delivered to the consumers and their expectations. In accordance with the gap analysis, managers may have to undertake business impact analysis for each of the decisions for impact on service delivery performance. The framework provided in the paper allows service providers a better understanding towards designing service system in achieving increased consumer satisfaction.

## Limitations

Although the research focused on data collection from the executives about the dimensions that are important to customers based on respondents' own knowledge and experience in the field, there is a scope to do further research by directly collecting data from the consumers on service quality dimensions that are important to them. However, this research provides some guidelines to the researchers while initiating such studies as it provides the framework of perceived service quality for seeking responses on various dimensions of service quality. The proposed framework may not be applicable for all kinds of financial services and hence may need modifications of this conceptualization to make it more appropriate for specific services.

# Corporate Universities in an Era of Globalization: Strategic Evolution and Worldwide Trends

*Marcella Simon, marcella.simon@postgrad.curtin.edu.au  
Curtin University of Technology, Australia*

## Abstract

Since the 1990's, business and academic literature have paid increasing attention to the emergence and evolution of corporate universities in the USA and Europe and, more recently, in emerging economies, notably India. The paper reviews the emerging literature, both academic and corporate- in the context of current developments in corporate universities worldwide, notably the impact of new learning technologies, shifting functions and alignments with organizational goals, changes in composition and characteristics of teachers and learners, and increasing emphasis on partnerships with traditional universities and other stakeholders and service providers. Notwithstanding the growth in this literature, there has been striking a paucity of analysis of the development of corporate universities in the context of strategic issues such as global competitiveness and alignment with development of human capital. This survey of the current literature on corporate universities in their various forms and geographical locations will inform scholars and practitioners in the disciplines of Management and Education.

## Introduction

It is difficult to readily identify a distinct and well established scholarship on the subject of corporate universities (CUs). However, the term does appear throughout both academic and corporate literature with a range of definitions, connotations and implicit links with more established areas of management scholarship. CUs have been identified, described and analysed primarily in corporate training and education as well as human resource management (HRM) literature. Since the 1990's, references to CUs in the business and academic literature have paid increasing attention to the emergence and evolution of CUs worldwide and particularly in USA and Europe and, more recently, in emerging economies, notably India. As this paper contends, the salient features of CUs suggest strong relationships to the broader trends of globalisation, talent management and workplace learning. All three trends have established themselves in a well identified and growing business and academic literature. Nonetheless, there remains a striking paucity of consistent analysis of the evolution of CUs in relation to inter-related developments in globalisation, talent management, and workplace learning. This paper proposes directions for extending and enriching the extant analysis of CUs. Drawing on a critical review of the recent literature on CU, the paper recommends an integrated approach across emerging strands of literature on CUs as well as on globalisation, talent management and workplace learning. This will enrich our understanding of the contemporary and future evolution of CUs.

This approach in this paper is five-fold. First, the notion of CUs is examined critically by surveying definitions in the extant literature, reviewing reported trends in the incidence and typology of CUs, and summarising the dominant strategic perspectives used to describe CUs. Second, the scholarship on globalisation and its related impact on talent management and workplace learning are examined as a foundation for analysing the dynamics of the evolution of CUs. Third, to illustrate possible insights from working across these streams of literature, two questions which could be framed within a broader research agenda are advanced and elements of possible responses are drawn from disparate management and CU literature. This provides an indication of the utility of building a more unified framework for analysing the contemporary evolution of CUs. Fourth, the utility of the proposed integrated approach for analysing CU evolution is further motivated by examining regional patterns of both CU literature and actual practices of CUs. Finally, based on these literature and empirical surveys, a preliminary research agenda is sketched to more firmly frame future analysis of CUs within the related management scholarship on globalisation, talent management and workplace learning.

## Corporate Universities: A critical literature review

Using 'corporate university' as a key word, this researcher identified and reviewed 150 articles published during 1997-2007 as well as five books. This search revealed that the extant business and academic literature on CUs embraces a wide range of definitions and perspectives, all of which provide insights into the evolution, role, purpose, changing settings, and dynamics of CUs.

### Dominant Definitions and Attributes of CUs

In the business and academic literature, description and perspectives on CUs are wide ranging. CU definitions vary as do the functional attributes associated with CUs. Among the most frequently cited publications in the literature as well as pioneering books to use the term in the title is *Corporate Universities : lessons in building a world-class work force*, (Meister, 1998) which defines a CU as “the strategic umbrella for developing and educating employees, customers, and suppliers in order to meet an organization’s business strategies” (underline inserted). This compares closely to the definition in *The Corporate University Handbook* (Allen, 2002) :“A corporate university is an educational entity that is a strategic tool designed to assist its parent organization in achieving its mission by conducting activities that cultivate individual and organizational learning, knowledge, and wisdom” (underline inserted). Beyond definitions, these two and other sources in the CU literature fit differently within the constellation of entities which are self-styled CUs and those with different self-descriptions which nonetheless share CU-like attributes. This can be illustrated by considering CU target audiences, the distinction between CUs and traditional universities, and different nomenclature for entities with CU-like attributes.

According to Meister (1998), CUs largely offer learning programs exclusively to employees. However, some CUs, notably Motorola University, also include clients, partners, suppliers, and other stakeholders as participants. Walt Disney University actively markets and sells its programs to outsiders but still focuses on employees as its core business, distinguishing it from a traditional university (Allen, 2002).

Allen (2002) explains that a CU, unlike a traditional university or even a for-profit university such as the University of Phoenix, does not have education as its primary product offering. This is consistent with Walton (2005) who conducted a word search of websites for traditional and CUs and discovered little mission statement overlap between university and CU websites, other than a shared focus on “life long learning”. At the same time, there are former CUs such as the Arthur D. Little School of Management that have opened their services to the public and become traditional universities (Meister, 1998). There are also CUs that offer their employees credit for courses and degrees, but they are few in number and grant credit and degrees in partnership with traditional universities. (J.Meister, 1998; S. Taylor and Paton, 2002).

The CU nomenclature alone is inadequate for identifying entities which carry out the functions described above. Other entities share the functional attributes of CUs implied in these definitions. Yet they do not carry one or the other of the two words in the compound term “corporate university.” For example, an entity sharing the functional attributes of self styled CUs can also be called an institute, school, academy, varsity, centre, or college, depending on the inclination of the organisation (“The corporate university: riding the third wave,” 2005; S. Taylor and Paton, 2002). Some studies suggest that half of all CUs do not have the word university in their title (Prince and Beaver, 2001). Similarly, the label “corporate” does not appear in some important entities which nonetheless share attributes of CUs according to different definitions. They included public sector institutions and non governmental organizations. For example, in the *Handbook of Corporate University Development*, (Paton, Peters, Storey, and Taylor, 2005) L. Taylor and Fryer, (2005) profile the issues and challenges in implementing a CU for the massive National Health Service in the UK.

The description, functional analysis and nomenclature of the CU phenomenon are therefore diverse. It is noteworthy that both Meister (1998) and Allen (2002) refer to the “strategic” character of CUs. In fact, the role of the CU as “umbrella” or “tool” which aligns learning programs with organizational objectives is the most widely accepted concept in the literature and distinguishes the CU from a traditional training department (Walton, 2005). A benchmarking study from Corporate University Exchange (“Update on CUs,” 2005), defines CUs as tying “corporate learning efforts directly to overarching business goals.” Further analysis below refers to this strategic character of CUs. This attribute provides for analytical links to the inter-related phenomena of globalisation, talent

management, and workplace learning. These phenomena are posited in this paper as fundamental to understanding the dynamics of evolution of CUs.

#### **Prevalence and Drivers of CU evolution**

Another significant aspect of CUs concerns their evolution and projected growth. These have been reported in different ways. Walton (2005) estimates that there are over 2000 CUs worldwide. According to Andresen and Lichtenberger (2007), as of the turn of the century, forty percent of the Fortune 500 companies had established CUs. Salmi (2000) reports predictions by 2010 of the number of CUs outnumbering traditional universities.

The prevalence and projected growth of CUs are impressive. It is useful to also briefly consider the historical origins of CUs as well as factors underpinning the growth in their numbers. The existence of CUs can be traced back to the post WWII era. The General Electric John F. Welch Leadership Centre at Crotonville is an often cited example of a CU prototype founded in the 1950's which has withstood the test of time and continues to evolve (Durett, 2006). Another CU prototype is "Hamburger U" at McDonald's ("Face value: The burger king," 1999; Galagan, 2006). Both can be seen as among the forerunners of CUs which remained few in number until the 1980's, when the term was introduced in the literature (S. Taylor and Paton, 2002). CUs then rose in popularity during the 1980's in the USA and during the 1990's in Europe ("Strategy by degrees," 2005). An analytical review of the CU literature indicates that this growth has largely been analysed as a response to the following drivers:

- Emphasis on knowledge management and the learning organization (Altman and Iles, 1998; Jansink, Kwakman, and Streumer, 2005)
- Availability of learning technologies enabling a company to offer employees standardized products and processes at a distance and removed from time constraints (Murray, 2005; Watkins, 2005).
- Increasing global competition for skilled employees, particularly at the managerial level (Authers, 1999).

#### **Strategic Perspectives on CU Design**

As strategic tools of organizations CUs, as defined above in the extant literature, tend to reflect organizational cultures (Barley, 2002). This strategic dimension of CUs is also distinct from other issues such as organization, governance, funding, staffing, marketing, technology, and metrics. All these are significant issues in the development and implementation of a corporate university initiative and also constitute the main focus of the extant CU literature (Allen, 2002; J. C. Meister, 1998; Paton et al., 2005; Wheeler and Clegg, 2005) These tactical and operational issues are however not a focus of the present paper. Instead, this paper takes the strategic characteristic of CUs, as identified in the extant literature, as a fundamental point of departure for exploring the evolution of CUs to developments in globalisation, talent management and workplace learning.

There are several strategic perspectives for CUs found in the literature. This researcher has categorized four: structure oriented (content and mode of program delivery), developmental (stages of CU maturity within and across organizations), role oriented (function and purpose within the organization), and process oriented (how the CU supports and aligns with key organizational processes and strategies). As illustrated below, these four perspectives are useful in analysing CU evolution over time and in different localities.

Structure-oriented perspective: Salmi (2000) discusses the range of modalities of delivery, whereby a CU may operate under any combination of delivering courses or programs : (1) via a network of physical facilities (Disney, Toyota, Motorola); (2) completely virtually via e-learning (IBM, Dow Chemical); or (3) via partnerships with traditional universities (Bell Atlantic, United Technologies). Although many CUs outsource portions of their CU programs and operations to private educational firms or institutions of higher learning, several companies such as Accenture offer complete outsourcing of CU services from design and development to delivery and calculation of ROI (J. Meister, personal communication, March 11, 2007). S. Taylor and Paton (2002) offer a typology of CUs along two dimensions: (1) the nature of learning from basic skills training to more advanced forms of knowledge sharing and research; and (2) the mode of delivery from completely virtual to classroom and campus based. Based on these axes, there are four archetypes of CUs: (1) the "training school", exemplified by McDonald's Hamburger U., delivers skills training in a classroom setting; (2) computer based training on the company intranet such as Shell Open University; (3) the "chateau experience" where leaders get away from the pressures of daily work to bond and strategize such as Boeing's Leadership Development Centre; and (4) the "polymorphous" university exemplified by Cap Gemini Ernst & Young, which may offer a combination of (1), (2), or (3).

Developmental perspective: Using data obtained at a 2000 global corporate university conference, Rademakers and Huizinga (2000) identify three phases of CU development: (1) fragmented training operations are centralized and the goal largely remains skills training and knowledge dissemination; (2) the linkage with company strategy is formed and CUs become the “knowledge backbone” of the organization; and (3) organizations actively generate and disseminate knowledge utilizing largely internal resources such as internal case studies and managers as instructors.

Role-oriented perspective: Fresina (1997) describes three distinct strategic roles of the CU within the organization: (1) reinforcing and perpetuating behaviour that reflects the organizational culture; (2) managing change; or (3) driving and shaping the organization. Wheeler (2002) employs a similar taxonomy when categorizing CUs according to drivers at the firm level: (1) using the label of “university” to gain prestige; (2) employee competency and career development; (3) leadership development to provide for effective management teams and succession planning; (4) alignment with specific business strategies such as globalisation, productivity, process improvement, and/or empowerment; (5) business development initiatives exploring, developing, and planning for new opportunities; (6) educating and managing the customer and supplier relationship; or (7) change management facilitating a “transformation process as a company embarks on a new strategy or is in the process of merger or acquisition.”

Process-oriented perspective: Prince and Stewart (2002) describe four types of processes present in the organizational context of a CU: (1) knowledge systems and processes including the technology for capturing, analysing, and disseminating knowledge; (2) networks and partnerships, both internal and external to the organization; (3) people processes including HRD policies, programs, and procedures; and (4) learning processes including creating a culture for learning supported by top management. At the centre of this model lies the CU as a conduit and facilitation device, linking and aligning to these key processes through information sharing, coordination, evaluation, and other activities. Andresen and Lichtenberger (2007) identify two types of CU strategies: (1) CU learning strategies that are directly aligned with organizational strategies; and (2) contextual strategies that have an indirect effect. Learning strategies evolve in their complexity from employee skill delivery to business initiatives and environmental scanning. Contextual strategies include knowledge management, boundary spanning, and dissemination of a common organizational culture and vision.

#### **Evolution and Sustainability of CUs**

In keeping with its focus on the strategic aspects of CUs, the literature review in this paper assessed what the extant literature considers to be the strategic value of CUs, how this value is measured and sustained, and how CUs evolve in response to changing strategic challenges of corporations. Here too, there is a wide range of views in the extant literature, as is selectively illustrated below.

Field (2005) reports that CUs have been shown to improve employee performance and reduce turnover. At the same time, Taylor and Patton (2002) report that CUs can and do occasionally fail, due to an inability to cope with rapid changes in corporate structures and policies. CUs are increasingly becoming means for parent organizations to demonstrate good corporate citizenship. The University of Toyota, for example, opens its doors to outside organizations that are able to benefit from their “lean thinking” manufacturing process and has provided training to the U.S. military and police departments at no charge (Spector, 2007).

Also noteworthy is the evolution of CUs in response to strategic opportunities and challenges. According to the Corporate University Exchange (CUX, 2006), the sustainable CU model has evolved from that of a traditional university to the structure of a corporation and is likely to be “virtual”. Teare (2004) also predicts that CUs will be less reliant on the symbols and trappings of traditional universities as they deliver a “parallel, equivalent, but different paradigm in business and management education.” CUs are also changing in response to evolutions in adult education and workplace learning. Blended solutions, action learning, communities of practice, podcasting, just in time learning, and simulations are increasingly part of the CU repertoire. There are also numerous firms offering outsourced learning solutions to CU clients and an enhanced willingness on the part of business schools to create joint degree and non-degree programs with CUs (Meister, 2006).

Clearly, elements of strategic evolution of CUs appear in the literature. Yet, it is striking that there is little focus as well as little or no consensus on how CUs have evolved in response to strategic business challenges which elsewhere have been linked to globalisation. For example, business response to the challenge of global talent

management would be an obvious shaper of CU evolution. Rademakers and Huizing (2000) conducted a survey at Global Corporate University week in 2000 and did not find talent management to be a priority for CUs. However, according to (CUX, 2006) and (Field, 2005) talent management and leadership development have become top priorities for CUs worldwide, increasing the sustainability of CU influence within the organization. As suggested below, a research gap may lie in the interstices between the extant CU literature and the inter-related literature on globalisation, talent management and workplace learning.

## **The Impact of Globalisation on Talent Management and Workplace Learning**

This paper argues for the heuristic value of linking the analysis of CU evolution to the dynamics of three related developments – globalisation, talent management, and workplace learning. Relevant aspects of the literature on these topics are reviewed here to help situate and analytically frame the contemporary dynamics of CU evolution.

Part of the difficulty of relating the phenomenon of CUs to globalisation may be that definitions and analyses of the latter abound and vary. Nonetheless, this paper argues that most analyses of globalisation which are relevant to CUs tend to share a common concern with capturing a series of economic, political, technological, demographic, cultural, and other shifts which are shaping the size and nature of the global marketplace. Within this plethora of definitions, globalisation can be broadly typified as the “complex integration of capital, technology, and information across national boundaries in such a way as to create an increasingly integrated world market...” (Salmi, 2000). While the literature of globalisation generally recognises it as a phenomenon that is not new, much emphasis is placed on the impact of the contemporary process of globalisation on shaping the behaviour of firms facing an increasingly competitive environment. At the same time, globalisation has ushered distinctly different processes of internationalisation as so-called “born global firms” and “international new ventures” have emerged which are international players almost from inception in contrast to older and more established multinational enterprises (MNEs) which internationalised starting from a strong home country base (Mathews and Zander, 2006). Future CU evolution could parallel this new dynamic of international firm creation, with both phenomena being closely related to globalisation. They are therefore further considered in the research agenda on CUs proposed in this paper.

Related to globalisation is the challenge of talent management which this paper contends is central to understanding the future evolution of CUs. Chambers, Foulon, Handfield-Jones, Hankin, and Michaels (1998), in a landmark article published in the *McKinsey Quarterly*, introduced the concept of a growing “war for talent” and the need for firms to undertake a process of strategic talent management. Talent management situated in the context of human resource or human capital management can be defined as the strategic recruitment, development, and retention of talent for competitive advantage (Michaels, Handfield-Jones, and Axelrod, 2001). Focussing on relevant issues for CU evolution, the following citations from the talent management literature highlights six global workforce trends that impact upon and inform talent management developments and practices in the 21<sup>st</sup> century.

- Demographics in developed countries (USA, Europe, and Japan) have resulted in an aging population, many of who are retiring early. These trends will result in a severe shortage of skilled labour, exacerbated in nations reluctant to import large numbers of immigrants to compensate for the loss (Frank and Taylor, 2004).
- Both workers and jobs are becoming increasingly global, with the number of jobs in high-wage locations moving offshore set to increase dramatically, although estimates differ (Tucker, Kao, and Verma, 2005; Farrell, Laboissière, Pascal, Rosenfield, de Segundo, Stürze, and Umezawa, 2005).
- Technological advances have enabled a surge in remote working arrangements and virtual teams. The ability to network across time zones and cultures has become an imperative in a global talent supply chain (Pucik, 1996).
- Due to economic and demographic changes, as well as migration patterns, the global workforce is increasingly diverse, necessitating cross cultural skills in communication, teamwork, and leadership at all levels (Rodriguez, 2005).

- Technical innovations that have created products and processes that are “information” intensive, giving rise to a new skilled category of employee termed the “knowledge worker.” This class of worker has become “autonomous and empowered” on decisions affecting working conditions and career paths. (Tucker, Kao, and Verma, 2005).
- With increasingly complicated global operations and an increasingly diverse workforce working at locations around the world, some virtually, there is a pressing need for global leadership competencies at the managerial level (Cabrera and Bowen, 2005).

This paper contends that the above related developments in globalisation and talent management are fundamental shapers of the contemporary evolution of CUs. In order to more robustly frame the contemporary dynamics of evolution of CUs, these factors should be considered in conjunction with related shifts in the nature of workplace learning. Workplace or enterprise based learning situated in the context of human resource or human capital development has traditionally occurred at the individual level to provide the firm with sufficiently “trained” personnel. However, attention is beginning to be paid to the motivational aspects of learning, particularly as the need to attract and retain talent intensifies. At the individual level, the opportunity to learn is a both a motivating force and a career necessity in a rapidly changing and sometimes unstable economic environment. In 2005 Towers Perrin undertook a survey of 86,000 employees in 16 countries, focusing on workplace practices that influence employee motivation. They found “the most important element influencing engagement, defined as the “willingness and ability to contribute to the organization’s success,” is the possession of sufficient opportunities to learn and develop new skills” (O’Neal and Gebauer, 2006). Firms are quickly realizing that “high performance global companies must create an inclusive culture where people are self challenged...”(Jacobs, 2005). The MOW study assessing the relative importance of managerial work goals across eight Asian nations found the “opportunity for learning” to be a universal preference (Pearson and Chatterjee, 2004). Edwards, Raggatt, Harrison, McCollum, and Calder (1998) address life long learning in the context of globalisation as a “key instrument in developing a competitive, multi-skilled workforce.” The article also mentions the strategic imperative of work place learning in the life long learning context in dealing with ever changing career paths and uncertain economic environments, necessitating individuals to continuously update their resumes with new competencies.

Notwithstanding this traditional and continuing focus on individual skills as a major thrust in workplace learning, attention is also starting to shift toward the concept of the “learning organization” whereby learning becomes a collective and sustainable process embedded in organizational systems and culture (Marquardt, Berger, and Loan, 2004). The literature on the “learning organisation” has also evolved in tandem with a closely related literature of knowledge management which has also grown in recent years partly as a result of competitive pressures related to more rapid global diffusion of information. Although not a focus of this paper, these developments are noteworthy because of the implications they have for how organisations structure themselves to better acquire and use knowledge at the global level. Indeed, to a large extent, the recent evolution of CUs can be seen as a response to the imperative of effective organisational learning and knowledge management processes coupled with a drive for acquiring, developing and retaining scarce global talent (“Survey: Everybody’s doing it,” 2006; S. Taylor and Paton, 2002). This paper suggests that a preliminary analytical framework for integrating analysis of CUs into established areas of management scholarship can be found at the nexus of the scholarship on globalisation, talent management, and workplace learning with certain overlaps into scholarship on organisational learning and knowledge management. Pointing to a possible broad research agenda on CU evolution, the next section illustrates the scope and utility of bridging CU literature with other areas of management scholarship. It posits two research questions on CU evolution which could draw on both empirical elements of the extant CU literature and concepts from the three areas of management literature considered above – globalisation, talent management, and workplace learning

## The Dynamics of Corporate University Evolution in the Context of Globalisation

Although “corporate universities are a global concept” (Monga, 2006), the CU literature surprisingly contains very limited direct references to the impact of globalisation on CU products and processes. The scant academic and corporate literature on CUs in a global context largely consists of case studies of MNE workplace learning strategies addressing specific issues such as global leadership development. Other literature specifically focused on CUs discusses the development of the phenomenon in specific geographic contexts (U.S and Europe) and most recently, in emerging markets (e.g. India), as also documented below. Nonetheless, several “entry points” are available to bridge the CU literature with established management literature and through which the phenomenon of CU evolution can be more robustly and analytically framed in relation to globalisation, talent management, and workplace learning. This discussion underpins the research agenda proposed in the conclusion of this paper.

One entry point is the abundant literature on the internationalisation of human resources development and enterprise learning, both as structural responses to changes in the dynamics of international business and as specific competencies for leaders, managers, and employees. Pucik (1996) points out that MNEs have traditionally focused on expatriate management selection and support to the detriment of an organizational culture that is truly global. Grainger and Nankervis (2001) posit that globalisation has transformed the nature of business operations and subsequently the role of the expatriate and expatriate preparation and training. Expatriates have increasingly been joined by international managers who are locally or regionally based and global managers, who may be third country nationals. Global managers will require a broader set of knowledge and skills, ostensibly that come with experience as well as formal learning. Regarding the competencies required in the international firm Marquardt and Berger (2003) and Marquardt et al. (2004) emphasize the need for learning at the individual and organizational level that will address: (1) leadership development; (2) basic educational skills; (3) cross cultural competencies for overseas assignments and global teams; and (4) policies that are strategically aligned globally and locally responsive, entitled “glocal.”

The set of knowledge and skills mentioned above, coupled with a global organizational awareness and paradigm shift have been abundantly referenced in the literature as “global mindsets”. A global mindset can be defined as “an openness to other cultures that facilitates international dealings and decisions” (Rhinesmith, 1995). Global mindsets can exist at the individual and organization level. Gupta and Govindarajan (2002) illustrate an advanced organizational global mindset by quoting the CEO of a U.S. based household accessories company’s strategy as “combining Chinese costs with Japanese quality, European design, and American marketing.”

Although discussion of global competencies and mindsets usually takes place at a managerial or executive level (Dainty, 2005), the literature contains examples of international adaptations in perspective and behaviour by front line employees and their supervisors in global service delivery firms. Traditionally these firms have been located in the tourism and hospitality industries, but due to increases in outsourcing and offshoring, have been joined by financial services, IT, the consulting industry, and call centres. In his book on global call centres Granered (2005) discusses employees’ awareness and adaptation to the cultural values and communication styles of customers worldwide as a success variable. He also makes specific recommendations of training activities based on best practices in global customer service in the hospitality industry, such as the Ritz Carlton (“The Ritz-Carlton Company: How It Became a 'Legend' in Service,” 2001). In their book on multicultural customer service (Aguilar and Stokes, 1996) provide a framework and exercises for training employees in cross cultural awareness and techniques based on the Walt Disney Company’s success in creating international tourism destinations.

These emerging strands of literature can suggest at least one significant research question relevant to the evolution of CUs. How can and how do multinational companies employ workplace learning and, more specifically CUs, in building a global corporate culture? Possible responses to this research inquiry can be extracted and synthesised from the disparate management and CU literature. Ananthram and Chatterjee (2004) identify “boundary spanning activities” and international experience as key factors in nurturing global mindsets. Boundary spanning activities can include “international strategic alliances, joint ventures, international mergers and acquisitions, international supplier agreements, global responsibility designations, global team participation, ad hoc project groups, networks, shared tasks or jobs across national boundaries.” While some of the activities listed above are the

consequence of strategic global decisions, others can be designed and implemented as learning activities to enhance global awareness and strengthen mindset competencies at multinational organizations.

This line of inquiry can be pursued by borrowing from Wisniewski and Laubenthal (2006) who posit a global learning culture framework that requires learning operating structure and protocols, technical communications capabilities and a “cultural exchange program that increases buy-in, promotes understanding and shares best practices.” Applying the concepts from Ananthram and Chatterjee (2004) and Wisniewski and Laubenthal (2006), empirical responses to the research question above can be found from examples of formal and informal global learning initiatives in the CU literature. Meister (1998) describes tactics taken by mature CUs such as Motorola and General Electric to create global awareness and share best practices worldwide such as benchmarking field trips for executives followed by teams of technical and staff workers. GE has opened their training centre at Crotonville to high potential Chinese managers from other companies as potential partners (Meister, 1998). Stanek (2001) at General Motors recommends global mentoring programs as a means to identify and develop the mindset of high potentials worldwide. TRW, a global technology, manufacturing, and service company headquartered in the U.S. has created a 20 day “global leadership program” whereby senior managers from worldwide operations are brought together for campus based learning and a team based action learning assignment in a TRW country location (Neary and O’Grady, 2000). Ernst & Young regularly conducts cultural exchanges of learning experts worldwide, even periodically pulling local subject matter experts off their regular jobs to build global content libraries with learning teams at headquarters (Wisniewski and Laubenthal, 2006). Heineken, with 60,000 employees in 170 countries, established Heineken University in 1998 and hosts 1300 employees annually at its Amsterdam learning centre along with provision of an extensive virtual business education program, culminating in the Heineken Business Challenge, an annual global entrepreneurship simulation (Pollitt, 2005).

Broadly related to the above is another illustrative research question pertaining to the evolution of CUs in the context of globalisation, talent management, and workplace learning. How can MNE CUs help meet the twin challenges of developing a global corporate culture while operating in diverse cultural environments?

The experience of Motorola University, one of the best known examples of a CU as global learning enterprise, provides some insight. Motorola University was established in 1979 and has grown into a worldwide facility covering 100 sites in 24 countries (Shaw, 2005). Motorola is known as a training and development leader, requiring all employees to complete at least 40 hours of training per year (Authers, 1998). Motorola University China was established in 1993 and launched a range of educational programs for customers and suppliers in 2002 (Goff, 2002). This expansion represented a major investment in human resource development, particularly the development of a managerial cadre and the emphasis away from traditional training to strategic learning partnerships in the region (“Motorola University and higher education- the exception that proves the rule?,” 2003).

China particularly experiences a lack of managerial talent in the 40-50 year old age cohort due to an interruption of education during the Cultural Revolution of 1967-1976 (Law, 2006). The new high potential Chinese workers, dubbed “high flying dragons” are motivated by career advancement and the opportunity to work overseas. China also faces the same shortage of “soft skills” capabilities due to a tradition of emphasising technical skills in the education sector (“China discovers its soft side,” 2006).

In order for Motorola and other MNEs with CUs in China to be successful in utilizing their CUs to attract, develop, and retain the next generation of “high flying dragons” and create global managers with local capabilities also known as “glocal” managers- they may need to combine Western style principles such as meritocracy and equity with traditional cultural values and practices (Shaw, 2005; Dam, 2005). Motorola’s emphasis on long term relationships in China is compatible with the “long term orientation” identified as a cultural dimension in Asian countries, particularly China (Hofstede, 2005). However, according to Shaw (2005), cultural barriers still exist in the adoption of e-learning as opposed to traditional classroom instruction and forms of management development, such as coaching which breaks down traditional “guanxi” relationships.

## Worldwide Evolution of CUs: a Comparative Literature and Empirical Review

Before extending the two illustrative questions above into a broad research agenda, it is also useful to briefly consider how both the CU literature and CUs themselves have actually evolved in various geographic settings. This further motivates the general interest in this paper in the impact of globalisation on CU evolution. The emphasis below is on broadly comparing CU developments in Triad and periphery economies as well as other regions with a view to motivating unexplored questions in various settings regarding the future evolution of CUs. These include issues of possible future convergence and divergence in MNE CU practice worldwide, shaped by twin global and local forces impacting on MNEs.

### **The Comparative Development of CUs in Triad Economies: the United States, Europe, and Japan**

Europe and the United States provide interesting cases of both comparison and variance in their CU literature as well as CU practices. One noteworthy pattern in CU research is the predominance of corporate literature over academic literature in the U.S. and the reverse in Europe. In the U.S. benchmarking research has largely been performed by consulting firms and disseminated as industry newsletters and reports by private organizations such as the Corporate University Exchange (CUX), International Quality and Productivity Centre (IQPC), Corporate University Enterprise (CUE), and Best Practices, LLC. Most of the peer reviewed literature in English found by this researcher originated in universities in the United Kingdom, followed by the Netherlands and Germany. The Open University Business School in the UK, for example, has established a Corporate University Project, which “aims to provide the first analytic and empirical study of a significant development in workplace-based learning” (“The Corporate University Phenomenon,” 2005).

Although CUs grew in popularity in Europe in the 1990s, their numbers are by some accounts still in the low hundreds. This is relatively small compared to the U.S. (Blass, 2005). Common practices in the U.S. and Europe include “running training centres as businesses, involve leaders as teachers, influence how and what people in the company learn, measure the value of their investments in education, and experiment and coordinate and innovate new partnerships with universities and business schools” (Blass, 2005). Among European MNEs with well established CUs are Lufthansa, Siemens, Daimler Chrysler, Heineken, BAE Systems, Isvor-Fiat, Body Shop, Nestle, and Unilever. In one of the few comparative case studies of CUs, Renaud-Coulon (2002) examined CUs in nine European countries and discovered some distinctions from the U.S. model such as a greater reluctance to use the label “university”, a more selective learner base comprised of more executives and high potentials and fewer customers and suppliers, more limited use of rewards and diplomas, more use of the “chateau model” (Prince and Stewart, 2002), and more frequent use of the “cost centre” rather than the profit centre financial model. Andresen and Lichtenberger (2007) conducted an analysis of 15 CUs in Germany with comparable size to their U.S. counterparts and also found a more limited selection of learners but a “wider range” of action internationally.

Although Renaud-Coulon (2002) described a reluctance on the part of European CUs to adopt e-learning solutions, Bradshaw (2000) reports that several European Universities have been recognized by Corporate University Exchange for their development of online teaching including Lufthansa’s School of Business, Cap Gemini Ernst & Young University, and the University for Lloyds TSB. Lufthansa, the first CU in Germany founded in 1998, has also been recognized for their innovative use of partnerships with business schools (“Another award for Lufthansa’s corporate university” 2007). An interesting development in Europe has taken place around the Corporate Learning Improvement Process (CLIP) administered by the European Foundation for Management Development and adopted thus far by Daimler Chrysler Financial Service Academy and ten other leading European CUs (Boone, 2006). CLIP serves as a quality assurance and accreditation mechanism that involves a review process lasting several days, allowing self assessment against benchmarked practices (Anderson, 2005).

CU developments in Japan illustrate many of the imperatives of globalisation. Major Japanese corporations such as Toyota, Nissan, and Fujitsu, have established CUs with extensive global networks. Mike Morrison, dean of the University of Toyota, founded in 1998, has written of his experiences designing a university that supports dealers and employees worldwide (Morrison, 2002). Although the University of Toyota is headquartered in California, the principles of *kaizen* (continuous improvement), signifying small changes as opposed to the American

tendency for bold moves, and *genchi genbutsu* (go look, go see) are displayed on the walls and incorporated in “lean enterprise” training principles and practices such as “just in time” learning (Spector, 2007; Summerfield, 2002).

#### **CUs in Emerging Markets: The Indian Experience**

Paradoxically, emerging economies with huge labour pools, such as India and China, perhaps best illustrate the imperative of CU evolution driven by talent management needs. Over the past five years, increasing attention has been paid to the rapid growth of the Indian economy and specifically the international success of Indian firms in the IT industry (Sengupta, 2006a). Despite India’s growing population and number of graduates from institutions of higher education, the Indian economy is facing a “talent famine” where qualified individuals are in short supply (Sengupta, 2006b). There is expected to be a 500,000 labour shortfall in the IT sector alone by 2010 (“Survey: The world is our oyster,” 2006). Opportunities have lured back Indian expatriates (Pocha, 2007), Indian companies are going abroad to recruit technical talent in North America, Europe, and Australia (Sengupta, 2006a) and outsourcing technical operations in rival economies such as China (Rai, 2004). Indian firms are also facing another problem with regard to talent; graduates of public institutions in India often lack the ability to transition from a somewhat rigid academic system into fast paced industries that require flexibility, problem solving, and adaptive leadership (Mahajan, 2007).

As with the situation in China described above, MNEs in India have undergone initiatives to develop a pipeline of job-ready employees, using the resources and expertise of their CUs. IBM Corp. is establishing a Development and Executive Centre in Bangalore that will, among other strategic initiatives, enhance the software development skills of Indian students (“IBM Triples Investment in India,” 2006). Motorola University, teaming with government and private sector partners, is opening the Motorola School of Communication Technology in Hyderabad, offering higher education and research and development opportunities spanning IT and telecommunications industries (“Motorola U to set up school in India,” 2000).

Indian firms are developing workplace learning initiatives to keep pace with the need for technical and managerial talent. Of the 29 organizations lauded by the American Society of Training and Development for their ability to “leverage learning to achieve amazing results”, five were Indian firms: Tata Consultancy Services, Wipro Technologies, Reliance Industries, ICICI Bank Limited, and Gecis International Holdings (“29 Organizations That Leverage Learning To Achieve Amazing Results,” 2005).

Among rapidly growing Indian firms are “born international” enterprises that must almost from inception, attract, develop, and retain talent worldwide. Raghuram (2001) wrote a case study focused on the human resource development challenges faced by Infosys, an IT consulting and services firm headquartered in Bangalore. Leadership development and promotion occurs in a compressed format, whereby a new 22-year old hire may become a manager at age 24 and a vice president at 35 years. In response, Infosys has invested 300 million dollars (US) in building a CU in Mysore with the capability of training 13,500 people at one time (“The Academic System Is Not Market Responsive; A BT-NASSCOM panel ponders on a looming qualitative talent crunch, and looks for longer-term solutions,” 2007). Infosys was the first company founded in Asia to receive the Corporate University Exchange Excellence award for “aligning corporate learning to business strategies” (“Infosys wins prestigious Annual Corporate University Xchange Excellence Award for ‘Aligning Corporate Learning to Business Strategies,’” 2002).

Satyam Computer Services, another Indian IT and consulting services firm, has experienced an expansion of staff from 100 to 30,000 associates worldwide in 15 years. The Satyam School of Leadership, located in Hyderabad, was founded in 2005 to provide “entrepreneurial leadership opportunities” to the top 5 percent of associates in defined areas, thus “growing leadership” faster than the competition (“Satyam Plans Corporate University to open the Satyam School of Leadership to develop and nurture leaders to accelerate the company's growth,” 2005). Eighty per cent of Satyam’s learning programs take place virtually or in an alternative to classroom based learning such as “coaching, mentoring, job rotations, and self study” (Cohen, 2007).

#### **CU Development in Other Regions**

There is a variety of literature focusing on CUs in other regions. Canadian organizations have been recognized in the literature for their innovative learning programs such the Bank of Montreal Institute for Learning (El-Tannir, 2002), the TELUS Corporation’s Leadership Expectation Program (“29 Organizations That Leverage Learning To Achieve Amazing Results,” 2005), and the Eaton School of Retailing, which was founded in partnership with a Canadian

university in 1994 to train Eaton employees but has now branched out to other retail organizations (Morin and Renaud, 2004).

Australia has a long tradition of distance education and corporate partnerships with traditional universities to develop and deliver learning initiatives (Dickson, 2002). Holland and Pyman (2006) conducted a case study of the Coles Myers Institute, CU of the largest private sector employer in Australia and found a strategic focus on career development at all levels, including certificates and diplomas offered in conjunction with Deakin University.

According to Gqubule (2006), CUs are making an inroad in South Africa. SAB's Training Institute, founded in 1992, is the oldest recognized CU in South Africa, offering on site programs as well as on-the job "learnerships" in all aspects of the business. A unique life skills program is entitled "resilience" and serves to reinforce organizational loyalty ("Investing in people," 2006). Finally, while there is evidence of a growing CU presence in Russia (Skovorinsky, 2006), Brazil, and the Middle East (CUX, 2007) the literature on developments in these location is not readily accessible or scarce within corporate or academic journals.

## **Conclusion: Towards a Unified Analytical Framework and Future Scholarship on CUs**

It would be presumptuous to presently specify a single appropriate or even likely set of future models for CUs, especially for MNEs, based on our presently available research on both CUs and globalisation and our understanding of the contemporary dynamics of CU evolution under globalisation. However, at least four significant developments can be identified or postulated, based on developments reviewed above, as an indication of how globalisation might plausibly shape the evolution of CUs worldwide:

- The talent shortage experienced by MNEs worldwide and an emerging role for CUs as motivators as well as developers of talent;
- The imperative of global companies to develop specific competencies needed in a global climate and the related role of CUs in developing and delivering these competencies;
- Some limited evidence of convergence as well as divergence in CU practice (notably in contrasting experience of the US and Europe) as well as twin global and local shapers of MNC CU strategies; and
- Specific CU innovations in firms situated in the periphery, especially in emerging economies, and specifically in the case of "born global" firms emerging in these and other economies.

These developments themselves suggest a rich and useful research agenda which can draw from a synthesis of findings and approaches from the CU literature and emerging research in globalisation, talent management and workplace learning. More specifically, and drawing on the limited and selective review above of these streams of literature, the following non-exhaustive set of research questions, among others, can be suggested as fruitful areas for further inquiry:

- If workplace learning strategies can be used to attract, develop and retain talent in MNEs, what roles can CUs play to implement these strategies?
- How might CU strategies vary among MNEs with a globally diverse workforce according to imperatives of fostering a global corporate culture versus adapting to possibly different workplace learning requirements which are determined by specific culture and locality?
- Are there patterns in CUs of "born global" firms and newly emerging MNEs from the periphery which suggest distinctly new approaches to workplace learning and talent management compared to past CU strategies in more established MNEs?

In conclusion, it is suggested that various streams of literature briefly and selectively reviewed here can all benefit from a more unified approach to these and other related questions and also enrich our grasp of the strategic, comparative, and dynamic aspects of CU evolution as underpinned by globalisation.

## Abstracts

The purpose of the current study was to investigate and compare similarities and differences among three major ethnic groups as consumers of post-graduate education (i.e., Western-Australians, Eastern-Asians and Eastern-Indonesians-Malaysians). Central was the mediating role of personality factors (i.e., self-construal and perfectionism dimensions) in the relationship between culture and complaint or compliment behaviors noted in postgraduate business education at Curtin University of Technology. The quantitative research design depicts an understanding of the relationships between cultural links among personality factors and complaint/compliment strategies; findings confirm sundry aspects of cultural links. Results also indicate a strong statistical significance demonstrating differences among the three major ethnic/cultural groups in relation to independent self-construal, interdependent self-construal and socially prescribed perfectionism; these differences influence the inclination of post-graduate business education students to select particular communication strategies, and demonstrate that complaint and compliment strategies in higher business education are affected not only by ethnic origin, but also by personality factors which underlie consumer behaviors.

## Introduction

In today's climate, this is imperative as the growing importance of marketing higher business education, use of marketing techniques and increasing enrolments of international students within Australia put pressure on tertiary institutions to create a greater awareness of their offerings. In marketing, customer satisfaction is the basic entry point for business practices to provide good service quality by setting higher barriers to market entry and reinforcing organizational competitive advantage. Evidences have indicated that, across cultures, there are differences and similarities in the process of customer satisfaction and behavior intention (Liu, Furrer & Sudharshan, 2001; Liu & McClure, 2001; Barnlund & Araki, 1985).

The extant literature on customer satisfaction has its roots in marketing; higher education has been managed under somewhat different environments and situations than private 'for-profit' organizations. Athiyaman (1997) clarified the relationship between perceived quality and satisfaction within university education and suggested that all service encounters should not be forgotten that the purpose of services is student satisfaction. In the application of customer satisfaction theory to higher education in business it has been argued that students are not always customers (Alford 2002), but a quarter of the role (Guolla 1999), and that higher business education is not 100% about business practices as other business industries, but an example of quasi-commercial activities (Brookes 2003). According to the perspective of above cited role play, it is very stressful for an organization's service provider; being in a passive position depends on receiving the corresponding feedback from satisfiers and dissatisfiers.

Ideally, as highly satisfied people spread positive word-of-mouth or highly dissatisfied people spread negative word-of-mouth among students, peer word-of-mouth acts as a powerful influence which is a free walking, talking, living advertisement for any educational institutions, Especially in Asian countries, the word-of-mouth referral behavior is common (Money, Gilly & Graham 1998). Essentially, the possibility for satisfiers or dissatisfiers at the completion of their studies, whereby students complain/praise to institutions and service providers directly or indirectly via sundry channels, should be given a great deal of attention. With the increasing use of the Internet, word-of-mouth communication among satisfiers or dissatisfiers will spread faster and further when the phenomenon

of communication breaks geographical boundaries; it drives many service practitioners to re-focus on students' reactions on service quality.

In higher education of business, hundreds of publications on the subject of quality, such as quality management frameworks (Owlia & Aspinwall 1996; 1998), student satisfaction (Athiyaman 1997), measuring customer satisfaction in higher education (Aldridge & Rowley 1998), research has been geared strongly toward demonstrate students' psychometric performance, but examination of the effects on behavioral responses across culturally has received very little attention. In practice, managing to moderate or reduce the dissatisfaction of current customers/consumers can protect an organization's market share, profitability and product positioning. Unlike complaint behavior, compliment behavior has received little attention.

No matter whether students use complaints and compliments, behavioral responses to satisfaction would lead to useful or subjective information as signals to the service providers. Yet, people perceived service quality differently would not lead to the same behaviors. In relation to communication style, it is noted that it is not culture that complains or compliments, but people. General speaking, dissatisfaction alone may not lead people to consider complaining (Bearden & Mason 1984; Halstead & Droge, 1991) and the presence of situational and personal factors may determine whether people complain or not (Day, Grabicke, Schaetzle & Staubach, 1981). Furthermore, while recognizing the influence of culture in shaping personality, culture is defined as the result of individuals learning from experiences in their environment (Axelson 1993). Although there is a wide range of individual differences in any given culture, different people frequently do not perceived situations similarly or choose to act in them in a similar way. However, cultural influences can be beyond one's active control and it is an unconscious and automatic act to default behavioral and affective reactions to certain events and objects (Rozin 2003).

There is limited information related to how culture affects complaint and compliment behavior through an individual personality, thus, the rest of this paper is organized as follows. Firstly develop the conceptual model and associated research hypotheses that address the possible linkage; the mediating role of personality factors (i.e., self-construal and perfectionism dimensions) in the relationship between culture and complaint/compliment strategies. Then, to describe the sample and measures employed in the study and follow by reporting the empirical research results. Finally, conclusions from this study have important managerial implications to service providers, identifying study limitations and proposing future research directions.

## **Literature Review, Research Hypotheses and Conceptual Framework**

Based on the literature review, there are sundry factors related to complaint or compliment behavior that can be addressed accordingly.

It is evident logically that there is no universal model that can fit in all organizations and all customers or consumers. Even though higher education institutions practice business-like activities, they cannot apply 100% of the customer-oriented marketing theories and techniques without tailoring them to fit into their operation. For example, in the case of a complaint response, if a student fails the study program, it is difficult to seek redress, replace, refund or compensate the goods/services. A similar discontinuity occurs, when a student is extremely satisfied with an encountered service; they cannot leave a big tip to service providers as a complimentary response. Such a response could be viewed as a serious breach of behavior in higher education and, depending on its timing, may be viewed as bribery attempt.

In marketing, satisfaction/dissatisfaction is the internal state of a psychological process which is similar to attitude. The feeling of dissatisfaction may cause people to complain, complain can be manifest in different ways, i.e., exit, voice, negative word-of-mouth behavior and their party responses (Singh, 1988, 1990). Liu and McClure (2001) have argued that consumer complaint behavior (CCB) has been primarily western-oriented. Their empirical investigation compared CCB in a collectivist culture (South Korea) and an individualist culture (United States of America); results showed that customers in different cultures do have different complaint behaviors patterns (i.e., voice responses, private responses and third party responses), especially in actual behavior, the following hypothesis:

*H1:* Postgraduate business students with different ethnic origins differ in complaint responses (i.e., 9 complaint strategies: a. oral express directly to service provider, b. post it on the internet, c. write a letter or card to service

providers, d. telling friends and families, e. convince friends and families, f. write a letter to the media, g. report the issue to a higher authorities, h. take legal action, i. do nothing or forgot it-not to complain).

The primary compliment researches were prone to focus on linguistics to show cross-linguistic and cultural communication aspects of the politeness phenomena, i.e., giving and acceptance (Ye, 1995; Lim, 2000; Holmes, 1988; Saito & Beecken, 1997) in relation to speakers of English for learners from different cultural backgrounds. Meanwhile, complaint or compliment acts often arise out of contrasting experience to confuse people who live in more than one culture; even it is received no complaint does *NOT* mean satisfaction, e.g., the complaint acts in Asian culture emphasize ‘harmony’ and ‘face-saving’, while for felt dissatisfaction, Asians prefer to complain to their social group or keep silent instead of directly complaining to a poor service provider. Western people are taught to express their emotions freely like ‘read me as read my face’ whereas Asian people would hide their emotion behind a neutral face. For compliment acts in Western culture, Australians are likely to praise family members in public as a courtesy, or a female dressed up may show friends ‘I look pretty, don’t I’ to gain more compliments; but those acts would be viewed as ‘self-praise’ which should be avoided in Confucian or Buddhist cultures. Furthermore, literature shows that personal norms and rules that guide behavior directly affect communication behavior and cultures have no existence except as they are manifest in the behavior of the people who constitute them (Barnlund & Araki 1985), thus,

*H2: Postgraduate business students with different ethnic origins differ in compliment responses (i.e., 9 compliment strategies: a. oral express directly to service provider, b. post it on the internet, c. write a letter or card to service providers, d. leave a gift to express appreciation, e. telling friends and families, f. convince friends and families, g. write a letter to the media, h. report the praises to a higher authorities, i. do nothing or forgot it-not to compliment).*

On the basis of services marketing and cross-cultural psychology literature, Liu, Furrer and Sudharshan (2001) depicts how culture influences behavioral intentions toward banking services and hypothesized relationships between Hofstede’s cultural dimensions (i.e., power distance, individualism, masculinity, uncertainty avoidance, and long-term orientation) and the five categories of behavioral intentions (i.e., loyalty to the company, propensity to switch, positive word of mouth, negative word of mouth and complaining). Moreover, the majority of the studies of the similarities and differences in individual psychological processing in various cultural and ethnic groups to indicate that culture is an antecedent to human thought and behavior (e.g., Furrer, Liu, & Sudharshan, 2000; Berry, Poorting, Segall & Dasen 1992; Trianis, 1994). However, the role of culture was defined in work-related values to generalize Hofstede’s findings to the whole culture.

In many past studies, culture was assumed rather than measure directly, drawing upon Individualism-Collectivism (I-C) score. It assumed I-C was a set of values, beliefs, attitudes and behavioral norms used as a conception for different cultural syndromes (Triandis 1995). Since the 1990s, cultural psychologists have looked at more differentiated, more meaningful variables to identify collectivist and individualist identities and societies, and the shift in relations between East and West. Markus and Kitayama (1991) assumed that cultural-level individualism and collectivism have a parallel in individual level differences. A conceptual framework has been developed to examine personal self-construal and cultural identity (Marcus & Kitayama 1991, 1995; Singelis 1994, 1995). In the past, both individualism-collectivism and independent- interdependent self-construal were conceptualized by researchers as bipolar dimensions. Recently, more researchers have agreed that the two self-views were neither orthogonal nor mutually exclusive, but rather coexist within every individual (Markus & Kitayama 1994; Gudykunst et al. 1996; Singelis & Brown 1995; Singelis, Bond, Sharkey & Lai 1999). The two aspects of self can coexist within the individual (Aaker & Lee 2001; Brewer & Gardner 1996) and can vary in a given culture, across ethnic cultural background within Western or Eastern society. In addition, evidence has been documented (Kwan, Bond & Singelis 1997; Singelis & Sharkey 1995; Gudykunst et al. 1996) that, at the aggregate or cultural level, self-view differences have been found whereby individuals from Asian samples, (collectivist, East-Asian culture) tend to see themselves as less independent and more interdependent than those in North American/Western Europe (Individualist) samples.

People with an independent self tend to be unique, strive for their own goals, express their own viewpoint and are direct in communication whereas people with an interdependent self-construal which is a ‘flexible, variable’ self tend to emphasize external features such as status, roles and relationships that are more indicative of how one relates to others (Markus & Kitayama 1991). Members of individualistic cultures with independent self-construal in

their social interaction reflect a tendency to be pointed, direct, clear, unambiguous and concise in the choice of verbal tactics in conversations (Kim 1994) whereas those in collectivist culture are more indirect. According to Asker and Schmitt (2001, p. 562), cultural difference arising from traditions and religions (Buddhism versus Christianity), life philosophies (e.g., Confucianism versus the Enlightenment) and socialization processes (e.g., child-rearing practices that encourage differentiation versus assimilation) tend to foster the asymmetric development of the independent or interdependent self.

*H3A: Postgraduate business students with different ethnic origins differ in*

*1: Independent self-construal*

*2: Interdependent self-construal*

Moreover, Markus, Kitayama & Heiman (1996) suggested self-construal is the traits that demonstrate points of distinction about the nature of self through the method of cross-cultural comparison that have been explored.

In the psychology literature, when people are optimistic about their chances of success, they are less likely to engage in a defensive pessimism or doubt their ability to buffer the self from possible failure (Norem & Cantor 1986). Crocker & Park (2003) exemplified that most studies assume that when person perceived actual or anticipated success or failure, perfectionism or lower self expectations will be elicited as a mean of self-protective strategy. In marketing literature, Kopalle & Lehmann (2001) found an effect between perfectionism and expectations; they found that consumers who are perfectionists will have higher expectations than do non-perfectionists. If people can lower their stated expectations, an outcome can increase potential satisfaction. Nowadays, perfectionism has been given a new perspective as multidimensional approaches (Rice & Lapsley 2001), not a disorder but personality construct with adaptive as well as maladaptive. Studies comparing 417 African-American and White college students (Nillsson, Lupini & Tatem 1999) on two different perfectionism scale MPS (Hewitt & Flett 1991; Frost, Marten, Lahart & Rosenblate 1990) reported statistically significant differences between African American and White students on four subscales, with African American students scoring higher on other-oriented perfectionism and parental expectations, and lower on concern over mistakes and parental criticism. Mor, Day, Flett & Hewitt (1995) conducted a study of professional performance and found that both self-oriented performance dissatisfaction in terms of career progress and unhappiness with performance. Thus, even though perfectionist may deliver on accomplished performance, their exceptionally high standards may undermine the satisfaction associated with performing and may result in disappointment, which may be internalized into a negative self-view.

Kowalski (1996) suggested that individual personality related differences might influence a subject's complaint behavior. For example, if individuals affected by social concern have a high degree of fear of negative evaluation, that negative feeling will be likely to result in dissatisfaction that will lead to complaints. When outcomes are highly desirable but uncertain, people tend to protect themselves from disappointment by engaging in a variety of cognitive and behavioral strategies (Pyszcaynski 1982, as cited in Crocker & Park 2003, p. 14).

*H3B: Postgraduate business students with different ethnic origins differ in*

*1: self-oriented perfectionism*

*2: other-oriented perfectionism*

*3: socially prescribed perfectionism*

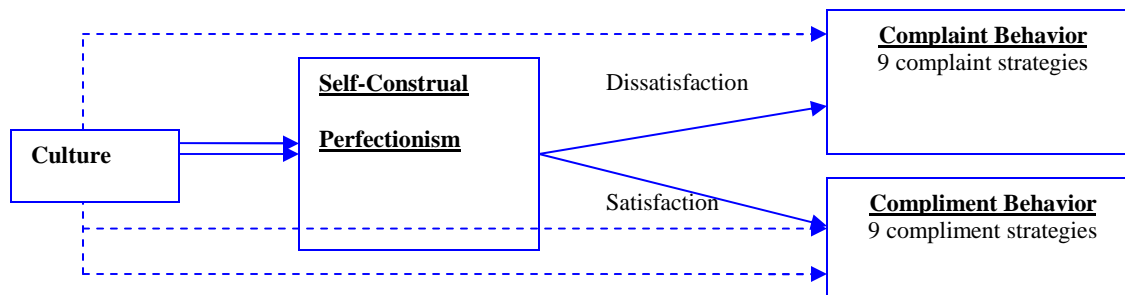

For international students pursuing advanced knowledge, postgraduate life in a host country can be filled with stress; from their cultural and language differences and preferred learning styles distinct from local students, it may be expected that postgraduate business students would be affected by social concerns and hold a high degree of fear of negative evaluation; in that case, their negative feelings may well result in dissatisfaction that will lead to complaint or not. Conversely, how is their compliment strategy when they perceive satisfaction toward service?

A proposed conceptual model is presented; FIG. 1 depicts the mediating role of personality factors in the relationship between culture and complaint or compliment strategies that were investigated any difference or similarity in higher business education context.

 FIG. 1: CULTURAL ORIENTED MODEL OF COMPLAINT/COMPLIMENT

## Method

### Subjects

Participants were selected across Curtin Business School, from a number of business courses and were at least in their second semester of their postgraduate study, the volunteer lecturers consented to distribute questionnaires in their classes as a take home survey.

Participants were informed that they would be filling out questionnaires about their personal feelings and attitudes. Once participants had filled out a questionnaire they were excluded from responding in other classes. Informed consent was obtained from all participants and students were advised that could withdraw at anytime without prejudice or penalty. In addition, students were able to return questionnaires anonymously.

### Mediating Independent Variable

It included Self-Construal Scale (independence self- construal and interdependence self-construal) and perfectionism (self-oriented, other-oriented, or socially prescribed perfectionism).

The Self-Construal Scale (SCS) is designed to measure individual levels of independence self-construal and interdependence self-construal as separate dimensions by assessing “constellations of thoughts, feelings, and actions” (Singelis 1994, p. 584). In short, the purpose of adopting SCS is to determine the cultural identities of the participants. The SCS consists of 24 items comprising 12 on each of two dimensions. Each item is rated on a 7-point Likert scale, with answers ranging from 1 (*strongly disagree*) to 7 (*strongly agree*).

Two separate scores are calculated, one for the strength of the independent self and one for the interdependent self. The scales are scored by adding each respondent’s scores for all the independent items and the interdependent items, and divided by 12 respectively to get the mean score for the items. Singelis reported coefficient alphas of 0.74 for the Interdependence subscale and 0.70 for the Independence subscale.

The Multidimensional Perfectionism Scale (MPS, Hewitt & Flett, 1991) is a 45-item scale consisting of three subscales that correspond with the authors’ hypothesized dimensions of perfectionism: self-oriented perfectionism (e.g. “I demand nothing less than perfection from myself”), other-oriented perfectionism (e.g., “Everything that others do must be of top-notch quality”), and socially prescribed perfectionism (e.g. “My family expects me to be perfect”) with 15 items in each of the dimensions. Respondents are asked to rate their agreement with statements based on a 7 point Likert scale ranging from 1 (*disagree*) to 7 (*agree*).

These distinct dimensions of perfectionism have reported reliability coefficients of 0.88, 0.74, and 0.81 for self-oriented, other-oriented and socially prescribed perfectionism, respectively (Hewitt & Flett, 1991). Research on the MPS based on college student samples has shown that it reflects three empirically distinguishable dimensions and has good test-retest reliability over a three month period (0.88, 0.85 and 0.75 for the subscales of self-oriented, other-oriented, and socially prescribed, respectively). MPS has construct validity with other measures of perfectionism (Chang & Rand, 2000). In their research on perfectionism and it relationship to college student

adjustment, Chang and Rand (2000) reported Cronbach's  $\alpha$  coefficients of 0.78, 0.71, and 0.76 for self-oriented, other-oriented, and socially prescribed perfectionism subscales, respectively.

#### **Dependent Variable**

In being reworded and refined to redesign the construct of complaint and compliment instrument for postgraduate business student, to rephrase and built on the constructs of Singh (1988) and Ho (2003) by focus group of a number of academic staff and postgraduate students within the school to develop a rang of appropriate compliment and complaint responses became necessary. The reason is most selected measures of several dependent variables that were known to be related with complaining behavior and compliment behavior in for-profit organizations, it cannot be employed 100% directly in higher business education context.

Complaint Strategies including 9 negative responses i.e., a. oral expression directly to service provider, b. post it to the internet, c. write a letter, email or card to service providers, d. tell friends/families about this bad experience, e. convince friends/families not to experience/use/enroll, f. write a letter/email to the local newspaper (media) about the bad experience, g. report the issue to a higher authorities, h. take legal action against the institution (represent lawful action), i. do nothing or forgot it (not to complain).

Compliment Strategies including 9 positive responses i.e., oral expression directly to service provider, b. post it to the internet, c. write a letter, email or card to service provider, d. leave a gift to express appreciation, e. leave a gift to express appreciation, e. tell friends/families about this pleasant experience, f. convince friends/families to experience/use/ enroll it, g. write a letter/email to the local newspaper (media) about the good experience, h. report with praise to a higher authorities, i. do nothing or forgot it (not to compliment).

Each complaint and compliment response was measured on a five-point Likert scale, with 1=Never, 2=Unlikely, 3=Somewhat Likely, 4=Quite Likely, 5=Highly Likely. The coefficient Cronbach's alphas is from 0.643 to 0.758 for the complaint strategies and from 0.642 to 0.768 for the compliment strategies, thus, approximated or exceeded 0.6 which is commonly regarded as an acceptable level of internal consistency.

#### **Data Analysis**

To investigate whether different culture/ethnic backgrounds will affect complaint responses, compliment responses, perfectionism dimension and self-construal dimension. The hypotheses will be tested by several one-way ANOVAs were performed and where the normality assumption could not be justified, the non-parametric techniques such as Kruskal-Wallis Test, Mann-Whitney test and tests of variance equivalence suggested unequivalent variance for the groups; the *Scheffé test* was performed in the present study. Apart from ANOVA, the principle statistical analysis technique was Bivariate Pearson Correlation, the purpose of which was to identify significant associations between the culture, personality factors and complaint/compliment behavior.

The commonly accepted level of significance in most business and social research is 5%. However, owing to the large number of tests performed in this study and, consequently, the increased risk of a Type 1 error, the 1% level of significance was adopted throughout the research.

## **Result**

Data was obtained from a sample of 261 postgraduate business students' enrolment from countries with diverse cultures: 109 (42%) were ethnic group 1=Western-Australian, 105 (40%) were ethnic group 2=Eastern-Asian and 47 (18%) were ethnic group 3=Eastern-Indonesian and Malaysian. After approximately 620 questionnaires were distributed, the valid returning rate was 42%.

Reliability analysis was conducted for each scale and subscale. Cronbach's alphas for the scales measuring dependent variables i.e., the overall complaint behavior and compliment behavior were 0.706 and 0.702. The alphas of the subscales in the multidimensional perfectionism scale, all samples yielded alphas of 0.879 on self-oriented perfectionism, 0.720 on other-oriented perfectionism and 0.765 on socially prescribed perfectionism. The alphas of the subscales in the self-construal scale, all the samples yielded alphas of 0.704 on independent self-construal and 0.733 on interdependent self-construal. Those  $\alpha$  are consistent with the published standards.

**ANOVA**

TABLE 1 shown findings partially support *Hypothesis 1*; significant differences occur between postgraduate business students with different ethnic origins and the complaint strategies of ‘oral direct expression to service provider’, ‘post it on the Internet’ and ‘telling friends/families’ only. In addition, TABLE 1 shown findings partially support *Hypothesis 2*; significant differences occur between postgraduate business students with different ethnic origins and the compliment strategies of ‘post it on the Internet’ and ‘telling friends/families’ only.

**Correction**

As show on TABLE 3 and TABLE 4, aggregately, it is only some component dimensions, e.g., independent self-construal, interdependent self-construal and aspects of prescribed perfectionism are related to complaint and compliment strategies, but it is impossible to say that the entire concept is related.

TABLE 3: CORRELATIONS BETWEEN SELF-CONSTRUAL AND COMPLAINT/COMPLIMENT

**Discussion**

In regard to the complaint strategy or compliment strategy, two things have been identified from this relationship between the actions and cultural groups. Firstly, there is a significant but not large to indicate that cultural related personality factors only make a PARTIAL contribution to the behavior. It may be argued that other variables might give a more accurate prediction to criterion variables than cultural linked personality factors. The fact is quite substantial for complaint or compliment behavior in the higher business education context; thus, complaint and compliment behavior are neither a shallow concept nor effected only by ethnic origins in a diverse culture campus without considering personality factors in communication strategies. Secondly, difference between the tendencies of cultural groups to engage in some pattern of complaint behavior, such as 'oral directly complain to service provider', 'post complaint on the Internet' and 'telling friends/families about dissatisfaction' or in some pattern of compliment behavior, such as 'post compliment on the Internet' and 'telling friends/families about their satisfaction experience' would find.

Conclusions from this study have important managerial implications to service providers, the senior academic and administration staff of Curtin Business School can learn that students' culturally connected personality factors are related to their tendencies to engage in different complaint or compliment strategies. Statistically significant findings show that there is a linkage between culture and complaint/compliment behavior such that academic and administrative staff cannot rely sole on the verbal and visual cues of face-to-face communication for service evaluation. They must not draw hasty conclusions regarding satisfaction or dissatisfaction from the presence or absence of this form of communication. Generally speaking, oriental students do not express complaints on the face-to-face basis to the service providers, so staff should not think that all is going well just because they do not received any complaints.

Unexpectedly, the original stereotype image was broken when the Eastern Indonesian-Malaysian group was separated from the oriental students, and findings indicated that there are significant differences between the Western-Australian, East-Asian and Indonesian-Malaysian cultural groups. Similarly, in the case of compliment behavior, the fact that staff does not receive direct positive feedback from a particular group of postgraduate students should not automatically be interpreted as a sign of dissatisfaction. They may not be culturally or otherwise inclined to express themselves in that particular form. Staff should therefore broaden their awareness of other forms of feedback and try to provide alternative means to encourage the expression of feelings about the services provided. Some professional staff training in this area may be beneficial.

For those in academic management roles who are inclined to study the relationships between personality and compliment/complaint behavior, the following broad relationships may be informative.

- Stronger 'independent self-construal' tends to encourage direct oral expression.
- Clients with stronger 'interdependent self-construal' or 'socially prescribed perfectionism' are more inclined to post their compliments and complaints on the internet.

The following relationships between the manifest cultural groupings and compliment/complaint behavior also emerged:

- The Indonesian-Malaysian group and the Western-Australians students were more inclined to complain orally to the service provider than the East Asian students, however,
- There was no apparent difference between the groups in expressing compliments orally.
- East Asians are more inclined to put their compliments and complaints on the internet than the other groups
- The West Australian students had the highest inclination to convey their satisfaction and dissatisfaction to family and friends.

Differences between cultural groups could also be identified in terms of their actual satisfaction and importance they place on specific service attributes. Their respective inclinations to express compliments and complaints in different ways provides a useful means of more accurately monitoring the performance of each service with respect to that cultural group in an ongoing way.

Although the findings indicate that staff cannot rely only on face-on-face communication to gather information on dissatisfaction or satisfaction and other channels may be necessary, it is nonetheless highly desirable to create a friendly environment to encourage and educate the students to speak out freely so that service providers may know immediately where the problems are and what improvement tactics can be used. Other strategies such as cooperating with relevant personality criteria in the student selection process or managing student expectations in

relation to service quality and encouraging students to be more independent would improve satisfaction and diminish complaints.

In conclusion, this research has provided academic management with a valuable tool within the higher business education context. It makes a useful contribution towards the effective interpretation of on-going and incidental client compliment/complaint behavior. While it is recognized that personality is not an obvious cue for the academic or management staff, the identified culturally related personality variables offer a partial explanation for various compliment or complaint behaviors. It means that in the medium-term, changes in some of the relevant personality factors may be possible with encouragement leading to more direct and useful feedback. In the meantime, the observed associations between the cultural groupings and their tendencies to prefer certain modes of expression provides management with useful information (based on visible ethnic origin) to anticipate the type of complaint or compliment strategies they are likely to engage in.

### **Research Limitation/Future Work**

The primary limitation of this study is the scope and size of its sample. The current study investigated postgraduate business students' behavioral responses and was conducted only in Curtin Business School, West Australia; only used three cultural groups to infer that those cultures promote a string of personality factors which limits the generalizability of the findings.

However, the study does provide evidence of culturally linked personality factories exist to draw implications for postgraduate business education service providers. This would suggest the possibility there are steps toward developing and encouraging independent self to orally express out directly to service provider that may add to student satisfaction. Also, even where there is dissatisfaction, clients should be encouraged to speak out, thus service providers may know where the problem is and what improvement tactics can be used. Other strategies such as cooperating with criteria in the student selection process or managing student expectations in relation to service quality and encouraging student to be more independent would improve satisfaction and diminish complaints.

Therefore, the identified variables appear to have a partial explanation for various behaviours. It means, in the long-term, changes in the string of personality factors or the culture can be influenced by some personality factors and the complaint/compliment behavior itself can change. Meanwhile, the findings provide partial evidence, but further elaborated explanations about cultural grouping itself provides far more useful information to help management identify the person from visible data and to anticipate what type of complaint/compliment strategies they are likely to engage in within the higher business education context.

## Abstract

This study is to develop a map of Casualization for accounting education in universities in Western Australia to 1) analyze the responses from Casual staff to determine their views about the conditions of employment; and 2) examine issues of importance to casual staff. The value of contributions: 1) It has practical importance for the long-term development of accounting education in Australia because it will provide evidence of casual staffs' lived experiences in the Accounting schools within which they work, and 2) it will add to Australian knowledge about the extent of the use of casuals. This qualitative case study uses a natural setting as the source of data to investigate Casualization which incorporates the language of staff as they relate their experiences. The pilot interviews suggest some essential issues which portray and highlight casual staffs concerns, expectations and disappointments.

## Introduction

The study is to develop a Map of Accounting Education in universities in Western Australia that which reflects the casualisation of teaching and the management arrangements of units/courses in accounting schools. The scope of this study is limited to the learning/teaching of Accounting in universities in Western Australia. As indicated in the background universities have been transformed, in particular the role of academics has changed. These changes have been occasioned by changes in technology; the use of the Web and Internet for teaching has meant that teachers have worked with technical people like course designers, programmers, and Web persons to develop learning materials and new educational experiences for students. It is also true that work place conditions have changed. Academics are now more accountable; staff must be flexible and have more diverse interests as they try to relate to a changing student profile, reduced funding and declining numbers of tenured academics. An example of such changes is the separation of teaching from research.

The consequence is that many teaching staff are no longer tenured and staff/student ratios have increased over time. Because universities are unsure about sustaining growth in enrolments they now use casual staff because such use gives them flexibility. It also buffers the impact of reduced or reducing enrolments, and allows universities to marginally cost their teaching operations. Specifically this study analyses responses from casual staff to determine their views about the conditions of employment, and examines the employment arrangements in place for accounting in four universities in Western Australia.

The research questions for this study are specified from casual staffs' perspectives:

1. What are the benefits of casualization?
2. What are the causes of casualization?
3. How do casual staff perceive their role in universities?

As Johns, The National Director of Education for CPA Australia (2002, p. 5) noted:

The attraction of academic freedom is eroding in the face of heavy workloads, reduced time for research and poor salaries compared with industry...CPA Australia is concerned about the long term prospects for future recruitment.

Workloads have increased. Academics complain of excessive teaching loads and excessive administration duties, not to mention the need to conduct research. As a staff member noted:

Most of my colleagues do not have higher degrees, and without that there is little hope for research or career advancement, despite their teaching excellence...the current situation will mean good

people will leave!

Demsky et al., (2002, p. 2), referring to the changes in higher education in America, assert that:

Too many maps and navigation instruments that were once effective guides are now obsolete, and too much in higher education's traditional language no longer describes actual conditions, notwithstanding its continued rhetorical appeal.

There is one map of particular concern for this study, the existing structure of the teaching force in Accounting Schools in Western Australia. The theory underpinning this study of Casual Staff in Accounting Schools in Western Australia is Managerialism. This theory represents a new university system, a system imposed on universities by reduced Federal funding introduced to improve the efficiency, effectiveness, and productiveness of Australian Universities.

## **Background**

Universities in western nations have dramatically changed in the last two decades. Australian universities in 2006 are multi-purpose internationalized businesses. The change from independent loosely run public entities began in 1987 with the issue of a Green (discussion) Paper on Higher Education which signaled the governments' intention to make universities and other Higher Education institutions accountable for contributing to the economy. The issue of the White (policy) paper in July, 1988 and the passing of legislation to create a Unified National System of Higher Education (UNS) confirmed the federal government's intention to merge small universities and give the new universities the power and freedom they needed to carry out the new agenda proposed in the White Paper (1988). At that time there were 65 colleges and universities. Rather than develop a public/private sector the government had decided to privatize public universities – the advent of business-like universities—meaning that they would be able to manage and determine their futures.

In 1987 universities were in financial difficulty – a problem caused in part by Federal/State relations as dictated by the Constitution. Australia is a Federation consisting of a central government, 6 states (Victoria, New South Wales, Queensland, Southern Australia, Western Australia, and Tasmania) and two territories (the Northern Territory and the Australian Capital Territory, Canberra). The Constitution sets out the rights and responsibilities between the States and Territories and the Federal Government. For example, the Federal Government is responsible for all matters which affect the country as a whole (e.g., external affairs and security), and States and Territories are responsible for all matters which affect their constituents (e.g., education and health). In 1946 (after the war), the States agreed to cede taxing powers to the Commonwealth in return for social security benefits for their citizens. The loss of this power would ultimately weaken the States' financial strength.

Until the end of World War II only five universities and a number of technical and teacher training colleges provided post secondary education in Australia. Ex-servicemen were granted the right of entry to university if they chose to study, so it soon became clear that more education facilities were needed. In 1966 a new second tier post secondary education system was legislated for. Five Colleges of Advanced Education (CAEs) were spread around the states. In addition the Federal Liberal/Country Party Government agreed to contribute \$1 for every \$1.85 paid by the States to ease the cost of higher education. When the Federal Labor Party (who had been out of power since 1949) was returned to power in 1972, they agreed to take over responsibility for higher education from the States. The Labor government introduced significant changes over and above the funding of higher education, so much so that it ran out of money and was dismissed in 1975.

In between times a Liberal Coalition Government led by Malcolm Fraser failed to right the economy, so the Labor Party was returned to power in 1983. Thus began a 12-year period of economic reconstruction to make Australia internationally competitive. First in 1984 the Australian dollar was floated and the Australian banking system was deregulated. One of the strategies for expanding trade was a decision in 1985 by the federal government to introduce full fee international marketing of education as an export industry; no limits were placed on the number of students that could be enrolled. At home they announced that a \$250 Higher Education Administration Charge (HEAC) would be payable by all students in 1987 (it changed in 1989 to HECS). This 1989 development relieved the federal government from increasing expenditures on higher education, but it created serious problems in

university management.

In 1991 an Open University managed by Macquarie University was also piloted. And so the market slowly matured and expanded to include by 1993, a private company *Deakin Australia*, which developed with partners to provide education in accounting, architecture, and engineering. Deregulation required new arrangements between the university and the government. University managers became institutional managers, and collegial decision-making was reduced. Thus universities were effectively transformed into private entities. Significant freedoms were given in exchange for fiscally responsible management and less funding from government, i.e. all restrictions on teaching/enrolling overseas students were removed by 1994 as the new Unified National System of Higher Education was put in place. There were now thirty seven (37) merged universities and two (2) private universities, making 39 universities in all.

The Higher Education sector was thereby effectively deregulated with the full authority of the federal government. This also signalled the privatisation and marketization of universities; privatisation meaning the transfer of state activities (and costs) to the private sector, particularly in the reduction of state provision and regulation. The privatisation and marketization of higher education allowed universities to sell education places to students, both in Australia and overseas. So began a new phase as universities entered into the marketization and branding of their universities.

The Labor Government was defeated in 1996 by the Liberal Coalition Parties led by John Howard. The Howard Government continued the policies put in place by the Labour Government, that is, to reduce government funding for higher education. It also commenced an overview of higher education in Australia, and by 2000 came to the conclusion that students should contribute more toward the cost of a university degree. Thus regulations were passed to allow universities to charge fees to Australian students based on the demand for courses. In the meanwhile the Federal government continued to fund degrees at a pre-determined level and students continued to pay HECS. By the end of 2000, the target for enrolments/graduates set by Labor Party in the late 1980s was reached. This figure represented a 43.38 per cent increase in enrolments over 1990 and confirmed the transformation of an elite university sector in 1970 to a mass education sector in the 1990s.

## **The Drivers of Change**

There are many drivers of these changes, the most important of which are neo-liberalism, globalisation, and academics' reluctance to change of their own accord.

### **Neo-liberalism**

Neo-liberalists tend to define all social, economic and political issues as problems of management (Fitzsimons, 1999). Their objective is to improve efficiency in areas of government by redefining cultural issues as economic ones. Similarly management control is decentralised in the interests of efficiency. From the perspective of neo-liberalists higher education is treated as a private good – available for sale, no longer in limited supply, ideal for market forces so that... 'Radical change or restructuring of an institution of higher education means either fewer and/or different faculty, professional staff, and support workers'. Other neo-liberal strategies in higher education include:

1. Treating all organizations as business relationships,
2. Defining education as efficiency and accountability,
3. Treating educational courses as commodities,
4. Changing the teacher/student relationship to one of producer/consumer, e.g. the need for textbooks, performance criteria and so on.

Moreover neo-liberal strategies are global. The International Monetary Fund (IMF) in promoting trade liberalisation had this to say in 2002: 'a global market offers greater opportunity for people to tap into more and larger markets around the world. It means that they can have access to more capital flows, technology, cheaper imports, and export markets' (IMF, 2000).

### **Globalisation**

Another predominant driver is globalisation. Changes in Western Universities are attributed to global and

international developments (Deem, 2001). Most academics and politicians agree that changes to the power of nations, especially in respect of economic deregulation, are reflected in social policy and the provision of welfare. First, governments seem to be reluctant to fund public services, and second public funded organisations must enter or create a 'market', using a managerialist approach. Globalisation is defined as 'the extension of social relations over the globe (Poullaos, 2004, p. 716), and as the widening, deepening and speeding of world wide interconnections in all aspects of contemporary social life from the cultural to the commercial, the financial and the spiritual (Held, et al, 1999, p. 2). Globalisation is a 'central driving force...reshaping modern societies and the world'. (Held, et al., 1999, p. 7).

Globalisation is seen as the triumph of desire over law, i.e. social affairs (property and human rights aside) are 'settled through market decisions' (Roberts, 2004, p. 464). Competition for students who want flexible programs encourages strategies like using more contract and casual staff because they are effective and flexible. Strategy is one managerial aspect that demonstrates how higher education has changed. Similarly assessing research quality using journal rankings, citations, and student evaluation, is another.

The information revolution suggests that experience, power and culture are increasingly organized around networks. Enabled by information technology (including telecommunications), networking logic has spread throughout society to the point where presence in or absence from networks can become "critical sources of domination and change" (Castells, 1996, p. 469). Whereas Boyce (2002) is concerned that such networks are exclusionary and impact on local communities, Poullaos notes that networks are a means of analysing "the exclusionary basis of globalisation" (p. 583).

#### **Academics' Attitudes towards Change**

Another driver was the attitude of academic staff to change. Change was often resisted by academics, people tended to protect their positions, resources were often unfairly distributed, and strategic options were often not considered. The combination of all the effects of managerialism makes it essential to identify their impact on staffing, specifically casualization, to make learning and teaching conditions in accounting in higher education transparent.

## **Literature Review**

### **Managerialism**

The theory underpinning this study is managerialism. Managerialism is variously defined. According to Edwards (1998) managerialism has four components; managerial ideology, economic efficiency, as perpetuation of class consciousness by managers, and manager as a moral agent for the common good. Enteman (1993) defines managerialism as an international ideology, an economic, social, and political order of advanced western democracies in which the new societies are defined as equivalent to the sum of the transactions made by managements of organizations. Ferlie et al., (1996, cited in Deem 2001, p. 10) defines it as a concept used to refer to ideas about changes in the way publicly funded institutions are managed. Managerialism, now a common feature of management in education and management control is decentralised in the interests of efficiency.

#### **Effects on Universities**

Globalisation has had significant adverse effects on universities. This part provides some effects of globalisation on universities.

1. Freedom of speech has been fettered i.e. Universities now control their employees using classical management strategies like authority, discipline and centralisation,
2. Funding sources include fee paying students, offshore teaching, and industry partnerships in research or consulting, reduction of operating costs, i.e., by enlarging classes, contract teaching, the shifting of administrative tasks to schools, faculties, or divisions, and
3. The education sub system has been expanded to include:
  - 1) Delivery of education overseas,
  - 2) Student evaluation of teachers (SET) has been introduced, and
  - 3) An expanded research sub system.

In sum, the effects of Managerialism have been felt at every level of the university:

- 1) Sources of funding have been extended to include fee paying students, offshore teaching, and industry partnerships in research or consulting.
- 2) Operating costs have been reduced, i.e. much teaching is undertaken by contract staff.
- 3) Internal users must pay, i.e., accounting schools pay a cost centre for the stationery they use-administrative tasks have been shifted to schools, faculties and divisions, and budgets have been tightened.

Moreover the education sub system has been expanded to include new private universities. Deloitte, Touche, Tomatsu (1998, p. 1) note that universities, particularly newer ones, increasingly rely on borrowings. In addition the private sector is asked to support academic appointments (cited in Lafferty & Fleming, 2000, p. 259).

#### **The effects of Managerialism**

Deem (2001, p. 7) identifies four (4) concepts of change in universities: globalisation, internationalisation, ideology, and entrepreneurialism. The effects of Managerialism have been felt at every level of the university. Below are some instances of these effects:

1. Management structures have changed,
2. There is a new management style, and
3. The Academic Profile has been changed.

#### **Management Structures have Changed**

Vice-Chancellors and their advisors 'have increasingly assumed the role and powers of corporate CEOs' (Parker 2002, p. 609). Members of the Senior Executives Service (SES) now have specialized roles in areas like teaching and learning, international, academic, research, and so on. Schools, faculties, and divisions have been refined/downsized and the breadth of their control has been redirected. Thus control and accountability has been re-routed from the university Senate to the (SES) executive group.

#### **There is a New Management Style**

University Vice Chancellors have restructured their Universities. They now have a small number of faculties, divisions, or strategic business units (SBUs) (Parker 2002, p. 606). SBUs, which are presided over by Deans are accountable to Vice Chancellors, and specialist Pro Vice Chancellors or Deputy Vice Chancellors. This group constitutes the senior executive (SES) management team. Its members have significant power and authority over committees. Thus one committee has been substituted for mutual accountability between academic committees. Communication is top down as top management develops policies and passes them down for comment.

Collegial management by committee has been replaced by professional management by the executive. Such replacement has reversed the traditional model in which the administration was answerable to an academic management committee. Moreover managers of functional units like marketing, Alumni, international programs, and research now have authority to act on behalf of the university in raising revenue. The end result is that the decision-making layers have also been reduced.

#### **The Academic Profile has been Changed**

Middle management, i.e. Heads of Department, now manage budgets largely dictated by senior management, while full-time, tenured or tenurable academics are engaged mainly in teaching and research, and some administrative roles. Fixed-term or short-term contract (casual) staff usually teach in the high-enrolment, (often first-year) subjects, while a large pool of casual staff, mainly postgraduate students, are also engaged in daily teaching.

The 'user pays' principle has expanded in higher education, particularly through the Higher Education Contribution System (HECS), whereby students pay for part of the cost of their education, payable either *via* fees on enrolment or after graduation through the income tax system.

#### **Power of Management is Stressful**

The implementation of corporate managerialism in the Australian university sector has increased tension as evident in the following changes:

1. Universities have been restructured along line-management principles (from Vice-Chancellors, down through a senior management stratum, to departmental heads).
2. Performance management schemes have been introduced.
3. Academic tenure has been substantively eroded, permitting easier dismissal of tenured academic staff,
4. Organizational units deemed financially unviable have been eliminated or reduced, and
4. There is an increasing emphasis on competitive marketing of both universities and individuals. (Lafferty &

Fleming, 2000, p. 260)

### **Effects on Academic Climate/Culture**

Change always alters the culture of an institution (Kezar & Eckel, 2002, p. 295) because it changes various assumptions and organisational behaviours, processes and products. Change is also, 'deep and pervasive, affecting the whole institution'. However, whereas it is always intentional it takes time to become apparent. (Kezar & Eckel, 2002, p. 296)

## **Casualization**

Massification has expanded access to university and helped to reduce elitism but this new university structure has affected staffing in Higher Education. It has changed university maps. For example, institutional competition has increased and changed the relationship between government and universities. Moreover, globalisation and marketization have changed the balance in higher education from internal concerns to external concerns, that is, how universities situate themselves in the marketplace and reconfigure their missions to ensure their financial survival. For example, increased student numbers have caused teachers to change their teaching and assessment methods, and students are now required to pay for basic teaching materials and photocopying, among many changes (Bradley, 1995, p. 13). The Dawkins 1988 reforms in higher education in Australia had four objectives:

- To improve participation rates in higher education,
- To improve access to higher education for underrepresented groups.
- To improve the efficiency and effectiveness of these organizations, and
- To make institutions more responsive to Australia's economic and social needs (Karmel, 1990, p. 31).

Note that the focus of these reforms is on participation and efficiency, not on quality.

### **The Structure of Academic Employment**

Academics can be employed in a number of ways, i.e. casual or fixed term contract or permanent/tenured appointment. In addition universities provide an extra 3% for TESS (the Tertiary Education Superannuation Scheme).

In respect of casual staff (the word part-time is not used) the award provides a salary scale for lecturer, tutor, demonstrator and supervisor, and for marking, and if there is sufficient money, for staff development. However, the award salary for casual staff is capped at 60% of the normal teaching load of a full time staff member.

The structure, which is increasingly bureaucratized, includes senior managers i.e. the Vice-Chancellor, and senior bureaucrats who can negotiate their salary with the governing body (generally the Senate). This is one example of how private university managements now use private sector strategies to achieve their goals; another Map that is not understood.

At the system level there has not been any systematic attempt to articulate in detail the goals for higher education in Australia. None of the major national enquiries have seriously addressed the issue (Linke et al, 1984, p. 20). Teaching is a delicate business requiring as it does teaching, research, caring, student management, and administration. All is not well in academe however. The Evatt Foundation commented in 1994 (p. 106) that academics' morale had diminished due to:

- Increased workloads,
- Increased pressures to be all things, teachers, researchers, entrepreneurs, and administrators,
- Increased internationalization leading to competition for scarce resources, and decline in promotion opportunities, and
- Increased bureaucratic decision-making, with increased reporting and administration requirements without additional support.

### **Casualization of University Staffs**

The current system of casual academic employment is creating an academic underclass, a secondary academic labour market subject to abuse, insecurity, lack of resources, and increased work responsibilities. Casual labour is beyond scrutiny and incapable of being reviewed which raises the question of teaching as a priority and the merits of staff contributions to the university.

Casual labour provides flexibility for universities- it is presented as best practice (Bradley, 1995), but this expression probably obscures the real reasons, which are, a) cost savings and cutbacks and b) university expansion coupled with financial prudence. This explanation emphasizes outcomes management which tend to be reduced to the efficient economic management of human and financial resources.

The academic 'Profile' is government's vehicle for changing universities, while tenure is regarded as an obstacle to adjusting the labour market, suggesting that the use of casual staff has assisted in changing university academics' roles, as follows:

- Changing the nature of academic work,
- Creating a new contingent work-force,
- Charging fees for education, and
- Reducing academic involvement in governance.

Gumport and Zemsky (2003, p. 34) contend that academic work has been unbundled in American universities as evidenced by the separation of research and teaching. Rice (2004, p. 28) confirms the casual/full time split. For example, new non-tenured staff are functionally specialised, that is, either teaching only or research only staff – a matter of great concern because it is the marriage of research and teaching that made universities great institutions.

#### **The Status of Casual Staff**

Casualization provides many *cost/benefits* for universities. They do not pay for:

- Study leave and long service leave, and
- Outside studies programs, and
- They do not provide support services; and office space etc. is also limited. (Lundy & Warne, 1990, p. 215)

Perhaps the major positive benefit of casualization is that it helps universities to respond to sudden increases in student numbers, and affords opportunities to change tack quickly (Bradley, 1993, p. 154). Nonetheless, casualization is an international problem. Casual staff are a marginalised work force (Bassett, 1998). Leatherman (1997, p. A12) contends that there are now so many part-timers in American universities that departments are called 'faceless'.

#### **Evidence of Marginalization**

Casuals are throw-away academics and not considered part of the faculty (Kirov, 1991, p. 41). Whether such staff are rehired depends on enrolments, so employment for casuals is uncertain and insecure (Fine et al, 1992, p. 51). Research indicates that even if such academics belong to a union they are left out of academic decision-making processes (Rajogopal & Farr, 1989, p. 267). Gappa and Leslie found for example that casuals felt vulnerable and dissatisfied with their second grade status (1993, p. 43). Restrictions in using fixed term contracts imposed by the Industrial Relations Commission (see Healy, 1998) may further exacerbate the position, that is, casual staff may be used in order to avoid disputes or legal action.

The growth in student numbers over the last twenty years (together with funding cuts) has led to an increase in casual staff; a model described by Handy (1993, p. 20) as a minimalist (flexible) model, underpinned by cost cutting and the notion that staff are expendable. Such staff are exploited, paid by the hour, and do not ordinarily receive paid leave, research funding or office facilities. According to Castleman et al. (1995, p. 9) 'flexibility' is an insidious word in a teaching context. Casual staff members are paid an hourly rate (Bradley, 1995, p. 154) and their duties may or may not include consultation time with students. Moreover, casual staff members have no claim over the infra-structure.

With few exceptions casual staff is treated as second-class citizens (Rice, 2004, p. 30). For example, staff have been categorised into core and non core, meaning that of the three classes of staff, *viz.*, tenured, full time untenured, and casual staff, only the full time tenured are core, those who perform all the traditional roles an academic undertakes, i.e. teaching, research and service. There is thus a need for an academic centre of gravity.

#### **Reasons Why Casualization Occurs**

For many universities, there is a substantially increasing reliance on casual staff (lecturers, tutors) to meet their teaching needs. For example casualization provides

- More flexibility and diversity with staff arrangements (to provide teaching opportunities for PhD) students, release staff for overseas teaching, and teaching relief for senior staff, and
- Less government research funding, and cost savings to departments/institutions.

Casualization provides many cost/benefits for universities; for example they do not pay for:

- Study leave and long service leave, or
- Outside studies programs.

#### **The Trend towards Casualization**

Casualization has grown rapidly over the past two decades. Casual work has always been the largest of the non-permanent categories. Notwithstanding the everyday understanding, casual is a form of employment in which the worker is deprived of many rights and benefits, including no entitlement to paid annual leave, public holidays, sick leave, notice of dismissal or redundancy pay. It is unprotected because part time staff miss out on many types of social protection developed for permanent employees, and other forms of employment including fixed-term employment, apprenticeships and traineeships. Worsening staff/student ratios are being exacerbated not only by increasing enrolments but by the shrinking number of academic staff due to natural attrition combined with unattractive salaries and poor working conditions.

The number of full time employees declined during the 90s and casual employment accounted for the net growth in employment. According to the Australian Bureau of Statistics a casual employee is an employee who is not entitled to paid annual leave and paid sick leave. At August 2003 there were 2,239,000 (or 27.6% of all employees) such persons. This figure rose from 830,000 or 15.8% of all employees. (Campbell, 2004, p. 87)

## **Significance**

This study is significant for two reasons:

1. It has practical importance for the long term development of accounting education in Australia because it will provide evidence of casual staffs' lived experiences in the accounting schools within which they work.
2. It will add to Australian knowledge about the extent of the use of casuals. It will identify, who they are? what they do? How they feel about their work? and complete part of the picture of the teaching of accounting in Schools of Accounting in Australia including Tasmania.

## **Research Method**

This study is a qualitative case study, incorporating expressive language and the "presence of voice in the text" (Eisner, 1991, p. 36). Qualitative research processes cover a range of interpretive techniques which aim to describe, translate and make sense of the changing educational environment. Qualitative research uses the natural setting as the source of data. The researcher attempts to observe, describe and interpret settings as they are, maintaining what Patton calls an "empathic neutrality" (Patton, 1990, p. 55). He notes that there are no "absolute characteristics of qualitative inquiry, but rather strategic ideals that provide a direction and a framework for developing specific designs and concrete data collection tactics" (Patton, 1990, p. 59). These characteristics are considered to be "interconnected" (Patton, 1990, p. 40) and "mutually reinforcing" (Lincoln & Guba, 1985, p. 39).

It is important to emphasize the emergent nature of a qualitative research design. It is not possible or appropriate to finalize research strategies before data collection has begun for example, because the researcher's objective is to observe and interpret meanings in context (Patton, 1990). Qualitative research proposals should, however, specify the primary questions to be explored and what the data collection strategies are. The particular design of a qualitative study always depends on the purpose of the inquiry, what information will be most useful, and what information will have the most credibility. There is no strict criterion for sample size (Patton, 1990). 'Qualitative studies typically employ multiple forms of evidence..., and there is no statistical test of significance to determine if results count' (Eisner, 1991, p. 39). Judgments about usefulness and credibility are left to the researcher and the reader. Nonetheless because the objective is to improve accounting education, it is necessary to use a case study approach because as Hughes and Berry (2000), and Eisenhardt (1989) point out, a case study is necessary when a fresh, comprehensive perspective is required. These conditions apply to Maps in Universities which (according to NCPI *Beyond Dead Reckoning*, 2002), are now urgent. More importantly there are signs in Australian

accounting schools that the level of work of full time staff (particularly those that teach and administer) is getting out of hand. Finally it is also expected, given that quality is an issue in Accounting Education that measurable constructs and testable hypotheses will emerge.

## **Data Collection**

The primary method for this study is the interview. Interview research may collect specific data. However interviews provide different data using observations: they allow evaluators to capture each project participants' point of view and those of staff and others associated with a study. The use of interviews can be understood because the data collection method assumes that participants' points of view are meaningful, knowable, and that these points of view affect the success of the study. An interview, rather than only a survey, was selected because interpersonal contact is important for searching the limits of the topic and following up interesting comments if desired.

The interview process has three stages. First, a pilot study using 2 (two) casual staff from Curtin University will be conducted to test the relevance of the research method and strategies (their experiences as casual staff and their feelings about their status), and to adjust them if required.

Second, once the pilot study is complete, the survey will begin. Twenty casual staff members will be randomly selected from each of the universities (Heads of School/Unit controllers will be asked for names). Those casual staff members who agree to be interviewed will be sent a questionnaire requesting background details and consent to participate.

The third stage involves the interview proper in which participants will be asked to expand on their experiences and to raise issues of concern to them. The objective is to get them to talk, so prompts will be necessary.

## **Data Analysis**

It is always difficult to summarize taped interviews because the interviewee may withhold information given that a permanent record is being taken. It is also difficult to reduce interview data. Thus key aspects of the interviews will be identified as the interviewer listens to the tape. A set of key words will be developed from the first two (pilot) interviews to reduce further the evidence to be used. In this way key words will be built around the structure of the substantive interviews. Access to this information and the point to point summaries will provide a reference to the content of each point made in each interview. This information will then be coded. All summaries will then be examined for inconsistencies and tape recordings will be checked to confirm or resolve any inconsistencies. When these procedures have been completed, a summary of the views and perspectives of each interview will be returned to the interviewee to confirm the record, giving the interviewee an opportunity to agree/verify that the contents are a 'true' record of the interview.

Once this stage is complete, a second reviewer will be asked to code the information using the above system and to confirm the reliability of the coder. The criteria for agreement include;

- a) that the same section of the taped interview represents a point,
- b) that the same key word for each point summarized is used by both coders, and
- c) that the two summaries of each point have the same meaning (see Keeves, 1997, p. 300).

In sum, interviews and other material will be analyzed in an iterative process to distinguish interviewees' views, concerns, expectations, and disappointments. These concerns, expectations, and disappointments will be highlighted and used in the recommendation for a new Map.

## **Summary**

A pilot study was conducted to trial the interview instrument and at the same time to encourage casual staff to agree to an interview. Accounting casual staff were identified and a request was sent to each one inviting them to be part of the survey. The instrument asked for personal and professional details. Casual staff were invited to respond and also

requested to return the completed form to the supervisor with contact details. All casual accounting staff responded and all questions on the survey were answered.

Prior to the interviews all casual staff in the School Accounting were invited to participate in this study. The invitation letter assured the interviewees that their participation was voluntary and that they could withdraw at any time. A set of interview questions was prepared following a literature review for these pilot interviews. Two respondents were selected and contacted to see if they would participate in the pilot interviews. Both accepted the invitation. The two interviewees for the practical pilot interviews were chosen based on their levels of experience and their teaching histories. The next step therefore was to identify from the responses which questions to ask. This was not a difficult task because the interviews were not structured. The talking was done by the interviewee with minimal prompting (ideally) from the interviewer. One of the hazards of this approach is that interviewees can ramble on but that was a risk which seemed worthwhile in the pilot stage. It was assumed that the staffs' real feelings would come through using this approach.

The pilot interviews were carefully analyzed to determine what the interviewees focused on. Three distinct issues emerged, i.e.

First, Lack of Policies in three (3) aspects

- a. Lack of resources
- b. Lack of training
- c. Lack of paid consultation time

Second, Lack of Recognition, specifically

- a. Lack of a sense of belonging
- b. Lack of interaction with unit controllers and other staffs

Third, Lack of Communication (including feedback)

- a. Lack of feedback
- b. Lack of security
- c. Lack of input into teaching
