Managing the “Intangibles”: Business and Entrepreneurship Perspectives in a Global Context

Nature and Scope of the Conference

Compared to tangible assets, “intangibles”, or knowledge-based resources, are among the most important determinants of institutions, business and industry performance. Recognizing their role in promoting entrepreneurship, firm performance and socio-economic advancement, several developed countries have recently estimated the economic value of R&D and other forms of innovations, and have integrated them into the measurement of GDP. At the same time, several studies have questioned the net benefits of globalization and the impact of “intangibles” on the level and distribution of income and wealth. These mixed results indicate that the role of intangibles and knowledge resources as a source of equitable development is an open issue and hence of significance for theoretical and empirical research. In this framework, the 13th Conference of the Society for Global Business and Economic Development (SGBED) invites empirical and conceptual research with a focus on the role of the “intangibles” in advancing equitable development in a global business and institutional perspectives.

Topics

- Human Capital Management
- Knowledge Management, Online Education, Higher Education & Executive Training
- Knowledge Transfer within and Across Organizations
- Innovation and knowledge diffusion Role of Information Communication Technologies (ICT), R&D Networks, Technology Clusters, Science Parks, Business Incubators

Contextual Success Factors for Social Entrepreneurship: Comparing Africa and India

Abstract

President Uhuru Kenyatta of Kenya in 2009 said that “Social Entrepreneurship has come of age” (Kenyatta, 2009). He was at the celebration ceremonies of the Schwab Social Entrepreneur of the Year award, sponsored by the Schwab Foundation for Social Entrepreneurship. Social entrepreneurship has in the last twenty years been recognized internationally as a new and more serious effort to address humanitarian problems such as poverty and disease. The Schwab Foundation and a growing number of similar organizations are attempts to promote social entrepreneurship globally, especially in the developing world. Their programs identify successful social entrepreneurs and social enterprises and help them to expand their social impact. The Ashoka Social Entrepreneurship Foundation has over 3000 successful social entrepreneurs, called Ashoka fellows, they are helping to expand their social impact. Information about Ashoka fellows is posted on the Ashoka Foundation’s website. What factors led to the initial success of these social entrepreneurs? In this study we compare successful social entrepreneurship in Africa and India. The basic premise of this study is that the roads to successful social entrepreneurship in Africa and India are significantly different, given the fairly obvious differences in the political, economic and socio-cultural environments in the two regions. Among the leading differences are political unity and stability and political disunity and instability in India and most African countries, respectively. For the purpose of the study, we compare 105 African fellows with 75 Indian fellows. We found significant differences between African and Indian fellows in terms of the specific poverty/economic development issues they attempted to address, the population segments they focused upon, and the factors that inspired them to become social entrepreneurs. There were no differences related to how the fellows financed their social ventures.

Introduction

Aleke Dondo, the founder of the largest microfinance organization (Juhudi Kilomo) in Kenya was the Schwab Social Entrepreneur of the Year in Africa in 2011. Celebrating this award, Mr. Uhuru Kenyatta, then deputy prime minister of Kenya and currently Kenya’s President, declared that “Social entrepreneurship has come of age” (Kenyatta, 2009). Mr. Kenyatta was merely echoing what many observers on the subject have been saying for the last 20 years. Indeed, in the last 10 years the judges for the Nobel Prize as well as the Right Livelihood Award have recognized the contributions of leading social entrepreneurs and awarded three of them these honors. One recipient is Muhammad Yunus of the Grameen Bank. Social entrepreneurship is being celebrated because it attempts to address social problems traditional entrepreneurs and governments fail to address. Social entrepreneurship uses innovative business models to provide long term solutions to “wicked” problems, problems that defy simple solutions due to their complexity (Neck, Brush & Allen, 2009). Problems such as wide-spread poverty and disease have tended to grow worse world-wide, even in developed countries, following near depression-level world recession (Borker & Adam, 2012).

Humanitarian problems such as poverty, disease and hunger, have attracted the attention of the international community. The eradication of poverty is in fact the top goal among the 8 UN-backed Millennium Development Goals (UNDP, 2001). Above, we referred to the Schwab Social Entrepreneur of the Year Award. The award is sponsored by the Schwab Social Entrepreneurship Foundation. Other similar foundations include the Skoll Foundation for Social Entrepreneurship, the Acumen Fund for Social Entrepreneurship and the Ashoka Foundation for Social Entrepreneurship. Together with philanthropists, such as the Bill and Melinda Gates Foundation, the social entrepreneurship foundations promote social entrepreneurship internationally (Credit Suisse, 2010). Although their focus is on the eradication of poverty in the developing world, recent economic problems in developed countries have made them more active in these countries (Borker & Adam, 2012). These foundations provide different forms of support to social entrepreneurs in Africa, Asia and Latin America. One typical form of support for social entrepreneurs is electing potentially highly successful social entrepreneur to the Fellowship Program of the foundation. By far the largest of such programs is the Ashoka Fellowship. There are over 3000 Ashoka fellows worldwide. To be elected to be a fellow the social entrepreneur must already have a well-established social enterprise. The social enterprise must show signs of social impact scalability. It is this scalability that attracts the attention of the social entrepreneurship foundation. Thus, awardees of fellowships are successful social entrepreneurs. But what made them successful or how did they succeed?

In this study we compare successful social entrepreneurship in Africa and India. The basic premise of this study is that the roads to successful social entrepreneurship in Africa and India are significantly different, given the fairly obvious differences in the political, economic and socio-cultural environments in the two regions. Among the leading differences are political unity and stability and political disunity and instability in India and most African countries, respectively. Equally well-known are the economic differences. India's economy is an established emerging economy. Most African economies are still developing, and barely growing. Nine of the 10 poorest countries in the world are in Africa (<http://foxbusiness/markets/2012/09/14/10>, 2014). Society-wise, both regions have tendencies towards collectivism, but considerably more so in most African countries than in India (Kiggundu, 2002). J. Kerlin (2006), in her study "A comparative analysis of the global emergence of social enterprise", divided the social enterprise world into seven regions. She found Africa and India to belong to completely different regions. In the Southeast Asia region, to which India belongs, the emphasis of the social enterprises was "sustainable development". In the Africa region it was self-sustainability.

Literature Survey

Even though there is a growing interest about social entrepreneurship, there doesn't appear to exist a common definition of this concept. To complicate matters, the definitions of social entrepreneurship and approaches to social entrepreneurship have been found to vary according to geographical regions (Kerlin, 2010). J. Kerlin (2010), in her study "A Comparative Analysis of the Global Emergence of Social Enterprise" identified seven world regions in her comparison of social enterprise and social entrepreneurship approaches, namely, United States, Western Europe, Japan, East Central Europe, Argentina, Southern Africa, and Southeast Asia. The author's analysis was based on country case studies in the seven regions. Southern Africa was represented by Zambia and Zimbabwe, countries with economic, political and social characteristics roughly similar to those in the rest of sub-Saharan Africa.

Kerlin found Africa and India to belong to completely different regions. In the Southeast Asia region, to which India belonged, the emphasis of the social enterprises was "sustainable development". In the Africa region it was self-sustainability. Other differences between Africa and Southeast Asia (India) related to the importance of international aid to the regions, being much higher in Africa than it is in Southeast Asia. Further, while state capability was weak in both Africa and Southeast Asia (India), it was much weaker in Africa than in India.

Social entrepreneurship is a form of entrepreneurship (Meyskens et. al 2010). But it is entrepreneurship that focuses on social problems. Morse and Dudley (2002) stated that social entrepreneurs and social entrepreneurship combine a spirit of enterprise and a spirit of community in order to bring about community improvement. This concept of social entrepreneurship is complicated by the fact that nearly all legitimate enterprises, i.e., socially and legally sanctioned enterprises, are connected with a certain degree of community spirit, to the extent that any enterprise satisfies a community need (Austin, Stevenson & Wei-Skillern, 2006). Traditional enterprises provide employment opportunities and pay taxes. Other things being equal, traditional entrepreneurs and the market system can take care of all people's needs. Also, again other things being equal, the government can use tax revenues to finance and provide purely public goods, goods that are consumed collectively, such as police protection.

Unfortunately, there is no country where all things are equal for traditional entrepreneurs and government to produce and cater for all social needs. This is particularly true in poor developing countries. First, there aren't enough traditional entrepreneurs (Seelos, Mair, 2004). This is a problem many governments have tried to address. Where government programs aren't working fast enough to create new entrepreneurs, there is a need for social entrepreneurs. Essentially, social entrepreneurship addresses failures in market and public sectors (The Economist, 2014).

Social entrepreneurship is not the only way humanitarian needs such disease, illiteracy and hunger can be addressed. Almost all these afflictions of the poor can be directly met through donations of money and materials. Enlightened philanthropy, corporate social responsibility and civil society organizations have been making donations towards the alleviation of human miseries for years (Deeds, 2007; Barr, Fafchamps & Owens, 2005). All these arrangements are humanitarian needs-oriented. But they aren't necessarily socially entrepreneurial. However, in this paper we focus on entrepreneurial initiatives that create social value by bringing about lasting improvements in the well-being of those afflicted by poverty, disease, and hunger (Deeds, 2007).

A growing amount of literature now exists that attempts to explain patterns that characterize successful social entrepreneurship and social enterprises. One major study by S. Alvord, D. Brown and C. Letts (2004), all of Harvard University, examined seven highly successful social enterprises world-wide and identified four key patterns in these social enterprises. The seven cases included the Grameen Bank in Bangladesh, Self-Employed Women's Association (SEWA) in India, Se Servir de la Saison Seche en Savane et au Sahel (Six-S) in Burkina Faso, Africa, and the Green Belt Movement in Kenya, Africa. The four patterns related to core innovations, adaptive leadership capacity, operational organization, and scaling up strategy. All four patterns existed in all seven cases, but in different forms and degrees, depending upon environmental contexts. For example, while the core innovation for the Grameen Bank was to initiate a Micro Credit Package to assist poor women in Bangladesh, Six-S (Burkina Faso, West Africa) built Local Capacity by promoting networking of village organizations. Among the 7 cases only 2, in India and the U.S, employed movement building initiatives, mostly because of the high degree of tolerance to political challenges in these two countries. This was not a feasible option in Burkina Faso. J. Mair and I. Marti (2006) defined social entrepreneurship as "the interaction between social entrepreneur and context. Thus, the context can enable or constrain the appearance and success of social entrepreneurship.

B. Urban points out that while social problems are the central driver for social entrepreneurship, the key driving forces for social entrepreneurs arise out of political institutions, economic institutions and social-cultural institutions. It is deficits in these institutions that bring about social problems to which social entrepreneurs respond. Thus, undemocratic political institutions cause political upheavals to which social entrepreneurs often have to respond. A good case in point is the near civil war that followed the 2007 presidential elections in Kenya. Several social enterprises were launched to help people who had been dislocated by the inter-tribal fighting (<https://www.kickstart.org/>, 2012). It is also true that effective political, economic and social institutions can provide opportunities for social entrepreneurship. Thus, religious freedom encourages the establishment of faith-based social enterprises. The encouragement of social capital in a society is also good for social entrepreneurship, just as it is for commercial entrepreneurship. M. Sharir and M. Lerner (2006) in their study on gauging the success of social ventures found the entrepreneur's social network to be the leading factor, among the eight factors they discovered, behind the success of social enterprises. The presence of political unity and stable government in a country are also positive factors for the development and success of social entrepreneurship, again as it is for commercial entrepreneurship (Rangan, 2003).

Methods

To study the differences in social entrepreneurship in Africa and India we used Internet-based data available on the Ashoka Foundation for Social Entrepreneurship website. The Ashoka Foundation is the biggest international organization that supports social entrepreneurs. The organization celebrates social entrepreneurship success by electing the social entrepreneur to become a Fellow in the organization's social entrepreneurship network. To qualify for the election, the social entrepreneur must demonstrate scalability to broad-based social impact of his or her initiative. In order to be elected to be a Fellow, the social entrepreneur prepares a detailed statement. The statement is evaluated on a five-fold criteria: newness of idea, creativity, entrepreneurial quality, social impact of idea, and ethical fiber (Ashoka.org, 2014). Currently there are over 3000 Ashoka Fellows from all regions of the world. By analyzing the information on the Internet related to African and Indian Fellows, we expected to discover, among other things, differences in the nature of innovations used by social entrepreneurs, differences in the population segments targeted by social entrepreneurs, differences in financing social enterprises, differences in the strategies used to scale up the social impact of social enterprises, differences in the career backgrounds of social entrepreneurs and differences in the factors that inspired the social entrepreneurs to undertake the initiatives.

The Ashoka Foundation categorizes social fellows into five fields: Economic Development, Civic Engagement, Environment, Health, Human Rights, Learning and Education. We decided to focus on the field of Economic Development, because of its direct connection with poverty alleviation. One reason for our interest in poverty alleviation is that Poverty is the number 1 of the 8 UN-backed Millenium Development goals and Africa has the largest number of the world's poorest countries (UNDP, 2001). The study covers 105 African and 75 Indian Ashoka fellows. These were the entire populations under the Economic Development field on the Ashoka Social Entrepreneurship Foundation website

when it was checked late 2013. The differences between African and Indian fellows were significant or not significant according to the Chi-square test of population differences. Table 1 shows the African countries to which African fellows belonged.

TABLE 1: ASHOKA FELLOWS AFRICA POPULATION

Afr. Country	Number of Fellows	Afr. Country	Number of Fellows	Afr. Country	Number of Fellows
South Africa	22	Mali	5	Mozambique	1
Nigeria	19	Cameroon	2	Niger	1
Kenya	17	Ghana	2	Rwanda	1
Burkina Faso	14	Zambia	2	Benin	1
Zimbabwe	6	Senegal	2	Tanzania	1
Uganda	6	Gambia	1	Togo	1
				Total	105

Findings

Table 2 shows the five sectors/areas of social issues upon which the surveyed Ashoka fellows focused: Rural Development, Job Skills for Employment, Rights for Disadvantaged Communities, Appropriate Technology and Development of Entrepreneurs. The table indicates that the emphasis placed upon these issues differed between

TABLE 2: MAJOR SECTORS AIMED AT BY SOCIAL ENTREPRENEURS*

Ashoka Fellows from	Rural Development	Job Skills for Employment	Equal Rights	Appropriate Technology	Entrepreneurial Skills	Total
Africa	32%	13%	27%	20%	9%	n=104
India	21%	12%	47%	15%	5%	n=75
Total	27%	12%	35%	18%	7%	n=179

*Chi-squared = 7.962, significant at p=.05

African and Indian Ashoka fellows. These differences were significant according to Chi-square tests. As can be seen in table 2, the surveyed African Ashoka fellows placed a lot more emphasis on rural development than did their Indian counter-parts. Thirty two percent (32%) of the 104 surveyed African fellows had their focus on rural development. The equivalent number for Indian fellows was 21%. On the other hand, Indian Ashoka fellows placed more emphasis on rights for disadvantaged communities than their counterparts in Africa. As can be seen in table 2, 47% of the Indian fellows directed their organizations towards problems faced by disadvantaged communities. The comparable figure for African fellows was 27%. An example of an Indian social enterprise which was aimed at problems faced by disadvantaged communities is a “women and child development service center” near Calcutta, India. The center was started by a divorced Muslim woman to help divorced Muslim women access services traditionally denied to divorced Muslim women. Another example is Sammaan Foundation. The organization was started to help rickshaw operators own their rickshaws instead of renting them. As a result rickshaw operators can save enough money to access healthcare, which was previously unaffordable.

There were also some striking similarities between African and Indian fellows: the focus on job skills for employment, entrepreneurial skills and appropriate technology was low in both African and Indian fellows. Table 3 shows that the population segments targeted by African fellows differed significantly (Chi-square=10.684) from those targeted by Indian fellows. While 34% of the African fellows targeted rural peasant farmers, the corresponding number for Indian fellows was 23%. On the other hand, Indian fellows targeted the general community more heavily (43%) than African fellows did (28%). Other differences shown in table 3 relate to youth and

entrepreneurs. Although the percentages were low overall, African fellows targeted the youth twice as frequently as the Indian fellows. This pattern was reversed in relation to entrepreneurs.

TABLE 3: POPULATION SEGMENTS TARGETED BY SOCIAL ENTREPRENEURS*

Ashoka Fellows from	Rural Farmers	Youth	Women	Entrepreneurs	General Community	Total
Africa	34%	17%	16%	5%	28%	n=105
India	23%	8%	15%	12%	43%	n=75
Total	29%	13%	16%	8%	34%	n=180

*Chi-squared = 10.684, significant at p=.05

Table 4 shows the career backgrounds of the African and Indian fellows covered in the study. The career backgrounds of the two groups differed significantly (Chi-square=36.441). As can be seen from table 4, 52% of the

TABLE 4: SOCIAL ENTREPRENEUR'S CAREER BEFORE LAUNCHING SOCIAL ENTERPRISE*

Ashoka Fellows from	Educational Institution	Government	Self-Employment	Volunteer in Existing Charity	Social Activism	Total
Africa	16%	52%	13%	17%	2%	n=103
India	11%	19%	32%	18%	20%	n=74
Total	14%	38%	21%	18%	10%	n=177

*Chi-squared = 36.441, significant at p=.05

African fellows were government employees before embarking on their social enterprise initiatives. The corresponding number for Indian fellows was 19%. On the other hand, 32% of the Indian fellows were self-employed (business owners) before initiating their social enterprises. The corresponding number for African fellows was 13%. Other significant differences between African and Indian fellows related to backgrounds in education and social activism (long-term involvement in social causes). Sixteen percent of the African fellows held teaching or administrative jobs in institutions of learning at various levels. The corresponding number for Indian fellows was 11%. On the other hand, 20% of the Indian fellows had been social activists (community organizers) for long periods in their lives, often since high school, and rarely holding regular jobs. The corresponding number for African fellows was only 2%. An example of an Indian long-term social activist is the owner of an organization that helps poor women beggars at temples become independent entrepreneurs. She had been an activist to help beggars since high school. Her M.A. degree dissertation was on street beggars in temple complexes.

Table 5 shows the social entrepreneurs' sources of inspiration. African and Indian fellows in the study were inspired significantly differently (Chi-square=6.558, significant at p=0.05). A big majority (61%) of African fellows were inspired by personal experiences, invariably bitter, in order to embark on their social enterprises. The corresponding number for Indian fellows was 42%. An African fellow whose personal experience of rural farming poverty inspired him to act is the owner of "Market Information Points" in Western Kenya. The social entrepreneur

TABLE 5: SOCIAL ENTREPRENEUR'S MAJOR SOURCE OF INSPIRATION*

Ashoka Fellows from	Personal Experience	Concern for Others	Family	Total
Africa	61%	36%	3%	n=102
India	42%	51%	7%	n=74
Total	53%	43%	5%	n=176

*Chi-squared = 6.558, significant at p=.05

witnessed how small farmers, including his parents, were being exploited by middlemen. His organization provides farmers the information they use to negotiate with crop buyers. On the other hand, the most common (51%)

inspiration for Indian fellows was sympathy for others. The corresponding number for the African fellows was 36%. An example of a social enterprise that arose out of sympathy for others is a legal services organization that was set up to stop atrocities visited on poor organic farming groups in Maharashtra state in India.

Table 6 shows the sources of financing used by African and Indian fellows in their social enterprises. The table clearly shows that these sources hardly differed between African and Indian fellows. The financing patterns did.

TABLE 6: FINANCING THE SOCIAL ENTERPRISE

Starting Up*						
Ashoka Fellows from	Owner's Resources	Government Resources	Charity Support	Formal Borrowing	Multiple Sources	Total

Total	83%	4%	7%	2%	4%	n=173
Expanding**						
Africa	48%	9%	19%	5%	19%	n=100
India	44%	12%	18%	7%	19%	n=73
Total	46%	10%	18%	6%	19%	n=173

*Chi-squared = 5.491, not significant at p=.05; **Chi-square= 0.890, not significant at p=.05

differ between starting social enterprises and expanding them. For starting social enterprises, internal resources were immensely important. Eighty four percent of the African fellows and 82% of the Indian fellows depended on own resources to initiate their social enterprises. Charity funding was a distant second source for both African and Indian fellows. To expand their social enterprises the fellows in both groups still depended a great deal (around 45%) on their own resources, especially in terms of revenues generated from sales of products and services. However, this is about only half of the corresponding numbers for financing the start-up phase. Charity funding toward social enterprises nearly tripled (from 7% to 18%) as the social enterprises grew. It seemed that the more established the social enterprise was, the more attractive it became to charity funders, such as the Bill Gates Foundation (Aldashev & Verdier, 2009). Table 6 also shows that using multiple sources of funding rose as social enterprises became more established.

Discussion and Summary

As expected, Ashoka fellows in Africa and India are similar and different in significant ways. Most of these similarities and differences appear to be contextually-based. In this section we refer to 5 areas of similarities and differences between African and Indian fellows: Different areas of emphasis (rural development vs. equal rights), Different targeted populations (rural farmers vs. general community), Different career backgrounds (government employment vs. self-employment/business ownership), Different sources of inspiration (personal experience vs. concern for others) and Similar sources of financing (owner resources and charity funding).

As we stated in the introduction there are vast opportunities for social entrepreneurs in every country today. These opportunities are a function of multiple deficits in a given country. In this paper the deficits emphasized are economic and political. There are vast differences between Africa and India. Economically, India has an emerging economy, while most sub-Saharan Africa countries are poor and barely developing. Politically, India is the largest democracy in the world, while most African countries are still unstable and are governed by oppressive regimes. That the eradication of poverty is the top objective of 32% of the African fellows included in this study is not surprising. On the other hand, movements in support of disadvantaged communities, politically, socially and economically, were the most important focus (47%) of Indian fellows. This heightened focus on equal rights issues is possible in India because challenges, political or otherwise, are tolerated (Alvord, Brown & Letts, p.2004). The same patterns can also be seen in terms of the population segments targeted by the fellows included in the study. The African fellows targeted rural farmers to a much greater degree than their Indian counterparts.

The majority (52%) of the African fellows were government employees before embarking on their social enterprises. This is most likely a reflection of the dominance of government employment in the formal sector in most African countries (worldbank.org, 2014). On the other hand, as many as 32% of the Indian fellows had been self-employed/business owners before becoming social entrepreneurs. This is probably a reflection of the relatively more developed entrepreneurial class in India. Moreover, another 20% of the Indian fellows had been social activists for a long time, some of them since high school. This could be the result of the presence of several social entrepreneurship development programs in India. One such program, and one that is quickly catching up with the big social entrepreneurship foundations in the U.S. and Europe, is the “Tata Champions of Change” (Tatasechallenge.org,2014).

African and Indian fellows differed significantly in terms of the major circumstances or factors that inspired them into social entrepreneurship. A very large majority (61%) of the African fellows had first-hand personal experience with the social problems they address in their social ventures. We pointed out earlier that rural poverty (rural development) is the key social problem African fellows emphasized in their social ventures. They most likely grew up around poverty. On the other hand Indian fellows largely (51%) started social ventures in sympathy with others’ adverse circumstances, such as beggars around temples and the homeless on the streets. Fighting the “system” on behalf of others’ suffering, in a democratic society, is a very attractive option for social entrepreneurs (Alvord, Brown & Letts, 2004; Datta & Gailey, 2012).

Social entrepreneurs in Africa and India appear to face similar problems in financing their social ventures. Like commercial entrepreneurs most social entrepreneurs finance their start-up costs internally (Allen, 2013). There do not appear to be major reasons why African and Indian fellows should differ in terms of financing start-up social ventures. For both African and Indian fellows government and charity financial support increases as social ventures grow. The increases in these sources of funding are again almost identical for African and Indian fellows. Thus, external financing is more available for expanding social ventures than it is for starting them up. This is also the pattern for commercial ventures. While social entrepreneurship is different from commercial entrepreneurship, the two are similar in many respects (Meyskens, et al, 2010).

Study Limitations

The study was based on self-reporting by the Ashoka fellows studied. The Ashoka foundation requires every candidate for election to fellowship to write a semi-structured statement in which the candidate describes his or her accomplishments and future objectives. The statements have specific sections, which probably act as guidelines for preparing the statements. The volume/depth of information given in the statements varies from candidate to candidate. Consequently, comparing candidates was not always easy. A better approach to study Ashoka fellows would be to interview them after reading their candidacy statements.

Another limitation of the study related to the African fellows population. It was biased toward 4 countries, three of them some of the most prosperous in sub-Saharan Africa. Seventy two of the 105 African fellows come from South Africa, Nigeria, Kenya and Burkina Faso. None of these countries is one of the 9 African countries on the ambiguous list of the 10 poorest countries in the world. Unfortunately, this study limitation is also a statement about the limitations of international social entrepreneurship foundations. They are not yet reaching the countries where poverty is most rampant.

Intangibles and Entrepreneurial Capital

Abstract

The purpose of this paper is to increase and supplement the existing literature on Entrepreneurial Capital (EC) and to analyze how large Italian companies develop and enhance this intangible element. To this end, the research observes the different definitions of entrepreneurial capital that literature offers and propose a new construct focusing on the positive relationship between EC and Intellectual Capital (IC) This is done through attracting the right potential of human capital and viewing EC as a fundamental component of intellectual capital. Consequently, the works aims to provide an overview on the current level of EC in Italian organisations and how does it affect value creation.

This research provides researchers and managers with unique insights into the evolutionary nature of the relationships between distinct entrepreneurial variables and explains how to enhance corporate entrepreneurial and intellectual capital, thus highlighting companies' abilities to manage their EC in order to create economic value, growth, innovation.

Keywords - Entrepreneurial Capital, Intellectual Capital, Risk-taking, Proactiveness and autonomy, Aggressiveness.

1. Introduction

The purpose of this paper is to increase and supplement existing literature on Entrepreneurial Capital (EC) and to analyze how large Italian companies develop and enhance this intangible element. To this end, the research observes the different definitions of entrepreneurial capital that literature offers and defines the variables suggested by previous literature proposing a new definition for our research project. Entrepreneurial capital is defined as a stock of competences and personnel's attributes related to proactive, risky and aggressive decision-making and behavior. The empirical research aims to provide an overview on the Italian state of art of the current level of EC in Italian organizations and to understand how does it affect value creation.

Therefore, the purpose of this paper is to show preliminary results from the Italian research unit of an international project on intellectual capital and value creation led by Lappeenranta University of Technology – LUT (Finland).

The two key academic discussions addressing knowledge in organisations are Intellectual Capital (IC) and Knowledge Management (KM) streams of research. In particular, IC literature focuses on intangible resources that contribute to value creation (e.g. Edvinsson and Malone, 1997; Sullivan, 1998) that is “knowledge-based resources that contribute to the sustained competitive advantage of the firm” and “knowledge that can be converted into profits”. However, very few earlier studies systematically combine IC and KM practices to examine key knowledge-related factors impacting value creation in firms.

Yet the main question of the overall project is: “How do IC assets and their management practices interact to create value?” and the common goal of the international research team is to examine the current state of IC stocks and KM practices, and how these interact in firms' value creation.

Academic Partners involved in the project are the following:

- Lappeenranta University of Technology, Finland (The Core Team)
- University of Rome 3, Italy
- Hong Kong Polytechnic University, China
- Deusto Business School, University of Deusto, Spain
- St. Petersburg University Graduate School of Management, Russia
- Educons University, Serbia
- Universidade Lusíada, Portugal
- Academy of Economic Studies, Bucharest, Romania

In most studies IC has been seen to consist of three elements: human capital, structural capital and relational capital (e.g. Bontis, 2001; Guthrie, 2001). The IC literature helps in identifying intangible resources stock within the firms and in assessing it. However are the above-mentioned three elements sufficient?

In our research design we suggest that also three other elements could be included in IC visualizing and mapping: “renewal capital”, in terms of innovative solutions, products and services available for the firms, “trust capital” (i.e. trust embedded in firm’s internal and external relationship) and “entrepreneurial capital” (i.e. competence and commitment related to entrepreneurial activities in the organisation) (Kianto, 2007; Kianto, 2008; Kianto et. al., 2013).

Within the overall project, the Italian research unit will focus on EC. In particular it will be analysed how medium- and large-sized Italian companies develop and enhance this intangible element. Consequently the research questions of our investigation are the following: What is the current level of EC in Italian organisations and how does it affect value creation?

To this end, our investigation aims to highlight the importance of EC as a stand-alone component of IC. As a secondary step we’ll analyze variables suggested by previous literature trying to understand this phenomenon and we’ll propose a definition that fits our research design. The emerging definition is that EC concerns competences and attributes the possessed firms’ personnel and related to proactive, risky, innovativeness and aggressive decision-making and behaviour.

Our research agenda will provide academics and managers with unique insights into the state of art of corporate EC in Italian companies. Furthermore this research will set the agenda for improving EC practices of Italian companies and will allow future comparison with firms from other countries currently involved in the same project, identifying different pathways to success.

2. Literature Review

2.1. Previous studies in the field of Entrepreneurship

Sharma and Chrisman (1999) maintain that the concept of entrepreneurship includes not only processes of creation of new organizations (Gartner, 1988) but it encompasses a broader set of activities including carrying out new combinations (e.g. product or process innovation) within existing organizations, organizational innovation and organizational transformation through strategic renewal. They provide a comprehensive definition of entrepreneurship encompassing “acts of organizational creation, renewal or innovation that occur within or outside an existing organization”. In this definition innovation is an entrepreneurial activity since “it involves new combinations that may dramatically alter the bases of competition in an industry, or lead to the creation of a new industry”, even if innovation might not immediately generate a new venture creation.

According to this definition, “Entrepreneurs are individuals or groups of individuals, acting independently or as part of a corporate system, who create new organizations, or instigate renewal or innovation within an existing organization” (Sharma and Crishman, 1999).

Entrepreneurship can be studied at an individual and collective level (independent and corporate entrepreneurship). Independent entrepreneurship is the process of creation of a new organization by individual(s) not associated with an existing organization. Corporate entrepreneurship concerns processes of organizational creation, renewal or innovation instigated by an existing organizational entity (Sharma and Crishman, 1999).

Scholars who have studied entrepreneurship at the collective level, wondered what are attitudes and behaviors that express the presence of entrepreneurship in an organization. The concept of entrepreneurial orientation (Miller, 1983; Covin and Slevin, 1989; Lumpkin and Dess, 1996) was introduced referring to a firm’s strategic orientation (Wiklund and Shepherd, 2003), capturing specific entrepreneurial aspects of decision-making styles, methods, and practices that inform a firm’s entrepreneurial activities (Lumpkin and Dess, 1996). This construct has been described as the product of three to five dimensions, including autonomy, innovativeness, risk taking, proactiveness, and competitive aggressiveness (Covin and Slevin, 1989; Miller, 1983; Lumpkin and Dess, 1996). Consistently with Covin and Slevin (1991), in most studies only three dimensions have been considered, commonly propensity of firms to be innovative, proactive to the market place opportunities and be willing to take risks.

Entrepreneurship scholars have attempted to explain a firm's performance by investigating its entrepreneurial orientation. Positive associations between business performance and entrepreneurial orientation have been found by Wiklund and Shepherd (2003), Zahra (1991), Zahra and Covin (1995) (see Rauch et al. 2009 for a summary)

Some authors claim that in order to understand the level of entrepreneurial orientation in an organization it's important to consider not only the characteristics of the firm as a whole (Lau et al., 2012) but also those of employees and managers working within a firm. Organizational and individual levels are in fact connected, as organizations' entrepreneurial orientation is the result of entrepreneurial behaviors and attitudes of people involved in organizations. These behaviors are influenced by organizational factors such as strategies, structure, reward systems, organizational boundaries, management style (Hornsby et al., 2002; Kuratko et al., 2005).

It follows that in order to analyze the level of entrepreneurial orientation in an organization, it is important not only to verify the existence of such factors within the firms, but also to verify the existence of entrepreneurship' dimensions in individuals working within the firm (employees and managers).

Accordingly EC can be defined as the entrepreneurial behavior exerted in an organization, i.e. the courage, initiative taking and pro-activeness demonstrated by organizational actors. Consistently with resource-based perspective (Barney, 1991) of entrepreneurship the success of a business is deeply affected not only by its tangible and financial capital, but also by the quality of its entrepreneurial capabilities. According to Erikson (2002), EC is a multiplicative function of entrepreneurial competence and commitment. The former is defined as the "capacity to identify and pursue opportunities, and to obtain and coordinate resources", and the latter "reflects the capacity to see ventures through to fruition". EC consists of a set of human capabilities that represents a very important asset and a source of competitive advantage for a business. In fact it facilitates the identification of new opportunities, enhances the ability to gather, organize and manage resources and to use them in profitable activities.

2.2 Intellectual capital and Entrepreneurial capital: links and relationships

Intellectual capital has been defined as "the total stock of capital or knowledge-based equity that the company possesses" (Dzinkowski, 2000). IC is either the end product of a knowledge transformation process or the stock of organizational knowledge itself. IC incorporates three main components that together form value: human capital, organizational (structural) capital, and customer (or relational) capital (Bontis, 2001; Guthrie, 2001).

Human capital refers to and includes know-how, education, work-related competencies, and psychometric assessments. McGregor et al. (2004) define human capital as the size and quality of broader labor markets, but also as the sum of individual competencies in organizations. Teece (2000) recognizes that knowledge assets or products result from the experience and expertise of individuals. However, the "physical, social, and resource allocation structure" of organizations are important if such experience and expertise is to be translated into competencies that help generate knowledge products (Teece, 2000; McGregor et al., 2004).

The term structural capital reflects these allocation structures and includes assets such as corporate culture, management processes, databases, organizational structure, patents, trademarks, and financial relations. Engstrom et al. (2003, p. 288) suggest that structural capital "includes all non-human storehouses of knowledge in organizations."

Finally, relational, or customer, capital refers to, in part, organizations' customers, brands, customer loyalty, and distribution channels. Customer capital also refers to consumers as repositories of information and knowledge that is valuable to organizations (Bontis, 1998).

For the purpose of our research we deem that EC (roughly intuitively defined as the competence and commitment related to entrepreneurial activities in the organization) should be taken into consideration as a stand-alone element of IC in the light of the following rationale:

- in an unsteady and unpredictable business environment, like today, EC might be found as one of the most influent intangible to enhance corporate value;
- the construct of EC is characterized by several attributes which, in the traditional definition of IC, refer both to human capital (i.e. entrepreneurial competence and behavior) and structural capital (i.e. entrepreneurial corporate culture and processes).

Consequently, EC - as well as renewal and trust capital - should be considered a specific and important dimension of IC (Kianto et al., 2013) even if most authors consider human, structural and relational capital as main IC components.

Particularly, Kianto et al (2013) discuss the nature of knowledge that can be conceived both as a stock or a resource and as a process or a practice. The Authors suggest distinguishing between static and dynamic perspectives on knowledge for understanding organizational value creation and performance, that is the IC stocks and the KM practices (see Table 1). Renewal capital refers to the ability of an organization to continuously develop itself through learning and innovation (see e.g. Kianto et al., 2010) and is intended in terms of innovative solutions, products and services available for the firm (Kianto, 2008). Trust capital concerns the trust embedded in a company's internal and external relationships (Mayer et al., 1995), while EC deals with the competence and commitment related to entrepreneurial activities in an organization (Erikson, 2002). This broader definition of IC is based upon a "wide understanding of knowledge, as not only the explicit outcomes of knowledge-intensive work such as patents, formulae and actualized products, but also as the tacit potential of organizational actors to e.g. flexibly react to unexpected situations and rapidly changing customer demands" (Kianto et al., 2013, p. 1475).

TABLE 1- INTELLECTUAL CAPITAL STOCKS AND KNOWLEDGE MANAGEMENT PRACTICES

IC stocks' components	KM practices and mechanisms
Human capital	Strategic KM practices
Structural capital	Organizational structural arrangements
Relational capital	KM-friendly organizational culture
Renewal capital	ICT practices
Entrepreneurial capital	Learning mechanisms
Trust capital	KM-related HRM practices Knowledge protection practices

Source: Kianto et al., 2013, p. 1476.

Entrepreneurial capital (Erikson, 2002) can be defined as entrepreneurial behavior exerted in an organization, i.e. the courage, initiative-taking and pro-activeness demonstrated by organizational actors. Moreover, EC is defined as a stock of competences and personnel's attributes related to proactive, risk oriented, innovativeness and aggressive decision-making and behavior.

The concept of EC has been developed only recently (Lam et al., 2008). There is not a specific and autonomous line of studies on this topic, as the theoretical strands that have touched on this theme are accrued in different contexts, following prospects that do not always converge. On the one hand, as mentioned above, the concept of EC has been introduced in the context of studies on IC and KM. In this sense, the EC, together with renewal capital and trust capital, is conceived as a "new" component of the IC in addition to the traditional ones of human, structural and relational, capital (Kianto et al, 2013).

Moreover, as we'll see in the previous section, in the vast body of entrepreneurship studies, several links can be found with reference to the attributes that underline the construct of Entrepreneurial orientation (EO) and the Corporate Entrepreneurship (CE) (Lumpkin and Dess, 1996, 2001). In this context EC is viewed as a stock of competences and personnel's attributes related to proactive, risky and aggressive decision-making and behavior (Khandwalla, 1976/1977; Voss, Voss and Moorman, 2005), in the sense that the organization's personnel excel at identifying new business opportunities, initiate actions autonomously, as well as the level of freedom and independence in the way personnel work, while aggressiveness is conceived in terms of the organization's personnel courage to make bold decisions (Hughes and Morgan, 2007).

On the other hand, the concept of EC has been developed in the context of an emerging body of research (Erikson, 2002; Firkin, 2003, Shaw et al., 2009; Stringfellow and Shaw, 2009; Harvey et al., 2011) which highlights the crucial role that non financial resources play in facilitating firms' success (Anderson and Miller, 2003; Pret and Shaw, 2010) and underlines that, to date, little attention has been paid to the convertible, multifaceted nature of EC (Shaw et al., 2008). These studies identify the dimensions of EC, which, in addition to economic capital and social capital include the cultural capital and symbolic capital. Specifically, with reference to small and medium-sized enterprises (SMEs) Pret and Shaw, 2010) and Lam et al. (2008) demonstrate how non-financial components of EC are

relevant with respect to the SMEs' competitiveness and development and how their limited financial resources are offset by the other EC components.

EC has been defined in various ways. It has been seen as a subset of social capital (Audretsch and Monsen, 2008), as a derivative of Bourdieu's concept (Firkin, 2003) and as a multiplicative function of entrepreneurial competence and commitment (Erikson, 2002). Principally, the concept of EC builds on the resource-based view of entrepreneurship (Alvarez and Busenitz, 2001; Barney et al. 2011; Conner, 1991) and focuses on the importance of entrepreneurs' access to financial and non-financial resources (Erikson, 2002), such as human, social and symbolic capital (Davidsson and Honig, 2003; Roomi, 2013; Zott and Huy, 2007).

In his study Erikson (2002) traced a practical framework of EC presenting a model of EC defined as a multiplicative function of entrepreneurial competence and entrepreneurial commitment, which are the foundation for enterprise generation and performance. Extending the Ulrich's (1998) proposition of IC he underlines how the relationship between entrepreneurial competence and commitment is a multiplicative one rather than additive as both components. Inherent in this view on competence is the capacity to identify opportunities (opportunity recognition) and to increase perceptions of opportunities (Krueger and Dickson, 1994).

A similar construct is used when social capital is conceived as the sum all actual and potential resources that can be accessed through a durable network of relationships (Bourdieu, 1986)

Building on the afore mentioned resource-based (RB) perspective of entrepreneurship (Brush et al., 2002), the notion of EC suggests that in addition to financial capital, the entrepreneurial process is affected by the other types of capital possessed by entrepreneurs or available to them through networks and relationships (Firkin, 2003). Entrepreneurship scholars have variously identified non-financial capital as including the physical, organizational, technological, human, cultural, social and symbolic capital of business owners and their firms. Specifically, Gorton (2000) and Firkin (2003) provide detailed accounts of the value of Bourdieu's (1986) perspective on capital for the field of business ownership: even when entrepreneurs possess identical amounts and types of economic, human and social capital, differing values may be placed on the EC they possess Firkin (2003). Specifically, et al. (2008) operationalized the impact of EC on SMEs' reputation and performance.

Extending this perspective, Firkin (2003) suggests that the concept of EC is based on the total capital that an individual possesses and the value placed on this composite form of capital. Due to the difficulty to isolate and separate individual forms of capital these are characterized by an overlapping nature and convertibility. He refers to this interplay (how each form of capital can be converted from and into other forms of capital) as the convertibility of capital: if individuals possess high levels of human capital in terms of their education and experience, it might be expected that this would convert into their possession of high levels of social capital in terms of their networks and contacts.

Pret & Shaw (2010), exploring the importance of EC for small firms, inquiry how and why entrepreneurs utilize non-financial resources to achieve success. Their findings highlight the importance of social, cultural/human and symbolic capital to small firm owners who are often restrained by limited financial resources (Burns et al., 2012) and illustrate the fundamental role of these non-financial resources in supplementing craft entrepreneurs' economic and financial capital.

In the light of this brief literature review, we can deduce that EC represents a critical intangible asset that can contribute to firm's value creation, both for SMEs and medium and large enterprises, especially in periods of turbulence and economic crisis. Entrepreneurial and renewal capital represent key resources of organizations enabling high innovation performance and organizational growth and increasing the effectiveness in responding to future challenges and radical changes in the market. The first results of the survey (presented in the second part of the paper) show that EC and renewal capital are measures that have discriminant validity and internal reliability. Thus, they are relevant for measuring the growth and innovativeness potential of established medium and large firms.

3. Research Design: from Entrepreneurial Orientation to Entrepreneurial Capital

For the purpose of our research, drawing from the above-mentioned literature, EC is comprehensively defined as a stock of competences and personnel's attributes related to proactive, risky, innovative, independent and aggressive decision-making and behavior (Lumpkin and Dess, 1996).

Proactiveness means taking initiative by anticipating and pursuit new opportunities and participating in emerging.

Risk-taking reflects an acceptance of uncertainty and risk inherent in original activity. It's typically characterized by resource commitment to uncertain outcomes and activities.

Aggressive decision-making is the intensity with which a firm chooses to compete and efforts to surpass competitors reflecting a bias toward out doing rivals. It also includes the authority and independence given to an individual or team within the firm to develop business concepts and vision and carry them through to completion.

Innovativeness reflects firm's propensity to engage in a new idea/ processes and also new creative solution and opportunities (Wiklund, 1999).

Independence is the ability and will of people working within an organization to be self-directed in the pursuit of opportunities and to exercise their creativity without being limited by organization's constraints.

To further address how these dimensions are related to performance and value creations, we here overview several hypotheses. In fact to draw our research design it is necessary to examine how each individual variable of EC might influence business performance and value creation. We will explore above-mentioned dimensions and will investigate why each of them might have a positive influence on business performance and value creation.

HP 1: Proactiveness is positively linked with performance and value creation

Proactiveness represents a forward-looking perspective where firms actively seek to anticipate opportunities to develop and introduce new or improved products, instigate changes to current strategies and tactics, and detect future trends in the market (Lumpkin and Dess, 1996; Slater and Narver, 1995). Proactive firms, through proprietary learning and experience effects gained over time, tend to be more attuned to changes and trends in the marketplace, which yields opportunities to the firm to meet expressed and latent needs ahead of competitors (Hamel and Prahalad, 1991).

Firms' proactiveness is characterized by intentional change. That is, by forces acting on information to make change not merely anticipating it (Bateman and Crant, 1993). This alleviates the risk of complacency by ensuring firms are better placed to serve markets in the short term and shape them in the longer term. The emphasis on anticipating and acting on future needs orients the firm to seize initiative and act opportunistically in the marketplace thereby shaping demand (Miller and Friesen, 1978).

HP 2: Risk-taking is positively related with performance and value creation

Risk-taking represents a willingness to commit resources to implement projects, activities, and solutions that contain inherently a high level of uncertainty regarding the likely outcomes (Lumpkin and Dess, 1996). When deciding to take risks, firms must tolerate one of two possible scenarios - the first being the risk of failing and second the risk of missing out on an opportunity (Dickson and Giglierano, 1986). The former is caused by fear whereas the latter is caused by inaction. A tolerance of risk-taking orients the firm toward action and induces it to embrace uncertainty. Timely risk-taking has been associated with strategic decision speed and both have subsequently been linked to improved business performance (Eisenhardt, 1989). Risk-oriented firms combine opportunity-seeking behavior with constructive risk-taking to generate a bias for exploration and exploitation (Baird and Thomas, 1990; Lumpkin and Dess, 1996). Risk-taking managements usually seize opportunities and make commitments of resources before fully understanding what action needs to be taken (Covin and Slevin, 1991). Such an approach seeks to take advantage of evolving situations by capitalizing on the fact that markets rarely stabilize for any length of time. Risk aversion renders firms passive to developing new market opportunities which is likely to deteriorate performance in an age of rapid change (Miller and Friesen, 1982).

HP 3: Aggressive decision-making is positively related with performance and value creation

Firms that are highly aggressive see competitors as enemies that must be conquered.

Aggressiveness can be implemented through the mobilization of resources to launch direct attacks on competitors with the aim of overwhelming their market efforts, steadily erode their competitive strengths, or establish advantage through continuous offensive tactics (Davidson, 1987).

Aggressiveness can improve performance because the emphasis on out-doing and out-maneuvering competitors strengthens the firm's competitiveness at the expense of rivals (Lumpkin and Dess, 1996). Examples of the manifestation of such an aggressive competitive strategy include aggressive price competition, market entry with a new or superior offering, fast-following a rival into a market, continuously exploiting information, and using unconventional surprise tactics.

Such an emphasis on acquiring market share and customers by aggressively targeting rivals' weaknesses should improve performance because it undermines competitors' ability to compete and restrict the ability of competitors to anticipate and respond to what the aggressive firm will do next. Since the aggressive firm does not sit still and constantly implements incremental and adaptive change to undermine competitors, it is hypothesized Autonomy conveys the freedom to employees to encourage them to be self-directed, to exercise creativity, pursue opportunities, and champion new ideas which are essential for effective entrepreneurial activity to occur Lumpkin and Dess, 1996).

Autonomy is, therefore, an important driver of flexibility, which is an essential attribute if a firm is to be able to respond promptly to environmental change and market signals by quickly reconfiguring its actions and activities (e.g. Grewal and Tansuhaj, 2001). Flexibility is created when people within the firm are given freedom to apply their human capital in ways that help the firm to change adaptively and be responsive to the needs of its markets and actions of its rivals. A lack of autonomy would likely result in passivity when change is needed to initiate effective response to opportunities and threats to performance. The presence of autonomy, in contrast, should encourage a greater flexibility in the firm to facilitate active and reactive response to change. Although some framework of coordination is likely to be needed, on balance we expect that autonomy will be beneficial to improving business performance.

HP 4: Innovativeness is positively related with performance and value creation

Innovativeness represents a bias toward embracing and supporting creativity, experimentation, technological leadership, and R&D in the development of products, services, and processes to generate novel solutions to customer needs and problems (Hughes and Morgan, 2007). It is said to be present when firms pursue active implementation of new ideas, products or processes not merely their generation (e.g., Hurley and Hult, 1998).

Calantone, Çavuşgil, and Zhao (2002) establish that firm innovativeness has a positive impact on performance and contributes to competitive advantage by facilitating creative thinking within a firm's learning activities. Innovativeness also improves the application of market intelligence acquired through market orientation activities, which can benefit performance (Han, Kim, and Srivastava, 1998; Hurley and Hult, 1998). Also, a study by Hult, Hurley, and Knight (2004) uncovered that innovativeness benefits business performance regardless of market turbulence. Innovativeness changes the way firms apply market information (e.g., Slater and Narver, 1995) and informs the generation of intelligent solutions.

HP 5: Independence is positively related with performance and value creation

As stated by Lumpkin and Dess (1996) "autonomy is the freedom granted to individuals and teams who can exercise their creativity and champion promising ideas that is needed for entrepreneurship to occur". Independence is a fundamental dimension of entrepreneurial orientation Creation of new businesses is in fact the result of independent people who have chosen to act autonomously and not be bound by the constraints imposed by existing organizations. Autonomy therefore is an essential resource for the creation of new businesses. In existing organizations where autonomy is a key dimension, employees are encouraged to freely express their ideas, to promote innovative projects and proposals for renewal, so that they are actively involved in entrepreneurial activity. Autonomy is therefore an important driver of firms' flexibility, as it allows them to be able to respond promptly to environmental change and market signals by quickly reconfiguring their actions and activities (Hughes and Morgan, 2007).

3.2. Research Methodology

While the Italian research unit focuses on the EC, the overall research design aiming to understand links between IC managing and value creation. In the next paragraphs, the following steps will be addressed:

- 1) Operationalizing variables;
- 2) Survey Data Collection;
- 3) Target Respondent;
- 4) Public Data Collection.

1) Operationalizing variables

Operationalizing variables in social science involves defining a concept so that it can be measured. All variables defining Entrepreneurial Capital were addressed and discussed in meetings of the international working group.

As far as Entrepreneurial Capital is concern, the following are the operationalized variables and the related statement included into the questionnaire (Tables 2-3):

TABLE 2 –EC VARIABLES

ENTCAP	<p>Concept: Entrepreneurial capital</p> <p><i>Variables:</i></p> <p><i>Risk-taking</i></p> <p><i>Proactiveness</i></p> <p><i>Autonomy</i></p> <p><i>Aggressive decision-making</i></p> <p><i>Innovativeness</i></p>

TABLE 3 – STATEMENTS RELATED TO EC

To what extent do the following statements on the entrepreneurial orientation apply to your company?	
(1 = completely disagree, 5 = completely agree)	
	1 2 3 4 5
ENTCAP1	Risk-taking is regarded as a positive personal quality in our company.
ENTCAP2	Our employees take deliberate risks related to new ideas.
ENTCAP3	Our employees are excellent at identifying new business opportunities.
ENTCAP4	Our employees show initiative.
ENTCAP5	The operations of our company are defined by independence and freedom in performing duties.
ENTCAP6	Our employees have the courage to make bold and difficult decisions.
ENTCAP7	The operations of our company can be described as creative and inventive.

It must be noted that in the social sciences, much of what we study is measured on what would be classified as an ordinal level. In our questionnaire we then assign a value of “1” if interviewed Completely Disagree with the statement, up to a “5” if they Completely agree with the statement. The finalized research instrument (survey questionnaire) was distributed in the beginning of September 2013 by the LUT research team.

The questionnaire has been written in English. Partners should take care in translating the questionnaire to their own language, also with the help of a professional language expert in the first step. The core message of each item should remain the same to ensure the same meaning across countries.

Additionally, the questionnaire was finally reviewed in its linguistic style by the Italian research team to ensure that Italian respondents could easily understand the statements. The survey was conducted in exactly the same format in all cases. This means using all of the items in the survey, and in the same order, and with the same scales. The data were collected using survey questionnaire by the end of the year 2013.

Publicly available data were collected right after the primary data collection has ended.

2) Survey data collection and targeted population of firms:

Target population was made up of Italian limited liabilities companies with 100 or more employees. From AIDA database 2000 companies were randomly extracted in order to respect sector, size and geographical stratification existing in the population. Up to April 2014 105 questionnaires were received and the response rate is therefore 5,25%. After deleting unobtainable or unavailable firms and questionnaires with missing data, the final Italian dataset included 100 feasible responses (details on the Italian companies sample can be required to the authors).

3) Targeted respondent/informant:

In each firm a key informant was involved in the survey, mostly CEO and HR/KM Director. Data was collected using an internet-administered survey questionnaire. In order to make respondents comfortable and willing to fill the questionnaire, information about survey's origins and aims was given. Furthermore confidentiality was emphasized.

The data have been collected from October 2013 and March 2014.

4) Public data collection

Additional economic and financial ratios have been obtained from AIDA database, which contains economic and financial information for Italian firms. Descriptive analysis techniques will then be applied and differences according to industry and size will be explored. The following Corporate Performance measures were collected:

- Return on Assets (ROA): last three years;
- Return on Equity (ROE): last three years;
- Growth in Revenue: last three years;
- Growth in Turnover/Sales: last three years

Control variables are the following:

- Sales/Turnover (2010, 2011, 2012);
- The number of personnel (2010, 2011, 2012);
- Year of Foundation/Establishment ;
- Market to book value or Price to book value (P/B), if available;
- Industry information (NACE coding highly preferable, or other official industry coding).

4. First Results

In the following, first findings of our survey are presented in table 4.

TABLE 4 –FIRST FINDINGS
Frequency of answers (%), Tot. = 100 questionnaires

VAR	KEY WORD	1	2	3	4	5
ENTCAP1	Risk taking	2	20	19	40	19
ENTCAP2	New ideas	7	26	30	30	7
ENTCAP3	New business	8	30	32	25	5
ENTCAP4	Initiative	4	20	31	35	10
ENTCAP5	Independence	5	19	32	35	9
ENTCAP6	Difficult decision	10	22	38	24	6
ENTCAP7	Innovativeness	3	22	31	27	17

As a general overview,, more than sixty % of all respondents (value = > 3) agree that in their companies there is a satisfactory level of Entrepreneurial Capital as defined by the above-mentioned variables.

In particular it seems that **Risk-taking** is regarded as a positive personal quality in the 78% of the companies (value = > 3). While, on the other side the 38% of respondents deem that in their company employees could be more proactive at identifying **new business opportunities** (value <= 2).

5. Conclusions and a Research Agenda

As stated in Introduction this is a first conceptual paper on “IC and Value creation” aiming to:

- enlighten the overall framework of the international project and the specific role of the Italian unit;
- explain why EC should be considered – for the purpose of our investigation – as a stand-alone element of IC;
- illustrate the research methodology of the Italian research unit;
- define and operationalize the concept of Entrepreneurial Capital.

In the first step the Italian research team will address a deep analysis of data gathered in order to describe what is the current level of EC in Italian medium-sized and large companies. Clusters of firms by dimension, activity sector and geographical location will be investigated.

Future research agenda considers comparison with results emerging in other Countries in order to address environmental variables effects on EC, IC and corporate performance. Finally, next year causality relation between EC and value performance will be tested.

Rich-to-poor Diaspora Ventures: How Do They Survive?

Abstract

This paper develops a first conceptual understanding of motivations and success/survival factors of 'rich-to-poor Diaspora Entrepreneurship (DE)' by focusing on an individual's cultural intelligence and learning ability. Rich-to-poor DE addresses entrepreneurial activities conducted in developing or emerging countries by diasporans originated from developed ones. Despite the growing research interest in the phenomena of DE and its increasing importance for societies and economies in the last decades, previous researchers have almost solely focused on entrepreneurship by diasporans whose country of origin is an emerging or developing one ('poor-to-rich DE'). This type of DE has been considered to be driven mainly by necessities, an outcome of the lack of financial and economic alternatives in their home countries (Cohen, 1997). Evidence from business practice, however, shows the existence and significance of rich-to-poor DE (e.g. Elo, 2013; Horiuchi, 2010). The aim of this paper is to clarify the difference between rich-to-poor DE and poor-to-rich DE and to develop research propositions as for motivations and success/survival factors of this type of entrepreneurship based on cultural intelligence theory (Earley, 2002) and learning theory.

Introduction

In recent years, entrepreneurial activities of diasporans have attracted increased research attention. Diasporans and their descendants are migrants who maintain a relationship to their country of origin (COO) (Safran, 1991). These people are in a special cultural constellation, being embedded in multiple cultures and societies of different countries (Drori, Honig, & Wright, 2009). Unlike the conventional image of immigrants who are losing their connection to their COOs gradually over time and generations, one of the significant characteristics of diasporans is their persistent sense of home country orientation (Brubaker, 2005). The diaspora phenomenon is of growing societal, political and economic significance, since the number of diasporans worldwide has been drastically increasing and their economic activities go beyond national borders. One of the facilitators of the increase of diaspora population is the rapid development of communication and transportation technology in the last decades which has made it easier for them to maintain the relationship to their home country, even though they live for a long time outside of the country they originate from.

Diaspora entrepreneurship (DE) comprises the entrepreneurial activities which are carried out in a transnational context and initiated by actors who are embedded in at least two different socio-cultural and economic arenas (Drori, Honig, & Wright, 2009). Compared to other types of entrepreneurship, DE comprises idiosyncratic advantages as well as disadvantages caused by its transnational nature. Since their business activities cover two or even more countries, they are more likely to encounter difficulties driven by liabilities of foreignness (Terjesen and Elam, 2009; Zaheer, 2002) and institutional constraints in several countries (Yeung, 2002). In spite of these disadvantages, some of previous literatures suggest that these entrepreneurs who undertake cross-border activities have unique resources with a positive impact on their business success such as diaspora networks (Kuznetsov, 2006). Besides this, their often global mindsets, their creativity, imagination and intuition put them into a more favorable position. In this vein it is also possible that their international profile is to some extent perceived as a market-relevant asset in their country of residence (COR). This plugs in the notion of 'assets of foreignness' as portrayed by Nachum (2010) and Freiling and Laudien (2012).

DE is highly heterogeneous due to the idiosyncrasy of the people founding such businesses. There are different possible dimensions subclassifying diasporans such as motivations for becoming diasporans (Cohen, 2008) or socio-economic and educational background (Leinonen, 2012). The degree of economic development of COO and COR is regarded as an important dimension for diaspora classification. For instance, diasporans originating from a developing country who become diaspora entrepreneur in a developed country (poor-to-rich DE) are different from those from a developed country who establish their business in a developing or an emerging economy (rich-to-poor DE) in many aspects (Elo, 2013). While their decision for immigration in case of poor-to rich DE is most likely driven by financial reasons such as lack of vocational alternatives in their COOs in the former case, 'rich-to-poor diasporans' have obviously more alternatives in their home market – and elsewhere. Therefore, it can be considered that their motivation to become diaspora entrepreneur is different than that of the former group. Despite of high degrees of heterogeneity of DE, previous

researchers have, however, predominantly focused on the economic and entrepreneurial activities initiated by poor-to-rich diasporans who move to richer countries seeking for a higher quality of life or better career opportunities. Originating from developed economies and giving up their career opportunities in their COO, however, is a still under-researched, yet empirically observable topic. What is particularly unknown is rich-to-poor diasporan's motivation and their entrepreneurial activities. Why do these people voluntarily leave their COO in face of uncertain conditions in the targeted COR? What are the enabling factors of successfully implementing this sort of entrepreneurship in terms of corporate survival? This paper responds to these research questions by focusing unique cultural as well as learning competencies of diasporans on the individual level. Our study contributes to diaspora, opportunity and intercultural interaction theories by establishing a first theoretical understanding of rich-to-poor DE with regard to their motivations and success/survival factors.

The structure of this paper is as follows: first the conceptual background will be presented along with diaspora entrepreneurship, cultural intelligence and learning theory. Second, the methodology applied to this paper will be briefly introduced. Third, based on the theoretical background we will develop research propositions in regard of the motivation of rich-to-poor diaspora entrepreneurs and success factors which are related to their individual competencies. Finally, an outlook will be presented.

Conceptual Background

Diaspora Entrepreneurship

Entrepreneurial and economic activities of diasporans have recently attracted substantial research attentions, since the total number of diasporans worldwide is growing. As globalization advances, the number of people who live outside of their COO has increased. According to the World Bank's 2011 migration and remittances report, more than 215 million people live outside their country of birth around the world, representing 3 percent of the world's population (World Bank, 2011). If migration continues to grow at the same pace as over the past twenty years, some analysts predict that there could be 405 million international migrants by 2050 (International Organization for Migration). The nature of diasporans has been changing as well. The number of migrants is and many maintain a strong connection with their home country. It is ascribed largely to a commitment to the culture of the COO but in close relation to the technical advancement of communication and transportation and therefore the prevalence of email, the internet, free or cheap internet phone based telecommunication, social networks and air travel (Tung, 2008). In addition to this, as heterogeneity of the population in many formerly mono-cultural cities and nations increases, various measures of both material and social support are offered, which makes the life of people living in foreign circumstance easier (Riddle, 2008). Thank to immigration policy and these supportive conditions, the number of people being classified into diaspora, who live outside COO and have home country connections, is increasing.

Barnard and Pendock (2013) notes that diasporans can also be influenced by negative feelings and affect regarding their COO. The negative experiences in COO may be one factor stimulating migration, but they clearly impact the loyalty and emotional relationship of an individual with his/her COO in diaspora. In addition to socio-economic and cultural factors also affect many increase mobility and the willingness to migrate. In terms of refugee-migrants, the reason to migrate is not based on economic or business opportunities, therefore their subsequent entrepreneurship in host country is constructed on a different logic and process than that of non-refugees. Therefore, there are various stimuli and processes related to becoming migrant and their entrepreneurial activities.

What explains the growing significance of diaspora entrepreneurship is not only the increasing number of diasporans worldwide, but also its growing impact in various manners. It is considered as a rich resource that brings promising prospects for economic growth such as remittance (Riddle, 2008) and diaspora FDI (Nielsen and Riddle, 2009). Diasporans are in such cases not simply a direct investor but play a role of knowledgeable bridge between two countries. Emigration of high-skilled people is used to be regarded as 'brain drain' to their COO. However, especially when they have moved from a less to a more developed country, their exposure to the more developed context can accelerate the introduction of new technologies and practices to their less developed homeland. Therefore, researchers in the last decade have initiated to shift the concept from 'brain drain' to 'brain circulation' (Teferra, 2005; Saxenian, 2005), which suggest that migrants often fulfill an important role as sources of new knowledge and innovation for their people

in their COO. To sum up, the contribution to their COO that diasporans make is often significant. Huang and Khanna (2003) maintain that without the diaspora contribution, the rapid economic development China and India have experienced in the last decades would have not been realized.

In the previous literature, DE has been observed from various perspectives both on macro and micro level. General macro environmental conditions with an influence on DE have been identified. Diasporans operate in two environments (COO and COR) and they are very different in terms of their level of development, political and legal aspects, socio-cultural dimensions, and technological development (Nkongolo-Bakenda & Chrysostome, 2013). Living in two different contexts require diaspora entrepreneurs a high degree of flexibility. Newland and Tanaka (2010) identified six factors which foster DE both in COO and COR: (i) strong economy, (ii) diaspora engagement policies (e.g., tax breaks, training centers, and educational institutions), (iii) good governance (low level of corruption and well-functioning public institutions), (iv) access to financial capital (good jobs, status, and loans), (v) favorable perception of entrepreneurship, and a (vi) a critical mass of human and social capital. Besides these factors, previous researches on institution have provided substantial understanding of this phenomenon on the macro level. Since diaspora entrepreneurs are embedded in multiple institutional environments, they must surmount the institutional constraints of two or more localities (Yeung, 2002). Drori et.al. (2009) argue that diaspora entrepreneurs are not simply passive adherents to institutional constraints, but actively mold them to suit their own unique initiatives. Riddle and Brinkerhoff (2011) regarded diaspora entrepreneurs as institutional agents who experience new institutions in COR and change the institutional environment of their home country. The emerging of diaspora in the COR is regulated by immigration policies. In addition, it has been widely discussed how economic activities of diasporans influence policy making of the COO. As previously discussed, DE has substantial positive impacts on their COOs in regard of homeland investment and knowledge transfer. There are also positive effects for COR. For this reason it is naturally a momentous issue for policy-makers how to develop favorable environment for diasporans (Talib, et al., 2012).

On the micro level, motives to become diaspora entrepreneurs as well as various factors which influence DE from the resource and capability perspectives have been discussed. Recent literature on DE has been inconclusive with regards to their motivations. Even though various motivations can be named, they are categorized in mainly two groups: business opportunity and some sort of homeland sentiments (Lin and Tao, 2012). Especially the altruistic character of motivations for DE has attracted considerable attention (Gillespie et.al., 1999; Nielsen and Riddle, 2010). When entrepreneurial activities are driven by opportunities, it is opportunity entrepreneurship. This type of entrepreneurship can be further distinguished as improvement-driven opportunity entrepreneurship, when entrepreneurs additionally seek to improve their income (Xavier et.al., 2012). While these two factors can be seen as pull-factors, there are also push-factors for diasporans to become entrepreneurs. Diasporans face often difficulties with career chances in COR in comparison to local population for several reasons: first, they experience cultural or linguistic problems in COR. This happens more likely when the culture and the language of COR are different from that of COO to a large extent. Second, academic and vocational qualifications they acquired in their COO are often not acknowledged properly in COR and therefore they are often forced to work in an underqualified position. This sort of qualification problems are relevant not only to diasporans from developing or emerging countries whose educational institutions are not as established as in developed countries but also to those from developed countries. For instance, many North American immigrants have no choice but becoming English teachers in Finland, since their American qualifications are undervalued (Leinonen, 2012). Third, diasporans often encounter so-called 'glass ceilings' in the course of their career, even though they perform as well as local employees at companies (Lin and Tao, 2012). For these reasons, diasporans may become self-employed in COR due to the lack of available vocational opportunities.

Besides motives for DE, a number of factors on the individual level have been identified by previous researchers. While various perspectives influencing DE, recent research has illuminated the significance of networks in entrepreneurial constellations of diasporans. The network diasporans organize or utilize is diversified: host, home, and the commonly called 'diaspora network' as well as social and entrepreneurial networks (Kuznetsov, 2006). Recent researchers have focused on this diaspora network as a unique entrepreneurial resource of diasporans and a possible success factor (Kuznetsov and Sabel, 2005, Saxenian, 2000). This kind of network, which is called diaspora network, offers various resources which advantage diasporans' economic activities such as labor from migrant pools at competitive cost, market-related information, suppliers, technologies and business practices (Light, Bhachu & Karageorgis, 2003).

Until now, mainly Chinese, Taiwanese and Indian diaspora networks, such as Chinese diaspora networks in Silicon Valley and Taiwanese venture capital in the United State, have been researched (Saxenian, 2000; 2002; Saxenian and Hsu, 2001). Diaspora networks also offer chances to diaspora members to see role models of former diaspora entrepreneurs. Having entrepreneurial role models is usually associated with a positive predisposition toward entrepreneurship, concretely for ethnic entrepreneurs (Toledano and Urbano, 2008). In addition to the three network factors which diasporans are involved in, family social capital has been named by some researchers as one of the influencing factor to DE. The family plays a supportive role when diasporans establish and operate small businesses. The family can be also seen as potential financial capital for DE (Sanders and Nee, 1996).

Even though various researches on DE have been conducted in the last decades, previous research has not succeeded to ascertain the full scope of this phenomenon, since it is highly heterogeneous. The dimensions that classify diasporans are diverse. For instance, diasporans can be grouped after their educational level. Unlike uneducated migrants, the highly qualified migrants, who are generally called ‘elite migrants’, are not seen as economic or social threats for the CORs (Leinonen, 2012). Therefore, immigration laws of many European countries provide for preferential treatment for elite migrants (Gropas & Triandafyllidou, 2007). Cohen (2003) classified diasporans by their nature of migrations: victim diasporas (Africans and Armenians), labor and imperial diasporas (indentured Indians and the British) and trade and business diasporas (Chinese and Lebanese). Another dimension for diaspora classification is the level of economic development of COO and COR. Elo (2013) made a categorization of diaspora entrepreneurs following the grade of economic development of COO and COR (Table 1). According this table, diaspora entrepreneurs are classified into nine groups by the level of economic development of COO and COR (developing, emerging and developed countries). The majority of previous researchers observed entrepreneurial activities in developed countries operated by diasporans either from developing or emerging countries. One of their primary motives for immigration is generally seeking for realizing a better life. We call such kind of entrepreneurial activities ‘Poor-to-rich’ DE. This type of DE has been regarded as necessity entrepreneurship, an outcome of the lack of financial and economic alternatives in their home countries (Cohen, 2003). Evidence from business practice, however, suggests that there are also people from developed economies in which an attractive employment market is given and higher levels of living standard are realized, courageously leaving their home country for living in an economically less developed country for founding a new business. E.g., Elo (2013) reported a case of German entrepreneurs in her narrative study about entrepreneurs from various nations in Uzbekistan. Horiuchi (2010) researched Japanese entrepreneurs in China in his ethnographic study. We call the entrepreneurial activities in developing or emerging economies operated by diasporans who are originated from developed countries ‘Rich-to-poor’ DE. To date, this type of entrepreneurial activities has been neglected by previous diaspora research.

TABLE 1: TYPES OF DIASPORA ENTREPRENEURSHIP

		Country of Residence		
		Developing	Emerging	Developed
Country of Origin	Developing	Developing market diaspora entrepreneurship (c.f. intra-regional diaspora in SE Asia)	„Lonely starter“ style diaspora entrepreneurship	High asymmetry-based classic diaspora entrepreneurship
	Emerging	„Early starter“ style diaspora entrepreneurship“ (c.f. Chinese and Indian in Africa)	Emerging market diaspora entrepreneurship (cf. Chinese in Brazil)	Medium asymmetry-based classic diaspora entrepreneurship
	Developed	„Colonial style“ diaspora entrepreneurship (cf. German in Senegal)	„Pioneer style“ diaspora entrepreneurship	Developed market diaspora (cf. US-Americans in Finland)

Source: Elo (2013)

Since evidence and propositions from prior research are found based on the poor-to-rich DE, it is essential to explore whether and to what extent they are appreciable to the case of rich-to-poor DE. The initial situation and

environment of rich-to-poor diaspora entrepreneurs are fundamentally different from that of the poor-to rich type. While economic and market situations in COO are less attractive compared to COR in the case of poor-to-rich DE and this economic gap largely justifies their strong motivations to move to a richer country and become entrepreneur, people from developed countries must have other reasons to leave their home country which offers attractive economic conditions and career opportunities to realize an adequate standard of living. It is also questionable, whether homeland sentiments (Lin and Tao, 2012), one of the pull factors for DE, which previous research has identified, can explain their motivation to become rich-to-poor diaspora entrepreneurs.

Despite of the findings from many studies that emphasize the role of diaspora network as an important resource (Kuznetsov, 2005; Saxenian, 2000; Dutia, 2012), actually there is very little empirical evidence, in what way and how intensive host-country based diaspora networks are relevant to entrepreneurial activities of rich-to-poor diasporans. Whether these diaspora networks are crucial in this case is questionable for mainly three reasons. First, the total number of diasporans from developed countries is smaller, since they experience generally no financial pressure to leave their country – compared to diasporans from developing or emerging economies. Therefore, the availability of such comprehensive diaspora networks is not comparable to that of Chinese or Indian ones. Second, rich-to-poor diaspora entrepreneurs are often aware of different ways how to develop a new business based on similar solutions in different settings. Insofar, they have often not only more resources and competences available compared to poor-to-rich DE but also blueprints of working business models in mind. Third, a large portion of the population in developed economies has often a rather cosmopolitan lifestyle where the role of tradition and religion is not of great significance. In such cases diaspora networks, which require intensive contributions of members and where shared uniqueness of cultural values and norms compared to these of the COR is essential, do not have the comparable relevance to them. Therefore, it seems possible to assume that rich-to-poor DE does not rest so much on the host country based diaspora network factors compared to poor-to-rich ones. Instead, it is implicitly assumed in extant research that the individual per se possesses crucial capabilities for cross-cultural contexts (Hart, 1974; 2011) and plays therefore an important role as a success factor also in diaspora business. For this reason, we focus on individual capabilities and experiences of diasporans to explore factors influencing the success of this sort of entrepreneurship. This paper attempts to conceptualize the success factors of this kind of ventures in the light of cultural intelligence ('CQ') theory (Van Dyne, Ang, & Livermore, 2010, Earley & Mosakowski, 2004) in connection with learning theory (Cohen and Levinthal, 1990; Baron, 2004; 2006; Ardichvili et.al., 2003).

Cultural Intelligence (CQ) Theory

While a number of ideas of different intelligences such as social intelligence (Vernon, 1933), emotional intelligence (Goleman, 1996; Salovey and Mayer, 1990) have received extensive attention, these intelligences failed to include cultural dimensions and are not necessarily fully applicable in contemporary cultural situations (Earley and Ang, 2003) and diaspora settings. Due to their multiple cultural embeddedness, diasporans operate in culturally demanding situations in comparison to other types of entrepreneurs. Therefore, it is assumed that diaspora entrepreneurs are required to have unique capabilities to handle culturally challenging situations. CQ is helpful to understand why some individuals are more effective than others in dealing with situations that are culturally diverse (Ang, Van Dyne, and Koh, 2007). While most people meanwhile know the importance of intelligence quotient (IQ) and emotional intelligence (EQ), one's ability to lead and interact with effective emotional sensibilities, as measurement of one's capability in business environments, CQ has attracted attention as a new criterion for one's intelligence that can not be explained by IQ and EQ. CQ addresses one's intellectual capabilities to cope with intercultural settings and challenges. CQ is defined as an individual's capability to effectively deal with situations characterized by cultural diversity (Earley and Ang, 2003).

Its general structure consists of three facets including cognitive, motivational and behavioral elements (Earley, 2002). According to Earley (2002), CQ reflects cognitive processing capacities in various ways. Thereby two factors play a significant role: cognitive flexibility and reasoning skills. Cognitive flexibility is critical to CQ, since people are required to constantly reshape and adapt themselves to understand new setting in new cultural situation. In order to build higher maturity levels of CQ, strong reasoning skills are also essential, since a person attempts to make sense of a meaning of significant cues in the environment by means of inductive reasoning, when they come into situations which can not be judged based on their own cultural criteria. Another important aspect of cognitive

functioning in connection with CQ is a person's metacognition. Metacognition refers to thinking about thinking, or knowledge about cognitive objects (Flavell, 1987). Metacognition is critical, as one is required to bring together patterns into a meaningful picture without knowing what the right picture might look like. Possessing (meta-)cognitive capabilities is not sufficient. One must be motivated to use this capability and produce a culturally appropriate response. While cognitive CQ refers knowing what and how to do and motivational CQ refers to having the wherewithal to persevere and exert effort, the third facet of CQ, behavioral CQ, relates to responses to a given situation based on one's behavioral repertoire (Earley and Ang, 2003). Earley (2002) argues that a person with a high CQ has a propensity to determine where new behavioral patterns are needed and how to execute them effectively in new cultural contexts. Based on the theoretical concept of CQ, this paper will explore diasporans' cultural capabilities and develop relevant research propositions.

Learning Theory

Since diasporans' cultural knowledge and capabilities change and evolve as they are influenced by learning, taking particular note of learning capacities on the individual level of diasporans provides also a certain understanding of success of rich-to-poor diasporans' businesses. Diasporans are embedded to a certain extent in social institutions of their origin and home societies (Drori, Honig, & Wright, 2009). Their double interconnectedness in two different 'worlds' provides them, consciously or not, with a diverse cultural background which may be related to their ability to learn external knowledge. For the purpose of exploring diasporan's learning ability, we first discuss their absorptive capacity. Absorptive capacity is defined as the learning ability to recognize the value of new, external information, assimilate it, and apply it to commercial ends (Cohen and Levinthal, 1990). Cohen and Levinthal (1990) argue that mainly two factors influence on absorptive capacity: prior related knowledge and the diversity of the background. Due to the cumulative character of learning processes, people can learn more efficiently when learning objects are related to their prior knowledge. Along with prior knowledge, diversity of the background plays also a significant role for one's learning. When uncertainty regarding the knowledge sphere exists where potentially useful information might emerge, possessing a diverse background increases the possibility that incoming information will be related with a part of their knowledge. This enhances the efficiency of learning. In the section of research propositions, we will discuss diasporan's learning capabilities based on their absorptive capacity and how they influence on the success or survival of rich-to-poor DE.

Methodology

This is a conceptual study which reviews and develop the theoretical discussion on motivation as well as success factors of DE by employing a novel synthesized perspective. While there are indications for the importance and relevance of rich-to-poor DE (Flisi and Murat, 2011), the factors of successfully running these businesses are largely unknown. There are partial explanation for some aspects, but yet there is no study available focusing on these success factors. Therefore, we build on prior research on successfully implementing new ventures as well as on research on migration entrepreneurship or poor-to-rich DE, respectively. The object of interest is the individual, the diaspora entrepreneur, and the endogenously generated success factors. For developing a first understanding of the particular profile of rich-to-poor DE and the drivers of corporate survival of this type of new ventures we employ a theoretical lens. This lens is informed by theories of cultural intelligence (Earley & Mosakowski, 2004) and learning theory. Cultural intelligence theory (Earley & Ang, 2003) is chosen to address the capacities of people and organizations to deal with different and often complex intercultural environments. Individuals' absorptive capacity theory (Cohen and Levinthal, 1990) is chosen to address the learning ability which outcomes measures (e.g. corporate survival) of rich-to-poor DE. They allow a deeper understanding of the cognitive dimension of establishing these ventures. These theories provide us with potentially relevant cause and effect structures that help in explaining corporate survival regarding DE. Corporate survival as explanandum is chosen as an adequate indicator of new venture performance (Chrisman et.al., 1999; Freiling, 2012). The aim of this paper is developing research propositions on the motivations for DE as well as the factors influence corporate survival, while pinpointing assumptions on the differences between poor-to-rich DE and rich-to poor ones. Insofar, the design of this paper is explorative and conceptual.

First, we review the extant research and analysis. There the concepts and findings are explored and analyzed with our lenses and focus, then these are reflected and built into synthesized assumptions. This is carried out in a team of three researchers providing as sort of triangulation effect (Denzin, 1978). Together with the rich extant research which provides the ground for the development of propositions, and some preliminary findings (Elo, 2013), we reflect the gaps and create novel research propositions and question the validity of some extant assumptions. A conceptual design is chosen to guide future research activities by causal structures proven in different research contexts that are highly related to prior research on DE phenomena. This procedure is much more framed than interpretive research designs based on qualitative research (Piekkari and Weich, 2005). The reason for narrowing down the topic by this theoretical framing is the considerable complexity of the topic. Otherwise the field of research would be rather wide open. In later steps of reality checks it is possible to consider other explanatory forces of corporate survival rather than the ones derived from theory. Since prior research suggests a considerable explanatory power of learning and CQ-related issues it deems useful to select this approach. This study intends to derive a larger set of research propositions that could be empirically tested. The purpose is to move from general assumptions towards more specific assumptions to assist and develop the research on DE, although we are aware that rich-to-poor DE can be very idiographic and context specific. The set of propositions can be selected to match the research questions and the empirical research.

Research Propositions

Based on research on DE in relation with theoretical lens we discussed above, we will discuss motivations and success factors of rich-to-poor DE to develop research propositions in this section.

Migration is driven by its push and pull factors which differ for refugees, irregular and regular migrants. The origin of the entrepreneurship may lie already in the pre-migration phase, but we concentrate on the post-migration phase. The reasons why some diasporans decide to become entrepreneurs can be classified into push and pull factors. The difficulties immigrants generally face in CORs are regarded as push factors. Many of diaspora entrepreneurs either from developing or emerging economies have been seen as necessity entrepreneurs (Cohen, 2008), since they do not have other options to provide themselves and their family members with a financial basis for living. Thus, they found a company by themselves. Diasporans usually encounter a number of problems with language, culture and therefore career chances (Leinonen, 2012; Lin and Tao, 2012). The general lack of job opportunities in CORs results in the higher rate of self-employment within migrants compared to non-diasporans (OECD, 2010).

However, rich-to-poor diasporans are in a different position from poor-to-rich ones. In the case of diasporans from a poor country living in a developed economy, it maybe a suboptimal option to stay in CORs due to their strong economy, high living standards, political stability and advanced social welfare which are not available in their COOs. There are also numerous migrant workers who seek also temporary employment abroad, but who do not have the possibility to start entrepreneurial activities. In general, the poor-to-rich diasporans suffer from limited resources and may also be subject of economic pressure in the form of remittance expectations. On the contrary, rich-to-poor diasporans have a choice to go back to their home country, if they are not willing to overcome the difficulties in the job market of CORs. As Leinonen (2012) points out, there are also people from developed countries who decided to emigrate from their home country for their marriage partner from a different country which forms a pull factor. However, these people are not representative for rich-to-poor diasporans. For this reason, it can be assumed that push factors do not play a significant role for rich-to-poor diasporans. When pull factors are more relevant when comparing rich-to-poor DE to poor-to-rich DE, there is an impact on corporate survival for push factors are very often related to necessity entrepreneurship and a more defensive position of the new venture. Thus, rich-to-poor DE is much less defensive and opportunity driven (Block and Sandner, 2007; Baum and Locke, 2004). This can have a positive impact on corporate survival. Therefore, we propose that:

P1. Rich-to-poor DE is less necessity driven and defensive which is positively related to corporate survival.

As for pull factors for DE, it has been observed that diasporans start their own business connected with some kind of homeland sentiments that might have an impact on the kind of business (Lin and Tao, 2012). Diasporans have homeland sentiments on different levels.

Diaspora entrepreneurs may act in one or several markets in parallel. Here, we focus on COR-based investments, but diasporans often invest and venture also in their COO and may also use their intercultural competences for business and investment in third countries. Some diaspora homeland investments can be explained by their altruistic motivations, while others are motivated by the personal wish to stay in touch with their COOs. In many cases, it is a suboptimal situation that drives people from economically underdeveloped countries to migrate into a developed country. They leave their homeland not because they do not like their country anymore, but because they do not have any chance to realize the life they wish due to weak economic, politics or institutions. In other words, some of poor-to-rich diasporans would possibly stay in their home country, if their COOs provided better conditions (Lin and Tao, 2012). In such cases it can be considered that people have a strong wish to stay connected to their homeland and to contribute the improvement of economic as well as living situation of their COOs (Gillespie et.al., 1999). The decision to move to a economically less developed country for rich-to-poor diasporans is less influenced by negative push factors as they do not exist in similar intensity and scope in developed countries. Hence, the pull factors need to counterbalance the lack of push factors in some way, possibly also in the form of entrepreneurial opportunity.

Starting a business as a person from a developed country makes sense from an economic point of view for several reasons. First, the markets of developing or emerging countries become attractive, when the rate of economic development is higher than in developed countries. The rapid economic advance creates new business chances, as the living standard of population becomes higher. In China, for instance, the so-called 'new middle class', who used to be belong to the low class and can now afford better products, has arisen due to the drastical economical development in the last decades (Farrell et.al., 2006). These people have started to consider the quality of products and got interested in products from developed countries (Horiuchi, 2010). This sort of new demands are regarded as new business opportunities for people from developed countries. Second, early-stage capital for new businesses in emerging or developing economies is lower than in developed countries. Horiuchi (2010) argues that only 10% of early-stage capital is required in Shanghai compared to Tokyo. Third, the markets of developing and emerging markets are not yet mature and saturated, thus establishing unique selling propositions (USP) is easier outside of COO from the competitive point of view, when domestic products or services that are common in the COO but not outside are offered. Due to the existence of a myriad of competitors offering similar products or services, establishing a successful business in COO is a difficult challenge for many entrepreneurs. However, if product concepts which are specific to a developed economy are brought to developing or emerging countries, there are not many competitors who offer similar products and therefore establishing a USP is much easier than in contexts of developed countries. Besides these economic advantages, the decision to move out of their COO can be explained by dissatisfaction, emptiness and frustration with their home market as well as variety seeking. Since the gap between the rich and the poor in developed countries is smaller, people have a sort of dilemma that they cannot get out of the middle class regardless their qualification and personal efforts for their career. On the contrary, accessing the upper class life is easier in developing or emerging countries. Some rich-to-poor DE is motivated by this middle-class dilemma (Horiuchi, 2010). For these reasons discussed above, we can develop the next research propositions:

P2. Rich-to-poor DE is motivated mainly by the opportunity to achieve unique selling propositions in developing or emerging countries and thus to contribute to corporate survival.

P3. Rich-to-poor diaspora entrepreneurs are motivated to start their business in developing or emerging countries as means to develop their life dreams, overcome the middle-class dilemma and to energize their lives which has a positive impact on corporate survival.

Leinonen (2012) pointed out the significance role of marriage and family ties in the life decisions of migrants. Possessing strong personal relationships in COR on the individual level can be a driver of migration. For instance, American migrants in Finland she observed in her study would not have come to Finland, if their partner were not from Finland and they did not want to live with their partner in their home country (Leinonen, 2012). Such migrants have strong personal ties to local people which could be advantageous for their entrepreneurial activities, since they are native speaker of the country and naturally know the market situations well. When such migrants decide to start a business, they are assumed to rely on these personal ties with local personals to a substantial extent. Therefore:

P4. Rich-to-poor DE is positively influenced by COR-based individual-level personal relationships (strong ties: partner, close friends) that contribute to corporate survival

As we discussed in the section on the conceptual background, we will focus on individual capabilities of diasporans as success factors of rich-to-poor DE. Since diasporans live in culturally complex situations and their businesses spread to two or more countries, we can estimate that intercultural competencies play an essential role for the success of their business. Therefore, we will explore their culture-related capabilities along with the theoretical lens of CQ (Van Dyne, Ang, & Livermore, 2010, Earley & Mosakowski, 2004). CQ is defined as an individual's capacity to deal effectively in situations characterized by cultural diversity (Earley and Ang, 2003). CQ is highly related to interaction in business environments of diasporans. Starting DE is realized through communication and negotiations with various related actors such as cooperation partners, employees, or co-founders in culturally demanding settings. Antal and Friedman (2003) discussed that individuals with higher intercultural skills possess an ample repertoire from which various action strategies dealing with situations are conducted and can realize more effective interaction. CQ is conceptualized along three dimensions, namely a cognitive, a motivational and a behavioral one (Earley, 2002). We will discuss diasporans' CQs along with these three elements respectively.

Cognitive CQ is a dimension for an individual's capability to deal with cultures and reflects cognitive flexibility and reasoning skills. Since high CQ levels require a capability of modifying one's self concept (and concept of others) in new complex configuration, flexibility and a capability to inductively reorganize one's self concept is necessary. Earley (2002) argues that bi- or multi-cultural persons, who have an awareness of more than a single culture, are an exceptional case, since their self concept is so complex that they can reflect the flexibility needed for CQ. Diasporans are those who are embedded in multiple cultural contexts (Drori, Honig, and Wright, 2009) and can therefore be assumed to have a higher flexibility as well as capacity to reshape a self concept to understand a new cultural setting. Furthermore, compared to poor-to-rich diasporans who tend to rest strongly on their ethnic network in CORs, the role diaspora network plays for rich-to-poor diasporans is not that significant for mainly three reasons: first, the total number of diasporans from developed countries is smaller and therefore the size as well as the intensity of diaspora networks in each city are not comparable to that of poor-to-rich diasporans, second, rich-to-poor diasporans are expected to have more individual resources and competencies and therefore they do not have to rely on networks so much, and, third, the large portion of people from developed countries often has a somewhat cosmopolitan lifestyle and therefore do not need access to ethnic networks so much to share their culture and religion. For this reason, diasporans originated from developed economies are more likely to exposure to intercultural interaction in CORs. They are more experienced in a sort of detective work to ascertain significant cues in the environment, which lead the stronger reasoning skills. In addition to cognitive flexibility and reasoning skills, high cognitive CQ requires a higher level of learning thanks to metacognitive CQ (Earley, 2002). In order to be successful as entrepreneurs outside the home country without depending on diaspora networks, it is essential to understand the culture of COR thoroughly. A number of companies attempts to train their employees by providing country-specific information (Earley, 2002), since many literatures recommend the adaptation strategy of a six-stage model by Benett (1996) as the appropriate one for the majority of expatriates to deal with cultural differences. This model identifies six strategies to handle cultural differences: (1) denial of difference, (2) defense, (3) minimization, (4) acceptance, (5) adaptation and (6) integration. The adaptation strategy is defined as knowing enough about different cultures to “ (...) intentionally shift into a different cultural frame of reference” and modify their behavior to fit the norms of another culture (e.g. Earley & Erez, 1997). However, many cultural training programs fail, since this approach over-emphasizes superficial information about specific cultures and does not offer general learning principle (Earley, 2002). Since rich-to-poor diasporans are required to have a deep understanding of the host culture, an effective meta-strategy is useful to overcome cultural difficulties. Therefore, we propose:

P5-a. Due to the double cultural interconnectedness, rich-to-poor diasporans possess a richer cognitive background and more flexibility than local entrepreneurs, which is positively related to corporate survival.

P5-b. Since rich-to-poor diasporans are required to make sense of a new cultural context without a significant ethnic business community of their COO, they possess a stronger cultural reasoning skill, which is positively related to corporate survival.

P5-c. Through cultural learning processes, rich-to-poor diasporans develop metacognitive CQ, which is positively related to corporate survival.

In order to build considerable intercultural competencies, possessing high cognitive CQ is not sufficient. One has to be motivated in learning new cultures and believe in their own capability to acquire and use the knowledge and

produce a culturally appropriate response. Earley (2002) argues that self-efficacy plays an important role in motivational CQ, since successful intercultural interaction is based on a person's sense of efficacy for social discourse in a novel setting. He maintains that a person with a weak sense of self-efficacy tends to disengage in learning new cultures after experiencing early failures. Motivational CQ includes intrinsic motivation, the degree to which you enjoy culturally diverse situations, and extrinsic motivation, the more tangible benefits you gain from culturally diverse experiences, and self-efficacy (Van Dyne, Ang, and Livermore, 2010). Unlike the case of poor-to-rich diasporans who live in part unwillingly in a foreign country, many of rich-to-poor diasporans proactively decide to move to a foreign country, while giving up the comfortable market and living situations of their COOs. They are assumed to have a stronger willingness to establish the new life in COR and to have a higher motivation to learn new cultures compared to poor-to-rich diasporans. Moreover, rich-to-poor diasporans interact personally with many local people in CORs and they are experienced in intercultural communication as well as negotiations. Therefore, they are more likely to be confident in their own capabilities to deal with culturally novel situations.

P6. Rich-to-poor diasporans benefit from personal motivation and stronger self-efficacy in understanding culturally new situations, which is positively correlated to corporate survival.

Behavioral CQ is the action dimension of CQ which refers to the individual's ability to act appropriately in a range of cross-cultural situations (Van Dyne, Ang, and Livermore, 2010). While mimicking every behavior of people from another culture is impossible, there are certain behaviors that should be modified when one interacts with other cultures. For instance, giving one's business card to another person only by one hand means arrogance in the Japanese business environment and the person might be regarded as impolite, even though it is a normal way in Western culture. When Japanese managers have negotiations in Western countries, their expression can be misleading, because they mostly smile and try to avoid mentioning something negative in a direct way, even though they are unsatisfied. Adapting one's behavior to a target culture is a significant part of intercultural interaction. By behaving in a similar way as people from another culture, people can ease situations and make others feel comfortable. In culturally complex situations where diasporans operate, knowing where new behavioral manners are required and how to execute them effectively is essential in order to smoothly launch intercultural negotiations.

P7. Possessing high behavioral CQ allows smooth intercultural interactions and is, thus, positively related to corporate survival.

P8. Advanced learning skills of the entrepreneur affect the employment of cognitive abilities which are necessary for successful opportunity development and thus contribute to corporate survival.

As previously discussed, diasporans are assumed to have unique learning capabilities due to their double social and cultural embeddedness (Drori, Honig, & Wright, 2009). We explore their learning ability illuminated by absorptive capacity on the individual level. Absorptive capacity is influenced by prior related knowledge and the diversity of background (Cohen and Levinthal, 1990). Diasporans possess a richer cultural and social background due to the longtime living experience acquired in the COR and the regular contact to the COO. Based on socio-cultural and business knowledge of the COO and the COR, diasporans' background is highly diverse compared to non-diaspora entrepreneurs. Therefore, we assume that diasporans possess a greater absorptive capacity and therefore higher learning abilities.

The learning ability is connected to entrepreneurial opportunity recognition. According to Baron (2004), opportunity recognition can be regarded as 'the cognitive process (or processes) through which individuals conclude that they have identified an opportunity' (Baron, 2004; Page. A1). Opportunities can be seen as complex, discernible patterns (Baron, 2004; 2006). Baron suggests that it is necessary to fully understand how individuals identify complex patterns to consider two cognitive models: the prototype model (Smith, 1995) and the exemplar model (Hahn and Chater, 1997). In the prototype model it is assumed that people compare newly encountered stimuli or events with existing prototypes to determine whether they belong to specific categories (Baron, 2004). As for opportunity recognition, the closer the match between information which is potentially relevant to business opportunities and individuals' existing prototypes, the more likely they identify an opportunity. The exemplar model suggests that individuals compare new events or stimuli with specific exemplars of relevant concepts in their memory. This exemplar includes a number of examples of business opportunities they have encountered in the past. As we discussed above, diasporans are assumed to have a higher learning ability compared to non-diaspora populations and therefore they acquire external knowledge more efficiently. For this reason, we can assume that diasporans also have a wider

variety of prototypes as well as exemplars, which enhances individuals' cognitive diversity. Possessing a high level of cognitive diversity is positively related to entrepreneurial opportunity recognition (Baron, 2006).

While the discussion above is applicable to diasporans in general, rich-to-poor discussion above is applicable to diasporans in general, rich-to-poor diasporans have an additional attribute. Ardichvili et.al. (2003) discuss that especially prior knowledge of market and customer knowledge increases the likelihood of successful entrepreneurial recognition. Rich-to-poor DE can be stimulated by new developments in the COO that often runs ahead of the development in the COR. Such entrepreneurs have extensive knowledge of the market and products/services which are common in developed countries but not yet in developing/emerging ones. Therefore, we can assume that rich-to-poor diasporans more likely recognize entrepreneurial opportunities in which they can utilize their market knowledge of their home country in COR (Fig. 1). Identifying and selecting right business opportunities are one of the crucial abilities to become successful entrepreneurs (Stevenson et.al., 1985). Therefore we propose:

R9: Rich-to-poor diasporans can recognize entrepreneurial opportunities which are not recognized by other types of entrepreneurs due to their high learning abilities, which is positively related to their corporate survival.

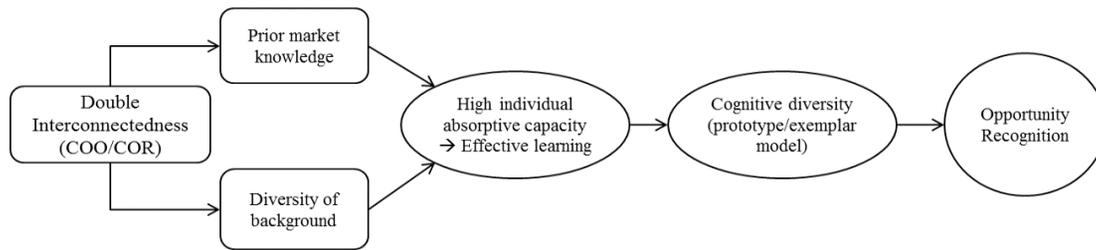

FIG. 1: OPPORTUNITY RECOGNITION OF RICH-TO-POOR DIASPORA ENTREPRENEURS

Discussions and Research Prospect

The extant research provides a plethora of aspects related to diaspora and entrepreneurship, but many findings are rather case- and context specific. Based on our review on related concepts, extant research and current assumptions, we created a first conceptual understanding of rich-to-poor DE and developed research propositions for their motivation and success/survival factors. First, by contrasting poor-to-rich DE and rich-to-poor DE from a viewpoint of the economic situation as well as business environment surrounding diaspora entrepreneurs in COOs and CORs, we discussed the motivation of diasporans from developed countries to start new ventures in economically less developed countries. We proposed that such sort of entrepreneurship is rather opportunity-driven, since developing/emerging economies offer several attractive market conditions such as: (i) increasing demand for new products/services caused by the rapid economic advance, (ii) early-stage capital for new business is lower than in developed countries, (iii) USP is easier to establish due to favorable competitive situations, (iv) the chance to overcome 'middle-class dilemma' (Horiuchi, 2010). Subsequently, we identified a gap in the body of knowledge in terms of rich-to-poor diaspora and the endogenous success factors on the individual level. The inherent intercultural context in DE suggests advancing the understanding of abilities and intelligence that are either personal traits and talent or learned competences or a combination of both. Since the education level is often concerned as an important a priori success factor for success in international business and diaspora research, we focus on individual CQ (meta-cognitive, cognitive, motivational, behavioral) and learning. We argued that diasporans are different from mono-cultural entrepreneurs as they are more culturally capable and exposed to a double interconnectedness. We proposed that rich-to-poor diaspora entrepreneurs possess all the three types of CQ at a high level and therefore they are able to communicate or negotiate in intercultural contexts in an efficient way, which is positively related to their corporate survival. Besides CQ, we also discussed diasporans' absorptive capacity on the individual level. We proposed their

double interconnectedness in COOs and CORs enhances their absorptive capacity, which eventually leads to successful or unique opportunity recognitions.

DE is a highly heterogeneous phenomenon. Despite of previous research efforts, the whole picture has not been clarified successfully. Even though the phenomenon of rich-to-poor DE exists and has been observed in practice, it has largely been neglected by diaspora research. Our study contributes to research on DE by taking the first step to establish theories of rich-to-poor DE. Theoretical implications are expected to be significant once the propositions are tested empirically. We expect the employment of these propositions to be able to develop important findings the entrepreneurship research in terms of personal characteristics and dynamics in learning and behavior that explain essential building blocks of venturing and corporate survival. In addition, we assume that many of the proposed factors and the respective influences, when explored and tested, provide novel insights to the dynamics and forces that regulate the degree of success and perhaps event the element of success. Qualitative methods are suitable as the first empirical study, since rich-to-poor DE is a new and under-researched phenomenon. Through observation in detail with the aid of qualitative methods such as case study method or depth-interview, further aspects or factors might be identified.

As the individual level is one of the crucial elements to be understood, both for diaspora ventures but also for DE support policies, we found that the aspect of CQ requires further attention as a potentially strategic success factor. Diaspora entrepreneurs and their learning processes are beneficial to the individual, the venture, and potentially also the COO and the COR. The generated success should be considered as one of the goals also in the supportive policies of COR, the lack of policy understanding may create substantive hindering factors for efficient employment of positive spillover effects. Transition and developing countries have yet to improve their employment of entrepreneurial potential of diaspora.

Future research is also needed to clarify the role of other dimensions of diasporans such as educational background, generation, diaspora lifecycle and genders. Which differences exist between well-educated rich-to-poor diaspora entrepreneurs and uneducated ones? What are motivations and influencing factors of the second-generation diasporans in developed countries whose parents immigrated from developing/emerging countries? In which stage of personal migration history do they become diaspora entrepreneurs? Do female rich-to-poor diaspora entrepreneurs have different motivations or competencies than male ones? Exploring how these dimensions influence on rich-to-poor DE is needed to enhance the understanding of this phenomenon.

The impact of intrapreneurship in a modern enterprise

Abstract

This paper investigates intrapreneurship, competition and company efficiency in large Slovenian companies in order to provide unique in-depth firm-level evidence and management implications on the extent to which companies exploit available internal business potentials. The survey data for the sample of large Slovenian companies and statistical methodology are used to analyse the association between intrapreneurship, competition and company efficiency. The empirical results confirmed the significant impact of the internal business potentials on the operating results of the analysed companies. The utilization rate of internal business potentials was only partially or ill-used, reflecting the internal potential source of unused business opportunities as one of possible ways to improve competitive advantage and company efficiency. The originality/value is in unique in-depth survey evidence and original empirical results with management implications emphasizing the importance of long-term managerial strategy towards innovation and encouraging creativity as the basis for successful internal corporate business strategy to improve competitive advantage and company efficiency.

Introduction

The aim of the article is to establish an association in what degree Slovenian companies take advantages of intrapreneurship or internal entrepreneurial potentials within the company. The research is based on the investigation of the willingness of company employees, particularly of the company managers, for re-establishing of favourable internal entrepreneurial climate in searching for individuals and groups of employees, which are willing for intrapreneurial challenges within the company as a way to increase the company's market competition and company efficiency.

More specifically, the scope of the article is to assess the presence of intrapreneurship in the Slovenian companies and how it is recognized among the company employees, particularly among the enterprise managers, as a factor for company market competition in a way to achieve the company long-term success. Findings are important for theory of intrapreneurship, market competition and company efficiency, and for management decision making process to achieve better company business results arising from an existing intrapreneurship in the company or from its introduction to increase company's market competition during restructuring and adjustments to rapid economic changes.

The theoretical background and foundations for this research are economic theoretical insights and empirical analysis of entrepreneurship, intrapreneurship with human resource management, market competition and company efficiency in the ways of functioning of the internal corporate culture in the modern company and its competitive markets (Parker, 2011; Kuratko *et al.*, 2009). The corporate social responsibility to internal employee motivation might also play an important role for intrapreneurship (Koellinger and Thurik, 2012). The extent of intrapreneurship is analysed for the sample of the Slovenian companies focusing on how the employees, particularly managers, perceived intrapreneurship as the source of the company's market competition and company efficiency success. We investigate the extent to which intrapreneurship can affect the operating results of the company in competitive markets.

The rest of the paper is organized in the following ways. The next section presents the basic theoretical and empirical knowledge of entrepreneurship (e.g. Schumpeter, 1951; Birch, 1993; Bailey, 1984; Antončič and Hisrich, 2003; Audretsch and Keilbach, 2004; Audretsch *et al.*, 2006; Timmons and Spinelli, 2006), intrapreneurship and the ways of functioning of the internal culture of entrepreneurship in modern businesses on company efficiency in competitive markets (e.g. Schollhammer, 1981; Pinchot, 1985, 2002; Duncan *et al.*, 1988; Garvin, 2002; Hisrich, 2009; Kuratko *et al.*, 2009; Drucker, 2001). The following section presents and explains the empirical results of the analysis of the surveys and interviews in the Slovenian companies. The next section presents managerial and policy implications, while final section derives main conclusions.

Theory of entrepreneurship and intrapreneurship

In the global market competition to succeed by the business operators it is necessary to develop new products and doing business better and faster than their competitors. These developments require a different corporate culture, which differs from traditional views of the internal organizational culture. Modern companies need to develop necessary entrepreneurial culture within existing businesses, as part of the innovation process in order to contribute to the competitive survival of existing and growth of new companies in rapidly changing competitive markets.

Entrepreneur and entrepreneurship

Entrepreneurship as an opportunity for business entrepreneurial activities is mainly pertained with small businesses. Entrepreneurs are creative individuals who are able to connect the ideas of organizational and manufacturing resources to enable them to derive an entrepreneurial venture. The link of ideas, entrepreneurial skills and the means of production can enable a small business to grow quickly into a large organization (Birch, 1993; Audretsch and Keilbach, 2004; Timmons and Spinelli, 2006). During the recent economic recession period, large companies have faced difficulties and have tried to solve them by reducing the number of employees. On the other hand, the importance of small businesses for the national economy has been the most important. Small and medium sized enterprises in harsh economic and financial conditions may play an important role in labour market flexibility. Namely, with growth of their output sales, they may attract labour into employment, particularly those who have lost jobs in large companies and have flow into unemployment. Some of them may even establish own self-employment or small firms. However, it is necessary that small businesses are not only a creator of new jobs, but also an important source of innovation and entrepreneurial activities (Schumpeter, 1951; Bailey, 1984; Audretsch *et al.*, 2006; Zahra et al, 2009).

The reason that economic theorists, with the exception of Schumpeter (1951) focusing on large companies, in the past did not include entrepreneurship in their economic models, mainly lies in the fact that the impact of entrepreneurship on economic growth is difficult to define and even harder to quantify in the production function. Since the 1980s a focus in literature on economic growth and development has changed. Particularly, Birch (1993) conducted the study on the employment of all U.S. firms during the period 1969-1979. His research showed that during this period the companies with one hundred or fewer employees created 81% of jobs.

Intrapreneurship

The concept of intrapreneurship is considered as an entrepreneurship within large companies. Employees in large companies generate new ideas and identify new business opportunities that are aimed to be realized within the existing business support mechanisms. The traditional view of corporate entrepreneurship defined entrepreneurship is an internal process where an individual within the existing system is looking for business opportunities, without taking into account the established formal channels (Stevenson, 1990). Some researchers have used a narrower definition focusing primarily to corporations, while smaller companies were excluded from the study (Schollhammer, 1981; Drucker, 2001; Garvin, 2002). The advantage of companies that are able to engage the business-oriented individuals or groups within their existing businesses lies in an ability to quickly detect problems and business opportunities in a business environment in which they operate, and then try to creatively solved them, leading to a process of market restructuring in order to improve competitiveness of their products. Internal entrepreneurs have a possibility to use the existing commercial infrastructure and sales networks and the financial stability of companies in which they operate, allowing them considerable advantage over individuals acting as sole proprietors (Pinchot, 1985). Later, the need for a new orientation of the internal entrepreneurship or intrapreneurship change in strategic managerial thinking, which is recognized in the older, larger organizations (Pinchot, 1985). Such organizations are hierarchically organized and have a bureaucratic structure as an outcome from their historical performance and their size. Age of the organization and its size have a negative impact on the development of domestic entrepreneurship. Corporations that aim to create a favourable environment in support to an entrepreneurial mode, they need to invest in capable individuals within corporations. They need to change the mindset of employees and stimulate entrepreneurship within a corporate environment (Dollinger, 1995; Morris et al., 2008). The internal business potentials are also crucial for early beginners' enterprises in their market competition and survival (Drucker, 2001).

Intrapreneurs are persons who are willing to take a risk and responsibility for own decisions in the case of failures, and persons with influence and prestige in the organization, who know how to use the informal relationships within the company. Their goal is not only the development of new technologies and products, but also the best use of all other support mechanisms available within the company in order to increase market competition. All these are doing with the one goal, to penetrate and succeed with innovation in market competition (Duncan *et al.*, 1988).

Intrapreneurship, market competition and company performance

Modern companies need intrapreneurship as a source of innovation, which in turn leads to better management of markets and thus more efficient company performance in market competition. The company's success has also association with innovators and creative individuals. This also depends on individuals who have an entrepreneurial approach and ability to implement a good idea into a real product or service, even if they are employed in large organizations. Without widespread distribution of entrepreneurial energy, without a number of individuals or groups who are able to realize ideas and innovation, many new products would have never occurred to the consumers. Yet, businesses without such persons would get stuck in place (Pinchot, 2002).

Jay (1996) described two types of managers that are needed in the contemporary organized company: yogis and commissioners. The yogis have a vision and are creative, but they lack to keep order. The commissioners do not have vision, but they achieve objectives and accurately perform their tasks. Both personal characteristics are rarely integrated in a single person. The idea of intrapreneur promises solution of this paradox between order and innovation.

Two main problems are related to providing incentives for promotion and maintaining of intrapreneurship within the corporations in competitive markets: question of strategy and tactical questions (Duncan *et al.*, 1988). Among strategic questions, there are necessary measures that directors and other top managers should very often publicly stress the importance of innovations for company, creativity and innovation inside the company. This should have priority due to concrete and symbolic reasons, innovativeness should be supported by awards and bonuses, and top management should recognize that creative employees are motivated by ethical creativity and ethical competition. As a tactical question is how to remunerate intrapreneurs in competitive market environment.

Methodology and data

The purpose of the research is to investigate to what extent the surveyed companies relied to internal business potentials available within the company as a way for market competition to increase company's efficiency and success. The surveys with a written questionnaire covered seventeen companies of which completed answers to a written questionnaire were returned by fifteen companies. The conducted surveys focused on determination of the implementation of intrapreneurship in the surveyed enterprises and how its accelerated internal business processes in order to affect the better business results in competitive markets. The structure of the questionnaire follows the thematic strands focusing on the key issues faced by the businesses in the introduction and implementation of intrapreneurship:

- To what extent issues of intrapreneurship are known to the company's management, and if known, to what extent it is introduced and implemented in the business processes?
- To what extent intrapreneurship has affected the company's business operation?
- To what extent utilization of internal business potentials has affected the company's efficiency in competitive markets?

Following from these research questions, we set the following three hypotheses (H):

H1: Incentives for introduction of intrapreneurial activities are higher in companies in which management is aware of the importance of intrapreneurship.

Consequently, we expect a positive correlation between intrapreneurship activities and management knowledge of intrapreneurship.

H2: Active development of innovation culture in the company is positively associated with introduction of intrapreneurial activities in the company.

Again, a positive correlation is expected.

H3: Companies with more developed intrapreneurial activities achieve higher gross value-added per employee than companies with less developed intrapreneurial activities in competitive markets.

The unique in-depth surveys were used to obtain data and to test the set hypotheses. Advantages of the method used are mostly in its anonymity, relatively low costs for data collection and opportunities for comparative analysis of performances between the analysed companies. The sample of seventeen surveyed companies was selected primarily on the basis of their size and ability to obtain all relevant answers regarding to their internal business operations. Two respondents were selected in each of the surveyed companies in order to obtain a realistic picture of the internal corporate operations. Out of the seventeen companies involved, the answers were obtained from the fifteen ones.

The respondents in the surveyed companies were employed primarily in senior managers' positions such as managers of individual business units within the company system, while the administration and their professional staffs were not included in the sampling procedure as their answers would be less relevant for our analysis. The surveyed companies were selected primarily on the basis of their minimum size, which allows internal business operations. The surveyed companies were selected from different economic activities, which covered trade, other service activities and manufacturing production activities.

As a sample limitation, it is not stratified on all population of large companies in Slovenia. In terms of achieved average gross value-added per employee, it is biased in direction of more efficient companies, in which intrapreneurship processes are not a new phenomena as they are in a high degree already used. While this sample limitation and relatively a small sample size are limitation for making general conclusions for all Slovenian population of companies, the results are indeed useful for understanding the phenomena of intrapreneurship in the studied companies and its role for company's market competition and company efficiency in newly emerging market economies.

Among the surveyed companies, 46% of businesses belonged to the group of companies with over one thousand employees per company, 27% of companies with five hundred to one thousand employees, and 27% of companies where the number of employees ranged from two-hundred-and-fifty to five-hundred. Total employment in the surveyed companies was 30,124 employees, which means on average 2,008 employees per the surveyed company. In the comparison with the number of employees in the Slovenian companies in 2008, this means 4.9% share, while 13.5% share among all employees in the Slovenian companies with more than 250 employees.

Among the surveyed companies by main economic activities, 27% were in services, 53% were in manufacturing and 20% in trade activities. The surveyed fifteen companies represented 4.6% of total population of the Slovenian companies with more than 250 employees (IPMMP, 2008). By gross value-added per a company, the surveyed companies (37,218 euros) exceed the Slovenian average by 95%: 27% of the surveyed companies were below the Slovenian average, 27% of the surveyed companies were close to the Slovenian average, and 46% of the surveyed companies were above the average for the Slovenian companies. The surveyed companies generated 37% of net revenues from sales of goods and services in the domestic market and 63% in the foreign markets (PASEF, 2008).

Analysis of intrapreneurship in the surveyed companies

Knowledge of internal businesses

The analysis of the frequency distribution of the encounters with the intrapreneurship shows that 59% of the respondents occasionally faced with intrapreneurship. This result suggests the relatively non-intensive use of internal business operations. The degree of linear correlation between the degree of implementation of internal business processes and internal rate of encounters with entrepreneurship is 0.96 indicating a strong linear dependence between the variables (Table 1). The high value of the correlation coefficient indicates a strong linear relationship between the level of respondents encountering intrapreneurship and the level of intrapreneurship process, which is logically associated with the fact of the presence of knowledge of the conditions of the internal business planning and implementation of internal business processes.

TABLE 1: THE CORRELATION BETWEEN THE PASSING OF ITS AND ITS PROCESSES (LIKERT SCALE 1-5)

Question:	never	rearyly	occasionally	frequently	mode
The frequency of encounters with ITS	2	2	18	8	2
Implementation of processes necessary for the operation of ITS	2	1	22	3	2
Correlation coefficient					0.96

Source: Surveys of 30 respondents in the fifteen companies in Slovenia, 2009 - Note: ITS – Intrapreneurship

Implementation of internal business processes

The assembly, which refers to internal business processes, gives an insight into the relationships within the company. This should enable the development of innovative processes that support the corporate hierarchy in a search for competitive market positions. Table 2 presents the availability of necessary resources and use the business plan, which demonstrates the maturity of the internal entrepreneur venture.

TABLE 2: ANALYSIS OF RESPONSES REGARDING INTERNAL BUSINESS PROCESSES (LIKERT SCALE 1-5)

Question:	Average value	Median	Mode	Standard Deviation
Development of innovation processes	3.6	4	4	0.96
Support in the corporate hierarchy	3.7	4	4	0.92
Means for the realization of the project	3.2	3	3	1.06
Assistance of external partners	3.5	3.5	4	0.97
Application of business plan	3.7	3	4	1.02
Average	3.5	3.5	4	0.99

Source: Surveys of 30 respondents in the fifteen companies in Slovenia, 2009

The analysis of the quality of relationships that enable the development of internal business processes indicates that these relationships were sufficient to allow for internal business operations. This finding was confirmed with the most common answer 4 "often allow" (Likert scale 1-5). The level of support in the corporate hierarchy, which allows the realization of the project, was found at a satisfactory level because 40% of respondents believed that they had the adequate support that was often available, while 30% of them had occasionally support. The results of the use of a business plan for an appropriate application suggest that 60% of the respondents believed on their often used in a practice, of which 20% were required to be used. The most common response was concentrated at 4 (frequently, Likert scale 1-5).

The introduction of intrapreneurship

The assembly, which refers to the introduction of intrapreneurship in the Slovenian companies, covered the fields of corporate culture, innovation goals, guiding entrepreneurs to understand their role and training of internal entrepreneurs to realize the business opportunities in competitive markets (Table 3).

TABLE 3: ANALYSIS OF RESPONSES REGARDING INTRODUCTION OF INTRAPRENEURSHIP (LIKERT SCALE 1-5)

Question:	Average value	Median	Mode	Standard Deviation
Defining corporate culture and support systems	3.6	4	4	0.84
Defined objectives of innovation	3.7	4	4	0.76
Recognition system for ITS	2.4	3	2	0.94
Understanding the importance of ITS	2.8	3	3	0.73
Training for business opportunities	2.6	3	3	0.80
Average	3.0	3.4	3	0.82

Source: Surveys of 30 respondents in the fifteen companies in Slovenia, 2009 - Note: ITS - Intrapreneurship

The analysis of corporate culture and support systems that do not hinder innovation has shown that 47% of the respondents believed that the companies in their corporate culture were defined only partly and 27% were clearly defined. The aims of innovation in 35% of the surveyed companies were clearly defined, while 54% were only partially defined. The surveyed companies believed on a fairly importance of internally guided entrepreneurs in understanding the importance of intrapreneurship and its rules. The average rate of introduction of intrapreneurship in the surveyed companies was concentrated at 3.4 (Likert scale 1-5), indicating insufficient importance of intrapreneurship in the surveyed companies.

Relationship between the employees' attitudes and internal corporate programs

The analysis of the relationship between the employees' attitudes and internal corporate programs provides the evidence on the extent to which managers emphasized the importance of innovation, creativity and innovation in the enterprise on one hand, and the relationship between the employees attitudes and volunteer assistance on the other with tasks and projects that helped to increase market competition and company efficiency

The survey results suggest on the appropriate situation in the surveyed companies: 60% of the respondents answered that managers in their companies often emphasized the importance of innovation for the company, and in 27% of the surveyed company's innovation was a continuous process. The appropriateness of the individual awards for their innovation was only in 15% considered as the appropriate reward, while the others believed that the material and moral incentives in their companies were not enough and too little to sufficiently promote innovative practices of creative individuals. The average score was 3.4 (Likert scale 1-5). In short, the results of the relationship between the employees attitudes and internal corporate programs were ranged with the average score value of 3.6 (Likert scale 1-5) and the most common rating was 4.

Intrapreneurship, market competition and company efficiency

The impact of intrapreneurship on the business performance of the surveyed companies and the influence of utilization of internal business potentials on the competitive market position of these companies are analysed to determine the extent to which corporate intrapreneurship affect business performance and to evaluate the impact of utilization of internal business potentials on a competitive market position.

Impact of intrapreneurship on internal business operations

Set of five questions relate to the identification of the impact of intrapreneurship on internal business operations of the surveyed companies (Table 4). The analysis of the responses provides the insights into the extent to which business-oriented individuals and groups of individuals influenced the success of the company through the influence of internal corporate focus on increasing sales and the importance of internal corporate organization for business success in competitive markets.

TABLE 4: ANALYSIS OF RESPONSES REGARDING INFLUENCE OF ITS ON THE BUSINESS
(LIKERT SCALE 1-5)

Questions:	Mean	Median	Mode	Standard Deviation
ITS as a source of innovation	3.8	4	4	0.85
ITS-consumer-products	3.9	4	4	0.90
ITS-sales increase	3.5	4	4	0.90
ITS and success in the future	4.0	4	4	0.96
Average	3.8	4	4	0.90

Source: Surveys of 30 respondents in the fifteen companies in Slovenia, 2009 - Note: ITS - Intrapreneurship

The analysis of the impact of entrepreneurial individuals and groups of individuals on the company's success confirmed that 24% of the respondents believed that business-oriented individuals had a direct impact on the company's

success contributing to new products and services, which would not be possible without them. Yet, 50% of the respondents believed that the intrapreneurs had a significant impact on the success of their businesses.

It is interesting to note that although only 20% of the survey companies conducted intensive internal business processes, the results suggest that in 74% of the surveyed companies employees considered that intrapreneurship had a significant impact on the number of new products and services. The average score of total responses to the question lies at the value of 3.9 (Likert scale 1-5). The analysis of the impact of intrapreneurial orientation on the increased domestic sales confirmed that only 10% of the respondents believed that their internal business operation had a very significant impact on increasing sales and consequently their business results. On a significant impact of intrapreneurship on sales growth believed 50% of the surveyed companies, while as important by 23%. How important was the internal corporate structure for the surveyed companies to operate successfully in the future in competitive markets, this is confirmed by the concentration of the results at an average value of 4 (Likert scale 1-5). The majority of the respondents believed that the internal corporate structure was one of the basic conditions that the surveyed companies achieved successful performances in domestic and foreign markets.

Market competition and unused internal business potentials

The analysis of the responses to a set of questions related to the impact of utilization of internal business potentials assessed the extent to which the internal business potentials were unused. The results suggest that 73% of the respondents considered that a better internal corporate structure affected the market competition of the companies on both domestic and foreign markets. Yet, 23% of the surveyed companies believed that the impact of intrapreneurship on the company's competitive position was of the great importance at the average value of 3.9 (Likert scale 1-5).

In the final part of the questionnaire the respondents were asked the question to what extent they believed that their companies were in the inner untapped intrapreneurial potential. The answers confirmed that the surveyed companies had on average 54% of unused internal business potentials. This means that the optimal utilization of their results can be improved significantly.

Most of the surveyed companies (57%) believed that their internal business potentials were only partially utilised. Therefore, better internal corporate structure would contribute to better performance and market competition of the surveyed companies.

Statistical analysis of causalities and hypotheses testing

The statistical analysis is conducted on the basis of the survey data. Our focus is on three associations to test the set three hypotheses: between knowledge of intrapreneurship and introduction intrapreneurship in the analysed company; between impacts of intrapreneurship on company business performance and implementation of intrapreneurial processes; and between implementation of intrapreneurial processes and knowledge of intrapreneurship and gross value-added per employee that the company achieved in market competition. The results are biased to the sample selection and the conduction of the questionnaire used for the surveys. However, we are aware of this shortcoming in the interpretation of the results.

Dependence between the internal knowledge of intrapreneurship and the introduction of intrapreneurship

Linear association between the internal knowledge of intrapreneurship and the introduction of intrapreneurship in the surveyed companies is investigated by the correlation analysis. The results of the analysis confirmed the set H1 on the interdependence of the variables studied. Both curves of the respondents responses are situated in the range of values from 1.3 to 4.0 (Likert scale 1-5). The degree of linear correlation between the studied variables is 0.75 suggesting the strong presence of the knowledge of intrapreneurship and the introduction of intrapreneurship. This holds for 56.2% of the surveyed companies employing the linear dependence: $0.75^2 = 0.562$.

Dependence between the impact of intrapreneurship in the business and the implementation of internal business processes

The results presents responses regarding the impact of intrapreneurship on the internal business operations and the introduction of the intrapreneurship. Both curves of the respondents' responses fall in the range of values between 2.2

and 4.7 (Likert scale 1-5). The degree of the linear correlation between the studied variables is 0.59. This confirms the set H2 on the presence of the knowledge of intrapreneurship and the introduction of intrapreneurship in the surveyed companies. The linear dependence is of 34.8%.

Dependence between the degree of implementation of internal business processes and knowledge of intrapreneurship, and the gross value-added per employee in the surveyed companies in market competition

The degree of the linear correlation between the average value of responses to a set of questions about the level of knowledge of the intrapreneurship within the company and gross value-added per employee in the company amounted to 0.44. This implies a 19.6% linear dependence between the pair of variables. The correlation coefficient between the average value of responses to a set of questions about the level of implementation of internal business processes and gross value-added per employee amounted to 0.27, indicating a 7.3% linear dependence. Therefore, the correlation coefficients between the pairs of variables are low. This does not confirm the set H3 on the strong relation between intrapreneurship and the company efficiency in market competition.

Reliability of the responses

The reliability of the responses in estimating the dependencies between the variables is tested by employing the chi-square (χ^2) test in order to prove the set of assumptions used. Developing an innovation culture in companies, intrapreneurship in businesses and the degree of utilization of internal business potentials were those variables that significantly affected the adoption rates of intrapreneurship in the surveyed companies. Variables such as knowledge of intrapreneurship, intrapreneurship process and attitude of employees to internal corporate programs do not show a statistically significant effect on the introduction of intrapreneurship in the surveyed companies.

The results suggest that the impact of independent variables on the adoption rates of intrapreneurship is only partly confirmed. Only some of independent variables such as developing of innovation culture have impacts on the internal business operations and the level of untapped business potentials has affected the decision in the surveyed companies up to the stage of the introduction of intrapreneurship.

Managerial, policy and research implications

The comparisons of the empirical results between the degree of the implementation of the internal business processes and the achieved value-added per employee show rather small 7.3% linear association, but more in-depth investigation confirmed that the companies with the higher degree of the implementation of the internal business process or the intrapreneurship achieved higher value-added per employee. This implies an importance of the intrapreneurship in corporate organization for company's performance in competitive market environments.

Employees of the surveyed companies were sufficiently aware of the internal corporate stance as an essential element of a new organization allowing to deals with global market competition. Long-term strategic and policy orientation of management, highlighting the importance of innovation with encouraging creativity were the basis for successful internal entrepreneurial orientation of the surveyed companies. The empirical results suggested that the degree of emphasis on the importance of innovation by management was at a satisfactory level, indicating that the surveyed companies were aware of the importance of innovation. However, this has not played yet adequate importance. The level of creativity and innovation within the company suggested a slightly weaker result, indicating both the lack of long-term orientation of management that would allow the creation of appropriate conditions for the development of innovation culture. One of the major advantages over conventional internal business enterprise was an individual mobilization of existing resources, which should be available to an internal entrepreneur. The results confirmed that the surveyed companies perceived availability of resources, as satisfactory, while at the same time confirmed the lack of detectable and established, quick and informal ways of obtaining and using available resources of the company. Very low utilization rates from internal business potentials confirmed that the majority of the surveyed companies believed that their internal business potentials were only partially used, or ill-used, suggesting the internal potential source of untapped business opportunities and its potential as one of possible ways to achieve advantages in market competition.

By examining the forms of intrapreneurship in the surveyed companies, the empirical results provide a useful information tool for research and practice of a degree of recognition, establishment and implementation of internal business processes. The sample was biased towards more efficient Slovenian large companies by the gross value-added per employee. Yet, the studied internal business processes were not a new phenomenon in the surveyed companies. Among the limitations are the sampling procedure and a relatively small sample size. Although the empirical results do not allow making generalisation of the surveyed companies to the whole Slovenian company population, the results are to a greater extent relevant for the large sized Slovenian companies.

Conclusion

The empirical results suggest that corporate intrapreneurship in the surveyed companies was not a new phenomenon, but on the contrary, in most of the surveyed companies they were familiar by intrapreneurial activities and their benefits have already successfully exploited. To summarize, the intrapreneurship was found important as in the surveyed companies the role of the internal business operation played importance in implementation activities. A comparison of detection of intrapreneurship in the surveyed companies with the most successfully organized domestic businesses as global companies confirmed that the surveyed companies still placed greater emphasis on the existing product and services than on new product development, marketing and distribution activities in market competition. The change of business culture with at least equal emphasis on developing new products and services and innovative marketing approaches would have significantly greater impacts on their market competition by increasing sales. The greater utilisation of untapped, internal business opportunities of the Slovenian companies, would largely contribute to better performances in market competition by better results in the domestic markets and more effective penetration in the foreign markets. Under-utilization of internal business potentials suggests a lack of long-term strategies and managerial policies and practices with insufficient market targeting in more competitive market environment in order to exploit the companies advantages that can be offered by intrapreneurship. Long-term orientation of management with the companies' abilities to define the mission and vision-oriented businesses with sufficient emphasis on innovation, entrepreneurship and intrapreneurship developments are the ways allowing creating the appropriate corporate culture for increasingly competitive market environment. An intrapreneurial culture is necessary to be created within the existing companies as a necessary part of the innovation process to contribute to the survival of the existing companies in market competition and potentials for growth of new companies in rapidly changing markets.

Accelerating entrepreneurship via intensive learning programs

Abstract

In the last decade a new instrument aimed at stimulating entrepreneurship has emerged: the accelerator program. It addresses the need to “accelerate” entrepreneurship by conducting a very intensive program, starting with the selection of particularly promising ideas and aimed at defining business projects attractive to investors. A very interesting, yet barely explored aspect, concerns the learning mechanisms within these programs. On the basis of the literature on entrepreneurial learning, and knowledge management, this paper aims at identifying the learning mechanisms and the knowledge roles within them. A longitudinal case study concerning an accelerator program operating in Italy since 2012 is conducted. The empirical analysis reveals a stratification of the mechanisms of learning, supported by different knowledge roles throughout the program. Although the limitations of the study, the results may provide a basis for future research.

Key words: accelerator programs, entrepreneurial learning, start-up, knowledge roles, learning mechanisms

1. Introduction

In the last decade the use of accelerator programs, which represent one of the most advanced tools to support and promote entrepreneurship, has quickly established. Their increasing use has not been accompanied by a significant attention from scholars. Only recently they are beginning to examine the accelerator, even using the lens of learning (e.g. Migliaccio, Rivetti, & Capasso, 2014).

Starting from the most recent studies on venture accelerators, based on a theoretical background mainly concerning learning and especially entrepreneurial learning, the objective of this paper is to investigate the accelerator programs intended as intensive programs of learning. The research questions are the following: What mechanisms of learning are found within acceleration programs? What roles of knowledge, directed to trigger and favor the learning mechanisms above, are found in the programs?

The paper is organized as follows: the second section examines the accelerator programs from the perspective of project management; the third section considers the accelerator programs using the lens of learning, with a particular focus on the dynamics of learning and the roles of knowledge; the fourth section briefly reviews the methodological path; the fifth section is dedicated to the case of study; the sixth section presents the conclusions, limitations of the study and directions for further research.

2. Acceleration programs and business projects

Venture creation is a dynamic process that can be examined by considering the behavior of individuals that contribute to it (Garner, 1985; Gartner & Carter, 2003). As pointed out by Liao and Welsch (2008), different patterns of activity, which can be carried out at different times and in a different order, contribute to venture creation. This experimental process, which involves dynamic experiential learning (Kolb, 1984), is conducted through trial and error.

Over the years various instruments to promote and support entrepreneurship have arisen, first of all incubators (Hughes et al. 2011), designed to create an environment able to stimulate and favor the entrepreneurial process and to provide services in support of it. Incubators are business support process, designed to support the development of startups by providing "services and resources tailored to young firms" (Isabelle, 2013; NBIA, 2014). More recently, programs aimed at accelerating the entrepreneurial process in the short period have been designed. Miller & Bound (2011, p. 3) point out that an acceleration program is characterized by “an application process that is open to all, yet highly competitive; provision of pre-seed investment, usually in exchange for equity; a focus on small teams not individual founders; time-limited support comprising programmed events and intensive

mentoring; cohorts or ‘classes’ of startups rather than individual companies”. Although these elements may occur with different intensity, we can consider them common to all acceleration programs.

In this paper, starting from what stated by Halt et al. (2014), we consider the definition of accelerator programs provided by Migliaccio et al. (2014). In particular, acceleration programs are considered instrumental “to “accelerate” entrepreneurship in a very limited period of time” e “to this end, it provides not only financial resources, but also services instrumental to the formation of an organizational knowledge base adequate to contribute to the success of the nascent firm and to the definition of a project that is attractive to investors (Migliaccio et al., 2014, p. 3).

The accelerator, according to its specific characteristics, contributes to the entrepreneurial process, whose output can be a new firm (Gartner & Carter 2003). The emphasis on the management of multiple business projects leads us to apply some concepts of project management. The placement of the acceleration program within the project management approach seems particularly appropriate to analyze the dynamics of learning within and between projects. We believe that the program of acceleration can be interpreted, albeit with the necessary distinctions, according what stated by Archibald (1992), who defines the program as an initiative taking place in the long term, characterized by the involvement of multiple projects. The main element of differentiation, with respect to this definition, relates to the time. Accelerator programs are "time limited support" (Miller & Bound, 2011), generally of short duration, being aimed at accelerating the process of creation/discovery of entrepreneurial opportunities (Alvarez & Barney, 2007, 2010), interpreted as a learning process. Instead, element of strong similarity is the multiplicity of projects included in the program. In fact, among the aspects common to accelerator programs highlighted by Miller & Bound (2011), particular emphasis concerns the focus on classes of projects rather than on single projects.

3. Learning within acceleration programs

The entrepreneurial process is a learning process (Corbett, 2005). It is not only about individual learning, but also collective learning. Indeed, its effectiveness is also related to access to multiple sources of external knowledge and therefore to the transfer of knowledge which fuels the knowledge base of the nascent firm. For the purposes of entrepreneurial learning are important not only psychological characteristics and skills of the individual, but also the creation of an environment that encourages it (O'Shea & Buckley, 2010). An accelerator program helps to create virtuous learning contexts based on the positive relationship knowledge - trust, which feed on each other, and become ecosystems (Miller & Bound 2011). During the program, the process of entrepreneurial learning is accelerated (Miller & Bound, 2011). To this end, as highlighted by Migliaccio et al. (2014), “are provided, among others, services instrumental to the formation of a knowledge base of the nascent firm adequate to favor the success of the initiative”, especially through didactic modules, completion of the team and networking.

The accelerator favors entrepreneurship by performing the functions of educator, connector and validator (The World Bank, 2011), which can be considered in a knowledge-based view, in order to appreciate their contribution to the knowledge base of the nascent firm. The function of “educator” is especially instrumental to the promotion of experiential learning; the function of “connector” favors learning by interacting; the function of “validator” “is mainly due to the mentorship and to the creation of an environment favoring the emergence of start-ups” (Migliaccio et al., 2014).

The learning peculiarities within the programs of acceleration are closely related to the characteristics of the organization that manages them and the specific objective to be achieved. With regard to the first aspect, upstream of the acceleration program often there is an organization that has a stable core and leverages an extensive network of partners, whose composition of which is subject to variations from year to year. This certainly impacts on accessible knowledge. In addition, for the effectiveness of knowledge transfer, it is necessary to develop learning mechanisms independent from the composition of the participants and to ensure appropriate roles of knowledge. On the other hand, as shown in project management literature, these requirements are found in all projects, complex works that are characterized by high novelty, whose realization involves different parties, who often work for the first time together. The objective can be identified by considering the point of view of the organization or that of

the entrepreneurial teams participating to the program. The team aims to overcome the validation phase, becoming graduated and then making the nascent firm attractive to investors. It should be noted that not all the teams arrive at the graduation and even fewer are funded by investors. In addition, still remains, albeit to a lesser extent, the risk of failure of startups (Miller & Bound, 2011). In case of failure, however, knowledge resulting from the process of entrepreneurial learning can be used in other entrepreneurial initiatives. As for the accelerator, the organization behind the program, the main objective is the return on investments. Moreover, the program offers benefits in terms of learning also for the accelerator, and new knowledge can be reused in new programs.

Learning takes place through mechanisms stressing the collective dimension and is facilitated by multiple roles of knowledge. Regarding the mechanisms, experiential learning, the individual and team level (Kayes, Kayes, & Kolb, 2005) is combined with the non-experiential learning (Zollo & Winter, 2002), which is achieved through the articulation and the codification of knowledge, mechanisms "that go beyond the semi-automatic processes of stimulus-response and the accumulation of experience" (Zollo & Winter, 2002, p. 341).

The entrepreneurial team is the main *locus* of entrepreneurial learning. The accelerator creates the conditions for the team evolve into a community of practice (Wenger, 2000); it also ensures the conditions favoring mechanisms of learning, supported by specific roles of knowledge (Davenport & Prusak, 2000). Scholars propose different knowledge roles, each of which supports specific learning mechanisms (e.g., knowledge gatekeepers, facilitators, etc.).

One of the most important figures for the transfer of knowledge, mostly abstract, it is the teacher (Drucker, 1999) (often a university professor or a professional). As regards the other roles of knowledge, with reference to the knowledge facilitator, in this paper we consider the definition of Roth & Styhre (2002, p. 1), which identify him as an individual who helps a community of practice (for instance a new product development team) to codify, decodify, articulate, express, and tell stories about their skills, experiences, know-how, capabilities, in brief their knowledge of certain areas", laying the basis for overcoming the "knowing-doing gap" (Roth & Styhre, 2002), thus promoting the launch of the entrepreneurial initiative. Instead, the knowledge gatekeeper is identified as "an individual who acts as a knowledge interface" (Cranefield & Yoong, 2006, p. 233) between the organization and external sources of knowledge which are found in his network.

4. Methodology

To address the research questions, we decided to conduct a longitudinal case study (Yin, 1994), referring to an acceleration program operating in Italy since 2012, with reference to the period 2012-2014. The program was chosen since it seemed particularly appropriate with respect to the phenomenon under investigation. Different research methods were taken into account, and in particular (Woodside, 2010): semi-structured interviews, analysis of documents and non-participant observation.

5. The case of study

SeedLab is an acceleration program established in 2012 and currently promoted by TTVenture, closed-end fund with headquarters in Milan. It focuses on the pre-seed stage of entrepreneurial projects focused on different areas (web, biotech, new materials, cleantech, life-science, agrofood), with a particular emphasis on technology transfer, which have in common the possibility of exploitation of the technology.

The program is characterized by a careful initial selection of entrepreneurial projects and is designed to validate them. At least in the early stages the program is characterized by a remarkable fluidity of the team, which are then stabilized, and a climate favoring the creation of relationships with external subjects, in particular industry experts and potential partners.

In detail, it is possible to identify two modules (one didactic and the other of incubation), following the initial selection. The didactic module, which aims to provide the basis of enterprise management, is designed also to encourage interaction with teachers and among aspiring entrepreneurs. The incubation module is designed in order to define in detail the project in a climate of interaction and cooperation with the mentors and external parties.

The program is completed with a pitch day, during which the projects are presented to investors, institutional or not, who evaluate the opportunity to invest in them. Among graduated teams, then, are selected those whose projects seem of considerable interest, in order to spend some months in Silicon Valley to improve their entrepreneurial projects.

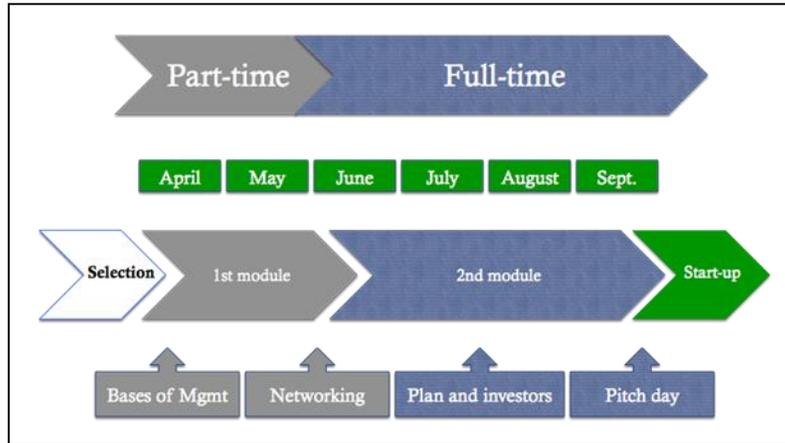

FIG. 1 THE SEEDLAB ACCELERATION PROGRAM (SOURCE: SEEDLAB, 2013)

With regard to the first research question, considering the learning mechanisms defined by Zollo and Winter (2002) and applied to projects by Prencipe and Tell (2001), it is possible to identify the activities that, in the SeedLab program, tend to favor them (Table 1).

TABLE 1: LEARNING ACTIVITIES AND MECHANISMS WITHIN THE ACCELERATION PROGRAM

Learning activities	(Prevalent) learning mechanism
Training on the job, incubation activities	Experiential learning
Networking	Knowledge articulation
Planning	Knowledge codification

Experiential learning is promoted especially by training on the job, through which teams are assisted by mentors in carrying out activities related to the definition of the project, and by incubation activities, instrumental to "address open issues of the project to define an effective and credible business model" (Migliaccio et al., 2014). Knowledge articulation is accomplished through interaction within the team, with the mentor, the other teams and with others involved in the acceleration program; in fact, even the didactic module is designed in such a way as to encourage not only lectures, but also networking among program participants and between them and the teacher. Finally, knowledge codification takes place especially during incubation, when the teams are dedicated to planning.

Considering the practice-oriented categories of knowledge (Savage, 1996) most commonly used in studies on entrepreneurial learning (Williams Middleton & Donnellon, 2014), we can examine how the program favors their acquisition (Table 2).

TABLE 2: LEARNING ACTIVITIES AND KNOWLEDGE CATEGORIES

Learning activities	Knowledge categories
Lectures, training on the job	Know what
Lectures, training on the job, pitch	Know why
Lectures, training on the job, incubation activities	Know how

Know what is vehicled mainly by teaching, placed mostly in the first part of the program, and by training on the job, through the mentor. The team acquires the know-why even during the pitch day. Finally, know-how is developed thanks to lectures, training on the job and the various activities implemented during incubation, instrumental to the development of plans. In addition, the three categories of knowledge considered here, and especially the know-how, can be developed through experience (Kolb, 1984).

Turning to the second research question, it can be noted that the acceleration program involves different actors performing knowledge roles. Teachers, active especially in the first module, serve as educators, being responsible for the transmission of knowledge to individuals belonging to entrepreneurial teams. The teacher acts primarily on the transfer of abstract knowledge, that is entrepreneurial know-what (Gartner & Carter, 2003).

Mentors tend to perform more than one knowledge role. First, they are "knowledge gatekeeper" (Cranefield & Yoong, 2006), since they relate the team with external sources of knowledge that are part of their web of relations; in this way, while not triggering a particular mechanism, they create the conditions so that the team learns from external sources. In addition, they act as "knowledge facilitators"; in fact, assisting the team in translating its ideas in the project, they ensure the articulation, sharing and proper application of knowledge transmitted by the teacher and pre-existing knowledge. In this way, they operate downstream of the transfer process, favoring the overcoming of "the knowing-doing gap" (Roth & Styhre, 2002, p. 1) by applying knowledge to the plans; therefore, they favor the articulation as well as the codification of knowledge. Even business students operate during the program as "knowledge facilitators", although, compared to the mentor, they have a different role, mainly oriented to the application of the acquired and pre-existing knowledge to the project.

6. Conclusion

Accelerator programs constitute a particularly effective instrument to support entrepreneurship. A very interesting aspect, barely explored by scholars, concerns the learning dynamics that are developed within these programs. In fact, beyond the aspects concerning the financial support and the validation of business ideas, it should be emphasized that accelerator programs are intensive programs of learning. Its functions of educator and a connector, highlighted by scholars along with that of validator (The World Bank, 2011), can be reconsidered in this perspective.

On the basis of the literature on entrepreneurial learning and knowledge management, this paper identifies the learning mechanisms and the knowledge roles directed to trigger and favor these mechanisms within the programs of acceleration. We have developed the empirical analysis with reference to SeedLab, an acceleration program operating in Italy since 2012. With regard to the first research question (What mechanisms of learning are found within acceleration programs?), the empirical analysis reveals a stratification of learning mechanisms throughout the program, although specific mechanisms prevail in specific phases. Turning to the second research question (What roles of knowledge, directed to trigger and favor the learning mechanisms above, are found in the programs?), it should be noted that different knowledge roles are employed in the context of the accelerator, some of them can be related to specific knowledge mechanisms. Some knowledge roles create the conditions for learning from external sources (mentors: knowledge gatekeepers), others act as educators (teachers), and still others favor the articulation and codification of knowledge (mentors and business students: knowledge facilitators).

The managerial implications of the paper are summarized below. Since the acceleration program is a program of entrepreneurial learning, in order to better carry out its function (effective and fast learning), it should create appropriate conditions relating to: identification, within the program, of activities instrumental in: ensuring that the teams accumulate experiential knowledge (e.g., through incubation activities), evolve into social learning systems

(Wenger, 2000), and interact with external parties, especially those included in the network of the program; presence of qualified figures who perform knowledge roles, designed to promote directly or indirectly the mechanisms of learning.

The main limitations of the paper can be found in the impossibility to generalize the results using the method employed. The results may, however, provide a basis on which to build future research.

Tunis*EM Lyon Business School, France

ENTREPRENEURS' SOCIAL SKILLS AND ACCESS TO EXTERNAL RESOURCES: THE ROLE OF SOCIAL CAPITAL

Abstract

Consistent with the previous studies investigating the relationship between social competencies, entrepreneur's success and access to essential resources, this research intends to add new findings concerning the mediating role of the social capital which enhances the effects of several social skills.

Results indicate that the entrepreneurs' proficiency at persuasiveness, ingratiation and personal emotional intelligence is significantly related to their access to vital resources, especially venture capitalists' financing and useful information. These effects are mediated by the entrepreneurial social capital, which is based on an extensive network involving weak and non redundant ties.

The implications of these findings assist entrepreneurs in the Tunisian High-Technology field in understanding the process by which social skills increase the level of social capital to gain access to paramount resources and success at the survival/development stage of the entrepreneurial process.

Keywords: social skills; entrepreneurs; new venture; access to vital resources; social capital; High technology field.

1. Introduction

A large body of research in several fields, such as sociology, health science, Strategic Management and Human Resource Management, has largely dealt with social skills as competencies that allow individuals to interact effectively with one another (Riggio et al, 1993)

Most of such findings argue that social skills play a key role in achieving success, overall performance and satisfaction with life in general (Perrewé et al, 2000; Witt and Ferris, 2001, 2003; Ferris et al, 2005, 2007).

In the field of Entrepreneurship, Baron and Markman (1998, 2003), Baron and Brush (1999), as well as Baron (2004), provided a considerable contribution to quantitative research on social competencies when they reported on the development of several empirical studies emphasizing the strong beneficial effects of specific entrepreneurs' social skills on their success.

Their work helped establish some support for social skills measures and their positive effects on new venture outcomes.

Indeed, a detailed review of the preceding research findings, which was outlined by Markman and Baron (1998, 2000, 2003), Baron and Tang (2009), reveals that several social skills are more likely to significantly influence the entrepreneurs' financial success, outcomes and new venture performance. These skills incorporate: (a) persuasiveness (the proficiency at wielding the effective tactics for social influence by convincing others to change their points of view, and even their behavior towards the desired goals; Cialdini, 2000), (b) impression management (the skill at inducing good first impressions on others; Riggio and Riggio, 2001), and (c) emotional intelligence (the capacity of recognizing one's feelings and those of others, and managing his emotions as well as his relationships with everyone; Goleman, 1998, Goleman et al, 2002).

Furthermore, in consistence with other previous studies conducted by Ferris et al (2005), Hochwarter et al (2006), Cantner and Stutzer (2010); Baron and his colleagues (1998, 1999, 2003, 2009) have drawn attention to the importance of social capital (defined as the set of connections and interactions existing in the network of the entrepreneur, which enable him to gain access to other resources; Kim and Aldrich, 2005). These authors also indicated that social capital helps entrepreneurs gain access to people who are important for their success (such as potential partners, consultants, potential customers and suppliers, venture capitalists). They presumed that specific social skills may lead to social capital by expanding and improving the entrepreneur's network.

All the research findings mentioned above are important. However, they called for more considerable attempts to fully explore the content domain of entrepreneurial social skills and examine their implications in different contexts and at different stages of the entrepreneurial process.

The present study is built on previous advances and aims at extending their scope in several ways.

First of all, we examined the effects of social skills at a particular stage of the entrepreneurial process: the new venture survival/development. For this purpose, we adopted the new venture creation process proposed by Bruyat and Julien (2001), Fayolle and Bruyat (2001), and Fayolle (2007). These scholars divided the entrepreneurial process into three distinct, but complementary phases:

(1) The trigger: this happens when the entrepreneur is highly motivated so that he can't abandon the idea of setting up a project;

(2) The commitment: this occurs when the entrepreneur devotes the majority of his time, energy and money to assemble the different elements of the project;

(3) The survival/development phase: it is carried out when the new venture is above its breakeven point enhancing the entrepreneur to look for viability and expansion.

Referring to several lines of evidence (developed especially by Johannisson, 2000; Elfring and Hulsink, 2003; Tornikoski and Newbert, 2007, ...), it appears that the survival/development stage is the most critical one because it enables the entrepreneur to gain stability and consolation once he has succeeded in solving the problems related to the lack of legitimacy, uncertainty, scarcity of resources, and informational asymmetry.

Second, the current research is inspired by Baron and Tang's (2009) findings but seeks to examine the effects of the entrepreneurs' social skills on their access to external essential resources rather than on their success throughout the survival-development stage.

Indeed, we underlined that, in this phase, entrepreneurs are looking for the simultaneous development of the current and potential products/ services, the attraction of new customers, and the increase of the company's sales and market share in order to reach a certain financial and commercial stability (Fayolle, 2007)... The ultimate entrepreneurial success is, then, strongly dependent on the degree of access to outside essential resources, such as financing, information and support (Brush, 1992; Cable and Shane, 2002; Stuart and Sorenson, 2005; Groen, 2005).

The stream of these findings coupled with additional ones advanced by Elfring and Hulsink (2003), Ravasi and Turati, (2005) and Fayolle (2007) led us to argue that the main problem that threatens the new venture survival is the lack of resources. According to the researchers mentioned above, these resources encompass essentially financing as well as the useful information whose acquisition requires socially skilled entrepreneurs and good communicators.

Third, we have chosen to conduct our survey in the Tunisian context (not studied in previous researches) where entrepreneurship is being more and more encouraged in order to enhance economic growth and reduce unemployment rate. More precisely, we have opted for new ventures undertaken in the High- Technology sector, which witnesses a high environmental turbulence but generates high profits. In such current context, entrepreneurs who decide to invest should build and manage well their relationships with the key customers, investors, and all the key persons operating in famous and multinational High-Technology firms. This enables them to acquire resources that they need for the development of their new projects.

On the basis of all these considerations, we suggest that, when all the other factors are equal, social capital enables Tunisian High-Technology entrepreneurs to gain access to external vital resources thanks to their social skills. Then, the High-Technology field offers an appropriate context for the current study.

2. Theoretical development

As mentioned above, the main target of this study is to dwell on the basic social determinants of the entrepreneurs' success. The emphasis is put on the manner by which a new venture, recently involved in the market and disadvantaged to established organizations, can go beyond its liability of newness. To do so, its nascent founder is called to obtain and recombine paramount resources the venture needs to acquire a certain reliability and stability (for more details, see Delmar and Shane, 2004; Tornikoski and Newbert, 2007).

In what follows, we first propose some hypotheses related to the effects of the entrepreneurs' social capital on their access to outside vital resources. Then, we point out the key role of specific social skills by developing

hypotheses concerning not only their impact on the access to relevant external resources, but also on the social capital development.

2.1. Effects of social capital

In compliance with the previous studies conducted by the network theory advocates; Baron and Brush (1999) as well as Baron and Markman (2000, 2003) have drawn attention, at least in a way, to the importance of the social capital (defined as the set of connections and interactions in the entrepreneur's network, enabling him to gain access to other resources; Kim and Aldrich, 2005).

These authors have indicated that social capital helps entrepreneurs gain access to people who are willing to support the development of their ventures.

For this reason, we focused on the bridging social capital perspective advanced by Burt (1992, 2000), then by Adler and Kwon (2002). This view describes social capital in terms of weak and non redundant ties in a large network of relationships. Unlike strong ties built with family members and close friends, weak ties correspond to the vague, occasional or fortuitous acquaintances which don't generate an emotional investment (Dubini and Aldrich, 1991). However, the non redundant ties constitute contacts that don't give access to the same sources of information and then to the same people (Burt, 1992, 1997). Finally, the extent of a network is approached by the number of contacts the entrepreneur knows.

The preceding considerations lead us to propose the following hypothesis:

Hypothesis 1: A high level of social capital assists the entrepreneur to gain access to financing.

On the basis of the research orientation developed by Cable and Shane (1997, 2002), and Batjargal and Liu (2004) who underlined that a developed entrepreneurial social capital generates access to financing, we can hypothesize that:

Hypothesis 1a: A high level of social capital assists the entrepreneur to gain access to financing.

Furthermore, following Nahapiet and Ghoshal (1998), Seibert and colleagues (2001), Yi- Renko et al (2001), Uzzi and Lancaster (2003) as well as Cantner and Stutzer (2010), we argue that new ventures operating in uncertain areas benefit more from their non redundant, weak and numerous ties to acquire useful information they need for the development of their new ventures. Thus, we can suggest the following testable hypothesis:

Hypothesis 1b: A high level of social capital assists the entrepreneur to gain access to relevant information.

2.2. Effects of social skills

Once again, focusing on the conceptual insights and empirical findings suggested by Baron and Markman (1998, 2003); Baron (2004); Baron and Tang (2009), we will focus, in what follows, on the most relevant social skills in the Tunisian High-Technology context in order to push forward a more coherent view of their beneficial effects on the access to useful information and financing.

These social competencies involve:

(1) Persuasiveness: it refers to the capacity for changing the attitudes or behaviors of others in the pursuit of compliance (Dillard and Marshall, 2003; Dillard, 2004). It represents the aptitude to control and influence the answers of others towards the expected directions (Cialdini, 1994, 2000; Ewart et al., 2002).

Gartner et al (1992) and Baron and Markman (1998; 2003) have argued that entrepreneurs' proficiency at social influence contributes to their success.

On the basis of these findings, we can propose the following hypotheses:

Hypothesis 2: The entrepreneur's skill at persuasiveness has a positive impact on his access to essential resources.

In this perspective, the entrepreneur's success is explained by his ability to quickly obtain the adhesion and support of the current and potential investors (venture capitalists or bankers) ideas or goals. Baron and Markman (2003), and Chi, Baron et al (2008), pointed out that persuasiveness may change the investors' attitudes and *decisions, as well as other stakeholders' ones, towards the entrepreneur's desired goals. Then, we can propose the following hypotheses:*

Hypothesis 2a: The entrepreneur's skill at persuasiveness has a positive impact on his access to financial resources.

Hypothesis 2b: The entrepreneur's skill at persuasiveness has a positive impact on his access to the relevant and useful information.

(2) Impression management: it is defined as the proficiency at making good impressions on others and inducing positive and favorable reactions to them (Schlenker, 1980; Wayne and Liden, 1995). According to Baron and Tang (2009), it includes two distinct components: **ingratiation**, which refers to the efforts provided in order to induce high degrees of esteem on others by expressing liking for them or asking for their advice and Feedback (Wayne and Ferris, 1997) and **self-promotion**, which involves the ability at positively presenting his own skills and accomplishments in order to increase one's appeal to others (Bolino and Turnley, 1999);

These research findings corroborate those of Baron and Markman (1998, 2003) and Baron (2004). Moreover, Baron and Tang (2009) added that the amount of efforts made by entrepreneurs to make a first good impression on others and induce high degrees of liking in them- defined as ingratiation- could strongly influence the entrepreneurs' success.

Hypothesis 3: The entrepreneur's skill at ingratiation is positively related to his access to the essential resources.

Hall and Hofer (1993), Timmons (1994), Zacharakis and Meyer (1995) as well as Shepherd et al (2007) stressed that venture capitalists' decisions concerning their investment in the assembly and development of new ventures are strongly dependent on the profile of entrepreneurs, their current behaviors, their competencies and their experiences, by "the manner which is the person himself".

These considerations bring us to propose this hypothesis:

Hypothesis 3a: The entrepreneur's skill at ingratiation is positively related to his access to financial resources.

Moreover, Baron and Tang (2009), referring to Lewicki and Wiethoff (2000), Ferris et al (2005), argued that impression management tactics used by the entrepreneur, and based on ingratiation and flattery, engender high levels of trust and liking of others. This may, in turn, provide the entrepreneur with a large array of information. Thus, we can hypothesize that:

Hypothesis 3b: The entrepreneur's skill at ingratiation is positively related to his access to the relevant information.

(3) Emotional Intelligence: it represents the ability to perceive and express one's feelings adaptively, the adeptness at understanding, regulating and monitoring emotions in oneself and others (Mayer and Salovey, 1995, 1997; Mayer et al, 2001; Goleman et al, 2002).

The scholars have also advanced that Emotional Intelligence could be an important predictor of success not only in personal relationships and family functioning, but also in the workplace (Goleman et al, 2002).

Goleman (1998) distinguished between two clusters of emotional skills: the first one is called personal emotional intelligence and refers to self-awareness and self-management (understanding and controlling one's internal states, preferences, intuitions and resources); the second represents social emotional intelligence and encompasses social awareness and relationship management (understanding emotions of other people and dealing well with them).

To adapt the previous findings to our present context, we will focus, in what follows, on the personal emotional intelligence which seems to be more efficient for gaining access to external useful resources (according to qualitative research findings). Thus, we propose the following hypothesis:

Hypothesis 4: The entrepreneur's skill at personal emotional intelligence has a positive impact on his access to the essential resources.

More specifically, Soros (1987), Gardner (2004) and Bandura (1995, 2001) highlighted that self-awareness, self-confidence and self-efficacy have positive impacts on self-fulfilling, handling changes, pursuing goals, and improving success in obtaining the desired resources. On the basis of this reasoning, we can test the following set of hypotheses:

Hypothesis 4a: The entrepreneur's skill at personal emotional intelligence has a positive impact on his access to financial resources.

Hypothesis 4b: The entrepreneur's skill at personal emotional intelligence has a positive impact on his access to the relevant information.

Additional lines of evidence provide support for our prediction that socially skilled entrepreneurs will develop their network of relations and then their social capital more effectively so that they both raise their status within the market, and provide essential resources for the development of their new ventures.

In this perspective, Baron and Markman (2000, p.1) reported that « Specific social skills, such as the ability to read others accurately, to make favorable first impressions, adapt to a wide range of social situations, and be persuasive, can influence the quality of these interactions»; they added that « social capital is often the result of such skills».

In line with these assumptions, Diener and Seligman (2002) mentioned that «persons with high various social skills tend to have social contacts wider than those with low social skills».

Similarly, Baron (2004, p.222) revealed that «social skills may provide an important foundation for the development of social capital».

Hypothesis 5: The entrepreneur's social skills are positively related to the development of his social capital.

Furthermore, Meurs (2008) used Conservation of Resources theory to support that social capital resources are gathered, maintained, and employed to reach desired personal and organizational goals by the socially skilled individual. The resources he proposed are the most valuable, rare, inimitable, and non substitutable (Barney, 1986, 1991). He argued that a socially skilled person is better able to discern the resources that fall into those categories and to strategically employ them in the pursuit of his desired goals.

In this regard, we suggest testing these hypotheses:

Hypothesis 5a: The entrepreneur's skill at persuasiveness is positively related to the development of his social capital.

Hypothesis 5b: The higher the entrepreneur's skill at ingratiation, the higher his social capital's level will be.

Hypothesis 5c: The entrepreneur's proficiency at personal emotional intelligence has a positive impact on the level of his social capital.

3. Method

3.1. Sample and Procedures

We combined qualitative and quantitative approaches. For the qualitative method, we conducted ten pilot studies with new venture successful entrepreneurs committed to the High- Technology sector. Face-to-face interviews were carried out with these entrepreneurs to collect the main required data in order to adapt our investigation to the current Tunisian context. Moreover, we interviewed four experts in the High-Technology field. Each interview lasted between 30 and 50 minutes. Based on feedbacks during the qualitative research (pilot studies and expert interviews), we have chosen to limit our research to the most common highlighted social skills that distinguish the successful entrepreneurs. These social skills are persuasiveness, impression management and emotional intelligence. A first version of the questionnaire was then made. Four academicians were consulted to make sure that all the items chosen in our questionnaire transmit well the content of their appropriate constructs. A revisit of the wording of certain items was made for each scale to ensure considerable overlap in language and concepts. Furthermore, relying on the framework established by Besson and Haddadj (2003) for adapting an international survey instrument, the initial English version of the survey was translated into French. The French version was later retranslated into English by an academician. Some changes were made to correct any inconsistency made when comparing the French and English versions of the survey.

Our final survey instrument was prepared after pre-testing the questionnaire obtained next to 30 participants.

To constitute our sample, we have referred to multiple sources of information (such as the agency of Industry and Innovation Development, the chambers of commerce, and the communication lead officers in technology parks, respectfully in Tunis, Sousse, Sfax and Monastir).

A first list of 320 new High-Technology ventures (created since 2007) has been reviewed. Out of 320 representative entrepreneurs of these ventures, only 120 accepted to answer with complete data, reflecting a response rate of 37.50%.

3.2. Common Method Variance

Given the nature of perceptual data using a single source of information, it is always possible that some degree of common method bias may exist. The presence of a common method variance would threaten both the validity and analysis of the

data if a single latent factor accounts for all the observable variables. We adopted Harman's one-factor test to investigate the common method variance (for more details, see Podsakoff and al, 2003). All the items that we have used to measure the independent and dependant variables were entered into an exploratory factor analysis. The results revealed the presence of eight factors with eigenvalues greater than one (respectively to Kaiser criterion) and the first factor explained only 14.392 of the total variance. Thus, there is no significant common method bias in our data.

3.3. Measures

Whenever it was possible for us, we adopted measures from the literature. However, an arrangement of certain items and exclusion of others was necessary to increase the scale's assessment and enhance the credibility and usefulness of interviewees' feedback data. The new final instrument resulting from this work contains the concise and understandable items which reflect more accurately the content of their relative constructs.

For each construct, the correspondent items were subject to Principal Component Analysis (PCA) with varimax rotation which creates orthogonal-not correlated factors. For this reason, we first examined the interitem correlation matrix within each construct and dropped those that show low correlations. As a rule of Thumb, we kept only the items which contribute to a KMO's value greater than 0.7 and an eigenvalue greater that one by each factor (relatively to Kaiser-Mayer-Olkin measure of sampling adequacy, Bartlett's test of sphericity and Kaiser criterion). For some factors, we accepted a KMO's value close to 0.65.

In addition, we checked the reliability, stability and unidimensionnality of each construct. Cronbach's Alpha for each construct was greater than 0.70, the cutoff value suggested by Nunally (1978).

Social skills

As mentioned above, we referred to the empirical scope of the social skill conceptualization considered by Markman and Baron (1998), Baron and Markman (2003) and Baron and Tang (2009). A 1-5 point Likert-type reflective scale ranging from one representing "strongly disagree" to five representing "strongly agree" was used to measure the specific social skills that we have chosen in the present research. Each rating is a single item on a 5-point scale. Higher scores reflect higher levels of social skills. The measurements employed are described and presented in details in Table 1, as follows.

TABLE 1: RESULTS OF FACTOR ANALYSIS OF SOCIAL SKILLS' MEASURES

Items	Factor1	Factor2	Factor3	Factor4	Factor5
Persuasiveness					
1- I am very good at getting other people to do what I want in most situations	-0.015	0.133	-0.113	0.862	0.146
2- If I set out to persuade someone to change his views on an issue, I am usually quite successful in doing so	0.054	0.094	0.078	0.877	0.182
3- I don't find any difficulty to speak in front of a large group of people	0.005	0.023	-0.095	0.856	0.175
Personal Emotional Intelligence					
4- I understand and recognize my own emotions, and their effects, my strengths and my limits	0.035	0.949	0.036	0.028	-0.018
5- I always control my disruptive emotions as well as my impulses	0.000	0.973	0.048	0.031	-0.026
6- I usually actualize my potentialities and I do my best to meet a standard of excellence	0.019	0.959	0.008	0.049	0.047
7- I am capable for adapting my feelings and to appropriate them in any situation	0.060	0.804	-0.004	0.156	0.015
Social Emotional Intelligence					
8- I can sense others' feelings and perspectives, and taking an active interest in their concerns	0.979	0.011	-0.061	0.031	-0.016

9- I can easily guide individuals, groups and generate enthusiasm in a team of work	0.932	0.007	-0.038	0.037	0.019
10- I can usually create a group synergy in order to pursue collective goals, when I work with many persons	0.932	0.096	-0.063	-0.016	0.031
11- I am capable of building long-lasting, mutual and satisfying relationships with others	0.927	0.007	-0.033	-0.001	0.001
Self-promotion					
12- I can easily talk proudly about my education and experience	0.107	0.029	0.740	-0.066	-0.107
13- I make others aware of my qualifications and abilities	-0.114	-0.087	0.783	-0.118	-0.167
14- I make other people aware of my accomplishments	-0.009	0.076	0.762	0.013	-0.059
15- I let others know that I have a lot of competencies in my domain	-0.192	0.044	0.767	0.031	0.120
Ingratiation					
16- I do personal favors for others to show them that I am friendly	0.027	0.007	0.015	0.171	0.770
17- I use flattery and favors so that others like me more	0.030	0.005	-0.127	0.187	0.861
18- I have no trouble praising others for their accomplishments so that they consider me a nice person	-0.028	-0.081	-0.104	0.118	0.845
Eigenvalues	3.968	3.449	3.192	2.101	1.355
Percentage of variance explained	20.143	19.291	13.324	13.177	12.204
Cumulative Percentage of variance explained	20.143	39.434	52.758	70.609	78.139

Persuasiveness

A five-item evaluation of the participants' persuasiveness was taken from the instrument used by Markman and Baron (1998). However, in our context, only 3 of 5 items are gathered in a single latent factor. Persuasiveness explains 78.667% of the total variance (KMO= 0.734). Items 4 and 5 were less correlated to other items. Therefore, they were dropped.

Impression management

The eight-item scale developed by Baron and Tang (2009) was employed to measure Management impression. In their work, Baron and Tang referred to the instrument of Bolino and Turnley (1999) and obtained two distinct constructs: ingratiation (four items) and self-promotion (four items). Once a factor analysis is conducted for the eight items, one item is dropped because it is less correlated with the second factor (ingratiation). Then, seven items are fitted in with their two convenient constructs, with eigenvalues greater than one and explaining 65.256% of the total variance (KMO=6.73).

As noted above (in the theoretical development), of the two dimensions of impression management, self promotion seems to be inappropriate for the present study and especially for the Tunisian context as it induces negative reactions on the majority of the interviewees. Therefore, we retained only ingratiation.

Emotional intelligence

Several suggestions of measures are highly recommended by researchers who made great efforts in working on Emotional Intelligence. We referred to those proposed by Markman and Goleman (1998); Goleman et al (2002); Bar-On (2005) and obtained a concise nine-item scale appropriate to our research, by taking into consideration the data collected for the qualitative approach. The items related to influence are dropped to avoid any multi-collinearity between persuasiveness and social emotional intelligence. Once a factor analysis is performed on the nine obtained items, one item is eliminated (Item 6) leading to two distinct factors with an acceptable level of KMO (KMO= 0.806). These two factors correspond respectively to the personal emotional intelligence (4 items) and the social emotional intelligence (4 items), with eigenvalues greater than 1. Together, they explain 87.782 % of the total variance.

Once again, of the two distinct aspects of emotional intelligence, social emotional intelligence items seem to be less coherent with the objectives of our study. Hence, we have chosen to limit our emphasis to personal emotional intelligence which was more evoked by experts in our qualitative research.

Social capital

As noted above, we refer to the bridging social capital view which incorporates weak and non redundant ties in an extended network of relations. Following the previous researches (Burt, 1992, 1997, 2000; Seibert et al, 2001), we presented the social capital as a multidimensional construct including the structural non redundancy, the number of weak ties and the size of the entrepreneurs' network. We kept these measures as metric ones. The size of the entrepreneurs' network corresponds to the number of people who helped these entrepreneurs, in some way, with the development of his project during the last six months (the maximal size of the network was ten). Weak ties are occasional or professional and correspond to distant relationships between the entrepreneur and his peers (friends, customers, colleagues). These weak ties are also supposed to assist the entrepreneur in the development of his new venture.

Structural Diversity (SD) measurement arises from Borgatti and colleagues' (2002) software (UCINET VI) which calculates the structural constraint (SC) of each entrepreneur's network. SD is derived from SC as follows: $SD = 1 - SC$.

A metric three-item scale is then developed to assess the entrepreneurial social capital.

The network size, the number of weak ties and the SD gathered in one factor: the entrepreneurial social capital. This factor eigenvalue is greater than 1 and explain 77.779% of the total variance (KMO= 0.687).

Access to financial resources

On the basis of Batjargal and Liu's (2004) research, we measured access to financing with three items: (a) The number of articles, which protect the investor's interests and his property rights in the convention that we have signed, is limited; (b) The period separating the date of the investment decision and the effective injection of the financing is short; (c) The difference between the initial amount of investment and the financing that we have really obtained is negligible. We slightly modified the original scale by converting it to a 1-5 point Likert-type reflective scale to make some arrangement and homogeneity between the two dependant variables. These items explain 73.830 % of the total variance (KMO= 0.705).

Access to useful informational resources

We operationalized access to the relevant information with reference to Lee and al's (2002) as well as to Baron and Tang's (2009) scales and obtained this four-item scale, taking into account feedbacks arising from our qualitative research: (a) we can easily search and locate the relevant technical and commercial information required for the development of the venture; (b) It's quite easy for us to gain access to the relevant technical and commercial information; (c) we can easily get the technical and commercial information that we need for the project; (d) we can quickly gain access to the useful technical and commercial information needed for the development of the venture. These items are positively correlated with each other and lead to a single latent factor explaining 78.294% of the total variance (KMO= 0.835).

All the items were maintained for the two dependant variables.

4. Results

As noted above (in measures' step), an Exploratory Factor Analysis (EFA) was conducted to check if the proposed factors are appropriate to the data we have already collected. For this reason, a factor analysis was performed with PCA and yielded interpretable factors which represent the variables we have selected for the current study. All the refinement efforts already made on the factor analysis (by SPSS software) for social skills' variables are reported in Table 1. This table indicates that all the items converge highly towards their corresponding constructs, and that there are no cross-loadings. Besides, all these factors present eigenvalues greater than 1 and explain 78.139%

of the total variance. Social capital, access to financing and access to the relevant information were also subject to PCA, following the same procedure and providing effective results (as noted in measures' step).

Then, a confirmatory factor analysis was conducted using a structural equation modeling to examine the reliability of each construct, the convergent validity and the discriminant validity of all the constructs. Accordingly, we used Partial least squares (PLS), a covariance based approach, dedicated to test and estimate the causal relationships between dependant and independent variables in a single systematic analysis (Urbach and Ahlemann, 2010).

4.1. Assessment of reliability and construct validity (outer model assessment)

The reliability of each construct was determined by calculating the Cronbach's Alpha used for assessing the internal consistency reliability (assuming that all the indicators are equally reliable; Cronbach, 1951) and the Composite one (taking into account that the indicators have different loadings (Henseler et al, 2009). Table 2 indicates that Cronbach's Alpha values and Composite reliability for all the constructs of the present study are well above the cutoff of 0.7, as recommended by Chin et al (1996).

The convergent validity involves the degree to which the items reflecting each construct converge in comparison with those measuring different constructs (Urbach and Ahlemann,

2010). A commonly applied criterion is the Average Variance Extraction-AVE- proposed by Fornell and Larcker (1981). The proposed threshold value is 0.5. So, the AVE must be higher than 0.5. Besides, Chin (1998) as well as Chin and al (2003) indicate that we should check the indicator reliability applied to seek out how much of the indicators variance is explained by the corresponding latent variable. This implies that the loading values of the items must be higher than 0.7, with a significant t-value level (higher than 1.96) (Geven and Straub, 2005). As shown in table 2 below, loadings for the indicators of each construct used in the current research are higher than 0.7, with a significant t-value. The AVE of each construct is also higher than 0.5.

TABLE 2: CONVERGENT VALIDITY, FACTOR LOADINGS AND RELIABILITY

Construct	Indicators	Loadings	t-value
Persuasiveness ($\alpha=0.864$, CR=0.913, AVE=0.779)	PersS1	0.907	37.769
	PersS2	0.923	53.424

Notes: α = α de Cronbach; CR= Composite Reliability; AVE=Average Variance Extracted

The discriminant validity refers to the extent to which the different constructs differ from one another (Zhu et al, 2006). In the PLS approach, two measures are commonly used: The Fornell-Larcker criterion and the “Cross-loadings” criterion proposed by Chin (1998).

The first criterion requires a construct to share more variance with its assigned indicators than with any other construct. Thus, the AVE’s square root of each construct should be higher than the correlation between any pair of other constructs (Gefen and Straub, 2005). The details reported in Table 3 indicate that the square root of the AVE (diagonal elements of the correlation matrix) is greater than the absolute value of the inter-construct correlations (off-diagonal elements).

According to the second criterion, the loadings of the measurement items of each construct must be larger than any of those of the other constructs. Otherwise, each construct indicators load very high (Chin, 1998-b, Gefen and Straub, 2005).

As shown in table 4, for each latent variable, all the loading values of the items are larger than any other factor’s loading values.

TABLE 3: DISCRIMINANT VALIDITY (1): MATRIX OF LATENT VARIABLES’ CORRELATION

Overall, we can use all the constructs to test the hypotheses that we have proposed.

4.2. Assessment of path coefficients and overview of inner model fit measures

The results of the interaction analyses dealing with the access to financing and to the relevant information as dependant variables are reported in table 5.

TABLE 5: SUMMARY OF PATH COEFFICIENTS OF STRUCTURAL MODEL AND PLS STATISTICS

Variables	4-Social capital	5-Access financing	6-Access relevant information	Hypotheses
1-Persuasiveness	0.150 **	0.162 **	0.163 ***	Hypotheses 2a, 2b and 5a supported
2-Ingriatiation	-0.012 ^{ns}	0.081 ^{ns}	0.207 **	*Hypothesis 3b supported *Hypotheses 3a and 5b not supported
3-Personal Emotional Intelligence	0.646 *	-0.167 ^{ns}	0.194 ***	*Hypotheses 4b and 5c supported *Hypothesis 4a not supported
4-Social capital		0.364 *	0.251 ***	Hypotheses 1a and 1b supported
R ²	0.472	0.144	0.2925	
f ²	0.030(1) 0.748(2)	0.078 (4)	0.038 (4)	
GOF	0.483			

As shown in the table 5, the entrepreneur's social capital is positively and significantly related to access to financing ($\beta= 36.4\%$) as well as to the relevant information ($\beta= 25.1\%$). Consequently, hypotheses 1, 1a and 1b are supported.

In addition, results provided support for the prediction that several social skills, such as social persuasion, ingriatiation and personal emotional intelligence, are positively and significantly related to the access to the relevant information (β values are respectively 36.4%, 20.7% and

19.4%). Hypotheses 2b, 3b and 4b are then supported. Out of the three social skills, which we have selected in the current study, only persuasiveness is positively and significantly related to the access to financing ($\beta=16.2\%$). Hypotheses 2a is then supported. However, no support is found for hypotheses 3a and 4a. Indeed, personal emotional intelligence has a negative impact on the entrepreneurs' access to financing; whereas ingriatiation is weakly linked to access to financing and both values associated with these social skills didn't attain statistical significance.

Moreover, the results indicated that persuasiveness and personal emotional intelligence are positively and significantly related to the entrepreneurial social capital, supporting a large effect of personal social intelligence ($\beta=64.6\%$) in comparison with persuasiveness ($\beta=15\%$). Hypotheses 5a and 5c are supported, but no support is found for hypothesis 5b, related to ingratiation.

In order to explain the endogenous latent variables' variance, we assessed the key target construct level of the coefficient of determination- R^2 for the social capital, access to the relevant information and access to financing.

The R^2 for entrepreneur's social capital is 0.472, which means that social skills explain 47.2% of the social capital's variance. R^2 for the access to financing is 0.144, whereas the R^2 for the access to the relevant information is 0.292. According to Chin (1998-b) and Ringle (2004), values around 0.67, 0.333 and 0.19 are respectively considered as substantial, moderate and high. Then, R^2 associated to social capital is high; R^2 for access to the relevant information is moderate, whereas R^2 relative to the access to financing is weak.

The difference between the squared multiple correlations is used to assess the overall effect size f^2 for the interaction where 0.02, 0.15 and 0.35 are respectively considered as small, moderate, and large effects (Cohen, 1988; Ringle, 2004). We found an effect size of 0.038 for access to the relevant information, 0.078 for access to financing (respectively to the expected effects of the social capital) and 0.748; 0.030 for social capital (respectively to the expected effects of Personal Emotional Intelligence and Persuasiveness). All these value sizes have small to medium effects, except that of the size linked to Personal Emotional Intelligence and related to the social capital.

We also found a Global adjustment Indicator-GOF of 0.483 which means that the overall explanation power of the model is high. (Henseler et al (2009) advance that values around 0.1; 0.25 and 0.36 are respectively considered substantial, moderate and high).

Figure 1 presented below shows, in details, all the relations between the entrepreneurs' social skills, their social capital and their access to financing and useful information.

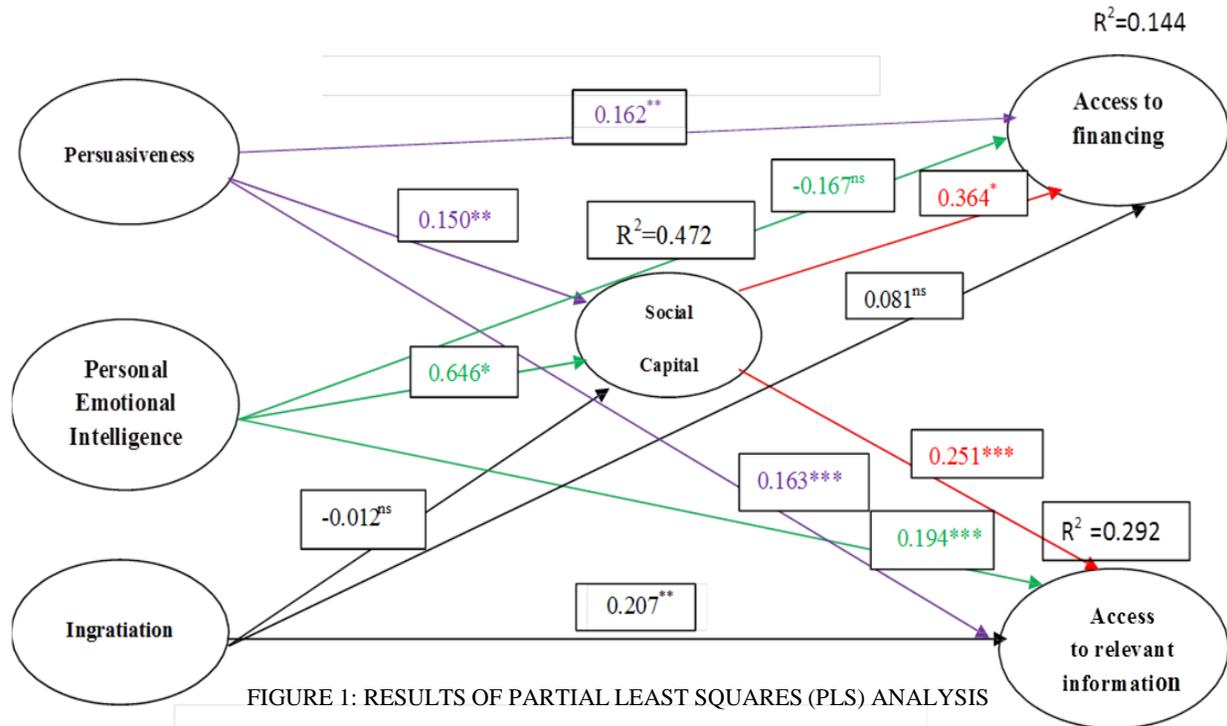

FIGURE 1: RESULTS OF PARTIAL LEAST SQUARES (PLS) ANALYSIS

Overall, the results provided some evidence that socially skilled entrepreneurs are more likely to enlarge their social capital. This capital is, in turn, largely used by entrepreneurs to obtain the external paramount resources they will need for the survival/development of their new ventures.

5. Discussion

The results of the current study are consistent with the findings of the previous studies which have largely underlined that specific entrepreneur's social skills have a significant impact on their financial success and their new venture performance (Baron and Markman, 1998; 2003; Baron and Brush, 1999; Baron, 2004). Recent additional findings reported by Baron and Tang (2009) have also drawn attention to the mediating role of two variables: the entrepreneur's effectiveness in acquiring information and their success in obtaining essential resources. These mediators may interfere between the entrepreneurs' social skills and their new venture performance. However, unlike in previous researches, conducted in the American and Chinese contexts (focusing especially on social perception, social adaptability, impression management and expressiveness), we have chosen to emphasize social competencies which are the most relevant in the Tunisian High-Technology context: Persuasiveness, emotional intelligence and impression management.

Moreover, we aim at shedding new light on the central role of entrepreneur's social capital.

Baron and Marksman's (2003) assumption indicates that "social capital may well exert its primary impact early in the process ... whereas the effects of social skills in interacting may persist and continue to shape the nature of the entrepreneurs' relations with such persons on a long-term basis". However, we provided several lines of evidence for predicting that, even in the survival/development stage of the entrepreneurial process (which is a problematic phase). Hence, the entrepreneur requires some support from his acquaintances to expand his activities. On the basis of an extensive body of research advancing that social capital enhances the entrepreneurs' access to relevant resources (financial and informational resources), we believe, as mentioned earlier, that specific social skills have a great influence not only on access to the required resources, but also on the development of entrepreneurial social capital. In this perspective, three sets of testable hypotheses were proposed leading to three clusters of results.

First, the hypotheses proposed on the basis of Baron and Tang's reasoning support that the specific social skills we have mentioned above, especially social persuasion, exert strong effects on the access to outside resources. Access to the relevant information is gained essentially through ingratiation, but also by social persuasion; however, access to financial resources is facilitated only by persuasiveness. These findings aren't surprising because access to financing depends a lot on the venture capitalists' decisions and their mental analysis process. Venture capitalists accept to invest in a new project, accept the risk and sign on an ambiguous deal once entrepreneurs convince them of their project value. In other words, thanks to their ability to come up with logical and structured arguments, talented entrepreneurs become more likely to attract the key investors and induce positive reactions on them (Cable and Shane, 2002; Batjargal and Liu, 2004; Zacharakis et al, 2007).

Second, the presented hypotheses support that persuasiveness and personal emotional intelligence are significantly and positively related to the social capital, while ingratiation has no impact on the development of the social capital. In the Tunisian business context, it seems that key persons, such as venture capitalists, customers, suppliers or other professional contacts, aren't very tempted by flattery, liking or other-enhancement efforts and tactics which come from the entrepreneur. These persons are, however, influenced by the entrepreneurs' proficiency at social persuasion and personal emotional intelligence. In this perspective, it is important to underline that the entrepreneurs' personal emotional intelligence, related to self-confidence, self-efficacy, emotional self-control and self-assessment, exerts a strong impact on the development of their social capital ($\beta = 64.6\%$). This means that the more the entrepreneur is self-confident and emotionally intelligent, the greater the contacts he will have (especially weak and diversified, non redundant ties, which are more important and beneficial than strong ties in turbulent and uncertain sectors, such as the High-Technology field (Elfring and Hulsink, 2003; Bhagavatula and al, 2010).

Finally, the results support the prediction that social capital contributes to the access to financing as well as useful information. Unlike previous studies, which underlined especially that strong ties are more likely to enhance access to financial resources (Cable and Shane, 2002; Batjargal and Liu, 2004), this current research indicates that, even if the social capital, is made up of weak ties, it could facilitate the entrepreneur's access to equity funds. However,

the low value of R^2 associated to access to financing could be explained by the fact that strong ties are more likely to influence access to financial resources.

The hypothesis suggested to support the relationship between the social capital and access to the relevant information is supported. This result confirms the previous findings indicating that weak and non redundant ties have a positive impact on the access to useful information (Seibert and al, 2001).

6. Conclusions, limitations and implications for future researches

The findings of the present research have several important implications.

First, at the broader level, this study explains the process by which entrepreneurs can gain access to vital resources at a critical stage of the entrepreneurial process: the survival/development of the new venture. At this phase, entrepreneurs encounter several problems such as resources scarcity, uncertainty, and lack of legitimacy ...and therefore have to enhance their access to key persons and key resources in order to tackle such problems and attain viability and performance.

Effective tactics based on social persuasion, personal emotional intelligence and other enhancement efforts have largely been developed by psychologists and even professionals to improve careers' success. This current research is consistent with the growing argument which advanced that such techniques could also be used in guiding training programs dedicated to entrepreneurs in order to enhance their social effectiveness at interaction and communication with people from a wide range of backgrounds and cultures, enabling them to avoid social errors and achieve their goals in different social settings.

Second, this present study adds new findings to the existent body of knowledge by exploring the way by which specific social skills assist entrepreneurs in enlarging their social capital. In other words, we have helped to shed some light on the slight theoretical framework dedicated to the relationship between social skills and social capital. Indeed, some previous studies conducted by Baron and Markman (2000), Baron and Markman (1998, 2003) have indicated that socially skilled entrepreneurs are more likely to have high levels of social capital, without providing any empirical support. The current research provides some empirical evidence concerning the impact of several social skills (especially persuasiveness and personal emotional intelligence) on the enlargement of the entrepreneurial social capital. This capital measure is based on the network extension as well as on the number of weak and non redundant ties. In this way, we attempted to offer some practical understanding of the process by which social factors adhere to raise High-Technology entrepreneurs' access to outside paramount resources.

Third, the previous researches conducted especially by Baron and Markman (1998, 2003), Baron (2004), and Baron and Brush (1999) emphasized the positive impacts that the social skills exert on the entrepreneurs' financial success and new venture performance, in different industries, such as Cosmetics, Biotechnology, High-Technology. More recently, Baron and Tang (2009) have based their suggestions on the role that the social capital plays in moderating the effects of social skills on the access to essential resources (human, financial and informational resources). Consistent with their findings, we have chosen to focus on the impact of social skills on the access to resources which are crucial for the survival/development of a Tunisian high-tech new venture. These resources are useful information and financing. Efforts along these lines would arm such entrepreneurs with social tools in order to enhance their success and relieve economic growth.

We believe that this study has also some limitations that should be mentioned as follows.

First, there is a bias impact of some measures related to social competencies and social capital in the sense that social skills measures are based on Likert-scale responses and provided, in a part, by experts and entrepreneurs interviewed in the qualitative research. Besides, while the social capital has been measured by referring to weak, professional and non redundant ties that an entrepreneur had built during his entrepreneurial process; other researchers have assessed social capital with strong and tense ties, especially when talking about its effects on financial success (Hansen, 1999; Jensen and Greve, 2002; Inpken and Tsang, 2005). Thus, it is worth noting how our measures of social capital and Batjargal and Liu's ones differ, but complement one another regarding the results they provide for access to financing. In a similar manner, other researchers underlined that social capital should be approached either by strong and dense ties it involves, or by the mix of weak/strong ties it includes (Hite and

Hesterly, 2001; Elfring and Hulsink, 2003). That's why another perspective could be oriented to the measurement of social capital by the mix of strong and weak ties it encompasses in order to study their joint benefits on the entrepreneurial success.

A second empirical limitation that could be addressed in the future is related to the investigation period in which the data was taken. Our research was conducted at a definite time, with reference to the cross-sectional method. It didn't allow us to assess the entrepreneur's social competencies and social capital level at various and successive points in time. It is so recommended to carry out a longitudinal analysis to outline the enlargement of the social capital and the resources gained through time, as long as the social skills are developed.

Third, the present findings are related only to the Tunisian High-Technology sector. Therefore, we cannot confirm whether the specific social skills we have mentioned (ig., persuasiveness, personal emotional intelligence and ingratiation) are relevant ones in other fields.

An additional stream of researches would be addressed to other contexts to replicate our findings in other sectors. Hence, it is recommended that several lines of researches explore the process by which proficiency at social interaction would enlarge the social capital of the entrepreneur and ease his access to essential resources in other fields, such as Agriculture, Industry and Biotechnology.

Antecedents of Entrepreneurial Activity: Theory & Evidence from Asia

Abstract

Purpose - In this paper, we attempt to compare entrepreneurial attributes of MBA students, the next generation business people, from two important Asian countries, India from South Asia and Japan from East Asia (India, being an emerging country and Japan, a developed country).

Design/ Methodology/ Approach - A survey was conducted among MBA Students in India and Japan and they were measured on entrepreneurial personality index and a comparison exercise was undertaken done to understand whether entrepreneurial traits are innate personality factors or learned cultural behaviour. For the proactive personality measurement, Bateman and Crant's (1993) questionnaire, consisting of seventeen traits is used.

Findings - The findings indicate that although, India has established itself in Information technology and information enabled services primarily through entrepreneurship, the country still has to go a long way as compared to developed countries such as Japan where entrepreneurship is widespread.

Research Limitations/ Implications- The results contribute to the development of theoretical and knowledge bases, that will be of interest to research and policy communities. However, the results are limited to a single survey, using cross-sectional data.

Practical Implications - Both, the causes and consequences of entrepreneurship are a matter of extensive scientific debate as well as of great policy importance. A high level of entrepreneurial activity is assumed and shown to contribute to innovative activities, competition, economic growth and job creation. The main goal is to examine if an entrepreneurial activity is related to business acumen imbibed through society and culture or is it an innate personality factors in a country context.

Originality / Value - The level of entrepreneurship differs considerably across countries and periods. We put forward a theoretical framework to denote the linkage between entrepreneurial attitude, proactive personality and culture in this study.

Keywords: Entrepreneurship, Proactive personality, India and Japan, Culture.

Introduction

The entrepreneur is an economic person, who tries to maximize his profits by innovation. Innovations involve problem solving and the entrepreneur gets satisfaction in solving problems (Higgins, 1964). It has been revealed from research that people who choose entrepreneurial careers look for greater financial and psychological rewards than regular employment. Entrepreneurship is measured by self-employment and has become an increasingly prominent characteristic of industrialised economies. The definition of an entrepreneur has evolved in last three centuries, from someone who bears risk by buying at a low price and selling at a higher price; to the creation of new enterprises of which the entrepreneur is the founder. An entrepreneur is driven by motivation. According to McClelland (1961) and Say (1963), an entrepreneur is one who brings together the factors of production, provisions of continuing management as well as risk bearing. Schumpeter (1950) envisioned that an entrepreneur is the agent who provides an economic leadership that changes the initial conditions of the economy and causes this discontinuous dynamic change. Entrepreneur is considered as an innovator (Tamizharasi G and Panchanatham N , 2010).

Entrepreneurship is gaining increasing respect from the scholars as a field of research as well as practical application worldwide as a means to achieve wealth creation and personal fulfilment (Ma and Tan, 2006). History has proven that with each economic downturn,

it is the entrepreneurial drive and persistence that brings us back (Kuratako, 2006). Entrepreneurship has attained a special importance in the control of economic growth and industrial development in the rapidly changing socioeconomic and socio-cultural climates both in the developed and developing countries (Tamizharasi G and Panchanatham N, 2010).

The study of entrepreneurship has relevance today, not only because it helps entrepreneurs better fulfil their personal needs but also, because of the economic contribution of the new ventures. More than increasing national income by creating new jobs, entrepreneurship acts as a positive force in economic growth by serving as the bridge between innovation and market place. Entrepreneurship is often viewed as a catalyst for economic

growth. Through innovation, hard work, and a willingness to accept financial risk, the entrepreneur takes advantage of previously undiscovered opportunities for arbitrage and profit (Kirzner, 1997). This quest for profit, and the possibility of personal and financial failure, aid in ensuring that an economy's resources are used efficiently. Successful entrepreneurs provide employment opportunities to others, generate innovation, spur economic growth, and contribute to state and local governments in the form of tax revenue.

Research revealed that some common traits of entrepreneurs are the capacity to innovate, to bear risks, to foresee the prospects of the project, confidence and competence to meet unforeseen and adverse conditions. But can these traits be generalized across countries and culture? In the current scenario, we have a broad spectrum of different countries with respect to the economic structure and cultural factors.

Entrepreneurial Attitude

Attitude differs across individuals. Attitudes are not permanent features. Attitude is defined as a mental and neural state of exerting readiness, organized through experience, exerting a directive or dynamic influence upon the individuals with regards to all objectives and situation, Allport (1935). Stimpson *et al.* (1991) reported that entrepreneurial attitude orientation consists of four broad dimensions such as achievement, self esteem, personal control and innovation. There was considerable difference in all four dimensions of the discriminate functional analysis of entrepreneurs and non-entrepreneurs. The scores of entrepreneurs were significantly higher in innovation, achievement and personal control. Both groups however showed marginal difference on self-esteem (Tamizharasi G and Panchanatham N, 2010).

An entrepreneurial attitude can be understood as the desire of starting one's own business. Entrepreneur risks time and money in search of opportunities to create value. Creativity and proactive behaviour are the underlined preconditions. The concept of entrepreneurial leadership has become increasingly important because organizations must be more entrepreneurial to enhance their performance, and to improve their capacity for adaptation and long-term survival. Proactive individuals may be more successful in entrepreneurial leadership and may contribute more to the organization. In recent times organizations are keen on hiring employees who have entrepreneur traits because of their belief that such people can bring changes by finding innovative solutions and new practices (Victor et al, 2009). They are pathfinders who change their organization's mission or find and solve problems (Durand & Shea 1974).

Harris, Michael and Gibson, Shanon (2008) examined the entrepreneurial attitudes of undergraduate students enrolled at multiple universities in the USA their result indicated that majority of students possessed entrepreneurial attitudes. Furthermore, both student characteristics and entrepreneurial experience were found to be associated with certain entrepreneurial attitudes. Lajovleva, Kolvareid and Stephan (2011) used The theory of Planned Behaviour to predict entrepreneurial intentions among students in five developing and nice developed countries. The findings indicate that respondents from developing countries have stronger entrepreneurial intentions than those from developed countries. Moreover, the respondents from developing countries also score higher on the theory's antecedents of entrepreneurial intentions – attitudes, subjective norms and perceived behavioural control – than respondents from developed countries. The findings support the Theory of Planned Behaviour in developing and developed countries.

Proactive persons identify opportunities and take initiative. They keep trying to bring change (Crant, 1996). The proactive dimension of behaviour in an entrepreneur is inherent in fulfilling the needs to manipulate and control the environment. The proactive personality index is a great contribution to the literature and has the potential for bringing better understanding into the personality and entrepreneurship relationship. Proactive personality measurement assesses a person's disposition toward proactive behaviour. Studies done by J. Michael Crant and Thomas S. Bateman suggest that the proactive personality index may be useful in identifying people with the personality variables predictive of entrepreneurial behaviour (Higgins 1964).

Proactive Personality

Bateman and Crant (1993) developed the proactive personality concept, defining it as a relatively stable tendency to effect environmental change that differentiates people based on the extent to which they take action to influence their environments. Individuals with a prototypical proactive personality identify opportunities and act on them, show initiative, take action, and persevere until meaningful change occurs (Crant, 2000.). In contrast, people who are not proactive exhibit the opposite patterns: they fail to identify, let alone seize, opportunities to change things. Less proactive individuals are passive and reactive, preferring to adapt to circumstances rather than change them (Crant, 2000). As work becomes more dynamic and decentralized, proactive behaviour and initiative become even more critical determinants of organizational success. For example, as new forms of management are introduced that minimize the surveillance function, companies will increasingly rely on employees' personal initiative to identify and solve problems (Michael Frese, Doris Fay, Tanja Hilburger, Karena Leng, Almut Tag, 1997).

Crant (2000) defined proactive behaviour as taking initiative in improving current circumstances or creating new ones; it involves challenging the status quo rather than passively adapting to present conditions. Employees can engage in proactive activities as part of their in-role behaviour in which they fulfill basic job requirements (Crant, 2000). For example, sales agents might proactively seek feedback on their techniques for closing a sale with an ultimate goal of improving job performance.

Extra-role behaviours can also be proactive, such as efforts to redefine one's role in the organization. For example, employees might engage in career management activities by identifying and acting on opportunities to change the scope of their jobs or move to more desirable divisions of the business (Crant, 2000). Crant (1995) demonstrated that proactive personality accounted for incremental variance in the job performance of real estate agents after controlling for both extraversion and conscientiousness. Proactive personality seems more specifically tailored to predicting motivation in learning contexts than the more general Big Five factors and facets (Major, Turner & Fletcher 2006). Proactive personality appears to have the potential for providing further insight into the personality trait- entrepreneurship relationship (Crant, 1996). The proactive personality scale measures a personal disposition toward proactive behavior, an idea that intuitively appears to be related to entrepreneurship (Crant, 1996).

In a study conducted by Crant (1996) that examined the relationship between proactive personality and entrepreneurial intentions, proactive personality was positively associated with entrepreneurial intentions. This may also be the case for entrepreneurial leadership; because people with a proactive personality may be more inclined to mobilizing the resources and gaining the commitment required for value creation that the entrepreneurial leader faces. More proactive people may have a greater desire to become entrepreneurial leaders in order to help create value for their firm.

Framing the Entrepreneurial Context

India has emerged as second fastest growing economy in the world.. With GDP growing at 8+ percent, the Indian economy has recorded remarkable growth in exports, FDI etc compared to developed countries. According to the Global Entrepreneurship Monitor 2006, one in every ten Indians is engaged in some entrepreneurial activity or the other. India is ninth in the Global Entrepreneurship Monitor (GEM) survey of entrepreneurial countries. It is highest among 28 countries in Necessity based entrepreneurship, while 5th from the lowest in opportunity based entrepreneurship.

According to GEM (2009), countries are grouped into three stages of economic development as defined by the World Economic Forum's Global Competitiveness Report: factor-driven, efficiency-driven and innovation-driven. This classification in phases of economic development is based on the level of GDP per capita and the extent to which countries are factor driven in terms of the shares of exports of primary goods in total exports. Factor-driven economies are primarily extractive in nature, while efficiency-driven economies exhibit scale-intensity as a major driver of development. At the innovation-driven stage of development, economies are characterized by their production of new and unique goods and services that are created via sophisticated, and often pioneering, methods. As countries develop economically, they tend to shift from one phase to the next. India is still a factor driven economy.

The liberalization, which was started in 1991 and the Information Technology boom during the second half of the 1990's, have been significant factors, leading to a wave of entrepreneurship sweeping through the Indian sub-continent.

A lot of entrepreneurship activity is centred on the IT (Information Technology) industry in India; but, there are a few outstanding examples in other fields. This new breed of entrepreneurs seems to make their own rules and revolutionized the way business was done. They used a winning combination of customer insight, industry knowledge, and out of the box thinking to create winning innovations. To a large extent, the society appears to be risk averse in India. People in India, compared to Japan usually seek secure and long-term employment, such as government jobs. Social Attitudes, lack of capital, inadequate physical infrastructure and lack of government support are major factors of hindrance. Japan has the second largest economy in Asia, whereas India is ranked as Asia's third largest economy. The liberalization of the economy in the 1990s has paved the way for a huge number of people to become entrepreneurs. The Government has encouraged entrepreneurship by providing training and also the facilities to succeed, particularly in the rural areas. One style of innovation that really works in a country as large and diverse as India is grassroots innovation.

India, with its abundant supply of talent in IT, management, and R&D, has become the hot bed of outsourcing of services from all parts of the globe where companies can reduce their costs. On the other hand entrepreneurial waves date back to 1950's and 1960's, in Japan when Japanese society and government undertook efforts for growth with slogans such as "Sell to the strangers", "Double income", and "Export led growth model"

The Indian entrepreneurs appear to think big and gone global in the recent years whereas lot of Japanese firms had gone global and growth global in 1970s and 1980s. The recent spate of global acquisitions by Indian industry leaders has forced the business community the world over to sit up and take notice of Indian economic power. The Tata-Corus deal set the tone and was followed by

Birla's acquisition of Novelis. The policy changes enabled a scalable and sustainable model for creating a new breed of entrepreneurs in the years to come. Access to seed capital is one of the key areas of potential investment. Venture Funds have entered the Indian market, but these funds are more focused on 'growth capital' rather than 'seed capital'.

Three pillars of Entrepreneurship

Today's knowledge based economy is a fertile ground for entrepreneurs. Therefore, we feel that it is important to create the following 3 pillars which in turn would help grooming successful entrepreneurs. This theoretical proposition can be depicted as Figure 1.

Pillar 1. Right Business Environment for Success:

Entrepreneurs have taken the following steps to achieve success in the past. In countries such as India the firms start slow with capital borrowed from family and friends, the CEO playing the role of salesman and strategist.

Pillar 2. Access to 'Smart Capital':

For a long time, Asian entrepreneurs, particularly Indian entrepreneurs, have had little access to venture capital. It is true that in the last few years, several Venture Funds have entered the Indian Market. Venture capital funds in the form of seed capital is known as smart capital.

Pillar 3. Networking and Exchange:

Entrepreneurs learn from experience- their own and that of others. The rapid pace of globalization and fast growth of Asian economies present tremendous opportunities and challenges. Through planning and focus, entrepreneurs can aspire to create a pool of entrepreneurs who might be the region's –and the world's–leaders of tomorrow.

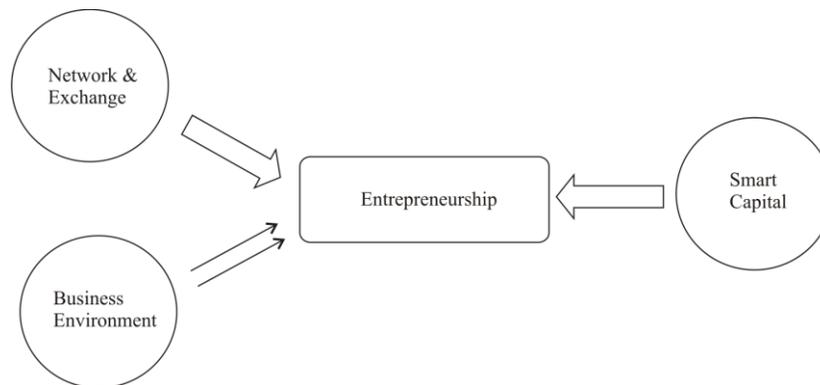

FIGURE 1 Three Pillars of Entrepreneurship
The framework developed by the author

In nutshell, it is worth noting that although the concept of entrepreneurial competencies is used widely by government agencies and others in their drive for economic development and business success, the core concept of entrepreneurial competencies, its measurement and its relationship to entrepreneurial performance and business success is in need for further rigorous research and development in practice (Mitchellmore, Siwan and Rowley, Jennifer, 2010).

Research Objectives

In this study, we compare entrepreneurial attitudes of MBA students in India with that of Japan. The main hypothesis is that proactive personality traits are greatly influenced by one's culture and not innate personality factors. If this is true, MBA students in an emerging economy such as India would not score as high on the proactive personality index as would MBA students of the developed countries where models of entrepreneurship are well established.

Methodology

An instrument containing 17 questions that measure proactive personality (Appendix A) was administered to 83 MBA students in India and in Japan. This self-report measure of proactive behavior was developed by Bateman and Crant to measure a person's disposition toward proactive behavior as a general construct that predicts behaviors intended to effect change (Schumpeter 1950).

An individual's total score will range between 17 and 119 on this instrument. The higher one's score, the stronger the proactive personality. Previous work by Bateman and Crant has determined that scores above 85 indicate fairly high proactivity. The average age in the sample is 23 years. We used SPSS to perform Independent Sample T Test on both the groups to find out if there is any statistically significant difference on each item of Bateman and Crant personality index.

Analysis

The overall average score on the Bateman and Crant instrument is 84.69 in the case of the MBA students in India. According to Bateman and Crant, this score is close to fairly high proactivity score 85. The MBA students in Japan scores 90.08 on Bateman and Crant's personality index that is much more than the Indian MBA students. The empirical findings in Table 1 shows scores of each group.

TABLE 1: Empirical Findings –Scores

		India	Japan
	Bateman and Crant Instrument	Average Score (N=83)	Average Score
1	I am constantly on the lookout for new ways to improve my life.	5.325301	6.27907
2	I feel driven to make a difference in my community and maybe the world.	4.626506	5.581395
3	I tend to let others take the initiative to start new projects	4.385542	4.465116
4	Wherever I have been, I have been a powerful force for constructive change.	4.614458	5.023254
5	I enjoy facing and overcoming obstacles to my ideas.	5.84337	5.255814
6	Nothing is more exciting than seeing my ideas turn into reality.	5.060241	5.534884
7	If I see something I don't like, I fix it.	4.554217	4.930233
8	No matter what the odds, if I believe in something, I will make it happen.	5.301966	5.325581
9	I love being a champion for my ideas, even against others' opposition.	5.169459	5.534884
10	I excel at identifying opportunities.	4.915663	5.046512
11	I am always looking for better ways to do things.	5.277108	5.674419
12	If I believe in an idea, no obstacle will prevent me from making it happen.	5.01494	5.204362
13	I love to challenge the status quo.	4.640964	4.813953
14	When I have a problem, I tackle it head-on.	5.001241	5.325581
15	I am great at turning problems into opportunities.	4.902439	4.860465
16	I can spot a good opportunity long before others can.	4.578313	5.023256
17	If I see someone in trouble, I help out in any way I can.	5.481928	6.209302
Sum		84.692415	90.088081

Individual questions with particularly high ratings (mean scores of 5.5 or higher on a 7-point Likert-type scale) of Indian students include:

- I enjoy facing and overcoming obstacles to my ideas.(5.84)

Individual questions with particularly high ratings (mean scores of 5.5 or higher on a 7-point Likert-type scale) of Japanese students include:

- I am constantly on the lookout for new ways to improve my life. (6.27)
- I feel driven to make a difference in my community and maybe the world. (5.58)
- Nothing is more exciting than seeing my ideas turn into reality. (5.53)
- I love being a champion for my ideas, even against others' opposition. (5.53)
- I am always looking for better ways to do things. (5.67)
- If I see someone in trouble, I help out in any way I can. (6.20)

We performed the T Test at 95% confidence interval to see whether there are any statistically significant differences between the scores on each item between the two groups of Indian MBA students and Japanese MBA students. Table 2 - shows the group statistics, mean, standard deviation and standard error of the two groups. Table 3 shows Independent Sample T Test.

TABLE 2: Group Statistics T-Test
Group Statistics

	Students	N	Mean	Std. Deviation	Std. Error Mean
I am constantly on the lookout for new ways to improve my life. Japan	India	83	5.325301	1.2698035	.1393790
	Japan	43	6.279070	.7343796	.1119918
I feel driven to make a difference in my India community and maybe the world. Japan	India	83	4.626506	1.3408301	.1471752
	Japan	43	5.581395	.8791922	.1340756
I tend to let others take the initiative to start new projects India initiative to start new projects Japan	India	83	4.385542	3.8661487	.4243649
	Japan	43	4.465116	1.5329529	.2337731
Wherever I have been, I have been a powerful force for constructive change. Japan	India	83	4.614458	1.3419255	.1472955
	Japan	43	5.023256	1.0575887	.1612808
I enjoy facing and overcoming obstacles to my ideas.	India	83	5.084337	1.3986476	.1535215
	Japan	43	5.255814	1.2168074	.1855614
Nothing is more exciting than seeing my ideas turn into reality.	India	83	5.060241	1.5409009	.1691358
	Japan	43	5.534884	1.1411948	.1740306
If I see something I don't like, I fix it.	India	83	4.554217	2.0674776	.2269352
	Japan	43	4.930233	1.3869348	.2115056
No matter what the odds, if I believe in something, I will make it happen.	India	83	5.301966	1.3294511	.1459262
	Japan	43	5.325581	1.2095046	.1844477
I love being a champion for my ideas, even against others' opposition.	India	83	5.169459	1.3574559	.1490001
	Japan	43	5.169459	1.3574559	.1490001

I excel at identifying opportunities.	India	83	4.915663	1.2897799	.1415717
	Japan	43	4.915663	1.2897799	.1415717
I am always looking for better ways to do things.	India	83	5.277108	1.2328161	.1353191
	Japan	43	5.674419	1.0628114	.1620772
If I believe in an idea, no obstacle will prevent me from making it happen.	India	83	5.014940	1.3021515	.1429297
	Japan	43	5.209302	1.1863939	.1809234
I love to challenge the status quo.	India	83	4.640964	1.3404619	.1471348
	Japan	43	4.813953	1.2199886	.1860465
When I have a problem, I tackle it head-on.	India	83	5.000000	1.3525045	.1484567
	Japan	43	5.325581	1.1489318	.1752105
I am great at turning problems into opportunities.	India	82	4.902439	1.2333809	.1362041
	Japan	43	4.860465	1.2263262	.1870130
I can spot a good opportunity long before others can.	India	83	4.578313	1.2407755	.1361928
	Japan	43	5.023256	1.0115611	.1542616
If I see someone in trouble, I help out in any way I can.	India	83	5.481928	1.2529131	.1375251
	Japan	43	6.209302	.9400643	.1433585

The table 2 describes the means and standard deviations of different items for the measurement of entrepreneurial attitude of each group: Indian MBA students and Japanese MBA students. The mean represent the average score of each item with the overall scores for the groups on a seven-point scale. To arrive at any conclusions that one group of students is significantly have more entrepreneurial attitude than another, we need to examine the statistical significance of the result (t-test information).

Table 3: Independent Sample T Test

For ease of accommodating large data on single page, instead of writing the complete item of Bateman and Crant Scale, we have used alphabets to represent the 17 items of Bateman and Crant personality index. The 17 items correspond to A to Q alphabet respectively. For example alphabet A correspond to item 1 i.e. “I am constantly on the lookout for new ways to improve my life” and alphabet B corresponds to “I feel driven to make a difference in my community and maybe the world” and so on.

An independent samples t-test was conducted to examine whether there was a significant difference in items of entrepreneurial attitude between Indian MBA students and Japanese students. The table 3 describes independent samples t-test information to ascertain whether there is a significant difference between the two groups in their entrepreneurial attitude. Before examining the t-test information, we must decide whether we can assume equal variances or not. Below the section of t-test for equality of means, we need to focus on the sig (2-tailed) column – this is the p-value.

The test revealed a statistically significant difference in the following items:

Item A: I am constantly on the lookout for new ways to improve my life.

The p-value (sig.) for item A for the Levene’s test is .001, it is below .05, hence we cannot assume equal variances, and the t value is

5.334. The p-value is .000 for the t-test for equality of means, here we are checking on the sig (2-tailed) column – this is the p-value. This p-value is related to independent samples t-test and shows that there is a significant difference between the two nationality groups with respect to item A. The table 1 shows the average score or means of items A as 5.32 for Indian students and 6.27 for Japanese students. Japanese students score significantly higher than the Indian students.

Item B: I feel driven to make a difference in my community and maybe the world.

The p-value (sig.) for item B for the Levene's test is .004, it is below .05, hence we cannot assume equal variances, and the t value is

4.79. The p-value is .000 for the t-test for equality of means, here we are checking on the sig (2-tailed) column – this is the p-value. This p-value is related to independent samples t-test and shows that there is a significant difference between the two nationality groups with respect to item B. The table 1 shows the average score or means of items B as 4.62 for Indian students and 5.58 for Japanese students. Japanese students score significantly higher than the Indian students.

The test revealed significant difference in variances but mean is not significantly different in the following items:

Item D: Wherever I have been, I have been a powerful force for constructive change.

The p-value(sig.) for item D for the Levene's test is .043, it is below .05, hence we cannot assume equal variances, and the t value is

1.87. The p-value is .064 for the t-test for equality of means, here we are checking on the sig (2-tailed) column – this is the p-value. This p-value is related to independent samples t-test and shows that mean is not significantly different between the two nationality groups with respect to item D. The table 1 shows the average score or means of items D as 4.61 for Indian students and 5.02 for Japanese students. Japanese students score significantly higher than the Indian students.

Item F: Nothing is more exciting than seeing my ideas turn into reality.

The p-value(sig.) for item F for the Levene's test is .036, it is below .05, hence we cannot assume equal variances, and the t value is

1.95. The p-value is .053 for the t-test for equality of means, here we are checking on the sig (2-tailed) column – this is the p-value. This p-value is related to independent samples t-test and shows that there is no significant difference in the mean of the two nationality groups with respect to item F. The table 1 shows the average score or means of items F as 5.06 for Indian students and 5.53 for Japanese students. Japanese students score significantly higher than the Indian students.

On the basis of our study, we postulate a with a theoretical framework that entrepreneurial attitude is a function of proactive personality and culture, which can be depicted as shown in Figure 2.

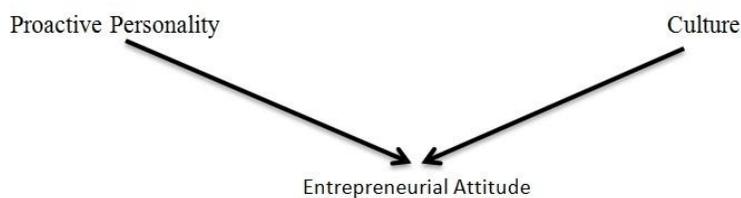

Figure 2

Conclusion

It is interesting that Indian MBA students and Japanese MBA students, though showed overall proactive personality 84.69 and 90.08 on Bateman and Crant instrument, yet had such strong differences on individual items. MBA students in India have not scored as high on the proactive personality index as MBA students of the developed country Japan. Indian students have scored higher than Japanese students on:

Item O: "I am great at turning problems into opportunities" Item E: "I enjoy facing and overcoming obstacles to my ideas"

Indians students scored almost same on:

Item H: "No matter what the odds, if I believe in something, I will make it happen",

One possible explanation for the difference is that, on average, Indian students understand the degree of difficulty for the entrepreneur and degree of bureaucratic hassles in India yet they believe that if one tries than they can groom themselves as successful entrepreneurs.

The hypothesis in this study is that proactive personality traits and entrepreneurial attitude are greatly influenced by one's culture and not innate personality factors found to be untrue as both the group are above the threshold of 85 score on personality index. However, since the scores are different so influence of culture cannot be ignored. Last, but not least, Regardless of the differences, both Indian and Japanese MBA students exhibit overall proactive, entrepreneurial attitudes, lending evidence to the conclusion that proactive personality attributes may be based more on inherent personality factors rather than strictly cultural learning. However, how those attributes are then demonstrated or expressed may be driven by cultural realities. Thus we conclude with a mathematical equation. Ie, Entrepreneurial attitude= f (pp, c) where pp stand, for proactive personality and c stands for culture.

Entrepreneur as an Intangible Asset

Abstract

The purpose of this paper is two-fold: One, to present the argument that entrepreneur is an important, albeit, difficult-to-measure intangible asset. Two, to discuss what we do know about measurement of other intangible assets at the macro as well as the firm level. Lack of an operational definition of entrepreneur continues to plague empirical research on the role of entrepreneur for innovation. Many proxy measures for entrepreneurs have very little to do with technological innovation. The innovative use of Q ratio as a measure of “entrepreneurial fever” and the works of Baumol (1993) and Keller (2004) that focuses on *imitating entrepreneur* are promising. There has been significant progress in the measurement of other intangible capital such as R&D. Intangible assets far exceed the level of tangible assets in the US economy and the conventional accounting practice of expensing intangibles results in a distorted and misleading picture not only at the firm level, but also at the macro level.

Introduction

A central feature of the new economies of the developed as well as many of the emerging economies is the growing importance of intangible assets. The term “intangible assets” is often used interchangeably with knowledge assets and intellectual capital or intellectual property when the claim is legally protected such as in the case of patents, trademarks, and copyrights. Baruch Lev (2001, p.5) provides definition of intangible asset as “a claim to future benefits that does not have a physical or financial (a stock or a bond) embodiment”. By this definition, R&D stocks and broadly defined human capital clearly come under the category of intangible assets. One should add to this list marketing assets that are becoming the defining feature of many firms, small and large, in the new economy. Such assets include not only investment in promotional effort to create and sustain a brand name, but also investments in channel development, a well-trained sales force, carefully developed relationships along the entire spectrum of supply chain and more-- all driven by intangible assets embedded in what has come to be referred to as information and communications technology (ICT).

Intangible assets, particularly assets related to knowledge and entrepreneurial skills are inherently difficult to measure because, often, organized and competitive markets either do not exist for them or are weak when they do exist. As a result, academic discourse on intangible assets occurs with data that is subject to relatively wide margin of error or no data. More important, as Baumol (1993) suggests, an intangible asset of great importance for innovation and economic growth, entrepreneurship, is not found in formal models. The growth model developed by Aghion and Howitt (2010) utilizing exit and turnover data of firms and workers would be one of the few exceptions.

The purpose of this paper is two-fold: One, to provide a historical context for the role of entrepreneur in the innovation process and present the argument that entrepreneur is an important, albeit, difficult-to-measure intangible asset, which is the subject of Section I. Two, to discuss what we do know about measurement of intangible assets at the macro as well as the firm level, which is the subject matter of Section II followed by concluding remarks in Section III.

Entrepreneur and Entrepreneurship: Schumpeter and Beyond

Baumol(1993) famously noted that “the entrepreneur is at once one of the most intriguing and one of the most elusive in the cast of characters that constitutes the subject of economic analysis”(p.2). He observes further that, although the entrepreneur has long been recognized as central for the vitality of the market economy, it was not until Joseph Schumpeter his function was clearly defined only to disappear again from the theoretical economics literature. Schumpeter defined entrepreneur as the *innovator*—the act of bringing a novel idea into operation— not to be confused with either the inventor or the capitalist whose task it is to take risk and get rewarded for it. Note that the contemporary view of entrepreneur considers risk taking as one of her/his chief attributes. Thus, Schumpeter (1936) in *The Theory of Economic Development* wrote:

“Although entrepreneurs of course *may* be inventors, just as they may be capitalists, they are inventors not by nature of their function but by coincidence and vice versa” (pp. 88-89).

Later, in *Capitalism, Socialism and Democracy* Schumpeter (Third Edition, 1942) adds some glorified language to describe the entrepreneur and the entrepreneurial function:

“To act with confidence beyond the range of familiar beacons and to overcome that resistance requires aptitudes that are present in only a small fraction of the population and that define the entrepreneurial type as well as the entrepreneurial function. This function.....*consists of getting things done.*” (italics added. p. 132).

It is important to note that Schumpeter’s entrepreneur “gets things done” by exploiting opportunities through “*new combinations*” to produce not only innovations in terms of new products and processes, but also adaption of new and better sources of inputs as well as new forms of business organization and marketing methods. Moreover, Schumpeter (1942) of *Capitalism, Socialism and Democracy* couldn’t be clearer about the obsolescence of the entrepreneurial function, a phenomenon he calls “crumbling walls”. He concludes:

“The perfectly bureaucratized giant industrial unit not only ousts the small or medium-sized firm and “expropriates” its owners, but in the end it also ousts the entrepreneur and expropriates the bourgeoisie as a class which in the process stand to lose not only its income but also what is infinitely more important, its function” (p. 134).

Galbraith (1967) takes Schumpeter’s glorification of the entrepreneur and her/his eventual demise a step further:

“The great entrepreneur must, in fact, be compared in life with the male *Apis mellifera*. He accomplishes his act of conception at the price of his own extinction” (pp.88-89).

Baumol (1993) questions whether it is even possible to describe what entrepreneurs do beyond generalities since an entrepreneurial act must always be different from anything that has been done before. Therefore, he suggests that “....anyone who writes about entrepreneurship has two choices—either to deal with the past, or to discuss something other than activities that today constitute entrepreneurship”(p. 15).

The social status of entrepreneurs was indeed high as far back as 1800 BC in Babylonia. They were members of the elite classes carrying the title of *damgar* or *tamkarum* (Hudson 2010).\ Painstaking estimates by Gelderblom (2010) suggest that in 1620 about 12 percent of the population 15 to 64 years of age in the city of Amsterdam in the Dutch Republic—known as the country of entrepreneurs—were entrepreneurs. Note that there is no clear definition of entrepreneur underlying such estimates. The largest group of entrepreneurs in Amsterdam was shopkeepers, many of whom today would be classified as small business owners who may or may not be “entrepreneurs”.

Colorful language aside, lack of an operational definition of entrepreneur continues to plague empirical research about entrepreneurs and entrepreneurship. It is easier to talk about who are not entrepreneurs. They are not just managers who manage other peoples’ money taking no risk themselves, nor are they simply investors who may not have active role in the business. To be sure, there is no dearth of proxies and indicators of entrepreneurship.

De Nardi, Doctor, and Krane (2007) classify “entrepreneurs as those households in which the head declares being self-employed as a primary job, owning a business (or a share of one), and having an active management role in the firm” (p.19). Such households are referred to as self-employed business owners or, SEBs. By this classification, households headed by entrepreneurs make up about 7 to 8 percent of the US population. The single largest category of SEBs was in professional practices like doctors, lawyers, and accountants followed by construction, retailing wholesaling and the like. However, note that many of the professional practices, even if they are entrepreneurial, have little to do with technological innovation Schumpeter had in mind.

Some scholars look at entry and exit data of firms as indicators of entrepreneurial fever. For example, the data presented by Hathaway and Litan (2014) that business dynamism measured in terms of entry and exit in which entrepreneurs play a critical role has been on the decline in the firm entry rate—firms less than one-year old as a percent of all firms—has been on a steady decline since 1978 while the exit rate has held steady notwithstanding the rise during the Great Recession. Births and deaths of business *establishments* are also considered as indicators of business dynamism. Data on births and deaths—in contrast to data on entry and exit data—are not affected by events such as mergers, takeovers, and reclassification. Birth at the establishment level is considered by some researchers as an especially good indicator of entrepreneurial activity. Establishment birth rate, like the entry rate, has been on a declining trend since 1993, while the death rate has been declining since 2001 Sadeghi (2008). The data reported by Hathaway (2013) on percent change in new firm formation relative to 1980 base for high-tech (defined by the presence of high share of workers in science, technology, engineering and mathematics occupations), ICT high-tech, and total private sector is more relevant to the measurement of entrepreneurial activity related to technological innovation (Figure 1). However, the conclusion from this data that the sharp drop in new firm formation in high-tech and ICT-high-tech since 2002 –from their respective peaks of about 400 percent and 200 percent relative to 1980—portends bad news for future productivity and economic growth is a bit premature. Schumpeter understood better than anyone that a burst of entrepreneurial activity will be followed by a sharp decline, which he argued causes business cycles.

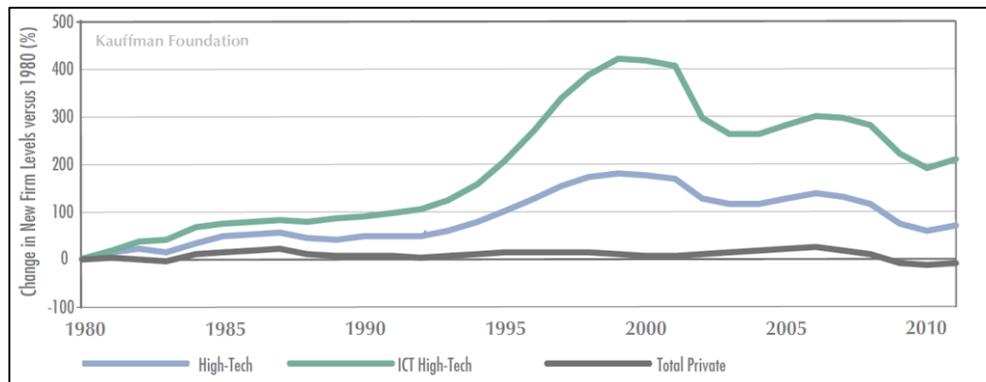

FIGURE 1: NEW FIRM (<1 YR.) FORMATION-CHANGE VERSUS 1980 (%)

Source: Hathaway (2013), U.S. Census Bureau, Business Dynamic Statistics and special tabulation; author’s calculation.

The trouble with most proxies of entrepreneurship is they seem to be far removed from indicators of technological innovation. For example, the rather sharp decline in entry observed by Hathaway and Litan (2014) is not reflected in the data on productivity, at least not yet. For example, average annual growth in multifactor productivity over the 1987 to 2007 period had shown no signs of decline. In fact, the growth rate has increased from 0.5 percent in 1990-1995 to 1.4 percent between 2000 and 2007. Not surprisingly, the rate of growth declined to 0.4 percent between 2007-2011, the period which included the Great Recession followed by 1 percent growth during 2010-2011 (USDL 2013). Nor does it show up in venture capital financing--sometimes known as angel investment--of high-tech projects (Figure 2). On the other hand, the sharp decline in the share of US patents granted to independent inventors-- from about 21 percent in 1978 to 7 percent in 2011—is, consistent with Schumpeter’s “crumbling walls” prediction that innovation will increasingly become the stuff of the large corporation or “corporate entrepreneurship”. This is not withstanding the contribution of individuals who started out as entrepreneurs like Bill Gates, Steve Jobs, Jeff Bezos, Larry Page & Sergey Brin, Narayana Murthy and scores of other lesser known personalities, but still fit Schumpeter’s definition of an entrepreneur. None of them started out as inventors or capitalists but all of them were innovators who exploited ideas through “new combinations” and got things done. It should be noted also that the

distinction between invention and innovation becomes very blurred in the present day context of science-based entrepreneurial firms in the bio-tech and software sectors, for example.

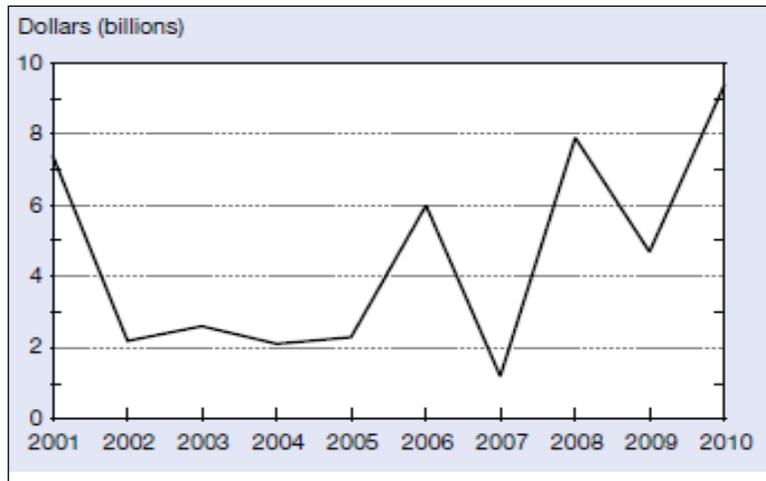

FIGURE 2: ESTIMATED US ANGEL INVESTMENT:2001-2010

Source: Global Entrepreneurship monitors, <http://www.gemconsortium.org/default.aspx>;
 U S Census Bureau, PopulatioEstimates,<http://www.census.gov.popest/estbygeo.html>, accessed 15 May 2011.Cited in NSB (2012).

In contrast to Schumpeter’s *innovative entrepreneurship*, Baumol (1993) introduced the term *imitative entrepreneurship*, which involves transfer of technology from one firm or one geographic location to another. Baumol and other economists (see Keller 2004, for example) suggest that the *mere imitator* Schumpeter refers to plays a central role in the rapid diffusion of technology within and across countries. This is particularly important for the economic growth of the developing countries that depend on the developed world’s technologies. One need only consider how Indian imitative entrepreneurs have become major players in the generic drug segment of the global pharmaceutical industry and ultimately helped create the beginnings of a fully integrated world class pharmaceutical sector in India (Rao and Klein 2013).

Another source of entrepreneurship measurement is the Global Entrepreneurship Monitor (GEM) sponsored by Babson College (USA), Universidad del Desarrollo (Chile), and Universiti Tun Abdulrazak (Malaysia). London Business School (UK) founded the GEM. The sponsorship by the three educational institutions culminated in annual reports containing entrepreneurship-related data on participating countries. GEM’s Adult Population Survey (APS) is based on a random sample of 2000 adults between 18 to 64 years of age in the participating countries. The GEM 2012 Report authored by Xavier, Kelly, Kew, Herrington, and Vorderwulbecke (2013) published survey data on early-stage total entrepreneurial activity (TEA)—the central measure of GEM-- among other data. The TEA rate consists of the percentage of individuals aged 18-64 in a country/economy who are in the process of starting or are already running new businesses. By this measure, the US with 13 percent ranks highest among the 30 countries including EU (22) and non-EU countries (7). Note, however, TEA rates tend to be high in economies with low GDP per capita and low in high GDP per capita economies. The highest rates were found in Sub-Saharan Africa (28%) and Latin America/Caribbean (17%) regions indicating necessity-motivated entrepreneurship and perhaps relatively low corporate presence. By contrast, lower rates in high GDP per capita economies suggest opportunity-motivated entrepreneurship and high level of corporate entrepreneurship. Again, these findings leave us with the *presumption* of a positive relationship between start-up rates and innovation without much empirical support.

Anokhin and Wincent (2012), utilizing data for 35 countries over the 1996-2002 period, attempted to do just that. They operationalize a country’s innovation with two measurements of the dependent variable-- patent applications

and total factor productivity (TFP) -- and relate them to the GEM's measure of TEA (independent variable) and several other control variables. The authors conclude "that on balance, there is a weak relationship between start-up rates and innovation" (p. 41). The relationship is not uniformly positive across countries. The relationship is positive in the high GDP per capita countries, but negative in the low GDP per capita countries, a finding consistent with the pattern of TEA in rich vs. poor countries noted above. Another earlier study by Bowen and Dirk De Clercq (2008)-- based on data for 40 countries over the 2002-2004 period-- used the GEM's TEA measure (i.e. a country's start-up rate) as the *dependent* variable and related it to independent variables such as financial capital targeted at entrepreneurship, educational capital targeted at entrepreneurship, government regulation, and the level of corruption and found that the allocation of entrepreneurial effort is positively related to a country's *targeted* financial and educational activities toward entrepreneurship, and negatively related to a country's level of corruption. An important implication of this study is policies to promote entrepreneurship need to be targeted.

Estimates of Intangible Capital for the U.S Economy

It has long been recognized in the economics literature that unaccounted intangible assets in the economy may be so large that the traditional practice of excluding most intangible investment such as R&D would result in a distorted picture of the level of GDP as well as its sources of growth. Pioneering estimates of intangible capital for the U.S economy by Corrado, Hulten and Sichel (2009) suggest that intangible capital in 2003 was \$3.6 trillion, an amount that exceeded the level of tangible capital by 36 percent (Figure 3 and Table 1). Almost half of the intangible capital is in the form of capitalized scientific and non-scientific R&D (an example of the latter is development of new motion pictures and other forms of entertainment), which the authors labeled as innovation property. Investments in on-the-job training by firms and computerized information accounted for 29 percent and 14 percent, respectively followed by capitalized value of advertising to build brand equity at 7 percent.

TABLE 1: ESTIMATED VALUE OF INTANGIBLE CAPITAL, BY TYPE, 2003
(IN BILLIONS OF CURRENT DOLLARS)

Type	Amount	Percent*
Computerized Information (includes software)	\$ 511.9	14.1%
Innovation Property		
Scientific	922.3	25.4
Non - Scientific	864.4	23.8
Economic Competencies		
Brand Equity	271.8	7.5
Firm – Specific Resources	1,065.6	29.3
Total	\$ 3,636.1	100.0

Source: Corrado, Hulten, and Sichel (2009), Table 2, Page. 676

*Percentages may not add up to 100 because of rounding.

The methodology underlying estimates of the components of intangible capital involves painstakingly estimating constant dollar stocks of investments in R&D, computerized information, on-the-job training, and advertising with appropriate depreciation rates. More likely than not Corrado-Hulten-Sichele (hereafter CHS) estimates of intangible capital are understated. To cite just one example, capitalized value of advertising, which the authors call brand equity is vastly understated, considering advertising is but a small fraction—perhaps no more than a third—of total promotion mix which includes personal selling, public relations, and sales promotion that are also aimed at building brand equity (Rao and Klein 2013). Moreover, depreciation rates applied to stocks of advertising (60 percent per year), firm-specific resources (40 percent) and R&D (20 percent) are quite conservative. More important, in a just-published study, Eisfeldt and Papanikolaou (2014) claim to be the first to emphasize that a large part of the most quantitatively important category of intangible capital—essential talent—is not accounted for because it is not possible for firms to fully own the cash flows generated by inputs from key talent. Put differently, key talent, not the firm, owns the cash flows associated with the intangible capital to the extent such capital is portable. The authors call this the missing capital estimated to be 50 percent of the measured market value of capital, which does not show up anywhere in the conventional accounting of intangible capital.

A different approach to measuring the value of intangible capital at the macro level comes from Tobin's Q, which is the ratio of market value of firms to replacement cost of *tangible* assets. Under competitive markets and no measurement errors, the Q ratio is expected to be 1.0. A ratio greater than 1.0 indicates, among other things, monopoly profits (which show up in the market value, the numerator) created in part by intangible assets such as capitalized value of R&D, brand equity, and the like, which are not counted in the denominator, the replacement cost of tangible assets. The Q ratio also reflects measurement errors in the calculation of replacement cost of tangible assets. Consistent with the rapid growth of *measured* intangible assets in the economy estimated by CHS, the Q ratio has risen rapidly from 0.28 in the early 1980s to 1.64 reaching a peak in 2000 at 1.64 and dropping to 0.57 during the 2007-2009 financial crisis before rising again to current level of 1.10 (Short 2014) Tobin's Q has been interpreted as an index of "speculative fever", which predicts the fluctuations in the economy's investment activity.

More recently, Phelps (2013), winner of the 2006 Nobel Prize in economics, reinterpreted the Q ratio as an indicator of economy's dynamism in terms of prospective new ideas. Phelps plotted a hybrid measure of Tobin's Q in 1988 against labor productivity in 1996 for nine European countries plus US, Canada and Australia and a strong

positive relationship between the two variables (Figure 7.3, p.188). He suggests that the current Q ratio is a good predictor of future productivity and hence “entrepreneurial fever” and innovation as well.

Note that the observed positive relationship between the Q ratio and measured labor productivity could be due to rapid growth of intangible capital during the same period experienced by 12 countries in the sample. A question arises whether entrepreneurial fever and speculative fever are one and the same.

The Case of “Missing” Intangible Capital at Microsoft

Hulten (2010) provided an estimate of missing intangible capital for Microsoft that is 96 percent (\$67 billion) of its conventional balance sheet assets at \$70 billion in 2006. (If one were to apply the same ratio to Microsoft’s 2013 balance sheet assets, the missing intangible capital of the firm would be \$138 billion). Hulten’s estimate of intangible capital comprised of 52 percent R&D stock; 41 percent related to sales and marketing; and 7 percent related to general and administrative stock in 2006. The addition of intangible capital causes shareholder equity to jump from \$40 billion to \$106 billion and return on equity to drop by 50 percent, from the conventional rate of 31.4 percent to intangibles-adjusted rate of 15.7 percent.

Employing macro-level growth accounting methodology, Hulten (2010) was also able to provide estimates of the sources of Microsoft’s growth in real output between 1988 and 2006. Intangible capital accounted for 44 percent of growth in output, while tangible capital a mere 7 percent. The second largest source of growth was total factor productivity (TFP)—residual after the contribution of all inputs are accounted for—which contributed 21 percent. Contribution of labor input to Microsoft’s growth, like the contribution of tangible capital, was a mere 10 percent and the remaining 18 percent was attributed to intermediate input (TABLE 2).

TABLE 2: SOURCES OF MICROSOFT’S GROWTH, 1988 – 2006

Sources	Percent
Intangible Capital Input	44.3%
TFP	20.7
Intermediate Input	18.3
Labor Input	10.0
Tangible Capital Input	7.0
Total	100.0

Source: Calculated from Hulten (2010), Table 6, Page. 3

One thing is clear from Hulten’s work. That is, intangible capital is an important and growing component of corporate assets-- as it is in the economy-- but not accounted for in the conventional balance sheets, thus resulting in a misleading analysis of the firm’s performance. That said, there are serious theoretical and empirical issues—some noted by the author himself in Hulten’s Microsoft study. For example, the macro-level sources-of-growth model used by Hulten to analyze Microsoft assumes perfectly competitive markets, constant returns to scale, exogenous technological change, and little uncertainty about the outcome of investments. None of these assumptions hold for Microsoft as Hulten himself notes. Moreover, it may be said that Microsoft was founded and run, at least initially, by a Schumpeterian entrepreneur, whose large and obvious contribution to its growth shows up nowhere in the sources-of-growth model.

Concluding Remarks

Among the 20th century economists Schumpeter was the first to assign central role for the entrepreneur and the entrepreneurship in the innovation process. Even Picketty (2013), who believes that the entrepreneurial argument does not justify vast inequalities in wealth, concedes the importance of entrepreneurs for innovation. Although the entrepreneur of Schumpeter's *The Theory of Economic Development* (1934) who seeks to upset the existing equilibrium and move the economy to the new equilibrium has been greatly supplanted by the large corporation as Schumpeter predicted in his *Capitalism, Socialism and Democracy* (1942), she/he is hardly out of the picture. One need only consider the entrepreneurship of Bill Gates, Steve Jobs, Jeff Bezos, and scores of other individuals like them who successfully challenged the very corporate giants who are supposed to leave no room for them. It is a safe bet that the world will continue to produce such entrepreneurs, albeit, to a different degree in different societies reflecting their institutional structure. This is despite the fact that, in the US nonfarm business economy, producers of technological innovation (individuals and firms) are able to capture only a tiny fraction—little over 2 percent—of the super-normal or the “Schumpeterian profits” as Nordhaus (2004) refers to them in his pioneering study. Still, measurement of entrepreneurs and entrepreneurship, much less their contribution to the economic wellbeing of the society has been challenging. Many of the available measures such as entry and exit rates and counts of self-employed businesses, for the most part, have very little to do with innovative entrepreneurship Schumpeter had in mind. This is not withstanding recent work by Hathaway (2013) and others who began looking at new firm formation of high-tech firms. Moreover, recent cross-country studies found only a weak relationship between start-up rates and innovation. This is one reason why entrepreneurial effort as an input into the production process has not found its way explicitly into many empirical models of economic growth. However, Phelps's (2013) innovative use of Q ratio as a measure of “entrepreneurial fever” across countries is promising as are models of technology transfer within and across countries -- built around the behavior of *imitating* entrepreneurs -- developed by Baumol (1993), and Keller(2002).

Much progress has been made in the measurement of other intangible assets. There is little doubt about the importance of the value of measurable intangible assets in the form of capitalized values of R&D, software, brand names and the like in terms of their level as well as growth in the economy. Estimates of intangible capital for the US economy by Corrado, Hulten, and Sichel (2009) exceed the value of tangible capital by 36 percent and almost half of it is in the form of scientific and non-scientific R&D. More likely than not, the value of intangible capital is vastly understated, not least because a large part of the most quantitatively important category of intangible capital—essential talent—is not accounted for because it is not possible for firms to fully own the cash flows generated by inputs from key talent. One of the implications of the growing importance of intangible capital is capital deepening and its contribution to growth in labor productivity is greater and total factor productivity (TFP) growth lower than would be the case otherwise.

Not surprisingly, firm level estimate of missing intangible capital for the Microsoft by Hulten (2010) was 96 percent of the value of conventional balance sheet assets in 2006. Hulten describes the picture of Microsoft that emerges from his study is a story about the successful use of knowledge inputs to produce knowledge outputs. Note that accounting for intangible capital reduces return on equity and narrows the gap between market-to-book ratios significantly. Thus, the conventional accounting practice of expensing intangibles results in a distorted and even misleading picture of performance not only at the firm level, but also at the macro level.

Innovative entrepreneurs: who are they?

Abstract

Do entrepreneurs differ from ordinary people? This question is often asked but seldom answered in research. In spite of the fact that anyone can start up a company, certain personal characteristics and behavioral patterns may be beneficial for running an enterprise.

In this study, entrepreneurs' personality types will be analyzed and compared with ordinary population with Finnish sample. Additionally creativity and innovation orientations of different personality types are compared in order to find out who are the innovators.

It was found that the most typical entrepreneurial personalities are often intuitive, spontaneous, curious, adaptable, and open to what is new and changeable. On the contrary, 70% of the population favors a planned, organized and predictable life style avoiding risks and surprises in their daily life, and they are more seldom entrepreneurs. The results can be utilized, for example, in entrepreneurial education and in mentoring start up candidates.

Introduction

Entrepreneurs as individuals differ from other people, that is, entrepreneurs' personality structure differ from the average, at least statistically. Of course we must not forget that entrepreneurs of different fields or different forms of enterprising might be connected with different characteristics of entrepreneurs. However, already Joseph Schumpeter (1934) saw real entrepreneurs as innovators and their role as the key driver of economic growth. He talked about "creative destruction" in which new innovations replace the old ones. We are in the search of intangible human capital that should be recognized, trained and unleashed to ensure that the smaller countries can withhold and improve their positions in the global economy.

The importance of the personality of potential entrepreneurs is usually ignored in promoting entrepreneurship. When explaining entrepreneurship there has usually been two different aspects: role of the environment has been one of the key factors to explain entrepreneurship. Secondly, the focus has been on finding the differences between entrepreneurs and non-entrepreneurs. Previous studies have found some differences but they have mostly ignored the personality aspect. In this study, the role of the environment has not been forgotten but we focus on the association between entrepreneurial creativity and personality in order to find out the innovative entrepreneurs. Schumpeter (1973) also indicated that becoming an entrepreneur requires tendencies that are unique. McClelland (1961) suggested that a high need of achievement, risk-taking ability, preferences for challenge, acceptance of personal responsibility and innovativeness are the characteristics of an entrepreneur. Other traits that are found to describe entrepreneurs are for instance tolerance of ambiguity and internal focus of control (Begley & Boyd, 1986).

The majority of the studies dealing with entrepreneurship and personality have focused on finding one description of entrepreneurs, or characteristics, which are typical of entrepreneurs. However, these studies have mainly ignored the fact that the entrepreneurs of different fields, or the different forms of entrepreneurship, might be connected with different characteristics or traits. In other words, there might be, not only one "true" personality of entrepreneur, but also many personalities, which might favor different forms of entrepreneurship. Also the entrepreneurs' orientation to networking (Routamaa & Varamäki, 1998) or internalization (Routamaa, Vesalainen & Pihlajaniemi, 1996) differs from each other depending on personality type. An enterprise can actually take multiple forms requiring more or less of training and various skills, like those of an expert entrepreneur, farmer entrepreneur, entrepreneur in a co-operative movement, scientist entrepreneur, venture capitalist, franchising entrepreneur, partner entrepreneur, businessman, shopkeeper, intrapreneur etc. – there is a good number of alternatives. It is not necessary for an entrepreneur or the founder of an enterprise to have all skills, since one can outsource sub-functions, purchase from a network or from a joint venture, subcontract etc. In a very basic form all you need is a mobile phone and good organizing skills. This should be emphasized in entrepreneurial education amongst young people. It can be concluded that the personality structure of entrepreneurs differs from general population (Routamaa 2008, 2011). But also entrepreneurs differ from each other and different

personality types favor different entrepreneurial identities. All SMEs are not innovative in the Schumpeter's 'creative destruction' meaning, that is all entrepreneurs are or need not to be especially innovative.

Since Schumpeter (1934), entrepreneurial characters in general have received a lot of attention in previous research (e.g. Smith, 1967; Stanford & Curran, 1976; Carland, Hoy, Boulton & Carland, 1984; Routamaa & Vesalainen, 1987; Gartner, 1989; Timmons, 1989). However, in spite of the dominant importance of entrepreneurship in economy, entrepreneurs as personalities have got relatively little attention. Most often, a trait approach has been used to illustrate entrepreneurial characteristics, like for example the need for achievement, internal locus of control and the propensity to take risks (e.g. McClelland, 1961; Hornaday & Aboud, 1971; Timmons, 1978; Welsh & White, 1981; Borland, 1974; Brockhaus, 1982; Markman & Baron, 2003; Marcati, Guido & Peluso, 2008; Dvir, Sadeh & Malach-Pines, 2010). More recently, the Five-Factor Model of personality has been applied to compare entrepreneurs and managers (Envick & Langford, 2000; Zhao & Seibert, 2006). It may be asked, however, whether the entrepreneurs constitute a homogeneous group such that it can be described using common traits. Are the trait tests able to identify different kinds of enterprising personalities? The still picture of a person in trait approach is a very narrow view in comparison of dynamic type, and the system of judging and perceiving explained in the next section. Empirical research has not found any trait that is consistently associated with entrepreneurship (Järnlström, 2002).

The basic question here is whether it is possible to identify the most potential, innovative entrepreneurs in terms of personality preferences or types.

Personality and personality types

Through the ages, an open question has been whether entrepreneurship is an innate talent, or can it be learnt. However, it can be assumed that there are more and less entrepreneurial oriented people. People also have some innate characteristics useful for entrepreneurs, for example, some of us are more easy-going salesmen than others and some better at recognizing great opportunities. Some people have better risk tolerance than others, and risk takers more likely to start their own business. Big part of this has to do with personality, which is mostly inborn. However, in spite of the dominant importance of entrepreneurship in economy, entrepreneurs as personalities have got relatively little attention. Most often, a trait approach has been used to illustrate entrepreneurial characteristics, like for example, the need for achievement, internal locus of control and the propensity to take risks (e.g. McClelland 1961; Hornaday & Aboud 1971; Timmons 1978; Welsh & White 1981; Borland 1974; Brockhaus 1982).

In this study, the Myers-Briggs Type Indicator (MBTI) was used to conceptualize and assess personality. It is based on Carl Jung's theory of psychological types and it reports personality preferences on four scales: Jungian Extraversion – Introversion, Sensing – Intuition, Thinking – Feeling, and the Judging – Perceiving preference added by Briggs and Myers (see e.g. Myers & McCaulley, 1985). According to Myers (1992) "the MBTI is primarily concerned with the valuable differences in people that result from where they like to focus their attention, the way they like to take information, the way they like to decide, and the way they like to adopt". Usually one pole dominates over another. The eight preferences are identified in sixteen types, each representing a certain preference order (Myers & McCaulley 1985). Briefly illustrated the preferences or dimensions are (Myers 1992):

Extraversion	(E)	Interested in people and things in the world around them. Breadth of interests.
Introversion	(I)	Interested in the ideas in their minds that explain the world. Depth of concentration.
Sensing	(S)	Interested in what is real and can be seen, heard and touched. Reliance on facts.
Intuition	(N)	Interested in what can be imagined and seen with 'the mind's eye'. Grasp of possibilities.
Thinking	(T)	Interested in what is logical and works by cause and effect.
Feeling	(F)	Interested in knowing what is important and valuable. Warmth and sympathy.
Judging	(J)	Interested in acting by organizing, planning, deciding. Organization.
Perceiving	(P)	Interested in acting by watching, trying out, adapting. Adaptability.

As stated by Myers & McCaulley (1985), "according to theory, each of the 16 types results from a preference for one pole of each of the four preferences over the opposite pole. A preference of any dimension is designed to be psychometrically independent of the preferences of the other three dichotomies, so that the preferences on the four

dichotomies yield sixteen possible combinations called types, denoted by the four letters identifying the poles preferred (e.g., ESTJ, INFP). The theory postulates specific dynamic relationships between the preferences. For each type, one process is the leading or dominant process and a second process serves as an auxiliary. Each type has its own pattern of dominant and auxiliary processes and the attitudes (E or I) in which these are habitually used. Determining these dynamic relationships is enabled by the J-P dichotomy of the MBTI. The characteristics of each type follow from the dynamic interplay of these processes and attitudes”.

In order to interpret the association between type and entrepreneurial identities, the types are next briefly illustrated (Myers & McCaulley, 1985):

-ISTJ Quiet and serious. Succeed through concentration and thoroughness. Practical, orderly, matter-of-fact, logical, realistic, and dependable. See to it that everything is well organized. Take responsibility. Make up their own minds as to what should be accomplished and work toward it steadily, regardless of protests or distractions.

-ISFJ Quiet, friendly, responsible, and conscientious. Work devotedly to meet their obligations. Lend stability to any project or group. Thorough, painstaking, accurate. Their interests are usually not technical. Can be patient with necessary details. Loyal, considerate, perceptive, concerned with how other people feel.

-INFJ Succeed by perseverance, originality, and desire to do whatever is needed or wanted. Put their best efforts into their work. Quietly forceful, conscientious, concerned for others. Respected for their firm principles. Likely to be honored and followed for their clear visions as to how best to serve the common good.

-INTJ Have original minds and great drive for their own ideas and purposes. Have long-range vision and quickly find meaningful patterns in external events. In fields that appeal to them, they have a fine power to organize a job and carry it through. Skeptical, critical, independent, determined. Have high standards of competence and performance.

-ISTP Cool onlookers, quiet, reserved, observing and analyzing life with detached curiosity and unexpected flashes of original humor. Usually interested in cause and effect, how and why mechanical things work, and in organizing facts using logical principles. Excel at getting to the core of a practical problem and finding the solution.

-ISFP Retiring, quietly friendly, sensitive, kind, modest about their abilities. Shun disagreements, do not force their opinions or values on others. Usually do not care to lead but are often loyal followers. Often relaxed about getting things done because they enjoy the present moment and do not want to spoil it by undue haste or exertion.

-INFP Quiet observers, idealistic, loyal. Important that outer life be congruent with inner values. Curious, quick to see possibilities, often serve as catalysts to implement ideas. Adaptable, flexible and accepting unless a value is threatened. Want to understand people and ways of fulfilling human potential. Little concern with possessions or surroundings.

-INTP Quiet and reserved. Especially enjoy theoretical or scientific pursuits. Like solving problems with logic and analysis. Interested mainly in ideas, with little liking for parties or small talk. Tend to have sharply defined interests. Need careers where some strong interest can be used and useful.

-ESTP Good at on-the-spot problem solving. Like action, enjoy whatever comes along. Tend to like mechanical things and sports, with friends on the side. Adaptable, tolerant, pragmatic; focused on getting results. Dislike long explanations. Are best with real things that can be worked, handled, taken apart, or put together.

-ESFP Outgoing, accepting, friendly, enjoys everything and makes things more fun for others by their enjoyment. Like action and making things happen. Know what's going on and join in eagerly. Find remembering facts easier than mastering theories. Are best in situations that need sound common sense and practical ability with people.

-ENFP Warmly enthusiastic, high-spirited, ingenious, imaginative. Able to do almost anything that interests them. Quick with a solution to any difficulty and ready to help anyone with a problem. Often rely on their ability to improvise instead of preparing in advance. Can usually find compelling reasons for whatever they want.

-ENTP Quick, ingenious, good at many things. Stimulating company, alert and outspoken. May argue for fun on either side of a question. Resourceful in solving new and challenging problems, but may neglect routine assignments. Apt to turn to one new interest after another. Skillful in finding logical reasons for what they want.

-ESTJ Practical, realistic, matter-of-fact, with a natural head for business or mechanics. Not interested in abstract theories, want learning to have direct and immediate application. Like to organize and run activities. Often make good administrators; are decisive, quickly move to implement decisions; take care of routine details.

-ESFJ Warm-hearted, talkative, popular, conscientious, born co-operators, active committee members. Need harmony and may be good at creating it. Always doing something nice for someone. Work best with encouragement and praise. Main interest is in things that directly and visibly affect people's lives.

-ENFJ Responsive and responsible. Feel real concern for what others think or want, and try to handle things with due regard for the other's feelings. Can present a proposal or lead a group discussion with ease and tact. Sociable, popular, sympathetic. Responsive to praise and criticism. Like to facilitate others and enable people to achieve their potential.

-ENTJ Frank, decisive, leaders in activities. Develop and implement comprehensive systems to solve organizational problems. Good at anything that requires reasoning and intelligent talk, such as public speaking. Are usually well informed and enjoy adding to their fund of knowledge.

In addition to the types, the dimensions (E, I, S, N, T, F, J, P) illustrated above as well as the pairs (EN, NT, ST, etc.) and temperaments (SJ, SP, NF, NT) of the personality in relation to entrepreneurs and innovativeness will be concerned.

Earlier studies

Concerning the MBTI preferences, Carland (1982), Barbato and Durlabhji (1989), Carland and Carland (1992) and Allinson, Chell & Hayes (2010) found that entrepreneurs tended to be more often intuitive thinking (NTs) whereas typical owner managers or managers were sensing judging (SJs). Carland, Carland and Higgs (1993) found NTs (intuitive thinking) displaying the highest entrepreneurship tendency, i.e. NTs, as distinguished from the other temperaments (ST, SP, NF), fit the traditional view of entrepreneurship in that the NT preference was highly correlated with innovation (cf. also Keirse & Bates, 1984). NT is a visionary who enjoys complexity and is an architect of change, sees long- and short-term implications, and focuses on possibilities (Keirse & Bates, 1984). These results uncovered that entrepreneurs tend to be NTs but also NPs (intuitive spontaneous). Referring to Asikainen and Routamaa (1997), NPs were found to be most creative. Also ENFPs produce individualistic and original ideas. Accordingly, Asikainen and Routamaa's (1997) view sounds logical. According to Ginn and Sexton (1988), fast-growth entrepreneurs tended to have significantly higher N, P, and NP orientations than managers. These results were in line with Routamaa et al. (1996), who found more Es, Ns, ENs, NTs but also NJs than ISs and IJs (introvert judging) among internationally oriented entrepreneurs. It could also be concluded that SPs and IPs are more locally oriented entrepreneurs, and also SJs seem to prefer traditional, local fields of low risks, that is, NPs as entrepreneurs may be more suitable in global and new business areas with high risk. SP has often been mentioned as the typical entrepreneur - negotiates well, is good in a crisis and is a risk taker. However, SP lives for the moment and does not like theory or routine (see Keirse & Bates, 1984).

Reynierse (1997) found that entrepreneurs had significantly higher Ps and lower Js. Further, entrepreneurs were more EPs, NPs, and TPs (thinking spontaneous) than IJs, SJs, and FJs. In her study of business students, Järnlström (2000) found that Ns and Ps chose relatively more often creativity (entrepreneurial) and autonomous career anchors than Ss and Js. Järnlström (2002) found also that the J-P dichotomy of the MBTI played the most important role separating entrepreneurial aspirations from organizational employment aspirations. Intuitive (N) and perceiving (P) preferences were more associated with entrepreneurial aspirations, whereas sensing (S) and judging (J) were more associated with organizational employment aspirations.

Envick and Langford (2000) compared entrepreneurs and managers using the Five-Factor Model of personality. Their results indicated that managers are significantly more conscientious (playful, neat, dependable) and agreeable (team-oriented, trusting, considerate) than entrepreneurs. That is, entrepreneurs were more impulsive, careless and unorganized as well as more self-interested, cool and skeptical. Managers were also more social (warm, optimistic and talkative) than entrepreneurs, who were a little more independent, reserved and hard-to-read. Entrepreneurs for their part were more adjusted (stable, confident and effective vs. nervous, self-doubting and moody) and open (imaginative, curious and original vs. practical, unimaginative, literal-minded) than managers, but not to a significant degree. These results support those reported above at least regarding the frequency of perceiving preference among entrepreneurs. Impulsive, careless and unorganized entrepreneurs are able to act in a

flexible, spontaneous and changing environment. This corresponds with P preference of the MBTI. However, Routamaa, Koskinen & Koskinen (2010) found that entrepreneurs are more extravert (E) and feeling (F) than salaried managers, in addition that entrepreneurs were significantly more spontaneous (P).

Routamaa (2008, 2011) found based on 2960 observations from Finland that ESFP, ESTP, INTP, ISTP, ENTP and ENFP are the six most entrepreneurial types based on the occupation statistics of the sample, see table 1. The common preference for all entrepreneurial types is perceiving (P), that is, they all are spontaneous, interested in acting by watching, trying out, adapting. The typical managerial types, ISTJ, ESTJ, and ENTJ (see Routamaa & Ponto, 1994; Routamaa, Honkonen, Asikainen & Pollari, 1997; Routamaa, Yang & Ou 2010; Routamaa & Ou 2012) are not among the top six entrepreneurial types. The most entrepreneurial types prefer a flexible, spontaneous and changing environment whereas the managerial types, in Finland, prefer a structured, organized and planned environment. What is the relationship with creativity and the most entrepreneurial types? This question will be concerned next.

TABLE 1: ENTREPRENEURS' TYPE DISTRIBUTION (CURSIVE), MIXED POPULATION'S TYPES, AND ENTREPRENEURS' RANKING POSITION AMONG THE OCCUPATIONS IN EACH PERSONALITY TYPE

ISTJ 8,9% 12,3% 32.	ISFJ 0,0% 5,4% 44.	INFJ 0,0% 1,1% 39.	INTJ 1,8% 3,5% 33.
ISTP 3,0% 2,4 9.	ISFP 1,2% 2,1% 19.	INFP 0,6% 1,2% 40.	INTP 3,0% 1,8% 6.
ESTP 7,7% 5,1% 5.	ESFP 9,5% 5,4% 3.	ENFP 8,9% 7,1% 17.	ENTP 8,9% 5,6% 12.
ESTJ 20,2% 20,2% 19.	ESFJ 7,7% 9,8% 24.	ENFJ 4,2% 5,2% 33.	ENTJ 14,3% 12,1% 23.

Methods

A Finnish version of the Myers-Briggs Type Indicator, validated by the author, was used in the study to measure the personality types. The construct validity and reliability of the indicator has been presented, for example, by Asikainen (1996). The whole sample (N=189) is presented in table 2.

Measuring creativity was very challenging. At best, it could be done in laboratory testing but it would be very unpractical in correlation research. In general, the measures of creativity or creation are non-validated questionnaires indicating attitudes, opinions, manners, etc. A totally new measure was constructed (Routamaa 2013). Analyzing 332 observations answering some 230 items, a unique four-dimension model of creativity orientation was obtained using factor analysis to indicate creativity orientations. Four factors, i.e. the dimensions of creative behavior obtained were: 1) Meticulous planner, 2) Individualistic thinker, 3) Creative idea man, and 4) Creative law challenger. Internal consistencies of all four dimensions were at least satisfactory, with all Cronbach alphas over .75.

TABLE 2: DISTRIBUTION OF PERSONALITY TYPES IN THE STUDY.

ISTJ N= 14 %= 7,41	ISFJ N= 6 %= 3,17	INFJ N= 1 %= 0,53	INTJ N= 4 %= 2,12
ISTP N= 10 %= 5,29	ISFP N= 4 %= 2,12	INFP N= 1 %= 0,59	INTP N= 5 %= 2,65
ESTP N= 12 %= 6,35	ESFP N= 10 %= 5,29	ENFP N= 21 %= 11,11	ENTP N= 16 %= 8,47
ESTJ N=37 %= 19,58	ESFJ N=20 %= 10,58	ENFJ N=5 %= 2,65	ENTJ N= 23 %= 12,17

Meticulous planners are dutiful, punctual, and systematic. They do not stand disorganization and favor logical and well-defined methods. They respect customary procedures. Individualistic thinkers live their own way, want to be him/herself without caring others' opinions, take risks to express his/her opinion without caring what others think but are social. However, they do not necessarily have creative alternatives to things they criticize. Creative idea men may not have their feet on the ground, value creative people and imagination, question things even without solutions, believe own uniqueness and dreams are important sources of innovations, think new ideas without considering their usefulness, and trust own intuition in problem solving and question profundities. Creative law challengers are self-reliant, trust that their own ideas are the best, may brake moral norms, wave aside the rules, get bored easily, are independent, and so not want to be led.

In all, 198 respondents including business university students and professionals filled both the MBTI inventory and creativity orientation questionnaire for this study. Those who got the upper quarter in creative idea man's and creative law challengers' factors will be compared to the whole sample using The Selection Ratio Type Table (see Granade & Myers, 1987; Moody, Granade & Myers, 1993) which calculates chi-square or Fischer's test depending on the number in each cell. Next, it will be analyzed, which personalities are the most innovative.

Results

Who are the innovative entrepreneurs? We looked for the answer in the upper quartile of creative idea men (n=48) and creative law challengers (n=53).

In table 3, it can be seen that preference intuitive (N), cognitive style intuitive feeling (NF), pair intuitive spontaneous (NP), pair extravert intuition (EN), type ENFP, and intuitive dominance (Ndom) are overrepresented among creative idea men. Ndom means those who's dominating, that is strongest preference, is intuition. It may be noted that also ENTP and ENTJ are overrepresented among the creative idea men even though not statistically significantly. The small number of some type observations limits the analysis. Intuition (N) with spontaneous (P) seems to be a common link to creativeness.

In table 4, the creative law challengers are compared to the total sample. It can be found that preference spontaneous (P), pairs introvert spontaneous (IP) and thinking spontaneous (TP), cognitive style intuitive spontaneous (NP) are overrepresented among the creative law challengers. Even not statistically significantly, at the type level ISTP, ENFP, ENTP and also INTP are overrepresented. Also intuitive dominance is overrepresented even though not significantly.

It appears that intuition and spontaneousness are the basic elements of creativity. Spontaneous life style with intuition is associated with controlled chaos, and it is known that chaos leads to creative solutions.

Discussion

The results confirm the earlier studies on the relationships between personality and creativity. As mentioned, according to McCaulley (1990), riskier decisions might be expected from extraverted (E), intuitive (N), and feeling (F) types. Asikainen and Routamaa's (1997) results of resourceful thinkers and innovators corresponded quite a lot with McCaulley's (1990) view but emphasized the role of spontaneous (P). It must be noted, however, that depending on the type, feeling (F) can either restrict (e.g. ESFJ) or support (e.g. ENFP) new, daring creative solutions. As found by Brandt and Routamaa (2010), especially certain F-type women had more economic difficulties in business resulting to reorganization more often than other personalities. Creative idea men and creative law challengers are connected especially with extraversion (E), intuition (N), and spontaneous (P). Additionally, intuitive dominance (Ndom) is clearly connected with creative behavior. At the type level, ENFP, ENTP and INTP are most overrepresented among the creative factors.

The results obtained here are mainly supported also by Routamaa & Rissanen (2004) who found that ENFPs were the most willing to evaluate themselves as innovator entrepreneurs and INTJs, ISTPs and ENTPs seemed also to favor this identity slightly. ISTPs are often sole proprietors where the introvert spontaneity results original business ideas. The results also support the entrepreneurs' rankings in each type as presented in table 1. Further, as found by Routamaa, Vesalainen and Pihlajaniemi (1996) entrepreneurs with N-preference are more growth internationalization orientated and whereas S-preference entrepreneurs favor smaller, local enterprises. The results obtained here support these findings by showing that these specific entrepreneurial types are innovative personalities.

In all, the results obtained here supported by some earlier studies indicate, first, that there are certain differences in the creativity and innovativeness of different personalities. Secondly, there are certain personality types who are more likely to start their own enterprise. Some types prefer safe, risk-free and stable working environments whereas others search for self-fulfillment either in local small business or in more risky flexible environment seeking for growth or globalization. Undoubtedly, perceiving (P) is the most visible personality preference of entrepreneurs. In connection with that there may be many kinds of preference combinations. However, anyone can start up an enterprise and become an entrepreneur because there is a large variety of more or less challenging entrepreneurial identities available.

The results can be used in developing elementary and higher education and their teaching methods. Entrepreneurial education at all levels and coaches and mentors should take these personal tendencies into consideration. The results can also be used in encouraging potential people to start up a business. Both entrepreneurs and educators should have the knowledge how to develop self-knowledge needed in successful business. The Myers-Briggs Type Indicator is very useful both in research and in practical entrepreneurial training and entrepreneurial education.

Development of a Model for Human Capital Management for the Success of Corporates

Abstract

It is very difficult for an individual to do much or achieve alone but when different individuals unite and form teams, great things are possible. Thus team formation and sustenance is a very important area of research in today's world. This paper describes a novel, unique model to check team health taking commitment of individual members as the fundamental criteria. The model tries to mimic real life as closely as possible by considering all priorities any given individual might consider including family, leisure and work. This model can serve as a one-dimensional (commitment based) way to predict success or failure of teams. The paper specifies which components of the model can generate market revenue although it restricts itself from specifying exact prices. The model has potential to penetrate into our daily lives and become an indispensable part for all organizations and teams as the single way to check team health and rapport.

Introduction

Creation of effective teams is one of the most important jobs in today's goal oriented world and thus it demands the appropriate organizational environment. The information burden, task differentiation, and challenge of meeting the needs of customers provide a strong conceptual justification for teams, and there is evidence they can be effective. The idea is to engage every human in the world since that is the total available human capital which can be put together to form teams of various sizes and functions.

One of the challenges for leaders of today is that people feel team to be one single phenomenon whereas in reality there are many types of teams. Teams are different people coming together, assuming different roles, sharing a common goal, interacting with each other and performing tasks affecting the whole organization. There are many different types of teams such as (1) work teams accomplishing tasks on an ongoing basis in a specific organizational setting; (2) parallel teams addressing shared challenges; (3) project teams focusing on a one-time deliverable and have limited terms and (4) management teams are overseeing all the others.

Differences in teams are necessary to bring out diversity and also for being effective and up to the expectations. Thus it is now the job of leaders to monitor team health regularly and also find out reasons why expectations are not being met of that is the case. Thus, in this paper we create a model which can effectively help future business leaders to study the problems in the functioning of teams and make them more effective to expand profitability.

Literature Survey

Peel (1986) wrote in predicting corporate failure about results for the UK corporate sector. New variables which are not derived from profit and loss accounts and balance sheet items, but which are computed from annual company reports and accounts can be used to predict failure.

As is said 'Prevention is better than cure' researchers have made efforts to understand expected team performance. Cohen, S. Ledford, G & Spreitzer, G. (1996) gave a predictive model of self-managing work team effectiveness. They presented how teams using this model can be self dependant and increase their effectiveness to give a better profit margin to the company.

Ross, Jones and Adams (2008) gave a mathematical model to optimize selection of team members based on predictions of the team's success using a mathematical model as an empirical function of performance, behaviour, attitude, team member style and corporate culture.

Charitou, Neophytou and Charalambous (2004) drew empirical evidence for the UK European Accounting Review. They mentioned three financial variables, a cash flow, a profitability and a financial leverage variable and yielded an overall correct classification accuracy of 83% one year prior to the failure. Success is a result of creativity, flexibility and speed and not tight budgeting and control. Organizations are complex open systems deeply influenced

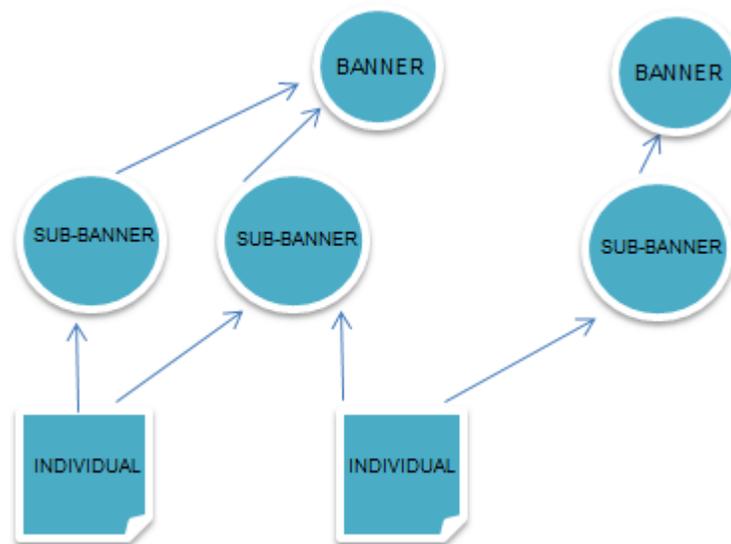

by and influencing their environment. Often intended actions will be diverted off course by external events or even by the political or cultural processes of the organization itself.

Balcaen and Ooghe carried out 35 years of studies on business failure, an overview of the classic statistical methodologies and their related problems. They understood that Any change must begin with a clear understanding of the assets and the constraints of the company’s administrative heritage. In some situations it may be necessary to underscore the company’s commitment to change by bringing new management particularly at the top levels of the company.

Modelling

Organizations, Institutions make up ‘Banners’. These ‘Banners’ are allowed to issue fresh cords for every individual who joins them. For example a university will be a banner issuing fresh cords every year for each individual who joins the university.

These cords *may* be cut when the individual leaves the organization/institution. The banner on its own does not directly interact with students. Just like in a college, there are clubs and just like in organization there are departments and project teams-so too in a banner there are sub-banners. Thus a banner contains a list of all the sub-banners which come under it.

Each banner has a unique banner number. Each banner will maintain a table like the one shown below.

BANNER:

SUB-BANNER NAME	SUB-BANNER NUMBER

... and so on as rows

The sub-banner is the direct link to the individual. The sub-banner will have four columns. The first two will be individual name and number. The next column will contain the expected commitment points for the particular row.

For example, in some college X (banner), in some club Y (sub-banner) of the college X, the requirement is to have a President, a Vice-President, a Secretary and a Treasurer. The club Y's faculty in-charge can set a minimum commitment requirement for the above post-bearers. As an example commitment level requirement of 1.5, 1.5, 1.25 and 1.25 (see individual account paragraph below-commitment levels can be between 0 and 3) can be set for them in the "expected commitment level column".

SUB-BANNERS:

Mapped to:

BANNER NAME		BANNER NUMBER	
INDIVIDUAL NAME	INDIVIDUAL NUMBER	EXPECTED COMMITMENT	ACTUAL COMMITMENT

... and so on as rows

An individual is assumed to have a total of 3 points of commitment. (The number 3 is taken randomly and has no statistical advantage over other numbers for this model).

INDIVIDUAL ACCOUNTS:

SUB-BANNER NUMBER	SUB-BANNER NAME	COMMITMENT POINTS

... and so on as rows

The sum of commitment points should sum to less than or equal to 3. However he can list several sub-banners under several different banners. For example a student might be active under the sub-banner Y of institution X and he might also be active in the sub-banner B of institution A.

Any sub-group looking to recruit individuals can request push ins from individual accounts under the banner. The push ins will follow the following algorithm:

Sub-banner s, Banner b, Individual i, Total Commitment for Individual 'i' c

Assume Sub-banner b considering recruitment of Individual i. S wants to know if i is committed to s, if not then s wants to know how open is i to add s in its commitment list.

IF s in i's commitment list THEN return i

ELSE

Return 3-c

The sub-banner can then decide to choose the individual or not to choose the individual based on those numbers.

The individual can update his commitment points on the go and these will reflect in his sub-banner account. The change in the sub-banner total will reflect in the banner account of the sub-banner. Thus the sub-banner will immediately realize the grimness of the situation and find a suitable replacement (on sudden negative indication of commitment from individual)

The individual, sub-banner and banner all have a calendar each. The individual's calendar will have the individual's account table (see above) spawning across the hours, days, weeks and years (if an individual has thought for the long term).

For example in college X at the beginning of semester student i plans to chalk out 1.5 commitment points for sub-banner academics under banner university u. On the day of registration the student fills his account calendar for the full semester with 1.5 commitment points for sub-banner academics. A week later he decides to participate in a

college fest event. He adds 0.5 commitment points for the sub-banner college fest. He will remove the 0.5 commitment points after the college fest is over.

The model is about planning. It will help individuals plan out their priorities and will let the concerned team/sub-group know about the variation in the individual's commitment in advance. The sub-group will have the last time stamp when the individual had committed to the said level of commitment points for the sub-group. Thus the sub-group might request the individual to keep updating his planned commitment level every month or week or as the case may be.

Discussion

The common mistakes that organizations make can be broadly discussed in five points.

1. Multiple personalities – A company must have its reason d'être. Otherwise decisions are made independently, depending upon local issues, or turf or latest crisis.
2. Lack of an exercise regimen – very little is done for the best people. Instead they spend an inordinate amount on remedial training, reskilling and probationary periods.
3. Power failures – stumbling around blindly in the dark. Strategies and plans are not tuned to what to "expect". What derails them is what they are not prepared for.
4. Balkanization – set of microclimates. Within this organization there are differences in the perceptions of the organization.
5. Greed – to build a new plant, to launch a new promotion, restructure without proper analysis.

The best way to prevent corporate failure is to identify the warning signs early and nip them in the bud i.e., quickly take actions to curb it and reform it. The corrective actions will be dependent on the situation at the moment. As soon as there are signs that there may be a failure it should be dealt with immediately and at that moment.

These may be related to a range of different functions within the business, such as financial management, marketing or production. It may sometimes be necessary to seek external advice to help to identify the problem. It is important that the managers of the business accept that there is a problem and that mistakes have been made and to move on to a solution, rather than apportioning blame.

The best strategy to prevent failure is to have effective management systems in place to begin with.

The management of performance has to be reviewed with new strategies and plans:

1. A bridge should be established to bridge the gap between csfs and strategic goals of the company.
2. Performance targets should be set at all levels and these should relate to the achievement of strategic objectives
3. Targets would have to be continuously reviewed against actual performance and again planned accordingly.
4. Development and additional training should be given at all times.

Conclusion

Every institution has flaws and is vulnerable in the market irrespective of how great the organization is. There is no law of nature that the most powerful will inevitably remain at the top. Anyone can fail at any point of time and most eventually do at some point of time or other. The possible causes of failure can vary from Financial, Economic, Technological and Strategic and so on. At micro level persons or societies directly connected with the corporates are adversely impacted when corporates fail. At macro level when corporates fail they may trigger economic or financial crisis that may have far reaching consequences on countries and persons not directly connected with them. But the key to prevent corporate failures and ensure profitability is to manage the most important asset of a company properly i.e., Human Resource. This paper tells in detail about a novel model which can be used to check whether the different teams in the company are functioning properly and efficiently and take necessary actions at the right time to help the company survive.

Social entrepreneurship and social innovation through the lens of the value co-creation process

Abstract

In the new Era of sustainability, a sub-discipline within the field of entrepreneurship called Social Entrepreneurship (SE) emerged as a global phenomenon in the academic literature. The paper aims to understand the concept of social innovation as a strategic and dynamic aspect of social entrepreneurship. Thus, an analysis of the links between social entrepreneurship and social innovation has been carried out through the lens of the value co-creation process drawing from the Service-Dominant (S-D) Logic perspective (Vargo and Lusch, 2008; Gummesson et al., 2010) and the Network Theory (Gummesson, 2007). The study aims to understand and explain what are and how works the links between social entrepreneurial activity and innovation process. As this paper demonstrates, social entrepreneurship generate “social value” in the circumstances that the development of innovative solutions spread out through forms of collaboration between social entrepreneurs and the customer involved in the value co-creation process.

Article classification: Conceptual paper

Key words: social entrepreneurship, social innovation, value co-creation, S-D logic, Network Theory

1. Introduction

In recent time, Social Entrepreneurship (SE) emerged as a new phenomenon in the area of investigation within the field of entrepreneurship and not-for-profit marketing literatures. It has been, in fact, varyingly described as a human response to social and environmental problems (Haugh, 2007), and refers to innovative activity with a social purpose (OECD 1999; Wallace 1999) in either the for-profit sector, such as in social-purpose commercial ventures (Dees and Anderson 2003). However, current conceptualizations of social entrepreneurship fail to adequately consider the concept of social innovation as a strategic and dynamic aspect of social entrepreneurship in the value co-creation process. To fill this gap, this paper contributes to an understanding of the existing theories and practices of social entrepreneurship and innovation in order to demonstrate that a combination of these two concepts is vital to organizational success and value. It recognizes the value co-creation as a useful path to investigate innovation and social entrepreneurship and to construct a holistic model that seeks to explain the links between social entrepreneurial activity and the innovation process.

2. Conceptual background and research questions

2.1. Literature review on Social Entrepreneurship (SE)

The recent field of social entrepreneurship is growing rapidly and attracting increased attention among both academics and practitioners in different sectors (Dacin *et al.*, 2010; Mair and Marti 2006; Zahra *et al.*, 2008; Defourny and Nyssens 2008; Hulgård, 2010). As emerged from literature review “social entrepreneurship is the engine of positive, systemic change that will alter what we do, how we do it, and why it matters” (Neck *et al.*, 2009, p. 7). This concept was first investigated in the 1990’s (Galaskiewicz, 1985; Waddock and Post, 1991; Selsky and Smith, 1994), and since then, Scholars have proposed more definitions including the creation of non-profits (Dees, 1998), the development of new structures to solve social problems (Fowler, 2000), the definition of innovative behavior for social objectives (Brooks, 2009; Mair and Marti, 2006), and the creation of social value activities (Austin *et al.*, 2006). Alternative theory argues that social entrepreneurship refers to the adoption of environmentally responsible practices and products (Schaper, 2002; Linnanen, 2005; Gerlach, 2000). Besides, it refers to the “creation of viable socioeconomic structures,

relations, institutions, organizations and practices that yield and sustain social benefits” (Fowler, 2000, p. 649). Generally, the term social entrepreneurship refers to the ”entrepreneurial activity with an embedded social purpose” (Austin *et al.*, 2006), and the social entrepreneur is viewed as an entrepreneur with a social mission (Dees 2001; Martin and Osberg 2007). Thus, this phenomenon embrace the simultaneous pursuit of economic, social, and environmental goals by enterprising ventures (Haugh, 2007) in which social entrepreneur is a change agent in the social sector (Dees 2001). In fact, “the primary mission of the social entrepreneur being one of creating social value by providing solutions to social problems” (Dacin *et al.*, 2011, p. 1204). In this field, “social value has little to do with profits but instead involves the fulfillment of basic and long standing needs such as providing food, water, shelter, education and medical services to those members of society who are in need” (Certo and Miller, 2008, p. 267). Social entrepreneurship is, therefore, the process of creating a social enterprise, that is an independent entity created to fulfill a social purpose but financially sustainable because of trading activities (Brooks, 2008) and a social entrepreneur is someone who creates a social enterprise to take advantage of an opportunity (Haugh, 2005). Besides, Scholars have identified four components of social entrepreneurship: 1) entrepreneurs – the people who pursue change; 2) ideas – how change can be achieved; 3) opportunities – for disrupting the equilibrium; and 4) organizations – which seek to bring about change (Light, 2008, p. 17). Thus, SE is “an effort by an individual, group, network, organization or alliance of organizations that seeks sustainable, large scale change through pattern-breaking ideas in what governments, non-profits and business do to address significant social problems” (Light, 2008, p. 12). Current literature recognizes three main steps which become useful in the overall comprehension of the SE process summarized in the table below (table 1). These are: opportunity definition; organizational launch and functioning and, financial resource collection and leveraging.

TABLE 1: THREE STEP IN THE SOCIAL ENTREPRENEURSHIP PROCESS

Opportunity definition	<p>“The cognitive process followed by entrepreneurs as they intentionally identify a solution to a specific problem or need because of diverse motivations, including financial rewards” (Dorado and Haettich, 2004: 6).</p> <p>“Opportunities to bring into existence new goods, services, raw materials, and organizing methods that allow outputs to be sold at more than their cost of production” Mair and Marti (2004: 3)</p>
Organizational launch and functioning	To become concrete, a social innovation needs a social impact theory, a specific business model and a composite social strategy (Guclu, <i>et al.</i> , 2002).
Financial resource collection and leveraging	The most quoted source of financing is a particular kind of patient capital (Bank of England, 2003): social venture capital or venture philanthropy (VP).

Source: adapted from Perrini and Vurro, 2006.

Additional studies consider social entrepreneurship as “a process involving the innovative use and combination of resources to pursue opportunities to catalyze social change and/or address social needs (Mair and Marti, 2006, pag. 37). It refers to a general process or overall business culture where social needs are addressed in an innovative manner, as an entrepreneurial activity with a social orientation or intent (Johnson, 2000) addressing a range of social issues in innovative and creative ways (Nicholls, 2006).

“Social entrepreneurship is a concept which represents a variety of activities and processes to create and sustain social value by using more entrepreneurial and innovative approaches and constrained by the external environment” (Brouard and Larivet, 2009 p. 11). In this context, “social enterprises have in common the principles of pursuing business-led solutions to achieve social aims, and the reinvestment of surplus for community benefit” (Haugh, 2006, p. 5). They are – defined simply – organizations seeking business solutions to social problems (Thompson and Doherty, 2006, p. 362). In this optic, “social entrepreneurs measure success by creating social capital, social change and addressing social needs. In contrast to for-profit organizations, in which profits are often distributed to their owners and shareholders, economic value creation in social enterprises is perceived as a by-product which allows the organizations to achieve sustainability and self-sufficiency (Fowler, 2000; Seelos and Mair, 2005). The

surplus production of social enterprises is reinvested in the development of organizational activities that ensures viability in tackling social problems or to be used for the benefit of people other than those who control the organizations (Defourny, 2001).

Literature review reveals that social entrepreneurship consists in an innovative process that include the identification of new solutions and opportunities to social problems (Shane, 2003; Mair and Marti 2004). In fact, it implies the ability to resolve social problems and satisfy a variety of stakeholders “needs to attain legitimacy over time” (Mair and Noboa, 2003; Uzzi, 1997). Despite, the increasing academic interest in the field of social entrepreneurship, few studies have investigated the links between social entrepreneurship and social innovation through the lens of the value co-creation process. Drawing from the theories of S-D Logic and Network Theory (Dacin *et al.*, 2010), this paper discusses the functions and contributions of social innovation in the process of creating and disseminating value. The forthcoming conceptual sections of this article attempt to address this limitation through the following research questions:

RQ1. *What are the links between social entrepreneurial activity and innovation process?*

RQ2. *What is the contribution of social innovation in the process of value co-creation?*

2.2 Social Innovation as a strategic and dynamic aspect of social entrepreneurship

Starting from the review of the main definitions of social entrepreneurship in literature, it is highlighted that social entrepreneurship is an innovative activity, in which innovation play an important role, as shown in the table below (table 2).

TABLE 2: SOCIAL ENTREPRENEURSHIP VS SOCIAL INNOVATION

Definitions	Primary components
<i>Social Entrepreneurship, to “one that emphasises innovation and impact, not income, in dealing with social problems”. The entrepreneur always searches for change, responds to it, and exploits it (Dees, 2003).</i>	- innovation - change
<i>“SE is seen as the innovative use of resource combinations to pursue opportunities aiming at the creation of organisations and/or practices that yield and sustain social benefits” (Mair and Noboa, 2003, p. 5).</i>	-innovative use of resources - opportunities - social benefits
<i>“Social entrepreneurship can be defined as the development of innovative, mission-supporting, earned income, job creating or licensing ventures undertaken by individual social entrepreneurs, non-profit organisations, or non-profits in association with for-profits”(Pomerantz, 2003, p. 25).</i>	- innovation
<i>Social entrepreneurship, the entrepreneurship leading to the establishment of new social enterprise, and the continued innovation in existing ones” (Sullivan Mort et al., 2003, p. 76).</i>	- innovation
<i>Social entrepreneurship that creates innovative solutions to immediate social problems and mobilizes the ideas, capacities, resources and social arrangements required for sustainable social transformations (Alvord, 2004, p. 262).</i>	- innovative solutions
<i>Social entrepreneurship is the construction, evaluation, and pursuit of opportunities for transformative social change carried out by visionary, passionately dedicated individuals (Roberts and Woods, 2005).</i>	- opportunities - vision - passionately individuals
<i>“We define social entrepreneurship as innovative, social value creating activity that can occur within or across the non-profit, business, or government sectors” (Austin et al., 2006, p. 2).</i>	- innovative - value creation
<i>“Innovative and effective activities that focus strategically on resolving social market failures and creating new opportunities to add social value systematically by using a range of resources and organisational formats to maximise social impacts and bring about changes” (Nicholls, 2006, p. 23)</i>	- innovative and effective activities - new opportunities
<i>“Social entrepreneurship is exercised where some person or group: 1) aim(s) at creating social value, either exclusively or at least in some prominent way; 2) show(s) a capacity to recognise and take advantage of opportunities to create that value (‘envision’); 3) employ(s) innovation, ranging from outright invention to adapting someone else’s novelty, in creating and/or distributing social value; 4) is/are willing to accept an above-average degree of risk in creating and disseminating social value; and 5) is/are unusually resourceful in being</i>	- new opportunities - employ(s) innovation - degree of risk - social value

<i>relatively undaunted by scarce assets in pursuing their social venture” (Peredo and McLean, 2006, p. 64).</i>	
<i>Social entrepreneurship strives to achieve social value creation and this requires the display of innovativeness, proactiveness and risk management behaviour. This behaviour is constrained by the desire to achieve the social mission and to maintain the sustainability of existing organisation. In doing so social entrepreneurs are responsive to and constrained by environmental dynamics. They continuously interact with a turbulent and dynamic environment that forces them to pursue sustainability, often within the context of the relative resource poverty of the organisation” (Weerawardena and Mort, 2006, p. 32)</i>	- innovativeness - proactiveness - risk management - social mission
<i>“We define social entrepreneurship as an innovative, social value creating activity that can occur within or across the non-profit, business, or government sector” (Wei-Skillern, et al., 2007, p. 4).</i>	- innovative and social value creating activity
<i>“We view social entrepreneurship broadly, as a process involving the innovative use and combination of resources and social arrangements required for sustainable social transformations” (Mair and Marti, 2007, p. 37).</i>	- innovative use - combination of resources
<i>“Innovative approaches to social change” or “using business concepts and tools to solve social problems” (Brock and Ashoka, 2008, p. 3).</i>	- innovative approaches
<i>Innovative and resourceful approaches to addressing social problems” (Case, 2008, p. 1).</i>	- innovative approaches
<i>“Social entrepreneurship encompasses the activities and processes undertaken to discover, define and exploit opportunities in order to enhance social wealth by creating new ventures or managing existing organisations in an innovative manner” (Zhara et al., 2008, p. 118).</i>	- innovative manner
<i>Social entrepreneurship can be defined as entrepreneurship that aims to provide innovative solutions to unsolved social problems. Therefore it often goes hand in hand with social innovation processes, aimed at improving people’s lives by promoting social changes (OECD 2010, p. 5).</i>	- innovative solutions - social innovation - social changes
<i>“The innovative use of resources to explore and exploit opportunities that meet a social need in a sustainable manner” (Mair and Ganly, 2010).</i>	- innovative use of resources - opportunities

Source: our elaboration.

Generally, social entrepreneurship involves the application of new approach in an effort to create social value (Certo and Miller, 2008) and social entrepreneurs are considered social innovators in a process of continuous adaptation, and learning (Casson, 2005, Dees, 1998). In fact, social enterprises primary objective is to create social value for the community that they serve through innovative business approaches (Kong, 2010, pag. 1). In this optic, social enterprises define innovative approaches in order to pursue social missions, improve their efficiency and effectiveness, and, at the same time, maximize their capability to constantly manage complex social problems in the competitive environment (Borins, 2000; Sullivan-Mort *et al.*, 2003; Waddock and Post, 1991; Weerawardena and Sullivan-Mort, 2006). According with the Schumpeterian thoughts, social entrepreneurship is inextricably linked with social innovation (Schumpeter, 1934; Casson, 2005; Certo and Miller, 2008; Mort *et al.*, 2002; Tan *et al.*, 2005). In fact, it can be defined as a particular form of entrepreneurship that aims to provide innovative solutions to unsolved social problems. Therefore, it often goes hand in hand with social innovation processes, aimed at improving people’s lives by promoting social changes (OECD 2010, p. 5). Social entrepreneurship consists in “the development of innovative, mission-supporting, earned income, job creating or licensing ventures undertaken by individual social entrepreneurs, non-profit organizations, or non-profits in association with for-profits” (Pomerantz, 2003, p. 25). In this optic, “social entrepreneurship strives to achieve social value creation and this requires the display of innovativeness, proactiveness and risk management behavior. This behavior is constrained by the desire to achieve the social mission and to maintain the sustainability of existing organization. In doing so social entrepreneurs are responsive to and constrained by environmental dynamics. They continuously interact with a turbulent and dynamic environment that forces them to pursue sustainability, often within the context of the relative resource poverty of the organization” (Weerawardena and Mort, 2006, p. 32).

Current literature recognizes that social entrepreneurship encompasses the activities and processes undertaken to discover, define and exploit opportunities in order to enhance social wealth by creating new ventures or

managing existing organizations in an innovative manner” (Zhara *et al.*, 2008, p. 118). Thus, social entrepreneurship is viewed as a process where individuals (social entrepreneurs) identify opportunities, locate resources and create value to serve a mission that sustains social values (Dees, 1998). To create value, social entrepreneurs adopt specific aptitudes and qualities, for example, they look for more innovative sources (McLeod, 1997) and at the same time they present a certain risk-tolerance and a strong desire to control the surrounding environment (Prabhu, 1999).

Literature review reveals some definitions of social entrepreneur in which the links with innovation is evident, as shown in the table below (table 3). Social entrepreneur, in fact, creates innovative solutions, mobilizes the ideas, capacities, resources and social arrangements for sustainable social transformations (Alvord, 2004, p. 262). He “play the role of change agent in the social sector by: adopting a mission to create and sustain social value (not just private value); recognizing and relentlessly pursuing new opportunities to serve that mission; engaging in a process of continuous innovation, adaptation, and learning; acting boldly without being limited by resources currently in hand; exhibiting a heightened sense of accountability to the constituencies served for the outcomes created” (Dees, 1998, p. 4). It is recognized that social entrepreneurs are “creative individuals who question the status quo, exploit new opportunities, refuse to give up and remake the world for the better” (Bornstein, 2004, p. 15).

TABLE 3: SOCIAL ENTREPRENEURS VS SOCIAL INNOVATION

Authors	Definitions	Primary components
Dees, 1998	<i>Social entrepreneurs “play the role of change agents in the social sector by: adopting a mission to create and sustain social value (not just private value); recognizing and relentlessly pursuing new opportunities to serve that mission; engaging in a process of continuous innovation, adaptation, and learning; acting boldly without being limited by resources currently in hand; exhibiting a heightened sense of accountability to the constituencies served for the outcomes created” (p. 4).</i>	new opportunities continuous innovation
Bornstein, 1998	<i>A social entrepreneur is a path breaker with a powerful new idea who combines visionary and real-world problem-solving creativity, has a strong ethical fiber, and is totally possessed by his or her vision for change.</i>	new ideas problem solving creativity
Prabhu, 1999	<i>Social entrepreneurs are persons who create and manage innovative organizations or ventures whose primary mission is the social change and the development of their client group.</i>	innovative entrepreneurs
La Barre, Fishman <i>et al.</i> , 2001	<i>Social entrepreneurs are dedicated innovators who are determined to tackle some of society’s deepest challenges by embracing new ideas from business.</i>	innovators

Source: our elaboration.

Thus, social enterprises are forced to be innovative in all their social value-creating activities to deliver public services (Dart, 2004; Fowler, 2000) and for the purpose of improving efficiency and tightening control. In this context, innovativeness is considered one of three core behavioral dimensions in the framework of social entrepreneurship along with proactiveness and risk management (Weerawardena and Mort, 2006). Social enterprises have, in fact, the ability to understand social needs, and then fulfill these needs through creative activities and initiatives (Austin *et al.*, 2006, p. 2).

2.3 Service Dominant Logic and Network Theory

In the academic literature, Service-dominant logic (S-D logic) is an alternative perspective to the traditional, goods-dominant (G-D) logic paradigm (Vargo and Lusch 2004, 2008a, 2008b; Vargo 2008). The traditional G-D view is based on the essential assumption that goods are the bases for exchange. According to G-D logic, the purpose of a firm is the production and distribution of products and goods which are embedded with value during the production process. In line with this view, the customer is thus seen as a “consumer,” of the value created by the firm (Normann, 2001). As emerged from literature review, the most important distinction between G-D logic and S-D logic is found in the different conceptualization of service. In the S-D logic view, “service” is the application of competences, for example knowledge

and skills for the benefit of another party. This perspective signals a shift not only from thinking about value creation in terms of outputs to processes and outcomes but also in thinking about the primacy of resources involved from operand resources usually tangible, that require some action to make them valuable – to operant resources – usually intangible, dynamic that are capable of creating value. In this optic, “all participants in the value-creation process be viewed as dynamic operant resources. Accordingly, they should be viewed as the primary source of firm and national innovation and value creation” (Lusch and Vargo, 2008, pag 2). On the premise that service is the fundamental basis of exchange (Vargo and Lusch, 2004), service systems are “value co-creation configurations of people, technology, value propositions connecting internal and external service systems and shared information” (Maglio and Spohrer, 2008, p. 18). It is essentially “a value co-creation model that sees all actors as resource integrators, tied together in shared systems of exchange – service ecosystems or markets” (Vargo, 2011, p. 220).

It is recognized that value co-creation is one of the core concepts of S-D logic perspective and has been used to convey the customer’s (and others’) collaborative role in value creation. Based on these conceptualizations, the customer’s role in co-creation is fundamental, in fact, value is always co-created. The process of value co-creation derived from an experience created in conjunction with other stakeholders (Prahalad and Ramaswamy, 2004; Vargo and Lusch, 2004, 2008; Vargo, *et al.*, 2008). In contrast with the traditional models of value creation, which suggest that value is created by firms (Normann, 2001), today, customers are always active participants in the value co-creation process. In this dynamic view, value co-creation is mediated by networks of interconnected relationships (Chandler and Vargo, 2011). The importance of network configurations in value co-creation has recently emerged due to the growing contribution in the context through which value is derived (Akaka and Chandler, 2010; Chandler and Vargo, 2011; Chandler and Wieland, 2010). Networks are, in fact, an excellent means of studying relational phenomena (Iacobucci, 1996, p. 15) and are considered as critical variables in the co-creation of value (Chandler and Vargo, 2011). In this optic, “when relationships embrace more than two people or organizations, complex patterns will emerge – networks. We, therefore, also talk about networks of relationships. What happens between the parties in a relationship is called interaction” (Gummesson, 2006, p. 342). The nature of networks in service ecosystems contribute in the process of value co-creation and in the formation of social contexts that frame exchange (Chandler and Vargo, 2011).

According to Ford and Hakansson (2005), interactions must be studied under a network paradigm because relationships cannot be understood through the perspective of a single company. In fact, “not only organizations live in networks, but also consumer citizens and employees” (Gummesson, 2006, p. 349). The adoption of network relationships is useful in understanding different viewpoints, processes, actors and relationships of value co-creation. In fact, the study of networks helps to identify different levels of micro and macro interaction in different aspects of exchange. Each individual actor requires a network of resources, in fact “no company alone has the resources, skills or technologies that are necessary to satisfy the requirements or solve the problems of any other and so is dependent on the skills, resources and actions of suppliers, distributors, customers and even competitors to satisfy those requirements” (Ford *et al.*, 2002, p. 2). This means that “the network setting extends without limits through connected relationships, making any business network boundary arbitrary” (Anderson *et al.*, 1994, p. 3). The nature of networks underscores the importance of collaboration in value co-creation. “The consideration of value co-creation through networks of relationships emphasizes the continual need for actors to interact and exchange with others in order to access the resources they need or want” (Lusch and Vargo, 2006a). In this view, value co-creation is derived through the interaction and exchange of resources, especially knowledge and skills, in a network of firms, customers, and other stakeholders.

3. Combining social entrepreneurship and social innovation through the lens of the value co-creation process

This section provided an analysis of the links between social entrepreneurship and social innovation through the lens of the value co-creation process. According to this, social innovation success depends on the interaction between customer and entrepreneur. In fact, an high degree of interaction creates the value-added innovation. Customers have the key resource of external information and act as value co-creator for social innovation. They negotiate with entrepreneurs about new requirements concerning collaboration for service innovation (). So, when the social entrepreneurs incorporate customers’ experience and capabilities into service co-creation, they are able to create

innovation. Furthermore, social innovation depends on a value network to embrace the customer’s co-creation of value (Michel *et al.*, 2008). Resources, especially operant resources in the network play a significant role in innovation development (Lusch *et al.*, 2008). During the social innovation process, there exist plenty of interactive activities between customer and firm. The idea of co-creation denotes an approach where customers are actively involved and take part in the design of a new offering. More specifically, co-creation has been defined as an active, creative, and social process, based on collaboration between firms and customers. Therefore, it is essential to clarify for whom value is co-created (what value there is for the customer and the firm), what kind of value is co-created (what kind of value), by what kind of resources and furthermore, through what kind of mechanism (table 6).

TABLE 6: VALUE CO-CREATION QUESTIONS

Value What kind of value for whom?		Co By what kind of resources?	Creation Through what kind of mechanism?
Customer	- What is the customer benefit? - How is the customer’s value creation supported?	- What firm resources are integrated into the customer’s value-creating processes?	- What is the mechanism through which firm resources are integrated into the customer’s processes?
Firm	- What is the firm benefit? How is the firm’s value creation supported?	- What customer resources are integrated into the firm’s value-creating processes?	- What is the mechanism through which customer resources are integrated into the firm’s processes?

Source adapted from: Saarijärvi *et al.*, 2013.

According to the S-D logic, value is not created by a firm alone, but applying all actors’ resources such as suppliers’ and customers’ resources (Michel *et al.*, 2008) in a process of networked collaboration (Miles and Kastrinos, 95). Value is co-created through the combined efforts of providers, suppliers, partners, customers, and other actors and is differentiated by different customers. So, it might know how customers co-create value by participating or using a firm’s offering (Michel *et al.*, 2008).

According to Vargo and Lusch (2004, 2008), customers, always, contribute to the co-creation of value. In this view, “the terms co-creation, co-production, and prosumption refer to situations in which consumers collaborate with companies or with other consumers to produce things of value.” (Humphreys and Grayson, 2008, p. 963). As this paper demonstrates, social entrepreneurship generate “social value” in the circumstances that the development of innovative solutions spread out through forms of collaboration between social entrepreneurs and the customer involved in the value co-creation process (see fig. 1). Social organizations view consumers as critical assets and attempt to build strong ongoing relationships with them in order to create social value. Today, the common understanding of the innovation process builds on the observation that it can be seen as an interactive relationships between producers and customers. These actors are seen to work together in an interactive process of discovery, realization and exploitation of a new idea. Innovative performance today is seen to a large extent as the ability of an innovative social organization to establish networks with customers.

The traditional approach towards value creation and innovation assigns a passive role to the customer described as, unaware and isolated with no participation in product development processes. This approach positions the customer ‘outside the firm’ whereas the execution of value creation and innovation happens inside the firm (Prahalad and Ramaswamy, 2004). In contrast to this perspective, the customer is valued as an active and integral part of the value creation process in the customer-centric approach. Today, the collaboration between customers and the social entrepreneurs occurs on a two-way communication basis. In fact, consumers want to take an active role in the new product development process of organizations in order to create value that corresponds to their demands. According to Prahalad & Ramaswamy (2004), social enterprises should acknowledge the fundamental shift from an organization-centric to customer-centric approach. As the customer-centric approach connects value creation to the market, organizations are able to benefit from customer experiences, ideas and knowledge through a direct interaction. Furthermore, Baldwin and Von Hippel (2009) stress the desirability of a transition from the entrepreneur-centric approach to an “open collaborative innovation” model by concluding that it will enhance social welfare.

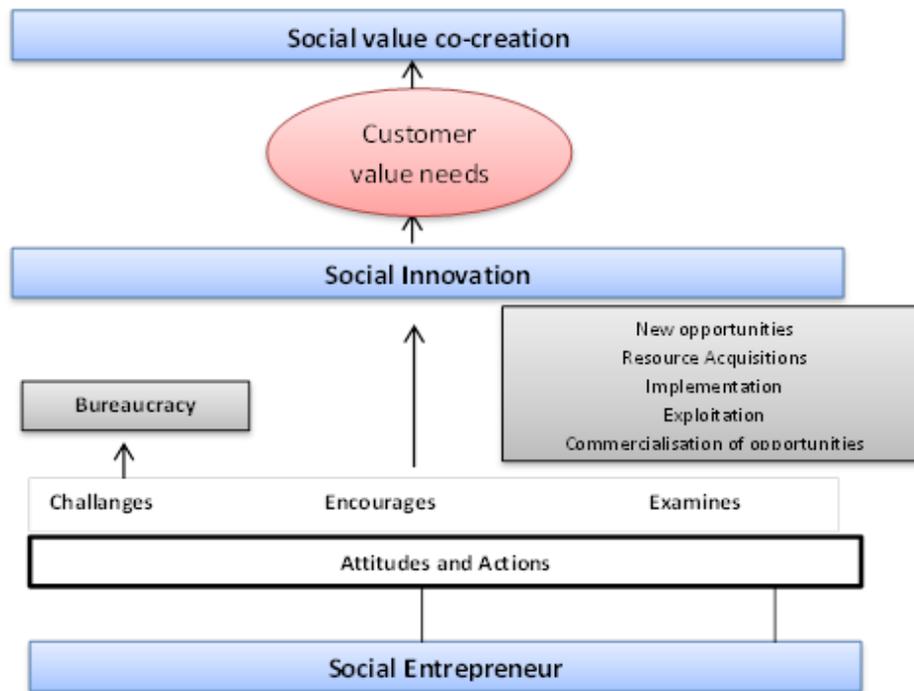

FIG. 2: SOCIAL ENTREPRENEURSHIP AND SOCIAL VALUE CO-CREATION

4. Implications and Conclusions

Some of the most effective methods for cultivating social innovation start from the idea that people are competent interpreters of their own lives and competent solvers of their own problems. Most social innovation is not created by a single entrepreneur but in collaboration with related stakeholders including customers, civil society organizations, local businesses, researchers and so on. It is becoming imperative for social organization involve customers in the social innovation. By engaging customers in the product or service innovation process, social entrepreneurs can hope for a better understanding of their needs and better acceptance of the innovation if the customer is involved in the design. The study has found that social entrepreneurship and social innovation are positively related to each other and a combination of the two is vital to organizational success and sustainability in today's dynamic and changing environment. Social innovation is a dynamic and holistic element in the process of value creation. Hence, the main practical implication of this paper is the identification of the missing link between social innovation, social entrepreneurship and end service user. The study could be considered a first step in a stream of research on different aspects of social entrepreneurship which are yet unexplored. This may involve in future, quantitative surveys, new practices and research challenges concerning social entrepreneurship in a service dominant logic perspective.

An Empirical Analysis to Assess Intangible Assets in Tunisia and Its Relevance in the Knowledge - Based Economy

Abstract

It is the first work to measure intangible investment in Tunisia based upon the CHS methodology and different databases and statistics. Expenditures on intangibles in Tunisia amounted to around 11 billion US dollar, accounting for around 25% of GDP in 2008. This paper attempts to find out how important intangible assets are in the present knowledge based economy like Tunisia. Intangible assets are country's weightless wealth which helps to obtain real growth and real profit for a company. Every country should understand that paying needed attention to knowledge management in general and to intangible assets especially may help to understand and nurture its core strength and competencies. This is how each developing and underdeveloped countries can create their own competitive advantage in the world market. More precisely, the country's intangible assets should be priced at fair market value. The strategic relevance of intangible assets management for a country's competitiveness, understanding the way these assets are converted into value is of paramount importance. It is very vital for the country to harness the value from its intangible assets. The further research in this field will develop not only the direction of testing researched models but also the direction of developing and testing other models of intangible assets valuation, management and optimal allocation of intangible assets in various countries.

1. Introduction

In today's economy, the intangible assets play a key role and have become very important in achieving sustainable development. The developed economies are becoming knowledge based economy. These intangible assets are generally obtained from traditional factors like labour, land and capital. However, the differentiating factors among the developing and developed countries have been the quality of knowledge management and innovation management. The main characteristics of innovation based economies are: knowledge replaces traditional factors of production land and labour as the fundamental factors of production. Intangible assets create a significant part of the value differentiator between countries. Intangible assets are non-physical sources of value generated by discovery, unique organisation designs, or rare human resource practices. These are non-material sources or creating country's value based on the cities capabilities, organisations' capabilities. They are non-physical in nature, they are capable of producing future economic benefits, and they are protected legally through intellectual property rights. The country like Tunisia has been able to harness economic benefits significantly in the past but the momentum has been lost due to changing socio-economic and political priorities.

2. Measurement of investment in intangibles

Various definitions of intangible capital are associated to various approaches to measuring intangibles: on the one hand, definitions of intangibles are mostly due to Schumpeter's classification based on product and process development, organizational change, management, marketing and finance (Schumpeter 1934). However, despite this great variety in defining intangibles, the common and durable problem is the 'invisibility' of many of these intangible assets which makes their measurement difficult. On the other hand, According to Sichel (2008), there are three recent approaches that can be used to measure intangibles; these approaches are the financial market valuation (Hulten et al., 2008), the alternative performance measures (Cummins, 2005) and the direct expenditure approach (Nakamura, 1999 and 2001). The latter approach was adopted By Corrado, Hulten and Sichel (CHS 2005; 2009) who developed a wide array of expenditure based measures for many intangibles employed by American firms and distinguished between three categories of intangible assets: computerized information, innovative property, and economic competencies.

Originally, the CHS method was applied to American data and it has now been the corner stone of many studies focused on different countries.

We use the same methodology as CHS (2005; 2009) for Tunisia for the purpose of creating a set of estimates for intangibles in Tunisia. It is worth to note that for some intangibles, it has been very difficult to construct reliable measures over time and it has been compulsory to make a number of assumptions to cope with the limited available information. Our estimates are a starting point in this area of study as it is the first attempt to apply the CHS methodology to measure intangibles in Tunisia.

2.1. Computerized Information

According to Corrado *et al.* (2005), computerised information consists of two elements: software and computerized database. In other terms and according to Miyagawa & Hisa (2013), 'Computerized information consists of custom and packaged software, and own account software'. For the custom and packaged software, we have no indication about how to calculate their value. That's why; we assume that this expenditure is about 35% of the total Information and communication technology (ICT) expenditure. These data is obtained from World Bank. However, we have total Information and communication technology expenditure per capita; to obtain the total of these expenditures for the whole population, we multiply the ICT expenditure by the population.

Since spending on software is not capitalized in the Tunisian System of National Accounts, we use the Miyagawa & Hisa's (2013) estimation method inspired from the JIP database. Hence, we begin by estimating the number of workers who are involved in the development of software for their own firms and their salaries to be able to assess the value of own account software. These data are obtained from the World Bank and the National Institute of Statistics (INS); the number of these workers is available for a period of four years spanning from 2005 to 2008, but we have the wage data only for 2007, this salary is in Tunisian dinars and we have to convert it in US dollars. In these conditions, we have assumed that the average monthly salary of each worker does not fluctuate from 2005 to 2008. The next step is to multiply the number of workers by the annual salary to obtain an estimation of the own account software investment.

2.2. Innovative Property

Two categories of innovative property: research & development and oil & gas & mineral exploration. These data are available from the World Bank and the National Institute of Statistics (INS). However, data extracted from INS are in Tunisian dinars and should be converted in US dollars. It is worth to mention that the second category is the sum of three groups as they are mentioned in the INS: oil and natural gas extraction, mines and petroleum refining.

As in Corrado *et al.* (2009) and Barnes & McClure (2009), we find other categories of innovative property:

- copyright and licence costs
- development costs in financial industry;
- new architecture and engineering design; and
- other science and engineering services (purchased and own-account).

Copyright and licence costs are obtained from the World Bank as charges paid for the use of intellectual property.

The financial services industry consists in research and development of new processes and products. Since it is not explicitly observed, development costs in the financial industry are approximated by only 20% of the total of financial services according to Corrado *et al.* (2005). These data are obtained from the INS and are in Tunisian dinars.

For new architecture and engineering design, Corrado *et al.* (2005) estimated their value as 50% of total expenditure on architectural and engineering. For our work, these data are obtained from the INS and are in Tunisian dinars.

Own-account other science and engineering investment is given by 'internal expenditure in research & development' calculated by the National Observatory of Science and Technology. However, purchased

other science and engineering investment were taken into account in other parts of expenditures as it is mentioned by Baldwin *et al.* (2009).

2.3. Economic Competencies

The third category of intangible assets is economic competencies. It consists of the brand equity, the firm specific human capital and the organizational capital.

Inspired by anterior studies focused on intangible assets, this study includes advertising expenditure as brand equity, direct and indirect firm expenses on training as firm-specific human capital and purchased and own-account organizational capital in the economic competencies category.

Advertising expenditures are estimated as 60% of total expenditures on advertising services and products. These data are due to MediaScan agency and Sigma Group.

Direct firm expenses are the costs of developing workforce skills such as training and indirect expenses consist of the opportunity cost of employee time spent on formal and informal training. Only direct expenses are available in the National accounts of Tunisia. Hence, we consider that investment on firm-specific human capital is given by the data on direct firm expenses.

Investment in organizational capital is composed of purchased investment in organizational structure and own-account investment in organizational structure. According to Corrado *et al.* (2005), purchased investment in organizational structure is approximated by the total revenue of the management consulting services industry which is between 10 and 20 TND million (UTICA Survey, 2011). To cope with this lack of data, we consider that this expenditure is of 15 TND million for the period of study. For the own-account investment in organizational structure, it is estimated as 20% of labour compensation of total management occupations (Corrado *et al.*, 2005). For this reason, we multiply the number of managers by their average salary. These data are obtained from the INS. However, it is important to mention that we have only the average salary for 2007. That's why we assume that this salary does not fluctuate for the period of study.

3. Results

In this part, we measure intangible assets in Tunisia in nominal terms for the period spanning from 2005 to 2008.

TABLE 1. NOMINAL INTANGIBLE INVESTMENT IN TUNISIA (IN BILLIONS OF US \$)

	2005	2006	2007	2008
Computerised information:	0.97	1.05	1.12	1.16
* Custom and packaged software	0.52	0.58	0.66	0.73
* Own account software	0.45	0.47	0.46	0.43
Innovative property:	4.06	5.22	6.93	8.49
* Scientific R&D	2.97	3.3	3.8	4.6
* Mineral exploration	0.56	1.63	2.51	3.09
* Copyright and licence costs	0.07	0.1	0.1	0.12
* Development costs in financial industry	0.03	0.03	0.04	0.04
	0.12	0.12	0.13	0.13

* New architecture and engineering design * Other product development, design and research	0.31	0.33	0.35	0.41
Economic competencies	0.8	0.83	0.84	0.91
Brand equity	0.02	0.04	0.04	0.05
Firm-specific human capital	0.38	0.39	0.4	0.45
Organisational capital	0.4	0.4	0.4	0.41
Total intangible investment	5.83	7.1	8.89	10.56
Intangible assets as a % of the GDP	16.95	18.27	19.87	24.21

Source: Authors' calculations

As it is shown in Table 2 and figure 1 and referring to Barnes and McClure's (2009) work, we can see a clear similarity between Tunisia, Japan and Germany in the composition of intangible investment (in terms of the main categories) with an important weight for the innovative property (Table 2). The share of the innovative property in the total amount of nominal investment in intangibles was more than 60%. Scientific research & development is the most important component of the innovative property. This result is, however, in contradiction with Muntean's (2013) findings mentioning that the economic competencies are the dominant category in intangible assets. Computerised information and economic competencies have approximately the same proportion in the composition of intangible assets in Tunisia.

FIGURE 1. COMPOSITION OF THE TOTAL INTANGIBLE INVESTMENT IN TUNISIA

Source: Authors' calculations

Figure 1 gives us an idea about the evolution of the intangible assets, three categories between 2005 and 2008; it seems clearly that only the innovation property has been growing during this period while

computerised information and economic competencies have known a steady stagnation. This can be explained by the government's efforts to encourage innovation.

To build just a small idea about the contribution of intangible investment to economic growth, we have calculated, in the last row of table 1, the percentage of these assets in the GDP.

The corresponding percentages are so high and exceed the rates mentioned in anterior studies. In fact, intangible assets account for 9% of GDP in Japan (Miyagawa and Hisa, 2013), 11% for United Kingdom in 2004 (Marrano and Haskel, 2006), 9.1% for Finland in 2005 (Jalava and Alenen, 2007), 5.2% in Italy and Spain, 7.1% in Germany and 8.8% in France (Hao, Manole and van Ark, 2008), 10% for the Netherlands over 2001-2004 (Van Rooijen et al., 2008), 13.2% for Canada in 2008 (Baldwin et al., 2011).

4. Conclusion

In Tunisia, it is found that innovation is playing a dominant role in intangible assets where are economic competencies and computerized information do have very small contribution to the overall economic growth and both of them have very small contribution. Intangible assets like Economic efficiencies and computerization, information & technology are not growing over the years in Tunisia. However, it seems that the government does encourage the growth of one type of intangible assets to improve i.e. innovation. The aggregate impact of intangible assets could be much more widely felt in the growth of Tunisian economy if the government could understand and encourage the simultaneous growth of all the intangible assets in the country. The knowledge, innovation are the intangible assets which have become a locomotive that defines the contemporary development of all the countries in the modern knowledge based world.

Intellectual capital information in sustainability reports: an analysis of Italian Banking sector

Abstract

In a knowledge-based economy Intellectual Capital is a main source for companies to gain competitive advantage. This study focuses on banking sector, which is one of the most knowledge-intensive industries. The aim of this paper is to examine empirically the level and the extent of Intellectual Capital (IC) information in the sustainability reports over the years 2006 and 2012.

Several empirical studies have examined the quantity and the nature of IC information disclosure in annual reports in different industries and countries, but few studies have analyzed the ICD in the financial sector. Banks policies regarding how they contribute to the conservation of energy and natural resources and recycling activities are important aspects of their social responsibility activities.

Introduction

The process of globalization, increasing competition, the development of IT, the prevalence of soft elements, intangible and human factors that have characterized the last few decades, have changed the sources of value and competitive advantage (Cordazzo, 2007; Petty and Guthrie 2000; Goh, 2007) and have changed the way companies operate. The assets that create value and create a competitive advantage to the company are no longer the machinery and equipment as intangible assets (Roos et al., 1997; Teece, 2000; Bontis, 2002), such as knowledge, information, the skills and competences (Roos et al., 1997; Quinn 1992; Nonaka and Takeuchi, 1995; Edvinsson and Malone, 1997; Choo and Bontis, 2002). The value of a company, therefore, depends not only on what can be accounted for, but also the not capitalized intangible assets, such as intellectual capital (Swart, 2006; Bernard et al. 2003; Teece, 2000).

Intellectual capital (from now will be used IC) is now recognized as one of the most important sources of value and competitive advantage (Edvinsson and Sullivan, 1996; OECD, 2006; Ordonez de Pablos, 2003).

The new international context has also influenced the banking sector deeply changing the competitive environment. Banks appear special for several reasons. First, they offer a wide variety of services, accept deposits and make loans, may purchase bonds (Matthews and Thompson, 2008); provide financial intermediation services similar to other financial institutions and offer service of liquidity and payment. It is the quality of services provided to customers that makes the difference and this depends on the intellectual capital within the bank. Factors for a long time underestimated and lightly managed, such as the strength of the relationship of the bank, its brand, the corporate culture and the values of human resources have become, with increasing competitive pressures and the progressive deterioration of profit margins, clear strategic priorities of these organizations. In such a context, the organizations, on one hand, and stakeholders, on the other hand, are interested in disseminating information on intellectual capital, the first, and to have information, seconds. External communication on intangibles, in fact, enhances the image, visibility and reputation of the bank, generating positive effects on performance.

In addition, through most complete and articulated disclosure, it complies with the provision of the law laid down in the third pillar of Basel II, which drives in order to increase the disclosure of both qualitative and quantitative nature for stakeholders. Given, therefore, the importance of intellectual capital, it is important to determine whether the companies have changed their practices in response to the disclosure of such changes.

The existing literature has analyzed the extent and nature of intellectual capital generally with a cross-country approach. Among these studies (Guthrie and Petty, 2000; Bukh et al, 2005; Bontis et al. 2003; Ordonez, 2003), those focusing exclusively on the financial sector and banks in particular are still limited (Khan and Ali, 2010; Mention, 2011; Abdifatah Haji and Mubaraq, 2012). The present paper fits in this last field. The aim of the contribution is, in fact, to study the nature and extent of the information of the components of intellectual capital (human capital, structural and relational) in the Italian banking sector companies. The choice of the banking sector for the analysis has different motivations. In the first place, it represents an interesting field of research, given the type of activity, a high

content of knowledge, which characterizes them. In addition, this sector, like others, has been affected by deeply changes that have created the necessity to develop different skills than in the past, making the management of intellectual capital one of the vital aspects of these organizations.

The management of intellectual capital has become in the new context more complex and characterized by a high degree of uncertainty, one of the driver to deal with the negative results that have characterized the sector as a result of the profound changes in the competitive environment. Banks, in other words, were pushed to expand the range of its powers, to apply innovative approaches, as well as to adopt strategic and organizational structure more dynamic and oriented to the strategic management of intangible resources. Even an external element should have an influence on the level of disclosure or the advent of Basel II and specifically the third pillar entitled "Market discipline". The objective of Basel II is to increase the disclosure of both qualitative and quantitative nature of the stakeholders¹, in particular on issues related to the operational risk management (such as procedures and policies related to operational risk management processes and information systems aimed at monitoring operational risk, or aspects of structural capital). These characteristics mean that the banking sector will come up as an interesting area to conduct research on intellectual capital (Mavridis and Kyrmizoglou, 2005; Goh, 2005; Reed et al., 2009).

Italy was chosen for two reasons. First, banks are a central sector in the Italian economy and should develop their information on intellectual capital; second, knowledge on intellectual capital in Italian companies are limited (Bozzolan et al., 2003; Bozzolan et al., 2006) and absent knowledge on the banks.

The analysis is conducted using the method, most widely used in the literature of similar studies, of content analysis. The nature and extent of information on intellectual capital are analyzed by examining the social reporting. The information thus obtained was summarized in an indicator of disclosure at the corporate level and subcategories. The main objective of the analysis is to evaluate, over time, the nature and the extent to which firms in the banking sector publicly provide information on their intellectual capital as a whole and for sub-category.

Compared to the existing literature, this paper allows to get an overview of intellectual capital disclosure with reference to Italian banks, context not yet investigated in spite of its dominant role in the economy; answers the question of longitudinal type information in terms of intellectual capital reporting (Mention, 2011) and highlights the relationships between the different components of intellectual capital. The paper is complementary to the studies of Bozzolan et al. (2003) and Bozzolan et al. (2006), who analyze intellectual capital disclosure in Italy with the exception of the financial sector, thus bridging the gap in the literature.

This paper is organized into three parts. The first part consists of introduction, definition of intellectual capital and literature review. The second part examines the research objective and the methodology. The last part analyzes data and present findings. Conclusion, limitation of study and ideas for further research are also described in the last part.

Theoretical background

Defining Intellectual Capital

There are several definitions that try to explain intellectual capital, since the beginning of its research (Brooking 1996; Edvinsson and Malone, 1997; Sveiby, 1997; Lev, 2001; Lev and Zambon, 2003). Stewart (1997) defines intellectual capital as "knowledge, information, intellectual property and experience that can be put to use to create wealth", whereas Bontis (1998) describes intellectual capital as "a set of intangibles (resources, capabilities and competences) that drives the organizational performance and value creation". Sveiby (1997) asserts, instead, that "Intellectual capital includes all employees, organizational knowledge and their abilities to create value added and led to sustainable competitive advantage", whereas Edvinsson e Malone (1997) define intellectual capital as the own of knowledge, information, intellectual property, technology, organizational, personal and professional skills that provide the company a competitive advantage in the market.

Numerous frameworks have been developed to classify and monitor intellectual capital (Brooking, 1996; Marr et al, 2004; Sveiby, 1997; Bontis, 1998) and the literature agrees in identifying intellectual capital as the combination of human resources (human capital), structural (structural capital) and relational (relational capital) of a company (Sveiby, 1997; MERITUM Project, 2002).

Human capital is the set of knowledge, skills, abilities, level of education, experience, talent, innovation, motivation, creativity, leadership, business skills, managerial skills, culture and business philosophy, managerial attitudes, individual and group experience, ability to face and solve problems. This section included skills (including knowledge and abilities); the attitude (motivation, leadership quality management) and intellectual agility (the innovative skills of the members of the company) (Bontis et al. 1999; Bontis, 2002; Daum 2003; Dubra, 2010).

Structural and organizational capital is know-how encoded within the corporate structure, the capacity for innovation, the efficiency of production processes and business consistency with the objectives of the corporate culture of the business, the degree of alignment and cohesion of the management and the structural capacity to meet and enhance their human resources, technologies, procedures, risk assessment methodologies, software, databases, patents, communication systems (Bontis, 2002; Daum 2003).

Finally, *relational capital* is the relationships established with the market and with their customers. It is therefore a wealth outside the company, is not inherent in the corporate structure. Included in relational capital are corporate image, network, long-term contracts, collaborations and cooperations (Bontis, 2002; Daum 2003).

The interaction of these three key elements generates value; management tends (more or less consciously) to enhance positive interactions between these elements extending the "area of value creation." In this sense the intellectual capital is more than the simple sum of these resources (Bontis, 1996; Bontis, 1998; MERITUM Project, 2002), in fact, closely interrelated with each other.

Why banking sector?

Banks are service companies with a high content of knowledge (knowledge-intensive) (Eurostat 2005), which essentially operate through human resources with high professionalism and operational processes which involve a major effort in the development and transmission of information (Rebora, 2003). In Italy they play an important role and, in fact, dominate the Italian financial system, representing at least 85% of the entire financial system (International Monetary Fund, 2012).

The sector, as well as in other countries, has undergone a big change that began as a result of deregulation, technological change and globalization. The development of new technologies has reduced costs and has changed/improved the quality and variety of services that the bank can provide customers (Berger et al., 2010), facilitated the development of new products and new channels to provide services, new banking and management costs (Beccalli, 2007), but at the same time has encouraged the presence of new entrants (Gardener and Molyneux, 1993). On one hand, deregulation and financial globalization, opening up to the international flow of capital, have increased the competitiveness and led to the introduction of new virtual services. On the other hand, the progressive reduction of barriers to entry (direct consequence of deregulation) and the greater ease of specialization within the field, parallel to the standardization of financial products and the rapid evolution of demand, have contributed in decisive extent, to raise the threshold of profit financial intermediaries, making it more complex and critical management of banking. Banks have, therefore, had to deeply rethink themselves seeking new business strategies (from a balance-sheet activities to off-balance, greater involvement in the capital market), new models of doing business (e-banking, mobile banking, role of technology), new business models (subcontracting, outsourcing, strategic alliances) and M&A. These changes have affected the nature and activities of the banks and created the need to develop new skills and competencies (human capital), but also in terms of organizational change processes and technologies (structural capital) and relationships with stakeholders (relational capital).

Intellectual capital in banks has its own specific such as: high and strong relation with customers, trust and reputation as the basis of competitive advantage, the information component of the production and distribution processes; the relational nature of long-term relationship with customers; the necessity for a rapid adaptation of the behavior of people in the light of the new product/process; the relevance of the service and assistance in the competitive policies of differentiation; the centrality of the participation of people to service system of the industry (Campbell, 2010).

Increasing competitive pressures, arising from the phenomena mentioned above and the increased complexity of the management of banking activity can thus be considered as determinants of the reasons for the increasing orientation to the strategic management of intangibles in the financial services. In banks, the main role is played by

human capital. Human capital is difficult to develop and managers must always seek to motivate employees in order to reduce the propensity to leave the bank.

Aside from the human contribution, banks face other typical characteristics of knowledge-intensive activities, such as technology and the frequent interaction between employees and customers. Still, banking activity implies a close relationship with customers, which is largely based on the integration of information and communication technologies to the development of new products and services, as well as for automation of process. The increasing automation in the manage of banking operations has a direct impact on the role of technology and, at the same time, however, raises concerns about security issues (confidential information, information accessibility, etc.) and processes for managing operational risks (operational risk management process). Operational risk is defined by Basel II as the risk of losses achieved in inadequate internal processes, human error, failures in operating systems or due to external events. With the advent of new ways of carrying out the business activity, such as online banking, banks could benefit from this by developing new services and / or products. Still critical to the bank is the quality of relationships with the supervisor, with the supervisory bodies (Bank of Italy, Consob, with reference to Italy). The reputation and trust-based relationships are other intangible factors (Castelo Branco & Rodrigues Lima, 2006). Finally, an external element, the advent of Basel II, and in particular, the third pillar entitled " Market disciplines ", should have an influence on the level of disclosure. The objective of Basel II is to increase the disclosure of both qualitative and quantitative nature for stakeholders. More specifically, the purpose of the third pillar is to " Encourage market discipline by Developing a set of disclosure requirements which allow Market participants to assess key pieces of information on the aim of application, capital, risk exposures, risk assessment procedures, and hence will the capital adequacy of the institutions " (Basel II, p. 226-228). These changes are reflected in the structural capital, and in particular we expect a greater disclosure of those items that are more directly related to the *operational risk management* (such as procedures and policies related to operational risk management processes and information systems aimed at monitor operational risk).

Each element of intellectual capital is, therefore, a critical resource for banks that must be managed internally, but should also be disclosed in order to build a good reputation (Toms, 2002; Xifra and Ordeix, 2009). On the other hand a good reputation helps to maintain a sustainable competitive advantage.

Literature review

Essentially two are the main field of study related to intellectual capital: studies that measure intellectual capital in economic-quantitative terms and studies on intellectual capital disclosure directed to highlight information on intellectual capital in the same way that the economic-financial information can influence the decisions of a potential investor (Rees and Sutcliffe, 1994).

Focusing on the latter topic, as our contribution falls in it, the first study is Guthrie and Petty (2000). The authors develop a framework of characteristics/attributes of intellectual capital, derived from Sveby's Intangible Asset Monitor to encode and analyze the annual reports of 20 listed companies in Australia for the year 1998, with the purpose of determining the level of the IC disclosure (ICD) in the Australian context. From this study many others start, generally focused on a single country, some analyse the presence of information on intellectual capital, others also the extension and others the quality of disclosure (Guthrie & Petty, 2000; Abeysekera, 2000; Brennan, 2001; Bozzolan et al., 2003). Generally the analyses are cross-industry even if sometimes the analysis focuses on a particular sector (Shareef and Davey, 2006; Scheneider and Samkin 2008). Limited are those that include banks in their sample analysis (Williams, 2001; Abdolmohammadi, 2005; Bontis, 2002; Goh and Lim, 2004; Guthrie and Petty, 2000; Oliveras et al., 2008; Vandemaele et al. 2005; Vergauwen and Alem, 2005; Oliveria et al., 2010; Khan and Khan, 2010) or focused only on the banking sector (Khan and Ali, 2010; Mention, 2011; Haji and Mubaraq, 2012). Banking activity, in fact, is a high-knowledge business services and its characteristics are suitable to be analysed in terms of IC, which represents a critical resource in the process of corporate value creation. The activities of banks requires human resources with a good education, qualified and continuously updated (Alvesson, 2000), generally involves relationships with customers and rely, in large part, to the development of new products and services, integration of information and communication technologies (ICTs) (Mention & Bontis, 2012).

Khan and Ali (2010) are the first authors to present a study that analyses the annual reports to assess the ICD in 20 listed banks in Bangladesh in the period 2007-2008. The framework of analysis is Sveiby (1997) as modified by Guthrie and Petty (2000). The authors, in order to take into account the characteristics of the banking sector, insert other items, such as "banks recognition for services", "banks market share", "banks reputation for services" and "number of training for employee." The method of analysis is the content and the items used are 21. The data are qualified with the value of "0" if the information is absent and "1" if the information is present and the unit of analysis is the word count. The information that prevail are those on human capital (65%) followed by those on the relational capital (20.8%), and those relating to structural capital (14.2%).

The second study is Mention (2011), who examines the practices of voluntary reporting on intellectual capital by analyzing the annual report of five European banks. The analysis is conducted over a period of nine years (2001-2009) through the content analysis, that identifies for each of the three categories (human capital, structural capital and relational capital), five subcategories² and different indicators. The framework used is Guthrie and Petty (2000) modified to take account of the peculiarities of the banking environment. The information acquired are qualified with the value "0" if absent, "1" if qualitative and "2" if quantitative in nature. The unit of analysis is the text unit. The analysis shows an increase in all categories of intellectual capital in the period and on average it should be noted that the category of major interest is human capital (43 % of the information), followed by the relational capital (34%) and then structural capital (23%).

The third study deals with the ICD in the banking sector is Haji and Mubaraq (2012), who examines, for the period 2006-2009, the annual reports of 20 Nigerian banks. These authors do not adopt a specific framework of reference even if they adopt the classic division of intellectual capital. The researchers identified 44 items and qualify the information with "0" if absent and "1" if present. The most consistent information are those relating to structural capital (average 36%), followed by those on human capital (34%) and then by the relational capital (30%).

All studies above cited were conducted in other countries; the absence of previous research justifies exploratory approach of this study, recommended in those situations in which knowledge about a particular topic are limited (Selltis et al., 1976). In the three studies mentioned, the method of research is content analysis³. This method, in fact, is the most appropriate in studies of disclosure of intellectual capital in annual reports, social reporting and other corporate documents (Yamagami & Kokubu, 1991; Guthrie & Petty, 2000; Unerman, 2000; Brennan, 2001; Bozzolan et al. 2003; Oliveira et al, 2006; Beattie and Thomson, 2007; Cordazzo, 2007; Vergauwen et al, 2007; Abeyesekera, 2008 Abeyesekera & Guthrie, 2005; Oliveras et al, 2008).

Research objective and methodological approach

Objective of this study is to investigate the amount and the type of intellectual capital information (human, relational and structural capital) reported in the sustainability reports of Italian banking firms. The analysis is conducted on a voluntary reporting documents, such as new forms of corporate disclosure, that may be useful to provide information based on intellectual capital (Zambon, 2003; Cordazzo, 2005) for the years 2006 and 2012. Specifically, the analysis is carried on the sustainability reports. The methodology of analysis, in line with the existing literature, is content analysis, which is a useful method to extract information (April et al., 2003), which allows to identify the different components of intellectual capital and to understand, analyze and describe information about the intellectual capital in the documents selected for the analysis. The objective of this method can be found to represent the behaviour of organizations in terms of intellectual capital disclosure.

This method consists in classifying the information contained within the document analyzed within a predefined category of items identified with the intent to capture aspects of intellectual capital that you want to analyze. The basic assumption of content analysis is that the amount of information available reflects the importance of the information (Krippendorff, 1980). The application of content analysis involves the classification of the information available in the various categories in line with a predefined schema or identified criteria (Guthrie and Petty, 2000; Abeyesekera, 2008). The application of content analysis involves reading the document of social reporting and coding of information based on the framework identified. In the contribution we have chosen to examine the level and extent of information on intellectual capital in the documents of voluntary reporting, in particular in sustainability reports, available on the website of the banks. It is, in other words, interested in analyzing the voluntary disclosure on IC, as it is considered important in

order to provide a complete view of the firm (Campbell and Rahman, 2009). The research analyzed the need for information to decision makers reveal that market participants consider important and useful information on the IC to make investments (Abhayawansa and Guthrie, 2010).

The items used to make the analysis follows the pattern for intangibles of Sveiby (1997), who identifies the internal structures (structural capital), the external structures (relational capital) and employee competence (human capital). To take account of the purpose and object of the analysis, the items of analysis have been modified according to the sector analyzed, in order to have a better convergence with the item that much more likely to be reported by banking institutions (Guthrie & Petty, 2000). In this context, useful references are Mention (2011), Shih et al. (2010) and Ordonez (2003), as will be specified. The content analysis, following the literature (Krippendorff, 1980; Weber, 1990), was developed in the following steps: a) definition of the unit of analysis; b) defining the categories and c) development of an unambiguous coding rules.

Definition of the unit of analysis

With regard to the first phase, the existing literature identifies as a unit of analysis a word, a sentence or paragraph. Milne and Adler (1999) believe the word is not reliable, because it has a different meaning depending on the context of reference of the sentence and is therefore considered the most appropriate sentence for this type of analysis. However, since a sentence may contain more information, including on different aspects of intellectual capital in order to avoid bias in the analysis could be considered the unit of text as the unit of analysis; in this case, the different information needs to be captured for the different components of intellectual capital. Items have been investigated focusing on information and not on the expression of the single word. Therefore the research has sought and counted the information expressed in the sustainability reports concerning each single item. Have been deleted the double information on the same item and information contained in the table and charts have been counted only in case if they supply an additional information not explained in the body of the report.

Defining the category

In this paper, intellectual capital is defined and analyzed using three broad categories: human, structural and relational capital.

Human capital consists of the set of skills and knowledge of employees who can be further improved with training. It includes also experiences that can be developed with training programs. Human capital can be analyzed at micro level (individual) or macro level (enterprise).

Relational capital is linked to the organization and its relationship with external elements such as customers, suppliers and shareholders. Examples of relational capital in banks are customers, brand loyalty, customer satisfaction, strategic alliance and coalitions.

The structural capital can be, instead, defined as knowledge created by an organization and which can not be separated from the same.

Consistent with the existing literature (Bontis, 2003; Guthrie and Petty, 2000; Striukova et al. 2008) for each category were identified sub-categories (items) and indicators (Table 2), trying to capture the most important aspects with regard to context analysis. The selection of items is the most critical aspect (Marston and Shrivess, 1991, Bukh et al., 2005) and in order to make this choice less subjective, items were selected taking into account the items identified in Mention's study (2011). Mention (2011) identifies a framework of analysis with reference to the study of Shih et al. (2010) on human capital in financial institutions and the study of Guthrie and Petty (2000) for the structural capital and relational adapting the items according to the banking sector. These items have been integrated with the indicators identified by Ordonez (2003) and subsequently with indicators derived from the study of some sample documents.

The coding process of intellectual capital information

The data was first coded by category and then by subcategory. In line with the purpose of this study to concentrate on the qualitative character of intellectual capital disclosure, repetitions were ignored. In order to identify the level of disclosure, the information was coded in a dichotomous way, whose value was set at "1" if the item is present and "0" otherwise. It was made this choice in order to avoid areas of subjectivity that tend to be present when the assignment of the value includes a weighing (Williams, 2001). The extent of disclosure was measured by counting the frequency

of the presence of the three categories and their subcategories. The frequency, in fact, indicates the importance of a particular element (Krippendorff, 2004). Finally we constructed a Disclosure indexes (ICI) (Haniffa and Cooke (2005); Ghazali (2007)). ICI calculate “the number of information-related items that a given report contains based on a predefined list of the possible items” (Bukh et al., 2005). The total disclosure score was computed as the unweighted sum of the scores of each item (Cooke, 1989). All items were considered relevant to all firms. The formula to calculate ICD_i is the following:

$$ICD_i = \frac{\sum_{j=1}^n D_{ij}}{n} \quad (1)$$

where D_{ij} assumes the value of “1” if were found information on the item and zero otherwise and “n” is the maximum number of items reported in the document.

The use of disclosure indices in studies of accounting and reporting of business practices is widely used (Marston and Shrivies, 1991, Guthrie et al., 2004), as these studies represent an aspect of the quality of disclosure that may be captured by a measure "sum" (Beattie, 2002; Bukh PN, 2005). To mitigate the main problem of content analysis (accuracy of information), the collecting data was conducted on sustainability documents separately by all the three authors and then compared where it showed discrepancies.

Sample and data

Listed banking sector firms in the Italian Stock Exchange are initially selected to represent the sample of the study. However data of some companies have been omitted because they are not fulfilling the sampling requirements of this study. Under such requirements, companies should have published their social reports for 2006 and 2012. In line with this requirements, thirteen firms have been excluded from the sample and four retained. The selected document for the analysis is the social reporting. The banks listed on at 31/12/2012 were seventeen, but only six draw up documents of voluntary reporting in five years. None of the analyzed banks draw up a real intellectual capital reports. All documents used are freely available online. The final sample consists of 4 companies, one (Monte dei Paschi Group) was excluded because of its Sustainability Reports 2012 could not be compared with 2006 because it consists only indicators and do not disclose narrative part. Therefore our final sample consists of the following companies: 1) Unicredit Bank, 2) Credito Valtellinese, 3) Ubi Bank and 4) Carige Group.

Results

Descriptive Analysis

Only 24% of the companies draw up sustainability reports in the period time considered. In banking sector, the main role is played by human capital and relational capital; in fact the examined companies disclosed information mainly on these type of resources while the lowest incidence occurs on structural capital both in 2006 and 2012.

Table 1 displays the number of human capital, relational capital and structural capital reported by the four aforementioned institutions over two-year period, 2006 and 2012. As illustrated in the table, the level of information disclosed follows a ascendant trend. To a certain extant, this observation supports the proposition that disclosure of intellectual capital increases over time, especially after the entry into force of the third pillar of Basel II (market discipline). In absolute terms, relational capital consistently ranks first in this study, unlike what is reported in the study of Mention (2011), both in 2006 (716) and in 2012 (837); human capital holds the second place (261 in 2006; 488 in 2012), while structural capital land on the third on (161 in 2006 and 168 in 2012). This result highlights the importance for the banking sector of the relational capital: this means trust and credibility from its customers and in generally from its stakeholders. In relative terms, the ranking indicates that relational capital is most disclosed, followed by human and then structural capital, which is consistent with prior studies (e.g. April et al., 2003; Guthrie and Petty, 2000; Oliveras et al., 2008; Striukova et al., 2008).

TABLE 1 – INTELLECTUAL CAPITAL IN THE EXAMINED REPORTS

	2006	%	2012	%
Human Capital	261	24%	488	33%
Structural Capital	161	14%	168	12%
Relational Capital	716	62%	837	56%
Intellectual Capital	1150	100%	1493	100%

Taken a closer look at the importance of each subcategory (table 2), it can be observed that the top five subcategories are “Training policies” for human capital, just to show the importance in this particular sector of the professional and learning training, the updating of the employee; “corporate culture and identity” for structural capital, to indicate the importance of some values, as trust, credibility, etc.; “Customers”, “Business partnership” and “Corporate action” for relational capital, to highlight that the relationship with customers and stakeholders are crucial for an institution. Corporate action refers to all initiatives in which banks are involved in, especially in no-profit organisms, or to promote cultural and sport events. It can be observed also a low level of disclosure of intellectual property, innovation capabilities and management process. A possible explanation for this may reside in the fact that banks may be hesitant to pursue patenting over their financial institutions in Europe due to the legal uncertainty surrounding the patentability of business methods and computer programs.

TABLE 2 – DISCLOSURE PER SUBCATEGORY

Cat.	Subcategories	2006	%	2012	%
HC	Employee's profile	36	3,14%	32	2,14%
	Knowledge	21	1,83%	22	1,47%
	Skills	35	3,05%	39	2,61%
	Attitudes	19	1,66%	18	1,21%
	Talent management	92	8,00%	196	13,13%
	Training policies	70	6,10%	181	12,12%
SC	Intellectual property	6	0,52%	3	0,20%
	information system and infrastructure	30	2,61%	26	1,74%
	Management process	3	0,26%	0	0,00%
	Corporate culture/identity	115	10,02%	123	8,24%
RC	Innovation capabilities	7	0,61%	16	1,07%
	Brand	23	2,00%	37	2,48%
	Customers	128	11,15%	191	12,79%
	Distribution channel	83	7,23%	109	7,30%
	Business partnerships	125	10,89%	181	12,12%
IC	Corporate action	357	31,10%	319	21,37%
	Total	1148	100,00%	1493	100,00%

As regards disclosure per items, it could be observed, consistently with prior literature, that for human capital few and sometimes none information are reported for overtime, employee’s experience, tea work, language, problem solving, creativity or pro-activity of the employee; whereas the most information reported are gender distribution, internal communication, recruitment policies and training programs. As concerns structural capital, very few information are reported for licensees, copyright; whereas the major information disclosed are corporate value and

vision. Finally, as regards relational capital information relates to shareholder value are not present, whereas information relates on sponsorship, environmental protection measures, relation with suppliers, collaboration and multichannel bank.

TABLE 3 – DISCLOSURE PER INDICATORS/ITEMS, GIVEN IN ABSOLUTE TERMS

Subcategories	Item	2006	%	2012	%
Employee's profile	staff	3	0,26%	4	0,27%
	manager	5	0,44%	4	0,27%
	gender distribution	8	0,70%	8	0,54%
	country of origin of human resources	1	0,09%	2	0,14%
	average age of employee	5	0,44%	5	0,34%
	n. full-time employee	4	0,35%	4	0,27%
	n. contracts	5	0,44%	3	0,20%
	Protected categories	5	0,44%	2	0,14%
	overtime	0	0,00%	0	0,00%
	education	6	0,52%	6	0,41%

Conclusion and future research

Considering the peculiarities of the banking sector, its being knowledge-intensive and the changes that have affected this industry, the study analyzes the level of information on intellectual capital of the banks listed on the Milan Stock Exchange. The study shows that the relational capital, as shown in previous works, predominates followed by information on human capital and structural capital then. Either way, the information level is quite high. Analyzing the trend shows a substantial increase in information related to human and relational capital and the structural remains almost constant.

The results have implications for policy and management. At the level of policy, Basel II drives to provide more information, particularly on intellectual capital, but to date there are no specific references on how to provide such information and this can make it difficult to implement the prediction of a balance of intellectual capital, especially if it is not mandatory. Therefore it would be desirable to develop a framework for this report may be directed to the preparation of the document and its comparability over time and somehow assure the reader about the goodness of the information contained therein. From the management point of view to an enterprise knowledge-intensive management of intellectual capital is essential. Prepare a report like this can bring benefits in terms of transparency, trust and reputation. So how management uses time and effort to identify its key resources so should communicate outside.

The study certainly has limitations and the principal is to be attached to the use of content analysis, unaccurate the subjectivity of interpretation even though there is a list of predefined items, secondly, the sample size does not allow to generalize the results even if it is recognized that judgmental or purposive approach offer comparable results to the use of probabilistic methods with small samples, even if our goal is not to generalize the results to the case of an exploratory study. The study is exploratory in nature and its goal is to expand your knowledge with reference to a sector that is still largely unexplored.

Regarding the future of the research, it could be useful accompany the content analysis of questionnaires to firms in the sample. This is because, as already mentioned, the technique of content analysis suffers from subjectivity.

End Notes

¹ More specifically, the purpose of the third pillar is to "Encourage market discipline by Developing a set of disclosure requirements which allow market Participants To assess key pieces of information on the scope of application, capital, risk exposures, risk assessment procedures, and hence will the capital adequacy of the institutions "(Basel II, p. 226-228).

² Human capital constitutes: knowledge, Skills, Attitudes, talent management e training policies; capitale strutturale: Intellectual property, information systems and infrastructure, management process, corporate culture, innovation capabilities; capitale relazionale: Bran, customers, distribution channel, business partnerships, corporate actions

³ Another common method of analysis in the study of intellectual capital is the VAICTM analysis. The methodology VAIC is instead used to measure the intensity with which a company produces value-added based on the efficiency of intellectual capital (P. Stale, Stale S., S. Aho) and its goal is to measure efficiency in 'use of intellectual capital (Pulic, 2000). The VAIC leads to determine a summary of the efficiency of the enterprise and efficiency of intellectual capital.

Managing Intellectual Property in High-tech Services: A case study of an engineering company

Abstract

Managing intellectual property (IP) in the customer- supplier relationships is a challenge for a high-tech service. The paper intends to find out how to handle the critical issues in the collaborations, such as how to protect of both the customer's IP and company's IP, how to manage IP fruits coming from the collaborations and how to serve the customer better. As IP protection is still problematical in China, the paper also studied the Chinese subsidiary of the case company. The longitudinal study investigated a Finnish engineering company. During 2011-2013, three face-to-face interviews were conducted in headquarters and one in the China Office. The empirical results indicate that knowledge management as an indispensable component of the IP management should be embedded into the daily business. Besides, the company's IP strategy in China highlights the importance of IP risk identification and the impact of the headquarters' good IP practices on the subsidiary.

1. Introduction

Intellectual property (IP) mainly including copyright and rights related to copyright, trademarks, patents, industrial designs and trade secrets as an intangible subject matter is part of intellectual capital [9]. IP is seen to be crucial to a company's core business activity, because IP provides the company a unique competitive advantage in the market place [4], [11], new solutions for money generation [11], and new strategies of maintaining its core competences [2].

With the rapidest economic growth, China has overtaken Japan to become the second largest economy in the world since 2011. China has been one of the most attractive markets among the emerging countries. However, the prevailing problem of IP misuse cause by the weak IP enforcement has frustrated foreign investors. China is now continuing on its path of institutional transition and development which requires a series reforms including strengthening IP protection [3], so there is a long way for China to establish healthy intellectual property right (IPR) regimes from the current fledging stage [10]. Thus, the law enforcement is the biggest challenge which foreign companies must face [5].

In business studies it seems that the theoretical foundation of IP management is rather weak. A lot of studies on the legal field proposed establishing a harmonized international IP realm. IP area has been long time mainly law focused. Literature has mostly discussed about the term "IP" from social, political and legislative perspectives. Until recently, literature has started dealing with IP from business perspective, but only with the limited number. The latest studies stress on proactive corporate IP measures which suggested that ahead of any problem, the foreign companies should develop their own corporate IP measures rather than overly count on legal protection measures. Studies on IP management in China, particularly from the foreign company's point of view, are even fewer. These studies generally discuss about IP protection strategies for international companies to respond IP abuses, no matter what kind of operation model the companies have and in which industries the companies are. In reality, IP management can vary in different operation model and industrial sectors. For example, the emphasis of IP management in high-tech service sector with business-to-business selling will differ a lot from that in manufacturing with business-to-customer selling.

This study exposes how IP management is done in a Finnish engineering company both in headquarters and in the subsidiary of China. The focus of the study is on the critical issues in the collaborations, such as how to secure the customer's IP and protect company's know-how as well, how to manage IP fruits coming from the collaborations and how to serve the customer better. This study gives the following contributions. First, contrary to the existing studies that have examined the IP strategy as a separate strategy from the company's business plan, this study regards IP strategy as a part of business strategy. Second, the research combines knowledge management with IP management. The study covers how to manage essential knowledge, critical know-how and core competence in the IP management, because without them the companies may not have the capability to create any IP, though the existing studies have put knowledge management and IP management into two research realms. Third, the study takes contingency factors such as industry-specific, company specific and system-specific into considerations in the analysis. Fourth, the

viewpoint of the study is analytic by looking at the relation between the IP management in headquarters and in China.

The next section is research methodology. Thereafter, the case company is presented under the two sub-sections 1) IP management in headquarters and 2) IP management in China, followed by the discussion section. The final section provides the theoretical and managerial contributions.

2. Research Methodology

In the study, qualitative research approach is chosen for the data collection. The advantage of the qualitative interview approach is that researchers can view the research topic directly and also obtain unexpected insights of inferences and explanations through interviews [12]. In the case study, the in-depth, semi-structured, face-to-face interviews were conducted to a company in the consulting and engineering sector. Headquarters of the company is located in Turku and its China subsidiary is in Shanghai. Senior Vice President and Senior Vice President in Marine Business Unit who is also in charge of IP management in headquarters as well as General Manager at Shanghai office were interviewed. The interview questions cover these ten issues: 1) background information of the company (e.g. history, business strategy etc.); 2) operation in China; 3) decision-making process to establish China Office; 4) human resource management and trainings; 5) the procedure of daily IP management; 6) the knowledge management; 7) phases of the collaboration; 8) motivations behind the collaboration; 9) IP problems encountered; 10) and the ways for improving IP management.

The interview with the General Manager at Shanghai Office took place before the one interview with both Senior Vice President and Senior Vice President in Marine Business Unit. The reason for that was it took time to evaluate the case after the first interview whether it was the right case for the topic and getting the acceptance for the second interview was not easy. In the case evaluation process, the rough data analysis was done. The analysis was based on these issues, such as 1) does the company know about IP; 2) does it have coherent IP management system; and 3) does it concern about protecting their business partners' IP. The strategy for the second interview was to focus on not only IP management in general, but also the central points as well as the questions which the General Manager at Shanghai Office was not able to answer. After about one and half years later, E built up the process system of handling the patents and IP matters. Hence, the third interview with Senior Vice President in Marine Business was conducted to keep update the rapid changes products taking place in the company since 2012 spring. During the semi-structured form of interviews, the field notes were made in order to follow up the discussion by asking the additional questions. Also, the researcher summarized what the interviewees told and asked the questions to make sure that there was no misunderstanding between the researcher and the interviewee. Interview data were recorded by the digital recording under the permission. The interview agenda was sent three week in advance, so that the interviewees would have time to prepare for the interviews. The duration of the interviews was about 1 hour. Besides, some documents like E's homepage, brochures of E's business perspective, PowerPoint presentation of E Shanghai Office and Information Security at Shanghai Office were studied to supplement the interview data. The interview transcriptions were coded into concepts and themes cf. [1]. Further inquiries were sent by email for clarifying certain specific issues after interview transcriptions were studied.

3. Case Company Profile

E is a leading Finnish consulting and engineering company in Scandinavia, specializing in marine, mechanical, process, R&D tools and software. The headquarters of E and its son company C are situated in Turku Finland. E started as a family company founded in 1970. In the 1980's after the 3D computer aided plant design system, software D was developed, competitiveness of E as a major player in the international market increased. D is the brand of the software and it has been registered as an international trademark. Software D licenses in 50 countries worldwide. E China located in Shanghai was established in 2008. It is the second subsidiary in the Asian market. The main service of E China concentrates on mechanical engineering.

3.1 IP management in headquarters

E highly concerns about IP management. It provides the services solutions for the customers based on the guidelines provided by their customers. If there is any invention or IP generated in the project, the ownership belongs to the customers. Handling transferring IP related matters to the customers is complex process. It involves the company's obligations of the

reasonable compensation toward the employees according to the Finnish law and the obligations to comply with the customer's guideline. Usually, it is difficult to decide how much should be the reasonable compensation. In principle, the compensation follows the 3-step guideline in the phases of IP related matters transfer, registration and further appropriation in 5 or 10 years. However, the customers have the different compensation guidelines as E has. In this case, E needs to on one hand keep track of the IP-related matter already transferred to the customer and on the other hand ensure that the company will get enough compensation from the customers if the customers later patent the IP-related matter and make money out of it. In order to avoid the conflict, every clause of the contract must be well-specified. When drafting the contract, E spends lots of time in discussing about the contract with the customers to make sure that all potential consequences are taken full consideration in advance. Securing the customers' IP and know-how is also defined in contract. The company has strictly followed the customer's policies, e.g. what should be kept in Finland. Above that, explicit rules in the daily routines have been set. For example, everybody who works with the customers should sign non-disclosure agreement. Also, everything in connection with the computer systems has been protected properly. At the same time, E enhances the importance of IP by developing the rights to meet the customer needs:

"To enhance the importance of IP means not only to generate the patent, but also to be able to find the solutions to the customers. That means before they order the vessel from the ship yard and when they think what kind of ship they need. Then we can help them. And also after delivering the vessel, we help them to develop the product in order to run the ship. "(Senior Vice President in Marine Business Unit

The motivation behind the collaborations in general is to acquire the external resource (e.g. expertise and human resource), so that the company has the enough capacity to compete for the big business. In the collaboration, many companies transfer the responsibility of checking that in the project other companies' patents are not violated. That is to say E must make sure that there is not a patent anywhere in the world related to the work it makes. Aside from it, most of those customers from the big companies, normally, request the ownership of improved or new created IP in their projects. In this case, E has to negotiate, define and balance it clearly in agreement the proportion of the co-ownership of the invention.

The IP proposal usually first goes through the decision making by the steering committee in headquarters to evaluate whether the IP has the market potential to file the application. In customer project-related invention, E also need to inquiry the customers about their interests in IP. The customers have the priority to own the IP. In 4 months, the steering committee must get back to the inventor. After the proposal is confirmed, some agent is hired for filing the IP. The agent is in charge of IP searching or checking based on the requirement of the law. Senior Vice President in Marine Business Unit commented:

"We more think about how important the patent can be from our business point of view. And the agent will be more looking at is it possible to patent. Because if somebody else has patent something if it's very close to it then... Well it's important for us to know that. We need to be careful with that not to use other ones' patents."

So far E has not had any conflict or argument with the customers. It has done well in improving the level of knowledge of IPR matters most related to E's own products and also related to the customers' products. During the recently one and a half years, E has established specialty groups comprised of people with specialties from different special areas in Helsinki and Tampere office. In this way E can develop the know-how and the knowledge between the people and thus is able to provide higher-level know-how for helping the customers improve their products. Still this is an on-gong process. The part of E's strategy in the future is to build up a more and more knowledge-based consultancy. Although as a new thing in the company, the process has not yet been structured, from now on E will continuously improve the IP system of the company:

"We need still to build in the process of making all kinds of IP and go through them. That means we are developing more and more products. We are in the process to get everyone in the organization to know what it's about. It's quite important to know what kind of contracts we make with our customers. Now we have increased the importance of IPR in our strategic planning and started to support our personnel to be active in the area of patents." (Senior Vice President in Marine Business Unit)

3.2 IP management in China

The main reason driving E to establish the subsidiary in China is to be close to the big Finnish customers that have operations in China. E's business strategy in China is to help and assist those Finnish companies already in China in high-class, high-technical engineering design consulting. The Finnish customers are the majority that E serves. But in

a long run, the business will also focus on Chinese companies. In the decision making process, the management team took care of the risk analysis:

"I guess it's important for everyone to know the risks involved. That the first step to know what is the risk. Then the next is to judge well and to compare with the risks and then you can sketch if you still need to do something or not." (Senior Vice President in Marine Business Unit)

"That's exactly. To be ready with the risks and take the worst case scenario and then look what happens." (Vice President)

The proposal was confirmed by the President and then it was approved by the supervisory board after the discussion from the management board. Quality analysis was done on finance and detailed business plan was made. That time E had no Chinese partners. Basically, E has not been involved in technology transfer to China. Information related product knowledge is remained in Finland and only generic engineering designs are used in China, because the customers are very concern about IPR problems in China:

"Some of our customers are very concerned about Chinese coping and IPR in that country. This type of information or design will never leave Finland." (Senior Vice President)

The new Shanghai Office is located in Caohejing Development Zone. Due to the increasing of the workload, nowadays Shanghai Office is under the direct control of the Tampere Office which is in charge of the knowledge and know-how development in Finland, so that E can transfer the know-how to help the Finnish customers in China. In the end of 2011, E China moved from the previous location which is distant to the center. The basic reason for moving was that the previous location was difficult to get people or companies to work with. In the new area, the company is more attractive, because it is closer to the universities. The new office has altogether 13 workers led by the Finnish expatriate. The office established the information security control system to protect the crucial knowledge. The system can be divided into these categories: human resources management, premises, infrastructure and way of working and computing restriction. E recruits through websites and networks. In the recruiting process, E keeps track of the engineers' competences of what they have done in the past. E prefers the employee who has long working histories in one company and tries to avoid recruiting the "job hoppers". The whole-hearted orientation for the new staff and continuous training including the security issues are provided:

"... Of course we give the training to our staff, training about the security issues. Always remind things of confidential agreements with the people, so everyone understands what the meaning is and what the purpose of these things is..." (General Manager at Shanghai Office)

The security issues are also included in the Employee Handbook. For example, "In case the Company suffers economic losses because the employee discloses trade secret(s), the employee shall take the obligation of compensation." (Power Point Presentation of Information Security System) In the employee's contract the company requires the employee to execute the duty of competition restrictions. The employee who involves in any customers' project, non-disclosure agreement should be signed. The employee should also know the entire non-disclosure contracts signed with the customers. The employee's expertise is an intangible asset to the company. In order to keep the key personnel, the same motivation system is used for Chinese employees as for Finnish ones:

"Well, we need to have competitive compensation package of course, salary bonus scheme, training and the good working environment that people would feel this is the place to work I mean. As we know in China obviously in big company area like Shanghai the salary has increased a lot. We have to follow the salary standard there." (Senior Vice President)

Information security in premises, infrastructure and way of working limits and controls the access to the premises and to all databases. Senior Vice President added: "When moving to the new office we have established different areas of the office, so we can protect, we can have an isolated area. There's no mobile phone. There's no memory card or anything or no internet connection. We can also have this type of confidential at the office." Waste paper must always put to the shredder. Paper copies of documents are minimized. The IT policy restricts the use of the network and mobile computing devices (e.g. laptops, handhelds, etc.). IT department manager and general manager are responsible in the user rights approval process. In addition, for special cases, such as secret R&D projects, E tightens restrictions to limit the access to workstations and internet. (Power Point Presentation of Information Security System)

E also has collaborations with Chinese companies and universities though only small amount of business.

Subcontracts were done both with the Finnish and Chinese companies. One Chinese company has been the subcontractor for E China for more than two years. E China found this partner through a series of steps: Googling, company visits, background information checking, evaluation procedure and selection. "We evaluated these suppliers. We checked these background and we get us as much as possible information about this. We have their business license, what kind of the statements, these kind of public statements... There were several different kinds of documents we wanted to get and we wanted to check everything, for example, if they paid the tax. And first task are small. Step by step we give big tasks to them." told by the General Manager at Shanghai Office. So far, E have undertaken a few projects in China. And "guanxi" (personal relation) will be built only when E China is big and strong enough.

In China, the registered trademark of D is the only IP. The agent in Finland handled things in the registration process. In the licensing, the trademark is protected by the unique technology attached to the software. Although E has not had any problems with IPR issues in China during these four-year time, E will take the legal procedure whenever any violation occurs.

4. Discussion

Engineering consulting belongs to the knowledge-intensive industry which requires the company to protect the customer's IP and the company's know-how. E has gone smoothly to tighten the knowledge and IP managements in the overall management system; otherwise the company will be in trouble. In headquarters, IP and know-how is controlled by the contracts and policies. In addition, the company has been constantly building up a better IP system to enhance the service level, for example forming the specialty groups.

The managers of the company understand the IP risks and engineering market in China. The targeted customers have been mainly the Finnish companies that the company already had business with them in Finland. This business strategy in China is quite special, because normally the foreign companies establishing the physical presence in China is from the considerations of cost-saving or huge market potential. But the strategy has well matched E's risk management capability in China since E was not familiar with the Chinese market before entering China. Also, the strategy matches the situation of the Chinese market. According to the General Manager at Shanghai Office, the outsourcing engineering market has not matured yet in China. Chinese companies want to keep the engineering design in their own offices. They don't want to use the subcontract. The business strategy of E seems to be cautious also in the whole decision making process. The business plan presented the perspective of operation in China. The financial analysis showed the profitability of plan. Thus, the business strategy can alleviate the most IPR risks.

Second, The system in headquarters was transferred to China, but more strict rules were embedded. Information security system has been integrated in the HRM to protect the essential know-how of customers' and the company's property, because the critical know-how covers a broad range in the engineering companies compared with other knowledge intensive industries. The uncommitted employees can be the source of IP risks for the company. In the recruiting, avoiding "job hoppers" can to some extent reduce the leakage of the crucial knowledge. On the other hand, motivation system can keep the talents in house, but also influence the job hopping behave as well. The continuous training can keep the employees aware of the information security issues. According to [7] education and training program should aim specially at educating employees about what information is sensitive and proprietary. When asked what has been done well in IP management, the General Manager of Shanghai Office mentioned this point: *"We have new worker here and this internal training we have constantly done so that everyone understand about these security issues."* But normally, employees too often only get trained in IP protection during the orientation days when they become new comers of the company [8]. The Employee Handbook of E and the contractual mechanism have defined explicitly the obligations of employees to diminish the possible risks. For example, information sharing with the cooperators (act as both partner and competitor) is restricted to the project. In China sometimes employees may unknowingly leak the sensitive information (e.g. trade secrets) to business partners, because they are not clear about what belongs to sensitive information and what does not [2]. Physical access control enables all the employees have access only to the information relevant to their work [8]. The proper information securing system in place has prompted the staff to aware the value of the knowledge in the model designing. In this way, E is able to maintain its competitive advantages in the market, as the General Manager said: "At the moment the product engineering that E

are doing is not in the market yet. So our clients and competitors have not seen these 3D models. They won't see beforehand and afterward."

Third, the comprehensive due diligence was conducted to assess the reliability of the potential partner. By company visits, E could know whether the company existed or not. In China, there are illegal companies called "Pi Bao Gong Si". These are companies with no funding, no operating site, no business operation and no regular workers, but with a company's stamp and few contracts they engage in fictitious transaction to deceive money. They change their contact information often, so that they will not be easily caught. In the virtual world, they also use internet as a modern tool to hunt the quarry. Also some companies not doing business well will exaggerate their business scope with a fancy internet page to attract the customers or business partners. It is well advised for foreign companies to obtain as much information as possible from different sources: 1) reviewing documentation; 2) asking questions; and 3) visiting candidates [6]. According to law, every legal entity must have authorized the business license and business registration certificate by local government. These documents will uncover the Chinese company's legal capacity such as registered capital, business scope and legal representative. The company can ask for financial information and the original certificates from the candidates. E managed successfully in the due diligence process. Moreover, building business relation with the Chinese partner from the small tasks to the bigger ones is wise. The small tasks that E offered in the beginning are like the threshold. Through these small tasks whether the Chinese partner is reliable and capable for the task can be revealed. Until the trust was built, the bigger tasks were given.

However, E China has not been active in building "guanxi" (personal relation) with Chinese companies and Chinese governments. That may become a problem later if it wants to start targeting local Chinese companies in the future. Building "guanxi" is indispensable for E to survive in the Chinese market, as guanxi has a predominant position in Chinese culture, the high impact of guanxi in the business world has been over time, even today in China's new and fast-moving business environment. Thus, when guanxi network is built, E is for sure to obtain more business opportunities in China, but not the other way around. It is likely that most foreign managers coming from the western countries may have difficulties in getting used to this concept in the beginning.

Last, IP problems cannot be revealed perhaps because the length of the time that company has been presented in China is not long. According to Senior Vice President in Marine Business Unit, the explanation was: *"Maybe we haven't made big project yet, so we haven't in the problem... It takes long time to get new market. If we think about three-or-four-year time, it's quite short time. Maybe we have not yet met the problems."*

5. Conclusions

5.1 Theoretical Implications

The case company has placed the IP strategy into its business strategy. The prudent business strategy, which fits well the company's situation and the Chinese market, indicates that risk management in the decision-making process can pave the way of IP management in China. This study points out that IP risks should be seriously taken into account in the risk management. But unfortunately, as IPRs are often associated with the legal matters, the importance of IP risk analysis has been ignored in the risk management of business studies. Moreover, the empirical study shows that knowledge management is an indispensable component of the IP management in the high-tech services. Nevertheless, the prior business studies have clearly divided knowledge management and IP management into two different topics. Therefore, complementary to the existing studies, IP risk management and knowledge management can also be regarded as proactive corporate IP measures. Last, the study indicates the contingency factors in IP management. The case suggests that knowledge management has an essential role in the high-tech services where the core competence relies a lot on the tacit knowledge from the talents. Therefore the prior studies on overall proactive corporate IP measures do not well applicable to the case of engineering services.

5.2 Managerial Implications

There are different kinds of risks involved in the different industries. Compared with the manufacture-based industry, knowledge asset is much more important to the high-tech services. Basically, companies in this sector should pay more attention to knowledge management and embedded it to the daily business routine to secure IPRs. Knowledge

management reflects not only in the all aspects of HRM, such as recruitment, training and retention, but also in the physical access control. In addition, the managers realize the importance of the talents. The motivation system that retains these talents in the company actually has reinforced the information security. Besides, the headquarters' good IP practices will have a positive impact on the subsidiary.

Regarding the market entry to China, foreign managers should fairly identify the risks in China to make the business strategy which is appropriate to the company's competence and the Chinese market. The analysis can help the company to prepare for the predicable IP risks with the reasonable business strategy before taking any practical actions. When collaboration with the Chinese partner, a thorough due diligence should be conducted beforehand

5.3 Limitation and further research

At the moment, trademark D is the only IP in E China Office. The main tasks of IP management in China are to protect the customers' IP/ property and the essential know-how of E. Besides, E China has not yet got into the Chinese market. Thus, at the current stage, the case study is not able to show how E will react to further risk exposure when E has other IPRs and frequent encounters with the Chinese companies. In the further research, as the establishing IP system of E is in the process and it will take very long time to make the system completely ready, five-year longitudinal study should be used to observe the changes in the organization. Further, more researches should be done in the future to discover the IP problems in the company. Having no problem in IP issue could be the truth, probably. But on the other hand, it could mean that either some problems are not recognized or the company did not want to disclose the problems to an outsider. In addition, comparison study can be made in other high-tech service companies, e.g., IT services which involves more advanced knowledge.

**MEASURING INTANGIBLES THROUGH THE BALANCED SCORECARD:
THE CASE OF AN ITALIAN COMPANY**

*Marco Gatti, m.gatti@univpm.it
Università Politecnica delle Marche, Italy*

MEASURING INTANGIBLES THROUGH THE BALANCED SCORECARD: THE CASE OF AN ITALIAN COMPANY

Abstract

In recent years, performance measurement systems (PMS) have received growing attention. Among these, the Balanced Scorecard (BSC), in particular, has been the object of a plethora of contributions. Its use, in fact, permits a multidimensional measurement of company performance, thanks to the contextual use of financial and non-financial indicators. Moreover, scholars have also underlined that the BSC allows companies to measure some of the intangible assets needed to improve organisational performance. The customer perspective as well as the learning and growth perspective, in particular, are tightly focused on some of the most important intangible assets that can deeply influence company results, namely the relationships with customers and the human and organisational capital that company strategy should be based on. Despite these distinctive features, the measurement of these relevant intangible assets is sometimes problematic and it can also limit the potentialities of BSC implementation. The aim of this paper is to explore some of the problems that can arise when a BSC is implemented, with particular regard to the information and measures focused on intangible assets, as well as the consequences thereof. In order to achieve this aim, a case study of an Italian company that has recently implemented a BSC is carried out. It sheds light on the role that the existing information system and the information it delivers can play with regard to the provision or the revision of measures pertaining to both the customer and the learning and growth perspectives, namely those perspectives in which intangible assets are more relevant. In doing so, the paper contributes to the literature on factors that can facilitate or hinder the measurement of intangibles within an organisation, as well as to the literature focused on the limits of BSC design and implementation.

1. Introduction

In recent years, the balanced scorecard (BSC) has received growing attention among scholars and practitioners (Kaplan and Norton, 1992; 1996; 2004; 2006). Its diffusion, from a theoretical and a practical standpoint, can be largely traced back to the fact that it allows a multidimensional measurement of company performance and, in so doing, the BSC overcomes some of the main limitations of traditional management control systems (Johnson and Kaplan, 1987; Lynch and Cross, 1991). In fact, thanks to its use, managers can control strategy implementation through the use of both financial and non-financial measures. Moreover, the fact that measures are linked through causal relationships allows managers to have a clear representation of the business they run and of the effects that their decisions can have on the company's performance (Kaplan and Norton, 2000). In light of this, BSC has been widely celebrated and its implementation has been studied in different contexts (Hoque, 2013). Scholars have paid particular attention to the design stage as well as to the effects that can result from its implementation. A plethora of studies have focused attention on the effects of BSC implementation on company financial performance, on organisational learning, on leadership and on many other aspects of organisations (Assiri et al., 2006; Agostino and Arnaboldi, 2012; Franco-Santos et al., 2012). Despite this, only a limited number of studies have paid attention to the role that the BSC can play with regard to the measurement of intellectual capital (IC) (Mouritsen et al., 2005; Wu, 2005; Bose and Thomas, 2007). In fact, Kaplan and Norton often refer in their works to the BSC as a useful tool for describing how intangible assets can contribute to the improvement of financial performance (Kaplan and Norton, 2000). Moreover, they underline the fact that by measuring intangible assets through the BSC, it is possible to verify and to monitor their impact on a company's financial performance and, as a consequence, it is possible to manage those assets in order to improve performance. Nevertheless, only a limited number of contributions have analysed the role that the BSC can play with regard to IC measurement and the problems that can arise when a company decides to implement such a system (Petty and Guthrie, 2000; Chen et al., 2004). Such problems are related to the company's need to provide a reliable measurement of the intangible assets that are normally considered within some of the perspectives in which a BSC is set up.

The aim of this paper is to contribute to filling this gap. In order to achieve this, a case study of an Italian company that has recently implemented a BSC will be presented. In particular, the case study will be used to show some of the problems that arose when the BSC was implemented because they predominantly concerned the definition

and the measurement of the key performance indicators within the customer and the learning and growth perspectives, i.e., those which are basically focused on intangible assets. More specifically, the role played by the existing information system and the information it provided will be analysed in order to show if and how it affected the measurement of some of the key performance indicators that were considered within the company's BSC.

The remainder of this paper is organised as follows. The next paragraph provides a brief literature review on the BSC and on the use of the BSC as a tool for measuring intangible assets. The third paragraph describes the research method used to carry out the case study as well as the theoretical approach adopted to interpret its findings. The fourth paragraph illustrates the company profile and the fifth and the sixth show both the design stage and the implementation stage, paying particular attention to the problems that arose when the BSC was implemented. Finally, some concluding remarks are presented together with the main limitations of the research.

2. Literature review

In recent years, the literature on the BSC has flourished (Franco-Santos et al., 2012; Hoque, 2013). From its introduction, BSC has attracted the attention of both academics and practitioners since it represents a useful multidimensional management control tool which is based on company strategy (Kaplan and Norton, 1996; Lawrie and Cobbold, 2004). Thanks to its use, in fact, managers obtain a set of measures which are focused on the key success factors the company strategy should be based on (Tayler, 2010). As a consequence, they can constantly control strategy implementation, its results and any changes in the external and the internal environment that could lead to a revision of the deliberate strategy. More specifically, the BSC allows a multidimensional measurement of the company's performance which can be seen from four different perspectives: the internal process perspective, the financial perspective, the customer perspective and the learning and growth perspective (Kaplan and Norton, 1992). Every perspective is monitored through the use of financial and non-financial indicators which permit a constant control over the results that the strategy implementation produces (Merchant, 1985; Lynch and Cross, 1991; Kaplan and Norton, 1992; 1996). Moreover, the fact that measures and targets are linked through cause and effect relationships allows the BSC to represent the company's strategy and to support managers in revising it, if necessary.

In light of what has been said, literature contributions have underlined the effectiveness of the BSC as a strategic management tool, namely a tool which allows managers to represent and to manage company strategy (Ahn, 2001; Malina and Selto, 2001; Malmi, 2001; Chenhall, 2005; Tayler, 2010). Moreover they have also highlighted the consequences that can arise when a BSC is implemented. In particular, they have focused attention on the impact seen on people's behaviours and learning (in terms of strategic focus, coordination and motivation) (Sandstrom and Toivanen, 2002; Papalexandris et al., 2004; Jazayeri and Scapens, 2008) as well as on company performance which has been analysed both in financial and non-financial terms (Speckbacher et al., 2003; Braam and Nijssen, 2004; Davis and Albright, 2004). Empirical and theoretical studies have also brought out the main criticisms that are linked to the design and, in particular, to the use of a BSC. From a theoretical perspective, it has been argued that, in many cases, it could be difficult to connect measures and to identify causal relationships among the four perspectives (Nørreklit, 2000). In addition to this, it has been claimed that the existence of a time-lag between the cause and the effect can lead to an incorrect representation and measurement of the effects of strategic decisions (Nørreklit, 2000, 2003). Moreover, scholars have also stressed the fact that one of the main criticisms concerns the need to balance the four perspectives, given that companies could be more oriented towards identifying and using measures for some perspectives (like the financial ones) rather than other perspectives in which it could be more difficult to select measures, especially because they have a non-financial nature. This is largely due to companies' inexperience with measuring their performance through the use of these kinds of indicators and consequently, to the fact that the existing company information system is sometimes unable to support the BSC implementation through the provision of an information flow.

Thus, it is clear that the BSC has attracted the attention of a large number of scholars who have focused on its different features as well as on the different contexts in which it has been implemented. Despite this great interest, only a limited number of studies have focused on the contribution that the BSC can give to the measurement of intangible assets. Two of the four perspectives the BSC is based on (customer and learning and growth), in fact, are clearly focused on some of the most relevant intangibles the companies need to manage, namely relational capital and

human capital. In light of this, a BSC could support the measurement of these intangible assets and it could also contribute to the visualisation and the measurement of their contribution to the achievement of financial results. Nevertheless, studies that have already analysed the relationship between the BSC and intellectual capital or, more precisely, the contribution that the former can give to the measurement of the latter are still scanty. In their paper, Mouritsen et al. (2005) compare the BSC and IC as performance management systems. Although they show that the BSC and IC are linked with regard to the contextual use of financial and non-financial performance, their contribution demonstrates that they clearly differ in terms of underpinning strategy which can deeply affect the way indicators are selected and interpreted. More specifically, within the BSC, indicators are put in a sequential structure of cause and effect because strategy is intended as a competitive strategy advantage, namely as a means to achieve a competitive advantage. As a consequence, indicators on intangibles need to be coherent and they have to show the contribution that intangibles can give to the financial performance. IC measurement, instead, is focused on the idea of a competency strategy. Consequently, indicators form a network around capabilities and they are not analysed in terms of cause and effects. Petty and Guthrie (2000) adopt a similar approach and they compare the BSC with some of the most relevant systems which have been studied to measure intellectual capital (like the Skandia value scheme, the intangible assets monitor and the intellectual capital account). In their article, they underline the fact that the systems share the commonality of the use of financial and non-financial indicators, although the BSC is more oriented towards the measurement of customer capital, whereas other systems are more focused on human capital. In a similar vein, Chen et al. (2004) have pointed out that the BSC is not particularly focused on human capital and so, it overlooks the relevance of knowledge management as a critical success factor for the company. In some cases, the relevance of the BSC in measuring intellectual capital has been deeply debated (Marr and Adams, 2004). What has been argued, in particular, is that the BSC is based on a distinction between information capital and organisational capital, while many scholars have classified information capital as part of the broader category of organisational capital. Secondly, the BSC is focused only on one kind of relationship, the one with customers. It completely overlooks the relationships with other stakeholders which can be relevant when measuring the relational capital of a company.

Wu (2005), instead, adopts a different approach. In her article, in fact, she suggests an integration between then BSC and IC, rather than focusing on differences between them in measurement. Through a case study, carried out in a company in Taiwan, she shows that a BSC can direct the creation, formation and measurement of IC and it can also contribute to strengthening the reporting for IC. Bose and Thomas (2007) also underline that while the BSC can be a valid tool for measuring and managing intellectual capital, it needs to be continuously nurtured and amended to reflect environmental changes. Similarly, other scholars have suggested the use of a BSC approach to measure intellectual capital or knowledge management (Fairchild, 2002).

What results from this brief literature review is that scholars have already debated the possibility of adopting the BSC to measure intellectual capital. In their works, they have shed light on the main advantages of the BSC and they have also raised important criticisms regarding the adoption of the BSC. What, up to now, has been substantially neglected are the problems that can arise when a BSC is implemented, in terms of measures that need to be selected to monitor those perspectives in which intangibles are more greatly represented, namely the customer and the learning and growth ones. Problems linked to the use of non-financial measures, in particular, have been already analysed in the literature on both management accounting systems and intellectual capital (Vaivio, 2004; Catasús and Gröjer, 2006). Despite this, contributions have not focused on the causes of these effects. This is even more important with regard to a BSC in which financial and non-financial indicators are deeply integrated and need to be calculated in order to ensure the proper functioning of the tool. The aim of this paper is to contribute to filling this gap by analysing the case study of an Italian company that has recently implemented a BSC.

3. Research method

The analysis is carried out through an interventionist case study (Lukka, 2000; Jönsson and Lukka, 2007; Suomala, 2010). The author, together with a team, was recently involved in a project concerning the design and the implementation of a BSC in an Italian company. Starting from October 2012, the team worked with the members of the company's top management to design the BSC. A series of meetings were held in which all the managers took part

and afterwards, the team met frequently with the controller and the IS manager to calculate the indicators and to put the BSC into use. Given the active role played by the author in the design and the implementation stages of the BSC, the case study will be analysed by adopting an interventionist approach. The author, in fact, was deeply involved in every stage of the BSC design and implementation, working within the company as a consultant. Thanks to his direct participation, he had the chance to know peoples' feelings about the project and to make notes of the comments made and criticisms raised by the managers during the design stage. This stage, in particular, required several meetings which were organised as workshops. During these meetings, in fact, managers had the chance to exchange their opinions and ideas about the company's strategy and to discuss them in order to identify a set of key performance areas on the basis of which it would then be possible to identify a set of measures. Following the design stage, the implementation stage was carried out by the team and the controller. In this stage, particular attention was focused on the measurement of the indicators as well as on the adaptation of the existing information system; the latter was necessary to provide the useful information needed to measure the indicators that were not already available.

Given the part played by the author and the whole team during the design and implementation stages, they could be considered "experts" in this case (Jönsson and Lukka, 2007). In fact, as academics, they were perceived as people with a deep knowledge of the topic and their role was not only that of direct participants in the BSC design. Rather, they guided the discussions among managers and fostered the convergence towards a common view of the company's strategy and of the best indicators that should be used to monitor it. Despite their role as "experts", the author and the rest of the team were not perceived as "outsiders". This, in fact, is one of the main limitations of the interpretive approach, since being perceived as outsiders could have led to a limitation of the information that people were willing to share with them (Lukka, 2000). This could have compromised the analysis, the understanding, and the interpretation of what happened on the research site. There are three primary reasons why this did not happen. First and foremost, the team was already well known by the group of managers that took part in the design stage, because they had already been consultants to the same firm when it decided to revise its management accounting system. Next, the BSC project had a very strong sponsorship by the CEO who felt very sure about its usefulness for the whole company and tried to convince all the people that were directly involved in the design stage of the same. Finally, the first meeting in which the BSC project was presented and introduced was opened by another academic who had a strong and lengthy professional relationship with the firm. As a consequence, he was perceived by people to be a trustworthy man and this inevitably favoured the acceptance of the project.

The main source of information was direct observation. During every meeting, in fact, the author and the other members of the team took notes of what people said and about their ideas and impressions. Moreover, several internal documents were analysed, as the existing information system and the information it provided at the moment in which the BSC was implemented within the organisation.

4. The company profile

The "Beta Spa" is an large-scale Italian retailer which distributes food and non-food products. It was founded in the late 1800s as a family business but, over time, it grew to become one of the biggest retailers in Central Italy. It predominantly worked as a small emporium until 1953 when the owners decided to significantly reorganize the company in a process that led to increasing the number of branches and expanding the product range to include food and clothes. In 1970, food became the core business and product quality as well as customer satisfaction became the key values for the company and the central themes of its business strategy. At the same time, new supermarkets were opened in different regions in the centre of Italy. This allowed Beta Spa to become one of the biggest players in this sector in the centre of Italy. Beta's activity is based on three different brands which correspond to different kinds of dealers. Each one is basically addressed to different customer targets and, as a consequence, each provides different products at different prices according to the specific customer needs.

Today Beta manages about 200 dealers thanks to its 2,500 workers. Its turnover in 2012 was 611 million Euros and a significant rise is expected thanks to the expansion strategy that is going to be implemented and that will lead the company to open new dealers in many different areas in Central Italy. The focus on customers' needs and their satisfaction as well as on the quality of the products and the links to local institutions have represented some of

the most important critical success factors for Beta Spa. Its strategy, in fact, is centred on these values and it is clearly formalised and communicated to every single worker within the company. Given the relevance that strategy has within the analysed company, in 2012 Beta Spa decided to start a project aimed at designing and implementing a BSC. This was done in order to allow the General Manager and top management to have a performance measurement system which would permit the constant supervision of company strategy and the critical success factors it was based on. In this perspective, the BSC was not originally thought of as a tool that could be used to monitor intangible assets. Rather, it was conceived as a tool whose primary aim was to support top management's strategic decision making as well to control results that resulted from the implementation of the company's strategy.

The project was composed of two different stages. The first concerned the design of the BSC and it involved all the managers. In this first stage, the company strategy and the critical success factors were discussed and shared among the participants in order to define the BSC architecture, namely the perspectives in which it was organised as well as the key performance areas (KPA) that needed to be monitored through selected indicators. The second, instead, concerned the implementation of the BSC, namely the phase in which indicators had to be calculated and information had to be put into the software that would allow the management of the BSC; both the team and the controller were deeply involved in this stage.

5. The design stage of the BSC

During the first stage, several workshops were organised in order to introduce the BSC, to illustrate its distinctive features as well as the reasons for which it was going to be introduced within the company. All the top managers, about fifteen people, took part in this stage. During the first two meetings, the BSC was presented and people started to become familiar with some relatively new terms like "key performance areas", "critical success factors" or "key performance indicators". According to Kaplan and Norton, this first stage is an educational phase in which the reasons why it is useful to implement a BSC and the way it should be designed must be clearly communicated to all the participants in the project. This allowed people to feel they were part of the project and to understand the contribution they were expected to give. Three other meetings were dedicated to the definition of the key success factors and to determining the most relevant ones, namely those that would be monitored through selected indicators within the BSC. According to Kaplan and Norton the BSC was applied to the four traditional perspectives: customers, internal processes, financial, and learning and growth. For every perspective, a limited number of key performance areas were identified (no more than four key performance areas for every perspective). Focusing the attention on the customer and the learning and growth perspectives, the main key performance areas were the following:

CUSTOMER PERSPECTIVE

Customer satisfaction

Customer loyalty

Cooperation with local institutions

LEARNING AND GROWTH PERSPECTIVE

HR competencies

Internal communication

Information system innovation

In the customer perspective what had to be measured, in terms of key performance areas, was the level of customer satisfaction, the level of customer loyalty and the cooperation with local institutions. Customer satisfaction and loyalty, in fact, were considered critical success factors for the company given that they were able to influence the financial performance and they represented relevant objectives for the company's strategy. At the same time, the company needed to cultivate and to develop its relationship with local institutions because this was perceived as a way to better serve its customers.

In the learning and growth perspective the topmost KPA was the level of competencies of all the people that worked in the company. Another relevant need concerned the increase in the level of internal communication. During the meetings that led to the definitive version of the BSC, in fact, top managers frequently said that a higher degree of communication among people was necessary in order to generate more coordination among the human resources. Finally, the third KPA concerned innovation in the company's information system. In particular, what was actually perceived as relevant was the need to renovate the way the company shared information about itself and its services as well as the way it kept in contact with external stakeholders.

On the basis of the abovementioned key performance areas, indicators were selected. Originally, the team operated by identifying the indicators that would allow the best measurement of every performance area. More specifically, for customer satisfaction it was suggested that a customer satisfaction index be adopted because, at that moment, there was no such index calculated in the company. Customer loyalty was measured by taking into consideration the so-called "fidelity cards", namely those cards that were distributed to customers, allowing them to benefit from special discounts for card-holders. Through these cards it was possible to determine the number of customers that went to the supermarket at least once a week and to compare this number with the total number of customers (determined on the basis of the total number of sales receipts). Basically, the underlying assumption is that a loyal customer is one who goes to the supermarket to buy something at least once a week. The quality and the relevance of the relationships with local institutions was measured through the number of projects that were activated every year with local institutions. In this first stage, the goal was to measure the company's ability to activate these relationships, rather than to look at their actual effectiveness.

With regard to the learning and growth perspective, the first performance area concerned the human resources competences. This was perceived as a particularly relevant question and the company clearly perceived the need to improve it at both the operational and the managerial level. Beta Spa was already measuring the level of competencies of their human resources, nevertheless it also acknowledged that the existing system was not completely reliable. This was due to the fact that the system was based on an evaluation made by the top managers. In other words, managers were called to evaluate the level of competences of their subordinates and, at the same time, they had to evaluate themselves through a self-evaluation. The consequence was that the level of competencies of the subordinates was always lower than that of the top managers. Moreover, the scale that was used was not considered capable of reflecting the real level of human resources competencies since it led to a concentration in the middle level and to a consequent standardisation of the final results. Despite these limitations, the company decided to adopt the abovementioned indicator in order to measure the average level of competencies of its employees.

With regard to the second key performance area, instead, it was suggested by the team that an internal analysis be carried out in order to measure, through questionnaires, the degree of information sharing among people who worked within the company. This was the key performance area for which the team had more problems in terms of measurement since it was an area which was perceived as critical for people but it was not actually monitored by the company. Finally, with regard to the last key performance area, the information system innovation, the team proposed that the company should monitor both the number and the impact of every single innovation project that was carried out. In order to do it, three indicators were suggested: the number of innovation projects that were submitted to the top managers in order to be approved, the number of projects that had been carried out by respecting the time planning and, finally, the impact of every single project in terms of benefits that it had been able to originate.

After having identified the abovementioned indicators, the design stage of the BSC was completed. The implementation stage, in fact, directly involved the team and the controller who were called to measure the indicators and to submit the final results to top management.

6. The implementation stage

The implementation stage directly involved the controller and the team. This stage is one of the most relevant and critical since it is during this stage that the BSC is put to work within the organisation. As a consequence, problems that are not normally noticed during the design can emerge and, in some cases, can lead to the failure of the BSC's implementation and use.

In Beta Spa, these problems manifested themselves and impacted on the measurement of some of the indicators that were originally introduced within the designed BSC. The existing information system, in fact, had already produced some of the information that was necessary to calculate the indicators. Despite this, when the implementation stage started it was clear that it would be possible to calculate only a limited number of indicators, in particular those that were predominantly part of the financial and the internal process perspectives. With regard to these perspectives, in fact, the existing information system already provided information necessary to calculate the defined indicators like EBITDA, ROI, rate of turnover growth, cash receipts per square meter of surface area, number of cash register receipts per hour worked, time to opening, etc. This leads to two considerations. The first is that Beta Spa did not have an information system only based on financial information, like many other companies. This was demonstrated by the fact that, in addition to the traditional financial information, the existing system also supported the provision of other information which was substantially quantitative and non-financial. The second consideration is strictly linked to the first and it concerns the company's culture which proved to be open to the measurement of particular aspects which were not directly linked to the economic or financial results. In other words, Beta Spa already perceived the importance of measuring quantitative (and non-financial) aspects of its activity. What deserves to be underlined is that there was the tendency to adopt an internal perspective which was predominantly focused on the effectiveness and the efficiency of the internal process. Information about external variables, in fact, was obtained through ad-hoc reports which were provided by a specialised company. Moreover, they substantially concerned competitors and their prices since this was perceived to be critical by Beta Spa in order to be competitive within its sector. This orientation towards the provision of non-financial information on effectiveness and efficiency, as well as the provision of financial information allowed the team to easily calculate indicators that, during the design stage, had been included within the financial and the internal processes perspectives.

Something different happened when the team started measuring the indicators which were part of the customer and the learning and growth perspectives. In this case, in fact, it clearly emerged that a gap existed since the company was not used to measuring these peculiar aspects of its activity. It is also necessary to underline that there was a significant difference between the way the two perspectives were actually perceived. In fact, the customer perspective was really perceived as one of the most critical. The customer and, in particular, his/her satisfaction was a central theme for the company's strategy, as already stated in the section dedicated to the company profile. This was also evident in the strategic guidelines that were displayed on the walls inside the company. In all of them, a huge emphasis was put on the customer and on customer satisfaction. Despite this, up to that moment, no particular indicators had been calculated in order to analyse the relevance and the strength of the company's relationships with customers. When the implementation stage was about to start, the marketing department was carrying out a preliminary customer satisfaction survey in which customers were asked to rate (from 1 to 10) some items in terms of their price-to-quality ratio and also asked to assign a score regarding the professionalism of the people that worked at the stores. By grouping together the number of customers that expressed a very positive answer (from 8 to 10), it was possible to calculate an index from which the degree of customer satisfaction was inferred. This analysis was only partially able to respond to the requests made by the team and the management accountant, since the BSC needed the measurement of customer satisfaction not only with regard to the professionalism of the workers and the economical aspect of the products, but also with regard to the degree of assortment and the quality of fresh products. Although the team tried to ask for an expansion of the existing questionnaire, the collection of data and information continued to be focused on the pre-determined topics; the reason given was that it would have been too difficult to change the questionnaire and the predisposition of the information system which had already been organised to collect and process the data on the basis of which the original questionnaire was structured. Minor problems arose with the other KPA which were introduced in the customer perspective. In this case, in fact, the existing information system already provided the information that was necessary to calculate the identified indicators. Although the latter were not already calculated, it would have been sufficient to extract data from the information system and to use it to calculate the indicators. So, in this case too, the existing information system played a relevant role in affecting measurement.

With regard to the learning and growth perspective, there were significant problems linked to measurement. As mentioned above, Beta Spa already had a system through which it measured the competence level of the company's human resources. What was being questioned was the reliability of the information that was provided by that system. The HR manager clearly stated that it was necessary to modify it in order to make it more reliable and able to express

the real level of competencies of the company's human resources. Despite this, during the meeting with the controller and the HR manager, it clearly emerged that they did not want to make any changes in the existing system, at least not at that moment. They suggested adopting the index that the system provided as a proxy for the degree of competencies, even though both of them were aware that it would not be sufficiently reliable. One of the reasons why this suggestion was put forward had to do primarily with the excessive time needed to adapt and make the existing system more reliable, thus requiring investments which, at that moment, the company could ill afford. Moreover, what was plain to see was the limited attention paid to this particular perspective of the BSC, as it was not considered to be as crucial as the other perspectives. Also, the controller very clearly pointed out and stressed the fact that problems would have emerged if a more accurate measurement of these items, linked to the level of the company's human resources, would have been suggested.

The situation was even more critical with regard to the other KPAs that were considered in the learning and growth perspective. In this case, in fact, the existing information system was not structured so as to provide information on the degree of information sharing or on the innovation of the information system and the subsequent impact. During the meetings, the team tried to underline the importance of providing this kind of information. When the BSC was designed, in fact, the group perceived these items as relevant for the future of the company. In other words, it played an important role in trying to convince the controller of the need to obtain this kind of information. Nevertheless, this was not viewed as a priority for the company. What was actually suggested by the controller was to avoid the measurement of the degree of information sharing and to adopt a proxy for the measurement of the information system innovation. Also in this case, what was proposed was to measure it through the number of new projects that were approved by top management without focusing on their impact. This indicator, in fact, was already available given that the controller constantly updated the company's Intranet by publishing every new project, together with its main features, that was approved by top management. In other words, the information provided by the existing information system was used again as a proxy to measure one of the indicators that were part of the BSC.

In light of what has been said, the implementation stage of the BSC led to a partial measurement of the indicators that were defined during the design stage. In particular, what deserves to be underlined is that the perspective in which the company experienced the most difficulties were those in which intangible assets were more present. In this specific case, the role of the existing information system was fundamental, given that it affected the measurement as well as the way measures were obtained in the customer and the learning and growth perspectives. This will be discussed in the next section.

7. Discussion and conclusions

Previous contributions on both accounting and intangibles assets have often shown that one of the main reasons for which the measurement of intangibles is sometimes problematic is strictly linked to the fact that they are normally measured through the use of non-financial indicators (Bornemann, 1999; Ittner and Larcker, 2003; Vaivio, 2004; Catasús and Gröjer, 2006, Chiucchi, 2013). The fact that companies are more accustomed to measuring their performance through the use of financial indicators can represent an obstacle for the measurement of what cannot be expressed and represented, whether in qualitative or quantitative terms. Hence, criticisms normally pertain to a limited ability to calculate non-financial indicators. What has been analysed through the Beta Spa case study is that problems can also arise when the company has a culture which is not strictly focused on the use of financial performance indicators alone. And the analysed case is even more significant since the tool which was implemented, the BSC, is a tool which leads the company to use both financial and non-financial indicators, in order to ensure an accurate measurement of the company's performance. In the case of Beta Spa, in fact, the adoption of financial and non-financial indicators was quite frequent. Before the BSC implementation, the company already used both kind of indicators to monitor its performance or specific aspects of it. This indicates that the problems the company experienced during the implementation stage cannot only be linked to the limited familiarity with the use of non-financial indicators. Rather, they lie, firstly, in the limited culture and knowledge of intangibles and their role in company performance and, secondly, in the role played by the existing information system. When the company was called to measure indicators in the perspectives which were more closely linked to intangibles (like the customer and

the learning and growth perspectives) a situation of “inertia” clearly emerged. It manifested itself through a tendency for postponing or avoiding the measurement which was justified by saying that there was not enough time and money to do it and that the resulting benefits would not be comparable to the costs that the company had to bear in order to adapt the existing information system to the new information needs. This kind of poor motivation inevitably shows that the limited knowledge of the importance and of the relevance that intangibles can have in affecting organisational performance can severely limit the attitude towards their measurement. And this is even more evident in the specific case of Beta Spa since the company did not have any problem in calculating other indicators (in the financial and the internal process perspectives) although they were not already provided by the information system at the time of the BSC implementation.

In addition to this, what deserves to be underlined is the peculiar role played by the existing information system. In Beta Spa, in fact, it was perceived and understood to be a tool from which proxies of the defined indicators would be gathered, rather than a system that was called upon to provide the requested and new information. In other words, the implementation of the BSC and the consequent need to also monitor some of the most relevant intangibles assets through it did not represent sufficient motivation to change and/or adapt the existing information system in order to make it able to provide the necessary (and new) information. It was not the “engine” that activated a revision of it. Rather, the existing system and the information it provided was assumed to be the source from which data would be collected; this data would then lead to the revision of the defined indicators, through the identification of proxies. It seems clear that in the case of the information system as well, a situation of “inertia” had emerged. However, this inertia had a considerable impact on the BSC and its implementation since it affected the measurement of intangibles by driving it towards the use of not entirely reliable information, as in the case of the human resources competences, or towards the reduction of the number of indicators through which relationships with customers and organisational learning and growth would be monitored, as in the case of the customer satisfaction index. In some cases, this inertia also led to the elimination of some indicators that were originally considered necessary to monitor some KPAs within the abovementioned perspectives. This effect, of course, is a sort of combination of effects which can be understood only in light of the limited culture on intangible assets and of the limited willingness to modify the existing information system.

The contributions made by this study are manifold. First, and foremost, it contributes to the literature on management accounting by showing some of the difficulties that can arise when a BSC is implemented (Schneiderman, 1999; Neely and Bourne, 2000). In particular, it shows that there can be a divergence between what is designed and its implementation since there are many variables that can influence the concrete adoption of a BSC. Moreover, the study also contributes to the literature on intellectual capital (Vaivio, 2004; Catasús and Gröjer, 2006; Chiucchi, 2013). It demonstrates, in fact, that problems that are normally associated with the measurement of intangible assets are not always strictly linked to the limited use of non-financial information. Rather, there is a cultural question and it is necessary to fully understand the role that habits and routines, especially those that are linked to the existing information system, can play with regard to the measurement of intangible assets. Thus, an analysis of the information system can be instrumental in providing a full comprehension of the phenomenon of inertia that can be traced back to the design and the implementation of systems used to monitor intangible assets.

CONVERTING KNOWLEDGE INTO FINANCIAL VALUE: LESSONS FROM A JOINT-VENTURE PROJECT

Abstract

In recent years, there is a growing attention on the role of knowledge within the value creation process as it is considered one of the most important factors of production for enterprises. If knowledge of an enterprise encompasses characteristics such as heterogeneity, imperfect imitation, imperfect substitutability or imperfect mobility, it creates a more lasting competitive advantage for the enterprise (Barney, 1991; Wernerfelt, 1984). The capabilities-based view also argues that the root of lasting competitive advantage is an organisation's capacity to create new knowledge (Edvinsson and Malone, 1997; Stewart, 1997). Thus, how an enterprise updates its knowledge base to bring innovation to its products, services, operation processes, management methods and strategies is a subject of urgent interest to researchers.

Knowledge creation and development processes can be internal or external. Due to the increasing level of competition that is characterizing the market and to the fact that knowledge requires time to be created, more and more companies tend to prefer acquiring new knowledge rather than developing it internally. Consequently, alliances become a strategic device useful to effectively apply and integrate the firm's knowledge resources portfolio very quickly, to build and enforce a sustainable competitive advantage (Baden-Fuller and Grant, 2004; Das and Teng, 2000; Parise and Sasson, 2002; Schildt, et al., 2005).

Enterprises can acquire new knowledge or techniques through various modes of interorganizational cooperation or alliance; these include: research contracts, licensing agreements, minority investments, equity acquisitions and joint ventures (JV). Among these cooperation or alliance modes, the deepest level of commitment and resource investment that can occur between cooperative partners is that of JV (Hyder and Eriksson, 2005; Spekman, et al., 1996). A JV can be described as an independent business entity that is co-created and co-owned by two or more legally distinct organizations (the parent organizations) that combines resources provided by partner enterprises.

The importance of knowledge flows in JVs has been attracting an increasing amount of attention from the research community. The focal point of these analyses are the relevance of the selection of the right partner, or the mechanisms, tightness and focus of JV control (Bleeke and Ernst, 1991; Gulati, 1999; Kogut, 1988; Kumar and Seth, 1998; Parkhe, 1993). Despite the importance of knowledge in JV, there are few studies concerning the role that knowledge measurements can play in JVs' context (Ordonez de Pablos, 2004; Zhao and Richards, 2012).

In accounting the adage "you can manage what you can measure" has boost the studies about how to measure knowledge (Andriessen, 2004; Guthrie, et al., 2012; Sveiby, 2004). These methods and tools underlie the idea that through measurement it becomes possible to mobilise knowledge in order to create value (Catasús, et al., 2007). More in depth, it is possible to find two main research perspectives: the static and the dynamic one. While the first perspective focuses on the stock of knowledge (static approach) in order to understand the difference between market value and book value, the dynamic perspective is centred on flows. Several scholars have highlighted that investigating knowledge dynamics allows understanding how knowledge creates value, how it works and what it does within the organisations (Kianto, 2007; Marr, et al., 2004; Mouritsen, 2006).

Studies about accounting for knowledge tend to be focused on intra-organizational knowledge, i.e. the stock and flows of knowledge created and developed within a specific organization (Chaminade and Roberts, 2003; Hensler and Huq, 2005; Mouritsen and Flagstad, 2004; Mouritsen, et al., 2001b), and therefore there is little research about inter-organizational knowledge, i.e. knowledge created and developed through cooperation or alliances.

Considering the call for investigations on inter-organizational knowledge flows, the aim of this study is to analyse a JV project from a value creation-value conversion perspective, i.e. the purpose of this investigation is to understand how the development of a JV can contribute to the transformation process of knowledge into financial capital. Within this aim, it will be also considered the role that a knowledge measurement system plays in order to support the management and control of the knowledge inflows and outflows within a JV project. In order to achieve this aim, the implementation process of an accounting system useful to control the inter-organizational knowledge flows of a parent company will be analysed adopting an interventionist research approach (Dumay, 2010; Jönsson and Lukka, 2005).

In comparison with previous studies, this one does not focus on accounting for knowledge flows within the firm but on inter-organizational knowledge flows. Moreover, due to the analysis of a case study adopting an interventionist approach, this study tries to bridge the gap between theory and practice.

The main results are as follows. First, it emerges that a JV can be considered as a value conversion device as it allows to transform knowledge into financial capital (Quevedo and Roberts, 2005). This result enriches the studies about how

knowledge creates value and how it influences the financial performance of a company showing that this process can occur not only within an organization but also between organizations. Second, within a JV development process, knowledge measurements assume different purposes and arise different accounting challenges in dependence of the phase in which the JV is (find, design or manage). Moreover, it emerges that the implementation of specific indicators allows better controlling of the knowledge inflows and outflows in order to balance them and to grasp the managerial attention on aspects of the relationships with the JV and the partner that are often overlooked.

1. Introduction

In the last decades, there has been a growing attention on the role of knowledge within the value creation process as it is considered one of the most important factors of production for enterprises. If the knowledge of an enterprise encompasses characteristics such as heterogeneity, imperfect imitation, imperfect substitutability or imperfect mobility, it creates a more lasting competitive advantage for the enterprise (Barney, 1991; Wernerfelt, 1984). The capabilities-based view also argues that the root of lasting competitive advantage is an organisation's capacity to create new knowledge (Edvinsson and Malone, 1997; Stewart, 1997). Thus, how an enterprise updates its knowledge base to bring innovation to its products, services, operation processes, management methods and strategies is a subject of urgent interest to researchers.

In accounting the adage "you can manage what you can measure" has boost the studies about how to measure knowledge (Andriessen, 2004; Guthrie, et al., 2012; Sveiby, 2004). These methods and tools underlie the idea that through measurement it becomes possible to mobilise knowledge in order to create value (Catasús, et al., 2007). More in depth, it is possible to find two main research perspectives: the static and the dynamic one. While the first perspective focuses on the stock of knowledge (static approach) in order to understand the difference between market value and book value, the dynamic perspective is centred on flows. Several scholars have highlighted that investigating knowledge dynamics allows understanding how knowledge creates value, how it works and what it does within the organisations (Giuliani, 2014; Kianto, 2007; Marr, et al., 2004; Mouritsen, 2006).

Studies about accounting for knowledge tend to be focused on intra-organizational knowledge, i.e. the stock and flows of knowledge created and developed within a specific organization (Chaminade and Roberts, 2003; Hensler and Huq, 2005; Mouritsen and Flagstad, 2004; Mouritsen, et al., 2001b), and therefore there is little research about inter-organizational knowledge, i.e. knowledge created and developed through cooperation or alliances. Due to the increasing level of competition that is characterizing the market and to the fact that knowledge requires time to be created, more and more companies tend to prefer acquiring new knowledge rather than developing it internally. Consequently, alliances become a strategic device useful to effectively apply and integrate the firm's knowledge resources portfolio very quickly, to build and enforce a sustainable competitive advantage (Baden-Fuller and Grant, 2004; Das and Teng, 2000; Parise and Sasson, 2002; Schildt, et al., 2005).

Enterprises can acquire new knowledge or techniques through various ways of interorganizational cooperation or alliance; these include: research contracts, licensing agreements, minority investments, equity acquisitions and joint ventures (JV). Among these cooperation or alliance models, the deepest level of commitment and resource investment that can occur between cooperative partners is that of JV (Hyder and Eriksson, 2005; Spekman, et al., 1996). A JV can be described as an independent business entity that is co-created and co-owned by two or more legally distinct organizations (the parent organizations) that combines resources provided by partner enterprises.

The importance of knowledge flows in JVs has been attracting an increasing amount of attention from the research community. The focal point of these analyses are the relevance of the selection of the right partner, or the mechanisms, tightness and focus of JV control (Bleeke and Ernst, 1991; Gulati, 1999; Kogut, 1988; Kumar and Seth, 1998; Parkhe, 1993). Despite the importance of knowledge in JV, there are few studies concerning the role that knowledge measurements can play in JVs' context (Ordonez de Pablos, 2004; Zhao and Richards, 2012).

Considering the call for investigations on inter-organizational knowledge flows, the aim of this study is to reflect on the role of knowledge measurement systems in order to support the management and control of the knowledge inflows and outflows within a JV project. In order to achieve this aim, the implementation process of an accounting system useful to control the inter-organizational knowledge flows of a parent company will be analysed adopting an interventionist research approach (Dumay, 2010; Jönsson and Lukka, 2005).

In comparison with previous studies, this one does not focus on accounting for knowledge flows within the firm but on inter-organizational knowledge flows. Moreover, due to the analysis of a case study adopting an interventionist approach, this study tries to bridge the gap between theory and practice.

The structure of the study is outlined as follows. The next section proposes a brief review of the prior knowledge of the basic elements of the study, followed by a description and in-depth analysis of the case study carried out. In the central part, an attempt will be made to make sense out of the case findings and to develop the theoretical arguments of the study. Finally, some valuable insights are extracted and systematised to draw some conclusions and to propose future research opportunities.

2. Accounting For Knowledge Flows In Joint Ventures: The State Of The Art

2.1 Joint Ventures And Knowledge Flows

A JV can be described as a new business entity that is created by two or more legally distinct organizations (the parent organizations). Parent organizations hold ownership interests and actively participate in the decision making activities of the jointly owned business entity (Geringer, 1991; Parise and Sasson, 2002; Park and Ungson, 1997).

The JV development process can be ideally subdivided into the following main steps:
find phase: the first phase involves determining alliance strategy decisions as well as screening and selecting potential partners;
design phase: the second phase includes structuring and negotiating an agreement with the partner and defining the partner's contribution to the JV;
manage phase: in the last phase organizations the JV starts up and is developed.

From a temporal point of view, these phases are sub-sequential multi-activity items with perfect concurrence (Ancona, et al., 2001a; Ancona, et al., 2001b) which can be mapped on a temporal frame to understand the process and the changes occurred in dependence of the time. It is also important to underline that the temporal distinction between them is not a quantitative concept but more a qualitative one because the division of the process in phases is conventional and it is important only to understand the changes and the different activities carried out by the management. It is essential to point out that as the phases are sub-sequential it implies that each phase influence the following. Moreover if a phase does not end with the expected result it can happen that the single activities of each step have to be repeated. For example, if the JV in the manage phase does not achieve the planned result it may happen that a new JV has to be developed with another partner and then the design phase may start for the second time.

Within the development process of a JV, specific flows between the parent companies and from and to the JV can be identified as transfer, transformation and harvesting (Berdrow and Lane, 2003; Harrigan, 1988).

“Transfer” is the migration of all or part of the existing resources between partners in the JV and between the partners and the JV itself. As mentioned above, JVs can be considered a strategic means to access resources, which are not widely distributed or exploited, providing opportunities and the potential for value creation. The quality and quantity of these flows depends on several variables such as the previous relationships existing between the partners or the provisions contained in the agreement signed by the partners: in the agreement, in fact, the resources to transfer, the timing of the transfer and the adopted techniques to realize the transfer are usually described in detail.

“Transformation” is the phase that develops inside the JV and it can be defined as the integration, implementation and leveraging of the resources transferred by each partner to the JV to create new resources which are the result of the JV activities. In other words, transformation takes place in the manage phase, when the JV starts working and the resources are combined to generate value. The quality and quantity of this flow depends on the attributes of the resources transferred and on the activity developed jointly by the partners and by the JV management.

Finally, “Harvesting” involves flows from the JV to the partners where they can be applied in other internal or external activities. This flow exists in any kind of JV, even if they are not planned (Baden-Fuller and Grant, 2004). In fact, it usually takes place during the manage phase, in a more or less explicit way, when the partners, through certain activities such as imitating or acquiring the resources transferred by the other partner, can apply these resources to their own situation. So, this last flow can be considered an effect of the harvesting. The quantity and quality of the harvesting flow depends on how intensively each partner takes part in the JV management.

2.2. Accounting For Knowledge

According to the adage “you can manage what you can measure” there is an increasing interest in measuring knowledge. In the literature it is possible to find several measurement frameworks and guidelines (Andriessen, 2004; Giuliani and Marasca, 2011; Sveiby, 2004). The idea of these models is to make the contribution of knowledge to the value creation process visible and understandable and, consequently, manageable.

More in details, it seems that two different (although related) perspectives on knowledge dominate (Brännström, et al., 2009; Brännström and Giuliani, 2009).

One perspective, that can be named as “static”, focuses on measuring the value of knowledge (Boeker, et al., 2005; Fincham and Roslender, 2003). The static perspective seems to spring from the fact that the capital market has valued the firms’ equity (much) higher than the book value (Edvinsson and Malone, 1997; Sveiby, 1997). Consequently, studies are oriented in visualising knowledge resources, in drawing their boundaries and in measuring their value in a specific moment. The main research questions are what knowledge is and how to measure it in order to increase its level and to report the overall value of the company. Here, knowledge is often assumed as something that can be relatively easily identified, located, classified, measured and, valued as any other resource. Consequently, the translation of knowledge into numbers is central in this accounting approach and the focus tends to be in developing indicators, classifications, methods and tools able to capture the stock of knowledge that belongs to a company in a specific moment in time. The main critiques of this approach are that it is not able to support a complete understanding of knowledge, its measurement and that the reporting models are mainly backward looking rather than future oriented and, finally, it concentrates the attention of the management and stakeholders on what a company owns rather than on how it uses its knowledge resources to produce superior performance.

The other perspective is instead centred on the dynamic aspects of knowledge (Fernstrom, et al., 2004; Giuliani, 2014; Meritum, 2002; Mouritsen, et al., 2001b). This perspective is also called as “dynamic”. According to Kianto (2007), three different conceptions of “dynamic” can be found in literature.

From the analysis of the extant literature, it seems that there are three main conceptions of “dynamics” that can be found (Kianto, 2007). The first one refers to the value creation process and, consequently, it focuses on the interactions and combinations among resources. This conception is centered on providing information concerning which resources can be used as levers to create value. Therefore, knowledge becomes a phenomenon of interactions, transformations and complementarities; consequently, it can be understood by focusing not only on the knowledge resources but also, if not mainly, on their contribution to the value creation process and the development of sustainable advantages (Cuganesan, 2005; De Santis and Giuliani, 2013; Edvinsson, 1997; Giuliani, 2013; InCaS-Consortium, 2008; Ling, 2012; Mouritsen and Larsen, 2005; Roos, 1998; Skoog, 2003; Wiig, 1997). The second interpretation of knowledge dynamics is related to creation and development activities. According to the Meritum Project (2002), these activities are the ones undertaken to acquire or internally produce knowledge resources, to sustain and improve existing ones, and to measure and monitor them. This dynamic nature means that knowledge has to be used and combined with other resources in order to create value (Giuliani, 2013; Marti, 2001; Meritum, 2002; Mouritsen, 2009; Mouritsen and Larsen, 2005). The last and third view is the one that matches the idea of dynamics with that of change. More in depth, knowledge enables a company to learn and to innovate and consequently to change proactively in order to survive in spite of the turbulent environment. Thus, it is important to study how knowledge changes over time, the sources and the processes of the change (Arenas and Lavanderos, 2008; European-Union, 2006; Giuliani, 2009; Green, 2006; InCaS-Consortium, 2008).

Although different in scope, these two accounting perspectives (static and dynamic) are linked together for at least three reasons. One, they evolve around the same practice: how to recognize, measure and report knowledge. Two, they both refer to the value creation dynamic: how to manage knowledge (i.e. the managerial perspective) so that potential value becomes realized value (i.e. the realization perspective). Three, the perspectives are based on a critique of “traditional” accounting (i.e. a critique of both management control models and financial accounting regulations), which are not compatible to knowledge firms.

Knowledge measurement models are mainly designed to visualise, understand and manage intra-organizational knowledge flows while they tend not to focus on the fact that knowledge flows can also occur between organizations, such as within the parent companies and their JV, and they also need to be controlled. In fact, while

there is a consolidated debate about inter-organization accounting in terms of how to account for costs and benefits of an alliance (Agndal and Nilsson, 2009; Coad and Cullen, 2006; Mouritsen, et al., 2001a; Van der Meer-Kooistra and Scapens, 2008), there is very little literature that considers how to account for knowledge. Thus, this study aims to do just that, to analyse the contribution that accounting can offer in managing a JV development process where knowledge plays a primary role.

3. Design Of The Study

In order to achieve the aim of this study a case study referred to the design and implementation of a system for measuring and reporting knowledge within a JV project is presented. The case study method was considered appropriate for finding elements, dimensions and events that are important and that have not been adequately considered into the accounting models, in general, and into the measurement of knowledge, in particular. Thus, this approach allows achieving a potential discovery of new conditions and interactions that are important for understanding the construction of time within organisations (Yin, 2003).

The actual research project was undertaken using an interventionist approach (Jönsson and Lukka, 2005; Lukka, 2005). This is based on a collaborative process between the researcher and client, with critical inquiry into problems of social practice in a learning context (Argyris, et al., 1985, p. 237; Coghlan and Brannick, 2001). The interventionist approach was chosen because it allows scientific research and innovative practical solutions to be developed (Kaplan, 1998; Kasanen, et al., 1993; Labro and Tuomela, 2003). Moreover, it offered the possibility, to the researchers participating in the project, to achieve an in-depth knowledge of the context, the variables and the process under analysis. Finally, the interventionist method has been chosen because, in accounting studies, in general, and in the literature about knowledge measurement, in particular, there is a strong call for case studies developed with this methodology in order to test and observe in practice concepts, methods and tools (Chiucchi, 2013; Dumay, 2010; Giuliani, 2009; Giuliani and Marasca, 2011; Guthrie, et al., 2012; Marr and Chatzkel, 2004), thus contributing to filling the gap between theory and practice and to enhancing the relevance of management accounting studies (Jönsson and Lukka, 2005).

It is also important to underline that the case study is examined from a longitudinal perspective. Since the interest lies in the design and implementation of a measurement framework, it is important to analyse the evolution of the process over time in order to properly interpret the collected evidence.

Alpha was deemed an appropriate subject for this study for the following reasons. First, Alpha's management is focused on knowledge: they strongly believe that the company can compete and survive in the market only by creating value-added products, and that this is only possible using its knowledge as a lever. Second, Alpha was the parent company that had to transfer to the JV its knowledge about design and production processes and part of its customer list while the other partner was called to transfer only tangible assets. Third, the company was interested in a long-term cooperation with the university researchers (Kasanen, et al., 1993; Labro and Tuomela, 2003) and consequently, it was an opportunity to understand and investigate the measurement and valuation process 'in vivo' or 'in practice' instead of merely 'in vitro', as usually happens (Dumay, 2013).

Data were collected from multiple sources such as annual reports, stakeholder impact reports, internal strategy reports, and semi-structured interviews. More in depth, the largest amount of information had been collected taking part to the focus group, promoted by the CEO and formed by the researchers, the CFO, the area managers, the purchase manager, the R&D manager, the production manager and the CEO himself. The purpose of the focus group was to design and implement some indicators dedicated to monitor the transfer flows from and to the JV. The focus group meetings were based on a semi-structured agenda proposed by the researchers and initially discussed with the CEO and the CFO, modified and then put into action. As planned, six meetings of about two hours each were carried out together with some meetings with the CEO and the CFO and some interviews with single members of the focus group and with some employees. Based on the specific requests of the focus group, the researchers supported Alpha's management in coordinating the discussions useful to design and implement the indicators. More details regarding the activities carried out by the researcher are illustrated hereafter.

4. The Case Study

Alpha is a medium manufacturing firm and an important European player in die-casting zinc and aluminium alloys and related activities for the production of gas burners and components for the automobile and household appliance industries. The company is composed of three Business Units: the first is dedicated to the contract co-design and production of household appliances for other companies; the second realizes its own designed and branded burners; the third is devoted to the contract co-design and production of automotive and technical parts (e.g. parts for gear boxes, car heaters, etc.)¹. In order to set foot in international markets, the company has created branches in USA and Romania. At the time of this research the company wanted to create new braches also in other countries in order to expand its market and to have branches close to the headquarters or the subsidiaries of its main customers. In fact, proximity to customers was considered a source of competitive advantage as Alpha would have been able to deliver its product in a shorter time and to “control and defend” its customers from the attacks of Alpha’s competitors, both local and international ones.

A quality management system -from die designing to manufacturing stages -is applied to make sure high quality standards are met in all of the Group’s facilities. The company’s production process is based on a continuous improvement philosophy: the organisation claims that it continually seeks to improve the level of quality, service and performance and reduce the amount of mistakes made to lower waste and production costs. The manufacturing process follows certified protocols for continuous quality monitoring. In order to put this continuous improvement approach into action, the company has implemented several managerial systems (such as management control systems, cost accounting systems, incentive plans, etc.) useful to monitor, control and develop the strategic processes.

The company is family-owned and the board of directors is formed by the father, who is president and CEO, the son and an external member who is the previous business consultant of the company. While the latter visits the company only for the board meetings, the father and the son work full time in the company. Most of the decisions are centred on and finally made by the CEO. At the organizational level, a significant role is also played by the CFO who is the CEO’s ‘right arm’; he not only takes care of collecting and producing all the information the CEO needs in his decision-making, but he also acts as the liaison between the CEO and the organization. The CEO and the CFO cooperate so closely, that it is possible to say that the company reflects their managerial styles.

Due to this managerial dualism, the company is managed by numbers, i.e. the CEO strongly relies on the numbers and reports that the CFO produces for him; consequently, the accounting system plays a relevant role in company management. The management accounting/control system adopted by Alpha is based on financial (e.g. turnover, production costs, quality and non-quality costs, etc.) and non-financial indicators (e.g. number and value of the orders, number of mistakes and amount of waste etc.). Within this system, the information relating to time is particularly relevant.

The mission of the company is represented by the willingness to become a trustworthy partner of its customers able to support their objectives through relentless technological research and innovation and paying great attention to functional, ergonomic, safety and codesigning aspects. To achieve that mission and maintain its competitive advantage the firm heavily invests on R&D, technical know-how, development and, last generation technology.

The JV project was promoted by Alpha to be able to follow and supply the subsidiaries created in Brazil by its main customer (a multinational company) and consequently to avoid the risk that some important competitors would enter in their rose of suppliers. Moreover, through this strategic device, Alpha would be able to access to a new growing market where die-casters have not the same level of competences, product and process quality and relationships with important players as Alpha.

In consequence of the aim of the JV, Alpha decided to propose to the potential partners a JV in which its main contribution would be mainly represented by knowledge such as market relationships, technical knowledge and production processes while the partner’s contribution would consist mainly in money and tangible capital.

First of all, the Alpha management started mapping the knowledge of the firm.

“We want to show to our potential partner what we have, our competences, our technical processes and our relationships... that is what makes the difference between us and the others...” (the CEO)

In order to accurately identify the resources to transfer a qualitative approach based on direct observation, through semi-structured interviews and data-analysis of company archives, was performed. Even some interviews to the main customers were of help to the management to understand the origin of the “plus” they recognize to Alpha.

In particular, at first the management of Alpha tried to identify the sources of its competitive advantage, i.e. the firm dimensions in which Alpha had an outstanding position in comparison to the whole market and to the companies operating in the Brazilian market (e.g. co-design competences, maintenance competences, relationships with multinational companies, etc.).

Moving from these elements, the management of Alpha discussed about the resources (knowledge, technology, etc.) that can be considered as necessary to create and maintain this competitive advantage. For example, in order to create and maintain the co-design service with the actual quality standards there was the need to have specific design competences, a database containing the information about the previously developed design projects and specific technology (PCs, software, etc.). This cause-and-effect approach was used to identify the resources moving from the identified sources of competitive advantage. The mapped knowledge resources were then classified to have clearer visualization (see table 1).

TAB. 1 -ALPHA KNOWLEDGE RESOURCES

Human Capital	Organizational Capital	Relational Capital
-Design and co-design competences - Die-casting competences -Production competences -Managerial competences -Language competences -Relational competences -Loyalty -Quality of the workplace relationships	-Procedures -Manuals -Database - Strategic Software -Organizational processes -...	-Relationships with prestigious customers -Relationships with customers who generate relevant profits -Relationships with other customers -Brands -...

More insights about some of the mapped resources are reported hereafter. Regarding human capital, the Alpha has developed a very specific and innovative design process, named “co-design”, that requires the active involvement of the customer in the design process and a specific know how of the Alpha’s designers. This process allows to limit the risk of making mistakes in the design process, to reduce the time of the design step and thus to save money. Moreover, regarding organizational capital, Alpha has created a database with all the projects developed with related notes, mistakes, solutions, etc. that allows the designers to have a structured knowledge about what to do and what not to do. Another specific resource was software created by Alpha useful to control the production process and to allow the customers to have real-time information about the processing of their orders. With reference to relational capital, Alpha is the exclusive or main supplier of some multinational companies that are difficult to acquire without developing an alliance with Alpha or starting a tough competition with Alpha itself.

From the mentioned list of resources, Alpha identified the ones that it was willing to propose and, in case, transfer to the JV and to the partner. The choice of the transferable knowledge was done balancing the need to transfer valuable resources interesting for the partner with the need to not disclose all the sources of the competitive advantage of the company, i.e. Alpha had to manage a trade-off between value and risk.

“We cannot disclose all our secrets, the sources of our competitive advantage because that will be too risky in case of failure of the alliance...” (the CEO)

After discussions, it was decided to propose to the potential partner to contribute to the JV with production competences, production processes and its relationships with prestigious customers. So, after having visualized its knowledge resources and defined the ones ideally transferable, Alpha started the selection of the partner.

Due to the fact that the JV would be mainly developed to supply Alpha’s existing customers and to have access to a new market, it was important to find a partner whose resources were useful to “replicate” the production process developed in Italy and whose commercial capital (relationships with customers, brands, etc.) had potential to be increased.

“We need to know if our knowledge is compatible with the one of our partner and with its equipment otherwise the JV will not work properly... its employee should be able to work according to our procedures, with specific equipment and to maintain the customer relationships we are going to transfer” (the CEO)

Consequently, the analysis of the partner resource portfolio was mainly focused on its technological equipment, IT, location, organizational structure and characteristics of its human resources (age, functions, competences, etc.). The idea was to find a partner whose tangible assets could be “easily” combined with the ones of Alpha in order to create value. The focus on the human resources was due to the fact that Alpha wanted to estimate if the employees of the partner would have been able to learn and apply new processes, techniques, etc.

As it would have been too complex to collect, interpret and compare correctly data related to the intangible aspects of the potential partners, the management decided to focus mainly on tangible resources.

“We can try to ask for specific measurements regarding processes or customers but we cannot be sure that they will be reliable and how we should interpret them... to be sure they should allow us to calculate them” (the CFO).

As mentioned by the CFO, the complexity of the measurements was related to their reliability, to the lack of a generally accepted way of calculating specific indicators (e.g. level of competences, etc.) and, in some cases, to the lack of data (for example some partners did not have specific technical information about the production process).

In base of the collected information and of the meetings carried out with the potential partners, Alpha made its choice. More in depth, Alpha made a first selection and identified,

among the list of the potential partners, 3 “finalists”. Then Alpha started a more in-depth analysis of these three potential partners in order to understand their peculiarities, their contribution to the JV, their expected return and their knowledge resources. This analysis was carried out through meetings with the CEOs and CFOs and collection of data from databases, internet, press, customers, middlemen, etc.

After the choice of the partner the design phase began. It is important to remember that in this step the focus of the analysis moves from the inter-partners transfer flows typical of the find phase to the transfer flows between the parents and the JV. Regarding the case study, we remember that while the flow of the Brazilian firm is represented by financial and tangible capital, the Alpha’s one consists in specific knowledge.

The definition and the negotiation activities imply, both for economic and juridical reasons, a precise definition of the quantity and quality of the transferred capital. The definition of qualitative and quantitative aspects lead, in this step, to a detailed description of the capital transferred and to a financial expression of the value of the assets, which is fundamental for the interpretation and comparison of the qualitative-quantitative aspects of the items transferred by each partner (tangible and/or intangible assets) and consequently defining the quote of equity of the JV that belongs to each of the parent companies.

In defining the value of the knowledge contribution of Alpha, the knowledge flows from Alpha to the JV had to be examined analytically. In particular, there was the need to identify the concrete benefits that this knowledge transfer would have brought to the JV and the process that Alpha had to carry out to realize the transfer itself, i.e. Alpha had to define when and how developing specific activities (e.g. training sessions) useful to create a specific knowledge within the JV.

“We do not have to pay anything to our partner in monetary terms but we have to pay the costs related to the fact that some of our employees have to go to Brazil to teach how to use a specific machine or to approach one of our customers... We have also to make the benefits of our contribution clearly visible to our partner...” (the CFO)

Once reached and signed an agreement with the partner, the JV was formed and started up. It means that the third phase, the manage one, began. In this phase, Alpha developed the planned training activities to transfer and implement production competences, commercial capital and procedures.

The combination of the resources (tangibles and knowledge) transferred to the JV leads to the generation of the knowledge transformation flow. Almost simultaneously to the creation and development of the knowledge transformation flow, the parents had the opportunity to use, for their other production processes and/or for different markets, some of the knowledge generated in the JV, acquiring it through their employees who worked in the JV.

Due to the relevance of these flows, there was the need to monitor and control them with specific indicators. In this section, only some of the indicators are the objects of comment. Attention is focused only on those held to be the most suitable to understand how the flows from and to the JV were monitored. In order to do that, the Meritum

tri-part model was adopted to classify the indicators. Thus the panel was divided into human capital, structural capital and relational capital and in each category the inflows and outflows for Alpha were considered.

TAB. 2 -ALPHA'S JV INDICATORS

	Human Capital	Organizational Capital	Relational Capital
KNOWLEDGE INFLOWS	-Level of managerial/language/technical competences of employees involved in the JV -...	-Data input in Alpha's database -...	-Economic benefits generated for Alpha by the JV -Relationships activated by Alpha through the JV -...
KNOWLEDGE OUTFLOWS	-Hours of training to the employees of the JV -Costs of training to the employees of the JV -N. of inspection in the JV -...	-Index of usage of the intranet/software -Index of shared usage of spaces -...	-Number and value of the orders transferred by Alpha to the JV -Investments in marketing activities carried out by Alpha with benefits for the JV -N. of meetings with the partner -...

As for the human capital, regarding the benefits for Alpha the idea was to monitor the increase of the level of specific competences in the employees of Alpha involved in the JV as it was expected that they would acquire new skills or develop their language or managerial competences. On the other hand, to be part of the JV Alpha had also to transfer knowledge and consequently it had to monitor all the training activities carried out.

Regarding the organizational capital, it was interesting to monitor the level of system integration of the JV with the firm. This cause the implementation of an indicator related to the usage level of the intranet created between Alpha, the other parent and the JV: the idea was the more the intranet is used the more integration exists. The same thought leads to the definition of an indicator that should represent the logistic integration that is to say the shared use of specific place such as warehouses, show rooms, etc.

Lastly, in the section related to the relational capital the benefits generated by the JV (mainly financial capital flows as dividends, extra sales, cost savings for economy of scale, etc.), its volatility and the activities developed to the JV have been monitored.

5. Discussion And Conclusions

Considering the call for investigations on inter-organizational knowledge flows, the aim of this study is to reflect on the role of knowledge measurement systems in order to support the management and control of the knowledge inflows and outflows within a JV project. In order to achieve this aim, the implementation process of an accounting system useful to control the inter-organizational knowledge flows of a parent company will be analysed adopting an interventionist research approach (Dumay, 2010; Jönsson and Lukka, 2005). As aforementioned, here the analysis is focused on the perspective of one of the parent companies.

The first result that emerge is that a JV can be considered as a value-conversion device as it allows to transform knowledge into financial capital (Quevedo and Roberts, 2005). In fact, Alpha transfers its knowledge to the JV (directly) and to the partner (indirectly) and obtains financial capital (dividends and other economic benefits from the JV). While on studies regarding single organizations this value-conversion phenomenon tends to be difficult to identify and quantify and therefore some argue that it can be just a “grand theory” (Dumay, 2012), in a JV it is visible and it can be visualised in a easier way. Figure 1 provides a representation of this phenomenon studied in Alpha where knowledge flows (K flows) and financial capital flows (FC flows) are indicated.

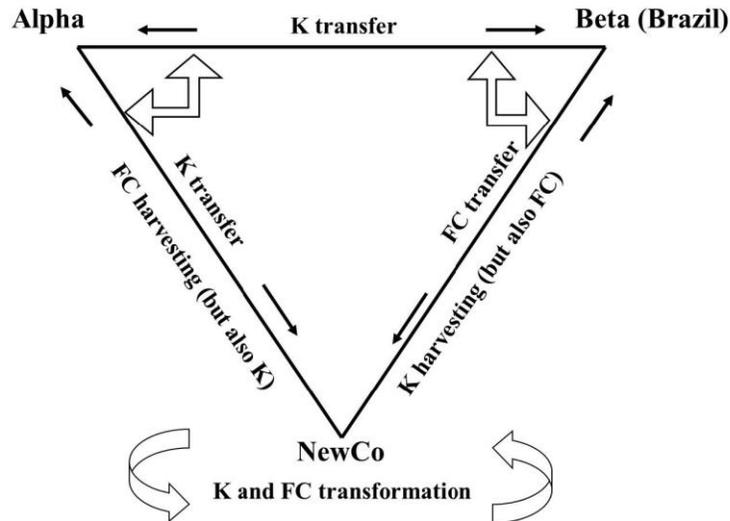

FIG. 1. VALUE-CONVERSION IN JVS.

This result enriches the studies about how knowledge creates value and how it influences the financial performance of a company showing that this process can occur not only within an organization but also between organizations and in this case the link between knowledge and value is not invisible but clearly visible and measurable.

Regarding the role of knowledge measurements within a JV development process, it requires to focus on each of the mentioned phases.

The first phase of a JV development process involves making alliance strategy decisions as well as screening and selecting potential partners. Measuring knowledge is first useful to understand whether the resources, which belong to the potential partners, are useful for achieving the success of the JV. In other words, it is important to understand if and how the knowledge of a company can be combined with the tangible and financial ones of the other company in order to create value. In fact knowledge creates value through interactions and connections and consequently they have to be possible in order to achieve the expected outcomes from the JV. The accounting problem that has to be solved regards how to represent this with numbers. The solution adopted by Alpha was to combine numbers with narratives in order to grasp the phenomenon under investigation as numbers per se were considered to be not understandable.

In the design phase, measuring knowledge is important to define the knowledge transfer flows. In fact it is in this phase that the partners define their capital contribution. Measuring knowledge is helpful to the JV participants to support and complement the financial valuation, which is fundamental in this phase because it allows for the interpretation and comparison of the quali-quantitative aspects of the items transferred by each partner (tangible and intangible assets). Moreover, a set of indicators which shows some of the qualitative and quantitative characteristics of the knowledge can be helpful in rounding out the information on the economic value of the transfer by highlighting some aspects which could otherwise be overlooked in the analysis and which are, instead, relevant to the future performance of the joint venture. For example, information concerning the number of customers, the solidity of the

relationships, the level and type of competences, the updating of software and databases and so forth are essential in order to fully comprehend the reciprocal coherence and adaptability of the resources brought in by the various partners as well as the potential contribution these resources will make to the success of the joint venture.

In the manage phase measuring knowledge allows monitoring the relationships both with the JV and with the other parent company. While there are several studies regarding the financial impacts of a JV on a company, there is only little research on the intangible impacts and on how to account for them. Alpha developed specific indicators for monitoring the knowledge flows from and to the JV and from and to the partner. In other words, these measurements involved not only the knowledge transfer and transformation flows (outflows) but also the harvesting flows (inflows). For example, a variation of the level of the competences of the partners' human capital can be related to the activities jointly developed by the parent companies' and the JV's personnel; an increase in the contents of a parent's database can be due to its integration with the one owned by the JV. Moreover it emerges that in order to monitor alliances it is not enough to focus only on the relational dimension of knowledge (relational capital) (Ordóñez de Pablos, 2004) but it can require a specific analysis also of human capital and structural capital and that specific indicators have to be implemented in addition to the most common knowledge-related ones (Ordóñez de Pablos, 2002).

In all, within a JV development process, knowledge measurements assume different purposes and arise different accounting challenges in dependence of the phase in which the JV is (find, design or manage). Moreover, it emerges that the implementation of specific indicators allows better controlling the knowledge inflows and outflows in order to balance them and to grasp the managerial attention on aspects of the relationships with the JV and the partner that are often overlooked.

Regarding limitations of this study it may be argued that they are related to the methodology adopted. In fact, some may argue that in action research projects the researcher can potentially influence the context under examination and be subjective in the analysis

(Middel, et al., 2006). In this case, even if the researchers took part in the process it was mainly for scientific and methodological support, according to the modest interventionist approach, and therefore the observed reality was not influenced and their perception of it was not altered or too subjective, considering the limited number of activities carried out (Middel, et al., 2006). Another limitation is related to the fact that this study focuses only on one of the actors of a JV and not on all of them. Even if this does not allow having a complete picture of the phenomenon, it allows having more details about the point of view of a parent company.

The findings provided by this research could be useful to those interested in analysing knowledge flows within JVs and the contribution that accounting can offer to visualise, understand and control them. Moreover, this study contributes to the discussions about knowledge dynamics offering not an intra-organizational perspective but an interorganizational one. Finally, this can represent an incentive for developing accounting systems useful to explicitly account for knowledge in JVs.

Future research opportunities can be found in more empirical studies with the ambitions to analyse more in depth how to account for knowledge in JVs and how measurements can influence the development of the JV.

Family Ownership Structure and Firm Value (Case study on Big-Cap Public Companies)

Abstract

Some previous researches proved the positive association between family ownership and firm value or companies' performance. Contrary with these results, Jiang and Peng (2011) found that Indonesia is one of the country in which family ownership structure has a negative association with firm value. Moreover, Claessen et al. (2000), stated that as of 16.6% of Indonesia's public companies are controlled by a single majority shareholder. Claessen et al. (2000) also stated that higher entrenchment occurred in Indonesia together with Philipina and Thailand. Besides that the low law enforcement and the lowest corruption index in Indonesia (Jiang & Peng 2011), add opportunity to the majority to expropriate the minority. Therefore, this research aims to prove that there is a negative association between family ownership structure and firm value in which negative entrenchment of the majority to minority exists. This study shows that family ownership has a significant negative effect on firm value at significance level of 10%.

Keywords: family ownership structure, firm value, negative entrenchment effect, expropriation

Introduction

Family ownership structure has become as one of the interested topics to be studied, particularly its effects on firm value. Villalonga & Amit (2006), Maury (2006), Jiang & Peng (2011), Barontini & Caprio (2005), Anderson & Reeb (2003), Claessen et.al (2000) are some of the researcher that actively studied this topic. Villalonga & Amit (2006) examined whether family ownership, control and management, influent firm value. By using the company's data-Fortune-500 companies, during the years 1994 to 2000, Villalonga and Amit (2006) found that family ownership creates added value if the founder acts as the CEO or the Chairman of the Board of Commissioners with CEOs recruited from outside.

Maury (2006) conducted a study to examine how the performance of a company controlled by the family (family-control) compared with companies that are not controlled by the family in 1672 non-financial companies in the region of Western Europe. The study ojective was to confirm the existence of control by the family, whether the performance of the family control better than non-family control, given the diversity of the various results of previous studies. The results showed that family-controlled companies is positively associated with higher performance than companies that are not controlled by the family.

Jiang and Peng (2011) observed whether the family ownership and control play an important role in major companies in Asia. since there is still a puzzle regarding the association between the family ownership concentration and control on the one hand and performance on the other, whether good, bad or not related. The study was conducted on 744 large public companies in eight Asian countries. The study was designed in two studies, Study I and Study II. The study II is study I added with a variable level of investor protection. The results of the study I showed that the existence of the family as the CEO is positively related to performance, supported by two countries. i.e Indonesian and Taiwan. The study II exhibited that the presence of the family as the CEO is positively associated with performance in the countries with low level of investor protection. Further, the existence of pyramid ownership on the contrary, was positively related to performance in countries with high levels of investor protection as supported by Hongkong, Malaysia and Singapore, except Indonesia and South Korea.

This result enhanced the previous research and provided better explanation on the diversity of the research related to whether family ownership contributes benefits to the performance of the company. This study successfully demonstrated that the supremacy of law in each country as shown by the level of investor protection is the useful factor to distinguish the presence or absence of a family control to the company's performance. It also entailed that the state is not always neutral in the relationship between family ownership and performance.

Barontini & Lorenzo (2006) searched 675 companies in eleven countries of Continental Europe. The purpose of the study was to investigate the association of ownership structure, firm value and performance. The

study indicated that family ownership structures did not decrease firm value and performance. The existence of company's founder control and the presence of descendant in the board of director were significantly affect firm value and performance. However, if the descendant as CEO, the company's value and performance were not different from non-family corporate ownership. The results are in line with the findings of several previous studies that family ownership is positively related to the performance and firm value. However, care should be taken in interpreting these results due to several factors that have not been anticipated in the test, such as the level of investor protection as conducted by Jiang & Peng (2011).

Anderson and Reeb (2003) examined the relationship between the family as the founding family, ownership and corporate performance in the 403 companies included in the S & P 500, for period 1992 to 1999. The results denoted that the performance of firms with founding family firm is much better than with nonfounding family firm. Based on further analysis, it was found that the relationship between the founding family firm performance is nonlinear, family CEO has better performance as compared to non-family CEO. Overall these results reject the agency hypothesis, in other words, family ownership is an effective ownership structure.

On the other hand Demsetz (1983) argues differently, that concentration of ownership is the result of a decision to maximize the profit made by the shareholders at this time, therefore there is no effect on firm value. Some research supports Demsetz, (Demsetz & Lehn 1985; Himmelberg et.al 1999); Demsetz & Villonga 2001). Claessens et.al (2000), specifically stated that Indonesia is a country with concentrated ownership, 16.6% of the total listed companies as a public company controlled by the family as a sole proprietor. Meanwhile, Jiang & Peng (2011) said that the level of rule of law in Indonesia is relatively low at 3.98 and has the lowest corruption index among the countries in the East Asia region, ie 2.15, implied that the level of investor protection is very weak. In such condition, the family ownership has a big opportunities to expropriate minority shareholders.

It is therefore interesting to study further in the context of Indonesia, where the level of investor protection is weak and corrupt, to prove allegations that family ownership does not have a positive impact on firm value due to agency conflicts between owners actually exist, the latter, this study once wanted to confirm the results research Jiang and Peng (2011), that in Indonesia, the presence of family ownership negatively affect performance

Theoretical review and hypotheses development

Family Ownership and Firm Value

The definition of a family firm or a company extensively owned by family, including (1) the company of one or more family members are as a director or board of directors or a majority shareholder, (2) a company that at least one of its members on the board of commissioners or management, (3) the company's largest voting rights or number of shares owned by the largest families, (4) the company's second generation of one or more family members are as management or directors, and so on (Villalonga & Amit, 2006).

Family firms have advantages compared with non-family companies, which can overcome the agency problem between owners and management. Berle & Mean (1932), Fama & Jensen (1983) supports that the presence of family ownership in the company can resolve agency conflict between owners and management, because the owner has an interest to oversee management to ensure management actions that do not conflict with the interests of owners. On the other hand, a tight family ownership may create agency problems between majority shareholders and minority shareholders (Shleifer & Vishny, 1997).

A number of studies have shown that the market appreciates firms with family ownership (Barontino dan Caprio 2005; Villalonga & Amit 2006; Anderson & Reeb 2003; Ying & Peng 2010 dan Maury 2006). The results of these studies demonstrated that family ownership structure is positively associated with increased firm value. But Anderson & Reeb (2003) noted that it is occurred, especially in countries that have well-established economic regulation. In countries with a low level of transparency, the presence of family ownership actually cause expropriation risk to minority shareholders. Furthermore, Maury (2006) warns that in countries with a low level of transparency, increased profitability can not be transferred into higher firm value.

Leemon & Lins (2001), revealed that companies's Tobins'Q in Asia where expropriation against minority shareholders exist, has declined an average of more than 12% compared to other companies. Meanwhile Claessens,

Djankov, Fan, and Lang (2000) stated that high expropriation occurred in countries such as Indonesia, the Philippines and Thailand, while in the countries of Malaysia, Singapore and Taiwan, there was evidence of expropriation. As it is known that Malaysia, Singapore and Taiwan have a higher level of investor protection than Indonesia, the Philippines and Thailand.

According to Claessens et al. (2000), Indonesia is a country with concentrated ownership, in which 16.6% of the public companies controlled by the family as a sole proprietor. Moreover, with the low level of law, at 3.98 and the lowest position of corruption index among the countries in the East Asia region, i.e 2.15 (Jiang & Peng 2011), also indicated that the level of investor protection in Indonesia is still very weak. It has provided a great opportunity for the majority to expropriate the minority.

In the Indonesian context, where the level of investor protection is weak and corrupt, then the ownership of the family actually increase the risk of expropriation of the minority shareholders or known as the agency conflict II. With the enactment of Law 40 of 2007, the rights of minority shareholders has indeed been accommodated, but these rights don not directly reflect a legal protection of minority shareholders. It is recognized that a perfect legal protection to minority interests according to the principles of good corporate governance is still hard to apply in Indonesia (Priyatna 2012).

There are two approaches used to explain the possible behavior chosen by the controlling shareholder (Siregar, 2007) which is a positive incentive effect (PIE) and negative entrenchment effect (NEE). Although both of these approaches are built by assuming the presence of excess control rights is the difference between control rights and rights to dividends (Jensen and Meckling, 1976; Shleifer & Vishny, 1997), but it is still relevant to explain the possible behavior of family ownership as the holder of significant control. PIE assumed that controlling shareholder has an incentive and huge capacity to observe management intensively, thereby increasing the company's value and lower the cost of equity. On the other hand, NEE argue that controlling shareholders will take advantage of its large capacity to undertake actions for personal gain at the expense of minority shareholders.

Regardless the results of empirical results proved that market appreciates firms with family ownership (Barontino and Caprio 2005; Villalonga & Amit 2006; Anderson & Reeb 2003; Ying & Peng 2010 and Maury 2006), this research is intended to build hypothesis using NEE argumentation. There are some reasons supported this choice, (1) the low level of investor protection in Indonesia (Priyatna 2012; Jiang & Peng 2011), in such condition, the likelihood of the majority shareholder to expropriate minority is very large, (2) according to Anderson & Reeb (2003); Maury (2007) and Jiang & Peng (2011), ownership concentration is only effective to the contries that have established rule of law and counter-productive for un-transparence countries, otherwise decreasing firm value, (3) The results of some of the previos research, Claessens, Djankov, Fan, and Lang (2000), Darmadi (2012) showed that Indonesia as a country with high level of expropriation, also Lemmon & Lins (2000) uncovered that companies Tobis'Q in Asia, where expropriation to the minority exist, have experienced a decreasing of firm value as of 12% and above, compared to other companies; (4) Ownership by a tight family may create agency problems between majority shareholders and minority shareholders (Shleifer & Vishny, 1997). Based on the NEE arguments, then the hypothesis of this study is:

H₁: Family ownership has a negative impact on firm value.

Control Variables

In many studies, the determinant of firm value other than the ownership structure, is the financial performance, company profiles associated with firm size, market share and firm age (Black, Jang & Kim 2006; Black, Carvalho, Khanna, Kim, Yurtoglu 2013; Baek, Kang & Park 2004). Black, Jang & Kim (2006) employed a number of control variables such as market share, leverage and growth as the important determinant of firm value. Wide market share indicates high potential profitability. However, this study uses the change in operating profit, as a control variable, not market share, since operating earnings more represent the real performance of companies than market share. Companies whose profits increased from time to time will be more attractive and positively appreciated by investors. Another control variable is the leverage. High leverage represents a high risk enterprise. Companies with high leverage will be negatively associated with firm value.

Growing companies will be more interesting to investors, some previous studies support a positive association between growth and firm. In contrast to previous studies that use R & D as a proxy for growth (Vilalonga

& Amit 2006, Black, Jang & Kim 2006; Black, Carvalho, Khanna, Kim, Yurtoglu 2013), this study chose sales as a proxy for growth, as sales better describe the actual growth experienced by the company and not just the potential for growth.

Research Methodology

Analysis Model

This study uses regression analysis to examine proposed hypothesis. Regression model is stated as below:

$$TQ_{it} = \beta_0 + \beta_1 FAMONR_{it} + \beta_2 LOBD_{it} + \beta_3 LEV_{it} + \beta_4 SGROWTH_{it} + \varepsilon_{it} \quad (1)$$

- TQ_{it} : Firm value of company i at period t
 $\beta_0, \beta_1, \beta_2, \beta_3, \beta_4$: regression coefficient
 $FAMONR_{it}$: family ownership of firm i at period t
 $LOBD_{it}$: Change of operating income of company i at period t
 LEV_{it} : Debt to equity ratio of company i at period t
 $SGROWTH_{it}$: Growth of company i at period t
 ε_{it} : error term

Operational Variables

Variables	Operational definition	Scale
1 Firm value (TQ)	is the value of the business as an ongoing enterprise. Firm value is measured by Tobin's Q, as follow: $\frac{(\text{Total Assets} - \text{Book value of equity}) + \text{Market value of equity}}{\text{Book value of total assets}}$	ratio
2 Family ownership (FAMONR)	company in which one or more family members act as a chief executive or are in a board of directors and as the majority shareholder (Vilalonga & Amit 2006). Majority shareholder limitation percentage is 10%, referring Siregar (2007); Claessens (2000) and La Porta (1999), that the 10% ownership level has been quite effective in controlling the company. Companies that meet the criteria of family members into the director / board of directors and have a share of at least 10%, given the numbers 1 and 0 otherwise.	nominal
3 Change in operating income (LBOD)	Operating income is income from the company's main activity which obtained by subtracting operating income to operating expenses. The formula changes in operating income is as follow: $\frac{\text{Operating profit}_{t-1} + \text{operating profit}_t}{\text{Operating profit}_{t-1}}$ Then, companies that have positive earnings change, given the numbers 1 and 0 if otherwise	nominal
4 Debt to equity ratio (LEV)	Proportion of equity that come from debt . $\frac{\text{Total Debt}}{\text{Total Equity}}$	ratio

5	Growth (SGROWTH)	The increased potential of the company to the next, as measured by growth in sales: $\frac{\text{Net sales}_{t-1} + \text{Net sales}_t}{\text{Net sales}_{t-1}}$
---	-------------------------	---

Sample

Data was obtained from annual reports published in the website Indonesia Stock Exchange (IDX) and the respective company websites, for companies whose annual report data is not found on IDX sites, whereas the database shareholder obtained from the OSIRIS. This study uses all large cap companies (big capitalization) in 2008, 2009, 2010 and 2011 based on documents Fact Book published by the Stock Exchange in the years. The selection of companies with large market capitalization, referring to Anderson and Reeb (2003), Villalonga & Amit (2006) and Jiang & Peng (2011), which uses large companies in their research, in addition, large firms are also more concern to investors and analysts than small companies (Chen & Jian 2006). Data qualified as sample as many as 146 observations, which is obtained from the following process:

The number of companies entering the big group of capitalization in 2008-2011	200
Companies that do not have complete data needed for the study.	(54)
The number of qualified samples to be processed	146

The data were processed with the aid of SPSS software version 19

Result and Discussion

The first classical assumption test on 146 observations, did not meet the four classical assumptions. The test results showed a number of data normality were identified as extreme data (outliers), a total of 37 observations were identified outliers are removed from observation and repeated testing. After dropping all outliers data, the second test against the 105 observations, shows the data meet the assumptions as indicated by multicollinearity VIF of each variable under 10 (appendix 1). There is no autocorrelation can be seen from the residual value of Durbin Watson for 1.289 is higher than the value of α is set at 0.05 (appendix 2). The model has also been free of heteroscedasticity, which can be seen from Spearman unstandardized residual values for all variables were above the $\alpha = 0.05$ level (Appendix 3).

However, the data still can not fully meet the assumptions of normality (Appendix 4). One cause of the data does not meet the normal distribution because there are several variables like FAMONR and LBOD as a dummy variable with a value of 0 and 1, so it can not meet the required normality. However, because the number of observations is large enough (> 30), then theoretically meet the normal distribution of data, other than that based on the data plot (box-plot) the data have shown a normal distribution, and the value of R2 and numbers suitability model (F-test) have shown an increase in compared with the values of these parameters on the initial test.

Profile of 105 observations that have met the classical assumption test and descriptive statistics are presented in Table 1. Panel A shows the sample by industry which dominated by a financial sector that is equal to 26% of the entire sample, and followed by the mining sector as much as 25%. Although the proportion is uneven, but almost all industry groups are represented except property sector, real estate and building. The number of observations is also fairly distributed between the family and non-family ownership.

TABLE 1: SAMPLE PROFILE

Panel A. Industrial Sectors and Ownership Structure

Industrial Sector

Agriculture	11	10%
Mining	25	24%
Basic Industries	13	12%
Others	3	3%
Consumer goods	9	9%
Infrastructure, Utilities & Transportation	12	11%
Finance	26	25%
Investment	6	6%
	<hr/>	
	105	100%

Ownership structure

Family	50	48%
Non-Family	55	52%
	<hr/>	
	105	100%

Panel B. Descriptive Statistic

	N	Minimum	Maximum	Mean	Std. Deviation
TQ	104	0.49	7.82	2.1463	1.4223
FAMONR	105	0	1	0.48	0.502
LBOD	101	0	1	0.69	0.464
LEV	105	0.22	12.05	2.9558	3.3471
SGROWTH	97	-0.21	1.03	0.2164	0.2341
Valid N (listwise)	96				

TQ = (total asset- book value of equity)+ market value of equity scaled by book value of assets; FAMONR = dummy variable of family ownership structure, 1= if family's member is assigned as a Chairman/CEO and has at least 10% of family ownership, 0 otherwise; LBOD = dummy variable of change in operating income, 1 if positive change and 0 otherwise ; LEV = total total debt to total equity; SGROWTH = changes in net sales

Panel B displays a general descriptive statistics for each variable. Regression analysis was performed on 96 valid observations , as presented in Table 1 above, because some variables are not available in full at 105 corresponding number of observations.

The model summary (Table 2), suggesting a correlation (R) are high among all predictor variables (FAMONR, LOBD, LEV, SGROWTH) with the response variable (TQ) of 0.539. Furthermore, the regression model also showed the adjusted R2 is quite high at 25.9% 0.259, it means that the changes of TQ variable can be explained by the four predictor variables together. Goodness regression model to the data can be seen from the F value of 9.296 and significant at $\alpha = 0.01$, respectively

Testing the main hypothesis of this study (Table 2), shows that FAMONR significantly negative effect on the value of the company, at the 10% significance level. It is proven that firms with family ownership is perceived negatively by the market, this result once again consistent with the results of the research Jiang & Peng (2011), Lemmon & Lins (2001), Claessens, Djankov, Fan, and Lang (2000), which found that Indonesia is one of countries with the high-level expropriation where family ownership is negatively related to performance. The majority shareholder entrenchment cause negative effects, which utilizes a large capacity to undertake actions for personal gain at the expense of the minority shareholders. This behavior is possible since the level of investor protection in Indonesia is still very weak (Priyatna 2012, Jiang & Peng 2011).

The dominance of family ownership in large-scale enterprises to be inefficient, as investors are aware of the increased risk of expropriation on these companies which resulted in a decrease in the firm value. The movement of large companies more closely followed by investors than small firms (Chen & Jian 2006). Therefore investors are more sensitive to any possible risks as a result of actions taken by large-scale enterprises, and quickly anticipate such risks in the valuation of the company. These findings, although still preliminary and still need to be further tested its consistency, successfully wrecked the opinion of Demsetz & Lehn (1985), Himmelberg et.al (1999) and Demsetz & Villonga (2001), that the ownership structure is not related to performance and merely the results of the current shareholders's decision to maximize profits.

TABLE 2: ESTIMATION MODEL

Regression model estimation					
$TQ_{it} = \beta_0 + \beta_1 FAMONR_{it} + \beta_2 LBOD_{it} + \beta_3 LEV_{it} + \beta_4 SGROWTH_{it} + \varepsilon_{it}$

FAMONR	-	-.465	-1.741	.085	*)
LBOD	+	1.041	3.425	.001	***)
LEV	-	-.209	-4.738	.000	***)
SGROWTH	+	-.986	-1.571	.120	
R		.539			
Adjusted R ²		.259			
F-stat		9.296 ***)			
***), *) = each significant, at lthe evel 0.01 dan 0.1					
TQ = (total asset- book value of equity)+ market value of equity scaled by book value of assets; FAMONR = dummy variable of family ownership structure, 1= if family's member is assigned as a Chairman/CEO and has at least 10% of family ownership, 0 otherwise; LBOD = dummy variable of change in operating income, 1 if positive change and 0 otherwise ; LEV = total total debt to total equity; SGROWTH = changes in net sales					

Control variables prove to affect the value of the company, namely the LBOD and LEV. High operating profit performance is perceived positively by investors, significant at $\alpha = 0.01$. The companies with good earnings performance show positively associated with firm value. In contrast, firms with high leverage indicates a high risk and perceived negatively by investors resulting in a decline in the value of the company, supported by the results of the test that the coefficient is significant at $\alpha = LEV 0.001$. Meanwhile, growth which proxied by sales, proved not significantly affect the value of the company.

Conclusion, Implication and Limitation

This study aims to determine the impact of family ownership on firm value in the context of Indonesia, where the level of investor protection is weak and corrupt, and to confirm the results of research Jiang and Peng (2011), rin particular the results of research that in Indonesia, the presence of family ownership negatively affect performance. A number of control variables are used to examine the determinants of the firm value in addition to the family ownership structure. Control variables used in this study is the change in operating income, which represents the risk and leverage growth proxied by changes in sales.

Research shows that family ownership structure negatively affect the firm value, at a significance level of 10%, consistent with Jiang & Peng (2011), Lemmon & Lins (2001), Claessens, Djankov, Fan, and Lang (2000), which found that Indonesia was a country with a high level of expropriation where family ownership was negatively related to performance. The majority shareholder entrenchment cause negative effects, which utilizes a large capacity to undertake actions for personal gain at the expense of minority shareholders. In addition it is evident that the change in operating profit significantly positive effect on firm value, whereas negatively affect leverage on firm value,

respectively at a significance level 1%. While the growth of the company which is proxied by changes in sales, not shown to affect the value of the company.

However, this study does not exercise control over the level of investor protection as done by Gompers et al. (2003), which uses antitakeover index (GIndex) which is based on entrenchment index (EIndex) by Bebchuk et.al (2009). This study only assume the level of protection against expropriation of investors or existing investors based on the results of previous studies. Future research should incorporate control variables investor protection index, in order to obtain more accurate results. Besides, future research could compare with companies that do not include a large company, to gain a broader generalization of the results of the study. Measurement of family ownership structure can be traced by using the ultimate ownership as done by Siregar (2007), not only by ownership imediat as done in this study.

**The Relationship between Intellectual Capital and Financial Performance of Listed
Companies – The case in Hong Kong**

Stephen C.Y. Li & Anthony C.T. Ku, s.li@cityu.edu.hk

The Relationship between Intellectual Capital and Financial Performance of Listed Companies – The case in Hong Kong

Background to study

When the modern business world is highlighting about value creation over production efficiency, it's inevitable that the focus of the companies would also have a big change. According to Seetharaman, Sooria and Saravanan (2002), the business world has been shifted from an industrial economy to knowledge economy. Basically, the basic resources would include not only natural resource, capital and labour but also knowledge.

The development of intellectual capital has been aroused interests from different parties. However, the value of intellectual capital may be overlooked due to the difficulties to quantify and measure. This paper aims to examine the influence of intellectual capital to companies in Hong Kong.

Intellectual capital, which is an intellectual material defined by Klein and Prusak in 1994 as to produce a higher valued asset by formalisation, capture and leverage. Highlighted by Elliott and Elliott (2012), the distribution of tangible assets and intangible assets in the 1980s was 70%:30%. However, the distribution was getting reversed to 30%:70% in the mid-1990s. Till now, the distribution of physical, financial assets and intangible assets is 5%:95%. The competition has been shifted to the competitive advantages and core competences based on the management of intellectual capital.

As early as Johnson and Kaplan mentioned in 1987, intellectual capital is vital in driving the overall performance of an organization. Bornemann et al. (1999) found that an organization which owns a better intellectual capital would achieve better performance and stronger competitive advantage than an organization which doesn't. Guthrie (2000) mentioned the progress of creating, capturing and disseminating knowledge within organizations cannot be stopped.

Leliaert and Rodov (2002) has been clarified the difficulty of reporting the value of intellectual capital. It's generally expected that a company with a higher degree of effort on creating value with knowledge and innovation assets would have a higher return on assets. .

As the public started concerning how knowledge could add value to an entity and even to the entire value base, this research aims to examine the influence of intellectual capital to companies in Hong Kong. By referencing to some listed companies in Hong Kong, several models could be demonstrated in a readily understandable way. Hopefully, the relationship between intellectual capital and company performance in Hong Kong could be found.

Literature Review

The current change of the economic environment

Sullivan and Sullivan (2000) mentioned as early as in the late 1990s, the business environment faced a dramatic change which the major value of organization had been switched from tangible assets to intangible assets and tangible assets were found to be a relatively little value to the value creation of the organizations.

Guthrie and Petty (1999) suggested that the evolvement of knowledge management missions brought out two missions. First, organizations would concern a continuing quest for them to develop a better system for creating, capturing and disseminating knowledge. Second, there is a growing awareness that how knowledge including marketing expertise could add value to a business and even to the entirely value base.

The introduction to intellectual capital

Intellectual capital, as known as a group of knowledge, is to produce a higher valued asset by formalisation, capture and leverage. It builds a higher level of competitive advantages for the companies. The key stakeholders could therefore be benefited (Klein and Prusak, 1994 and Marr, Schiuma and Neely, 2001).

Guthrie (2000) added his own thought on the above point and stated that intellectual capital is implicated in various aspects. For instance, economic, managerial, sociological and technological developments are all involved.

The implication is in a manner previously unknown and largely unforeseen, which is emphasised in four different areas. The first area is the information society, which the intellectual capital led to the revolution in information technology. The second area is the knowledge based economy, which the intellectual capital remarked the importance of knowledge. The third area is the network society, which the intellectual capital changed the pattern of interpersonal activities. The last area obviously is the organization, which the intellectual capital gives innovation and creativity to the organization. Competitiveness could therefore be enhanced.

The components of intellectual capital

Edvinsson and Malone theorized the idea of intellectual capital in 1997, intellectual capital can generally be split into three categories and various scholars agreed that (Starovic and Marr, 2003; Chen, Cheng and Hwang, 2005; Kok, 2007; Makki, Lodhi and Rahman, 2008; Ahangar, 2011; Maditinos et al, 2011; Fathi, Farahmand and Khorasani, 2013), which are human capital, relational (customer) capital and structural (organizational) capital.

Human capital generally refers to the knowledge, skills and experience of the employees. Organization would lose it if the employees leave. Examples like innovation capacity, creativity, vocational qualification, work-related knowledge and competencies, proactive and reactive abilities, entrepreneurial spirit and changeability (Guthrie, 2000; Starovic and Marr, 2003 and Fathi, Farahmand and Khorasani, 2013). Leibowitz and Wright (1999) suggested several indicators for measuring human capital, such as the replacement and acquisition cost, generalized training and employee development cost, percentage of outsourced personnel resources, development of cross-functional team structures and internal control and ethics.

Relational capital generally refers to all resources linked to the external relationships of the company, which comprises the contribution of human capital and structural capital to the relationship between the organization and its stakeholders. For instance, customer loyalty and satisfaction, company names, distribution channels, business collaborations, licensing agreements, franchising agreements, favourable contracts and negotiating capacity with financial entities (Guthrie, 2000; Starovic and Marr, 2003 and Kok, 2007). Leibowitz and Wright (1999) also suggested several indicators for measuring relational capital, such as creation and development of external relationships, brand loyalties, customer service expectations and market share.

Structural capital generally refers to the non-human resources of knowledge within the organization. In other words, knowledge resources are owned by the organization. It could be classified into intellectual property and infrastructure asset. The former one comprises patents, copyrights and trademarks. The latter one comprises corporate culture, financial relations, information systems, management philosophy, management processes, information systems, which is built to meet the market requirements (Guthrie, 2000; Starovic and Marr, 2003; Kok, 2007 and Fathi, Farahmand and Khorasani, 2013). Leibowitz and Wright (1999) suggested the indicators for measuring structural capital could be divided into process and innovation. The former one includes logistical efficiencies and administrative procedures, whereas the latter one includes renewal and development costs, change in product development and delivery cycle, adoption of industry quality standards and the organisation learning capacity.

The difference between intellectual capital and intangible asset

However, Guthrie (2000); Kok (2007) and Elliott and Elliott (2012) mentioned that users always get confused about the difference between intellectual capital and intangible asset. Guthrie (2000) clarified intangible assets could refer to goodwill, whereas intellectual capital is part of the goodwill. Kok (2007) concerned the difference on the clarified intangible asset as knowledge-based items owned by the company for making future economic profit, whereas intellectual capital as knowledge based equity that may not produce future economic profit directly.

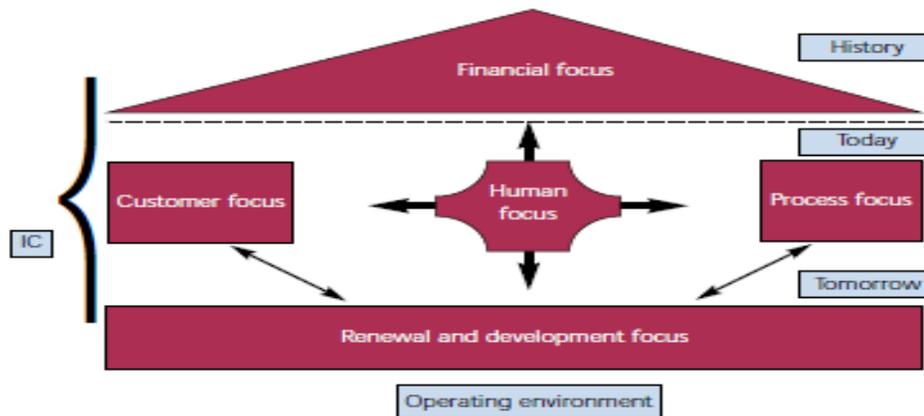

The measurement model of intellectual capital

A recent study (The Management Lab) mentioned Karl-Erik Sveiby was the first one to raise the issue of measuring human capital and study whether there would be accounting practices for it. Through his efforts, The Invisible Balance Sheet was published in 1989 and suggested the measurement of intellectual capital by dividing into relational capital, human capital and structural capital. This model arouses attraction of many Swedish-listed companies and be adopted soon. Furthermore, it was also adopted by Swedish Council of Service Industries as a standard recommendation for publishing annual reports. The milestone of intellectual capital started here.

Skandia navigator and IC rating model

The corporate director of a Swedish insurance company, Skandia AFS, was the first director theorises intangible asset as intellectual capital in 1994/95. Till now, Skandia AFS has provided six intellectual supplements for their own annual report by highlighting how intellectual capital be used as a hidden value for stakeholders' benefit.

According to Sveiby (2010), Leif Edvinsson developed Skandia navigator in 1994 for measuring intellectual capital. By using human focus as the driver of the measuring model, the effect of human focus on financial focus, customer focus, process focus, renewal and development focus and human focus.

VAIC model

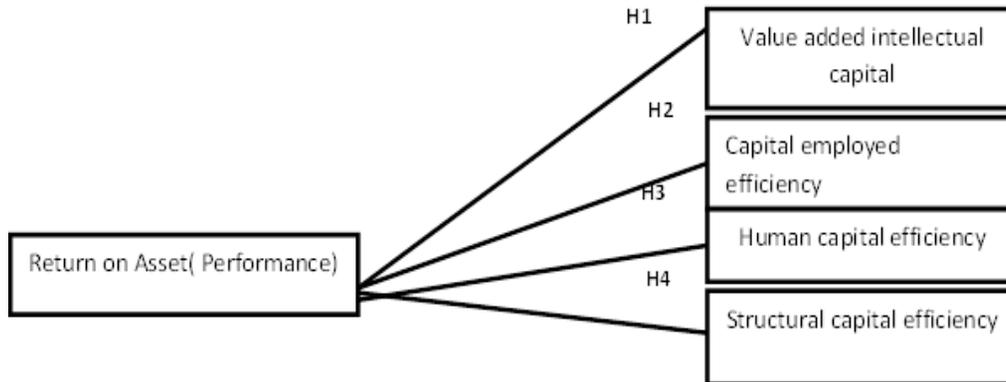

It is generally believed that the more the well-established model and the flourishing area would help the scholars have a further study. Pulic (2000a, b) theorized the market value of the organization is created by capital employed and intellectual capital, whereas the intellectual capital consists of human capital and structural capital. Value Added Intellectual Coefficient (VAIC) is therefore proposed. Under this model, users could find out the contribution of both tangible asset (capital employed) and intangible asset (human capital and structural capital) to the value creation efficiency of the organization. This model quantifies the intellectual capital through measuring the Capital Employed Efficiency (VACA), the Human Capital Efficiency (VAHU) and the Structural Capital Efficiency (STVA), which are the three components of VAIC. It is suggested that a higher value of VAIC generally means the organization value creation has been well managed and fully utilized.

Fathi, Farahmand and Khorasani (2013) evaluated VAIC model as a suitable and approved method for measuring intellectual capital. The data used in the model are mainly the accounting data, which gives users confidence on the observance and the verifiability. Notwithstanding the VAIC model consists of inherent limitation, its intelligibility, reliability and simplicity overcome the shortcoming. Besides, Veltri (2009) summarized the factors that considering VAIC model as the most popular model that being used in studies. First, the value added approach of the model helps organizations for making further analysis as it is consistent with Resource-Based View. Second, considering the application of the model is quite wide, it is suggested that VAIC model is applicable in both macro and micro economy. Thirdly, the data sources of the VAIC model are mainly financial oriented. It is generally believed that the data is reliable as it is audited and published in the financial statement and annual report. It raised users' confidence on the reliability of the measurement result. Apart from the reliability, it is considered that VAIC model enhance the shortcoming of the previous measurement model on intellectual capital. The VAIC model offers objective, quantifiable and quantitative measurement without adding any subjective grading or indicators into the measurement.

Research framework of the Study

The independent variable is Intellectual Value of the company which can be represented either by (1) Value Added Intellectual Capital (2) Capital Employed Efficiency, (3) Human Capital Efficiency, (4) Structural Capital Efficiency. This study is trying to examine whether Intellectual Value of a company will affect the Performance of the Company which can be measured by means of Return on Asset (ROA).

Suggested by Pulic (2000a, b), that a higher value of VAIC generally means the organization value creation has been well managed and fully utilized. This research aims to test the relationship between intellectual capital and company performance in Hong Kong. Therefore, the hypotheses are as follow:

Source: Adjusted from Public (2000a,b)

Variables definition and Measurement

Independent variables

The four components of the VAIC model (Pulic, 2000a, b) would be include in this study, which are:

Value Added Intellectual Coefficient (VAIC), which is the value of the intellectual capital.

Value Added Efficiency of Capital Employed (VACA), which is the value of capital employed efficiency.

Value Added Efficiency of Human Capital (VAHU), which is the value of human capital employed efficiency.

Value Added Efficiency of Structural Capital (STVA), which is the value of structural capital efficiency.

Before performing the calculation of VAIC, VACA, VAHU and STVA, several steps have to be taken (Pulic, 2000a, b). At the very first stage, Value Added (VA) is defined by the following algebraic equation:

$$VA_i = DP_i + Di + Ii + Mi + Ri + Ti + WSi$$

The Value Added of Firm i is calculated by summing up Firm i's depreciation expense (DP_i), dividend (Di), interest expense (Ii), minority interest (Mi), retained profit for the year (Ri), tax expense (Ti) and wages and salaries (WS_i). These information could both be found in the Annual Report of the 47 selected companies.

At the second stage, the components of VAIC have to be calculated before performing the calculations (Pulic, 2000a, b; Maditions et al., 2011; Fathi, Farahmand and Khorasani, 2013):

Capital Employed (CE) = Total assets - intangible assets

Human Capital (HU) = Total expenses spent on staff and employees

Structural Capital (SC) = Value Added - Human Capital

VAIC, VACA, VAHU and STVA could then be computed by using the above results:

$$VAIC = VACA + VAHU + STVA$$

$$VACA = VA / CE$$

$$VAHU = VA / HU$$

$$STVA = SC / VA$$

Dependent variables

It is considered that the dependent variable is the company financial performance (Maditions et al., 2011; Fathi, Farahmand and Khorasani, 2013). The financial performance, Return on Assets (ROA) would be calculated for the testing.

It is suggested by Maditions et al. (2011) that the Return on Assets could be used to show the organization

the relationship between the profitability and its total assets, which helps management measure the earning generated by the assets. It is calculated by the net income divided by the total assets.

Hypothesis Testing (Development of hypotheses)

Hypothesis 1: Companies with a greater value of intellectual capital have a better financial performance.

Hypothesis 2: Companies with a greater value of capital employed efficiency have a better financial performance.

Hypothesis 3: Companies with a greater value of human capital efficiency have a better financial performance.

Hypothesis 4: Companies with a greater value of structural capital efficiency have a better financial performance.

Sample and data selection

The final sample of this study includes 47 Hong Kong companies listed in the Hang Seng Index (HSI). These 47 companies could be classified into four main economic sectors: commerce and industries (22 companies), finance (12 companies), properties (9 companies) and utilities (4 companies). The data extracted record the financial information of those companies during 2010-2013. All of the data could be found from the website of those 47 companies.

The initial target of the investigation was to generate the value of intellectual capital by using the financial information of all companies that listed in the Hang Seng Composite Index Series during 2010-2013. The sample base is then reduced to the 50 constituent stocks listed in the Hang Seng Index, namely the blue chips. Considering there were insufficient information to gather from 3 companies, the final sample size is reduced to 47 companies, which represents 94% of the blue chips of Hang Seng Index.

In this research, VAIC model is used to quantify the value of intellectual capital of the selected companies in the Hang Seng Index. The VAIC model is suggested by different scholars as the most suitable and approved method for measuring intellectual capital (Veltri, 2009; Fathi, Farahmand and Khorasani, 2013).

This research aims to find out how intellectual capital influences the performance of company in Hong Kong. Using VAIC model could solve the difficulties of quantifying intellectual capital. The value of intellectual capital could therefore be calculated and used in the regression model and correlation model to find out the association between intellectual capital and company performance.

Descriptive Statistics

The profile of the 47 selected companies is provided in Table 1 (Appendix 1), which gives readers an idea of the sample. Covering a period of 3 financial years from 2010 to 2013, 22 companies came from commerce and industries sector, 12 companies came from finance sector, 9 companies came from properties sector and the remaining 4 came from public utilities sector.

Tables 2, 3 and 4 describe the minimum, maximum, mean and standard deviation of all variables during the year 2010/2011, 2011/2012, 2012/2013 respectively. Based on the data gathered in Table 2 to Table 4, an average figure is calculated for this 3 years period and being used to generate a descriptive table, Table 5. There are no negative figures in both models. The largest difference appeared in the Table 5 is the VAHU, with the minimum efficiency of 1.19 to the maximum efficiency of 75.27.

Tables 6 to 9 report the minimum, maximum, mean and standard deviation of all variables in Table 5 by sectors. The commerce and industries sector has the largest mean of VAIC at 11.4, whereas the finance sector has the smallest mean of VAIC at 7.99. There are only slight differences between the different sectors' variables except the VAHU. The largest mean of VAHU generated by the properties sector and the smallest mean of VAHU generated by the finance sector are 16.68 and 7.09 respectively.

Data analysis

Only result of the average figure from 2010-2013 would be showed in below, whereas the remaining results would be showed in the appendices.

Correlation analysis

The correlation analysis provides the readers a quick glance of the investigations. Table 10 depicts the result of correlation analysis for all variables of the average figure during 2010-2013. The correlation result is quite different between the dependent variables and independent variables. It is concluded that the return on equity and the market-to-book value ratio are only significantly related with VACA at the 0.05 level, whereas the VAIC are significantly related with VACA at the 0.01 level, VAIC and VAHU at the 0.05 level. There are significant relationship found between the STVA and all other dependent variables.

Hypothesis verification

Hypothesis 1

Hypothesis 1 set to test whether there is any significant relationship between intellectual capital (VAIC) and financial performance. Table 11 shows the result did give evidence to support there is a significant relationship between VAIC and ROA ($p < 0.05$). The coefficient between VAIC and ROA of the average of Years 2010-2013 was 0.348 (at the significant level of 0.017) and the regression result between VAIC and ROA (in average for 3 years) with Adjusted R^2 at 0.121.

Hypothesis 2

The hypothesis 2 set to test out whether there is any significant relationship between capital employed efficiency and financial performance. Table 12 shows the relationship between VACA and ROA in average for 3 years appeared to be highly significant ($p < 0.01$). The coefficient between VACA and ROA of the average of Years 2010-2013 was 0.709 (at the significant level of 0.000) and the regression between VACA and ROA (in average for 3 years) with Adjusted R^2 at 0.491.

Hypothesis 3

The hypothesis 3 set to test out whether there is a significant relationship between human capital efficiency and financial performance. Table 13 shows the result did give evidence to support there was a significant relationship between VAHU and ROA in the average of 2010-2013 was significant ($p < 0.05$). The coefficient between VAHU and ROA of the average of Years 2010-2013 was 0.341 (at the significant level of 0.019) and the regression between VAHU and ROA (in average for 3 years) with Adjusted R^2 at 0.097.

Hypothesis 4

The hypothesis 4 set to test out whether there is a significant relationship between structural capital efficiency and financial performance. The testing result in Table 14 failed to support if the companies have a higher value of STVA would have a higher ROA ($p > 0.05$). The coefficient between VAHU and ROA of the average of Years 2010-2013 was 0.108 and the regression between STVA and ROA (in average for 3 years) with Adjusted R^2 at -0.1.

Main Findings and Recommendations

To conclude, the acceptable result of the hypotheses testing shows the VAIC was positively associated with ROA. The result also shows the relationship between VACA and ROA was significant. With regards to the other two components of VAIC, VAHU is found that positively associated with the ROA.

The objectives to investigate the relationship between intellectual capital and company performance in Hong Kong and to compare the relationship between intellectual capital and company performance with previous researches are achieved by the hypothesis testing. Under the VAIC model, human capital efficiency is generally the greatest effort of the selected companies' development of intellectual capital. It implies the Hong Kong companies are willing to invest on human capital. A larger spending on it could be viewed as an incentive to employees to stay at the companies, in order to prevent the loss of human capital. To a certain extent, it responded the argument of Lewis (1997) and Roselander (1997), to hold a positive view on the spending on human resources and view the spending as an investment could help retain and attract talented people.

Compared to the previous researches, this paper is similar to the finding of Chen, Cheng and Hwang (2005), a research that investigates the relation between the value creation efficiency and financial performance in Taiwan, which had a finding that the effort of developing human capital in Taiwanese companies was the highest in the components of intellectual capital. It's also similar to the finding of Maditinos (2011), which are researches that investigate the impact of intellectual capital on firms' financial performance in Greece.

The acceptable result of the hypotheses testing set before shows the VAIC was positively associated with ROA, which is similar to the research result of Fathi, Farahmand and Khorasani (2013). Moving forward to the components of VAIC, the result shows the relationship between VACA and ROA was significant, which is similar to the research result of Chen, Cheng and Hwang (2005), Fathi, Farahmand and Khorasani (2013). With regards to the other two components of VAIC, VAHU is found that positively associated with the ROA, which is similar to the result of Chen, Cheng and Hwang (2005), Maditinos (2011) and Fathi, Farahmand and Khorasani (2013). Whereas the STVA was found that the relationship with the financial performance was not significant.

It's generally believed that the results would be useful. It is suggested that intellectual capital could be viewed as knowledge based equity that may not produce future economic profit directly (Kok, 2007). It's undeniable that the human capital is vital for value creation. Besides, the results remarked STVA has no relationship with return on asset. The situation is quite similar to that of VAHU. The mean score of STVA was declining from 2010, it would be worse than that of VAHU as it implies the management intended to stop the investment on structural capital. Considering the structural capital is difficult to manage and highly depends on the ability of management, such as patents, copyrights and trademark, corporate culture, management processes and financial relations. It is suggested that the linkage between human capital and structural capital would be very high. Stop investing either human capital or structural capital would affect the performance of other side.

Regarding the result shows the positive correlation between VAIC and ROA, VACA and both dependent variables, VAHU and ROA. Intellectual capital could be valuable to the listed companies in Hong Kong. Develop intellectual capital is almost a must in knowledge-based economy.

Practical implications

The results suggested intellectual capital would be useful and considerable to the management of the listed companies in Hong Kong. Develop intellectual capital is almost a must in knowledge-based economy to raise the competitive advantages.

Limitations

The study period for the sample is set for 2010-2013. An extended period is desirable for testing would raise the generalizability of this study. The current study only covered 3 years for the empirical test. It is recommended to extend the examination period to 10 to 20 years to raise the applicability of the future study.

Financial performance can be measured by means of Market to Book Value, Return on Equity (ROE) and Return on Asset (ROA). This research just based on ROA for financial performance. Furthermore, there are many other factors that lead to the success in company performance other than intellectual capital. It is a study that mainly focuses on the relationship between intellectual capital and company performance, the success or failure have not been fully explained and evaluated.

Future research

Therefore, future research is suggested to widen the research scope. The recommended future research areas are to study the ways to improve the management of intellectual capital; to study other factors that mostly affect the intellectual capital; and to study how the knowledge-based organizations benefited from the development of intellectual capital.

RESULTS OF HYPOTHESES TESTING

Independent Variable	Independent Variables (Company Performance)	Coefficient Beta	Significance Values	Adjusted R ² of Each Ind. Variable with Dep. Variable.
Value Added Intellectual Coefficient (VAIC)	ROA	0.348	0.017	0.101
Capital Employed Efficiency (VACA)	ROA	0.709	0.000	0.491
Human Capital Efficiency (VAHU)	ROA	0.341	0.019	0.097
Structural Capital Efficiency (STVA)	ROA	0.108	0.470	-0.010

whereas $VAIC = VACA + VAHU + STVA$

The role of intangibles in improving the predictive ability of internal rating systems

Abstract

This paper focuses on the use of intangibles as correction factors for an internal rating system (IRS). The purpose of this work is twofold. On the one hand, there is the will to make a real contribution in stimulating banks to consider the analysis of intangibles of firms as a lever to set virtuous rating models, capable of maintaining the predictive ability even in times of economic recession. On the other hand, it seeks to encourage companies to engage in the process of implementation, management and communication of intangible assets. In the current economic scenario, the intangibles contribute significantly to the construction of the competitive positioning of the company. It follows that the soft information have to be appropriately considered in order to consider key aspects of business management (growth potential, competitive capabilities, core competencies, governance model).

Introduction

The adoption of the internal rating system (IRS) is a factor that is reshaping the relationship between the companies and banks. The need of collecting and processing multiple information leads towards greater transparency of information and a more robust assessment of creditworthiness.

However, the observation of reality shows that the introduction of rating systems has increased, rather than diminished, the distance between the bank and the firm. One of the reasons is that the bank rating models assign the judgment of reliability to customers based primarily on quantitative information (i.e. balance sheet data) neglecting qualitative information such as the competitive position of the company and the presence of key competences. The application of automated procedures that read historical data and neglect the uncoded information could lead to an incorrect evaluation of the company's potential, making it more difficult to access credit. The rating system developed internally by banks uses, in fact, an approach Point in Time (PIT) and not Through the Cycle (TTC) to determine the probability of default (PD). The first is a rating system that changes from period to period, while the second produces a judgment of reliability of the borrower that tends to remain stable even in the presence of different economic scenarios.

The use of the PIT methodology feeds the phenomenon of procyclicality that occurs during periods of economic crises. The procyclicality is often accompanied by the credit crunch. Firms in financial difficulties are struggling to cover their needs through bank debt due to the deterioration of their credit rating. The scarce availability of financial resources heightens the criticality of the operational management. In economic context, where there is a prevalence of small and medium enterprises (SMEs), it is necessary to strengthen the role of the qualitative elements (the so-called soft information). Therefore it is crucial to intensify the collection of soft information and to find a way to incorporate them into the rating models.

The strengthening of the qualitative part has no alternatives in the firms' rating evaluation, especially for SMEs. This is due to two reasons: a) the smaller the firm, the lower is the dependence on macroeconomic factors in favor of specific factors of competitiveness (e.g. niche district, segment firms); b) it is necessary to orient the rating in a forward-looking perspective to guide the bank's positioning in the provision of credit and services.

In the long run it is essential to focus on the factors of competitiveness, especially in times of structural fracture. This is because the past has not yet given sufficient information to update the evaluation models. It is therefore necessary a thorough experiential analysis based on qualitative evaluations. However, the transfer of qualitative information into numbers, requires new solutions and methods of analysis. An example of the importance of qualitative information can be found in the study by Simon (2009) which identified the critical success factors of German SMEs. According to the study, German companies that have the best competitive performance are those that focus on product quality, efficiency, on-time delivery, customer proximity and problem-solving. Less important factors in determining the success of a firm appear to be the distribution network, the cooperation with suppliers and the advertising practices. Also the price and patents do not appear to be determining factors.

The paper is structured as follows. The first section is devoted to the review of the literature indicating the three main areas of concern of an internal rating system (mechanics of the models, rating philosophy, procyclicality). The second paragraph explains the reasons behind the choice of a dual track that distinguishes the measuring instruments of credit risk during the screening and the monitoring phases. In this context, it is addressed the issue of the collection and processing of information to estimate the probability of default. The third section focuses on the role that intangibles assets can play in affecting the PD of firms. The final section offers some concluding remarks in order to understand the potential and the opportunities related to the implementation of solid rating models.

Literature Review

The literature on rating systems have been widely developed in recent decades,, ranging from construction methods to uses related to bank management.

An initial conceptual framework of the rating philosophy can be tracked in the working paper of the Basel Committee (BCBS, 1999), which outlined a general scheme for the validation of rating systems. This was followed by a large and diverse literature that has investigated the issues in question from different points of view.

Among the works on the state of the art of the rating systems, it is important to mention the study of Albareto, Benvenuti, Moretti, Pagnini and Rossi (2008) and the survey of the Bank of Italy (2011). The latter refers to the end of 2009 and covers 398 intermediaries (38 medium-large and 360 small banks and cooperative banks) and its subject is the assessment of the factors used by the commercial banks and the dissemination of credit scoring models. With regards to the first point, nearly 90 percent of intermediaries use quantitative information to analyse the borrowers (for example, the reference is to the degree of utilization of credit lines or the frequency of trespassing). Only one third of the banks gives importance to qualitative information and personal knowledge of the customer. The statistical and quantitative methods contribute to a decisive extent on the assessment of credit risk of customers. The tendency to intensify the development of credit scoring models is attributed to the progressive use of new information technologies. While all banks tend to use credit scoring models for the activity of granting and monitoring credit, only few banks adopt an IRS to determine the pricing of a loan.

More generally, the contributions on rating systems that have taken place over time can be traced back to the following areas:

- the mechanics of the rating systems, namely the method of construction of the variables / measures of credit risk and the consequent use in the process of Credit Risk Management;
- the relationship between the rating philosophy of the rating, the size of the bank and the organizational structures;
- the procyclicality of credit ratings and the evolution of the rating systems during the current financial crisis.

Pioneering works in the area were carried out by Friedman and Sandow (2003) on the approaches for estimating the Recovery Rate (RR), by Vasicek (2002) on the estimation of the probability of loss of a loan portfolio and by Altman, Resti and Sironi (2002) on the interdependencies between RR and default rates and their potential effect on the procyclicality of capital ratio.

With regard to the relationship between the rating philosophy (statistical or judgmental approach), size and organizational choices of the bank, the literature has largely debated, arguing in relation to the relational or transactional approach used by the intermediary, to its size and to the concepts of functional and operative distance. The literature is unanimous in stressing that the adoption of credit scoring techniques is influenced both by the size of the intermediaries and their organizational structure. Generally, the larger banks have more human, financial and technological resources to invest in innovation techniques (including the measurement of credit risk) and have the ability to share the cost of investments on a larger loan portfolio. However, they present a higher number of issues related to the distance, as well as difficulties in the transmission of information that are not encoded within the structure, in the selection and monitoring of loans and in the formulation of proper incentives for local officials. The distance from the borrower may then reduce the weight of the soft information.

With regard to the systems of delegation, recent evidence on a sample of 400 Italian banks show that during the most acute crisis of 2006-2009, the role of local managers in determining the granting of loans to SMEs has weakened, as it decreased the index of decision-making autonomy. However, a valid IRS must act as the glue between

the mission and the strategic approach of the bank on the individual segments of the credit market. since the asset choice of the rating system is one of the most important components in various market segments.

The international financial crisis has highlighted some critical issues regarding the technical aspects of the rating systems as well as their operational use, especially with reference to the impact on the relationship between bank and enterprise. If bank's capital requirements depend on the credit rating, the increase in the minimum capital requirement for banks determines higher default rates and more frequent deterioration of ratings. Since it is more difficult to raise new equity during a recession, banks end up granting less credit to the economy in order to maintain the ratio between capital and assets at risk. This exposes companies to further financial stress, accentuating the recession even more.

Numerous empirical tests are focused on the procyclicality of the rating system. Catarineu-Rabell, Jackson and Tsomocos (2005) recognize the greater procyclicality of Basel 2 through a theoretical model of general equilibrium and examine the implications of stable rating models in comparison to cyclical or counter-cyclical patterns. Salis and Turri (2009) showed that in the current market turmoil the rating models that assume the independence between the PD and LGD appear no longer adequate to capture the actual risk of the borrower and the one related to the borrowing, leading to an underestimation of the necessary capital in adverse macro-economic conditions and to accentuate the procyclical effects already inherent in the regulatory models.

De Laurentis and Maino (2010) point out that the current methodological approach emphasizes the cyclical responsiveness of an internal rating system. Many IRSs still use a time-frame of one year. This horizon limits the length of time of validity and makes the evaluation of the customer relationship more unstable. The cyclical nature of credit ratings can be measured with reference to the volatility of default rating. A fully cyclic model will be able to perfectly predict the default rates through migration and it will follow the fluctuations over time, making them stable around the PD assigned to different classes.

Cannata (2011) highlights the cyclical effect of the crisis on a representative sample of the entire Italian banking system. Such evidence refers to the evolution observed in capital ratios, in risk weighted assets (RWA), in the default rates during the period 2008-2009. The author shows that the exposures treated with the IRS approach resulted in an increase in RWA (with particular reference to performing counterparties) and, therefore, an increase in the regulatory minimum capital.

Some of the measures introduced by the new Basel 3 regulations and, in particular, the counter-cyclical measures are born as a result of the renewed concern about the effect of the current procyclical capital rules induced by the recent economic crisis and the nature of the rating systems. The new counter-cyclical instruments identified by Basel 3 are designed to strengthen the resilience of banks in a crisis, to neutralize the level of cyclicity implied in ratings models and to ensure fair treatment between banks that adopt models with different philosophies.

Rating systems: a double track for custody and monitoring

In order to estimate the probability of default, it is important to take into account what information to consider and how to process them. Automated systems are the most used for the evaluation of retail customers: each information available is given a determined weight on the basis of a statistical model. The possible qualitative variables are converted into numerical values and then inserted in the statistical models that seek to understand the relevance to the estimation of default, based on the characteristics of loans in default in the past. It may also happen that the judgment emerged from the scoring systems is modified by the analyst, as they deemed suitable to represent the level of counterparty risk on the basis of qualitative inputs that the scoring model fails to capture.

As a first approximation, the bank tends to prefer the use of automated approaches when profit margins related to operations in certain customer segments do not advise to withstand high costs of investigation and monitoring for single-payer. The reliability of the statistical techniques tends to decrease with the size of borrowers. In such cases, the mechanisms of scoring is joined, in a more or less intense measure, by analysis derivable from the work of credit managers. Intermediaries tend to recognize a greater or lesser importance to the single information areas or to find a more or less extended set of information depending on the characteristics of the customers examined

and the choice in the portfolio segmentation. In this context the overriding mechanism operates. The judgment on the debtor could be modified by an operator through discretionary deviations, albeit limited and motivated.

The attention to the assessment of the creditworthiness of the company should not be limited at the time of the initial financing relationship, but it should embrace the whole relationship. Once the rating is determined, this has to be regularly updated so that it can deliver an actual risk level. It is therefore necessary to check the possible changes in the risk profile. These activities are typical of the phases of monitoring in order to understand the changes that the economic and financial situation of the debtor may undergo from time to time.

The different ratio underlying the two different moments of the credit relationship (screening and monitoring) raises the problem of distinguishing the tools of risk measurement, so as to enhance their use according to the specific purposes that a bank intends to carry out in a phase rather than in another. The monitoring tool tends to brand themselves to a strict adherence to counterparty risk and a strong sensitivity to the economic cycle, resulting in limited foresight to seize the debtor's prospects over the short term. The screening model must be broad and has to be able to contribute to the achievement of objectives such as those related to the process of determining the pricing and capital allocation. Function of multiple objective parameters (including the capital allocated to cover the credit risk, the costs of collection and operating costs), the price of a loan must be adjusted to take into account several factors, such as the relationship with the customer and market competitive pressure. In formulating the pricing policies, the banks have to confront with the purpose of the risk-adjusted returns, the target markets and the increase in lending volumes.

Inevitably the two models have to be guided by temporal logics and different content. The monitoring tool has a time horizon of twelve months and include information essentially credit relationship quality indicators. The analysis tends to reflect the current condition of the debtor, neglecting the potential of the company in the medium term and thus its ability to create value. The information used have self-determined character: more credit a bank grants, the less likely the tension of the credit lines. The myopia of evaluations, along with the instability of the estimate of the risk and the danger of procyclicality, prevents the Point-in-Time monitoring tool to be fully functional to the decision of granting or reviewing a loan.

For this purpose it is necessary to refer to a robust PD based on a complete set of information, able to fully ensure the process of direct knowledge of the company and its real opportunities for growth and profitability in the long term. It is therefore necessary to conduct analysis that enhance the contribution of soft information, retrievable from the ongoing confrontation between the company and the relationship manager, to the benefit of a greater predictive ability of the risk estimate. This is because the intangible assets are crucial for the reporting of specific risk factors, which are essential in the evaluation of SMEs.

The orientation versus a forward looking PD requires to grasp the long-run fundamentals of firms, especially when they are characterized by a small size and when the credit manager gives strategic importance to the relationship with the customers. A more TTC model is therefore a prerequisite for the successful integration of rating systems in decision-making and in the management of banking operations. The use of an IRS should extend beyond the granting of credit and its monitoring since it can affect the pricing techniques, the calculation of economic capital and the strategic plan of a bank.

The validity of the choice to use different approaches to credit risk management is also reflected in the operational practices of the Italian banking system. Analyzing the experiences of the 20 Italian banking groups listed at the end of 2011 with regard to the measurement and monitoring of credit risk, Altieri Pignalosa, Birindelli, Ferretti, La Ganga and Porretta (2012) show that in the phase of the measurement, the range of the rating models shows increasing levels of complexity and tend to have more judgmental connotations with the increasing importance of the counterparty. In general, there is a tendency to segment the portfolio companies on the basis of certain variables (size/revenue/funding entity, legal status, geographic area, sector of activity) which, when properly combined, allow to obtain homogeneous clusters for risk profile. In order to estimate the rating of each model it is necessary to consider the sources of information of a quantitative nature (balance sheet data, credit indicators), while qualitative information is used by relationship managers to change the rating (override). In the process of monitoring, early warning systems tend to focus on the analysis of the performance reports (daily check of trespassing, monthly monitoring of overdue unpaid invoices, quarterly reporting of pre-existing trespassing), on the loss of value of the collateral guarantees (to check the adequacy of the pledges and mortgages) as well as the negative returns of the system (verification of the anomalies on the return flows of the Bank of Italy).

Relevant intangibles in the process of assessing the creditworthiness

Over time, various analytical tools have been developed to measure and value the role of intangibles. Among others we report the analysis of the breakeven point in a strategic perspective, the pattern of the life cycle of the product and the one of the company, the learning curve and the cost curve of the industry, the Boston Consulting Group matrix, the General Electric/McKinsey matrix, the Ansoff matrix, the models proposed by Porter (i.e. five forces, value chain). Each of these models tries to extract the crucial variables to define the intangibles of firms.

The more mature attempt to systematically connect the business strategy with the economic and financial performance of the company has been accomplished by the program PIMS - Profit Impact of Market Strategies (Buzzell and Gale, 1987). The PIMS approach identifies a causal hierarchy ranging from three areas of structural factors (which characterize the business enterprise in a sustainable and indispensable way) to the financial results achieved. The project evaluates the impact of strategic variables (such as the concentration and diversity of supply, the strength of competition, the intensity of the investment, the product and service quality, the labor productivity) on performance and debt sustainability. In particular, the most significant variables are the attractiveness of the sector (defined as growth rate, concentration of suppliers and incidence of external purchases on production and international trade), the absolute and relative market share (compared with one of the major competitors), the quality and product differentiation, the level of vertical integration (added value of production) and capital intensity (mainly the rotation of fixed investment and working capital).

In order to strengthen the predictive content, an internal rating system needs to grasp the intangible resources that represent the lever on which the company builds its competitive advantage. Intangibles, entities without intrinsic tangible content, constitute a distinctive peculiarity of the firm. The condition of distinction stems from the availability of innovative, unique and long lasting factors.

The qualitative analysis incorporated into an IRS must thus enhance the role that the intangible assets of the company can play in order to properly evaluate the obligor's probability of default. The objective is to assess the entrepreneurial and managerial to drive the business by adopting strategic and operational decisions consistent with the firm's market and its resources. The evaluation of the quality profile is based on three main dimensions: the attractiveness of the industry, the competitive position of the company and the analysis of the strengths of the business organization.

The attractiveness of the sector depends on the environment in which it operates. The variables to be analyzed are the size of the market, its rate of growth, the profit margins, the degree of differentiation and concentration of the industry, the intensity of competition, the presence of barriers to entry, the bargaining power of customers and suppliers, the degree of risk and uncertainty and the general conditions of the external environment. These elements must be taken into account to define the characteristics of the macroeconomic environment, social and political as well as the historical and prospective trends in the industry. The attractiveness of the sector should be assessed taking into account the local and international competitive pressures and the pace of technological change.

Competitive positioning is the result that comes from interacting with multiple forces: the relative share of the market, the degree of sectoral diversification, the ability to deal with rivals for breadth and quality of the range of product/service, the relative position of cost, the distribution capacity, the presence in foreign markets, the degree of impact of the new products and the plant utilization, the company's image, the ability to negotiate with suppliers, the concentration of customers and their satisfaction. To operate successfully in the globalized economy, firms need to act on the competitive positioning by moving on a path characterized by the following guidelines: a) innovation: the continuous investment in process and product support the ability to compete of the Italian manufacturing sector; b) internationalization: the degree of openness to foreign markets is an indicator of the quality of the companies; c) proper sizing: competition in the global market requires firms to overcome some of the problems related to the small size (e.g. limited availability for investment in innovation and internationalization).

If these are the guidelines, it is also necessary to know what are the discriminating features of the company or its distinctive competencies on which to build competitive advantage. These competences include corporate governance rules, the know-how of the management, willingness to invest in research and development, the use of

technology, the degree of automation of the processes, the presence of quality systems and planning processes, the degree of dissemination of business knowledge, the quality of the organizational structure, the business climate. Below are recalled some of the variables mentioned above by offering some points for analysis.

The importance of corporate governance as a key competence increases as a function of the size and complexity of the corporate structure. Because a good corporate governance is a factor of competitiveness, variables such as the ownership structure, the statutory rules, the assessment of internal control systems, the planning and control management are relevant aspects as determinants of firms' default.

The know-how is the set of knowledge, procedures and methodologies which constitute the intellectual assets of the company. Although it is not always protected by a legal recognition, the know how of a company is kept confidential. Typical examples are represented by not patented information technology, hardly known and available outside of the context in which they were made. The presence of innovative knowledge allows the firm to maintain a privileged position in the market (at least for a predetermined period of time), including not only the scientific heritage pertaining to the ideas and technological innovations, but also to the personal knowledge acquired by individuals within the company. Covered by the know-how is also the knowledge closely related to personal skills and abilities, which can not be sold to third parties.

Investment in research and development, innovations in quality and in the range of products/services, the company's image, the procedural improvements on the operational and administrative control are often influential elements in the evaluation of the quality of firms in light of the dynamic environment in which they operate.

The presence of quality systems, control and planning is considered to be decisive for the success of a business. They allow firms to drive the company in a modern and attentive way. For example, a proper planning activity allows the formulation of economic and financial projections through a description of the assumptions and operational strategies. Indeed, it is essential to govern the company through a careful process of prediction. In particular, the business plan is a document that sets out in a systematic way the strategic directions of the company, by covering the main economic and financial objectives and actions that will be undertaken to enable the achievement of strategic goals.

In order to strengthen the validity of an IRS, it is necessary that its quantitative component is integrated by a qualitative interpretation of a firm and its potential. Building on this assumption, the rating models that are mainly based on hard information must broaden the horizon by appropriately considering the set of variables able to properly evaluate the attractiveness of the industry in which the company operates, its competitive position and its core competencies.

Concluding remarks

The internal rating system is one of the most far-reaching financial innovations of recent years, which has affected the entire loan process from assessment of the creditworthiness of the debtors to the pricing up to the management of complex portfolios of bank loans. Given the spread of the rating, the investment on the quality and completeness of the rating models plays a fundamental role to avoid misleading uses of the instrument and to further popularize its strengths.

These latter considerations are even more relevant in the current economic phase characterized by a deep fracture in the competitive dynamics. It is so appropriate to carry out an audit of the use of rating systems in order to understand whether the opinions on the creditworthiness of companies are sufficiently detailed to assess their actual ability to compete. At the same time, it is necessary to grasp if the IRS is sufficiently sighted in driving efficiency with the relationships between lenders and borrowers especially in an economic phase, such as the present one, in which the process of granting credit based on the rating has been facing difficulties higher than in a normal economic cycle.

The new environment requires a rethinking of the instrument as well as the explanation of the rating philosophy. The focus on the critical elements and the definition of the limits and potential use of the credit rating is a fundamental step to make sure that the spread of the rating represents a contribution to create value for all stakeholders and to promote the long-term content of the relationship between banks and firms.

In this context, the appropriate consideration of intangibles of the company is critical for two reasons. The first is the identification of the factors that should guide the design of an internal rating system, understood as a set of integrated tools, processes and procedures with different mix of automation and human judgment. The second is the need to provide guidance to the functional improvement of the methods of rating assignment, with particular reference to SMEs, which are a heterogeneous cluster. SMEs are different from each other as they operate in socio-economic and territorial composites, are often articulated in networks, have different operational and management maturity, have different intensities of capital and labor as well as diverse organizational, technical and legal complexity.

In addition to the assessment of the quantitative aspects of the enterprise, the attention must focus on the ability to incorporate in an IRS the intangibles of a company. In this sense, the rating must exceed the simple assignment of a score to understand the competitive advantage of a firm that is the foundation of its prospective value (and, conversely, of its risk). The revision and improvement of the rating process are a necessary step to ensure that the improvement of of bank-enterprise relationship favors the presence of a financial system capable of supporting the growth of companies and support them in difficult times, factor essential to the success of economic systems.

Is it Time for Internally Generated Intangible Assets to be Recognized in Financial Statements of U.S. Companies?

Abstract

Since the dawn of the Information Age, which has dramatic differences from the previous Industrial Revolution Age, valuation issues of intangible assets have generated many conceptual issues for accounting standard setters. The easiest way to deal with this is to ignore internally-generated intangible assets and only recognize these assets when externally obtained. However, the accounting profession itself is increasingly aware of the necessity to confront the knowledge-driven economy and recognizes that reporting systems have to be developed that reflect the increasing importance intangible asset have to organizations. In this paper we examine the issues surrounding the potential for reporting on internally generated intangible assets and the successful outcomes that could possibly result from such reporting.

Introduction

Intellectual property (IP) and intangible asset (IA) issues abound throughout the business world, touching nearly all aspects of a company, from product development to human capital, including staff functions such as legal, accounting, finance and line operations such as R&D, marketing and general management. This wide diversity of IP applications and stakeholders is a leading contributor to the complexity of managing IP, as each field has its own legal, regulatory and practitioner history. One aspect all these disciplines have in common is the need for valuation. The accounting profession itself is increasingly aware of the necessity to confront the knowledge-driven economy and recognizes that reporting systems have to be developed that reflect the increasing importance IP has. As of now only externally acquired IA are reported in financial statements and those elements that do not lend themselves to an independent valuation (human capital for instance) get lumped together in the recognition of goodwill, which accounting is controversial as well. The purpose of this paper is to examine the issues surrounding the potential for reporting on internally generated intangible assets and the successful outcomes that could possibly result from such reporting.

Standard-setters have reacted to problems that have occurred in reporting rather than anticipating areas where problems could occur to be proactive in enacting rules to deal with them. In the last few decades the area of intangible assets has been dominated by the discussion of accounting for goodwill alone. With the elimination of the pooling-of-interest method of accounting for mergers and acquisitions and the mandatory recognition of goodwill and the subsequent elimination of the requirement to amortize goodwill, interest in the area valuation of intangibles has been primarily focused on the accounting for goodwill. While goodwill may constitute a good portion of intangibles, for some companies other intangibles do amount to a significant item. As valuation issues of the other assets, such as investments, have been addressed with recent pronouncements, primarily to curb companies from overstating these items, it appears that the only area not being addressed is intangibles other than goodwill.

Literature Review

The issue of accounting for intangibles has been considered in earlier papers but most previous studies concentrate on definitions or disclosures not on valuation issues. Even at the turn of the century, researchers such as Holman and Kahn (2000) and Lev (2001) were recommending that the standard-setters allow companies to measure and disclose some of the intangible assets that were not allowed to be recognized such as intellectual capital and brand values. Quick & Goldschmid (2002) made recommendations to economists on how they could be useful to management in providing assistance in valuing these new intangible assets when allowed. Kaufmann and Schneider (2004) in their synthesis of the work done in the area of intangibles noted the differences in definitions and measurements world-wide and recommended that research be done that was more focused at giving companies tools to manage intangibles. Kristandl and Bontis (2007) reviewed extant literature and offered a definition for intangibles modeled on a resource-based view. Esquivel & Gornik-Tomaszewski, (2007) analyzed the then-issued SFAS 157 on fair value measurements

and proposed that the standard would increase consistency and comparability in impairment testing of intangibles. However they did not empirically test this proposition. White (2007) examined the use of intangibles in libraries and noted the lack of consensus in the definition and valuation of intangibles.

Basu & Waymire (2008) argued that intangibles usually were inseparable from tangible assets or other intangibles and hence it would be futile to try to value each individual intangible item. Skinner (2008) examined the recommendations for expanded disclosures and the recognition of additional intangibles and argued that these were not necessary, in his opinion, as the market seemed to already incorporate these items in their valuation of the companies' securities. Elwin (2008) in his discussion of Skinner's paper supported the conclusions drawn by Skinner and also concluded that changes in accounting for intangibles were not needed at that moment. Lev (2008), however, in his rejoinder disagreed with the position taken by Skinner and concluded that changes in the accounting for intangibles were quite necessary for undervaluation to not occur in companies' financial statements. In his reply, Skinner (2008) basically disagreed with the position taken by Lev.

Wyatt (2008) examined previous studies on the issue of value-relevance of financial and non-financial information in accounting for intangibles. She concluded that there might be a gap in the reporting of separate line items of expenditures on intangibles and recommended that standard-setters consider giving management more discretion in reporting value-relevant information on intangibles. Roslender (2009) provided an overview of the development of approaches to measuring and reporting intangibles and made recommendations for using the same method for recognizing intellectual capital. Arvidsson (2011) surveyed investor-relations managers at the largest companies listed in the Stockholm Stock Exchange and found that there was an increasing focus on non-financial information in the market and that voluntary disclosures compensate for any deficiencies of financial statements to disclose intangibles. Dumitrescu (2012) examined a sample of public companies in the Romania listed on the Bucharest Stock Exchange and concluded that companies do not place enough importance on disclosing information about intangible assets either due to their lack of awareness or the difficulty in measuring the value of intangible assets.

Measurement Issues

As the above review of the literature indicates, while the issue of disclosures of intangible assets has been dominant in accounting journals, not many recommendations have been made for valuation of these assets, especially when they are internally generated. The FASB does not allow the recognition and valuation of internally generated intangible assets due to the uncertainties involved in measuring such assets. These uncertainties may lead to manipulation of the reported financial position of the companies when such assets are over-valued. However, not recognizing these assets, especially as the nature of assets in the transition from manufacturing-based economies to the information age has changed drastically, clearly understates organizations' net assets in the U.S. marketplace. Two issues that result for the difficulty in valuing internally generated intangible assets are the problem of allocating costs incurred and the issue of separating these assets from others. Research & Development (R&D) costs are an example of the first issue. Due to the uncertainty of the results related to R&D costs, U.S. standard setters have determined that rather than choosing other methods (successful/unsuccessful or capitalize/amortize) which could allow some manipulation of the costs by companies, the only acceptable alternative is to expense these costs as companies incur them. This results in understating of income in the development years for companies incurring R&D costs, shifting this income to periods when the results of the R&D activities are actually realized. Two problems could occur with this approach. One is that companies may defer R&D activities in periods when they need to increase income, sacrificing the future for the present, which may threaten their competitive position. Secondly, pricing decisions made for products resulting from successful R&D activities could be impacted and lead to issues in the market place. If the prices are perceived to be high as compared to the production and distribution costs, there could be an adverse reaction in the market place and in some cases, especially for pharmaceutical products, may also lead to political pressures. In some cases companies may misprice their products, lowering of the sales price charged due to the R&D costs having been charged off to income in earlier periods which again may impact future periods.

The second issue of valuing internally generated intangible assets concerns the fact that the activities that result in these assets may also create others as also result in revenues in the period. Activities related to knowledge

creation and intellectual property (IP) fall into this category. Due to the difficulty in allocating costs, the standard setters prefer to expense all costs to revenues in the period. Any resultant intangible assets are thus not recognized in the period that they are created which also means they go unrecognized and understate the financial position of the companies until these are sold off to other companies. Most of these assets become part of the goodwill that is accounted for by the acquiring company. In the past goodwill was required to be amortized mandatorily but the FASB revised the standard to allow companies to carry these amounts indefinitely. Companies are required to assess if any of these amounts are impaired in each year and only write off these impaired amounts. Presumably companies would be using some valuation techniques to discern how much of the recognized goodwill has been impaired. However if the arguments to not recognize internally generated intangible assets are based on the fact that there is difficulty in separating the various elements that comprise these assets, these should probably apply to valuation of recognized goodwill as well. If however the standard setters are convinced that the valuation techniques to evaluate recognized goodwill and its impairment are adequate, then one can argue that these same techniques could be applied to value internally generated intangible assets as well.

Conclusions

Intangible assets are important resources to organizations, especially in the current Information Age. When corporations are not allowed to recognize internally generated intangible assets due to uncertainties in measurement techniques their financial positions are deliberately understated. While standard setters may be concerned more with overvaluations and hence focus more attention to limiting managers' choices in trying to manipulate overstatements, deliberately understating the financial position cause as many concerns to users of financial statements as do overstatements. This may also limit companies from obtaining sufficient capital to pursue all available strategies to develop and increase income from all sources including intangible assets, which ultimately affects the competitiveness of these companies in the global marketplace. Standard setters in the U.S. need to visit their position very soon on how to allow companies to incorporate valuations of intangible assets in the financial statements of companies.

Intellectual Capital as a determinant of Competitiveness: SMEs Manufacturing Industry in Guadalajara, Mexico

Abstract

The main purpose of this research is to analyse how the intellectual capital have the effects on the competitiveness in the SME's manufacturing located in Guadalajara, Mexico.

To determine the variables involved in this research, were analysed for the intellectual capital: the obtained information, intellectual capital developed and learning and feedback; and the competitiveness with other three factors: Financial Performance, Costs Reduction and Technology Use. The questionnaire was designed considering the competitiveness as dependant variable, and as independent variable the intellectual capital. Using the Likert scale in order to determine the degree of agreement or disagreement, and the survey was applied to 420 SME's. After this, it was applied questionnaires and demonstrated his validity. The results were analysed using confirmatory factor analysis (CFA), Cronbach's alpha and subsequently structural equation models (SEM).

Keywords: Intellectual Capital, Competitiveness, SMEs

Introduction

In a modern economy the process of entrepreneurship would be promoted not only by material background but also by immaterial (Mačerinskienė & Aleknavičiūtė, 2011), this condition is dictated by the changes in the organizational environment, companies require create value, but also consumers from implementing an organizational culture based on the desires and needs of customers, generating company loyalty (Atalay & Anafarta, 2011), those resources could make the difference between a competitive company or a noncompetitive company; actually innovation is the critical enabler for organizational value creation and sustainable competitive advantage (Chen & Huang, 2009), but the main obstacle for innovation is the low interest that organizations give to create the correct intellectual capital.

More than ever, intellectual capital must be viewed in organizations as a resource that despite its intangibility is on par with the tangible resources of the organization (Bounfour, 2003; Ross, et al., 2005), unlike any other resource, intellectual capital might be used to build a competitive strategy for international markets, becoming a significant source of values for modern companies (Szymura-Tyc, 2009) increasing their efficiency and effectiveness using tangible resources.

Theoretical framework

The traditional factors of production, labor, land and capital, are eclipsed into organizational distribution by the knowledge economy and intellectual capital, converting those non tangible resources into the most valuable factors of company competitiveness (Kavida, 2009); according to Majid, Lodhi and Rohra (2009), many competitive companies around the globe adopted Intellectual Capital as a strategy complement to increase their success improving the productivity and the efficiency in all senses.

Steward (1994) defined Intellectual Capital as the total stocks of collective knowledge, information, technologies, experience, organization learning, team communication systems and customer relations that are able to create values for a firm. IC includes intangible assets, capabilities and knowledge, which allow the development of basic processes of organizations, enabling the achievement of competitive advantages (Martin de Castro, 2011; Delgado, 2011; López, 2011; Navas, 2011).

Intellectual capital is becoming one of the important commercial assets of the 21st century is a way of describing a company's intangible assets that are vital for company success (Barsky & Marchant, 2000), for Bogdam, Balint and Farcas (2011), intellectual capital can be defined as knowledge that can be converted into a

value for organizations, in other words, intellectual capital is the sum of all knowledge that an organization is able to leverage in the process of conducting environmental management to gain competitive advantage (López-Gamero, et. al., 2011). Intellectual capital is knowledge that is valuable to an organization, is reusable and manageable (Singer, 2003).

Relational capital is defined as the set of relationships the company has with the environment. This type of capital is important because it provides an external evaluation of the market; provides information on trends and interests that show the agents of their environment, the relational capital is critical to make decisions, managers need to know how their investment in intellectual capital elements are linked to the performance of their companies (Wu, Tsai, Ceng & Lai , 2006).

Human Capital propose subcomponents such as the ability of employees or their satisfaction (Kaplan & Norton, 1996). Structural capital comprises all investments made to improve the experience and quality of the organization. Relational capital is included as well as culture (Saint Onge, 1996) organizational processes, intellectual property (Brooking, 1998) and customers or partners (Knight, 1999), and the intellectual capital as an intelligent and entrepreneurial organization, is in cash flow generation and competitiveness of its tangible assets (McDougall, 2005).

Fineman, Giza, Nahed, Lee & Hovda (2005), have suggested that intellectual capital is actually comprised two basic forms explicit knowledge and tacit knowledge, then, arriving to the knowledge economy has seen a decline in the relative importance of tangible resources, and demanded a paradigm shift to rely on knowledge and intellectual capital (Bontis, 1998; Guthrie, 2001).

This model could be used to increase the competitiveness into some industries that are references for the countries, in the case of Mexico, manufacturing industry is one of the most important industrial branch, just because provides commodities for national and international consumption; basically Intellectual Capital should be implanted and measured by a model that Veltri, Bronzetti and Sicoli (2011), design for the enterprises, considering market capitalization, Return to assets, Direct intellectual capital and scorecard. This intellectual capital measurement shows a pattern where a row within the organization processes must be planned in any of the four categories considered, besides that its effectiveness will be verifiable, writable and modified depending on the time and actions taken under different circumstances.

Competitiveness shows the ability to design, produce and commercialize superior products than those offered by the competition, is considered synonym of success, accomplishment of the objectives of the Enterprise (Bidu, Sala, Pantea, 2008). Chadee, Raman, Michailova (2011), define competitiveness as the ability to maintain and grow the business on a sustainable foundation. The sustainable growth can be determined as the most important method to evaluate the competitiveness (Bhattacharaya, Momaya, Iyer, 2009). It is generally recognized that the continuing competitiveness and economic growth are essential factors to sustain the standard of living and welfare (Balkytė, Tvaronavičienė, 2010).

Competitiveness is a different way of saying productivity, taking in consideration the rate of growth of a company in relation to other, (Krugman, 1994). The studies made by Krugman affirm that the best way of defining competitiveness is with the competitiveness-productivity relation, in which each of the companies fulfill their objectives, establishing standards in a certain period of time, as well as the growth in comparison to the others. Pucar (2012) also agrees that the only way to create a competitive advantage is through intellectual capital, arguing that the intellectual capital perspective can be a base for accelerated economic growth and development.

Tseng & Yeong-Jia, (2005) affirms that competitive success of an organization relates to the way in which tangible and intangible resources are managed. The intangible assets or intellectual capital includes structural human capital and clients. It plays an important role in competitiveness of a company and can increase profit. (Hazlina, Zubaidah, 2008).

The organizations that are constantly in an innovation process, are the first to stand out and show unlike any other, companies that innovate constantly is because they know the market needs are changing and they look forward to penetrate it, innovation is an essential factor for competitiveness, but it is also important to include internal factors such as technology and management, and external factors such as market structure and product position in the market, establishing that these factors are the ones that give an added value to the company (Gao, Liu, Song, Zheng, 2013).

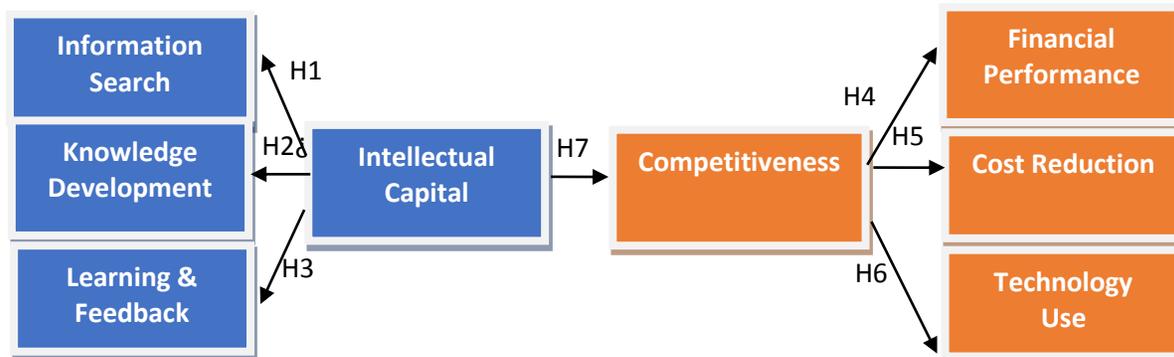

FIG. 1: THEORETICAL MODEL RELATING INTELLECTUAL CAPITAL AND COMPETITIVENESS
Source: own

Methodology

The surveys were applied in 418 SME's of manufacturing industry in the city of Guadalajara, Mexico, during July and August 2013.

Also, there are seven hypotheses that will contribute to this research:

H1: Higher level of new information, higher level of intellectual capital.

H2: Higher level of knowledge development, higher level of intellectual capital.

H3: Higher level of learning and feedback, higher level of intellectual capital.

H4: Higher level of financial performance, higher level of business competitiveness.

H5: Higher level of cost reduction, greater level of business competitiveness.

H6: Higher level of technology use, greater level of business competitiveness.

H7: Higher level of intellectual capital development, higher level of business competitiveness.

Similarly, to measure the level of competitiveness were considered the three factors proposed by Buckley *et al.* (1988): 1) *financial performance*, 2) *costs reduction*, and 3) *technology use*, all of these, measured by a scale of 6 items. All the items of the three factors are built by a level Likert type of 5 positions, with 1 = completely in disagreement to 5 = completely agree as limits.

To assess the reliability and validity of scales measuring of the level of intellectual capital and business competitiveness, a Confirmatory Factorial analysis (CFA) with the method of maximum likelihood and EQS 6.1 software (Bentler, 2005;) Brown, 2006; (Byrne, 2006).

Rates of statistical adjustment that were considered were the NFI, NNFI, IFC and RMSEA (Bentler & Bonnet, 1980;) Byrne, 1989; Bentler, 1990; Hair et al., 1995; Chau, 1997; (Heck, 1998).

Analysis and Discussion

The results of the Confirmatory Factorial Analysis (CFA) are presented in table 1 and shown that the measurement model provides a good fit of the data. As evidence of the convergent validity, the CFA indicates that all items of the related factors are significant ($p < 0.01$), which provides evidence of reliability and justifies the internal reliability of the scale of the business competitiveness (Nunally & Bernstein 1994); (Hair et al., 1995) show in table 1.

TABLE 1: INTERNAL CONSISTENCY AND CONVERGENT VALIDITY OF THE THEORETICAL MODEL

Variable	Indicator	Factor Loading	Robust T- Value	Cronbach's Alpha	CRI	VEI
Information search (F1)	CIB1	0.685***	1.000 ^a	0.866	0.862	0.535

Competitiveness	F4	0.787***	5.237	0.824	0.822	0.615
	F5	0.767***	5.223			
	F6	0.763***	5.218			

Related to the evidence of the discriminant validity, measurement of the scale of the business competitiveness level was through two ways which you can see in more detail in table 2. First, the range of 95% of confidentiality, none of the individual elements of the correlation factors matrix contains the value 1.0 (Anderson & Gerbing, 1988). Second, the variance extracted between each pair of factors is higher than its corresponding VEI (Fornell & Larcker, 1981). Therefore, based on these criteria one can conclude that the different measurements made on the scale show enough evidence of reliability and convergent and discriminant validity. See table 2.

TABLE 2: DISCRIMINANT VALIDITY OF THE THEORETICAL MODEL MEASUREMENT

Variables	Intellectual Capital	Competitiveness
Intellectual Capital	0.658*	0.159
Competitiveness	0.343 - 0.455	0.606*

*These values presented the estimation of the correlation factors with a confidence interval of 95%.

The hypotheses were tested in the theoretical model of innovation and business competitiveness, using the Structural Equations Model (SEM) software EQS 6.1 (Bentler, 2005;) Byrne, 2006; (Brown, 2006).

The nomological validity of the theoretical model was analyzed through the performance of the chi-square test, in which the theoretical model was compared with the measurement model, not finding significant differences (Anderson & Gerbing, 1988;)(Hatcher, 1994). The results of this analysis are presented in table 3.

TABLE 3: RESULTS OF THE THEORETICAL MODEL OF BUSINESS COMPETITIVENESS

Hypothesis	Structural Relationship	Standardized Coefficient	Robust T-Value
H1: Higher level of new information, increase the level of intellectual capital.	Information search. → Int. Cap.	0.226***	5.703
H2: Higher level of knowledge development, increase the level of intellectual capital.	Knowledge develop. → Int. Cap.	0.469***	7.114
H3: Higher level of learning and feedback, increase the level of intellectual capital.	Learning & feedback → Int. Cap.	0.366***	6.500
H4: Higher level of financial performance, greater level of business competitiveness.	Financial Perfor. → Competitiveness	0.571***	11.846
H5: Higher level of cost reduction, greater level of business competitiveness.	Cost Reduction → Competitiveness	0.222***	6.187
H6: Higher level of technology use, greater level of business competitiveness.	Technology use → Competitiveness	0.323***	7.999
H7: Greater level of intellectual capital development, greater level of business competitiveness.	Intel. Capital → Competitiveness	0.299***	0.8.677
<i>S-BX2 (df = 184) = 443.307; p < 0.000; NFI = 0.894; NNFI = 0.918; CFI = 0.934; RMSEA = 0.058</i>			

*** = p < 0.001

The table 3 shown the results obtained of the Structural Equations Model, with regard to the **H1** the results obtained, $\beta = 0.226$, $p < 0.001$, indicate that searching information has significant effects with the intellectual capital in manufacturing firms. As for the hypothesis **H2**, the results obtained, $\beta = 0.469$, $p < 0.001$, suggest that knowledge development also have significant effects in the intellectual capital. En the hypothesis **H3** the results obtained, $\beta = 0.366$, $p < 0.001$, suggest that the learning and feedback also have significant effects in the manufacturing firms.

Also, respect with hypothesis **H4** the results obtained, $\beta = 0.571$, $p < 0.001$, indicate that the financial performance has significant effects on the competitiveness level. In the hypothesis **H5** the results obtained, $\beta = 0.222$, $p < 0.001$), suggest that cost reduction also have significant effects on business competitiveness. The results obtained in the hypothesis **H6**, $\beta = 0.323$, $p < 0.001$, suggest that the technology use also has significant effects on business competitiveness. Finally, the results obtained in the hypothesis **H7**, $\beta = 0.299$, $p < 0.001$, presented that the intellectual capital has significant effects on business competitiveness.

Limitations

The first limitation, the sample considered companies from 20 to 250 workers, excluding the companies from 1 to 10 workers, which representing an important quantity of the total manufacturing SME's, then, for future studies should be important to consider these companies to analyze the effects of intellectual capital in business competitiveness.

A second limitation is that the questionnaire was applied to directors or CEO's level, and the results could differ in functional managers. Therefore, in future studies, it could be important to consider the opinion of customers and suppliers to analyze the results obtained.

Finally, it is important to go beyond the technical results and discuss in greater depth: what effects should in SME manufacturing if a more quantitative scale is used to measure the business competitiveness? What results would be in SME manufacturing if applies a more sophisticated model for the measurement of business competitiveness? What specific activities of the financial performance, the reduction of costs and the use of technology are those that most affect business competitiveness? These and other questions that may arise can be answered in future research.

Conclusions

This research had shown that SME's manufacturing in Guadalajara, have a good correlation between the dependent variable competitiveness with the independent variable intellectual capital, and the results expressed in this study appear to be consistent with the relation of factors technology use, costs and financial performance with the variable competitiveness, and also the factors information search, knowledge development, and learning and feedback are related with the variable intellectual capital.

These SME's are in a transformation process of administrative schemes, with a more cognitive and sustainable system, being conscious to create and generate new information, increasing knowledge development and learning and feedback knowledge in all the organization.

Relevance of Intangibles in European Companies' Balance Sheets – an Empirical Perspective

Abstract

This empirical research discusses the quantitative relevance of intangibles in European companies' balance sheets, represented by the share of intangible assets compared to a company's total assets. It analyzes 600 of the most important European companies from 24 countries across 19 industries along 3 key dimensions: size, industry, and geography.

In 2012, intangible assets on average accounted for a fifth (19.7%) of a company's total assets (median: 13.4%). However, this varies considerably by industry: from less than 1% for banks (0.7%) and real estate (0.1%) to more than 35% for media (41.3%) and health care (37.1%).

Concerning size, only a relatively weak – but statistically significant – negative linear correlation is observed between a company's revenues and its intangibles share. The analysis also yields that for nearly all countries the observed intangibles share does not deviate statistically significantly from the 'expected' share given a country's industry structure.

Introduction

For a multitude of companies, intangibles are a relevant aspect of their business. Such business-relevant intangibles exist in a huge variety of types, ranging from rather easy-to-grasp, concrete assets – for instance patents, licenses, software, or brands – to elusive, hardly quantifiable aspects, for instance knowledge-based resources or the skills and experience of employees. However, in contrast to this 'qualitative' relevance of intangibles, which has already received considerable attention, both from a scientific and from a business perspective, several 'quantitative' aspects, in particular the empirical relevance of the resulting intangible assets on a company's balance sheet from an accounting perspective, have been largely neglected so far. This paper will address exactly this aspect.

The research goal of this paper is thus to contribute to the discussion regarding the role and relevance of intangibles by depicting, from an empirical perspective, the quantitative relevance of intangibles in European companies' balance sheets, represented by the share of intangible assets compared to a company's total assets. Although this relative share of intangible assets in the balance sheet is not a perfect proxy for the relevance of intangibles – in particular as some specific intangibles are not capitalized in the balance sheet – it provides a very good indication for the quantitative relevance from an empirical accounting perspective.

The object for this empirical analysis consists of the intangible assets specified in the balance sheets of the annual consolidated accounts of the most important publicly traded European enterprises. However, given that the treatment of intangible assets – and thus its absolute and relative size in the balance sheet – is strongly influenced by the underlying accounting standard, this paper will focus only on companies using IAS/IFRS rules – which is the vast majority of listed European companies anyway – to ensure comparability and stability of the base data and validity of the findings. Furthermore, IAS/IFRS also presents a rather accurate picture of a capitalized intangible asset's value compared to some alternative accounting rules, for instance the national accounting standards in Germany (HGB), which disallow the appreciation of intangible assets above their original historical costs even if their intrinsic value has increased in the meanwhile.

The research paper follows a clear structure: The first part describes how the relevant data set, containing 600 European companies, was derived and provides some high-level insights. Subsequently, the assessment of the relative share of intangibles is conducted along three key dimensions, which are analyzed and discussed one by one: company size, industry, and geography. Finally, the overall results are condensed and summarized.

Object for analysis

Derivation of the data set for analysis

In order to obtain a representative sample of the most important publicly traded European enterprises, the data set for analysis is taken from the Stoxx All Europe 800 Index, which represents the 800 largest companies in Europe. This index has been selected as it covers – in contrast to many other ‘European’ indices – all European states, inside and outside the European Union (EU), both Euro and non-Euro countries, as well as enterprises from Eastern and Western Europe.

The analysis will be conducted based on the balance sheets taken from the group’s annual consolidated accounts for the financial year 2012, for reasons of data availability. In the case of a deviation between financial and legal year, the reporting period that covers the larger share of 2012 has been selected.¹ In a second preparatory step, the index’s original geographical allocation has been adjusted for a small number of companies; in particular, enterprises from UK-related territories, for instance Guernsey and Jersey, have been allocated to the UK for the purpose of this analysis.

As pointed out in the introduction, only companies preparing their accounts in line with IAS/IFRS are considered, for reasons of comparability. As a consequence, all non-IAS/IFRS companies have been taken out, in particular all companies from Turkey, selected companies from Switzerland, Russia and Great Britain that report according to US-GAAP, as well as various individual enterprises that also prepare their group accounts based on US-GAAP, for instance ASML from the Netherlands and Fresenius from Germany.

This left a total of 750 ‘eligible’ enterprises, from which a sample of 600 companies (80%) has been taken. In order to obtain a data set that very well represents the most important exchange-traded European companies across geographies, industries, and size, the sample was selected in such a way that it includes – for every industry and for each geography – at least two thirds of all ‘eligible’ companies and 90% of the respective industry’s or geography’s ‘eligible’ market capitalization.

Given that IAS/IFRS does not specify a fixed compulsory balance sheet structure (IAS 1.57) – in contrast for example to national accounting rules in Germany (§266 HGB) – the information regarding the total amount of intangible assets capitalized in the balance sheet can be either stated in one balance sheet item, or split into various positions. As a consequence, only for less than half of the companies (48%) data could be taken directly from the Bloomberg database (Bloomberg, 2014). For the remaining companies, the data had to be obtained manually based on the respective company’s published consolidated financial statements. In case of non-Euro financial statements, currency conversion was accomplished via historical values, using end-of-period exchange rates for balance sheet items and average exchange rate of the respective period for items in the profit and loss statement.²

High-level results

In total, the analyzed data set contains 600 European companies from 24 countries across 19 industries. The data set covers enterprises with highly differing sizes: revenues range from 52 million Euros to 364 billion Euros, market capitalization lies between 194 million Euros and 168 billion Euros. The total market capitalization of the analyzed companies amounts to 7.49 trillion Euros as of December 31st, 2012, representing 95.3% of the market capitalization of the ‘eligible’ European companies.

With regard to the underlying question of the relevance of intangibles for these companies, represented by the share of intangible assets compared to the total assets capitalized in the balance sheet, the high-level analysis yields an overall average share of 19.7% (median: 13.4%), meaning that, on average, one fifth of a company’s total reported assets are intangible.³ However, the range is very large, spanning from virtually zero up to about 80% in individual cases. This is also depicted in figure 1, which illustrates the distribution of the share of intangible assets across the data set:

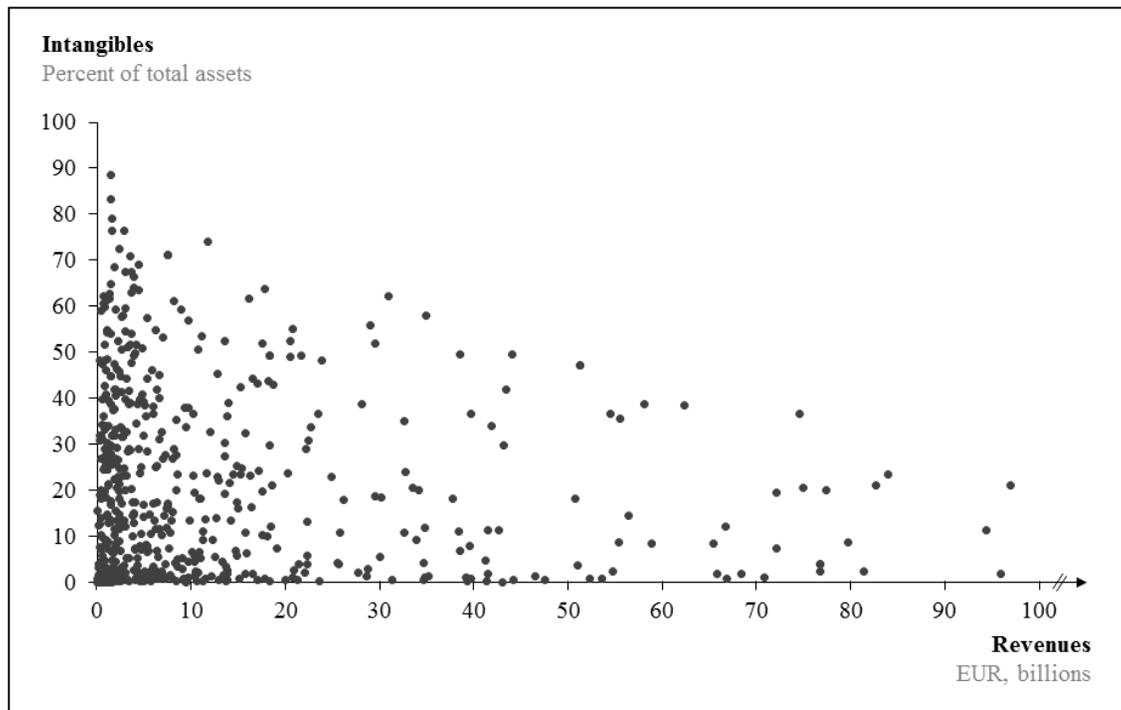

FIG. 1: DISTRIBUTION OF THE SHARE OF INTANGIBLES, 2012, CAPPED⁴

The above scatter chart illustrates that the data is obviously not normally distributed and potentially skewed, which is also indicated by the difference between mean (19.7%) and median (13.4%). In order to test this indication statistically, two skewness test statistics are calculated, as suggested by Doane and Seward (2011), with the null hypothesis being that the data is symmetrical: the adjusted Fisher-Pearson standardized moment coefficient ($G_1=0.9628$) and the Pearson 2 skewness coefficient ($Sk_2=0.9571$). Both statistics are far above the respective tabulated critical values⁵ (Doane & Seward, 2011), thus resulting in the null hypothesis being rejected in favor of the alternative hypothesis, which suggests non-normal skewness. As a consequence, it seems more adequate to use the median instead of the mean for the subsequent analyses.

Analysis by company size

Method

Whenever intangibles-based rankings are published in the media, large companies typically occupy the top-positions, for instance with regard to largest brand values (WPP Group, 2014) or highest investments into research & development (European Commission, 2013). This could, at first sight, let one believe that intangibles might be more relevant for larger companies than for smaller ones.

The resulting research question for this section is therefore to analyze whether there actually is a statistically significant linear relationship between an enterprise's size and its share of intangibles. For the purpose of this analysis, size is represented in two ways: revenues (representing the size of the company's operations) and market capitalization (representing its stock-market value-based size).

The analytical setup encompasses two components: a linear correlation analysis based on the full data set, and a linear correlation analysis based on decile-groups. For the first analysis, the Pearson product-moment correlation coefficient (r) is calculated to measure the degree of linear dependence between the share of intangibles and the

revenues respectively the market capitalization, based on the full data set of $n=600$ enterprises. Subsequently, a two-tailed t-test with $n-2$ degrees of freedom is conducted to determine whether the correlation coefficient r significantly differs from zero, with the null hypothesis being that r equals zero. For the second analysis, the companies are ranked and allocated into ten groups based on deciles with regard to their revenues (respectively their market capitalization) in ascending order. For instance, the first group (decile 1) includes the 60 companies with the lowest 10% of revenues, the second group (decile 2) contains the 60 companies with revenue ranks between 10% and 20%, etc. For each group, the median revenue (respectively market capitalization) and the median share of intangibles are calculated. Then the Pearson product-moment correlation coefficient is calculated across the ten groups, followed by a two-tailed t-test equivalent to the one described above.

Results

The linear correlation analysis based on the full data set with market capitalization as proxy for size yields a Pearson product-moment correlation coefficient of $r=0.04$, which could indicate a very small positive linear relationship. The subsequent two-tailed t-test results in the null hypothesis not being rejected at the 5% confidence level ($p=0.35$), which means that there is no statistically significant linear correlation between market capitalization and the share of intangibles.

With regard to revenues, the linear correlation analysis based on the full data set results in a Pearson product-moment correlation coefficient of $r=-0.10$, which potentially indicates a rather weak negative linear dependence. The respective two-tailed t-test results in the null hypothesis being rejected at the 5% level ($p=0.01$) in favor of the alternative hypothesis. This implies that there is a statistically significant linear relationship between the revenues and the intangibles share, but it is extremely small. This is also illustrated, to a certain extent, in figure 1.

For market capitalization, the linear correlation analysis based on decile-groups results in a Pearson product-moment correlation coefficient of $r=-0.38$. The respective two-tailed t-test leads to the null hypothesis not being rejected at the 5% level ($p=0.27$). This implies that there is also no statistically significant linear relationship for market capitalization on the group level. The linear correlation analysis with revenue-based decile-groups yields similar results ($r=-0.33$; $p=0.35$), i.e. no statistically significant linear correlation could be observed on a group-base.

Overall, there does not seem to be a linear correlation between market capitalization and the share of intangibles, but there is limited evidence for a – relatively weak – linear relationship between the relevance of intangibles – represented by the share of intangibles compared to total balance sheet assets – and the size of a company, represented by its revenues. However, in contrast to what one might have expected, this weak linear relationship is negative, i.e. larger companies, to a certain extent, tend to have a smaller intangibles share.

Despite seeming counterintuitive at first glance, this finding does not contradict the ‘intangibles facts’ stated earlier: larger companies on average very likely do possess a larger absolute number of intangibles assets, but the relative share decreases with size.⁶ Nevertheless, one has to bear in mind that the observed linear relationship is actually very weak.

Analysis by industry

Method

In qualitative terms, the underlying importance of intangibles differs considerably amongst industries, for instance due to a varying relevance of patents, licenses, R&D, software, etc. within the business model of each industry. Furthermore, the balance sheet structure is also highly dependent on the industry that a company operates in; for instance, the asset structure is completely different for manufacturing vs. service industry enterprises, or for banks vs. trade companies. As a consequence, one might expect that the share of intangibles also differs between industries.

This leads directly to the research question for this section, which aims to analyze whether there is a statistically significant difference in the share of intangibles with regard to industries. For the purpose of this analysis, all companies have been allocated to 19 ‘supersectors’ in line with the industry classification benchmark (ICB) as

provided by the Bloomberg database (Bloomberg, 2014). These ‘ICB supersectors’ are referred to as ‘industries’ throughout this paper.

For each of the 19 industries the median share of intangibles is calculated, referred to as ‘industry-median’ in the following paragraphs. Every industry-median is then individually tested against the overall median (13.37) with the null hypothesis being that the industry-median equals the overall median. Given the non-normal distribution and the partly small sample size, a non-parametric sign test is used (Fahrmeir, Künstler, Pigeot, & Tutz, 2007). It is expected that industries with an industry-median that is close to the overall median will not show a statistically significant deviation from the overall median. Therefore, in a second step, industries are tested against the first and third quartiles: industries with a median intangibles share above the overall median are tested against the 25%-quartile (2.19), those with an industry-median below the overall median are tested against the 75%-quartile (32.18). On top, in a third analysis, a set of three two-samples tests is conducted to test selected pairs of industries against each other, in order to examine whether their intangibles shares do differ pairwise. For this purpose, given non-normal distribution and partly small sample sizes, the non-parametric Wilcoxon rank sum test is selected (Newbold, Carlson, & Thorne, 2012), preceded by a Brown-Forsythe test of homoscedasticity⁷, to satisfy the Wilcoxon rank sum test’s requirement of homogeneity of variances (Fahrmeir et al., 2007).

Results

As expected, the result of the first analysis reveals considerable differences between industries with regard to the median share of intangibles, as figure 2 illustrates. Industries with a high qualitative importance of intangibles tend to have a higher share – for instance media (licenses) and health care (patents) companies – while the observed intangibles share is smaller for industries with a lower qualitative relevance of intangible assets.

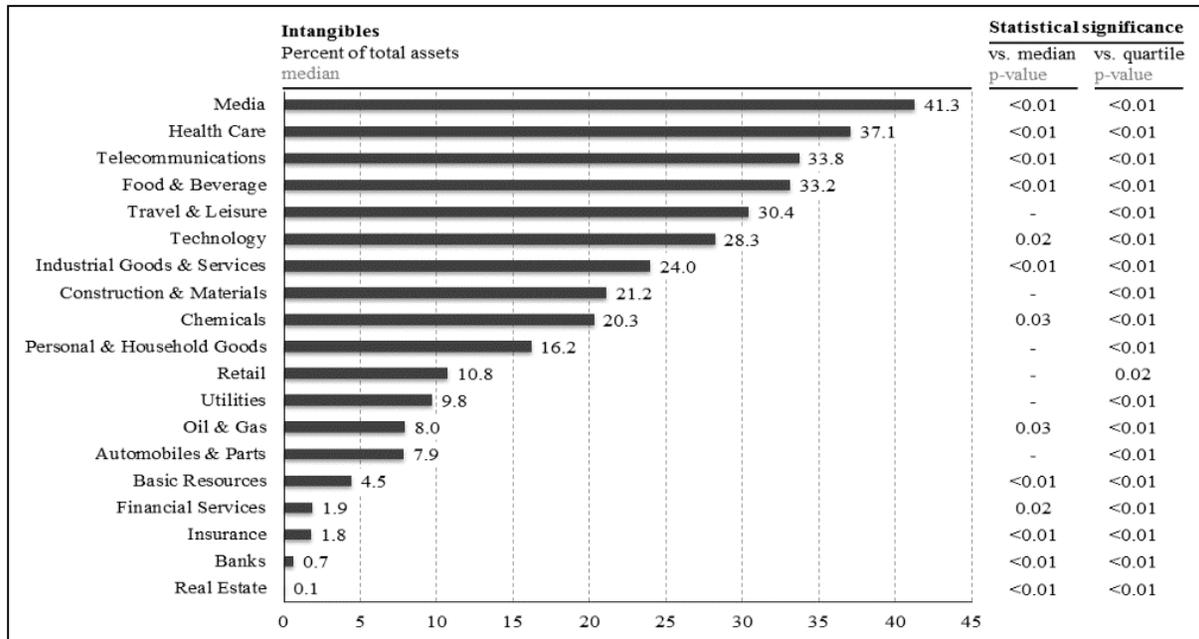

FIG. 2: SHARE OF INTANGIBLES BY INDUSTRY, 2012

The results of the first series of non-parametric sign tests indicate that, for the majority of industries, the respective industry-median differs statistically significantly from the overall median on the 5% confidence level, i.e.

the null hypothesis is rejected (p-values are provided in figure 2 above). For six industries, the results are not statistically significant, in particular for industries with a median that is close to the overall median, as expected.

The second series of non-parametric sign tests – incorporating the 25%/75%-quartile instead of the overall median – yields statistically significant results for all industries. The null hypothesis is rejected at the 5%-level in all cases (p-values are provided in figure 2 above) in favor of the alternative hypothesis, implying that each industry's intangibles share differs statistically significantly from the respective value of the 'opposite' 1st/3rd quartile.

The results of the third set of tests provide further evidence that there seems to be a statistically significant difference in the share of intangibles between industries. The first pair for testing is selected based on the results of the very first analytical series: out of the six industries with initially non-significant difference versus the overall median, two industries are selected: the 'middle' one of the 3 industries that are above the overall median (i.e. construction and materials) and the 'middle' one of the 3 industries that are below the overall median (i.e. utilities). Following the 'passed' Brown-Forsythe test, the one-tailed two-samples Wilcoxon rank sum test – with H_0 being that the industry-median of construction and materials is equal or less than the industry-median of utilities, and H_a stating that the former is higher than the latter – results in the null hypothesis being rejected at the 5%-level ($p=0.02$) in favor of the alternative hypothesis. This means that the intangibles share of construction and materials is statistically significantly higher than the share of intangibles of utilities. In a second set of analog tests, the telecommunications industry – selected as it is close to and slightly above the 75%-quartile – is compared against two other industries: personal & household goods (which has a 'semi-high' industry-median) and retail (which has a 'semi-low' industry-median). Subsequent to the 'passed' Brown-Forsythe pre-tests, both one-tailed two-samples Wilcoxon rank sum tests yield statistically significant results for both pairs at the 5%-level (p-values are 0.04 and 0.03), meaning that the share of intangibles is statistically significantly different for telecommunications compared to utilities or personal & household goods.

Overall, the results clearly imply that there are considerable differences between industries with regard to the quantitatively observable share of intangibles, and, as a consequence, that the industry in which an enterprise operates does significantly impact the observed share of intangibles. However, it must be pointed out that the analytical results do not claim that the intangibles share of each industry does differ from the share of every other industry. In particular for industries with very similar industry-medians – for instance insurance (1.83) and financial services (1.93) or food & beverage (33.19) and telecommunications (33.76) – this cannot be claimed. However, the analyses do show that there are statistically significant differences among certain industries and in particular between groups of industries, for instance between 'high-share' and 'low-share' industries, but also amongst 'high-share' industries like telecommunications and 'semi-high-share' industries like personal & household goods, or between 'semi-high-share' industries like construction & materials and 'semi-low-share' industries like utilities.

Analysis by geography

Method

The third and final dimension for analysis is related to the geographic location of a company, which could potentially influence the share of intangibles in the balance sheet, although there is no obvious argument with regard to the likely direction of a potential influence.⁸ However, as outlined before, industry is a key factor that influences a company's share of intangibles. Combining this finding with the fact that the industry structure differs considerably amongst countries, results in the requirement of incorporating the aspect of industry structure into the geographic analysis.

This is achieved by constructing a 'standardized' intangibles share for each country: for every country, the country's actual industry structure – as observed in the data set – is combined with the respective 'industry-medians' calculated earlier. The resulting standardized share of intangibles for a country represents a country's 'expected' intangibles share given the industry structure: it illustrates what the intangibles share for this country would be if all its companies had intangibles shares equal to the median share of the respective industry. If the observed intangibles share of a country is higher or lower than its 'standardized' one, then this difference must be due to a factor different from industry composition, as the influence of the industrial structure has been eliminated.

Resulting from the above considerations, the research question for this analysis is whether there is a statistically significant difference between a country's observed vs. its standardized intangibles share, which could potentially be interpreted as a hint towards a country-specific influence on the share of intangibles.

The data set contains companies from 24 different countries. For each of these 24 geographies the median share of intangibles is calculated, referred to as 'country-median' in the following paragraphs. However, only countries with a minimum size of at least 3 companies in the data set are taken into account when calculating the standardized intangibles share. As a consequence, 3 countries cannot be considered for the standardization: Croatia, Romania, and Slovenia.

Subsequently, every country-median is individually tested against its respective standardized intangibles share, in order to test whether the observed differences are actually statistically significant. Along the lines of the previous analyses, a one-sample two-tailed non-parametric sign test is selected for this purpose, with the null hypothesis being that the country-median is equal to the respective standardized intangibles share, and the alternative hypothesis being that they differ statistically significantly.

Results

Fig. 3 depicts the observed median intangibles share for each of the 24 countries resulting from the analysis as well as the standardized intangibles share calculated for every geography based on its industry structure:

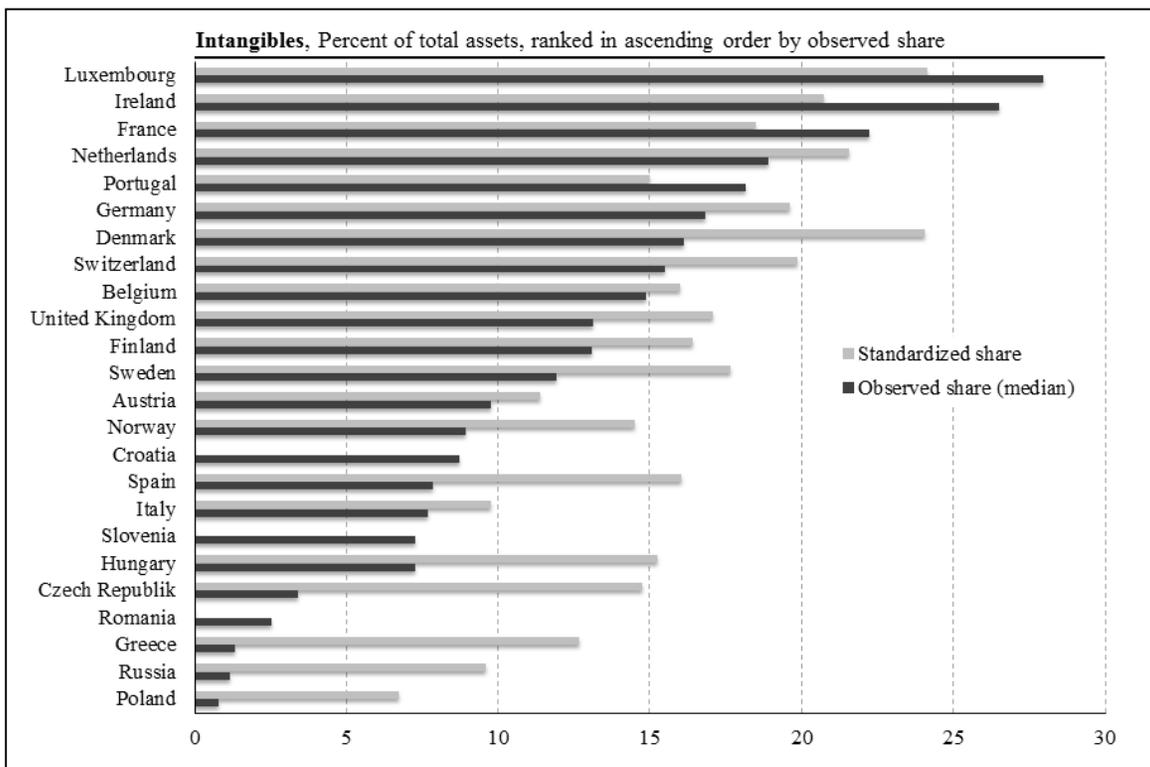

FIG. 3: SHARE OF INTANGIBLES BY GEOGRAPHY, 2012

As figure 3 illustrates, there seem to be – partly rather large – differences in the intangible shares. However, the analysis reveals that these differences are not statistically significant at the 5% level for the majority of countries.

Only for two countries, Poland ($p=0.02$) and Russia ($p=0.02$), the null hypothesis is rejected at the 5%-level in favor of the alternative hypothesis, implying that the observed intangibles share is actually statistically different from the standardized share. In fact, both countries have actual shares far below what one would expect given their industry structures, which could be interpreted as a strong hint towards a potential country-specific influence on intangibles in Russia and Poland.

For all other countries, the null hypothesis is not rejected at the 5%-level. This means that the observed deviations between country-median and standardized intangibles share are not statistically significant. It must be noted that these results do by no means imply or prove that both are equal; however, not finding a statistically significant deviation – for such a large number of countries – could potentially be interpreted as a valuable first hint that the standardized share might be an interesting reference point for a country's intrinsic intangible share and for detecting potential country-specific influences, as seems to be the case with Russia and Poland.

Summary and conclusions

The stated research goal of this paper was to contribute to the discussion regarding the role and relevance of intangibles by depicting, from an empirical perspective, the quantitative relevance of intangibles in European companies' balance sheets, represented by the share of intangible assets compared to a company's total assets. This has been accomplished by empirically analyzing 600 of the most important publicly listed European companies from 24 countries across 19 industries. These analyses have resulted in various highly interesting findings. In particular, four key insights can be distilled:

Firstly, intangibles are indeed highly relevant for European companies from a quantitative balance sheet perspective: in 2012, intangible assets on average accounted for a fifth of a company's total assets, which is definitely not a negligible share. This share varies considerably among companies, ranging from virtually zero to about 80% in individual cases. Furthermore, given that particular intangibles - for instance internally generated brands and goodwill - must not be recognized and shown as intangibles assets in the balance sheet (IAS 38.51 ff.), the 'true' share and relevance of intangibles could in fact be even higher.

Secondly, industry is a key determining factor for the share of intangibles, and thus for the quantitative relevance of intangibles. The observed intangibles shares differ considerably depending on the industry: for instance, while the median share of real estate companies (0.1%) and banks (0.7%) is very low, other industries like media (41.3%) and health care (37.1%) have a very high median share. The analysis also points towards statistically significant differences among many industries and in particular between quartile-based industry groups. In fact, industry clearly turns out to be the most important of the three analyzed dimensions.

Thirdly, there is no statistically significant evidence for pervasive country-specific determinants for the share of intangibles if the industry structure is taken into account. Only 2 out of 24 countries show a statistically significant deviation between the observed intangibles share and the 'standardized share', i.e. the 'expected' share given the country's industry structure: Poland and Russia; for all other countries there is no evidence for a significant deviation. As a consequence, this 'standardized share' could potentially be a very interesting reference point for a country's 'intrinsic' intangible share.

Fourthly, company size is much less influential than one might have expected. In fact, the analytical results yield only a relatively weak – nevertheless statistically significant – linear correlation between a company's revenues and its intangibles share; and this linear correlation is negative. This signifies that the relative share of a company's intangible assets – not the absolute value of intangible assets – tends to slightly decrease as company size increases. With regard to market capitalization, another potential measure for size, there is no statistically significant evidence at all for a linear relationship though.

In total, the research conducted in this paper generates valuable insights into an area that has not been addressed scientifically in detail so far, by providing an empirical perspective on the quantitative relevance of intangibles in European companies' balance sheets. The presented findings also enrich and complement the ongoing discussion regarding the role and relevance of intangibles.

Nevertheless, this research needs to be seen and understood primarily as a valuable starting point for entering this highly interesting yet relatively unknown area. There are plenty of opportunities for future research to validate, complement and extend the initial findings, for instance analyses covering additional financial periods or including further geographic areas.

End Notes

¹ This includes for instance financial years ending on March 31st, 2013, or on September 30th, 2012.

² In particular with regard to revenues, as these are necessary for the analysis by company size.

³ In fact, the true share (and thus the relevance) of intangibles is even higher, as various intangible assets – for instance internally generated brand names or customer lists – are not represented in the balance sheet.

⁴ The diagram is ‘capped’ at a revenues cut-off of 100 billion Euros to ensure legibility. The analyses throughout this paper do of course incorporate all companies in the data set, including those not shown in figure 1.

⁵ The tables present a 90% critical value only for sample sizes up to $n=500$ (0.179); the critical value for $n=600$ should be even slightly smaller. In any case, the obtained test statistics of 0.96 are far above that value.

⁶ Furthermore, with regard to the brand values mentioned earlier, these are in some cases not even included in the balance sheet’s intangible assets, as only acquired brand names are capitalized, in contrast to internally generated brand names, which must not be recognized in the balance sheet (IAS 38.63).

⁷ The Bartlett's test, which is often applied as standard test for homoscedasticity, must not be used here, as it requires a normal distribution. Furthermore, in contrast to the Levene’s test, which uses the mean, the Brown-Forsythe test uses the median, and is thus the most suitable test for the given purpose.

⁸ In fact, there are various arguments for a higher share as well as several reasons to argue towards a lower share of intangibles given one and the same initial situation of a company respectively a country.

**Why the Future of Transfer Pricing is linked to Improving
the Valuation of Intangibles**

Why the Future of Transfer Pricing is linked to Improving the Valuation of Intangibles

Abstract

The current debate on Base Erosion and Profit Shifting (BEPS) may well lead to a paradigm shift in international taxation. The respective reform agenda of the OECD addresses the challenges of valuating intangibles in the context of transfer pricing, aiming at ensuring that transfer pricing outcomes are in line with value creation.

Various political actors perceive the initiated reforms as being insufficient and advocate replacing the main paradigm of international transfer pricing, the so-called the arm's length principle (ALP¹), with a system based on formulary apportionment (FA). The advocacy of FA has gained a position of considerable strength within EU legislation, being embedded in the Commission's proposal for a common consolidated corporate tax base (CCCTB).

This paper will show that FA is ill-suited to account for the increasing impact of intangible assets on the value creation by multinational enterprises and thus does not constitute a panacea for BEPS.

The Economic Impact of BEPS

In its 2013 Report on BEPS the OECD references various headline news stories (e.g. New York Times, Guardian) in order to capture the prevailing public sentiment, namely a growing perception that governments lose substantial tax revenue due to aggressive tax planning (OECD, 2013). The referenced articles describe how MNEs (predominantly US corporations such as Starbucks, Microsoft or Google) manage to reduce their tax burden by taking advantage of differences between national taxation regimes. The development of the effective corporate tax rates of companies listed in the S&P 500 suggests that US based IT firms have been particularly successful in utilizing various sections of the US tax code. In his testimony before a US Senate Subcommittee, Ciesielski demonstrated that the effective tax rate of US based IT firms declined from 27,2% in 2006 to 22,7% in 2011, while for non-IT firms the rate only exhibits a modest decline from 32,0% to 30,1% (Ciesielski, 2012). Optimization of the effective tax rate is commonly achieved by utilizing rather elaborate corporate structures involving holding companies in combination with so-called hybrid companies (e.g. structures such as a "Dutch-Sandwich" or a "Double Irish"). A common feature of such structures is the location of the IP in an entity that is located in a low-tax jurisdiction and to subsequently utilize transfer pricing (royalty payments) to shift a significant part of the corporate profit to this entity².

It should be noted, however, that the effect described by Ciesielski is mostly attributable to an idiosyncratic feature of the US tax code, rather than being representative of widespread tax evasion practices of global MNEs. A plethora of similar studies have presented credible, albeit circumstantial, evidence for the existence of BEPS. Thus the core question to be addressed before embarking on respective reforms seems to be the following: Do scale and scope of aggressive tax planning call for a radical revision of international taxation?

Arguably, the most relevant descriptive empirical evidence to look at in this context is the development of tax revenues on corporate income in relation to GDP. The respective results should be interpreted with caution, as macroeconomic tax ratios will inevitably reflect the interaction of tax policies, location choices by firms as well as general business development. Still, a significant and sustained decrease in revenues from corporate income tax would provide a general indication of an erosion of national tax bases. The corporate income in relation to GDP, however, has been relatively stable over time (at about 3%) and thus provides no indication of significant revenue losses due to BEPS. As explained by the OECD, the general decrease in nominal tax rates since the 1980s was compensated by a broadening of the tax base. Hence, the OECD found that the relationship of corporate income tax to GDP does neither imply the existence or non-existence of BEPS practices (OECD, 2013). Naturally, the analysis conducted by the OECD was not limited to the relationship between corporate income tax and GDP. In fact, the entire second chapter of the Report was devoted to a review of recent studies on BEPS (about 20 in total). The respective conclusion was; "[...] with the data currently available, it is difficult to reach solid conclusions about how

much BEPS actually occurs. Most of the writing on the topic is inconclusive, although there is abundant circumstantial evidence that BEPS behaviours are widespread” (OECD, 2013).

Despite the inconclusive evidence, the European Commission has launched a large scale campaign against BEPS. The theme of the campaign is “the missing part – time to get the missing part back” and it is focussed on communicating that tax fraud, tax evasion and tax avoidance cause devastating damage to society. The missing part, or tax-gap, is quantified at 1.000.000.000.000 (that is one trillion EUR). That estimate of the tax gap also dominates the relevant communication of the European Parliament; “[...] an estimated and scandalous EUR 1 trillion of potential tax revenue is lost to tax fraud, tax evasion, tax avoidance and aggressive tax planning every year in the EU, [...], without appropriate measures being taken in response [...] this loss represents: a danger for the safeguarding of a EU social market economy based on quality public services” (European Parliament, 2013). It is somewhat surprising to learn that this estimate is derived from a single source – a study compiled by Richard Murphy on behalf of the Group of the Progressive Alliance of Socialists & Democrats (Murphy Report – Murphy, 2012). Even in case such a study would be in line with the scientific consensus, it appears reasonable that a political body would confirm its findings by looking at additional studies. Alas, the Murphy Report can hardly be described as being in-line with a scientific consensus. As elaborated above, the OECD has concluded that estimating the impact of BEPS with a reasonable degree of accuracy is not feasible. Further, the tax-gap estimate presented in the Murphy Report has been explicitly challenged as being a significant overstatement – amongst others by the UK government (HMRC, 2012). Despite all criticism that could be voiced against the Murphy Report, it should be noted that it presents a nuanced analysis in; i) admitting that estimating the tax gap is challenging and that results should be digested with care; ii) differentiating between tax evasion and tax avoidance (the latter being entirely legal) iii) Being quite clear on the fact that other studies estimate the tax gap attributable to tax avoidance to be significant lower. Aside from the HMRC study the Murphy Report specifically cites the results of study conducted by the Swedish tax authorities, “Specific reference is made in the report to this relating to transfer pricing and the use of tax havens. Over the whole range of reported tax gaps [...] tax avoidance represents just 8.2% of the total SEK 133 billion gap, but a much smaller part of course of the total tax take of about SEK 1,300 billion, in relation to which it is less than 1%” (Murphy, 2012).

In communicating their measures against BEPS neither the European Commission nor the European Parliament devote insufficient attention to empirical evidence. Even if one would accept the analysis of the Murphy Report at face value, it could be assumed that the respective political motions are worded more carefully. This institutional behaviour should be kept in mind when discussing whether arguments in favour of FA are politically motivated.

The Reform Agenda of the OECD

As stated in the Action Plan of the OECD; “Fundamental changes are needed to effectively prevent double non-taxation, as well as cases of no or low taxation associated with practices that artificially segregate taxable income from the activities that generate it” (OECD, 2013b). The three main pillars of the Action Plan are; i) facilitating coherence of corporate taxation at international level; ii) enhancing transparency as well as predictability and certainty of international taxation and iii) realignment of taxation and substance. The following analysis will focus on the realignment of taxation with economic substance (Actions 8, 9, and 10 of the Action Plan), which is crucial to evaluate transfer pricing outcomes.

In respect to transfer pricing, the OECD specifically focusses addressing the challenges relating to intangibles. The core challenges are adequately assessing the economic value of intangibles and the fact that intangibles (and hence respective profits) can comparatively easily be shifted to low tax jurisdictions. The counter-measures proposed within the Action Plan (Action 8) include; i) adopting a broad and clearly delineated definition of intangibles; ii) ensuring that profits associated with the transfer and use of intangibles are appropriately allocated in accordance with value creation and iii) to develop transfer pricing rules or special measures for the transfer of hard-to-value intangibles. While the Action Plan does not constitute a panacea for BEPS, the measures address the fundamental problems and thus seem generally suitable to improve the effectiveness of ALP. Despite the

evolutionary character of the Action Plan, it would be false to dismiss it as merely curing the symptoms. The counter-measures amount to a significant overhaul the current ALP-based system and have been evaluated as being a “milestone of international taxation” by some analysts (Musil and Schulz, 2013). Considering that the evidence for the existence of BEPS is circumstantial, the evolutionary approach adopted by the OECD seems to be sensible. The emphasis attached by OECD to improving the transfer pricing rules is further documented by its (Revised) Discussion Draft on Transfer Pricing Aspects of Intangibles (OECD 2013c). The Discussion Draft is intended to replace the current provisions of Chapter VI of the OECD Transfer Pricing Guidelines (“TPGs”) (OECD 2010) and constitutes an evolutionary improvement intended to provide clearer guidance on how to apply transfer pricing regulations to intangibles. In this context, Section A of the Discussion Draft is devoted to provide a holistic guidance on identifying intangibles (para. 39-63) including clarifications, e.g.: “In these Guidelines [...] the word ‘intangible’ is intended to address something which is not a physical asset or a financial asset, which is capable of being owned or controlled for use in commercial activities, and whose use or transfer would be compensated had it occurred in a transaction between independent parties in comparable circumstances [...]” (OECD 2013c, para 40). An important distinction is made by the OECD between different categories of intangibles (Section A3). In this context the OECD points out that depending on the relevant facts and circumstances it may be unjustified to allocate a premium return to an enterprise utilizing an intangible (e.g. know-how) that is of non-unique nature. Consequently, the OECD provides following definition; “Unique and valuable intangibles are those intangibles (i) that are not comparable to intangibles used by or available to parties to potentially comparable transactions, and (ii) whose use in business operations [...] is expected to yield greater future economic benefits than would be expected in the absence of the intangible” (OECD 2013c, para 51).

In sum, OECD clearly reemphasizes that the ALP should equally apply to transactions involving intangibles and those transactions which do not. Consequently, any valuation of transactions involving intangibles should be based on the principles outlined in Chapters I through III of the TPGs. Accordingly the OECD emphasizes that; “In cases involving the use or transfer of intangibles, it is especially important to ground the comparability and functional analysis on an understanding of the MNE’s global business and the manner in which intangibles are used by the MNE to add or create value across the entire supply chain (OECD 2013c, para 37). In the Annex to the Draft, the OECD provides 27 Examples to illustrate the guidance on special considerations for intangibles (one of which constitutes the basis for the micro-economic impact assessment conducted below). At this point it is not feasible to assess whether the reforms initiated by the OECD will be successful. To be sure, the OECD Action Plan contains various drawbacks and has been criticised as a “Trojan Horse”, which instead of providing an effective counter-measure against BEPS may create a range of severe additional problems³. On balance, however, it appears likely that the refined guidance on how to cope with intangibles in the context of transfer pricing is suitable for facilitating the realignment of taxation with economic substance.

The Reform Agenda of the European Commission and the European Parliament

In contrast to the rather evolutionary reform agenda of the OECD an increasing number of politicians and scholars advocate adopting more fundamental measures. In this context the European Parliament is one of the more notable advocates of introducing stricter regulations for international taxation. In its Report „on Fight against Tax Fraud, Tax Evasion and Tax Havens”, which was unanimously approved by the Committee on Economic and Monetary Affairs, the Parliament among others (European Parliament 2013):

- Asks the Commission to study the possibility of introducing European taxation on cross-border business models and electronic commerce. Urges the Member States to allocate adequate staff, expertise and budget resources to their national tax administrations and tax audit staff [...].
- Points out that legal proceedings against tax fraud are cumbersome and lengthy, and that those found guilty receive, in the end, relatively mild sentences, making tax fraud something of a risk-free crime [...] Calls on the Commission and the Member States to consider setting up measures to enable the social reuse of funds confiscated through criminal proceedings in cases of tax fraud and tax avoidance; calls, therefore, for a substantial part of the funds confiscated to be reused for social purposes [...].

- Deplores the fact that the Member States have not yet managed to reach an agreement on key legislative proposals such as [...] the 2011 Proposal for a Council Directive on a Common Consolidated Corporate Tax Base.
- Calls on the Member States to agree and implement the directive on a CCCTB by moving gradually from an optional to a compulsory scheme, as defined in its legislative resolution of 19 April 2012 on the proposal for a Council directive on a CCCTB.

The proposals contained in the Report would amount to shifting significant legislative competencies from the Member States to the EU. In the context of transfer pricing the last two proposals (number 4 and number 25 in the Report) directly referring to the CCCTB are of particular relevance. Considering that the Report is comprised of 75 proposals, it appears conceivable that the CCCTB may get lost in the shuffle. By essentially replacing the ALP with FA as the main paradigm of international taxation, the impact of adopting the CCCTB would, however, likely far outweigh the impact of other proposals. Before analysing the impact of such a paradigm shift, it appears worthwhile to recapture the central features of the European Commission's directive on a CCCTB (European Commission 2011):

- Common rules for computing the tax base of companies which are tax resident in the EU and of EU-located branches of third-country companies.
- No intention to extend harmonisation to the rates. Each Member State will be applying its own rate to its share of the tax base of taxpayers.
- A company that opts for the CCCTB ceases to be subject to the national corporate tax arrangements in respect of all matters regulated by the common rules. [Note: Considering the Parliament Report, it is legitimate to question whether CCCTB will be implemented as being "optional"]
- Consolidation constitutes an essential element, as it eliminates transfer pricing formalities and intra-group double taxation. Consolidation necessarily entails rules for apportionment of the result between the Member States in which group members are established [Note: Formulary Apportionment]

Put simply, the first step in applying the CCCTB is to calculate the taxable profit (loss) for an MNE as a whole by aggregating the results of all related companies with the EU. The second step is to allocate the taxable profit to the Member States in which the MNE operates. As stipulated in Article 86 of the Commission's Proposal; "The consolidated tax base shall be shared between the group members in each tax year on the basis of a formula for apportionment. In determining the apportioned share of a group member A, the formula shall take the following form, giving equal weight to the factors of sales, labour and assets [...]". – Note: Intangibles are not included in the "Assets" factor.

$$\text{Share A} = \left(\frac{1}{3} \frac{\text{Sales}^A}{\text{Sales}^{\text{Group}}} + \frac{1}{3} \left(\frac{1}{2} \frac{\text{Payroll}^A}{\text{Payroll}^{\text{Group}}} + \frac{1}{2} \frac{\text{No of employees}^A}{\text{No of employees}^{\text{Group}}} \right) + \frac{1}{3} \frac{\text{Assets}^A}{\text{Assets}^{\text{Group}}} \right) * \text{Con'd Tax Base}$$

Thus, for applying the CCCTB it is no longer required to establish what conditions independent enterprises would have agreed to in order to determine a transfer price. The respective assumption is that the ALP cannot be reliably applied (as, amongst others, it is subject to manipulations). Hence, advocates of the CCCTB generally argue that the apportionment formula is better suited to ensure the alignment of taxation and economic substance. An idiosyncratic feature of the current discussion is that a lack of emphasis regarding the fact that introducing FA would constitute a paradigm shift. It is, however, of the essence to appreciate that FA and ALP do not merely constitute two different technical approaches in the realm of transfer pricing.

A never-ending fight about the desirable paradigm for international taxation

Looking at the theoretical and philosophical-ideological roots of the two methods suggests that curbing the effects of BEPS would merely constitute a by-product of introducing FA. Tax commentators have battled each other for decades, debating the merits and shortcomings of ALP and FA⁴. The ALP has been internationally recognized for about 80 years. While it has been subject to continuous controversies, the consensus regarding the basic features of the ALP significantly contributed to the mitigation of disputes (double taxation) in cross-border transactions. One of

the main controversies, as pointed out by Wittendorf, continues to be whether the ALP is identical to fair value of financial reporting and whether benefits stemming from the relationship among members of a multinational enterprise (“organizational returns”) must be recognized or disregarded⁵. Hence, advocates of FA argue that applying FA “alleviates the conceptual flaw of the arm’s length principle by treating associated enterprises as a single unity for transfer pricing purposes” (Wittendorf 2011, p.248).

The main argument in favour of applying the ALP as main paradigm in international taxation is rather straightforward; its application is based on the facts and circumstances of each specific transaction. Determining what conditions independent enterprises would have agreed to will be highly challenging, mostly because the prevailing circumstances will be unique for each MNE and difficulties in determining the value attributable to intangibles. There is no denying that applying the ALP strongly relies on subjective assumptions. Provided one accepts that transfer pricing is not an exact science and that for most transactions a true (objective) price cannot be determined, the degree of subjectivity, however, should generally be acceptable. Ultimately, the taxpayer as well as the tax authorities will always have to substantiate their respective assumptions. While the burden of proof rests with the tax authorities, the authorities generally have adequate tool box of legal instruments at their disposal to level the playing-field. From a conceptual viewpoint, a consistent application of the ALP will result in an allocation of profits that closely approximates an allocation that could be expected to result on the market. The ALP is conceptually a feasible method for ensuring the alignment of taxation and economic substance in regards to the value-added by the individual taxpayer (as demonstrated below). The philosophical-ideological root of the ALP is that the allocation of the profits should as closely as possible reflect a market-based process.

Arguments in favour of adopting FA ultimately rest on the assumption, that it is superior to the ALP in regards to ensuring the alignment of taxation and economic substance. Advocates of the FA argue further that it is the conceptually pure method, because it accommodates the reality of firm integration and provides a straightforward solution for distributing tax revenues among jurisdictions – thus avoiding the “messiness of the current transactional arm’s length regime” (Cockfield 2004). There are, however, various conceptual flaws inherent in the FA, which render these assumptions to be somewhat questionable. Before addressing these issues, however, it is decisive to focus on the philosophical-ideological root of FA. In contrast to the ALP, the FA deliberately disregards the specific facts and circumstances of each transaction. Instead of basing profit allocation on the unique value-chain of an individual MNE, the profits of all MNEs will be allocated according to one formula. It appears rather implausible to assume that one formula (however well calibrated) will reflect the value-added of heterogeneous MNEs. One crucial aspect this regard is that FA does not account for intellectual property (see above). Considering that for many MNEs intangibles constitute key determinants of the value-added, applying a formula is unlikely to result in a close approximation of taxable profit on the market under comparable conditions. The degree of approximation could arguably be higher when the national or global aggregate is considered. The crucial point is that the philosophical-ideological root of FA does not focus on aligning taxation and economic substance at the level of the individual taxpayer. Instead, under FA national governments will make assumptions regarding the source of the value-added without the taxpayer being able to challenge these assumptions. Hence, the FA is conceptually a feasible method for ensuring the alignment of taxation and economic substance in regards to the different factors of production located in multiple jurisdictions – reflecting an “equitable” allocation of profits. As pointed out by one of the most prominent advocates of FA, Walter Hellerstein: „If one rejects [...] that the purpose of income allocation is to determine the ‘true’ source of income, and embraces instead the view that the purpose of income allocation is to effectuate an equitable division of income, then the theoretical question becomes which of the competing methods better serves this objective. From a theoretical perspective, it would appear to be no more difficult – and probably easier – to translate one’s judgements about an equitable division of income into a formula the apportionment factors of which reflect those judgements [...]” (Hellerstein 2005).

Taking the philosophical-ideological roots of the two methods into account could potentially add much needed depth to the discussion about BEPS. While the ALP is presented as the legal basis (loophole) for tax avoidance schemes, FA is touted as panacea. While it is certainly important to address the merits of this claim, the discussion should address the question whether the paradigm shift described above is desirable. It should be recognized that adopting the FA implies embracing the value judgements imbued in the respective apportionment formula. In this context, a higher degree of harmonization of the EU tax system can arguably be seen as a precondition

for an efficient implementation of the CCCTB. As outlined by Hellerstein; “If there is one lesson for the European Union in the US states’ experience with the choice of apportionment formulas, perhaps it is the manifestation of the strong tension that exists between what might be regarded from a collective viewpoint as a defensible formula for fairly dividing the income tax base among the states and a formula that maximizes an individual state’s economic interests” (Hellerstein 2005).

In sum, it is imperative to recognize that the decision of whether to apply ALP or FA includes a fundamental policy choice about the ultimate aim of international taxation. It should be evident at this point that conceptually FA is not designed to effect a closer alignment of taxation and economic substance for any specific MNE. Consequently, adopting FA cannot correctly be understood constitute an “improvement” compared to the ALP. In other words, the specific challenges posed for the effective application of ALP by BEPS (e.g. valuation of intangibles) are not addressed by FA. Instead, adopting FA effectively shifts the focus of international taxation away from determining assessing the relevant facts and circumstances for a specific MNE towards inter-governmental negotiations about an equitable division of income.

Aligning taxation and economic substance – the Litmus Test for the ALP

A number of macro-economic impact assessments have been conducted in order to quantify the effects of adopting the (C)CCTB. The essence of these studies can be summarized as follows; i) the effective tax burden for MNEs will (on average) remain rather limited; ii) the impact may vary considerably between Member States; iii) when consolidation and apportionment are considered the variation between Member States is significantly more pronounced; iv) there is no significant impact on aggregate welfare (in terms of GDP)⁶. The results should naturally be interpreted with caution, as the actual macro-economic effects will depend on the actual implementation. Taken together, the results strongly suggest that the macro-economic effects will not be decisive, neither from a theoretical nor a political point of view, when deciding whether the ALP or FA constitutes a more desirable paradigm for international taxation. Bearing the philosophical-ideological roots of the methods in mind this is not a surprising insight, as the decision will ultimately depend on the preferences regarding the purpose of income allocation – namely, alignment of taxation and economic substance in regards to the value-added by the individual taxpayer (ALP) or to effectuating an equitable division of income between governments (FA).

The ALP’s role as the paradigm of international taxation has mainly been questioned on the grounds that it proves conceptually ill-suited to ensure alignment of taxation and value creation in an economy that is increasingly globalized and dependent on intangibles. Due to the alleged conceptual shortcomings of the ALP in respect to capturing the economic value of intangibles, MNE’s are enabled to shift profits to low tax countries. As noted above, this challenge is somewhat ill-conceived as BEPS is mostly attributable to elaborate corporate tax structures utilizing rather than to conceptual shortcomings of the ALP. Nevertheless, the valuation of intangibles does constitute a serious challenge for the efficient application of the ALP. In order to capture the scope of the challenges and to assess whether the ALP is conceptually suited to prevent profit shifting and limit the utilization of tax avoidance schemes, it appears helpful to conduct a concise micro-economic impact assessment. In order to illustrate the impact of adopting FA on a micro-level, it appears worthwhile to include the CCCTB in the assessment. Due to the limited scope of this paper, it appears sensible to take a OECD case study as a starting point and to minimize the number of modifications and additional assumptions. The (simplified) example is based on a DCF analysis and following key assumptions (for details, please refer to OECD 2013c (Example 24)):

- Year 0: Company A (parent company) is situated in Country X (tax rate: 30%) and has developed various intangibles (patents and trademarks) relating to Product F. Product F is manufactured in Country X and supplied to affiliated distribution entities throughout the world (“Country W”, tax rate: 10%)
- Year 1: Company A sets-up a subsidiary (Company S) in Country Y (tax rate: 10%), transferring the production as well as the intangibles to Company S. The intangibles have a remaining “useful life” of five years.
- The distribution entities consistently sell 1000 of Product F annually. Revenues are expected to remain constant for the next 5 years. The selling expenses (SG&A) are constantly 100.
- Company A’s cost of goods sold (COGS) for Product F is 600; for the same volume Company S’s COGS are 500.

- An appropriate (arm's length) routine functional return for manufacturing is 5% of COGS. For the routine distribution function 2% of sales are considered arm's length. The discount rate (DCF) is set at 14%
- Three scenarios are considered; i) status quo (Year 0); ii) Company S manufacturing product F and selling to distributors (for simplicity cessation of Company A is assumed); iii) Company S acting as contract manufacturer on behalf of Company A (intangibles remain with Company A)
- The quantitative assumption for calculating the allocation of profits under CCCTB are the following:
 - scenario i) Company A (Sales: 0; Payroll: 300; Employees: 100; Assets: 200); Distributors (Sales: 1000; Payroll: 50; Employees: 25; Assets: 20)
 - scenario ii) Company S (Sales: 0; Payroll: 200; Employees: 100; Assets: 200); Distributors (as above)
 - scenario iii) Company A Sales: 0; Payroll: 20; Employees: 2; Assets: 5) Company S (Sales: 0; Payroll 200; Employees 100; Assets 200); Distributors (as above).

TABLE 1: CASE STUDY

Scenario i)						
Company A	Year 1	Year 2	Year 3	Year 4	Year 5	NPV
Revenues (internal)	880	880	880	880	880	
COGS	600	600	600	600	600

Distributors	Year 1	Year 2	Year 3	Year 4	Year 5	NPV
Profit - ALP NPV (14% DR)	For ALP the P&L of the Distributors remains as in scenario i)					62
<i>Profit - CCCTB NPV (14% DR)</i>	135	118	104	91	80	527

As emphasized by the OECD, in order to determine an arm's length compensation for the intangibles, the (realistically) available options for both the seller (Company A) as well as the buyer (Company S) have to be considered. The NPV determined in scenario i (673) constitutes the minimum ask price of Company A. Provided the production cost savings could be captured by outsourcing the production to a routine entity (without transferring the intangibles - scenario iii) the minimum ask price would be 853. The maximum bid-price of Company S would be 1.174 (scenario ii). Hence, application of the ALP yields a valuation of the intangibles falling within the range of 853 to 1.174. Depending on the underlying assumptions (e.g. useful life of the intangible, anticipated revenues, production cost savings) it the arm's length range can be rather broad. The Achilles heel of the ALP in the context of valuating intangibles can thus be seen in a comparatively high degree of uncertainty which is often be perceived as a lack of accuracy.

In order to assess whether the accuracy of applying the ALP is sufficient for ensuring alignment of taxation and economic substance, the above comparison with the CCCTB is rather instructive. This, admittedly oversimplified, case study illustrates the dramatic consequences of adopting the CCCTB from the perspective of an individual taxpayer (including many SMEs). Under each of the scenarios, the relative share of the total profit allocated to the Distributors according to the CCCTB is significantly higher than the distribution resulting from applying the ALP. While the Distributors are allocated about 42% of the profits (pre-tax) according to CCCTB, they receive between about 5% and 8% of the group profits when ALP is applied. In case the profits are primarily attributable to the characteristics of Product F (i.e. the respective intangibles) as assumed above, the profit allocation according to the CCCTB is divorced from economic substance. In case the functional and risk profile of the Distributors truly corresponds to that of a low risk distributor, an operating margin of 2% appears to more or less accurately capture the economic value added contributed by these entities (even an operating margin of 4% would merely result in about 14% of the group profits being allocated to the Distributors). As intangibles are excluded from formulary apportionment, the CCCTB is conceptually ill-suited to account for the increasing importance of intangibles for the value creation by multinational enterprises. In other words, even accounting for

the uncertainty involved in the valuation of intangibles when applying the ALP, the alignment of taxation and economic substance on the micro-level will generally be superior to an allocation based on FA.

Improving the Valuation of Intangibles - Vindicating the ALP

Based on the arguments outlined above, it can be surmised that the discussion on BEPS has been somewhat misguided – at least insofar as it relates to transfer pricing. Neither scale nor scope of BEPS seems to necessitate a radical revision of international taxation. Adoption of the proposed CCCTB, however, would amount to a watershed in international taxation. In contrast to the political rhetoric, replacing the ALP with FA will not result in a closer alignment of taxation and economic substance, particularly on the micro-level. Some of its advocates portray FA as a 21st century approach to international taxation, by arguing that the ALP was originally framed about a century ago and has failed to keep up with changes in the global economy⁷. As demonstrated above, there is little merit to this claim, as CCCTB is conceptually ill-suited to account for the value-added attributable to intangibles. The bottom line is that an “optimal” paradigm for international taxation does not exist. The decision between ALP or FA boils down to subjective ideological preferences regarding the ultimate aim of international taxation, namely alignment of taxation and economic substance in regards to the value-added by the individual taxpayer (ALP) or to effectuating an equitable division of income between governments (FA). An honest debate on the future of transfer pricing should acknowledge the philosophical-ideological roots of the two methods.

Those preferring to retain the ALP as the paradigm of international taxation (including the author of this paper) will be forced to find ways to improving the efficiency of the ALP. In this context, the reform agenda of the OECD, particularly on the transfer pricing aspects of intangibles, constitutes a welcome first step. In order to successfully vindicate the ALP, it will be particularly vital to limit the degree of uncertainty involved in the valuation of intangibles. Respective efforts should be devoted towards ensuring that the transfer of intangibles within MNE approximates market conditions as closely as possible. Enhancing the accuracy of the valuation of intangibles will help to credibly demonstrate that transfer pricing based on the ALP does not facilitate profit shifting by MNEs. In turn the political agenda my focus on the more relevant challenges in this respect, such as addressing the other five pressure areas of international taxation identified by the OECD, such as hybrid mismatch arrangements and treaty shopping.

In terms of enhancing the efficiency of the ALP, the efforts of academics and professionals in the field of international taxation and transfer pricing would likely benefit from a more intensive cooperation with experts from various fields of business studies. Worthwhile subjects for cooperative research could be:

- Value Chain Analysis: How to identify the value-added of intangibles? How to differentiate between market and organizational returns (e.g. see endnote 5)? How to improve a more nuanced and theoretically sound approach to distinguish between entrepreneurial and routine functions?
- Valuation of Intangibles: How to more accurately evaluate specific intangibles in the context of transfer pricing (patents, know-how, customer base etc.)? How to increase the reliability of DCF based evaluations (hypothetical arm’s length test)? Here the focus will be on i) ensuring more reliable and transparent underlying assumptions (e.g. useful life of intangibles) and on ii) conducting a transparent simulation of a negotiation between two related parties in order to determine a more refined arm’s length range (e.g. BATNA of the two parties)
- Others Issues: How to account for the entrepreneurial role in the (digital) knowledge economy? How to assess the transfer of knowledge within a MNE from a transfer pricing perspective (e.g. relocation of function or precondition for organizational returns?)

I am afraid, that given the limited scope of this paper, it was merely feasible to scratch the surface of the link between the valuation of intangibles and transfer pricing. Ideally, this paper will nevertheless make a small contribution towards a more informed (nuanced) debate about BEPS. The main lesson here is that while the efficiency or the ALP in terms of aligning taxation and value-added is constrained by a significant degree of uncertainty in respect to the valuation of intangibles, it does capture the economic reality of value creating by MNEs much more accurately as the CCCTB. In other words there is no compelling rationale for adopting the CCCTB other than philosophical-ideological preferences in respect to shifting the nucleus of international taxation to the macro-level. On the micro-

level, the effects of such a paradigm shift would likely be of substantial magnitude. Considering the comparatively limited scale of the challenges presented by BEPS, such a radical change of the institutional framework seems disproportionate and should be scrutinized much more critically. In this context, aside from ideological considerations, an evolutionary approach appears much more sensible. In ensure (public) political support of the ALP as the paradigm of international taxation, however, it will be required to substantially improve the efficiency of the ALP by reducing the degree of inherent uncertainty. In case the above presentation of some main aspects succeeds in sparking the interest of some researchers from the fields of business studies to apply their expertise and effort to the transfer pricing aspects of intangibles this paper was not written in vain.

End Notes

¹ The ALP constitutes; “The international standard that OECD member countries have agreed should be used for determining transfer prices for tax purposes. It is set forth in Article 9 of the OECD Model Tax Convention as follows: where ‘conditions are made or imposed between the two enterprises in their commercial or financial relations which differ from those which would be made between independent enterprises, then any profits which would, but for those conditions, have accrued to one of the enterprises, but, by reason of those conditions, have not so accrued, may be included in the profits of that enterprise and taxed accordingly’” – OECD 2010, p. 23.

² For an illustration of BEPS related tax structures, see OECD (2013), Annex C

³ In the context of intangibles Eilers emphasizes that an excessively broad definition (e.g. a Blackberry constituting a permanent establishment) would likely result in intense distributional conflicts regarding taxable revenue between governments - Eilers, S. (2013), BEPS – Eine Abkürzung saniert noch keinen Haushalt, in: v. Wartenberg et al. Steuerpolitik im Wahlkampf – ifst-Schrift Nr. 489 (2013), pp. 33-38.

⁴ Note: For a concise and entertaining summary, see Cockfield (2004) and Li (2004); Cockfield categorizes the tax commentators as either; “Doubting Thomases” (i.e. those favouring ALP, e.g. Oates and O’Brien), “Purists” (i.e. those advocating FA – e.g. Hellerstein and Li); Pragmatists (i.e. those proposing an incremental reforms without overthrowing ALP, e.g. Cockfield himself).

⁵ As explained by Wittendorf (p.239); “The total profits of a multinational enterprise may thus be broken down into a market return, which is attributable to the production factors, and an organizational return, which is attributable to the form of organization. The market return is similar for associated enterprises and independent enterprises, but the organizational return is distinctly different for associated enterprises. The crucial question is whether economies of integration should be considered under the arm’s-length principle.” (This “conceptual flaw” is readily acknowledged by the OECD – See OECD (2010), p.34).

Knowledge Management for Knowledge Development: Lessons Learnt While Implementing International Projects by Multicultural Teams

Abstract

Development and Technical Assistance (DTA) projects as a means for donors to transfer knowledge to recipient groups and organizations represent a clear case of managing knowledge transfer. DTA international projects support capacity building and sustainability, covering a wide range of knowledge areas, from technical to social, from political to environmental. Besides the specific expertise of the implementation team, there are the managerial knowledge and skills of the leader that facilitate relationships of team members with the locals and between team members. Most of know how comes through communication that comes through tacit knowledge.

As the focus of the DTA international projects is on continuous strategic improvement or organizational learning, they rely considerably on mutual understanding relationships – from information to knowledge to wisdom sharing. So, in order to assist knowledge management and development in the host organization, the implementation team needs to master knowledge management within the team. It looks that knowledge management and managing cultural diversity of a group are parallel processes – which is one of the main conclusions of the study.

Keywords: Development & Technical Assistance (DTA), International projects, Cultural diversity, Project management, Implementation team, Knowledge transfer management

Current DTA projects focus on innovation

More and more development and technical assistance (DTA) projects focus on capacity building and sustainability, heavily grounded on the transfer of knowledge, while employing project management and knowledge management. Often times DTA projects are built around new technologies and innovative solutions, hence knowledge transfer is a central point in project management. Even if in many cases theoretically prevails transfer of explicit knowledge - inventories of information relating to the new processes, there is always important accompanying transfer of tacit knowledge. Since donors are increasingly stressing innovation as a key condition for funding development and technical assistance projects, knowledge management is equally increasing in importance.

The challenge for a project manager is to organize and locate relevant content and expertise, necessary in the course of completing objectives and tasks in the planned timeframe. The goal for the project manager is to attain the goals with the resources allocated and make the best of those. Success depends on the optimal blend of people, and equipment, skills and knowledge. Generally the design stage focuses on comprehensive inventory of information, technologies, systems, strategies - knowledge that should be transferred, while in the planning stage best key experts are recruited to deliver that information. Filling the gap sometimes neglects the preparedness of the beneficiaries to absorb that amount and format of information, and also their willingness to change. The simplest innovation project spills over affecting social relationships, beliefs and values of the impacted group.

Transfer of knowledge induces changes of cultures

It is a fact that knowledge is critical to effective leadership, design and implementation of systems and projects, while linked to cultural norms and beliefs (Kakabadse, Kouzmin, & Kakabadse, 2001). However, the value of knowledge depends on the capacity of the group to transfer, share and exploit it, as basis for problem-solving and for the decision making processes. Knowledge also gathers truths, beliefs, and judgments conveyed through behaviors and communication, being influenced by and influencing at the same time the organizational culture. Since knowledge contributes to improved performance, building innovation, and competitive advantages, project managers have to turn to account the management of knowledge towards attaining objectives.

In his model March (1991) considers that an organization is defined through the beliefs of the members about the reality, or better said, through the knowledge that individuals have about the environment. Since the reality is one, it means the organization perceives the environment through the eyes of people. Just imagine a conversation between an Albanian and a Romanian, for example; if beyond verbal communication body language is used there might be problems since nodding the head has opposite meaning for each of them, and each decodes the message according to inherited culture. The level of knowledge of one organization is in fact the proportion of correct representation of the reality. However, the organizational code doesn't distinguish between true and false beliefs with respect to the reality, which is observed through the lenses of specific culture (individual, group, organizational, national). At the same time, the culture may be considered as the response of a group to the environment, surrounding reality, meaning that the group shares the same set of beliefs and values (Hofstede, Hofstede & Minkov, 2010).

From a different perspective the organizational culture represents the sum of knowledge that an individual, group or organization acquires in a given period of time, in the process of solving survival problems with respect to the surrounding environment and also solving internal integration (Schein, 2010). Hence, DTA projects along with new, innovative solutions transfer tacit and explicit knowledge, building new lives and new cultures. Knowledge transfer foregoes organizational learning which, for a team may be possible only if members have collaborative relation, and may be exploited if the attitude of the individuals and relationships lead to synergies.

Knowledge transfer and organizational learning

Considering that a team is actually a group of people that work together in order to attain an objective, interact and communicate information and ideas about the ways to reach the best decisions which would support members achieving maximum potential. Knowledge flows from individuals to teams, to organizations, and each transfer enriches the quantity and quality of knowledge, and after each transfer individuals, teams or organizations are richer, in a continuous spiral of learning (FIG. 1). Along with the transfer of knowledge the people may learn new habits, or even values, and acquire new cultural traits or trends in a perpetual transformation.

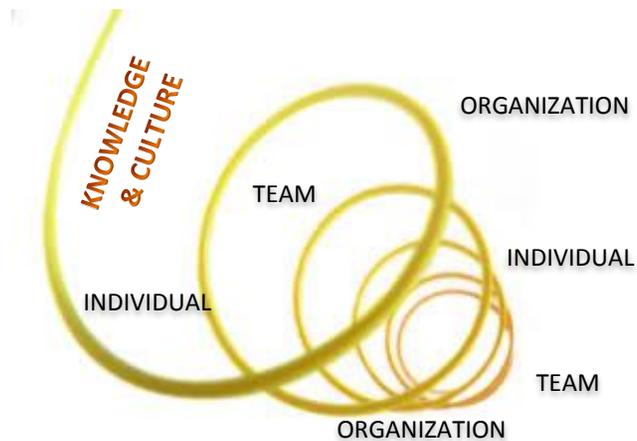

FIG. 1

DTA projects implementing innovation have to control the transfer of both explicit knowledge, in the codified format, but more importantly, they have to transfer the tacit knowledge to the recipient organization or group, which is many times difficult to express in the terms of reference. Experts have to teach beneficiaries to operate the equipment, technologies, systems and knowledge, the so-called know-how. The explicit knowledge, available many times without intervention has to be internalized and practiced, and the process involves direct communication, socialization, extensive personal contact and interaction. Lack of trust precludes transfer of tacit knowledge; hence

individuals, in building confidence, exchange beliefs and views, and learn unconsciously cultural differences that shape the way people perceive the surrounding environment, the world in general. In knowledge management the most sensitive aspect is the capacity to share, which is a function of level of trust and culture (Jennex, 2008). But DTA projects may introduce the risk of deculturalization of the recipient group in the effort to transfer tacit knowledge; hence experts should master communication for reconciliation of cultures and actually build partnerships. Examples from business are always strong evidences, like the case of the Renault – Nissan alliance (Cacciaguidi – Fahy & Cunningham, 2007), where cross-cultural operational teams took a long time observing both home environments before starting to work together. It was necessary to build effective intercultural business communication, and overcome intercultural differences to reach goal congruence. It was more than a business joint venture it was created a collaborative venture focusing on cross-cultural synergies (transfer of knowledge and cultures).

Organization's structure is determined by the flow of information and relationships between members. Individuals of an organization are influenced and influence at their turn the flow of information and the interactions between the members of the group. And thus the main vehicle for information transfer, communication, may be hampered, or facilitated by the cultural diversity. Communication contributes at the same time to strengthening group culture while altering original cultures of the members, through information exchange with members of different groups. While homogenous groups, from a cultural point of view, use high context communication, which contributes to easier transfer of tacit knowledge, culturally heterogeneous groups rely on low context communication, and transfer of primarily explicit knowledge (Hall & Hall, 1990). Thus, transfer of tacit knowledge calls for special relationships in the group.

DTA projects in multicultural environments are designed to transfer explicit knowledge, with expectations beyond that. Since stakeholders are rarely familiar with each other prior to the inception of the project, the communication plan is based on low context communication. In the implementation process, as team is established and members get to understand and at least tolerate cultural differences, a new parlance sees the light and blends the different styles, and culturally connects the team members. It is generally after the team has passed the forming, storming and norming stages and reached the performing stage (Tuckman, 1965), that transfer of tacit knowledge is feasible, in the context of a new culture, ephemeral, for the duration of the team.

From authors' experience the influence of cultural diversity on knowledge transfer is different if the implementation team is created to last longer or if it is a team of various short-term experts gathered for a complex technical assistance project. A team of experts would transfer explicit knowledge more efficiently, in spite of the diversity of its members not only from a cultural point of view, but also as areas of expertise, background, managerial and communication skills. Even though such a team is hardly manageable, since each expert acts like a manager, at least in his/her own area of competence, in the transfer of knowledge process predominates explicit knowledge, as a prerequisite of the terms of reference. The real value added of a DTA project is if the experts convey not only explicit knowledge, not even tacit knowledge, but guide beneficiaries to internalize the explicit knowledge and to some extent to turn tacit knowledge into explicit knowledge. It may happen that the experts never actually form a team, they do not pass through all stages (from forming to performing), and remain individuals in a group that comply with a set of rules and procedures. If the team is meant to last longer, in the same format for the whole duration of the project, then team building is more important, accommodating acknowledgement and tolerance of cultural differences, and transfer of tacit knowledge sometimes exceeds the transfer of explicit knowledge.

Cultural diversity impacts knowledge transfer

Knowledge management includes people, processes, culture, or technology, thus the organization gathers knowledge through the beliefs of those people, which leads towards a specific organizational culture. Knowledge management helps the organization in the learning process (Sanchez, 1996). Superior utilization of knowledge comes from sharing and storing information and, according to the Knowledge Spiral of Nonaka & Takeuchi (1995), tacit knowledge should be converted into explicit knowledge, and this includes team building, communication, and cultural disclosure. At its turn culture influences managerial processes (Hofstede, 2010) mainly through communication (code,

channel, feedback, interpretation, context), decision making process (problem definition, information gathering, analysis, alternative identification, implementation), motivation (depending on cultural dimensions masculinity-femininity and control of uncertainty), leadership style (depending on cultural dimensions power distance and individualism-collectivism), models and organizational structures (depending on cultural dimensions power distance and uncertainty avoidance).

Also, the SECI model of knowledge dimensions (Nonaka, 1991) reveals that the transfer of tacit knowledge (to tacit or to explicit), is strongly impacted by the cultural diversity of the group members, as well as the internalization in own mental models, hence each situation has its own specific due to the cultural differences.

Tacit knowledge that covers the internalized knowledge of which individuals are not aware includes or even coincides with specific cultural traits, while the explicit knowledge represents the assumed resources used in order to consciously complete tasks. From a different angle, knowledge has a content prospective and a relational prospective – and while the first one can be stored in a codified inventory, the relational prospective shows knowledge depends on the specific location, organization, environment – depends also on the specific culture. It is like the same picture is projected on different canvas, of different colors, and though the source is identical the results have individual aspects (FIG. 2). While the processes and frames are similar, the results are not identical. Practically, DTA projects, projects in general, may not be perfectly replicable. There is always the human, cultural factor; there is a different environment that empowers differently the transfer of knowledge. Ideally implementing agencies (should) have appropriate procedures for the design and management of projects to cope with cultural diversity in the process of knowledge transfer, and train managers to act accordingly.

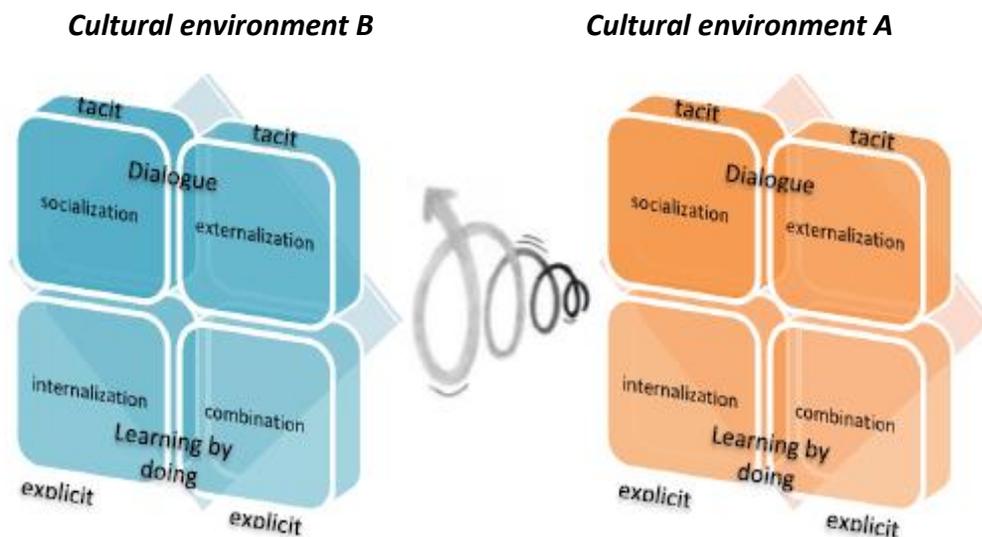

FIG. 2

It is a loop as new knowledge, abundant knowledge into an entity, group, team, community determines changes, it comes with alternatives to the old habits and challenges known values. But as soon as people understand, internalize, accept the novelty the culture itself may be influenced. And all it is about communication and community, about cooperation and exchange.

Replicating best practices

Davenport's definition (1994) specifies that knowledge management actually contributes to identifying, developing and utilizing organizational knowledge. Thus knowledge management represents a tool for project management, both converging to attaining goals, improving performance, making use of experience and lessons learned. Starting from the definition of Davenport (1994) "Knowledge management is the process of capturing, distributing, and effectively using knowledge". It is justified to interpret that a team is taking advantage of a real asset, which many times is difficult to measure and store.

DTA project management, especially involving multicultural teams, leads to retention of "best practices" or "lessons learnt" described as organizational learning towards improving processes and performance. But this is precisely the core principle of knowledge management – a dynamic process of creating new knowledge, finding new sources of knowledge, for the implementing or donor organization. Actually it is converting tacit knowledge extracted from the lessons learnt into reusable explicit knowledge, which may be codified and saved and transmitted. Experienced experts would find appropriate ways to transfer tacit knowledge to various groups from different cultures. Every implementation in every organization would be unique due to the unrepeatability of cultural environment, thus experts should "speak every language" actually to communicate in any culture.

One example from authors' experience is relevant for the impact of cultural diversity in the implementation of DTA projects. In 1992 UNIDO initiated a UNDP financed project in Romania for the promotion of SMEs, with a local team of experts managed by an experienced expat and receiving support from international experts. The main activities included provision of information and guidance to entrepreneurs to start or to develop their business, assistance offered to entrepreneurs to apply for loans or grants, organizing seminars, completion and publication of guides for entrepreneurs and finance for non-financial managers, feedback to governmental institutions. Being extremely successful UNIDO initiated a program to replicate the project in other developing countries, and thus members of the Romanian team became managers of similar projects in other developing countries, with the precise task to clone the project. The experience in Albania, in 1995 – 1997, with the bulk of knowledge already available, verified and organized, was not a success. The Albanian team had the opportunity to spend time with the Romanian team, with intensive and extensive training, and learn firsthand from almost four years of experience. Unfortunately, the project achieved modest results, partially due to the social unrest, but mainly due to the different attitude towards entrepreneurship and different approach to knowledge, and specific ways to transfer knowledge. Evaluation considered the local conditions, and also the skills of the manager as main causes of the poor results. But the same project document (only numbers being adapted to the local conditions and population) was then implemented in Kazakhstan, 1997 – 1999, by the same manager with similar resources. There were same information, same books to be translated and published, same management style, same procedures, though results were totally different. This team did not benefit from a similar internship to observe directly a successful example, and had less comprehensive training, but results were beyond expectations. The evaluation acknowledged the project design, the local conditions and skills of manager. The transfer of knowledge, tacit and explicit was efficient, one explanation being the compatibility in communication within the team and with the rest of stakeholders. The output in this case was very tangible and practical. The three projects of this example were similarly designed, procedures were similar, just cultural environments were different, and it made the difference.

Even not explicitly all times, to some extent project management contains, as built in, the knowledge management. A team leader has to organize resources and activities towards achieving specific goals. It takes knowledge and experience for an individual to match tasks and people with the required expertise and to facilitate team relationships in such a manner that all knowledge and expertise is put at work synergistically. For project and knowledge management should be a coordinator, a sponsor interested in reporting lessons learned. And this is valid for most of the technical assistance projects and initiatives. For industrial projects report and evidence of lessons learnt is mostly applied in the case of contractors or big international companies that have to develop and implement projects in various places, with different teams of diverse people. For example organizations like UNO or the World Bank have specialized departments to deal with various types of projects in specific regions. Also companies like IBM, Ford or Renault have to take into consideration locals' specific in managing projects and knowledge in order to expand businesses. These communities of practice (Wenger & Snyder, 1999) share lessons learned in order to take advantage of opportunities and better manage people and processes, and to some extent they function similarly with multicultural teams.

Conclusion

One of the strong points of international organizations, including those providing development and technical assistance is that they represent large, well organized networks essential for knowledge transfer and dispersion (Mudambi, 2002). It is a two ways process, and on one hand organization may provide knowledge to assisted communities in order to strengthen them, while absorbing knowledge from assisted communities and taking advantage of lessons learned. Communication and transfer of knowledge may be more or less efficient depending on the level of context of the communication, thus team absorbing differently the information based on the cultural specific.

Project managers operate with knowledge management, which at its turn depends on the way team is lead, and how cultural diversity is capitalized towards harnessing knowledge within the team. Thus strategies focus on proper utilization of the human assets, being knowledge, experience, skills or abilities. The wise use of knowledge depends on how data becomes information and then is turned into knowledge to make people wiser.

It is important to exploit both the exploratory dimension of the knowledge, creation, innovation as well as the transfer dimension of the established knowledge. Within a team both dimensions contribute to achieving objective, as members are invited based on their knowledge, experience, and competences in order to use those in a creative problem solving manner. In other words a project is a medium for creation and transfer of knowledge. Hence the communication between team members becomes increasingly critical and cultural diversity may hamper or facilitate the proper use of advantages.

Even though knowledge may be treated as objective, and may be coded, inventoried, shared, and transferred in the end it all depends on organizational culture, and it becomes very subjective (Nonaka & Takeuchi, 1995). This is the reason why organizations providing technical assistance need clear stages for evaluation, before, during and after the project or intervention closure.

Useless to say, DTA projects are about sharing knowledge, and replicating lessons learnt, which calls for an organizational language to enable individuals to understand and internalize it. More and more organizations need a cross-cultural language to communicate that knowledge and those lessons learnt.

“Explaining Knowledge Sharing Behaviours through an Organizational Form- and Motivation-Based Perspective”

Abstract

The importance of knowledge resources leads companies to adopt organizational forms likely to foster learning and knowledge sharing processes. However, for such processes to occur, employees should be motivated to initiate and feed them. Despite several studies focus on new organizational forms and many others on motivational issues for investigating organizational behaviors, a comprehensive view simultaneously exploring both organizational structure and the joint effect of intrinsic and extrinsic motivation (i.e. crowding effect) on knowledge sharing behaviour is missing.

Based on this, we posit that extrinsic motivation moderates the relationship between intrinsic motivation and knowledge sharing, as well as between integrative mechanisms and knowledge sharing. We test our hypotheses on survey data collected from 754 workers of 23 international manufacturing firms.

Our findings support our argument, suggesting practitioners to be aware of the complexity involved in designing flexible structures and providing rewards. The paper concludes by highlighting directions for future research.

Keywords: knowledge sharing, motivation crowding-effect, integrative mechanisms, new organizational forms, rewards

Introduction

The increasing relevance of knowledge resources has lead companies to move from hierarchical structures to organizational forms likely to foster learning and knowledge sharing (Daft and Lewin 1993). However, as knowledge resides in humans’ minds, it won’t be shared and exploited unless the individual will be willing to do so. Managers should thus care about the motivation underlying employees’ behaviours and, more precisely, about the dynamic relationship between intrinsic and extrinsic motivation (i.e. crowding effect) which drive them (Osterloh et al. 2001).

Despite several studies focus on new organizational forms, little work on how it actually relates to intra-organizational knowledge processes exists. Particularly, a comprehensive view investigating how structural and motivational factors jointly affect employees’ knowledge sharing behaviour is missing.

Building on the importance of the dynamics of motivation to new organizational forms (Osterloh et al. 2002), we aim at extending this field of study by looking at the management of motivation as a source of influence on the relationship between organizational forms and knowledge sharing. By empirically examining data of 754 workers from 23 international manufacturing firms, our purpose is to address the following research questions: “how does individuals’ motivation crowding effect influence knowledge sharing behaviours?” and “what’s the impact of extrinsic motivation on knowledge sharing behaviours when organizational integrative mechanisms are in place?”.

In so doing this paper hopes to contribute to the main conference topic by shedding light on the importance of strengthen interpersonal relationships and rethinking the role of extrinsic rewards, which rarely contribute to the individual and collective performance.

At the same time, it implicitly addresses the micro-foundations of resource development by focusing on individuals’ behaviors, critical to the organization’s success.

Theoretical Background

New Organizational Forms

The evolution of the competitive environment occurred over the last decades has forced companies to become aware that firms’ sustainable competitiveness relies on individuals’ knowledge and that, accordingly, the most strategic innovations are those exploiting individuals’ human capital (Foss 2002).

Given that knowledge is at the heart of organizational design (Holmström and Roberts 1998), most organizations have adopted organizational forms likely to foster the development of knowledge assets. The notion

of 'new organizational forms' indeed identifies new ways of structuring the organizations' boundaries and governing their internal relations (Foss 2002), often seen as the typical way of organizing in the knowledge economy.

Knowledge Sharing Processes

Effectively managing knowledge requires an appropriate knowledge sharing strategy, which help avoid the loss of strategic intellectual capital whenever employees leave the organization. Knowledge sharing (henceforth, KS) is a social interaction culture which stimulates individuals to mutually exchange experiences and know-how (Lin 2007), which may help solve problems and develop new ideas. Thus, it stimulates individuals to think critically and express their creativity while ultimately leading to enhance firm's innovation capability.

However, sharing knowledge is seldom a voluntary act, rather, it often follows a request. Accordingly, the literature distinguishes between two dimensions of KS: one related to the voluntary transfer of intellectual capital to others, the other identifying the process of specifically asking colleagues for help (Lin 2007).

Given that the two KS sub-processes have different nature and can be influenced by different factors, they can be analyzed separately. Here we conceive KS as resulting from others' request for knowledge.

Motivation Crowding Effects

In line with extant literature, intrinsic and extrinsic motivation are not additive as standard economists assume; human behaviour is rather simultaneously influenced by both of them (Frey and Jegen 2002). Although organizational behaviour studies have widely benefitted from Motivation Crowding Theory, existing research has left the analysis of the individuals' motivation crowding effect on KS processes almost unexplored. This is consistent with the knowledge-based view, which looks at individuals as 'benevolent cooperators' (Dosi and Marengo 2000), neglecting incentive issues and assuming that no individuals' opportunistic behaviours exist (Conner and Prahalad 1996).

Hypotheses Development

Intrinsic Motivation and Knowledge Sharing Behaviours

Employees' intrinsic motivation is likely to influence employees' KS behaviours (Brock et al. 2005). It leads individuals to perform an activity for its inherent satisfaction and interest rather than for other consequences it may produce. It is a critical element in cognitive, social, and physical development, because "it is through acting on one's inherent interests that one grows in knowledge and skills" (Ryan and Deci 2000: 56).

Intrinsically motivated workers tend to value knowledge generation for its own sake, to be curious, and not to feel threatened by different views; likewise, they are more likely to raise mutual trust and social capital (Osterloh and Frey 2000) and to look for learning opportunities. According to this, we posit that:

Hypothesis 1: Employees' intrinsic motivation is positively associated with their knowledge sharing behaviours within the organization.

Organizational Integrative Mechanisms and Knowledge Sharing Behaviours

Classic organization theory literature states that the need for sharing knowledge is contingent upon the interdependency between units and departments (Thompson 1967), which calls for integrative mechanisms to be implemented. Integrative mechanisms help establish communication channels between organizational parts (Mintzberg 1979) while facilitating knowledge dissemination and acquisition (Gupta and Govindarajan 2000). Particularly, horizontal coordination, usually consisting of teams and integration roles, is positively linked to communication and information needs, as it allows flexibility in task execution and provides a rapid solution whenever a need for KS arises. Given this, we hypothesize that:

Hypothesis 2: The implementation of organizational integrative mechanisms is positively associated with employees' knowledge sharing behaviours within the organization.

Motivation Crowding-out Effect

External incentives may undermine individuals' intrinsic motivation in two ways (i.e. crowding-out effect; Frey and Jegen 2002): when they perceive an external factor to be controlling their action, on one hand they react by reducing their self-determination because a shift in the locus of control from inside to outside the individual occurs; on the other hand, their self-esteem is lowered as they feel that their competences are not really valued.

This argument is particularly relevant when organizations seek to enhance individuals' KS orientations. Being knowledge a public good, it is likely that people may free ride on the efforts of others (Osterloh and Frey 2000) by benefitting from the collective advantages of organizational knowledge exchange, without personally contributing to the joint effort. This may be due to the fact that knowledge processes outcomes are hard to observe and to measure and, as such, make opportunistic behaviours more likely to occur. Based on this, we posit that:

Hypothesis 3: The positive association between employees' intrinsic motivation and their knowledge sharing behaviours is weakened when extrinsic rewards for KS are in place.

Interaction between Extrinsic Rewards and Integrative Mechanisms

Highly integrated organizations, equipped with cross-level communication channels, often fail in their attempt to foster KS activities, because of rewards systems which motivate employees to adopt individualistic behaviours, that is to motivate individuals to do something in order to achieve a separable outcome (Ryan and Deci 2000), such as career progression, bonuses, etc.

Therefore, even when the organization is formally implementing cross-level integrative mechanisms aimed at linking all organizational units, departments or work groups and increasing KS activities, an extrinsic reward system is likely to play a negative role in influencing individuals' KS behaviours. Given this, we offer the following hypothesis:

Hypothesis 4: The positive association between organizational integrative mechanisms and employees' knowledge sharing behaviours is weakened when extrinsic rewards for KS are in place.

The above discussion is summarized in the research model illustrated in Fig. 1 below.

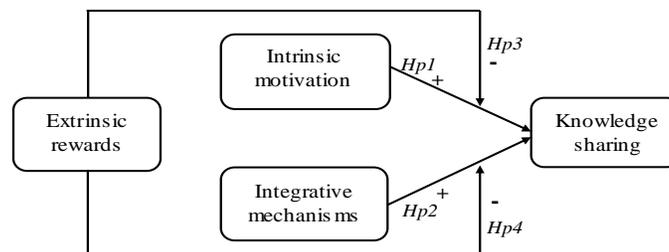

FIGURE 1: THE RESEARCH MODEL

Method

Data Collection

After pilot testing the questionnaire with managers of three companies, we collected web-survey data from 23 manufacturing firms located in a critical economic area in Central Italy (Tuscany) and operating in international markets. Together with the Human Resource Directors, we selected a sample of participants among those considered nodes of knowledge as they operate at the center of strategic information flows and possess information and knowledge critical to the firm's activity.

Out of the 1503 invitations sent out for participation in the survey, 754 questionnaires were filled in (50.1% response rate).

Measures

To operationalize all variables, we used self-reported measures (Spector 1994) and scales adopted in previous studies, based on multiple items and a seven-point Likert type scales.

Van den Hooff and Van Weenen's (2004) scale provided was used to measure our dependent variable, i.e. KS behaviour, conceived of as the process of sharing knowledge with those who ask for information. Responses are measured on a seven-point Likert scale ranging from 1 = "Strongly disagree" to 7 = "Strongly agree".

Intrinsic motivation was measured using Wasko and Faraj's (2000) scale and extrinsic rewards' four items were derived from Hargadon (1998) and Davenport and Prusak (1998) who ask for the extent to which respondents would like KS behaviours to be compensated with external factors. Both variables were measured on a seven-point Likert scale ranging from 1 = "Strongly disagree" to 7 = "Strongly agree". The measure of integrative mechanisms is derived from Gupta and Govindarajan (2000) whose measurement scale was anchored by 1 = "Seldom" and 7 = "Frequently".

We include the following control variables in the empirical analysis: employees' age and education level (years of education), whether they play a managerial role (dummy variable, 1=Yes, 0=Else), job autonomy (scale from Hackman and Oldham 1974; 1 = "Strongly disagree", 7 = "Strongly agree") and ICT use (scale adopted from Lee and Choi 2003; 1 = "Strongly disagree", 7 = "Strongly agree").

Results

Descriptive statistics and correlation coefficients are reported in Table 1. Most of the Cronbach alpha coefficients are above the minimum acceptable value of .70 (Nunnally 1978), while the integrative mechanisms' measure falls just below this criterion. However, we build on Peterson (1994) and agree that .60 may be the 'criterion-in-use'.

In order to test our hypotheses, we ran a hierarchical multiple regression analysis using Stata, whose results are illustrated in Table 2. In particular, Model 1 contains only the control variables, Model 2 includes all first-order associations between KS and intrinsic motivation, extrinsic rewards, and integrative mechanisms, respectively; Model 3 adds the first interaction postulated in Hypothesis 3 and Model 4 adds the second interaction posited in Hypothesis 4.

Before generating the interaction terms, we centered the three variables (i.e. intrinsic motivation, extrinsic rewards, and integrative mechanisms); accordingly, we ran the analysis by including also the other variables after centering them, with the only exception of the managerial role, being a dichotomous variable. Furthermore, in order to detect the presence of multicollinearity among explanatory variables, for each model we calculated the variance inflation factor (VIF). The VIF values are presented together with the regression results in Table 2.

As for control variables, we found that the ICT use as well as job autonomy is positively associated with employees' KS behaviours, that older employees are less oriented toward engaging in KS and that whether they play a managerial role in the firm matters - although the negative and significant impact emerges only when the explanatory variables are added (see Model 2-4, $\beta = -.14$, $p < .05$). Conversely, employees' education does not have a significant impact on their willingness to share knowledge.

The findings provide evidence about the positive association between individuals' intrinsic motivation and KS participation (see Model 2, $\beta = .44$, $p < .001$; Model 3 and Model 4, $\beta = .45$, $p < .001$) and integrative mechanisms and KS behaviours (see Model 2-4, $\beta = .07$, $p < .01$). Hypothesis 1 and Hypothesis 2 are thus supported. Moreover, the analysis shows a significant and negative moderator effect of extrinsic rewards on the relationship between employees' intrinsic motivation and the dependent variable (see Model 3, $\beta = -.06$, $p < .05$; Model 4, $\beta = -.04$, $p < .10$), therefore supporting Hypothesis 3. Finally, we found evidence about the moderating role that extrinsic rewards play in the relationship between integrative mechanisms and employees' KS behaviours. In this regard, Model 4 reveals that the relationship postulated in Hypothesis 4 is strongly significant ($\beta = -.04$, $p < .001$).

In order to better interpret these results, Fig. 2 and Fig. 3 illustrate the interacting relationship between, respectively, extrinsic rewards and intrinsic motivation, and extrinsic rewards and integrative mechanisms. As can be seen from Fig. 2, extrinsic rewards are more effective for low intrinsically motivated employees, who tend to increase their knowledge sharing involvement in case their behaviour is rewarded with extrinsic incentives.

Conversely, when employees are highly intrinsically motivated (dotted line), the implementation of reward systems for knowledge sharing behaviors leads them to decrease their participation in social interaction and information exchange.

As regards the interaction between extrinsic rewards and integrative mechanisms, Fig. 3 shows that the influence of reward systems is even stronger. Hence, when both variables take high values (i.e. high extrinsic rewards for knowledge sharing and high degree of organizational flexibility and horizontal coordination), employees are found to be less oriented toward sharing knowledge with others, than the case in which, beside high extrinsic rewards, the organization is rather mechanistic. In other words, those who perform best in terms of knowledge sharing orientation are those working within highly integrated organization and with low extrinsic rewards provided. When high integrated mechanisms are coupled with high extrinsic rewards, the potential value of helping individuals interact with each other is decreased.

Table 2 also illustrates the variation of the R2 as the variables are added in the analysis. We found that it increases from .16 in Model 1 to .35 in Model 4, thus indicating that our model is able to explain the 35% of the variance of the phenomenon of interest (i.e. employees' KS behaviours). More importantly, even though the most relevant increase in the R2 is determined by adding the main effect of the explanatory variables (see Model 2), the F-test is always highly significant, also when adding the first and second interaction (i.e. respectively, Model 3 and Model 4).

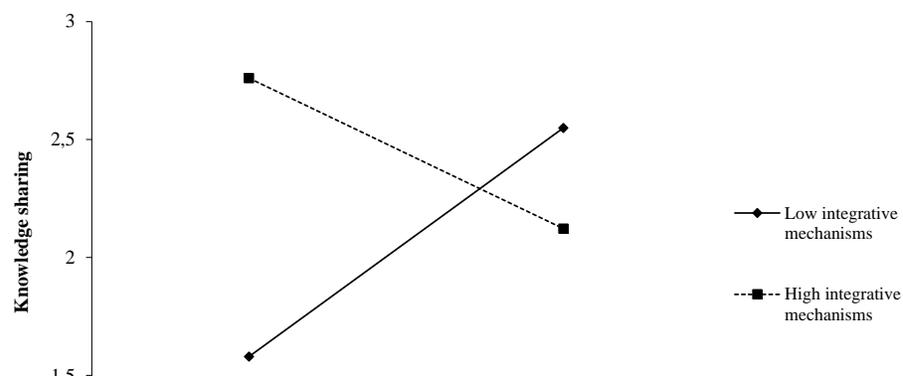

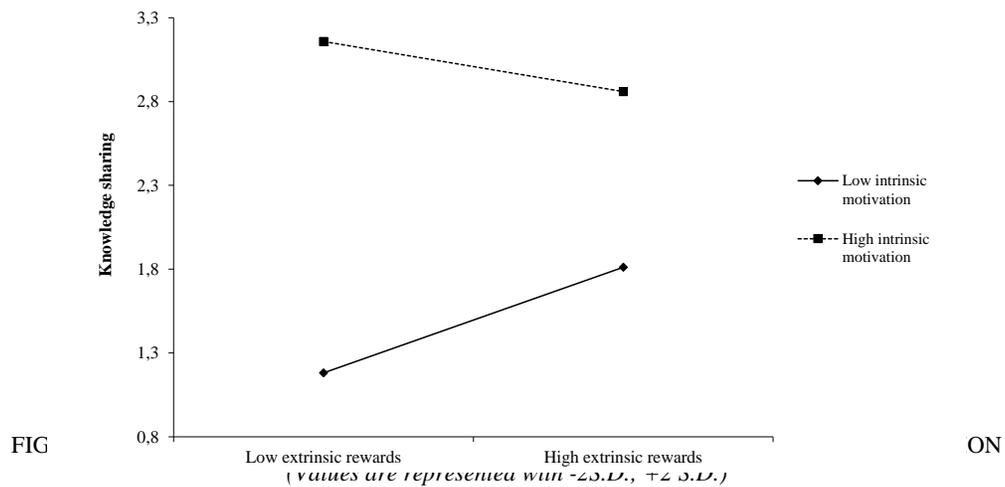

FIGURE 3: INTERACTION BETWEEN EXTRINSIC REWARDS AND INTEGRATIVE MECHANISMS
(Values are represented with -2S.D.; +2 S.D.)

Concluding Comments

This paper investigates KS behaviours by combining an organizational perspective (i.e. integrative mechanisms) with an individual one (i.e. motivation). By empirically examining a sample of 754 employees from 23 international manufacturing firms, we found evidence about the positive effect played by both individuals' intrinsic motivation and organizational integrative mechanisms on employees' KS behaviours as well as about the moderating and negative impact of extrinsic rewards reducing such positive effects. Overall, the results demonstrate the power of extrinsic motivators as effective moderators likely to shape individuals' actions and to lower the impact of organizational mechanisms aimed at increasing social interaction.

We did not find significance about the main effect of extrinsic rewards on our dependent variable (i.e. KS behaviours), confirming the existing lack of consensus about whether and how extrinsic incentives directly affect employees' KS behaviours.

Contribution and Implications

We believe that this paper provides interesting theoretical and practical contributions. First, it stresses the importance of providing an appropriate motivation management strategy, pointing to the need to avoid the crowding out effect of intrinsic motivation, which drives much of the employees' contribution to the organizational objectives (Osterloh and Frey 2000). Second, simultaneously analyzing both intrinsic and extrinsic motivation offers a more realistic view on the antecedents of individuals' behaviours. Third, investigating the way organizational integrative mechanisms affect KS behaviours is consistent with the literature supporting the organizational forms as a critical management tool which helps the organization align its strategy to the competitive forces (Dijksterhuis et al. 1999), by adopting the organizational form more likely to succeed (Lam 2000). Fourth, contributing to expand the literature on intra-organizational KS is always important because of its critical role in improving the firm's innovation capability and competitiveness. Accordingly, studying KS antecedents may allow managers to understand what really matters for it to occur.

Limitations and Directions for Future Research

Despite the potential we think is included in the paper, we are aware of its limitations. Given that data collection was limited to organizations operating in a highly specific area (i.e. Tuscany), the results may not be applicable to firms from different countries. Replicating the study on foreign companies could make our results more robust.

Moreover, cross-sectional data preclude from investigating possible endogenous effects in our model, so that one may derive alternative causal explanations regarding our hypotheses. Further research based on experimental or longitudinal data may help investigate the direction of causality.

Furthermore, the paper focuses only on certain individual and organizational KS enablers; future research could take into account other factors such as other types of individual motivation or other organizational factors. In order to enhance the self-perceptual assessment of KS activities, we think that an objective measure of them may be built by collecting, for instance, third-party and archival data.

Communities of Practice's dark sides Some evidences from a retailer organization

Abstract

Communities of Practice (CoP) are seen as a good opportunity for organizations to improve their own performance. When people with a shared passion join a CoP, they are able to add value to organizations, for example by helping drive strategy, or by exploring new lines of business. When members of a CoP choose a Social Network Website as a “place” to host their meetings and to share their thoughts, the practice performed within a CoP becomes public and - at least potentially - a corporate reputation issue arises. By analysing 62 pieces of content (posts) produced by 5.063 members across 6 weeks within a CoP hosted on Facebook and created by Italian employees of the French Company “Auchan”, we show how a “good” organizational practice can affect negatively the reputation of a company.

Introduction - Social Media Community of Practice and Corporate Reputation

This paper relies on the study of side effects of communities of practice (CoP), namely on those activities that are potentially in conflict with the main and publicly declared objectives (statements) of the company to which the CoP's members belong.

A Community of Practice is a group of people regularly engaged in sharing and learning, based on their common interests (E. C. Wenger & Snyder, 2000). According to scholars, there are three elements that render a Community of Practice. The first element is a well defined “domain”, i.e. one or multiple themes that are discussed by people who join the community. When a domain is clearly defined, members are stimulated to actively participate the debate, and they share ideas with others (Amabile, 1997; Csikszentmihalyi, 1997; Polanyi & Sen, 2009). The second element is “the community”, broadly defined as a number of people that share a finite social space and that are joint together by similar ideas and a shared sense of commitment (Bender & Kruger, 1982; Etzioni, 1995). The third element is “the practice”, namely the specific knowledge that the community creates about the domain. The practice is made of the whole set of ideas, tools and information that are generated by members (Argyris, Putnam, & Smith, 1987; Schön, 1983).

When members don't use physical interactions and meetings in order to develop their own practices, a “distributed” Community of Practice arises. There are several reasons why community's members use technology as the preferred way for communicate: sometimes they live in different countries, sometimes they are a huge number, sometimes they belong to different organizations or cultures. In all these cases, they choose not to use physical meetings as the main mode to connect with each other. For this reason, distributed CoP are also labelled as “virtual” CoP (Dede, 1996) or - more generically - “online” CoP (Figallo, 1998; Kim, Oh, & Swaminathan, 2006; Palloff & Pratt, 1999; Preece, 2000).

The above mentioned considerations about CoP are still valid in a virtual Community of Practice. In this case, many of the characteristics of the CoP are transliterated into a virtual space (like a website) where members can “meet” and share their practice. This behaviour is even more emphasized on social network websites, where the whole technological experience is built in order to favourite interactions among members and sharing of their experiences and opinions. As for any other virtual CoP, “social media CoP” use technology as the preferred medium for communication, but they enrich its “connective” function also by leveraging technology to share, comment and create content and practices that may not even exist outside of the social network website.

By exploiting an informal environment, in a CoP people with a shared passion are able to add value to organizations, for example by helping drive strategy, or by exploring new lines of business. For this reason CoP is considered a good way to reinforce commitment among organization's members, to make the learning curve of new employees shorter (Brown & Duguid, 1991) and to unveil insights, stories and frustrations among employees (E. Lesser & Prusak, 1999). When an organization is able to manage this groups, by addressing its members' cognitive

efforts into a unique flow, there is an increase of the social capital (E. L. Lesser & Storck, 2001). CoP are therefore viewed as a common context, in which relationships and connections are reinforced.

Because of the regular engage in sharing and learning of their members, CoP are considered as “enhancer of organizational performance” (E. L. Lesser & Storck, 2001). In particular, CoP are seen as good tools for problem solving, seeking of experience or information’s requesting, as well as discussion enhancing or knowledge mapping (E. Wenger, 2011). Thanks to the practice developed inside communities with shared interests, organizations are suitable to become more and more performative, because of the decrease in the learning curve of new employees (Brown & Duguid, 1991), the speeding up of response to customer needs and inquiries, the reduction of unhelpful or unrequired rework and the generation of new ideas for products or services.

Given the above background regarding CoP, in the past 20 years a wide range of contributions, mostly empirical or analytical, has been developed in order to validate CoP as a “good” organizational practice. The shared perspective about Communities of Practice is that they should be encouraged and stimulated: more specifically, a significant fringe of the literature is supporting the idea that CoP can be “cultivated”, namely helped to stay active and alive. According to this perspective, Community of Practices aren’t suitable to be “strictly” addressed - i.e. being designed to achieve a specific objective - but they can be “energized”, in order to maintain their learning capability (E. Wenger, McDermott, & Snyder, 2002). Despite the contributors’ effort to mitigate an “absolute rationale approach”, the idea of recognizing to CoP’s the ability to create value for the general organization (through the generation of collective knowledge and the positive effects on learning curve), is based on the assumption that the relationship between CoP’s behaviour and organizations’ strategy is knowledgeable and relatively actionable.

This approach appears as feasible for offline or even virtual Community of Practice, but it could be less valid when employees decide to use social network sites as a place to share their practices. Social Networking Sites (SNSs), such as Facebook, have become a major place of conversation, and the expression of experiences, attitudes and opinions, for people and companies, but when they are used as CoP, a tension potentially arises among preserving authenticity of the Community (namely, “cultivating it”) and maintaining the companies’ reputation, since members’ practices are available to the general public. Conversations in the Internet exist, like it or not to the companies, and this can have a deep impact on the perception of the corporate stakeholders: in a research perspective, how an employee’s Social Media Community of Practice affects the company reputation?

Corporate reputation has attracted interest from a wide range of academic disciplines (Chun, 2005; Fombrun & Riel, 1997):

- Accounting: reputation seen as an intangible asset and one that can or should be given financial worth;
- Economics: reputation viewed as traits or signals. Perception held of the organization by an organization’s external stakeholders;
- Marketing: reputation viewed from the customer or end-user’s perspective and concentrating on the manner in which reputations are formed;
- Organization: reputation viewed as the sense-making experiences of employees;
- Strategy: reputation viewed as assets and mobility barriers. Since reputations are based on perception, they are difficult to manage.

In order to answer this question, in this paper we are referring to “corporate identity and reputation” concepts introduced by a number of contributions lying both on an organizational and on a marketing-oriented literature.

According to this perspective, corporate identity (Fombrun, 1996) describes the set of values and principles that employees and managers associate with a company. Whether widely shared or not, a corporate identity derives from a company’s experiences, since it is founding its cumulative record of success and failures. Everyone of us, however, recognizes a company by its name and by the many presentations it makes to describe its actions, its plans, and intentions: namely we recognize a company by its corporate image. Sometimes a corporate image accurately mirrors the company’s identity; more often than not, the image is distorted (a) as the company tries to manipulate its public through advertising and other forms of self-presentation, or (b) as rumors develop by the unofficial statements of employees to peers, analysts, and reporters (Fombrun, 1996).

Corporate reputation embodies the general estimation in which a company is held by employees, customers, suppliers, distributors, competitors and the public (Fombrun, 1996). The key point is that “reputation consists of

perceptions – how others see you” (Fombrun, 1996). Customers expect reliability, investors and suppliers demand credibility, employees expect trustworthiness and communities expect responsibility. According to this perspective, it is useful to consider the “corporate reputation” as the summary view of the perceptions held by all relevant stakeholders (Chun, 2005), that is what customers, employees, suppliers, managers, creditors, media and communities believe the organization stands for, and the associations they make with it.

Given this background, we can state that corporate reputation deals with the gap that arises when the corporate image differs from the identity that the company tries to build through official communication (Davies & Miles, 1998; Fombrun, 1996): identity, desired identity and image (

FIG. 1).

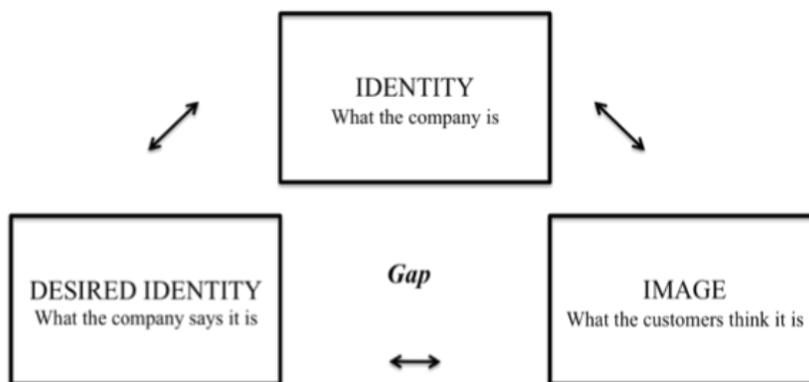

FIG. 1: KEY ELEMENTS OF CORPORATE REPUTATION

The Fombrun’s model sees the negative influence of employees’ rumors on corporate reputation as a “pathological” situation in a company’s life. In our case, however, we are interested in understanding if and how the dynamics expressed by the model can be confirmed also in a “physiological” situation: we are proposing a case in which an organizational practice which should have a positive impact on performance, could potentially increase the gap between the image and desired identity.

In other terms, we are looking for dark sides of CoP, namely we are studying unexpected (and undesired) effects of CoP on corporate reputation. This paper aims to investigate this issue, through the usage of the Fombrun’s model.

Methodology

The Social Network Sites are new online contexts that have become a precious source of data for researchers that can find a lot of spontaneous and intense conversations about a wide variety of topics. Accordingly to the above-mentioned literature, we analysed a CoP developed “inside” a Social Network Site, namely a “social media CoP”.

Content analysis is the technique often used to analyse transcripts of asynchronous, computer-mediated discussion groups in formal educational settings (De Wever, Schellens, Valcke, & Van Keer, 2006), and given the exploratory nature of this paper, we decided to use latent content analysis as main technique for data analysis. Literature review points out that content analysis using web data collected in a CoP can be carried out by professional and academic researchers with significant advantages (such as greater accuracy, timeliness, and lower cost compared to the offline alternative) in organizational and marketing research. As mentioned earlier, we preferred to use a latent content analysis with respect to a manifest one. We therefore run towards a process of identifying, coding, and categorizing the primary patterns in the data not just by counting the occurrence and frequency of specific words, but by searching for macro-topics within context, namely coding participants’ intent in the context (Mayan, 2009). This

specific technique is generally called “Thematic Analysis” (Guest, Macqueen, & Namey, 2012) and consists of the identification of “discourse patterns” through the assignment of “labels” that are able to summarize concepts and ideas represented by a post. We choose not to define labels in advance, but only during the reading of posts. We therefore analysed 62 pieces of content (posts) produced by 5.063 members of a social media CoP across 6 weeks. The content analysis produced 103 different codes, which were condensed in 7 content topics.

Moreover, in order to add meaning to the main categories that have been derived by the content analysis, and to determine the attitude of informants with respect to different topics, we introduced a sub-categorization built on “rating scales” that were based on the sentiment analysis of each content (Pang & Lee, 2005).

To ensure an ethical research approach, we identified ourselves in the Group, providing our credentials and subscribing the Group. Data collection is composed by: (1) dataset: the data directly traced from the computer-mediated communications of online community members, and (2) field notes: the data that we inscribed regarding observations of the community, its members, interactions and meanings.

The data analysed for the study are detailed in TABLE 3.

TABLE 3: THE DATA SET

<i>Metric</i>	<i>Value</i>
Group Members	5.063
Number of post analyzed	62
Sharing Index (average)	19,7 like
Timeline of conversations	28th, April, 2014 - 8th, June, 2014

Through the content analysis in a virtual CoP managed by employees of a major FMCG retailer, the paper aims to highlight:

1. What and How the CoP is sharing;
2. The potential reputational risk for the company due to CoP conversations.

The virtual CoP pinpointed is held on Facebook by the FMCG retailers’ own employees in the form of “open group” with 5063 members. The virtual CoP on Facebook matches the Kozinets’ guidelines (2010), being: relevant, active, interactive, substantial, heterogeneous, and data-rich.

3. The Case - A retailer's Reputation

Auchan is a privately owned France-based grocery retailer: in 2013, Groupe Auchan operates in 15 countries (including Italy), employs 302.500 people, and generates € 62.1 in revenue including taxes for the chains. More than a market leader, Auchan is fundamentally a channel champion, with large hypermarkets representing ca. 80% of its global sales: according to Planet Retail’s Report (2013), Auchan has emerged as one of the Top 3 global hypermarket operators. However, Auchan is not short on challenges due to increased competition in its home market, its wide exposure to crisis-hit southern Europe and aggressive expansion from local players in the BRIC countries. This is forcing the retailer to constantly innovate in order to remain one step ahead. Auchan set an ambitious long-term goal to achieve sales of EUR 100 billion by 2017. The original 2015 deadline was pushed back due to the economic downturn in Europe and eroding like-for-likes. Its status as a privately-held company, owned by its founding family, also puts it in a largely unique position. Auchan has more freedom to pursue long-term visions, independent of the short-term demands of financial markets, which pays off when it comes to entering difficult markets or perfecting new store concepts.

The shared mission of the French retailer is: “To improve the purchasing power and the quality of life of the greatest number of customers, with responsible, professional, committed and respected employees” (source: www.groupe-auchan.com). This mission is based on three fundamental values: trust, sharing and progress. Groupe Auchan builds on its employees’ capacity for business innovation by focusing on the sharing of power via the sharing of responsibility. This desire to encourage shop-floor initiative is reflected in the Group’s decentralized structure,

which gives significant autonomy to each subsidiary. In all of the businesses, independence, personal initiative, and involvement in the decision-making process are core concepts that the company instils in its employees throughout their careers. That accountability is central to professional development, and opens the doors of internal promotion to many employees (in the hypermarket branch, 32% of positions are filled through internal promotion).

In the retailing sector, very often Facebook pages/Groups are opened and managed by customers and, sometimes are held by their own employees, as in the case of the Auchan Italian employee page which makes fun of their customers². That social media CoP is the object of our research.

According to contributors, the vitality of a virtual CoP is a fundamental ingredient for making it successful and continuous over time. In order to assess the vitality of the analyzed CoP, we studied different engagement's metrics. These metrics revealed high members' participation frequency and spontaneity. During 6 weeks, there were 1,47 posts per day, and each post generated 19,7 likes as average.

We based our study on the content analysis of 62 statements released within a Social Media CoP hosted on Facebook and composed of 5.063 Italian employees of a retailer company, namely Auchan. Even if - according to its "formal domain" - this Community of Practice should "make fun of the Company's customers", we discovered that only 25,8% of contents are actually related to customers. Surprisingly, 27,4% of contents are focused on working conditions and conveys a negative opinion of members on this specific topic. The contents that are related to working conditions are the most engaging too. The most commented content is related to working conditions (44 comments), as the post that received the highest number of "likes" (134). Posts related to customers are not even in the top-five of the most liked contents.

Our content analysis seems to reveal a gap with the official mission declared by the company: "to improve the purchasing power and the quality of life of the greatest number of customers, with responsible, professional, committed and respected employees". According to thoughts shared inside the analyzed Social Media CoP, employees are not really satisfied with the working conditions and consider the management as not really interested in their needs.

By analysing the contents shared among the social media CoP of Auchan's Italian employees, we highlighted 7 main content categories (6 plus "others") that are shared more often. As with Grounded Theory (Glaser and Strauss 1967), data analysis has been continued as long as new insights on important topical areas are still being generated, and it has produced the data showed in TABLE 4.

TABLE 4: CONTENT ANALYSIS. WHAT MEMBERS ARE SHARING

<i>Category / Topic</i>	<i>Percentage</i>	<i>Sentiment</i>
Working conditions	27,4%	Positive: 5,9% Negative: 88,2% Fun/Ironic: 5,9% Neutral: /
Customers	25,8%	Positive: / Negative: 12,5% Fun/Ironic: 81,3% Neutral: 6,2%
Operations (assortment, promotion, ...)	12,9%	Positive: 37,5% Negative: 37,5% Fun/Ironic: 12,5% Neutral: 12,5%
Encouraging	9,7%	Positive: 83,3% Negative: / Fun/Ironic: / Neutral: 16,7%
Retail sector/actuality	8,1%	Positive: /

		Negative: 20,0% Fun/Ironic: 80,0% Neutral: /
Corporate (Auchan)	3,2%	Positive: 100,0% Negative: / Fun/Ironic: / Neutral: /
Others	12,9%	/

Data analysis highlights 7 different content topics, classified and categorized in:

1. Working conditions: posts discussing working conditions, such as working Sunday, contractual conditions, working hours organization, and so on.
2. Customers: posts describing customers' gaffe and oddity.
3. Operations: posts related with the everyday in-store life, with the sharing of merchandising photos, comments about promotions and in-store materials (Mondial's theme), assortment, uniforms.
4. Encouraging: common posts of incitement with the aim to say "come on!". The majority of them are shared links from other Facebook pages.
5. Retail sector/actuality: news and gossip from the retail sector (M&A, new opening and closure, ...).
6. Corporate (Auchan): information about the French management and the new local management.
7. Others: mainly off topic, or personal messages such as "missing dog".

While the majority of the post includes photos, a good variety characterizes the "sociality" of the posts, namely the number of shares and comments made on each content. TABLE 5 describes the most social post, in terms of numbers of Like and Comments.

TABLE 5: THE MOST RELEVANT AND "SOCIAL" POSTS

<i>Like ranking</i>		<i>Comments ranking</i>	
<i>(average n° Like/post: 19,7)</i>		<i>(average n° Comments/post: 4,9)</i>	
POST	TOPIC	POST	TOPIC
04/05 MRR, 134 Like	working conditions	30/04 FM, 44 Comments	working conditions
28/05 MB, 64 Like	operations	13/05 DM, 24 Comments	customers
25/05 LT, 59 Like	corporate (Auchan)	04/05 MRR, 23 Comments	working condition
03/06 LT, 54 Like	working conditions	29/05, CC, 20 Comments	operation
02/06 AA, 53 Like	other (<i>personal work anniversary</i>)	08/06 GCM, 20 Comments	off topic (<i>looking for a lost dog</i>)

Focusing in more detail on the results, the research shows that:

- Even if the group is named "Never say Auchan", customers' gaffes/mistakes are an excuse to meet people working in the same sector/company.
- The majority of the post concerning the customers has a positive ironic sentiment. On the other hand, the group permit to yell out about working conditions (especially about the working Sunday: a very hot topic).
- Colleagues are close each others, "The Company" is far from the store. The Group permits to discuss arguments that overcome the "single store dimension", reaching more wide topics and horizons: central management, competitors, and so on and so far. Very often the discussion through the comments highlights service level and retail practice with consistent differences across the Italian area.
- Most viral posts are the personal ones: the Group doesn't like general posts and off topics, but awards (with "Like" and comments) personal experience and stories, original photos. In the Group is possible to highlight some heavy

contributors.

- The lexicon used is very sectorial.

4. Concluding remarks

The main purpose of this paper has been to further our understanding of side effects of virtual CoP on corporate reputation. By integrating the marketing perspective with the organizational one, in order to propose an original research pattern, we gained both managerial and theoretical implications.

Unlike what happens in “traditional” (offline) CoP or in virtual CoP that are implemented on platforms with a restricted access, all the contents created by virtual CoP that are built within a Social Network website like Facebook (Social Media CoP) are potentially visible from anyone. In this case, the practice performed by the members of a community could potentially negative affect the whole corporate reputation, as predicted by the Fombrun’s model.

Given this premise, our case study shows the importance for management to constantly monitor the conversations that take place within a social media CoP. In this way, managers become more and more aware of the employees’ needs and expectations, drawing on information that otherwise would remain "hidden". Under this point of view, we have shown that social media CoP can provide valuable information to refine company’s HR policies.

Under a theoretical point of view, we firstly introduced the concept of “Social Media CoP”, intended as a virtual CoP that is hosted by a Social Network Website. Moreover, we see this case as a good opportunity to extend to Social Media CoP the well-known Fombrun’s model. In fact, through access to a CoP social, employees themselves can highlight any discrepancies between the current way of organizing a company and the official statements of the same. Just as explained in the Fombrun’s model, these factors can affect the image of the company that not only customers, but a wider range of stakeholders, including potential new employees, have.

This study constitutes a first step towards a deeper understanding of the relationship between the existence of a virtual community of practice created by the employees and the company's performance, through its impact on the corporate reputation - both at an external level (customers perspective) and at an internal one (employees perspective). This research has clear limitations. We considered a short time-span. We have analysed a single CoP, in a specific sector. We do not have reinforced content analysis with a specific analysis of the gap reputation. Despite these limitations, in our view the existence of a social CoP among employees from a company can be considered a two-sided phenomenon. Indeed, the case that we analysed highlights the risks of a negative impact on corporate reputation and the image perceived by both customers and potential employees. We see this as a side effect that is hard to predict and manage: for this reason we believe that this research field can be very promising and we therefore encourage contributors to perform similar studies on a different number of industries and to a larger number of Social Media CoP.

Impact of Mobbing on Health and Absenteeism among Nurses

University of Split, Faculty of Economics, CROATIA

Impact of Mobbing on Health and Absenteeism among Nurses

Abstract

Mobbing is a specific form of behavior in the workplace, in which one person or a group of them systematically psychologically (mentally) abuses and humiliates another person during a longer period of time. Effects of mobbing on working behavior, individual and organizational performances are coming more and more in the focus of research interest of modern management and human resources management.

This paper is based on a research performed on a random sample of 287 nurses working in the hospital centre in Split (KBC Split). The research was anonymous, carried on in June and July 2013, using a specific questionnaire. The results show that the overall exposure to mobbing was 38.7% - i.e. 38.7% of respondents declared that at some point of their employment they have been exposed to some cases of mobbing. The largest proportion of respondents who considered themselves as victims of mobbing has been found in the age group of 25-34 years old. Gender and level of education did not show any specific difference because the proportion of male respondents was very small compared to female (8,4% : 91.6%), and the level of education was quite uniform. Most commonly, mobbers were colleagues hierarchically at the same level as victims. Statistically significant indications were found that exposure to mobbing affects considerably both the health and the increased absenteeism among this occupational group.

Key words: mobbing, mobbers, organizational behavior, health, absenteeism

1. Introduction

To ensure to employees the best working conditions is not only a humanistic aspiration, but even a request and principle of the modern human resources management. Modern managers should pay attention not only to physical conditions of work of their employees, but to interpersonal and organizational relationships that will create a positive and motivating climate for employees. Such larger notion of (good, stimulating) working conditions is seen today as the key factor of individual, group and organizational performances (Bahtijarević-Šiber 1999). Or, in the other sense, bad, demotivating working conditions can significantly compromise work results at all levels.

Mobbing is today among the most frequent, but also most serious phenomena that is threatening positive and healthy working conditions in virtually all organizations, no matter of their size, industry, and work force composition. Mobbing is a complex phenomenon that begins with maltreatment and psychological abuse on working place, and finishes with very serious consequences that can endanger health of the (mobbed) individual, his/her social status and badly affect their social environment. The history of human communities is full of examples of humiliation, maltreatment, and abuse, but mobbing is specific because it is exclusively connected with work and working environment. Mobbing is a kind of disturbance in interpersonal relations at work that can be defined as psychological terror in work environment with hostile and unethical communication, systematic maltreatment from one or more persons directed towards one person that is put in helpless position, unable to defend him/herself. To be qualified as mobbing, the maltreatment has to be frequent (at least once a week) and performed over a longer period (at least six months). The mobber has a conscious intention (rarely unconscious) to harm the mobbed and/or to force her/him to leave the organization (Borić R, Šinko M, Prlenda S, 2009).

Mobbing is more and more present in organizations, which has been confirmed by numerous researches. Explanations from the increase of mobbing incidence vary from competition, globalization, organizational changes (privatization, mergers, restructuring), informatization, economic crisis, "new economy", insecurity of working places, 'flexible employment practices', ... - all leading to an ever increasing pressure on organization and employees.

The scope of mobbing problem in enterprises can be illustrated by the results of several researches:

- a) for those entering labor market, the risk to become victims of mobbing over next 30 years is 25% (Leymann, 1996.);
- b) according to one other Leymann's research (Koić, Filaković, Mužinić, Matek, Vondraček, 2003.), 20% Swedish employees (every fifth) had been exposed to mobbing, while 3,5% had experienced severe mobbing that lasted on average 6-15 months;

- c) the research of the Northwestern National Life Insurance Company 1993 (Namie and Namie 1999, in Kostelić-Martić, 2005, p. 25) has found that one of four workers in the USA was mobbed;
- d) the research of the Institute of Personal Development in Great Britain showed that one in eight workers was mobbed over last five years;
- e) Einarsen, Hoel, Zapf, and Cooper (2003), after the analysis of numerous researches from Europe concluded that: 1-4% employees had had serious difficulties with mobbing, 8-10% had experienced occasional mobbing, and 10-20% had been faced with negative social behavior at work;
- f) in Italy, over 1 million workers has been suffering consequences from mobbing (Ege, 2000);
- g) two large researches were carried on in Europe by the European Foundation for the Improvement of Living and Work Conditions. First research, from 2000 (Third European Survey on Working Conditions, Dublin, Ireland, 2000, according to Kostelić-Martić, 2005, pp. 25-26) that involved 21.500 employees from states members of EU showed that 2% of employees were exposed to physical violence from their coworkers. 4% were exposed to physical violence on their working place from persons outside organization. 2% of employees were exposed to sexual harassment, and 9% were exposed to mobbing. Results of this research showed big differences in mobbing incidence across countries: the highest incidence was found in Finland (15%), followed by Great Britain and the Netherlands (14%). The lowest incidence of mobbing was found in Italy and Portugal (4%). The same research found significant differences in different areas of work: the highest incidence of mobbing was recorded in state administration and defense (14%), followed by education and health (12%), while the lowest incidence of mobbing was found in electricity distribution, water supply, agriculture and fishing (3%);
- h) Second research of European Foundation for Improvement of Living and Working Conditions (www.eurofound.eu.int) was carried out in 2001, and its results were published in 2003. That research included 12 new member states of the EU, surveying 11.000 workers. It found an average rate of mobbing exposure of 6,9%. This percentage was something lower than in older EU states (EU 15), which was explained with cultural differences and lack of information (Kostelić-Martić, 2005, p. 28). The highest incidence of mobbing was found in Lithuania (10,5%) followed by Czech Republic and Slovakia (9,5%), while the lowest incidence of mobbing was found in Hungary (3,0% and Cyprus (3,5%);
- i) Namie (2000, in Rijavec, 2005), found that in the USA 16,8 % workers were victims of mobbing, while Paoli and Merllie (2001, in Rijavec, 2005) found that incidence in Europe to be 11 %;
- j) according to a research in Croatia (Koić, Filaković, Mužinić, Matek, and Vondraček, 2003) between 15,4% and 53,4% respondents (in different organizations) experienced some forms of mobbing. In that same research, 37,7-54,8% of respondents declared they experienced psychological problems connected with the situation at work.

Mobbing is basically a real aggression to an individual at work, planned and carried on by a group of co-workers. Every such group of mobbers has a 'ringleader' who is coercing and manipulating group members into mobbing the selected 'target'. A division can be made on 'horizontal' mobbing (when the mobbers are the co-workers from the same level as the 'target') and 'vertical' (when at least a part of mobbers – usually 'ringleader' – are from higher hierarchical level than the 'target'). Although it was believed that mobbing is dominantly present in the industries that are dominantly masculine (like army and police), it is more and more present (or discovered) in areas that are dominantly feminine.

Harassment on the workplace (including mobbing) was for a long time the problem that was not discussed, neglected and almost concealed. Authors of the book "The Bully at Work", Gary and Ruth Namie, named it a „silent epidemic“ (Namie and Namie, 2000). Because of accumulation of negative emotions, mobbing is causing different psychological and psychosomatic disorders to its victims (Leymann, 1990).

Health problems and symptoms at the mobbing victims are found on three levels (Borić, Šinko, Prlenda, 2009):

1. Problems at the socio-emotional level, which includes changes in mood – like depression, anxiety, obsessive ideacy (continuous thinking about the problem), feeling of depersonalization, panic attacks, social insulation, lack of interest for others, emotional dumbness ...
2. Changes (problems) at psychosomatic level: headache, sleep disorders, feeling of loosing balance with vertigo, digestion disorders, feeling of pressure on the chest, breathing difficulties, hearth problems, changes on the skin ...

3. Behavior changes (disorders), which are usually combined with or derived from problems at the socio-emotional and psychosomatic level – like irritation, aggression (hetero- or auto aggression), passivity (often with excessive need for sleep) or agitation and insomnia, eating disorders, excessive use and abuse of alcohol, cigarettes, or drugs, sexual disorders, and even passive or active suicidal tendencies.

How serious can be problems provoked by mobbing, show the researches that found that between 10% and 20 % of suicides in Sweden had had direct or indirect cause in problems at work (Leymann, 1996). In Italy that incidence has been estimated at 13% (Ege, 1998). The researches at the Clinic for Work in Milan (Italy) have found that 8,7% victims of mobbing developed the posttraumatic stress disorder (PTSD).

Besides problems, harms and cost that bear victims of mobbing, costs (damages) for the organization of work are also evident. Those damages for the organization can be located in three areas:

1. Cost because of the absence of the mobbing victim: mobbed employees have more frequent and longer periods of absence,
2. Costs of the lower productivity of the mobbing victim, and
3. Indirect costs because of lower motivation and productivity of other employees involved in or witnessing the mobbing.

A research (Bieneck, 2006) estimated that large German enterprises had had the absenteeism costs caused by mobbing around 100€ per employee. Direct costs of mobbing in the US have been estimated to US\$ 4 billion (Chapell and DiMartino, 1999).

Mobbing and all its problematic consequences can be found in all areas of human work. Still, work in service areas is probably exposed to specific conditions and risks that can increase the possibilities and incidence of mobbing. Contact with clients and need for more intensive internal communication to satisfy clients demands are much demanding than in 'classical' manufacturing. That brings more exposure to (possible) harassments from clients, higher responsibility on behavioral level, and stronger emotional involvement of employees.

Nurses and their work definitely belong to the category of jobs with specific and additional risk of mobbing. Besides general characteristics of service work, nurses' work is connected with specific working conditions (working in shifts, night work, work on weekends and holidays, higher health risks), higher pressure from all directions: from above (doctors, managers), same level (other nurses as the competition), and from below (lower staff, patients). All these characteristics not only increase probability of mobbing, but also can boost sensitivity of nurses to the mobbing. For that reason, this research has been directed to the incidence and consequences of mobbing among nurses in a large hospital in Croatia.

2. Incidence of mobbing and its influence on health and absenteeism on nurses in the KBC Split

2.1. KBC Split

Clinical Hospital Split (KBC Split) is the central hospital in Southern Croatia, located in the city of Split, but serving around 1.000.000 Croatian citizens from Southern Croatia (Dalmatia), around 500.000 citizens of southwestern parts of neighboring Bosnia and Herzegovina, and more than 500.000 tourists that visit those parts (mainly during summer season). The KBC Split is a complete and complex hospital with 13 clinics and all necessary supporting services, having 1.854 beds and employing around 3.200 employees. Those employees can be divided in several groups:

- ✓ Specialists physicians – 12% of total staff
- ✓ General physicians, interns, and volunteering physicians – 7% of total staff
- ✓ Nurses – 41% of total staff, or more than 1.300
- ✓ Other medical staff (physiotherapists, pharmacists, laboratory technicians ...) – 10% of total staff
- ✓ Nonmedical staff – 30% of total staff

Nurses are, obviously, the most numerous group of employees in the KBC Split (like in any other hospital). They are mostly female (94%, against 6% males in this category). Most of them have a high school education (79%), while 21% has a college (2 years) or university level of education.

2.2. Sample and research method

The research of mobbing among nurses in the KBC Split was conducted during June and July 2013 on a random sample of 350 nurses. Out of 350 approached nurses, 301 (86%) returned the questionnaire, but 14 (4,7%) of them were incompletely or incorrectly responded. So finally, 287 questionnaires represented the sample for this research, representing 21,9% of the total number of nurses in the KBC Split. The structure of the sample is presented in the Table 1.

As it can be seen from the Table 1, 263 out of 287 (91,6%) were female, against 24 (8,4%) males. Majority of respondents belonged to the age groups between 25 and 44 years (64,8%). Almost 70% of respondents had the high school education (69,3, while remaining 30,7% had college or university level of education. All these characteristic of the sample made it fairly large and representative. Following that, the results of the research can also be considered representative and relevant for this group and organization.

TABLE 1. SAMPLE STRUCTURE

		number	%
Gender	Male	24	8,4
	Female	263	91,6
Age	< 25	25	8,7
	25 – 34	109	38,0
	35 – 44	77	26,8
	45 – 54	54	18,8
	55 – 65	22	7,7
Education level	high school	199	69,3
	college and university	88	30,7

The instrument for this research was an anonymous questionnaire, constructed by authors, consisting of several groups of questions:

- demographic characteristics of respondents (gender, age, and educational level);
- questions about relationships with co-workers and superiors, and exposure to inappropriate conduct (answered on a 5-grade scale);
- questions about exposure to mobbing (previous and/or current);
- questions about the type of mobbing and mobber;
- questions about impact of mobbing to absenteeism;
- questions about consequences of mobbing to the health of mobbed person (where 5 possible types of effects were offered: nervousness, chronic tiredness, reactive depressive state, reactive psychotic state of paranoid type, and posttraumatic stress disorder that can lead to suicide).

Participants were given short instructions about the research and the questionnaire, and then left to fill the printed questionnaire freely and anonymously.

2.3. Incidence and type of mobbing

Table 2. summarizes the basic results on incidence of mobbing among nurses in the KBC Split – total and across the age groups.

TABLE 2. MOBBING INCIDENCE THROUGH AGE GROUPS

Have you ever been exposed or do you still consider yourself a victim of mobbing?				Total
No		Yes		
number	%	number	%	

Age	<25	17	68,00	8	32,00	25
	25-34	68	62,39	41	37,61	109
	35-44	46	59,74	31	40,26	77
	45-54	36	66,67	18	33,33	54
	55-65	9	40,91	13	59,09	22
	Total	176	61,32	111	38,68	287

Asked whether they have ever been exposed or do they still consider themselves a victim of mobbing, 111 out of 287 nurses that responded (38,7 %) answered with „Yes“. Comparing with the researches mentioned in the section 1, this makes a very high incidence of mobbing and suggests (confirms?) that nurses are the category especially susceptible to mobbing.

Although the lowest (in the relative sense) incidence of mobbing was recorded among the youngest, and the highest incidence was recorded among the oldest respondents, the trend was not uniformly increasing. As the question was asking for cumulative exposure to mobbing over the whole working life, growth of incidence with the age could have been expected, but statistically significant difference among the groups was not confirmed (Pearson Chi-Square was 5,119; $\alpha^* = 0,275$ which is $>5\%$).

Table 3. presents the mobbing incidence across the educational levels. Although some previous researches suggested that employees with lower status (in formal and educational sense) are more frequently and stronger exposed to mobbing (Mustajbegović, Russo, 2012), this research did not find significant differences between nurses with higher school and those with tertiary education.

TABLE 3. MOBBING INCIDENCE BY EDUCATIONAL LEVELS

		Have you ever been exposed or do you still consider yourself a victim of mobbing?				Total	
		No		Yes			
Education level	high school	121	68,8%	78	70,3%	199	69,3%
	college and university	55	31,3%	33	29,7%	88	30,7%
Total		176		111		287	

Table 4 is giving the incidence of mobbing directions: even 51 respondents consider themselves victims of both horizontal and vertical mobbing (46% of all those considering themselves to be exposed to mobbing). That could suggest that victims of mobbing are often mobbed from both directions – coworkers and superiors. Slightly higher incidence of horizontal mobbing is not statistically significant to allow the claim that horizontal mobbing is more present among the nurses in the KBC Split.

TABLE 4. MOBBING INCIDENCE BY THE POSITION OF THE MOBBER

	Have you been or are you still a victim of the horizontal mobbing	Total

		No	Yes	
Have you been or are you still a victim of the vertical mobbing	No	176	32	208
	Yes	28	51	79
Total		204	83	287

It should be mentioned that, because of very small share of males in the sample (and in total number of nurses in the KBC Split), analysis of differences among genders was ineffectual.

2.4. Connection between mobbing and absenteeism

Since the absenteeism is the most common and most visible indicator of problems and dissatisfaction with the situation at work, this research tried to establish existence (or non-existence) of correlation between the mobbing and absenteeism. First respondents were asked to evaluate directly connection between mobbing and absenteeism in their case (Table 5). While the case of 2 respondents that did not declare to be mobbed, but still responded that the mobbing led to higher absenteeism in their case can be considered insignificant (marginal) error, it is definitely significant that 35% of those that were mobbed responded that the mobbing led to higher absenteeism in their case.

TABLE 5. CONNECTION OF MOBBING WITH ABSENTEEISM

		Has the mobbing led to higher absenteeism in your case?		Total
		No	Yes	
Have you ever been exposed or do you still consider yourself a victim of mobbing?	No	174	2	176
	Yes	72	39	111
Total		246	41	287

The sick leave is dominant and virtually only significant type of absenteeism among the nurses in the KBC Split. Therefore, to research the influence of mobbing to absenteeism, they were asked about how often they went to sick leave (Table 6) and how many working days they lost because of that (Table 8).

Just the mere look at the Table 6 suggests the difference between those who were not exposed to mobbing and those who felt to be victims of mobbing. Although the number of those who declared themselves to have being victims of mobbing was in total much lower that the number of those who did not, the first were obviously more represented in the groups of those who were going more frequently on sick leave. Pearson Chi-Square was 64.285, while empirical significance was $\alpha^* = ,000$ ($\alpha^* < 0,01$).

TABLE 6. RELATIONSHIP BETWEEN MOBBING AND FREQUENCY OF SICK LEAVE

		How often do you go on sick leave?					Total
		Never	1 per year	2-3 times per year	4-5 times per year	More than 5 times per year	
Have you ever been exposed or do you still consider yourself a victim of mobbing?	No	82	76	16	1	1	176
	Yes	34	37	31	8	1	111
Total		116	113	47	9	2	287

Checking for statistical significance of this difference (Table 7), it showed an indisputable significant difference, with Pearson Chi-Square being 30,392, and empirical significance of $\alpha^* = ,000$ ($\alpha^* < 0,05$).

TABLE 7. CORRELATION BETWEEN MOBBING FREQUENCY OF SICK LEAVE

	Value	Df	Asymp. Sig. (2-sided)
Pearson Chi-Square	30,392 ^a	4	,000
Likelihood Ratio	30,433	4	,000
N of Valid Cases	287		

a. 3 cells (30,0%) have expected count less than 5. The minimum expected count is ,77.

Analyzing answers to the question ‘*How many days have you been annually (on average) on the sick leave during last 3 years?*’ (Table 8), it is again easily visible that those who declared themselves to have being victims of mobbing were more represented in the groups of those who spent longer periods on the sick leave (more than 20 days in a year). That difference was found to be statistically significant, with the Pearson Chi-Square of 61,511, and empirical significance $\alpha^* = ,000$ ($\alpha^* < 0,01$).

TABLE 8. RELATIONSHIP BETWEEN MOBBING AND DURATION OF SICK LEAVE

		How many days have you been annually (on average) on the sick leave during last 3 years?					Total
		Less than 10 days	10-20 days	20-50 days	50-100 days	More than 100 days	
Have you ever been exposed or do you still consider yourself a victim of mobbing?	No	106	57	10	3	0	176
	Yes	41	34	29	6	1	111
Total		147	91	39	9	1	287

Obviously all the respondents that (felt that) were victims of mobbing went more frequently on sick leave and were absent from work for much longer periods because of that. Such situation is not only the indicator that nurses exposed to mobbing suffer from significant (psychological and/or psycho-physiological) problems, but also lose significant part of their working time, which causes noticeable damages to their employer (KBC Split).

2.5. Connection between mobbing and health problems

Every maltreatment on the working place, and especially systematic and prolonged like mobbing, can cause health problems to the maltreated person. In this research, respondent have been asked about the kind of health problems that mobbing is causing to them. Although this way was not entirely objective (because respondents gave their own,

subjective diagnosis), it should be also noted that the respondents were nurses, knowledgeable and experienced enough to understand and recognize characteristics of health problems.

Table 9 presents distribution of responses about health problems that mobbing was causing to respondents (nurses at the KBC Split). Taking into account that the question was formulated as "*What kind of health problems is mobbing causing to you?*", it should not be surprising that respondents that did not declare themselves as the victims of mobbing, responded negatively to this question. On the other side, all the responded that they were exposed to mobbing, perceived some health problems connected with mobbing.

TABLE 9. RELATIONSHIP BETWEEN MOBBING, HEALTH PROBLEMS, AND AGE

	What kind of health problems is mobbing causing to you?						Total
	<i>Nothing</i>	Nervous-ness	Chronic tiredness	Reactive depressive state	Reactive psychotic state of paranoid type	PTSD that can lead to suicide	
<25	17	5	2	1	0	0	25
25-34	68	8	19	4	6	4	109
35-44	46	3	11	13	2	2	77
45-54	36	0	1	13	4	0	54
55-65	9	0	0	5	7	1	22
Total	176	16	33	36	19	7	287

Only 16 out of 111 respondents that were exposed to mobbing answered they felt (only) some nervousness as the consequence of mobbing. All other victims of mobbing experienced some more serious health problems. Most represented has been the reactive depressive state – 36 (32,6%) of respondents developed such problems. Even more worrying are the results that 17,1% nurses that were victims of mobbing developed reactive psychotic state of paranoid type, and 6,3% developed (by their own opinion) PTSD that can lead to suicide. The gravity of health problems experienced by particular age groups is obviously growing with the age. That relationship was found to be statistically significant, with the Pearson Chi-Square of 72,470, and empirical significance $\alpha^* = ,000$ ($\alpha^* < 0,01$). It could be obviously concluded that negative health consequences of mobbing show a cumulative effect and grow bigger with prolonged exposure to mobbing over the working life.

3. Conclusions

Mobbing can happen and is happening in virtually every organization and every kind of work. Hospitals are certainly not exemption, nor is the nurses' work. On the contrary, the result of this research showed that the incidence of mobbing among nurses is higher than it was found in most of previous researches. More than one third of surveyed nurses in a large Croatian hospital were exposed to mobbing at least once in their working life.

Most plausible explanation for that can be the nature of nurses' work, with a lot of pressure, tensions and grave working conditions, as well as the position of nurses between doctors and patients. Such a 'crucified' position of nurses does not change with the change (raise) of education level – the nurse is always the nurse, no matter how educated she is. Nurses are exposed equally to vertical and horizontal mobbing. The pressure from above comes from doctors and management, but nurses also fight each other very often and fiercely. The organization that was the object of this research has many characteristics that foster incidence and intensity of mobbing: competitive working environment, strict hierarchical structure, difficult working conditions, excessive working load, hostile organizational culture ... all that contributes to high incidence and severe consequences of mobbing in the KBC Split.

This research has confirmed that mobbing directly contributes to higher incidence and longer duration of absenteeism – completely in accordance with other similar researches carried out in Croatia (Beganlić et al. 2009). Clear and strong statistical correlation between mobbing and absenteeism has been confirmed, which means that for

victims of mobbing missing from work is not only necessity when they are physically incapable to work, but also a psychological escape when the pressure from mobbers is too strong. In any case, several nurses from this research reported that, due to mobbing, they were on sick leave between 50 and 100 days per year. Such long absences not only show the intensity of mobbing cases, but indicate very high losses (costs) for the employer.

Negative health consequences of mobbing have also been clearly confirmed in this research. Besides the professional risk of diseases transferred from patients, mobbing seems to be one other very strong medical risk inherent for the profession of nurses. Very serious health problems are developed by the victims of mobbing, adding to previously mentioned losses through absenteeism, but also meaning significant personal problems and losses for individuals. Cumulative character of such phenomena that has been confirmed in this research could be considered almost inherent professional risk for nurses.

All these conclusions could be used in several ways: to develop tools and practices to curb mobbing among nurses (and in hospitals in general), to improve individual resistance against the mobbing and negative effects of mobbing, to develop and introduce changes in organizational structures and processes, and finally to systematically work on development and promotion of the organizational culture that will reduce incidence and consequences of mobbing.

Intangibles and creation of value in an integrated formal and informal eLearning environment

Abstract

In the knowledge society intangibles are valuable for corporate competitiveness. Indeed, lifelong and ubiquitous learning, social semantic computing technologies, and open learning resources are urging organisations to meet their employees' learning needs more effectively. Stereotyped training does not guarantee efficacy; it has to be personalised and supported by informal learning communities to facilitate the flow tacit-explicit knowledge and subsequently to create value for the organization as a whole.

The shifting role of establishments in networked learning organizations is a decisive change that an integrated formal and informal eLearning environment, enhanced by an adaptive mechanism and web 2.0 and Social Semantic Web tools, can facilitate.

Starting from the results of *SSW4LL – Social Semantic Web for Lifelong Learners*, this paper investigates the impact of this integrated formal and informal eLearning environment on human and organisational capital, and how this environment contributes to the creation of value for a business organisation.

Introduction

In the knowledge society intellectual capital, also referred to as intangibles or knowledge-based resources, is a key asset for corporate competitiveness. Intangibles constitute the amount by which the market value of a firm exceeds its tangible (physical and financial) assets less liabilities (Magrassi, 2002), and encompass the capability of talented employees in modern innovative enterprises and the intellectual property they produce. Nowadays, intellectual capital contributes more to global economy than financial capital does, but its influence is not well grasped, nor quantified. Valuing and exploiting intangibles properly generates the income, and thus creates the value, that businesses need to function, be competitive and grow (Wiederhold, 2014).

Human, structural and relational capitals compose intellectual capital.

Human capital, the value that corporate staff develop through the application of skills, know-how and expertise, also covers how effectively an organisation uses its human resources in terms of creativity and innovation.

Structural capital, which includes organisational, process and innovation capitals, consists of the organisation's supportive non-physical infrastructure, processes and databases that enable human capital to function. Specifically, organisational capital includes corporate philosophy and systems for leveraging the organization's capability (Orlandi, 2012). Innovation is the shift of an idea into a new product or process thanks to the use of structured technical knowledge and skills. Innovation allows a business to differentiate itself from its competitors and to become more competitive on the market. Since innovation comes from creative ideas, it depends on the quality of the intangibles, particularly on the human capital, an organisation owns (Håkansson and Waluszewski, 2014).

Relational capital comprises customer relationships, supplier relationships, trademarks and trade names licences, and franchises (Orlandi, 2012).

On these premises, in the context of the knowledge society, the concepts of human capital and lifelong learning are very close each other. On the one hand, lifelong learning contributes to promote the development of social and human capital by continuous learning opportunities (Earp, Ott, Popescu, Romero and Usart, 2014), "throughout life, with the aim of improving knowledge, skills and competencies within a personal, civic, social and/or employment-related perspective" (European Commission, 2002). On the other hand, companies' effective performance is strongly related to their talent-driven approach. In this regard, the growing adoption of a lifelong learning vision, the affordances of ubiquitous learning and social semantic computing technologies, and the large amount of open learning resources available are posing to organisations the challenge of meeting their employees' learning needs and aims more effectively. Formal, non-formal and informal learning have become key words of this age; in particular, there is an increasing understanding that learning occurs for the most part outside the traditional formal situations (Leone, 2013). Formal

learning consists in the hierarchically structured, chronologically graded educational system running from primary through to tertiary institutions; non-formal learning takes place through education organised for specific learners with specific learning objectives, outside the formal established system; informal learning allows persons to acquire attitudes, values, skills and knowledge from daily experience, within the individual's environment (such as family, friends, peer groups, the media and other influences) (UNESCO, 1999). Formal and informal learning are more and more intersected; in fact, a growing use of informal networks is taking place in professional environments to acquire knowledge and competences. Stereotyped teacher-centred training does not guarantee efficacy (Leone, Guazzaroni, Carletti and Leo, 2010); it has to be personalised and supported by informal learning communities to facilitate the flow of tacit knowledge into explicit knowledge (Nonaka and Takeuchi, 1995) and subsequently to create value for the organisation as a whole. As a matter of fact, the "double link" described by Wenger, McDermott and Snyder (2002) is crucial for the survival and the development of both, community of practice (CoP) and formal organization: the first conducts the improvement of its members' expertise through informal interaction and learning; the second relies on experts grown in the CoP to identify and implement company strategies, to focus on objectives and outcomes of its working units, thus on performance and clients. As an evidence, the synergy between a CoP and the organization as a whole activates the cycle plan-do-study-act (Deming, 1993) in all the business processes and naturally leads to continuous improvement policy, that closes the circle on human resources as fulcrum and added value of the organization.

This evolution requires organizations to commit to and support an ongoing culture of learning across their community, a culture that recognizes and embraces a more holistic, dynamic and flexible approach.

The shifting role of establishments in networked learning organizations (Senge, 1990) is a decisive change that an integrated formal and informal eLearning environment, enhanced by an adaptive mechanism and web 2.0 and Social Semantic Web tools, can facilitate.

Starting from the results of the recent research experiences which the author has conducted with *SSW4LL – Social Semantic Web for Lifelong Learners*, this paper aims to investigate the impact of this integrated formal and informal eLearning environment on human and organisational capital as elements of intangibles, and how this environment contributes to the creation of value for a business organization.

Theoretical background

Changiness, adult lifelong learners and learning organizations: a learning theory

In a lifelong learning perspective, the combination of pervading technological development and the focus on the individual human resource's potential needs to be harmonized and exploited, in order to expand knowledge exchange, open to changiness (Rogers, 1961) and foster the shift of organisations into learning organisations. Changiness is a reliance on process rather than upon static knowledge, and change as a vision should be a constant in the workplace. Learning organizations embrace change and persistently create reference points to speed up an ever-evolving structure. Continuous improvement requires a commitment to learning, and learning organizations challenge all employees to tap into their inner resources and potential, and favour the development of their own community based on principles of liberty, humanity, and a collective will to learn (Senge, 1990).

Community and network are two facets of social structures in which learning occurs. The community relates to the construction of a shared identity around a topic or set of challenges. It expresses a collective, tacit and distributed intention to attend to a domain of knowledge and to support learning about it. The network consists in a set of interactions among participants who have personal reasons to connect. It provides a series of nodes and links that offer continuous occasions for learning (e.g., information flows, helpful linkages, joint problem solving, and knowledge creation).

Community and network often develop together. Social learning is enhanced by a dynamic interaction of both community and network processes. Such interplay combines focus and fluidity as it interlaces individual and collective learning. The work of nurturing learning needs to take advantage of this complementarity (Wenger, Trayner and De Laat, 2011).

To date, most of the actions of corporate training have been stereotyped and characterized by the inability to capture the skills developed during informal learning activities, the difficulty of reusing the knowledge that emerged

during individual and collaborative work, and resistance to exploit effectively and efficiently the existing skills (Mangione, Orciuoli and Salerno, 2012).

Consequently, workplace learning necessities to be enriched with technology-enhanced solutions suitable to meet simultaneously the personnel's needs and learning styles and the organization's requirements, in order to maximise its ability to learn, innovate and evolve (Argyris and Schön, 1996), and thus to value human and organisational capital.

Workplace learning is adult learning, organizational learning and knowledge management (Wang, Ran, Liao and Yang, 2010). The theories related to adult learning emphasize personal reflection, problem orientation and knowledge construction by means of social processes (Granito, Mangione, Miranda, Orciuoli and Ritrovato, 2014). Organizational learning refers to the models representing how organizations learn (Argyris and Schön, 1996). Lastly, knowledge management focuses on approaches and practices exploited in order to identify, create, represent and distribute knowledge for reuse, awareness and learning (Nonaka and Takeuchi, 1995).

Today designing online adult education means being able to build courses which favour generative learning, by shifting from a teacher-centred approach to a learner-centred one, from a linear learning system to a networked one, from an individual vision to a cooperative one, from a fixed programme to a project to be organized (Leone, 2013). Networked learning, variously underpinned by constructivism (Jonassen and Land, 2000), socio-constructivism (Brown, Collins and Duguid, 1989) or connectivism (Siemens, 2004), is manifested in Personal Learning Environments (PLEs) (Leone, 2013) and exploits information and communication technology (ICT) to facilitate connections: between learners, learners and tutors, a learning community and its learning resources. It is the fusion of these connections that provides the most powerful learning potential.

The learning that is made possible by social software tools is active, process-based, experiential (Kolb, 1984), anchored in and driven by learners' interests, and therefore has the potential to cultivate self-regulated, independent learning. Definitely, lifelong learners are self-regulated learners, that is they are able to recognize their need for further learning, and are proactive in gaining access to and accomplishing learning (Leone, 2010). Lifelong learners execute learning activities that lead to knowledge creation, comprehension and higher order learning by using processes such as monitoring, reflection, testing, questioning and self-evaluation. In addition, self-regulation works best when learners are provided with continuing feedback concerning the effectiveness of their learning approach (Zimmerman, 1990).

Indeed, a know-how (Engeström, 1990) is the result of full participation, on the one hand, and of freedom of action, on the other, which should inspire a competence-driven training approach. All this means thinking to complex learning activities, as complex is the competence for the multiplicity of its dimensions (Leone, Guazzaroni, Carletti and Leo, 2010).

Lifelong learners need personalized, participatory and social learning environments, and user-controlled professional growth. Recent research experiences have shown that an integrated formal and informal eLearning environment can facilitate this (Leone, 2013; 2014a; 2014b).

The role of intangibles in organisations: creation of value, measurement and evaluation

Typically, companies use their resources to produce goods and services to be exchanged on the market and achieve a positive return. In this process of creating value, both tangible and intangible resources are used, differently combined according to the organisation's intellectual capital. Thus, intangibles make the difference between production processes doomed to failure and competitive processes.

A company's innovative capability does not just depend on individuals' knowledge and potential, but specifically on their interdisciplinary and interactive thinking and action. The prerequisite for emerging innovation is embedded in social structures, as the synergy in the relationship of separate individuals (Bischoff, Vladova and Jeschke, 2013). More in detail, the learning value of a community derives from the ability to develop a collective intention to advance learning in a domain. The learning value of a network derives from access to a rich web of information sources offering multiple perspectives and dialogues, responses to queries, and help from others. This potential for spontaneous connections and serendipity is a key aspect of the value of networks for learning (Wenger, Trayner and De Laat, 2011).

Hence, appropriate measurement and evaluation procedures need to be developed for intangibles. Existing procedures for including important intangible results, such as the *Balanced Scorecard* (Kaplan and Norton, 1996), are not specific enough to serve as an adequately funded model. There are many other approaches and methods, however, for evaluating working knowledge (Sveiby, 2001).

The best known method is the *Skandia Navigator* (Edvinsson and Malone, 1997). The output of this method is the *Intellectual Capital Report*, that covers operational intellectual capital in addition to the annual report. The value of intellectual capital is determined by the *Skandia Market Value Scheme*, which places the market value within a hierarchical structure.

Another method is the *Intangible Asset Monitor* (Speckbacher and Halatek-Zbierchoswi, 2002), that is a system based on the knowledge organization for measuring the intangible asset. As a non-financial scorecard system, this method should be considered as an additional evidence of a company's financial success and its shareholder value.

As a whole, a correct approach should consist in identifying the relevant intangible resources, mapping the actions carried out by the management for their development, and analyzing their effectiveness and efficiency by measuring the impact on resulting business performance and enterprise value. This implies that the measurement of a company's intellectual capital requires the analysis of its strategy, organization and business model adopted, beyond the study of operating results or financial performance.

The following step should consist in the design of the indicators of their qualitative and quantitative level and of the management policies aimed at creating and developing the same assets. In particular, the value of human capital depends on the level and quality of skills, the organisation's ability to hold it and the business climate that encourages both the dissemination of knowledge in the company and contributes to employee loyalty to the company. Hence, in order to monitor these aspects of human capital *ad hoc* indicators should be used for the level of the skills monitored, of the staff's ability to achieve objectives, of the business turnover, of the various dimensions of the business climate. In addition, it is important to monitor the activities of creation and development of human capital by related indicators, such as training activities, coaching, team building initiatives.

The last step to take is to identify the links between intellectual capital and overall performance that can highlight how an effective management of intangibles contributes to an organisation's ability to generate wealth and maintain a competitive position. This phase is a prerequisite to the identification of potential financial and income flows attributable to the possession of a certain intellectual capital and therefore to the evaluation of such hidden value. As a matter of fact, in order to generate benefits, the indicators and the value of intangibles must be included in the company's reporting system. Among the benefits resulting from this measurement and evaluation process, there are: 1) it becomes possible to manage intellectual capital according to a strategic-financial approach to maximize the contribution of intangibles in the process of value creation (Deming, 1993); 2) the system allows to understand if, for example, an investment in training results in an increase in the economic value. Moreover, taking advantage of the significant opportunities offered by international accounting standards and, to a lesser extent, by national ones, the company can increase its capital base by giving visibility in the financial statements of its most valuable assets and therefore be able to attract more funding. Also from a financial standpoint, the company by communicating their intangible assets, may be able to improve its credit ratings under Basel 2 and therefore benefit from a lower cost of money (Giuliani, 2012).

An integrated formal and informal eLearning environment for learning organisations: the SSW4LL format

SSW4LL (*Social Semantic Web for Lifelong Learners*) is an adaptive, modular, flexible and integrated learning format which has been conceived to support the characterisation of adult lifelong learners' PLEs by implicit and explicit tools of personalisation, in a learner-centred framework (Leone, 2013; 2014b). The *SSW4LL* system, the technological architecture, is presented as a whole made up of components of formal and informal learning environments: Moodle 2.0 integrated with an adaptive mechanism (conditional activities) and some tools of Social Semantic Web (Semantic MediaWiki, Diigo and Google+), respectively. The *SSW4LL* format was successfully validated during the course *SSW4LL 2011* (Leone, 2013). Further experiences are in progress.

The *SSW4LL* format is devised for adult lifelong learners in general, rather than for one specific cluster within, and for the expansion of all knowledge domains. Besides, the *SSW4LL* format supports mobile learning, but ubiquitous learning features could be implemented as well, as an extension.

The synergy of formal and informal learning arises from the smooth integration of the different technological components, the light e-moderation of the learning environment by a facilitator, the support of a technical e-tutor and the

continuous enrichment of the initial learning resources (formal environment) by social software and Social Semantic Web tools (informal environment).

Use case scenario

Mark is a junior manager of Modern Art Museum in Amsterdam. He is a strongly motivated self-directed learner, as well.

Anyhow, work overload does not leave him much time to update his PLE as he would like to. Time constraints and information overload are difficult issues for Mark.

Since he has thought of dedicating some time to deepen his knowledge in Arts and Culture for a bit, he decides to enroll in a refresher course on this topic, the “Arts and Culture Online Course”, by the Rotterdam University, entirely online, in a learner-centred approach, over 3 weeks.

He is not new to technology-enhanced learning, but this is the first time he uses some of the tools provided within the course. For this reason, as soon as he receives his access to Moodle and Semantic MediaWiki, and the invitation to join in the Diigo course group and Google+ from the teacher-facilitator, he creates his accounts in these two.

He is familiar with social bookmarking and has already used Diigo search before, but he is not an enthusiastic user of social networks. He knows that he is not going to use Google+ so much during the course. However, he decides to log in Moodle to have a look at the video tutorials that the e-tutor has suggested for these first two warm-up days of technological familiarization; he is also curious to meet the other participants and happy to introduce himself in the participants’ forum.

When he logs in Moodle, he finds a welcoming post by his e-tutor and his reminder to complete the entry survey to express expectations and personal background. Having done this, Mark carries out the survey and immediately he visualises a video presentation of the course and a list of tutorials, user’s manuals and sandboxes.

Mark spends some time in Semantic MediaWiki sandbox; semantic annotation appears decisively useful to his goals in terms of knowledge construction and management, but he needs more time to practice.

At the end of the first two days, Mark has met 15 course peers in the forum (introductions), in Diigo and in Google+. He has used Diigo tools highlighter, sticky notes and tags, and he has shared a couple of resources, he has created the course circle in his Google+ account and has joined in the Google+ course community that had been created by his e-tutor.

He pleasantly realizes that, through his contacts in these social tools, he is already able to easily get to new resources and users related to the “Arts and Culture Online Course”.

During the third day, the e-tutor arranges a hangout for the following day by a Google+ Event tool. During this, he invites all participants to find out more in Moodle: learning modules are ready to be accessed. What is new to Mark is that learning is personalised: Mark logs in Moodle and can visualise the quiz *How do you prefer to learn?*; he completes it, he obtains a feedback about his learning style, he confirms it in a “choice” tool for the corresponding most suitable learning sequence and the system starts his sequence of learning objects (LOs). Mark is able to visualise the various LOs as he proceeds, and at the end he can move among them as he prefers. This allows Mark to both take advantage of a personalised scaffolded learning path and to decide autonomously what to do and how much time and effort to spend. He is also aware of his prior knowledge on the topic because he has answered a true/false quiz. He is free to spend as much time as he needs on each learning resource, and he can self-check his knowledge and skills as many times as he feels like through the self-assessment test.

Besides, he comments in the forum, he shares several considerations in Semantic MediaWiki and he links these in his Google+ Profile. Then he follows what is going on in the Diigo course group by the Diigo widgets in Moodle.

At the end of the first week Mark realises he has learnt more about Arts and Culture, but, above all, he has had the chance to learn to use new tools that can support him in managing his PLE. So, he is happy to transfer his new knowledge and know-how to his team at work.

Discussion

Online learning offers a wide range of information easily available and enhanced by multimedia and hypertext. The *SSW4LL* environment enables integration and coordination of theoretical and practical material, as well as encouraging the development of skills in logical reasoning, critical thinking, communication and self-directed learning.

This online environment has been designed for maximum flexibility. It allows participants from a variety of backgrounds to construct a study plan according to their learning goals, expertise and availability. In other words, flexible delivery includes learner control over content, time, place and method of learning.

SSW4LL gives lifelong learners equality of access and tailored learning. It helps to orientate the participant to independence and self-responsibility in learning, a basis for fostering lifelong learning habits (Leone, 2013).

The effectiveness of the training course *SSW4LL 2011* in terms of added value to human and organizational capitals was assessed by Kirkpatrick's (1994) four-level model:

- level 1 – reaction, a measure of participants' initial reactions to the course, assessed through an entry survey;
- level 2 – learning, a measure of the amount of information that participants learned, assessed by self-assessment tests at different steps;
- level 3 – transfer, a measure of the amount of material learned that participants actually use in everyday work, assessed by interviews;
- level 4 – value to the organisation, a measure of the financial impact of the training course on the bottom line of the organisation, assessed by interviews.

The use case scenario of the *SSW4LL* format and the results of the preceding research experiences of its implementation show that

this integrated formal and informal eLearning environment provides a collaborative context meant to make tacit knowledge emerge through action and applied learning (Nonaka and Takeuchi, 1995). The participants (lifelong learners) improve their competences in their domain by learning, solving, mentoring, and collaborating, producing tacit learning. The community and the network (Wenger, Trayner and De Laat, 2011) that arise create knowledge by combining prior knowledge in new ways and on the basis of a cyclical process characterized by four stages: 1. socialization (individuals exchange tacit knowledge); 2. externalization (individuals link tacit knowledge to explicit knowledge); 3. combination (individuals unite explicit ideas to create knowledge); 4. internalization (individuals extract knowledge from newly created organizational tacit and explicit knowledge through learning by doing) (Nonaka and Takeuchi, 1995). This model sustains that tacit knowledge is shared by the reiteration of the four-step process and it results in the shape of a "learning spiral".

The participants to *SSW4LL 2011*, through frequent and repeated interactions, generated an informal learning system to self-train and to validate its members' knowledge and competences, but much of their efforts and expertise are not fully recognized.

In this process an increasing flow of knowledge and skills empowers individuals (human capital), feeds innovation (within structural capital) and enriches the organization with self-confidence, trust and vision for change (organizational capital).

Conclusion and future directions

In the knowledge society intellectual capital is a key asset for corporate competitiveness. Nowadays, intellectual capital contributes more to global economy than financial capital does, but its influence is not well grasped, nor quantified. Few and general methods of measurement and evaluation are mentioned in research literature.

The concepts of human capital and lifelong learning are very close each other. Formal and informal learning are more and more intersected; in fact, a growing use of informal networks is taking place in professional environments to acquire knowledge and competences. Stereotyped teacher-centred training does not guarantee efficacy; it has to be personalised and supported by informal learning communities to facilitate the flow of tacit knowledge into explicit knowledge and subsequently to create value for the organisation as a whole. The *SSW4LL* format is a validated example of integrated formal and informal eLearning environment that could enhance intangibles.

As a whole, in a lifelong learning perspective, the combination of pervading technological development and the focus on the individual human resource's potential needs to be harmonized and exploited, in order to expand

knowledge exchange, open to changingness and foster the shift of organisations into learning organisations, rather into smart networked learning organisations in the near future. As a matter of fact, the widespread availability of broadband will allow smart working, that is the range of changes enabled by greater flexibility combined with greater use of ICT, thus more flexible working patterns, opening up new employment opportunities, and enhancing the productivity and the continuous professional and personal development of staff.

Executive Compensation in Intangible Intensive Industries

Abstract

This is a study of the effects of intangible and tangible expenditures on CEO compensation packages and on the price-performance-sensitivity of their shareholdings. The level of expenditures on intangible advertising and R&D activities has a significant impact on the annual CEO compensation contracts. Executive option grants are positively related to these expenses, and salary, bonuses and restricted stock grants are negatively correlated. These results correspond to earlier findings of a positive relationship between R&D spending and equity-based compensation. There is less evidence of relationships of CEO compensation with tangible depreciation expenditures. Without controls for industry, there appears to be a negative relationship between bonus compensation and depreciation. But, this association vanishes after controlling for industry effects. There is also evidence of a negative relationship of the levels of intangible and tangible expenses with the price-performance-sensitivity of CEO equity portfolios. But, this also disappears after controlling for industry.

Introduction and Review of the Literature

This is a study of the effects of the levels of intangible and tangible expenses on the design of CEO compensation packages and on the price-performance-sensitivity of CEO equity portfolio. Discussions of these relationships have a long history. Early studies by Smith and Watts (1992) and Gaver and Gaver (1995) suggest that firms with plentiful growth opportunities rely heavily on market-based compensation.

Accounting data is distorted in enterprises with high levels of research and development (R&D) expenses. Therefore, Chan, Lakonishok and Sougiannis (2001) argue that these firms should make heavy use of market-based compensation, because security prices quickly incorporate the benefit of these expenditures. Kole (1997) finds that R&D intensive firms make greater use of market-based compensation. In a slightly more refined analysis, Ryan and Wiggins (2002) find the R&D expenses are positively correlated with option-based compensation, but they are negatively correlated with restricted stock compensation. On the other hand, Aboody and Lev (2000) note that markets are also poor at determining the value of intangible opportunities. Therefore, Banker, Byzalov and Xian (2013) suggest that R&D intensive firms should make greater use of long-term incentive plans.

Several studies have concentrated on relatively narrow classes of firms that make heavy usage of intangibles. Anderson, Banker and Ravindran (2000) study the compensation of executives in the information technology industry. Bell, Landsman, Miller and Yeh (2002) examine employee stock option compensation for computer software firms. Ittner, Lambert and Larcker (2003), Murphy (2003) and Bebchuk and Grinstein (2005) have written on executive pay in new economy firms.

I take a different approach. Rather than concentrating on a narrow sector, I estimate two proxies for the use of intangible and tangible assets and study their relationship with the design of CEO compensation packages for a broad pooled cross-section of firms. The first proxy is the portion of total expenditures on advertising and R&D, and the second is the portion spent on depreciation on the other,

I use the ratios of the four major components of managerial compensation, salary, bonuses, option grants and restricted stock grants, to the total value of compensation as the dependent variables. Using the proportional measures capture the interactions among the elements. A change in the relative use of any one of the components affects the portions used of the other three. This approach actually embodies the character of the trade-offs involved in the design of CEO compensation packages. Previous empirical studies by Lewellen, Loderer and Martin (1987), Holthausen, Larcker and Sloan (1995), Ryan and Wiggins (2001 and 2002), Ittner, Lambert and Larcker (2003) and Lord and Saito (2012) have used proportional measures of some of the components of compensation.

In addition to the effect of tangible and intangible expenditures on annual executive compensation, I also study their relationship with the price-performance-sensitivity of CEO equity portfolios. Murphy (1985), Hall and Liebman (1998), Hall and Murphy (2002) and Core, Guay and Larcker (2003) all argue convincingly that managerial equity portfolios probably create much more powerful incentives to encourage wealth maximizing behavior than annual compensation. Jensen and Murphy (1990) find that in the preceding decades, managerial equity holdings did not seem sufficiently sensitive to changes in share price to properly align the incentives of executives with those of outside

shareholders. One reason often advanced for the phenomenal growth in stock-based compensation in the ensuing period is that these grants would increase the sensitivity of CEO equity holdings.

To test for the relationship between the levels of advertising, R&D and depreciation expenses I estimate a set of Tobit models employing the portions of the four major forms of annual executive compensation as the dependent variables. In the models of the price-performance-sensitivity of CEO equity portfolios I employ OLS regression. All of the models include a set of control variables commonly-used in studies of executive compensation. I then include the portions of advertising and R&D expenses to total firm expenses, and of depreciation expenses to total outlays. I estimate these models using one set of specifications where I do not control for industry fixed-effects, and a second set where I do.

I concentrate on the four-year period from 2002 to 2005. This is a relatively stable recent time-frame between the two serious market contractions in the 21st century.

For the relationship of the intangible advertising and R&D expenditures with the portions of the common forms of executive compensation there are clear results that shine-through regardless of the specification. These costs are positively correlated with CEO option grants, and negatively correlated with the portions of salary, bonus and restricted stock grant compensation. This corresponds with the earlier findings of Kole (1997), Chan, Lakonishok and Sougiannis (2001) and Ryan and Wiggins (2002).

Before controlling for industry fixed-effects there is evidence of a negative relationship between the portion of bonus compensation and tangible depreciation expenses. But, the significance of this association vanishes after including the industry dummy variables.

Similarly, there is significant evidence of a negative relationship of the price-performance-sensitivity of executive option portfolios with both the intangible advertising and R&D expenditures, and the tangible depreciation costs. But, these are also overwhelmed once the industry control effects are included in the specifications.

The remainder of the paper is organized as follows. In the next section I describe the econometric methodology to test for relationships of advertising, R&D and depreciation expenses with the forms of executive compensation and with the price-performance-sensitivity of CEO equity portfolios. Then I describe the data sources and characteristics. The empirical results are described in the fourth section. In the final section of the paper I summarize the results and draw conclusions.

Econometric Methodology

To assess the effects of the extent of intangible activities on CEO compensation and the price-performance sensitivity of the executives' equity portfolio, I estimate five models that take the general form:

$$\text{SALPC} = \alpha + \beta_1\text{LASS} + \beta_2\text{TEN} + \beta_3\text{LEV} + \beta_4\text{D-DIV} + \beta_5\text{D-FIN} + \beta_6\text{ROE} + \beta_7\text{RET} + \beta_8\text{SDS} + \lambda_1\text{ADR} + \lambda_2\text{DEP} + e. \quad (1)$$

In these models the dependent variables are the managerial compensation measures. This version is shown with SALPC, the portion of salary to total CEO compensation, as the dependent variable. The other three forms of annual CEO compensation are: BONPC, bonuses and long-term incentive payments as a portion of total CEO compensation; OPTPC, the portion of CEO compensation given as option grants; and RSPC, restricted stock grants as a portion of total CEO compensation. The fifth dependent variable is PPS, the price-performance-sensitivity of CEO equity portfolios. The independent variables are all drawn from the same fiscal year as the dependent variable.

I include eight widely-used control variables in the model. LASS is a proxy for firm size, the logarithm of total assets. TEN is the tenure of the CEO. LEV is a proxy for financial leverage, the debt-to-asset ratio. D-DIV is a dummy variable set to one if the firm pays a dividend and is set to zero otherwise. D-FIN is a dummy variable set to one if the firm operates in the financial sector and is set to zero if not. ROE is a measure of accounting profitability, the return on equity. RET is the firm's annual stock return for the fiscal year, and SDS is the annualized standard deviation of these daily stock returns for the year.

A widely used measure of intangibility is advertising and R&D expenses. The variable ADRD is the ratio of the sum of these two expense items to total corporate expenditures for the year. Because many firms fail to report these two expense items, I set missing observations to a value of zero. The level of depreciation expenses is a suitable proxy for the level of tangible expenses. So, I also include DEP, the portion of depreciation expenses to total expenses in the model.

While ADRD is intended to capture the use of intangibles, and DEP the use of more tangible assets, it is important to remember that firms with high levels of one measure will not necessarily have low levels of the other. For instance, firms in the pharmaceutical sector have high levels of both advertising and R&D expenses and depreciation. In fact, ADRD and DEP are mildly positively correlated. The Pearson correlation coefficient is about 5.65%, and the Spearman rank-order correlation coefficient is slightly over 14%. Both are statistically significant. I estimate the model with the price-performance-sensitivity of CEO equity portfolios as the dependent variable using an ordinary least squares (OLS) specification. But, the measures of the four forms of managerial compensation are all proportions with values between zero and one, and are continuous in that range. Wooldridge (2002, pp. 518-520) describes such a distribution as a “corner solution outcome.” He argues that the proper approach for such data is a standard censored Tobit model. Also, a large portion of the executives in the sample receive 0% of their compensation as bonuses, options or restricted stock grants (what are traditionally called left-censored values). Greene (2012, pp. 852–857) notes that a Tobit model is especially well-suited for a sample with a large cluster of observations at or near zero. Several earlier studies of executive compensation by Yermack (1995), Bryan, Hwang and Lilien (2000), Ryan and Wiggins (2001) and Lord and Saito (2012) that use proportional measures as the dependent variable employ Tobit models. All of these precedents suggest that Tobit specifications are the best approach to analyze the portions of the four components of annual CEO compensation.

The use of tangible and intangible assets probably varies strongly by industry. Murphy (1985), Himmelberg, Hubbard and Palia (1999), Palia (2001) and Lord and Saito (2010 and 2012) also show that there are important industry effects in CEO compensation. Therefore, I specify a second version of the models where I include dummy variables for the industry segments. I use the fifty Fama-French industry groups. The coefficient estimates could be significantly different after controlling for industry. Because this specification includes dummy variables for the financial services industries, D-FIN, the dummy variable for firms in these industries must be omitted from this specification.

Data and Sample Characteristics

I assess the relationship between intangible and tangible expenditures and executive compensation during the four-year period from 2002 to 2005. This timeframe is chosen because it is a relatively quiet period between the two severe financial crises of the 21st century. Therefore, the data are a pooled cross-section.

Most of the data for this study is culled from COMPUSTAT, EXECUCOMP and CRSP. The firms in the sample correspond roughly to the S&P 1,500, because the dataset is constrained by the information available on EXECUCOMP. I eliminate all firms missing any of the required variables.

The computation of most of the variables is reasonably straight-forward. As mentioned above, the numerator in BONPC is bonuses and payouts under long-term investment plans. The numerator for the debt-to-asset ratio is the sum of notes and long-term debt. The annual stock return (RET) and the annualized standard deviation of daily stock returns for the year (SDS) are estimated using the CRSP data for the fiscal year. Any firm missing ten daily observations or more for a year is eliminated.

The price-performance-sensitivity of the CEO's equity portfolio is probably least familiar to most readers. This variable shows the change in the CEO's wealth for a \$1 change in shareholder value. The denominator for this ratio is the total number of firm shares outstanding. The numerator is the sum of shares and restricted shares held by the CEO, plus the number of options the manager holds multiplied by an estimate of delta for this option portfolio.

I employ a widely used adaptation of the Black-Scholes-Merton model by Core and Guay (2002) to estimate the implied delta of each CEO's option portfolio. This calculation requires estimates of six parameters: share price, the strike price of the options, the time-to-maturity of the contracts, the volatility of the underlying shares, the risk-free rate, and the firm's dividend-payout-ratio. I use the end-of-fiscal-year share price as the market value. The strike price

is estimated as the difference between the end-of-fiscal-year share price and the ratio of the EXECUCOMP estimate of the intrinsic value of in-the-money options with the number of options held by the CEO. Following Core and Guay, I assume that all unexercisable options have a time-to-exercise of nine-years, and exercisable options have a time-horizon of six-years. I use daily stock returns from CRSP to compute the annualized standard deviations of daily stock returns for the fiscal year as the measure of volatility. I use the yield on seven-year Treasury Bonds in the month of the fiscal-year end as the risk-free rate. The dividend-payout-ratio is estimated using data from COMPUSTAT. The aggregate sample for the four-year period from 2002 through 2005 contains 5,233 firm-year observations. Summary statistics for this data are shown in Table 1.

The portions of the forms of executive compensation measures and similar to those presented by Lord and Saito (2010). Option grants are the greatest portion of CEO pay; over 30%. But, in the 21st century, restricted stock grants have grown rapidly in importance, in this period they represent almost 10% of executive pay on average. The price-performance-sensitivity of the CEO equity portfolios indicate that the typical executive gains or losses between 1.50¢ and 3.50¢ for a \$1 change in shareholder wealth. This is in-line with the findings of Jensen and Murphy (1990) and Lord and Saito (2010). About 54% of the firms in the sample pay dividends, and about 12% are in the financial services industries. The median and mean of the ratio of advertising and R&D expenses to total corporate expenditures are 1.78% and 6.34% respectively, and for the ratio of depreciation to total expenses they are 4.92% and 7.59% respectively.

Empirical Results

The results for the four Tobit model specifications without industry control variables are shown in Table 2.

Table 2

*- significant at 90% level, ** - significant at 95% level, *** - significant at 99% level				

The log-likelihood ratios suggest that all of the models have significant explanatory power. As suggested earlier many of the observations for bonuses, option grants and restricted stock grants are clustered at 0%, making the use of the Tobit model particularly appropriate.

First, consider the coefficient estimates for the eight control variables. Managers in large firms are paid lower salaries and higher portions of bonuses and option and restricted stock grants. Longer tenured executives are paid higher portions of salary and bonuses, and fewer equity grants. Managers at firms with higher financial leverage are given fewer option grants and more restricted stock grants. Firms that pay dividends provide higher salaries and fewer option grants. Managers of financial firms tend to receive greater bonuses and less restricted stock grants than executives in other industries. As expected, return-on-equity is positively related to bonus compensation. But, it is not correlated with the other three forms of compensation. Firms that have higher stock returns give their managers less salary and option grants, and higher bonuses and restricted stock grants. When stock prices are volatile, managers receive greater salary compensation and less bonuses and restricted stock grants. The results for the relationships of stock return and volatility with the four components of executive compensation are similar to those from Lord and Saito (2012).

The portion of expenditures on advertising and R&D is the proxy for the firm level of intangible usage, and is thus the primary variable of interest. This variable is significantly related to all four of the forms of annual CEO compensation. It is positively related with the portion of option grants, and negatively with the three other forms of compensation. This is consistent with earlier findings by Kole (1997) and, Chan, Lakonishok and Sougiannis (2001). Ryan and Wiggins (2002) and Lord and Saito (2012) find evidence that the reasons for granting restricted stock grants often differ from those for option grants. These results show that these relationships have persisted into the 21st century. The findings are also somewhat contrary to the assumptions of Aboody and Lev (2000) and Banker, Byzalov and Xian (2013).

I also include the portion of depreciation to total expenditures as a proxy for the use of more tangible expenses. In these specifications there is only evidence of a significant negative relationship between bonuses and depreciation.

The results for the model specifications for the four forms of CEO compensation that include dummy variables for the Fama-French industries are shown in Table 3.

*- significant at 90% level, ** - significant at 95% level, *** - significant at 99% level				

In the presentation of the results an intercept is not included, and I do not show the estimates for the fifty industry-specific dummy variables. Also, because of the inclusion of the industry-level controls, the dummy variable for the financial services industry must be omitted. Again, the log-likelihood ratios suggest that the models have significant explanatory power.

In these specifications, most of the signs and statistical significance of the coefficients on the control variables are similar to that for the models without the industry dummies. There are eight exceptions. In Table 2 the relationship between CEO tenure and option grants is negative. In Table 3 it is positive, and would even pass a significance test at the 90% level. The positive significance on the association between the debt-to-asset ratio and restricted grants has shrunk to the 90% confidence level. After controlling for industry, there is now statistical evidence that firms paying dividends provide higher bonuses. In the specifications including industry controls the significance of the relationships of restricted stock grants with stock return and the annualized standard deviation of daily stock returns have disappeared. Also, the significant negative relationship of the equity risk proxy with the portions of bonus compensation has shifted, and in Table 3 there is evidence at the 90% confidence level that the association is positive. Finally, there is now evidence of a significant negative relationship between option grants and the annualized standard deviation of daily stock returns.

The same correlations of the portion of advertising and R&D expenses and the four measures of annual CEO compensation seen in Table 2 still hold in Table 3. So the fundamental relationships between the use of intangible-based costs and the design of CEO compensation still shine-through after controlling for industry fixed-effects.

However, the inclusion of the industry controls causes important differences in the associations between the forms of managerial compensation and depreciation. In Table 2 it appears that there is a positive relationship between depreciation and bonus compensation. But, this vanishes in Table 3. On the other hand, after controlling for industry effects, there is weak evidence (at the 90% confidence level) of a positive relationship between option grants and depreciation expenses.

The results for the two models of the relationship explaining the price-performance-sensitivity of CEO equity portfolios are given in Table 4.

SDS	0.0112 (<i>0.0262**</i>)	0.0670 (<i>0.0247**</i>)
ADRD	-0.0278 (<i>0.0001***</i>)	-0.1405 (<i>0.0899*</i>)
DEP	-0.0301 (<i><.0001***</i>)	-0.1204 (<i>0.1435</i>)
Obs	5,096	4,871
Adj – R-Sq	0.2224	0.4697
F-Value	146.74***	74.13***
<p>*- significant at 90% level, ** - significant at 95% level, *** - significant at 99% level</p>		

Because of the nature of the dependent variable, these models are estimated using and OLS specification rather than Tobit. The R² of the model without industry controls is about 22%, and that with the dummy variables for industry fixed-effects is about 47%.

The coefficients and signs on the control variables suggest the price-performance-sensitivity of the managerial portfolios are positively correlated with CEO tenure, the dummy for financial services firms, stock return, the annualized standard deviation of daily stock returns. It is negatively correlated with firm size. Also, after controlling for industry, there is evidence of a positive relationship with the debt-to-asset ratio and the dummy variable for dividend paying firms.

In the specification without industry controls, there is significant evidence that the price-performance-sensitivity of CEO equity portfolios are negatively correlated with both the portion of advertising and R&D expenditures and with depreciation expenses. But, the significance of these relationships is markedly weaker or vanishes after including the dummies for industry fixed-effects. So, the industries seem to better explain the price-performance-sensitivity than the intangible and tangible based expenses.

Summary and Conclusions

The level of expenditures on intangible advertising and R&D activities by North American firms seems to have a significant impact on the annual CEO compensation contracts. Executive option grants are positively related to these expenses, and salary, bonuses and restricted stock grants are negatively correlated. This difference between option grants and restricted stocks is intriguing, but there is prior evidence of a positive association between R&D spending and option grants, and also for a negative relationship with restricted stock grants.

There is less support for relationships of CEO compensation and tangible depreciation expenditures. Without controls for industry, there appears to be a negative relationship between bonus compensation and depreciation. But, this association vanishes after controlling for industry fixed-effects.

There is also some evidence of a negative relationship of the levels of intangible and tangible expenses are related with the price-performance-sensitivity of CEO equity portfolios. But, this also is diminished or disappears after controlling for industry.

In sum, there are clear relationships of advertising and R&D expenditures with the components of annual CEO compensation; and these correspond to most earlier theoretical conjectures and with prior empirical findings. But, any relationships of CEO compensation design with depreciation seem to be swamped by the typical pay package design in the industries. The observed negative relationships of the price-performance-sensitivity of CEO equity portfolios with advertising, R&D and with depreciation expenditures, are also over-whelmed when industry fixed-effects are included in models.

Sungkyunkwan University, South Korea

Investigating how inter-firm relational features influence absorptive capacity and content creativity of a joint production team: focusing on media content business

Abstract

This study investigates the intangible processes involved in creation of creative contents in the broadcasting media industry where a broadcasting company frequently outsources production of its broadcasting contents to an independent production company. This production company typically organizes a production team which will be in charge of producing the contents. This study deals with the factors that influence creativity of the contents produced by the team. The research model proposes that inter-firm relationship features between the two companies affect the contents creativity and also that this causal relationship is mediated by work environment for creativity and learning capability of the production team.

A PLS analysis of the survey responses from 123 production teams indicates that inter-firm relational features defined by relational rents (Dyer & Singh, 1988) influence the contents creativity indirectly through work environment for creativity (Amabile 1996) and absorptive capacity (Zahra & George 2002). Specifically, we find that relational features such as resource complementarity and effectiveness of governance improve the organizational support for creativity and increase absorptive capacity of the production teams. Further, organizational support for creativity not only influences the creativity directly but also indirectly through enhanced realized absorptive capacity of the production team. Although this study deals with one single industry, i.e. broadcasting industry, its results offer significant implications for other related contents industries because of widespread outsourcing practices employed by many content aggregation and distribution firms.

Keywords: Relational Rents, Absorptive Capacity, Organizational Motivation, Creativity

Introduction

Many existing studies have claimed that outsourcing has a positive effect on the production process in the ICT or manufacturing industries by reducing costs and risks. However, in content industries (e.g., broadcasting, movie, and animation), which are not standardized and are based on the creativity of the resulting media, processes and cost reductions are not helpful by themselves.

In this study, we examine how creativity, which has an intangible value, affects cooperative relationships between industries. Creativity is mainly affected by management of existing knowledge. A relationship with a cooperative firm is an important factor that affects a company's intra-organizational structure, and thus, our research focuses on the flow and changes of this relationship. A firm that cannot maintain all capabilities and resources contracts business processes to third parties as outsourcing or off-shoring. In addition, large companies often relocate their main business functions to other SMEs to reduce risks and costs. In case of networks in Korea, 20–30% of all broadcasting content is produced through outsourcing to small independent productions to avoid, for example, regulations, high taxes, high energy costs, and costs associated with benefits defined in labor union contracts and those mandated by the government. Organizations in the media content industry, such as broadcasting stations (networks), have significant completion and creativity in their content quality because a large portion of their income depends on advertising and content sales. In particular, broadcasting is sensitive to the cognition of the audience because it has characteristics of experience goods. Therefore, highly differentiated content plays a critical role in increasing the competency of broadcasting stations. In this study, we attempt to outline an alternative reading of the causal model of the cooperative relationship between outsourcing production and broadcasting stations, and we review the level of completion and creativity of their content through objective research.

Empirical approaches to dealing with creative cooperation issues

Because broadcasting stations do not possess all capacity, they entrust some of the production to independent production as an outsourcing. Independent production is concerned with significantly more than new sources of media contents; in addition, it appeals to a new paradigm in broadcasting. However, in the competitive broadcasting industry, major broadcasting stations see independent production as a function for attaining higher levels of efficiency and not

as alternative sources of programs. It is critical to emphasize the relationship between these types of specialized businesses that promote creative content.

In the case of Korea, vertical business relationships between the independents(outsourcing) and the broadcasting station(ordering) are created because content syndication is not vitalized in industry. This industry environment complicates the development of creative content. Before research analysis, the face to face interview was conducted on 11 producers working in broadcasting stations. Through the this interview, we found the main topic of this research and recognized the key factors of environmental problems that we must address this research.

First, the problems for self-produced programs and outsourced production differ. In the self-production system, unstable investment for production and lack of manpower are the most critical. In the outsourced production system, conventional production systems forced by the ordering organization (i.e., the broadcasting station) and its excessive intervention are the most difficult to overcome. The self-production system can be characterized as having a resource issue, whereas an outsourced production focuses on intangible issues regarding the relations between organizations. Thus, the tangible factors of relational rents and organizational climate (which have high value at the single-firm level) are less significant between multiple organizations than in the single-firm case.

Second, the characteristics of the knowledge process differ between self-production and outsourced production systems. Among the respondents who discussed self-production, none mentioned a regular routine for absorbing and sharing knowledge on an organizational basis. At the single-firm level, the case where knowledge is transferred individually among teams is more frequent than that of the inter-firm level. On the inter-firm level, regular knowledge-sharing routines, such as reports and reviews, are important processes of production. From this result, a formation of knowledge-sharing routines in the production process of outsourced programs is easily affected by relations between firms.

The summarized description of the interview result is discussed in Fig 1. Through these industrial issues from pre-interview, some factors of the fieldwork are recognized and matched to the constructs of relational rents. For more practical results, we applied these concepts to the operational definition of survey tools for this research model.

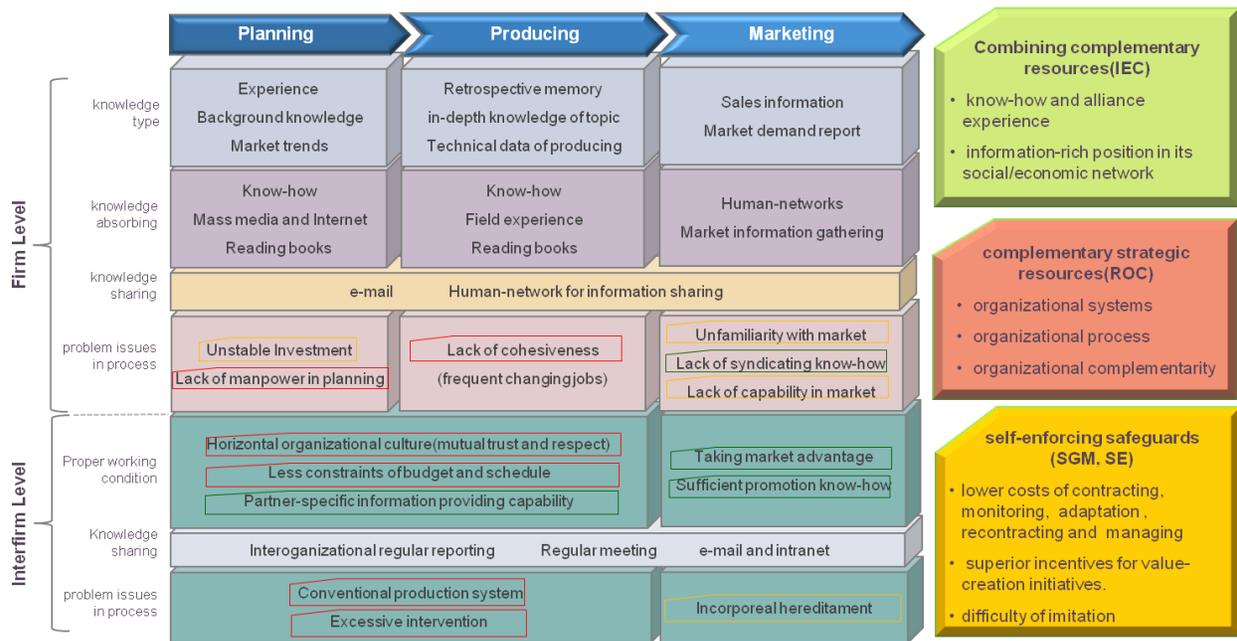

FIG 1. SUMMARY OF THE DEPTH INTERVIEW

Theoretical Background and Hypotheses

Relational View of Organizational Motivation and Absorptive Capacity

Relational Rents The concept of relational rents is suggested by Dyer and Singh (1998). They define a relational rent as “a supernormal profit jointly generated in an exchange relationship that cannot be generated by either firm in isolation and can only be created through the joint idiosyncratic contributions of the specific alliance partners.” This concept proved to be particularly applicable to explain the advantages of the interorganizational relationships of M&A and outsourcing. Relational view of interorganizational competitive advantages contributes to our understanding of how firms achieve above-normal returns.

Porter’s (1980) ‘Industry structure view’ provides insight that supernormal returns are primarily a function of a firm’s membership in an industry with favorable structural characteristics (e.g., relative bargaining power and barriers to entry). ‘The resource-based view (RBV)’ of the industry argues that differential firm performance is fundamentally due to firm heterogeneity rather than industry structure (Rumelt, 1984, 1991; Wernerfelt, 1984). To explain the interorganizational competitive advantage, Madhok (1998) comments that partnerships are especially valuable when they provide firms with an avenue for the sustained earning of rents in situations where competitive advantages require the synergistic combination of resources that a firm is unable to purchase through a market transaction or to develop internally in a timely and cost-effective manner.

Among the determinants of relational rents, ‘relation-specific assets’ are essential for a given transaction and cannot be redeployed for another transaction with no cost. In addition, once the asset is in place, the other party to the contract cannot be replaced without cost, because the parties are locked into the relationship to some degree. A firm has to find advantages by creating assets that are specialized in conjunction with the assets of an alliance partner (Dyer & Singh, 1998). Asset specificity enhances the trust between partners, which in turn leads to more cooperative behavior and higher partnership performance.

Organizational Motivation The componential model of Amabile (1988) for creativity and innovation in organizations has received relatively little attention from creativity research. According to this research, organizational motivation to innovate is a basic orientation of the organization toward innovation, as well as support for creativity and innovation throughout the organization. We define organizational motivation as a main factor for explaining the causal model of creative work and absorptive capacity. Motivation is not a goal in itself but serves to support a firm’s goals. The behavioral view of organization emphasizes intrinsic motivation, an approach that has had a long tradition in motivation-based organization theory (Argyris, 1964; Likert, 1961; McGregor, 1960).

Absorptive capacity Absorptive capacity is a firm’s ability to identify valuable external knowledge, assimilate or transform this knowledge into the firm’s knowledge base, and apply this new knowledge through innovation and competitive actions (Cohen & Levinthal, 1990). It can also be defined as a set of organizational routines and processes by which firms acquire, assimilate, transform, and exploit knowledge to produce a dynamic organizational capability (Zahra & George, 2002).

Our study adopts the framework developed by Zahra and George (2002). They posit that acquisition and assimilation capabilities are dimensions of potential capacity (PACAP), and that transformation and exploitation capabilities are those of realized capacity (RACAP). The theoretical distinction between potential absorptive capacity and realized absorptive capacity is important in evaluating the capacities’ unique contributions to a firm’s competitive advantage (Zahra & George, 2002). Potential absorptive capacity is significantly influenced by external sources and knowledge complementarity. Realized absorptive capacity represents ‘the ability to develop routines that facilitate combining existing knowledge with new knowledge’ and ‘the routines that allow firms to refine, extend, and leverage existing competences or create new ones by incorporating acquired and transformed knowledge into their operations’.

Furthermore, Zahra and George (2002) said that this distinction explains the reason why certain firms are more efficient than others in using existing absorptive capacity. Distinguishing between “potential absorptive capacity” and “realized absorptive capacity” shows that some firms are inefficient in leveraging their potential absorptive capacity, and therefore cannot improve their performance. First, the differing functions between these two concepts shows the various methods by which these two components contribute toward building the firm’s competitive advantage (Zahra & George, 2002). Second, exogenous and endogenous forces may influence potential

absorptive capacity and realized absorptive capacity differently, indicating that different managerial roles are necessary to nurture and harvest these two components of absorptive capacity (Zahra & George, 2002). Finally, a distinction between 'potential absorptive capacity' and 'realized absorptive capacity' provides a basis for observing and examining the fluid and nonlinear paths that organizations may follow in developing their core competencies.

Relational View of Organizational Motivation We argue that integrative interorganizational process mechanisms between the ordering (i.e., the broadcasting station) and outsourcing (i.e., an independent production) organizations can influence organizational creativity. To analyze this relationship, the relational rents of Dyer and Singh (1998) provide some groundwork for this study. Organizational creative performance is increased by the employment of organic organizational designs (Woodman et al., 1993). Wang et al. (2008) indicated that relational specific assets are important factors influencing organizational creativity indirectly. Both management support and open-mindedness positively affect the generation of creativity in interorganizational relationships (Wang et al., 2008). When two organizations perceive benefits from mutual interaction, the mutual motivation for interaction is high. The governance mechanisms (i.e., trust and contractual governance) significantly affect the conditions that facilitate inter-organizational creativity in interorganizational relationships (Wang et al., 2008). From these discussions, we can infer the relationship between determinants of relation-specific assets and organizational motivation. This reasoning leads to the following hypothesis.

H1: As an organization's 'relation-specific assets' increases in intensity, its level of 'organizational motivation' increase.

Relational View of Absorptive Capacity Dyer and Hatch (2004) describe how Toyota developed a competitive advantage with selected suppliers through superior knowledge-sharing processes. Increasing familiarity through interorganizational relationships and through belonging to a community increases an organization's absorptive capacity (Beise & Stahl, 1999; McMillan, Narin, & Deeds, 2000; Meyer-Krahmer & Meyer-Krahmer, 1998). Lane and Lubatkin (1998) infer from the compensation literature that the similarity of two firms' compensation policies serves as a proxy for the similarity of their knowledge-processing systems and norms. This suggests that the ability to assimilate new external knowledge is in part a function of the relative similarity of the ordering and outsourcing firms' compensation practices. Partner-specific interorganizational relationships allow a firm to enhance its absorptive capacity (Bowman & Hurry, 1993). Dyer and Singh (1998) also state that partner-specific absorptive capacities facilitate relational rents as determinants of interorganizational competitive advantages. From these discussions, we can infer the relationship between determinants of relational rents and organizational motivation. This reasoning leads to the following hypothesis.

H2a: As an organization's 'relation-specific assets' increases, its level of 'potential absorptive capacity' increases.

H2b: As an organization's 'relation-specific assets' increases, its level of 'realized absorptive capacity' increases.

Organizational Motivation and Absorptive Capacity Some researchers have shown the effect of organizational scope on absorptive capacity. Bowman and Hurry (1993) and McGrath (1997) use a real options approach to argue that allocating resources toward gaining experience in relatively unfamiliar areas helps maintain some absorptive capacity in those fields. According to the literature review, we consider organizational motivation as a representative factor explaining organizational creativity. Motivation promotes a working environment that expedites both formal and informal communication, which entails greater transfer and acquisition of knowledge as well as the development of behaviors that strengthen organizational learning (Slater & Narver, 1995). In particular, intrinsic motivation favors a decision-making consensus, which requires a significant commitment among different groups of employees (Walsh, 1995). The thought processes, idea generation systems, and motivation of creativity mechanisms are likely to facilitate the analysis and interpretation of the existing and newly acquired knowledge.

H3a: As an organization's 'organizational motivation' increases, its level of 'potential absorptive capacity' increases.

H3b: As an organization's 'organizational motivation' increases, its level of 'realized absorptive capacity' increases.

As we commented above, we distinguished between potential absorptive capacity and realized absorptive capacity to observe the mechanism of relational rents and organizational creativity in an interorganizational environment. Therefore, we create a temporary hypothesis of absorptive capacity for this research.

H4: As an organization's level of 'potential absorptive capacity' increases, its level of 'realized absorptive' capacity increases.

Content Creativity of Joint Production Team

Content Creativity Besemer and Trefiger (1981) suggest a creative product analysis matrix (CAPM) theory for measuring output creativity. The purpose of CAPM theory is to help cultivate more careful observation of created products and to focus judges' attention on relevant attributes of products by creating a three-factor model of creativity, which includes novelty, resolution, and elaboration, and synthesis. Novelty is newness in materials, processes, concepts, and methods of making the product, resolution considers aspects of how well the product works or functions, and elaboration and synthesis present stylistic components of the product. In addition, composing these three factors are nine facets: originality and surprise comprise novelty; logical, useful, valuable, and understandable make up resolution; and organic, well-crafted, and elegant form elaboration and synthesis (Besemer & Treffinger, 1981; Besemer & O'Quin, 1999).

Content Creativity through Organizational Motivation and Absorptive Capacity In this study, we define organizational motivation as a core factor for creative performance. Many existing studies have focused on the importance of motivation for creative work and have suggested that people rarely do truly creative work in an area unless they really like what they are doing and concentrate on the work rather than on the potential rewards. At the interorganizational level, the learning orientation stimulates the generation of creative ideas or approaches because firms are genuinely interested in mastering opportunities to exploit the potential of relationships with other firms (Wang et al., 2008). Absorptive capacity influences innovative performance and is essential for enhancing creativity (Cohen & Levinthal, 1989). They posit that the ability of an organization to recognize and use external information is crucial for innovation. Absorptive capacity increases the speed and frequency of incremental innovation because such innovations draw primarily on the firms' existing knowledge base (Helfat, 1997; Kim & Kogut, 1996).

H5 : As an organization's 'organizational motivation' increases, its level of 'content creativity' increases.

H6 : As an organization's 'realized absorptive capacity' increases, its level of 'content creativity' increases.

Research Model and Analysis

Research Model and validity test

We analyzed the effects that the main factor of relational rents have on organization results through the organizational factors, absorptive capacity, and organizational creativity. Relational rents' components regarding contractual objects are based on the study of Dyer and Singh (1998). Absorptive capacity and organizational motivation are characteristic causes that mediate relational rents and organization's creative results. Absorptive capacity has been measured using two factors, potential absorptive capacity(PACAP) and realized absorptive capacity(RACAP)(Zahra&George, 2002).

Zahra and George (2002) assert that external and internal factors have different effects on PACAP and RACAP; thus, to develop and apply the two absorption capacities, we need a different management approach for each. In other words, exact study results rather than simple theoretical cause-and-effect models are found by analyzing the effects that relational rents and organizational motivation have on these two factors. Reflecting interview result and literature review, we made our research model as Fig 2.

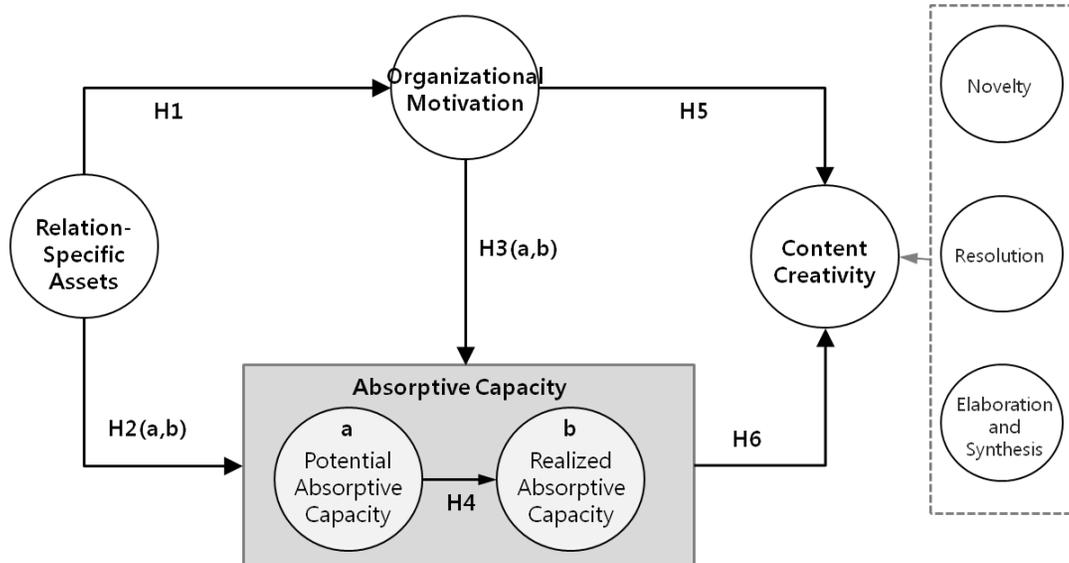

FIG 2. RESEARCH MODEL

A total of 163 survey forms were collected from independent production companies. In total, 40 samples were removed because of monotone responses and too many missing answers. The final dataset contained 123 valid responses. The sample characteristics reflected typical producers who produce broadcasting program outsourced by TV broadcasting companies, including terrestrial and cable networks. For each TV program, one response was collected using email or direct interviews over a period of 3 months. Table 1 summarizes the demographic information.

TABLE 1. SAMPLE DEMOGRAPHICS

Seg	Executive Producer (EP)	Chief Producer (CP)	Producer(PD)	Assistant Director (AD)	Etc	Total
Number of samples	17	16	68	6	16	123
Ratio	13.82%	13.01%	55.28%	4.88%	13.01%	100.00%

We used the Partial Least Square (PLS; Fornell & Bookstein, 1982) method to analyze the data from the survey for our research study. The PLS method is a well-established technique for estimating path coefficients in causal models and can be used to analyze the significance of the hypotheses using a bootstrap resampling. Construct validity is defined as the degree to which an operational measure correlates with the theoretical concept investigated. In this study, confirmatory factor analysis was conducted to assess the overall measurement models and to examine the convergent and discriminant validity. As shown in Table 2, all constructs satisfied this requirement.

TABLE 2. RESULTS OF VALIDITY TESTING

Construct	Convergent validity test					Discriminant validity test						
	AVE	Compo site	R Square	Cronbach's Alpha	Communality	ELS	NVT	OGM	RSA	RSL	RACAP	PACAP

	(>0.5)	Reliability (>0.7)	(>0.1)	(>0.7)	(>0.5)							
Elaboration and Synthesis (ELS)	0.809	0.927	0.843	0.882	0.809	0.900						
Novelty (NVT)	0.857	0.947	0.792	0.916	0.857	0.741	0.926					
Organizational motivation (OGM)	0.679	0.914	0.232	0.882	0.679	0.706	0.732	0.824				
Relation-specific asset (RSA)	0.515	0.807		0.716	0.515	0.480	0.364	0.482	0.718			
Resolution (RSL)	0.859	0.948	0.786	0.918	0.859	0.737	0.653	0.652	0.434	0.927

Structural Model Test

The structural model outcomes are presented in Fig 3. As a result, all R^2 are higher than 0.1. The R^2 value evaluates the explanatory power of each constructs. Both the main constructs of the hypothesis and the second-order constructs had R^2 values over the referenced level. The t-values are calculated using repetitive bootstrapping procedures, with 123 resampling iterations for both models. When calculated in Smart PLS, value of cases is set to 123 and that of samples is 500. Test results are summarized in in Table 2 and Fig 3.

TABLE 2. HYPOTHESIS TEST RESULT

Hyp.	Path	Coefficient(Std.error)	t-value	Test result
H1	Relation-specific assets → Organizational Motivation	0.482 (0.087)	5.482	Supported
H2a	Relation-specific assets → Potential Absorptive Capacity	0.211 (0.106)	2.006	Supported
H2b	Relation-specific assets → Realized Absorptive Capacity	0.040 (0.070)	0.564	Not Supported
H3a	Organizational Motivation → Potential Absorptive Capacity	0.405 (0.097)	4.011	Supported
H3b	Organizational Motivation → Realized Absorptive Capacity	0.316 (0.111)	2.662	Supported
H4	Potential Absorptive Capacity → Realized Absorptive Capacity	0.609 (0.144)	3.977	Supported
H5	Organizational Motivation → Content Creativity	0.617 (0.087)	7.078	Supported
H6	Realized Absorptive Capacity → Content Creativity	0.247 (0.094)	2.652	Supported

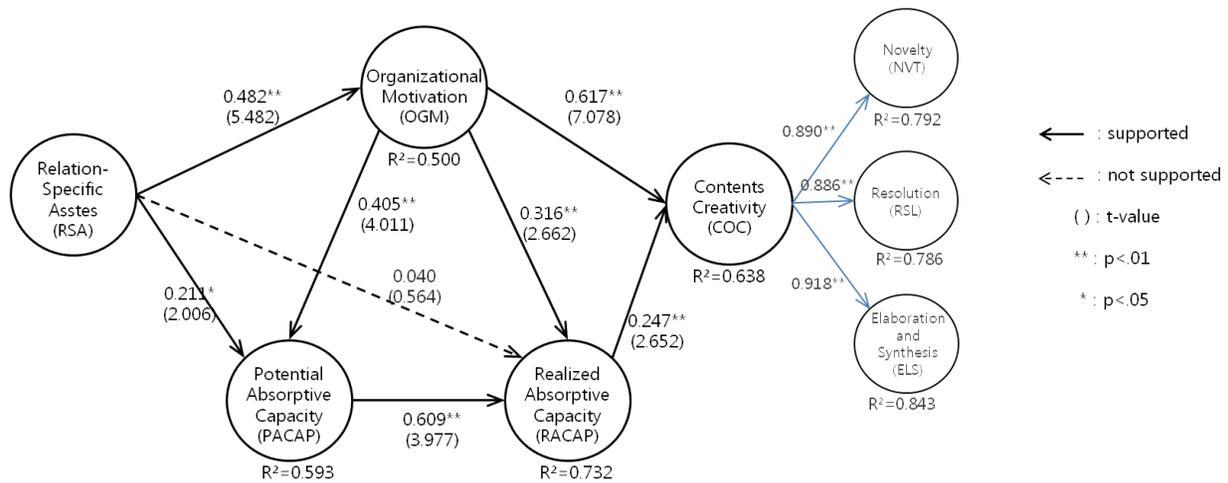

FIG 3. PLS RESULTS FOR RESEARCH MODEL

The remainder of the hypotheses were determined by testing the positive sign and statistical significance of the t-value for its corresponding path. As a result, all hypotheses except for H2b are supported ($p < 0.05$), but, H2b related to realized absorptive capacity is not ($p > 0.05$). Thus, relation-specific asset between two firms does not affect realized absorptive capacity. From this result, we can recognize that the different function between potential absorptive capacity and realized absorptive capacity affects the process of both determinants of relational rents and organizational motivation.

Conclusion

The determinants of relational rents, organizational motivation, and absorptive capacity exist in an indivisible circular relationship. Determinants of relational rents, organizational motivation, and absorptive capacity are shown to have a meaningful effect on creative results. In short, we infer that organizational motivation and absorptive capacity mediate relation-specific assets and content creativity through an empirical analysis.

The determinant of Relational rents, relation-specific assets, is formed through various relationships between industries and these relationships critically affect the project's outcome. In this study, we investigate the effects that the factor formation of relations of broadcasting stations and outsourced production have on knowledge management activity. Furthermore, we determine the meaningful effects that these relationships have on the organization's creativity formation process. If a strong relationship is achieved between the broadcasting stations and the outsourced productions, it has a positive influence on organizational creativity and absorptive capacities.

Zahra and George (2002) note that external and internal factors have different effects on potential absorptive capacity and realized absorptive capacity. In this study, we have verified that potential absorptive capacity and realized absorptive capacity have different effects on the result of the project. From the structural model, we can confirm that a strong link between ordering and outsourcing companies allow a coproduction team to release relational rents or long-term mutual creative benefits derived from long-term cooperative relations. Good relations with clients deliver rents to the design firm as they facilitate creative and innovative work (Sunley et al., 2008).

In this study, we analyzed the determinants of relational rents, organizational motivation, and absorptive capacity in cooperative relationships to generate content creativity. Although the determinants of relational rents increase between two firms, the cause-and-effect relationship of output's creativity can be determined by organizational creativity and absorptive capacity in a cooperative organization.

First, we analyzed the cooperative knowledge mechanism of an unmeasurable but qualitative result, creative content. Unlike the manufacturing industry, the content industry cannot standardize its product output. In particular,

broadcasting content maintains characteristics of public goods and has high fixed costs but low marginal costs because it has a different value chain than other general manufacturing products that leads to sales. Therefore, the quality of the results is not determined by lowering the manufacturing cost, shortening the lead time, and increasing sales volume; rather, it is measured by intangible values such as creativity and completeness. We have setup a theoretical model and verified our hypotheses based on existing studies to prove the effects on the cooperating process of knowledge flow, which is the most important factor for the knowledge industry.

Second, we provided two theoretical frames, organizational motivation and absorptive capacity, as mediators of the processes that the determinants of relational rents are affected by through interorganizational cooperation. Through this modeling, we verified that determinants of relational rents formed by organizational cooperation have indirect effects on an organization's creative result, which is explained as relational rents. In short, this study takes a major step in the development of the determinants of relational rents as a main factor effective on output creativity through cooperative system between firms. Theoretically, this study provides a new research model for this proof, reestablishing existing theory.

Lastly, this study is conducted for the case of broadcasting content, a single field, but it can be applied to various situations related to the knowledge industry. Broadcasting content, as a knowledge resource, has the same characteristics as information goods. Additionally, information is produced by horizontal cooperation or vertical contract relationships in many fields. Considering this context, this study result can be applied to various perspectives of studies related with cooperation of organizations and improvement of creativity in industry fields that require intangible value.

Examining the Role of Short Break on Proactive Behavior: A Self-Regulatory Resource Perspective

Abstract

Responding to the increasing research interest in the negative consequences of employees' proactive behavior, we investigate the negative effect of proactivity on well-being by focusing on the level of fatigue felt by individuals. We further examine the effect of taking a short break on sustaining proactivity. Drawing on the self-regulatory resource theory, we propose a positive relationship between proactive behavior and fatigue, but suggest that a short break could enhance the individual's ability to resume proactivity in a subsequent task. Through two laboratory experiments involving a total of 116 participants, we identified a positive association between sustained proactive behavior and fatigue. Additionally, we show that a break or short period of relaxation increased subsequent level of proactive behavior. Our findings suggest that keeping engaging in proactive behavior consumes self-regulatory resource, and hence leads to greater fatigue. However, this detrimental effect may be temporary if an appropriate intervention, such as a short break, is applied.

Introduction

Employees' proactive behavior at work, which can be characterized by the exercise of initiative, a change focus, and an orientation towards the future, is receiving increasing amounts of attention from organizational behavior researchers. Employees behave proactively in order to cope with rapid changes in the structure of work and the increasingly complicated and dynamic working environment (Belschak, Den Hartog, & Fay, 2010). Studies of proactivity consistently suggest that it has beneficial outcomes.

Nevertheless, since proactive behavior requires extra effort and resources, and breaks some existing rules and accepted practices, it could also have undesirable or detrimental consequences for the individual (Belschak et al., 2010; Grant & Ashford, 2008). Researchers have therefore begun to explore the "dark side" of proactivity in the workplace. Some empirical studies provide initial support for the existence of boundary conditions for the positive effects of proactive behavior (e.g., Chan, 2006). Unfortunately, the literature in this area has some theoretical shortcomings and so far no overarching theory of these detrimental consequences has been proposed. Furthermore, we have only a limited understanding so far of how individuals might cope with these problems so as to sustain their proactivity. To meet this need, this study aims to broaden the research base on the negative outcomes of proactive behavior by focusing on one such factor, namely fatigue. We also take this step further by investigating whether taking a short break is beneficial in maintaining proactivity.

Based on the self-regulatory resource theory, this study uses two laboratory experiments to examine the influence of proactivity on fatigue, as well as the impact of a break on sustaining proactivity. Fig. 1 presents the research framework. The current study contributes to the literature on proactive behavior in three ways. First, drawing on the theory of self-regulation (e.g., Baumeister, Heatherton, & Tice, 1994), Bindl and Parker (2009) propose a goal-regulatory process model of proactive behavior which depicts how individuals constantly regulate such acts through envisioning, planning, enacting, and reflecting. Such regulatory processes may well consume additional resources and energy. Unfortunately, few studies so far use this perspective to further explore the negative consequences of proactive behavior. Based on this theoretical framework, we propose that proactive behavior, as a type of self-regulating activity, utilizes one's executive function and therefore consumes resources from the common and limited pool available for general self-regulatory activities. Such resource depletion may be tiring (e.g., Cameron, 1973; Wright et al., 2007). We therefore argue that being proactive increases fatigue.

Second, the literature of proactive behavior has yet to investigate possible interventions to encourage individuals to continue being proactive even though demands are being made on their resources. Studies of self-regulatory activities show that there are several possible approaches to replenish depleted resources and enhance executive function, such as viewing scenes of nature, taking a short rest, experiencing positive mood, having a food break, and being given a motivational incentive (Baumeister & Vohs, 2007; Tyler & Burns, 2008). Accordingly, based

on these findings, we propose that taking a break after engaging in proactive behavior will enhance individuals' subsequent levels of proactivity.

Third, other than the work of Grant and Rothbard (2013), almost all existing research on proactive behavior uses a field study approach by collecting data from organizations. In this study, however, we use laboratory experiments to test our hypotheses. In these experiments, we create tasks which enable the proactive behavior of participants to be objectively measured, which may overcome the potential measurement bias of self- or other-rating of proactivity found in questionnaire surveys. In addition, the experiments are likely to provide more rigorous explanations of causality and strengthen the generalizability of our findings.

Theory and Hypotheses

Proactive Behavior and Fatigue

Rather than passively accepting events and reacting to them, being proactive implies mindfully planning, calculating, and acting in anticipation of what might happen in future, which places significant demands on executive function (Grant & Ashford, 2008). For example, an employee might use his/her initiative to question the effectiveness of an existing work procedure, and decide to raise these concerns with a supervisor. He/she may need to carefully prepare for such a meeting by considering the problems with the current procedure, formulating plans for improvement, and deciding on an appropriate time to communicate with the supervisor. Energy and effort are expended in accomplishing such preparation, as well as in the action itself. Given the self-regulatory nature of proactive behavior, it tends to consume resources drawn from the common and finite pool for self-regulation (Baumeister, Bratslavsky, Muraven, & Tice, 1998). Thus, employees who keep performing proactive behavior without replenishing these resources are likely to deplete their pool of energy, resulting in greater fatigue.

The majority of studies of the self-regulatory resource model use experimental methods (e.g. Baumeister & Vohs, 2003; Vohs et al., 2008). Their findings consistently demonstrate that when participants are required to conduct a further, different self-regulatory task after finishing the first one, their performance on the second task is poorer as a result of the reduction in the available resources (for a review, Baumeister & Vohs, 2003). Although these studies do not explicitly examine how the reduction in available resources affects fatigue, they consistently show a relationship between performing one self-regulatory task and impaired performance of a subsequent and unrelated such task. Some studies do suggest a positive relationship between self-regulatory behavior and individual fatigue, drawing upon the theory of self-regulatory resource. From a theoretical perspective, Muraven and Baumeister (2000) propose that self-regulation resembles a muscle that becomes fatigued by exertion and is therefore less able to function as demand continues. Cameron (1973) also suggests that individuals experience fatigue when their mental resources are taxed. Empirically, some experimental studies provide preliminary support for the idea that people engaged in a self-regulatory task tend to be more tired, as well as exhibiting higher levels of some of the physiological indicators of fatigue (such as blood pressure responses and variability in heart rate) (Baumeister et al., 1998; Finkel et al., 2006; Wright et al., 2007).

We should mention that we would not expect a significant increase in fatigue among employees who engage only occasionally in proactive behavior, since they may replenish their resources during the relatively long intervals between these actions. We focus here on the pattern of maintaining proactive behavior without any opportunity for restoring their resources in the interim. We therefore hypothesize:

Hypothesis 1: Performing proactive behavior increases fatigue.

As mentioned above, research confirms that the performance of a subsequent self-regulatory activity will be impaired because of the resource expenditure involved in accomplishing the first task (e.g. Baumeister et al., 1998; Vohs et al., 2008). For example, Vohs et al. (2008) found that effortful decision making, which requires executive function and self-regulation, weakens subsequent self-regulation capacity, as demonstrated by less persistence on unsolvable puzzles and more procrastination in the face of an upcoming examination. Such findings indicate that the resources remaining in the common pool determine individuals' subsequent capacity for engaging in self-regulatory activities. In this context, we speculate that performing proactive behavior may jeopardize individuals' ability to do so again immediately following completion of the first action. Furthermore, maintaining a constant level of proactivity

would not appear to be feasible, since such behavior consumes self-regulatory resources from the common pool. It is thus intriguing to consider how employees can sustain proactivity when their resources are being depleted by continuous proactive behavior. This question has yet to be explored.

Studies of self-regulatory activities and the limited resource model show that after an episode of self-regulation, the negative influence on subsequent self-regulatory capacity is temporary if appropriate interventions are applied (e.g. Danziger, Levav, & Avnaim-Pesso, 2011; Tyler & Burns, 2008). For example, Danziger et al. (2011) found that judges show an increased tendency to rule in favor of the status quo when they make repeated rulings, but this trend can be overcome by taking a break to eat a meal. This implies that a meal break can help replenish mental resources. Tyler and Burns (2008) investigated how individuals replenish their self-regulatory resources after depletion. Depleted participants who were given a short rest or relaxation period performed just as well on subsequent tasks as non-depleted participants. Several other studies examined the effect of glucose, suggesting that consuming, or even rinsing the mouth with, a glucose drink enhances self-regulation ability after participants have completed a self-regulatory task (Gailliot et al., 2007; Molden et al., 2012; Sanders, Shirk, Burgin, & Martin, 2012). This body of literature indicates that taking a break or briefly relaxing in between performing two self-regulatory tasks could replenish individuals' depleted resources, which in turn boosts the ability to self-regulate. Therefore, in line with previous studies, we propose that a break will positively strengthen individuals' subsequent proactive behavior. We accordingly hypothesize:

Hypothesis 2: Taking a break after accomplishing an initial proactive behavior enhances individuals' subsequent proactive behavior.

Experiment 1

Method

Participants and procedure. Undergraduate students from a Hong Kong university were recruited as experimental participants. Fifty-two students (27% male) participated in exchange for a US\$13 coupon. Their average age was 21.2 years.

Our aim in the first experiment was to test whether performing proactive behavior made participants more fatigued (Hypothesis 1). In Experiment 1, participants were required to accomplish a Lego modeling task in which they were given several opportunities to perform proactive behavior. Their fatigue was then measured. To be specific, the participants were firstly asked to complete a questionnaire including measures of positive and negative affectivity and proactive personality. They were then told to build a Lego model with the help of an instruction book. This task was divided into five phases, with the experimenter distributing the pieces for the next phase once the participants had accomplished each one. In the last four phases of the task, we intentionally provided an incorrect piece (the right shape but the wrong color) which they need to use primarily in each phase. Since the participants were required to build the model exactly as shown in the instruction book, the most proactive action to take in this situation would be to ask the experimenter about this problem as soon as they had discovered it. The response time, or the interval between the distribution of the incorrect piece and the participant notifying the experimenter of the error, was recorded as an indicator of proactive behavior. After finishing the Lego model, participants completed another questionnaire including measures of the perceived difficulty of the Lego task and their level of fatigue, as well as basic demographic information such as age and gender.

Measures

Proactive behavior. We used the response time, that is, the time elapsing between the distribution of the incorrect Lego piece and participants notifying the experimenter of the issue, to indicate the level of proactive behavior of the participants. If they did not ask at all, the response time was fixed as the amount of time required for that participant to complete the current phase of the model construction. Each participant therefore had four response times per task, corresponding to the four phases using incorrect bricks. Since the modeling speed of each participant (that is, the total amount of time taken to construct the model) would affect how quick they were to discover the incorrect Lego piece, we used the quotient of the sum of the four response times divided by the total time taken to accomplish the task as a measure of participants' proactivity. As a result, the smaller the quotient, the higher the level of proactivity.

Individual fatigue. Fatigue was measured using a 6-item scale developed by Chalder et al. (1993). Sample items are “I have problems thinking clearly” and “I have problems concentrating” (1 = strongly disagree, 7 = strongly agree; $\alpha = .92$).

Control variables. We controlled for participants’ positive and negative affectivity, proactive personality, and the perceived difficulty of the Lego model as rated by the participants.

Results

Table 1 presents the means, standard deviations, and correlations among the key variables.

We conducted hierarchical regression analyses to examine the relationship between proactive behavior and fatigue (see Table 2). In step 1, we entered the four control variables (that is, proactive personality, positive affectivity, negative affectivity, and perceived difficulty of the Lego task). In step 2, the variable of proactive behavior was also entered. The results show that proactive behavior during the experiment was negatively and significantly related to individual fatigue afterwards ($\beta = -.25, p < .05$). In addition, the change in R^2 after entering the independent variable (that is, proactive behavior) was significant ($\Delta R^2 = .06, p < .05$). Thus, individuals whose response time in the Lego task was shorter (and who therefore had engaged in higher levels of proactive behavior) experienced greater fatigue after accomplishing the task. Hypothesis 1 is therefore supported.

Discussion

Experiment 1 provides evidence of significantly increased fatigue when participants continued performing proactive behavior during the task (Hypothesis 1). It offers preliminary support for the self-regulatory resource perspective of proactive behavior, namely that it is a form of self-regulation and therefore expends self-regulatory resources. More importantly, when individuals engage in proactive behavior without resource renewal, their physical and mental well-being is likely to be impaired. Therefore, in Experiment 2, we created a condition in which participants could replenish their resources in order to examine how this intervention influences their proactivity.

Experiment 2

Method

Participants and procedure. Again, we recruited undergraduate students as participants from a Hong Kong university. Sixty-four (21.9% male) participated, in exchange for a US\$13 coupon. The average age of the participants was 21.1 years.

The goal of Experiment 2 was to examine whether a short break after engaging in proactive behavior could promote subsequent proactivity (Hypothesis 2). Experiment 2 required participants to complete two Lego modeling tasks. Participants in one subgroup were allowed to take a 10-minute break between the two tasks, and those in a control group were not. The conditions were randomly assigned to participants, with 32 participants taking a break and 32 participants not being offered one. Participants were told that the two tasks belonged to two different research projects so that they would not connect the tasks and their performances in each would be independent.

Specifically, the participants were firstly asked to build a Lego model according to the instruction book provided. This task was the same as for Experiment 1. After finishing the first Lego model, participants in the short break group were given a 10-minute break before commencing the second task. Participants assigned to this group were not allowed to communicate with each other or use their cell phones during the break. They were given some water and could listen to some light music in the laboratory, with the intention of helping them relax. After the break, these participants were asked to complete another Lego modeling task. Participants in the control groups did not get a break and were required to commence the second Lego task as soon as they had completed the first one.

In the second Lego task, participants were asked to build the model within five minutes and in strict accordance with the instructions. After the experimenter had distributed the Lego pieces, he/she told the participants that another experimenter who was in charge of the second task would come into the room with the instruction books. In the meantime, the participants were asked to click the “start” button of a countdown timer on the computer, which had been preset to five minutes, to remind them how much time they had to finish the task. However, nobody actually came in to distribute the instructions. Since participants only had five minutes, proactive individuals would be

expected to raise their hands and ask the experimenter about the instruction books. The response time (that is, the time elapsing between participants clicking the start button and inquiring with the experimenter), was recorded as an indicator of proactive behavior. After finishing the second task, participants completed a postexperimental questionnaire including basic information such as gender and age.

Measure of proactive behavior. For the first Lego task, we used the same response time as in Experiment 1 to indicate participants' level of proactive behavior. For the second, we used the response time, i.e. the time elapsing between participants clicking the start button and inquiring with the experimenter about the instruction books. The smaller the response time, the higher the proactivity level of the participant.

Results

T-tests were firstly used to examine the differences between the two experimental conditions in terms of gender, age, and degree major. The results indicated no significant difference between the two conditions (for gender, $t(62) = -.597$, $p = .553$; for age, $t(59) = -.958$, $p = .342$; and for major: $t(59) = 1.245$, $p = .218$). We also examined whether the level of proactive behavior in the first Lego task was different across the two conditions. The t-test showed no significant difference ($t(62) = 1.041$, $p = .302$). Finally, we tested for differences in the response time for the second task between the short break and control conditions. As shown in Fig. 2, response times during the second task were shorter after the 10-minute break ($t(62) = 6.258$, $p = .000$; for break condition, $M = 2.07$ (minute), $SD = 1.37$, for control condition, $M = 4.11$ (minute), $SD = 1.24$). That is to say, the level of proactivity increased under the short break condition. Hypothesis 2 is therefore supported.

Discussion

Experiment 2 further demonstrates that being continuously proactive exhausts individuals' self-regulatory resources. The findings also support our argument that when an opportunity is given to renew these resources, subsequent proactive behavior is enhanced (that is, Hypothesis 2 is supported). In other words, it confirms the positive intervention effect of short break on restoring individual resources and, in turn, sustaining proactivity.

General Discussion

Engaging in proactive behavior has potentially negative effects on individuals' well-being. This study has drawn on the self-regulatory resource theory (Baumeister et al., 1994; Muraven & Baumeister, 2000; Muraven, Tice, & Baumeister, 1998) to propose that the overall relationship between proactive behavior and fatigue is positive, and taking a break is a helpful way for individuals to sustain their proactivity. Our experimental findings support these propositions, showing that participants who had been continuously performing proactive behavior experienced higher levels of fatigue, but that taking a short break after the initial episode of proactive behavior enhanced their proactivity in the subsequent task.

Although the negative implications of proactive behavior have recently begun to receive more academic attention, no overarching theory which explains these consequences has yet been proposed. In this paper, we have approached the question from the perspective of the self-regulatory resource theory, which suggests that proactive behavior, as a form of self-regulatory activity, consumes such resources from a common and finite pool within each individual. Such expenditure could explain why being proactive may have some negative consequences for actors, such as fatigue. Additionally, according to this theory, appropriate interventions could be used to replenish self-regulatory resources, helping individuals to sustain their proactivity. These propositions have been confirmed by our empirical findings. We have therefore shed some light on these theoretical explanations of how proactivity has a negative impact on well-being.

Also on the theoretical front, our study enriches the current exploration of the possible personal costs of behaving proactively by empirically examining fatigue as an outcome. The results correspond to the findings of other studies on self-regulation (e.g. Baumeister & Vohs, 2003; Vohs & Baumeister, 2011; Vohs et al., 2008), which indicate that proactive behavior expends self-regulatory resources which, in turn, may have a negative effect on physical and mental well-being. To date, the literature has provided little detailed understanding of the possible "dark side" of being proactive. Our study confirms that being proactive may be a double-edged sword for individual

employees. While it may benefit their job performance or career, it may also be detrimental to their well-being.

Some people may be unsure whether or not they should engage in proactive behavior at work. Rather than suggesting that employees stop being proactive altogether, we agree that such behavior has a number of benefits and should be generally encouraged. However, performing proactive behavior consistently without the opportunity to restore one's resources, as shown in Experiment 1, leads to greater fatigue. That is to say, too much proactive behavior is likely to deplete individual resources and impair well-being. We therefore highlight the role of resource replenishment in this study, which is discussed further below.

We have investigated how individuals can maintain proactivity in subsequent activities while still fatigued by previous episodes of such behavior. The question of how individuals can cope effectively with the negative effects of being proactive has not been investigated in previous studies. However, this topic deserves some effort from scholars, since it would be helpful for people to understand what kind of interventions they can employ in order to maintain their proactivity. The results of Experiment 2 suggest that having a 10-minute break between two tasks, both of which gave participants the opportunity to be proactive, resulted in increased levels of proactivity in the second task compared with individuals who were not allowed to rest. Our findings are consistent with previous work on the limited resource model of self-regulation, which demonstrates that a short break is an efficient approach to recovering energy and resources and enhancing self-regulatory ability (e.g. Danziger et al., 2011; Sanders et al., 2012; Tyler & Burns, 2008). This study also suggests that facilitating a short break or period of relaxation after performing some kind of proactive behavior is one way in which employees could maintain their proactivity in the workplace. By this means, the negative aspects of proactive behavior could be counteracted, and being consistently proactive would not overburden individuals. Hence, we have demonstrated the positive intervention effect of taking a short break on sustaining proactivity among individuals.

This study also has important practical implications. Given the increasingly crucial role of employees' proactive behavior for both individuals and organizations (for a review, Bindl & Parker, 2010), it is vital to understand the potential negative consequences of this type of behavior. Alongside the existing strand of research into the personal costs of being proactive, our study shows that greater fatigue is one of these costs, since it depletes self-regulatory resources. To date, proactive behavior has been generally regarded as beneficial for organizations, but it is questionable whether it is also advantageous for employees; current evidence appears to be mixed. Unfortunately, however, a reduction in employees' well-being eventually affects organizational performance as well (Harter, Schmidt, & Hayes, 2002; Harter, Schmidt, & Keyes, 2003). Therefore, managers should realize that encouraging employees to be continually proactive is not always appropriate, since the well-being of individual workers and even the organization as a whole may be damaged by too much focus on this area.

Furthermore, based on the findings of Experiment 2, effective measures can be taken to offset these detrimental effects and help employees to maintain their proactivity. On a practical level, organizations can introduce several well-designed short breaks or relaxation periods for employees to replenish their resources during the working day. Such methods would help employees to avoid the double-edged sword of proactive behavior and enable them to continue to engage productively with it. This underscores the importance of resource replenishment in sustaining individual proactivity in the workplace.

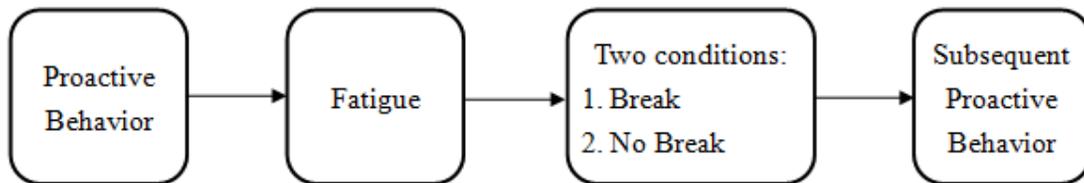

FIG. 1 RESEARCH FRAMEWORK

Notes. Response time is the duration of time between participants beginning the second Lego task and inquiring with the experimenter about the instruction book of the Lego model. The shorter the response time, the higher the level of individual proactive behavior. Break condition (32 participants): participants have a 10-minute break between the two tasks; Control condition (32 participants): participants do not have a break between the two tasks.

Get Strategic Human Resource Management Really Strategic: Strategic HRM in Practice

Abstract

There are human resource managers who do not have strategic human resource management in their companies, and they are aware of that. There are human resource managers who do not have strategic human resource management in their companies but they believe they have it. There are human resource managers who have strategic human resource management in their companies, and they are aware of that. But there are no human resource managers who would have strategic human resource management in their organizations, and they are not aware of that. The article is based on the author's empirical research in a large state-owned company.

The word "strategic" is a very frequent adjective that is used today especially in the theory and practice of business management. Unfortunately its meaning is not so clear as we could expect. For example, strategic partner would refer to the partner who is important, strategic resource would have similar meaning but strategic investor usually refers to the solvent investor who is interested in investment, and finally strategic planning refers more or less to the long-term planning. Of course, there are strategic management that refers to what? Five stages of the process? Beside this there are strategic human resource management, strategic marketing, strategic finance, and similar that refer to specific areas of business management. It is clear that there are several meanings of this adjective – such as important, capable, long-term, and probably some other. Which of these are related to human resource management system and its role in the organization? It looks like the adjective strategic has brought a „new jungle“ to the field of management. Because of that a short excursion to strategy, strategic planning, and strategic management would be necessary.

Strategy

What is strategy? There are a wealth of literature sources dealing with the term strategy. There are almost innumerable strategy definitions as well. The term is in frequent use since the early 1960s when strategic planning has become very popular. Later strategic management, and in the 1980s strategic human resource management came into use both in theory and practice of business management. As our perspective is business management we should avoid such "folklore" definitions of strategy as ...the art of war..., movement of troops, and similar because business strategy has nothing to do with armed forces. They have their own strategies. Notoriously known definition of strategy is... "the company's long-term plan for how it will balance its internal strengths and weaknesses with its external opportunities and threats to maintain a competitive advantage (Dessler, 2003). For better understanding of the definition let's take a practical example: You are located somewhere in the Central Europe and have a good reason (the objective) to get to Jerusalem. There are at least two ways to get there. One way is to move northward, the other to move southward. Both ways lead to Jerusalem but one of them is much longer. You choose the most appropriate way. It is your strategy how to get there. Strategy is the way, it is a choice. Because we are in the business area, strategy is the way how the organization will survive in its competitive environment. It is the organization's sustainability plan.

Strategic Planning

Strategic planning in its very beginning in the early 1960s involved managerial decision-making about the long-term goals of an organization. Strategic planning is a process that results in a strategic plan – the organization's long-term goal. Strategic plans have a strong external orientation because they deal with the long-term survival, value, and growth of the organization. Senior executives are responsible for the development and execution of the strategic plan that should include both the effectiveness in term of appropriate output, and efficiency in term of high ratio of outputs to inputs. Strategic planning emphasized top-to-bottom approach to goal setting. This means that senior managers and specialized strategic planning units have got legitimate power to develop objectives for the organization as a whole, and lower-level managers and organizational units did not get the goals or objectives but the tasks. Diversity of former individual

businesses competing in the single industry resulted in the broadening of business competition. Companies were forced to compete in more industries at the same time. Strategic decision makers required more specific information about different industries. In order to get that kind of information specific approach was developed under the name the Growth/Share matrix. This approach is in use till today under the name BCG (Boston Consulting Group) matrix. According to combination of business growth (high or low) and relative competitive position (strong or weak) this matrix consists of the four quadrants with a bit strange nicknames such as Stars, Cash cows, Question Marks, and Dogs. BCG matrix prescribed specific actions for businesses in each of these quadrants.

Strategic Management

As a result of increasing complexity of businesses and globalization trends in the mid 1980s, a new term was introduced into strategic planning process - strategic management. The idea was to involve managers from all parts of the organization in the formulation of strategic goals and strategy implementation. *From this point of view, strategic management is an integration of strategic planning and management into one process.* Classical scientific management is a process of planning, organizing, leading, and controlling. Strategic management is a process that includes the following five components:

- Internal assessment
- Environmental analysis
- Strategy formulation
- Strategy implementation, and
- Strategic control

If strategy is the way how the organization will survive in its competitive environment, it is clear that both the internal and external environment analysis are necessary. The key role in the process of strategic management plays the *SWOT analysis*. The acronym stands for strengths, weaknesses, opportunities, and threats. First two mentioned are related to analysis of internal environment, and the last two deal with external environment analysis. Beardwell, J. and Clayton, T. (Beardwell, Clayton, 2010) identified four approaches to strategy-making. These are the classical or rational-planning approach, the evolutionary approach, the processual approach, and finally the systemic approach. The fourth component of strategic management process – the strategy implementation - are the arrangements necessary to get strategy into practice. Process ends with strategic control which in reality means the feed-back information for decision-makers. Now, after a short excursion to strategy and strategic management we shall focus our attention on the issue of strategic human resource management.

Strategic Human Resource Management

Strategic human resource (management) is relatively new term both in theory and practice. First introduced in the mid 1980s it represents the present stage of human resource management evolution. The previous stages of human resource management evolution include *Purchasing* - focused on hiring and firing at best costs, *Labor Relations* – negotiating with unions representing company employees, negotiating talent for least costs, *Personnel* – focused on administering employee issues such as benefits, compensation, and employee relations, tends to have a strong emphasis on control, and *Human Resource* – represents primarily a name change with little substantive difference, regardless of the implication of a move toward being more strategic. According to Christensen, R. (Christensen, 2006), the strategic human resource role is managing organization and employee performance. Dessler (Dessler, 2003) believes that strategic human resource management is the linking of human resource management with strategic goals and objectives in order to improve business performance and develop organizational cultures that foster innovation and flexibility. In literature there are more approaches to strategic human resource management, For example, Beardwell (Beardwell, Clayton, 2010) describes best fit (or contingency) school, the resource-based view of strategic human resource management, and best practice approach. Under these approaches there are several models of strategic human resource management. For example contingency approach includes lifecycle model, competitive advantage model, and configurational model. Best practice

approach describes the high commitment models. Because of the aim of this article – to get strategic human resource management really strategic – detailed description of these approaches and models are not necessary. Besides this, theoretical models are necessary but strategic human resource management is also or most of all managerial responsibility in real business companies. Variety of theoretical approaches to strategic human resource management brings a kind of confusion over the differentiation between human resource management and strategic human resource management. As a result of that, the term „old wine in new bottles“ becomes popular between managers.

Empirical Research Results

Questionnaire comparative empirical research was conducted in two large companies. One of them – company A - is a state-owned company, and the other – company B - a private company. Each of the companies has over two thousand employees. Total number of managers involved in research:

Company A - 52 managers, 9 of that number are top managers (71,15 % questionnaire return ratio).

Company B – 31 managers, 6 of that number are top managers (77,41 % questionnaire return ratio).

There are both the line and staff managers involved in the research sample - including human resource managers.

Managers were asked to answer the questions focused on issues as follows:

- Is there strategy in (your) company?
- If yes, are the human resource managers and units involved in its structure?
- Are the human resource management specialists involved in strategy formulation or they get just the tasks to fulfil?
- Is the human resource management system role in your organization traditional or that of strategic partner of top management?
- Is traditional role of human resource really changing or it is just the „old wine in new bottles“?

There are a variety of answers that could be – and were - evaluated by such criteria like the particular company, management level, line and staff aspects, and similar. The most important conclusions related to strategic human resource management are the following:

- Almost 40% of top managers in the company B were not quite sure if there is any kind of strategy in their organization.
- According to some answers „strategy is about 80 page booklet that could be found in the general director’s office“.
- Great majority of managers including top managers believe that strategic human resource management means fulfilling the tasks the human resource managers have got from the company strategy.
- Human resource managers and specialists are not involved in strategy formulation.
- Majority of managers believe that human resource management activities are not exclusively only human resource manager’s responsibility.

As both companies are successful in their particular field of operation, it is clear that managers in both companies take strategic management more or less as a formal issue that is not directly related to the company success on the market. Situation in the practice could differ from the case of mentioned companies but still the results show how strategic human resource management in practice and specific theoretical models of strategic human resource management could be far from each other. If the company is successful on the market, is there strategic human resource management approach necessary? The answer „no“ would be politically incorrect, and managers are aware of that.

Why Strategic Human Resource Management

Strategic human resource management are present activities to get future results. Strategic human resource management is necessary today because the company is interested in the future results. Strategic management is about differentiation and competitive advantage. There are several ways to get competitive advantage. For example, technology, price, quality of products, and similar. Most of mentioned are quite easy imitable which means it is not long-lasting competitive advantage. Exception could be competitive advantage through people – human resource. Managers should be aware of the fact that competitive advantage through people is a process. It is not a simple result of hiring of appropriate people. It is a process of employee development. Why this competitive advantage is difficult

to immitate? The answer is simple – because the most important attribute of human resource as a competitive advantage is flexibility. It means the ability and readiness of people to meet not only today’s but also tomorrow’s high performance expectations. Not each human resource is the company competitive advantage. Competitive advantage through people is a result of human resource development process. Competitive advantage through people would be one of the results or an attribute of strategic human resource management. What are the others? Former idea of strategic management is the involvement of all managers in formulation and accomplishment of the company long-term objectives. Human resource managers are not or are not supposed to be an axception. Because of that, human resource specialists should be involved in all stages of strategic management process starting with internal environment analysis and ending with strategic control.

Get Human Resource Management Strategic

Wealth of literature describes strategic human resource management from different point of view. For example, some authors believe that human resource scivities are not, and never will be strategic because they are strictly operational (Dessler, 2003). Second group of authors believe that strategic role of human resource is to fit the company’s strategy. Finally, there are authors who describe strategic role of human resource in terms like strategic partner of top management, vertical inregration of activities, and similar. Of course there always will be advocates of each of these views but there are two issues that we should take into account:

- Strategic management is about the company’s competitiveness, and competitiveness directly depends on the company’s employees.
- Beside finance, marketing and operations, human resource management is an integral part or sub-system of the company management system.

If competitiveness depends on the company employees, and competitiveness at the same time is the key strategic issue – could human resorce be strictly operational issue? Probably not. Four sub-systems of the company management system are not independent entities (Rudy, at al., 2013). In correlation with each other they represent a kind of „ambrella“ over the company. If there is strategic management in the company - there should be strategic management of each its integral part. Based on these assumptions it could be said that the strategic human resource management role in the company is twofold:

- Equal partner in the process of strategic management.
- Build up the competitive advantage through people.

Become equal partner in the process of strategic management means to take part in all stages of the process of strategic management. At the same time it does not mean just to get invitation and be accepted at the business table. There is a general agreement both in theory and practice that human resource activities are not exclusive responsibility of human resource specialists and managers (Rudy, Rudyová,2008). Line managers should be involved in human resource activities as well. For example, compensation system design is a typical human resource specialists responsibility. But compensation of each individual worker according to compensation system is a line manager’s responsibility. In order to be an equal partner in strategic management process we should look also for greater involvement of human resource specialists in the company business activities. Human resource managers and specialists should understand business, value the company provides for customers, customers, technology, industry, competitors, and similar. That is what makes equal partner in the process of strategic management. Human resource is invited to the table not because they are experts in strategy formulation or because they are experts in human resource. They are invited because they are experts in human resource who understand business the company is involved in. Knowing the business and human resource expertise is the expected contribution of human resource specialists as the company stregetic decision-makers.

Build the company’s competitive advantage through people is the second of twofold role of strategic human resource management. If the classical role of personnel management was to get appropriate number of people, the strategic human resource management role is the development of people to get competitive advantage through people. A competitive advantage is an advantage over competitors gained by offering consumers greater value. It is the ability of the company to offer such added value to its product that competitors cannot. It is a set of capabilities or resources

giving an organization an advantage that leads to the company's higher performance compare to competitors. It is a question of differentiation from competitors. There are several ways to get competitive advantage. For example, price, greater benefits and services for customer, technology, quality of the products, but also the company's human resource.

Search for competitive advantage is one of the core activities of strategic management. The most complicated issue in searching of competitive advantage is its sustainability. For example, a company in an automotive industry introduced ABS system (from German Antilockbraking system) in its cars. Because of increased safety of cars with ABS system, the company gets competitive advantage through technology. But after a short period of time almost all companies in automotive industries followed the same way. The result – competitive advantage through technology is lost. It happens because competitive advantage through technology is usually easily imitable. The challenge for the company's strategy is to find a way of achieving a sustainable competitive advantage. That means the competitive advantage that cannot be easily imitable. Human resource is probably the only way to get relatively sustainable competitive advantage. It is so because factors that differentiate work force are focused on individuals. And there are no two identical individuals in the Universe. For example, organizational performance depends on the skills of employees, their motivation, and organizational support. Changing environment requires flexibility in all these three aspects. Getting competitive advantage through people as a second of the twofold role of strategic human resource management means the system of employee development focused on flexibility of workforce skills, its motivation and organizational support. This could be very difficult to imitate simply because of the company organizational culture.

The Multiple Attributes of Professional Workers in Engineering Consulting and Design Services Firms

Abstract

Engineering Consulting and Design Services Firms (ECDSFs), as Professional Services Firms (PSFs), are organizations using the specialist knowledge of their professional employees to deliver expert services to their customers. In the case of companies from engineering consulting and design services industry the employees, namely the professional engineers, exhibit multiple strategic attributes: they may be seen as critical, or strategic assets, internal suppliers, strengths and threats. The key challenges facing engineering consulting and design services firms are to better manage knowledge and to extend the knowledge management to encompass all members of the extended enterprise, meaning both the organization itself and its customers. The purpose of this paper is to present a general overview of the engineering consulting and design industry, the distinctive, employees-related characteristics of the engineering consulting and design services firms, also analyze the different attributes of the professional employees within these firms.

Introduction

Strategic management models and concepts have been evolving in the manufacturing or traditional services field on a continuous basis since the mid twentieth century but the overwhelming majority of works in this field gives the impression that all the models and concepts are generally, fully, and identically applicable to all industries, in particular to professional services industry - the engineering consulting and design services belong to - despite its distinctive characteristics (Scott, 1998; Sheehan, 2005; Malhotra & Morris, 2009; von Nordenflycht, 2010; Gand, 2010). But, although classic models and concepts may provide some strategic insights, managers of engineering services firms run the risk of applying misleading advice.

Within the professional services firms sector, Engineering Consulting and Design Services Firms (ECDSFs) are among the least studied entities (Rimmer, 1991; Boxall & Steeneveld, 1999; Kreitl *et al.*, 2002; Ou & Chai, 2007; Kaiser & Ringlstetter, 2011) as far as their business management is concerned. Moreover, the strategic researchers have paid little attention to the competitive environment of these firms and their behaviour determined by the actions of the competitive forces.

The ECDSFs, among others of the same knowledge-based and professional type, are worthy of attention since they played and are still playing an important role in the economic growth of countries in the world today (Kaiser & Ringlstetter, 2011), and it is assumed they will be playing a major role in the new „knowledge economy”. They are considered to be one of the hallmarks of the knowledge-based economy (Bagdoniene *et al.*, 2007; Aslesen & Isaksen, 2007; Smedlund & Toivonen, 2007; Bolisani & Scarso, 2013). That they have been unnoticed so far, is probably because their work is invisible for the general public, it is a very heterogeneous sector because they operate in a variety of fields, they are obscure, small and hidden in statistics as services or, in the best case, as professional services firms in general.

The analysis in this paper is supported by the literature from Professional Services Firms (PSFs) field and a combination of the two major approaches in strategic management – Market-Based View and Resource-Based View –, by the extant literature on strategic analysis, also draws from author's own practicing experience of more than 20 years in the consulting and engineering design industry, both as a design engineer also as a general manager of an engineering company.

The present paper is qualitative and descriptive in nature, starting with a general overview on the engineering consulting and design services industry, on the specific characteristics of professional engineering consulting and design services firms, then analyzing different attributes of the professional employees within ECDSFs. The paper ends up with a set of conclusions and managerial implications, also with a set of proposed directions for further research on the industry. The paper aims at contributing to collective knowledge of employees' strategic management in these special companies.

Engineering consulting and design services industry – a general overview

Engineering consulting and design services, as highly specialized activities, represent a key knowledge-intensive professional services sector that emerged during a later phase of global industrial development when a need for innovative solutions and improved design for construction projects, plants layout and technologies became evident. It has been seen as the key factor in the generation and definition of new technologies in advanced industrial economies, also as a key, risk-reduction factor in undertaking technology transfer from developed to developing economies.

Engineering consulting and design services include a wide range of activities, essentially intellectual, which are combined to optimize investment decisions in terms of choice, design and project management and implementation. The markets for engineering consulting and design services are therefore primarily related to the growth of industries (metals, mining, power, oil & gas, heavy machinery, cement, pulp and paper, chemical, etc.) and construction sector, and businesses in this industry tend to fluctuate with the cycles of growth and stagnation in manufacturing and production in major markets. Demand of consulting and engineering design services is regularly characterized by uncertainty, unpredictability, severe fluctuations, stagnation, or even discontinuity over time, depending on the economic cycles and investment policies of the potential customers.

Engineering consulting and design services are generally defined as highly specialized activities of intellectual nature, which identify, select, organize and apply technical/technological engineering knowledge and even create knowledge for purposes of investments and production of client firms. The outputs of these services do not feed the final consumption in an economy but represent inputs for other activities and processes of their client firms. Since these services are inputs in the value creation processes of other firms, they also have an indirect effect on the quality and efficiency of these firms' outputs (Löwendahl, 2005). They are characterized by certain methods/methodologies of work and often by a multidisciplinary approach (engineering, architecture, economics, finance, project management, ecology). The activities of engineering companies are intangible and "intellectual" to the extent that they involve skilled labour in terms of consulting, design and evaluation. The ECDSFs may provide any or all of a number of services, from consultancy to engineering, and these services can be categorized according to the stage of a project for which the services are provided. As such, there are services related to formulation of the project, research operations which explore various technologies available for a specific operation resulting in the choice of product design and technology to be used, project evaluation, basic and detailed engineering and design, procurement of plant components, preparation of bid and contract documents, supervision of fabrication and construction, commissioning, testing and start-up of a new plant, training of personnel, services related to the operation and maintenance of an industrial facility.

The ECDSFs are normally active and operate in the following sectors (Stroe, 2013):

- Civil (roads, bridges, railways, tunnels, airports, dams, harbours, docks, social utility buildings, water supply & treatment plants, sewerage systems, irrigation systems, land planning and architecture, commercial buildings, communication systems, hydrology, geology, etc.)
- Industrial (metals, mining, power, heavy machinery, ship building, aircraft, oil & gas, cement, glass, chemical, pulp & paper, nuclear, manufacturing facilities, power transmission & distribution plants, etc.)
- Military (guns, ammunition, defence systems, special machines and communication systems, etc.)
- Environmental (environment protection systems and plants, waste disposal and recycling, management and use of natural resources, etc.)

Engineering consulting services are particularly defined as activities involved in the identification and organization of technological knowledge, relating its possibilities and uses to the context of physical, technological, economic, social, and environmental requirements. Depending on the stage of a project for which the services are provided, consulting services can be grouped into three categories:

- Pre-investment consulting services, rendered before the materialization of an investment, in order to identify, prepare and evaluate projects and select the appropriate technologies. These services are provided (typically for industrial projects) before the actual start of engineering design and fabrication and comprise techno-economic,

pre-feasibility, project feasibility and evaluation studies (including market, location, technological, economic, commercial, financial and environmental aspects), preparation of terms of reference and invitations for tender;

- Project implementation consulting services, rendered during the execution of the project. These services comprise project engineering (choice of appropriate technology and equipment, engineering surveys, drawings, plans, diagrams, bills of materials, specifications, tendering, bids evaluation and contracting, negotiation of financial, commercial, know-how agreements, information systems), supervision of project execution (procurement, fabrication, construction, erection, installation), and commissioning and start-up (including personnel training);
- Consulting services for management and production, rendered during the operation stage of an investment which has already been materialized. These services comprise technical assistance and troubleshooting during operation/production, production planning and control, cost control and optimization, product design and development, process improvement, quality control and maintenance systems, sales and inventory systems, expansion programmes, personnel training, management information and control systems, etc.

Engineering design services, rendered mainly during the project implementation stage (project engineering), are particularly defined as activities involved in the application of knowledge in order to develop data, diagrams, drawings, models, simulation and calculation reports, product specifications, materials and fabrication specifications, wear and tear parts specifications, painting, packing, labeling, and transport specifications, procurement specifications for special plant components and equipment, risk analysis reports, instructions for assembly, erection, installation, commissioning, start-up, operation, maintenance, with the purpose of implementing physical facilities for economic activities, and of optimizing and maintaining the existing facilities.

As ECDSFs belong to the PSFs category which on its turn is a sub-group of the Knowledge-Intensive Firms (KIFs) or Know-How Companies group, the mutual characteristics of these types of companies relevant for the present analysis are (Løwendahl, 2005; Alvesson, 1995, 2004; Scott, 1998; Kaiser & Ringlstetter, 2011):

- Their services are highly knowledge-intensive, delivered by people with higher education, and frequently closely linked to scientific knowledge development within the relevant area of expertise.
- Their services generally involve a high degree of customization in order to comply with the clients' unique problems, although some solutions can be standardized and used to different clients.
- Their services involve a high degree of discretionary effort and personal judgment by the experts delivering the services.
- Their services require substantial interaction with the client firm's staff. For the ECDSFs, the interaction with the client is most intense in the early definition stages, whereas after the project proposal has been accepted, the design process takes place largely within the ECDSFs.
- Their services are delivered within the constraints of professional norms of conduct.
- Selling professional services to potential clients is very different from the mass-marketing of consumer goods or services, as it involves both interaction with the client and a high degree of uncertainty in terms of what is actually going to be delivered.

The business of ECDSFs consists in creative, complex, and customized problem-solving activities for their customers. If the industrial production companies create value within a „value supply chain”, the ECDSFs create value by solving their clients' problems through the application of knowledge within a „value shop”. A value shop is an organization that creates value by solving the unique problems of its customers and not by producing physical outputs starting from physical inputs (Thompson, 1967; Stabell & Fjeldstad, 1998). A value shop sells its own competences and the customers buy solutions to their unique problems (Fjeldstad & Haanaes, 2001). The five generic categories of primary value shop activities are problem finding & acquisition, problem solving, choice, execution, and control and evaluation (Stabell & Fjeldstad, 1998). Rather than being embodied in the process or product, knowledge resides in experts and its application is customized based on clients' needs (Sheehan, 2005). The activities in these firms are performed by highly qualified professionals and the outcomes are provided by the mental efforts of the professional employees. Whereas nowadays knowledge plays a role in all firms, its role is distinctive in engineering consulting and design services firms. For ECDSFs both their inputs and outputs are intangible. For professional workers (engineers, designers, experts) knowledge is simultaneously an input, medium and output of their work (Newell *et al.*, 2002) and is characterized by a high degree of intangibility. Even though for ECDSFs the outputs are

in form of written studies, drawings, plans, specifications, calculation reports, instructions, which are tangible, storable and reusable, the intangibility of outputs refers in this case to the lack of customers' capability to physically feel and assess the outputs because of the lack of specialized knowledge and information. ECDSFs primarily create value through processes that require them to know more than their clients, either in terms of expertise or in terms of experience in similar problem-solving situations.

As stated previously, both the inputs and outputs of PSFs in general and ECDSFs in particular consist in knowledge. In case of ECDSFs the output knowledge is delivered to customers embedded in form of feasibility studies, planning studies, technological solutions, technical specifications, conceptual/preliminary/detail designs, workshop drawings, plans, calculations reports, diagrams, erection and installation drawings and instructions, operation and maintenance instructions, etc. The knowledge-intensivity and general nature of ECDSFs mean that the only real and significant inputs for the value creation in ECDSFs are the education, knowledge, qualifications, experience, expertise, skills, and capabilities of the professional engineers and designers that perform the engineering services by identifying, selecting, organizing, applying, and delivering the knowledge to the customers.

The key strategic resource of ECDSFs, or critical asset, is the human capital who holds and owns knowledge, competences, know-how, capabilities, skills, expertise and experience. The ECDSFs build their strengths through their highly qualified engineers and designers. The number of highly qualified professional employees (professional engineers, designers, technical experts) doing knowledge-based engineering work out of the total number of employees usually amounts to 80 – 85% for large-sized firms and 95 – 97% for medium and small-sized firms. Personnel costs represent about 65 – 70% of all costs of the company due to professionals hiring. The human beings in ECDSFs are the equivalent of machines and equipment in the production companies and recruitment of highly qualified and experienced engineers and designers is the counterpart of investment in new machines and equipment in a manufacturing company (Sveiby & Lloyd, 1987). The difference is in the availability of highly qualified workforce in the labour market as compared to availability of machines and equipment in the product market. Moreover, it is not enough to be available on the labour market, they have to be suitable for specific jobs, and then the company has to be able to attract them. Once the professional engineers have been employed, they are not like machines and cannot be allocated to a project unless they themselves see that project as the most interesting option available to them at that moment and appropriate for their expertise. Education and motivation of the professional engineers in ECDSFs is, simply said, the equivalent of what maintenance is for the existing machines and equipment in the manufacturing companies. Know-how on their "invisible" balance sheet is the equivalent of fixed assets are on the traditional balance sheet of industrial production firms (Sveiby & Lloyd, 1987).

In current times the services that the ECDSFs aim to deliver are increasingly coming under pressure because of a continually changing environment. Because of the technological developments, globalization and changing roles of competitors, blurred identity of the industry, commoditisation of design, loss of specialism, scarcity of professional workforce and the „war" for staffing with engineering knowledgeable people, and shifting patterns of customers' demand, the ECDSFs need to take notice of these changes and seek out viable strategies through which they are able to continue their endeavours to drive innovation and economic growth thus fulfilling their mission and the critical role that they play within the national context.

The strategic attributes of professional employees within ECDSFs

The most important issue challenging the engineering consulting and design services firms is the supply of knowledge and know-how required for their production processes, also the use of expertise, experience, and capabilities. The core of the resource base of the ECDSFs resides in the professional engineers employed and their ability to solve whatever problems the clients may want them to solve. The professionals bring to the firm their expertise, their experience, their skills in relationship building and maintenance, their professional reputation, their network of professional peer contacts, also their established relationships with past, present, and potential clients. This means professional employees may be seen as „suppliers" of knowledge, expertise, and experience to the ECDSFs. These „strategic resources" are critical to the survival and success of the firm, thus being a „strength" of the firm, but they are to a very large extent owned and controlled by the individuals rather than by the firm itself,

thus becoming a potential „threat” for the firm. In this case, the professional workers may be considered both a „strength” and a „threat” for the firm that employs them. Therefore, they have multiple attributes, namely „strategic assets”, „strength”, „internal suppliers”, and „threat” simultaneously, even though they are parts of the firm and not of firm’s external environment (Fig. 1).

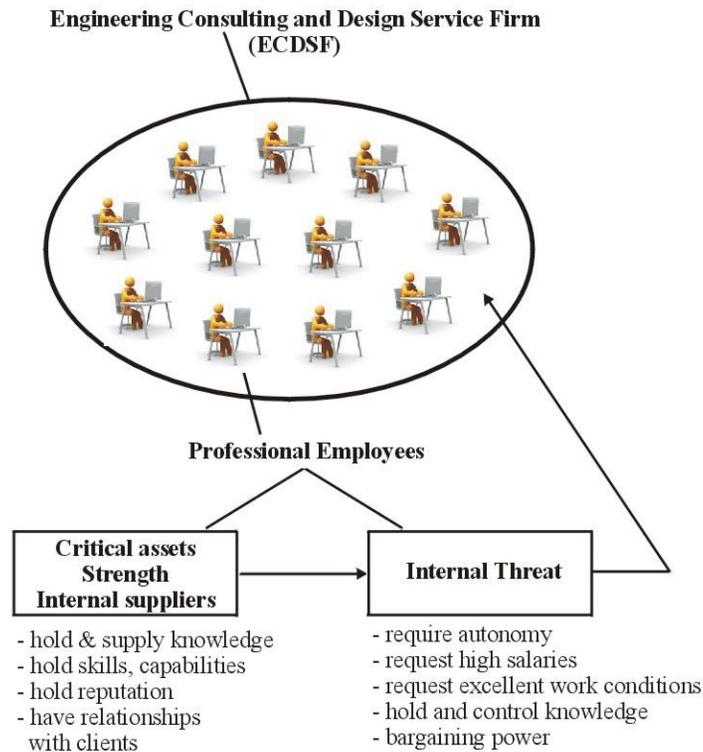

FIG. 1: THE ATTRIBUTES OF PROFESSIONAL EMPLOYEES IN AN ECDSF

In the case of ECDSFs one cannot speak of suppliers *per se*, as ECDSFs cannot purchase on a regular basis the essential inputs required for the production of their services. They mostly require highly qualified and experienced engineers and access to knowledge.

According to Porter, “... if strategy is stretched to include employees and organisational arrangements, it becomes virtually everything a company does or consist of. Not only does this complicate matters, but it obscures the chain of causality that runs from competitive environment to position to activates to employee skills and organisation.” (Porter, 1997:162-163).

As the most important resource of any organization is its human capital, the major and most valuable asset of any ECDSF is the highly trained and qualified professional workers (engineers, designers, technical experts) in the fields of engineering in which the company is active. They are called „critical assets” or „strategic assets” (Løwendahl, 2005). Such companies have all their value creation materialized through the mental efforts of their professionals during the process of organizing, applying, and delivering the knowledge to the customers.

It is argued that perhaps more than anything else, professional services firms in general and consulting and engineering design services firms in particular stand out from most other companies because of the extreme significance they place on the quality and motivation of their personnel (Alvesson, 1995; 2004). As Boxall and Steeneveld posit, „unless one thinks that neutron bombing will make no difference to business activity, the proposition

that the quality of human resource management critically affects firm performance is self-evident truth.” (Boxall & Steeneveld, 1999:443).

As Maister argues, PSFs in general – and ECDSFs in particular as a subgroup of PSFs – compete in two markets simultaneously: the “output market” for its services and the “input market” for attracting, motivating, and keeping its productive resources - the professional workforce (Maister, 1982; 1993). These two markets are closely related: loss in the latter may seriously affect the former. That is why it is of paramount importance for an ECDSF to optimally position itself both on the “output market” and “input market” between which there is a close relationship. The two primary processes in ECDSFs are recruiting and keeping the best professionals and winning the most interesting clients and projects. The two processes are not independent. If an ECDSF has the best experts in the world, it has a very strong position vis à vis competitors and is likely to win challenging projects. On the other hand, if an ECDSF is able to win the most interesting, challenging and rewarding contracts, it is then easy to attract the best professionals and if the probability of winning new interesting projects seems high, the professionals will remain with the firm. In case of ECDSFs the inflow and retention of qualified personnel is crucial (Fig. 2).

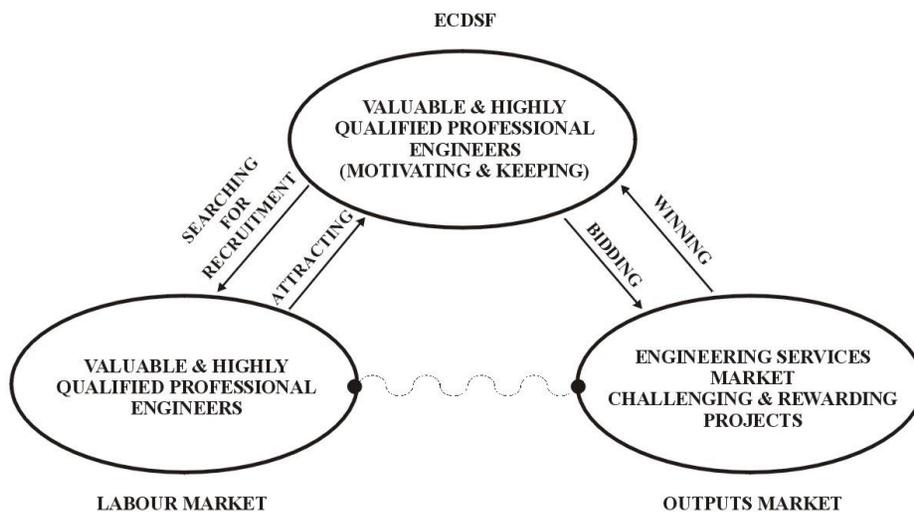

FIG. 2: INTERDEPENDENCY OF THE PRIMARY PROCESSES IN AN ECDSF

Drucker (cited in Kreiner & Mouritsen, 2003:233) emphasizes the dependence of organizations on personnel, and the strong bargaining position of large groups of knowledge workers and says that: “In knowledge work, the means of production is now owned by the knowledge workers. They are mobile and can work anywhere. They keep their résumés in their bottom drawer. Consequently, they must be managed as volunteers, not as employees. Only the unskilled need the employer more than the employer needs them”.

The highly qualified and skilled engineers and designers are the ones who enjoy the privilege of being the most powerful „suppliers” (of knowledge, expertise, experience, capabilities) to ECDSFs when the economy is booming or there is a high demand for their expertise in a certain engineering field the ECDSFs do not have in-house. In the same time, the professionals represent a „threat” to ECDSFs posing a financial risk on the firms because of their requests for higher compensation packages and work conditions. On the other hand, during economic slowdown, the bargaining power of employees and potential employees is very low. This is because the demand for their services reduces as the ECDSFs are facing difficulties in obtaining projects or are having few projects to handle with, thus not being able to fill the entire working capacity.

Thus, looking at what Porter refers to as the bargaining power of suppliers becomes a matter of the distribution of power between the ECDSF and the professional engineers they aim to attract, motivate and retain (Lorsch & Tierney, 2002). Mintzberg (1983) argues that in PSFs, the traditional top-down management approach is

difficult to implement. Professionals' striving for autonomy and the power they hold, as being the most valuable asset of the firm (Løwendahl, 2005), make it difficult for management to expect these professionals to do projects against their will. As indicated previously, the bargaining power of employees (engineers, designers) is significant as they essentially constitute the major asset base of the company, possessing a high degree of knowledge and informational power, also enjoying a high mobility. They can exert a high bargaining power, and thus a high financial risk for the firm, by demanding for better compensations and rewards which, if not granted, essentially determines the engineers to quit the company, with almost no loss of capabilities, and join a competitor ECDSF. This is because the biggest portion of costs is with professional staff's salaries and compensations. Or, some of the actual engineers and designers may leave the company and start their own business which will become a significant competitor for the "quitted company" because the employees leave together with their knowledge, expertise, reputation, and sometimes with a significant part of clients portfolio.

Although management is critical to ECDSFs success, the paradoxical fact is that professionals generally exhibit a high degree of autonomy. The fundamental reason for this lies in the reversed power structure of professional services firms, as the control over the most critical resources for value creation resides with the professionals rather than with owners of firm equity (Løwendahl, 2005).

This challenge might in fact be the most serious one an ECDSF may face with, as the attraction, motivation and retention of highly qualified, skilled, and experienced engineers determines the reputation of the company and quality of services that the company can provide. Therefore, an ECDSF must provide very good working conditions, attractive compensation packages and also challenging projects in order to attract and keep outstanding engineers because the „engineers are typically loyal to projects rather than to firms” (Løwendahl, 2005), and they primarily seek interesting and challenging projects.

One of the most fundamental strategic management challenges involves the management of competences and other intangible resources which are only partially controlled by the firm (Løwendahl, 2005). To the extent that the firm is highly dependent on competence and knowledge resources that are controlled by the professionals, the organization is highly vulnerable to the exit of these professionals. This is in line with the concern of Henry Michel, former CEO of engineering company Parsons Brinckerhoff, that “many people say that all our resources go down the lift in the evening after a day of work, and that the firm is then empty. That is why I see it as my primary concern to make sure that they want to come back tomorrow.” (Løwendahl, 2005:26). There is a strong reliance of engineering firms on their human resources, often on named individuals who are part of a built reputation of the respective firms (Fenton & Pettigrew, 2000). Departure of their key professional workers is the same as disinvestment in a manufacturing company (Sveiby & Lloyd, 1987). The most important threats are the groups of experienced employees leaving the company and establishing their own engineering services business. In this situation the managerial challenge to be addressed is to successfully motivate and retain the highly qualified and experienced engineers thus preventing them from leaving the company and becoming competitors. This requires carefully developed and successfully implemented human resources strategies within the company.

As to the generic strategies the ECDSFs can adopt, the general position is that they cannot follow cost leadership strategy because this is not a viable one. Since the greatest portion of an ECDSF's costs are personnel costs (compensation packages), if an ECDSF tries to reduce its staff or its wage bill, its quality of services will immediately fall and with it, clients will start defecting. Regarding the differentiation strategy, one can say that it is difficult for an ECDSF to sustain a differentiation strategy in a segment which is slipping in a cost-based competition, unless it is a local niche or specialist player. Differentiation in the world of ECDSFs does not simply mean having unique products. The products or methods and frameworks of ECDSFs are not particularly defensible. After a while, if they are successful, they will quickly be copied. Instead, differentiation means the quality of the intellectual capital, of the professional engineers of the firm embodied in its brand reputation. Another point of view for differentiation refers to the quality of relationships with the clients.

To conclude with, it is stated that while being the „critical, strategic assets” fostering the „strengths” of the firm, the most important „suppliers” for an engineering consulting and design company are the existing professional employees. In the same time, because of their bargaining power and vital dependency of the ECDSF on them, they may be seen also as a serious „threat” for the success or even survival of the firm.

Discussions and managerial implications

The managers of engineering consulting and design services firms rarely imagine the challenges that await them. Of course, projects schedules are tighter, products are getting more complex, quality and performance requirements are becoming higher, and budgets are shrinking. But these are all simply constraints and engineers are used to dealing with constraints. Strangely enough, the biggest challenges for the managers of ECDSFs today are not of technical but non-technical nature, which are often the stickiest. They need to take actions and pursue initiatives that will keep the engineering companies productive and competitive on the market.

It is concluded that the most important issue today for an engineering consulting and design firm is the suppliers of knowledge which are the highly specialized professional engineers and designers employed by the company or the professional engineers available or potentially available on the labour market. The most fundamental strategic management challenge involves the management of competences and other intangible resources, which are only partially controlled by the firm. The ECDSFs have to pay as much attention to maintaining and renewing its professional workforce as it does to winning new clients.

On the other hand, the professionals of the firm are simultaneously both „strength” of the firm generated by the quality of professionals who hold knowledge, skills and capabilities, and „threat” for the firm because of their bargaining power, vital dependency of the ECDSF on them as „suppliers”, autonomy and mobility.

Conclusions and directions for further research

The conducted theoretical analysis of suppliers in engineering consulting and design industry shows that ECDSFs in general are being faced with a number of challenges with strategical and managerial implications generated by the suppliers’ power and threat. The most critical seem to be the challenges arising from the input dependency the ECDSFs face with, i.e. the fact that the quality of the services rendered is directly affected by the professional engineers and designers working at the firm and how well the company manages to motivate and retain them while the “war” for staffing with engineering talents has already started.

As one can notice the conducted analysis referred to the engineering consulting and design firms in general (regardless the country, economic or industrial sector they operate in, firm’s history, firm’s culture, etc.) and revealed only the common features, challenges, and managerial implications resulting from the action of this competitive force. Therefore, detailed studies can be conducted at a global level by discussing the specificity of engineering consulting and design industry varying from country to country or, within a country, the firm’s specificity, history and culture.

These discussions and their conclusions may depend on a large set of variables and parameters to be taken into account, such as: the industrial development status of the country (highly industrialized, developing, low-developed, or under-developed country), the development perspectives of the country and influence of government policies, the historical evolution of the engineering consulting and design industry in the country, the market sector within the ECDSFs operate, the engineering disciplines in which they are specialized, the international linkage and technology transfer, the strategic approach and concentration on the development factors of the ECDSFs, the availability of professional workforce on the labour market and the actual “war” for staffing with engineering talents, globalization, deregulation, relaxation.

The discussions from the actual paper opened a research path and will be further developed and detailed by the author focusing on the Romanian industrial engineering consulting and design services companies providing professional engineering services for various industrial sectors (e.g. metals, mining, oil & gas, power, heavy machinery and ship building), both old companies established before 1990 and new companies established after 1990.

Turning Talent Strategy as a Successful Business Strategy for Malaysian Banking Industry: A Quantitative Analysis

Abstract

The aim of the study is to examine talent management practices in the Malaysian banking sector in an attempt to propose it as a business strategy. To realize this purpose, three variables, namely Talent Management Practices (TMP), Employee Value Proposition (EVP) and Talent Brand Strategy (TBS) are examined against 12 indicators of Malaysian banking talents by testifying their direct and indirect relationships. The five hypotheses of the study revealed that there are significant positive relationships between TMP, EVP and TBS, and EVP mediates the relationship between TMP and TBS in the Malaysian banking institutions. With these significant findings, it is suggested that Malaysian local banks regard talent strategy as a business strategy due to the acute shortage of banking talents in Malaysia by practicing talent management at all levels of organization. For that purpose, talent management needs to become a business strategy for Malaysian banks for their growth and profits.

Keywords: Talent Management, Employee Value, Talent Strategy, Intangible Assets

Introduction

According to the human source literature, talent management is a fundamental principle when creating an organization capable of learning, innovating and changing, and executing new processes. According to Blass (2007), talent management can be generally defined as additional management processes and opportunities that are made available to people who are talented in the organization. As businesses today are borderless within a global environment, talent is seen to be having the potential of a powerful source of competitive advantage. As such, talent requires finding, acquiring and retaining the right talent and these should have the full support of management that is necessary for sustainable competitiveness (Malaysia Productivity Corporation, 2009).

Additionally, according to Morton (2005), in order to effectively recruit and retain scarce labor, an organization needs to create and perpetually refine employee value proposition. On this basis, the researchers will identify the level of employee value proposition of talented people within the Malaysian banking sector. Specifically, according to Dell and Hickey (2002), employee value proposition makes clear to employees what extrinsic and intrinsic benefits they will expect in exchange for their labor, both now and in the future. To retain the best and brightest workforce, companies will need to optimize human capital through human resource and organization development strategy (Sweem, 2009). This means turning talent strategy to become a business strategy (Ong, 2009). On this premise, this study attempts to highlight the evolution of talent brand strategy and employee value proposition and subsequently the impact of talent management on talent brand strategy in the Malaysian banking industry. These three variables have linkage with strategic human resource so as to improve the business value of identifying, developing and retaining banking talents (Dewi, 2013). In fact, Malaysian banking industry has recorded a significant increase of turnover rate from barely 7.4% in 2012 to an alarming 13.3% in 2013 (Towers Watson, 2013). As such, the survey also reported that Malaysian banks are taking concerted efforts to improve their young bankers' intention to leave (Hussian et.al) with integrated talent development programs in order to attract, develop and retain their top banking talents into business strategy for strong growth and better profits (Guisse, 2009).

Objectives and Hypotheses of the Study

The general objective of this study is to examine the relationship between organizational differences (Talent Management Practices) and individual (or employee) effectiveness (Employee Value Proposition and Talent Brand Strategy).

Specifically, this study attempts to:

1. Examine the relationship between Talent Management Practices and Employee Value Proposition.
2. Examine the relationship between Talent Management Practices and Talent Brand Strategy.
3. Examine the relationship between Employee Value Proposition and Talent Brand Strategy.
4. Ascertain the mediating effect of Employee Value Proposition by examining its relationship with organizational differences, namely Talent Management Practices and Talent Brand Strategy.

This study attempts to test the following five hypotheses:

- H1: There is a positive relationship between Talent Management Practices and Employee Value Proposition
- H2: There is a positive relationship between Talent Management Practices and Talent Brand Strategy.
- H3: There is a positive relationship between Employee Value Proposition and Talent Brand Strategy.
- H4: Employee Value Proposition mediates the relationship between Talent Management Practices and Talent Brand Strategy.
- H5: Talent Management Practices and Talent Brand Strategy is mediated by Employee Value Proposition; hence proposing talent strategy to become a business strategy for Malaysian banking institutions.

Literature Review

The most effective talent management practices should be organization-specific and be responsive to the organization's unique business and its human capital context. Since this statement is based on D'Annunzio-Green et al. (2008), in ensuring individuals are given opportunities to develop skills and enhance their careers, talent management practices should encompass the whole of the talent management pipeline. For that to happen, Talent Management Practices must be completely aligned with an organization's mission, vision and values, and fully integrated into the organization's long term strategic planning. These aims are proposed by Hannum, Martineau and Reinelt (2007), in an in-depth review of designs for evaluating leadership development and using the evaluation to increase its impact on business.

The above needs were further reinforced by a subsequent report in August 2008 by McKinsey Malaysia & Co quoted as confirming talent to be an important Malaysian corporate resource over the next 20 years. As such, as demand goes up and supply of talent goes down, more and more Malaysian organizations will realize the importance of having talent strategy. In other words, companies should plan for management strategic focus on talent brand strategy and employee value proposition. This is essential to be done as there is acute shortage of banking talents in Malaysia (Taing, 2010) and supported by Zeti (2008) on the need for talent development in the Malaysian banking sector.

The researchers of this study are motivated to examine issues related to talent management practices in the Malaysian banking industry. This is done by examining Employee Value Proposition within an organization. These are important as Talent Management Practices form a powerful and systematic framework for understanding why employees differ in terms of their effectiveness in the banking industry (Boudreau & Ramstad, 2007; Lewis and Heckman, 2006; and O'Donnell, 2002). Since talent management practices is a business strategy and not a human resources strategy as proposed by Ong (2009), it can be generalized that the aim of talent management practices is to identify people in the organization who have more talent than others, and then to develop these people so that they become more experienced and competent, eventually able to play a greater part in the success of the organization, notably the competitive environment of the banking sector. Hence, proposing talent management as a business strategy becomes the thrust of this study.

Research Framework and Methodology

The research framework of this study comprises Talent Management Practices (TMP) as the independent variable, Employee Value Proposition (EVP) as the mediating variable, and Talent Brand Strategy (TBS) as the dependent variable. TMP consists of five dimensions, namely talent acquisition, competency management, leadership development, succession planning and performance management. TBS consists of three dimensions, namely

leadership brand, employee brand and working environment. EVP consists of four dimensions, namely EVP task, EVP contextual, EVP assignment specific and EVP sustainability. As a mediating variable, Employee Value Proposition is expected to mediate the relationship between Talent Management Practices and Talent Brand Strategy.

The population of this study consists of 1413 bank employees in the Malaysian banking industry. The population of bank employees will then be divided into I) Commercial Bank II) Development Financial Institution, and III) Islamic Bank. The differences between banks' employees and banks' category will determine the effects of Talent Management Practices on Employee Value Proposition in the Malaysian Banking industry. For this reason, the study has mailed 82 questionnaires to 1400 respondents with a return of 342 responses.

As this study employs the survey method, for data analysis, the authors use Structural Equation Modelling (SEM) as a model to test for direct and mediating effects, followed by Confirmatory Factor Analysis (CFA) to test for reliability and validity the survey instrument. After the questionnaires were collected, a running number was assigned to each individual respondent before the data were entered into the computer for analysis. The running number functions as an identification code for each respondent for the purpose of checking their responses if there was a problem with the quality and validity of data collected. The collected data were analyzed using the Statistical Package for the Social Sciences (SPSS) 17.0 program and Structural Equation Modeling (SEM).

Results and Discussions

In this section, a summary of the research findings are provided in relation to the four research objectives of this study.

Research Objective 1: The Relationship between Talent Management Practice and Employee Value Proposition

The first objective of this study is to examine the relationship between Talent Management Practices and Employee Value Proposition in Malaysian banks. The results indicated that Talent Management Practices were significantly positively related to Employee Value Proposition. This supports Dell and Hickey (2002) whose study confirmed that Employee Value Proposition is an important component that makes clear to employees 'what is in it for them'. In fact, Morton (2005, p 11) asserts that, 'Talent Management is integral to engaging employees in the organization'. This statement has brought together effective Talent Management Practices (TMP) and Employee Value Proposition (EVP) to the organization to make sure the organization can successfully acquire and retain the essential talents. As such, this study has confirmed on the significant relationship between TMP (that represents processes of talent program) and EVP (that represents retaining talented employees).

Going forward, Talent Management Practices were found to be positively related to Employee Value Proposition, thus supported the study by American Productivity and Quality Center (2004). The 2004 study found the followings: Talent Management components and accountabilities of senior leadership roles, finding talent (competency models, talent gaps, recruiting and assessment techniques), delivering performance (development performance management and retention) and talent metrics. This means that organizations differ with respect to some key issues such as level of management involvement, and the application of Talent Management components, processes and practices by different organizations. In addition, this study also reports that Talent Management Practices (TMP) focus on the most valued talent, such as having committed Chief Executive Officers and senior executives. This shows that the various Talent Management components can be coordinated into a larger system, as verified by the current study in which TMP represents the process system of talent development that is to be practiced and coordinated at all levels of the organization (Malaysia Productivity Corporation, 2009).

Uren (2011) identifies what talent management might need to look like in order to meet the future needs of an organization and the requirements of the upcoming generation of talented individuals. Samuel (2010) shared findings of how organizations can improve their performance by adopting a more strategic and personalized approach to talent management. Moreover, this is testified by the significant relationship between the system (TMP) and employees (EVP) in this study.

Interestingly, the findings of this study revealed that overall, the significance of the link between Talent Management Practices and Employee Value Proposition was found to favor large number of employees in Malaysian banks. The findings also indicated that employees in Malaysian banks possess a higher level of capability to function and

manage effectively Talent Management Practices as a system of talent development, and Employee Value Proposition in terms of valuing employees' commitment.

In summary, the first objective of the study was achieved as the results indicated that after examining the relationship between Talent Management Practices and Employee Value Proposition, Talent Management Practices were found to be significantly positively related to Employee Value Proposition.

Research Objective 2: The Relationship between Talent Management Practices and Talent Brand Strategy

The second objective of this study is to examine the relationship between Talent Management Practices and Talent Brand Strategy in relation to employees in Malaysian banks. The results indicated that after accounting for the relationship between Talent Management Practices and Talent Brand Strategy among employees in Malaysian banks, Talent Management Practices were found to be significantly positively related to Talent Brand Strategy. Therefore, the second objective of this study was also achieved.

The findings of this study supported the work of Gubman et al. (1998). This means that it provided empirical evidence with regards to connecting people to strategy to serve customers as this will build extraordinary results and having long term value. For this, they described the Hewitt alignment model of aligning strategy with talent and outcomes, and made the argument that there is a talent solution to many business problems; hence talent should become a business strategy. As documented earlier, after five years of extensive survey studies involving 120 companies by McKinsey & Company, Michael et al. (2001) highlighted the importance of ways to attract, develop and retain talent. As the present study testified that talented people are drawn to organizations that will help the organizations to develop new skills, knowledge and experience, it describes how Talent Management is integrated into the system and this integrative talent program can grow over time in the Malaysian banking sector. As such this requires an investment in talent (Zeti, 2008) due to the acute shortage of banking talents (Taing, 2010).

Therefore, the findings of this study indicated that attributes and behaviors support Malaysian banks' talent strategy. This is supported by a strong, significant relationship between Talent Management Practices (TMP) and Talent Brand Strategy (TBS). As such, the results of this study suggested that Malaysian banks need to be aware of the fundamentals of a corporate culture by diagnosing the organization's relationship with its employees and deciding on the form of management-employee relationship. This implies that banks need to have their own systematic talent program (TMP) and strategic leadership branding (TBS).

Research Objective 3: The Relationship between Employee Value Proposition and Talent Brand Strategy

The third objective of this study is to examine the relationship between the Employee Value Proposition and Talent Brand Strategy among the employees of Malaysian banks. As such, the findings of the study supported Dell and Hickey (2002) who empirically verified the relationship between Employee Value Proposition (EVP) and employer brand (Talent Brand Strategy). They found that the development of Employee Value Proposition is an important component of an employer brand. This is arguably a compelling approach when dealing with an impending labour crisis and this may as well be an effective strategy for enhancing the competitive positioning of an organization and its employer brand. At this point, this study validates on the need for Malaysian banks (organization as represented by TBS) to identify, recruit, develop and retain a pool of talents (employees as represented by EVP).

Likewise, this study supported the research by Morton (2005) regarding effective recruitment and retention of scarce employees. In other words, organizations that are able to successfully recruit and retain valued employees imply that they are committed to showing potential employees that they are valued, and opportunities exist for them. This means that effective employer branding (TBS) keeps current and potential employees continuously aware of the company's Employee Value Proposition (EVP) and its benefits. Therefore, this study has successfully achieved significant relationship between EVP and TBS, in the Malaysian banking sector. Thus, this study concludes with positive findings in relation to the relationship between Employee Value Proposition and Talent Brand Strategy. This also indicated that employees in Malaysian banks possess higher levels of capability to function and manage effectively Employee Value Proposition and Talent Brand Strategy.

In summary, the third objective of the study was achieved as the results indicated that after examining for the relationship between Employee Value Proposition and Talent Brand Strategy, it was found that the two variables were

significantly positively related to each other. The results also revealed a positive relationship between Employee Value Proposition and Talent Brand Strategy.

Research Objective 4: Mediating effect of Employee Value Proposition on the relationship between Talent Management Practices and Talent Brand Strategy

The fourth objective of this study was to examine the mediating effect of Employee Value Proposition on the relationship between Talent Management Practices and Talent Brand Strategy. The results revealed that Employee Value Proposition has partially mediated the relationship between Talent Management Practices and Talent Brand Strategy. This has fulfilled the fifth research objective of this study. One major implication of the inclusion of Employee Value Proposition in this study is to put to realization that an organization is responsible for the effects of Talent Management Practices and Talent Brand Strategy on employees.

The mediating role of Employee Value Proposition has been discussed by Dewi (2013) who clarified the process which subsequently led to employees and prospective employees to be attracted to remain with the organization. Her doctoral thesis also clarified about the role of organizational attractiveness and employee-based brand equity as these are important that will lead to the intention to apply, respond to job offers, and remain with the organization. As such, this study has validated on the need to have an integrated system of talent programs (TMP) involving recruitment, development and retention of talented employees (EVP) by Malaysian banks (TBS) due to the intensity of banking competitions (Zeti, 2008) and acute shortage of banking talents (Taing, 2010). This also calls for an integrated banking talent development (Syed et al., 2012).

With reference to Dell and Hickey (2002), employer branding establishes the identity of a company as an employer. Additionally, the results of this study are also in line with Morton (2005) as noted earlier on the significant relationship between TMP as a system of talent management, TBS as an organizational leadership branding and EVP as valuing the commitment of employees, with respect to the Malaysian banking sector. Based on these premises, the researcher has provided some evidence in relation to the mediating role of Employee Value Proposition on the relationship between Talent Management Practices and Talent Brand Strategy. In this regard, the present study was the first to examine the mediating effects of Employee Value Proposition on the relationship between Talent Management Practices and Talent Brand Strategy, by using employees of Malaysian banks.

In summary, the fourth objective of the study was achieved as the results revealed that Employee Value Proposition has partially mediated the relationship between Talent Management Practices and Talent Brand Strategy.

Concluding Remarks

Talent Management Practices (TMP) as a variable was found to be a significant predictor of Employee Value Proposition (EVP) and Talent Brand Strategy (TBS). This implies that TMP is an essential mechanism to generate creativity out of employees. This is important as TMP is able to facilitate EVP and TBS in Malaysian local banks. In addition, EVP in the empirical model is also found to mediate the relationship between TMP and TBS. In other words, EVP carries the influence of the TMP on TBS. This indicates that TMP will predispose bank employees in the Malaysian local banks to have effective EVP, which in turn will provoke TBS to develop talent systems, and enhance employers' commitment and employees' development. This study also provides critical insights by emphasizing and reinforcing on the importance of talent system for successful accomplishment of talent programs in Malaysian local banks. Particularly in this era of financial globalization, Bank Negara Malaysia has since 2008 been concerned about the acute shortage of banking talents; hence justifying the need for talent management to be a useful business strategy for banking businesses to remain competitive and profitable in the long run.

Psychological Aspects of the Business Development: Personality Factors of Successful Innovative Activity

Abstract

The present study focuses on personality factors which determine the effectiveness of the individual innovative activity. I analyzed relations between the most important psychological determinants of innovation: personal innovativeness, creativity, average intelligence, and novelty seeking. Obtained data showed that there is no significant correlation between innovativeness and creativity. This finding contradicts the idea that creativity and personal innovativeness closely relate to each other. But it looks as a partial support for the statement that creativity is the first step in future innovations. Performed analysis revealed no significant correlation between innovativeness and average intelligence. On the contrary, a correlation between personal innovativeness and novelty seeking was significantly positive ($r_s=.4$, $p<0.05$). Results of the study can be applied to various procedures and stages of the innovation management.

Introduction

Innovations are very important component of the successful entrepreneurship and business development. The effectiveness of the innovative process is determined by personal characteristics of those individuals who produce new ideas, as well as adopt and modify them. Creativity, personal innovativeness, intelligence, and novelty seeking could be regarded as the most important factors in this context.

Creativity

Creativity is often seen as an activity that is closely related with making new products in various forms. It is sometimes regarded as an ability to create a problem situation. In this context, creativity could be closely related not only with the creation of a new need or a problem situation, but also with construction of new knowledge criteria, which are important for the solution.

Schweizer (2006) regards creativity as a concept which comprises 2 processes: novelty finding and novelty producing. Novelty finding is closely related with individual need to cognition, as well as with abilities to remote associating, defocusing, and problem-solving. Novelty producing is determined by the following neurocognitive and personality traits: self-confidence, perseverance, egocentrism.

The investment theory sees creativity as an ability to “buy low and sell high” (Sternberg and Lubart, 1999). According to this theory, creativity is a confluence of six interrelated resources: intellectual abilities, knowledge, styles of thinking, personality, motivation, and environment.

Socio-cultural approach to the study of creativity regards it as the development of those ideas which could be generally accepted by others and society. Numerous empirical researches on creativity revealed also the role of the unconscious in creative process. It was shown that unconscious activity helps to select and evaluate prospective ideas (Ritter, van Baaren, and Dijksterhuis, 2012).

Crucial point in creativity research is an examination of its particular parameters. One of the most important quantitative characteristics of creativity is fluency (or productivity): the more ideas a person generates, the more unique ideas could be among them. One more quantitative parameter is flexibility (the number of semantic categories which generated ideas belong to). Originality (degree of novelty and innovative potential of new ideas) and feasibility (relevance of ideas to the topic or potential to be implemented in practical way) are the most important qualitative characteristics of creativity.

Innovativeness

An ability to adopt and apply new original novel ideas is closely related with innovativeness which is an important determinant of the development in various fields of human activity. According to the theory of diffusion of innovation, there are 5 categories (differentiated by the innovativeness level) which all people belong to: a) innovators, b) early adopters, c) early majority, d) late majority, and e) laggards (Rogers, 1995).

One of the most important points in the research on innovativeness is an exploration of particular ways of the new ideas adoption and their further implementation. Hirschman (1980) proposes two kinds of innovativeness: adoptive and vicarious. *Adoptive* innovativeness is closely related with the direct adoption of a new product, service, etc. It refers to the object. *Vicarious* innovativeness is a tendency of the subject to acquire new information about the new product, service etc. In contrary with adoptive innovativeness, it refers to a concept of the object. She also proposed one more kind of innovativeness: *use innovativeness* which is a person's ability to use the product, which had been adopted previously, to solve a new problem.

Some authors distinguish between cognitive and sensory innovativeness. Cognitive innovativeness is the subject's predisposition to be engaged in new activity and experiences, and to enjoy them. This activity stimulates cognitive abilities (Pearson, 1970). Sensory innovativeness is a tendency to "...enjoy internally generated experiences, such as fantasy and daydreaming and externally available thrilling and adventurous activities, such as sky diving" (Venkatraman and Price, 1990, p. 295).

Hirunyawipada and Paswan (2006) in their research classify consumer innovativeness into three levels of abstraction: global innovativeness, domain-specific innovativeness, and innovative behaviour.

Innovativeness could be also regarded as a determinant of innovative performance which depends on the productivity of person's interaction with the social environment. In this context innovative performance relates to particular personality characteristics: achievement needs, self-confidence, perseverance, assertiveness, proactivity, extraversion, and cooperativeness (Schweizer, 2006).

Novelty seeking

Novelty seeking is often regarded as a manifestation of individual's propensity to search for new information.

Hirschman (1980) distinguishes between two kinds of novelty seeking:

- seeking new information;
- varying choices among known stimuli.

She divides the concept of novelty seeking into two components. The first is an inherent novelty seeking that looks as a desire to find novel stimuli. It relates to accumulation of potentially useful knowledge and improvement of individual problem-solving skills. The second is an actualized novelty seeking which is associated with individual behaviour to acquire novel stimuli.

Manning, Bearden, and Madden (1995) consider consumer novelty seeking as a desire to look for new product information through mass media, direct product exposure, and various kinds of the commercial communications. Schweizer (2006) introduces the Novelty Generation Model (NGM) on novelty-seeking, creativity and innovative performance. In this model novelty seeking is regarded as the first stage of the whole novelty generation process which comprises also creativity and innovative performance. In accordance with the NGM, novelty seeking is determined by individual neurocognitive and personality traits: curiosity, excitability, impulsiveness, easily bored, disinhibition, and proactivity.

Intelligence and its relation with creativity

Intelligence is a basic psychological characteristic of an individual who is involved into innovation process. For many decades of scientific examination, it has been analyzed from various aspects. There are a lot of theoretical and experimental studies which provide us with definition and verified knowledge about this concept. On one hand, it could be regarded as an important determinant of innovation: to produce novel ideas and to implement them a person must have appropriate intellectual abilities. On the other hand, intensive intellectual activity could disrupt creativity and sometimes be rather harmful for the innovative performance. So, the role of intelligence in the individual innovative activity looks quite ambiguous. This ambiguity appears also in the relationship between intelligence and one of the most important determinant of innovation, - creativity. There are a lot of theories and models which examine this relation. In general, there are several approaches to the understanding of relations between them: intelligence and creativity look as components of each other; they are regarded as concepts which are associated with each other; they are independent from each other with partial overlapping; they are completely disjointed sets.

Classic in the psychology "threshold model" of the relationship between the mentioned concepts quite good explains not only this relation but also the ambiguous role of the intelligence in the context of individual innovative

activity (Guilford, 1967). In accordance with this model, complex relations between creativity and intelligence exist: a linear association below IQ=120 and weaker association or no association at all above this level.

Relation between creativity and innovativeness

In the scientific literature relationship between creativity and innovativeness has also been discussing. Creativity is closely related with production of new, original and potentially useful ideas. But these creative products could be regarded only as the first step in future innovations. Novel ideas and solutions become real innovations after their adoption and subsequent implementation.

Results of numerous studies examining the relation between creativity and innovativeness are quite controversial. For example, the relationship between these personal characteristics has been analyzed by Müseldili, Turan, and Erdil (2013). They found significant at the 0.01 level positive correlation between creativity and innovativeness. But Czop and Leszczynska (2009) found no statistically significant correlation between these characteristics of an individual who is involved into the innovation process.

Relation between innovativeness and novelty seeking

There are different approaches to the understanding of relationship between concepts of novelty seeking and innovativeness, too. Hirschman (1980) sees actualized novelty seeking and actualized innovativeness as different concepts. Actualized novelty seeking relates to the *behaviour* which focuses on an acquisition of new information. Actualized innovativeness refers to the direct acquisition of new information. In contrary, Venkatraman and Price (1990) see consumer innovativeness and novelty-seeking behaviour as the same concept. It can be seen as a need to get something new which is a predisposition to look for new products and services. It relates to the desire for new experiences and trying new products.

The main goal of the present study was an evaluation of correlations among main psychological factors which determine to a considerable degree the effectiveness of individual innovative activity: creativity, innovativeness, novelty seeking, and intelligence.

Method

Participants

The sample consisted of 145 students (92 males and 53 females) with ages ranging from 17 to 24 years ($M=19.45$, $SD=1.94$)

Materials

To measure creativity parameters Guilford's "Unusual uses" verbal test of creative thinking was used. In the course of individual creativity diagnostics, the following parameters were analyzed (Guilford, 1950):

- productivity (a total number of ideas proposed by a respondent);
- flexibility (a number of semantic categories participant's proposed ideas relate to);
- originality (singularity and statistical rarity of proposed ideas).

For the assessment of participants' innovativeness the Kirton Adaption – Innovation Inventory (KAI) was utilized (Kirton, 1989). That is a 32 item self-report scale. After processing of obtained data, a person can be located on a continuum ranging from highly adaptive to highly innovative. The average intelligence was assessed by Wonderlic Test. I assessed the degree of the novelty seeking by using the Zuckerman Sensation Seeking Scale (Zuckerman, 1979).

Procedure

Firstly, participants were given Guilford's verbal test of creative thinking "Unusual uses". They had to think up during assigned 6 minutes a maximum number of all possible applications of wooden ruler. Afterwards, they answered questions of the Kirton Adaption – Innovation Inventory and the Zuckerman Sensation Seeking Scale. Finally, they performed Wonderlic Test.

Results

All transcripts which had been taken from respondents were processed by the experimentalist assistant.

The most difficult and important point was assessment of participants' originality scores. It was done by using a five-point scale from not original (1) to highly original (5) in accordance with tables provided by the test "Unusual uses". Afterwards, a correlation analysis on the whole set of obtained data was performed. Results of the analysis are presented in Table 1.

TABLE 1: DESCRIPTIVE STATISTICS AND CORRELATIONS

Characteristics	M	SD	1	2	3	4	5	6
1.Fluency	12.15	4.12	1.0	.7**	.06	.19	.2	.35*
2.Flexibility	9.66	3.47		1.0	.14	.09	.31	.22
3.Originality	3.37	1.25			1.0	.08	.06	.08
4.Innovativeness	110.15	19.38				1.0	.4*	-.1
5. Novelty seeking	9.81	2.69					1.0	.11
6.Intelligence	28.74	5.31						1.0

**Significant at the 0.01 level

*Significant at the 0.05 level

As can be seen, there is no significant correlation between the most important personality factors of innovation: innovativeness and creativity. I found no significant correlation between innovativeness and average intelligence, too. On the contrary, a correlation between personal innovativeness and novelty seeking was significantly positive ($r_s = 0.4$, $p < 0.05$). It is also shown in the Table 1, that the fluency of participants' creative performance has positive significant relation with their intelligence ($r_s = .35$, $p < 0.05$) and flexibility ($r_s = 0.7$, $p < 0.01$).

Discussion

The main objective of the study was assessment of relations among different psychological characteristics of a person in the context of his/her innovative activity. Quite high significant correlation between fluency and flexibility of participants' creative performance has the evident explanation: the more ideas were generated by an individual (fluency), the more semantic categories would be related with this big amount of ideas (flexibility). Such a high significant correlation between fluency and flexibility takes place often in the assessment of creativity using "Unusual uses" test.

A significant correlation between fluency and average intelligence with the lack of significance of a correlation between flexibility and intelligence support the idea that rational thinking relates to the producing of quite big amount of similar ideas with low variety. The higher score of intelligence a person has, the more similar and semantically homogeneous ideas are tended to be produced by him/her. The analysis of obtained data showed that there is no significant correlation between intelligence and originality of participants' creative performance. Taking into account that originality was assessed in accordance with psychometric principle, this result means that one's average intelligence does not relates to statistical rarity of his/her ideas and divergent thinking, as well. Originality is often regarded as the most important parameter of individual creativity. So, the mentioned result could be seen as a

partial support for the idea that intelligence and creativity don't associate with each other. At the same time, it might be a promising point for future research on the topic to examine in more detail relations between particular components of the intelligence and originality of individual creative performance.

I found no significant correlation between innovativeness and average intelligence, too. This result looks as an argument which does not support the idea that cognitive processes are the most important components of the individual innovative activity. It could be also regarded as a ground to examine concept "cognitive innovativeness" in more detail. (Pearson, 1970). The mentioned finding also statistically supports the idea that individuals with high score of their intelligence are quite often not successful in the implementation of novel ideas.

It was shown in the introduction section that differences and similarities between novelty seeking and innovativeness is a quite controversial point in the research on psychological aspects of innovation (Hirschman, 1980; Venkatraman and Price, 1990). The analysis of the obtained data in the study revealed a significant positive correlation between these personal characteristics. This result looks as a support for the statement that novelty seeking and innovativeness are the same concept. But taking into account that this topic is very important and at the same time controversial, the point of relationship between novelty seeking and innovativeness needs to be examined in future research in more detail.

This study presents an empirically validated model of the relationship among psychological factors of successful innovation. It can have managerial and entrepreneur applications. Results of the present study could be also used for more profound understanding of the concepts of creativity, innovativeness, and novelty seeking. Revealed relations among some of the analyzed psychological characteristics could be used in developing of methods for enhancing the individual creativity and innovativeness, as well as in various procedures and stages of innovation management.

Relationship between leadership and variable compensation with psychological empowerment factors and the effectiveness of mid-level employees of Mexico's largest

Abstract

This research shows an analysis of literature regarding the factors affecting the employee effectiveness and the existence of this relationship in Mexican organizations. The relevance of this work is that the labor market has been studied through years, but for developing countries like Mexico there is still plenty to investigate. The hypothesis of this paper shows the relationship of the factors: Transformational Leadership and Variable Compensation, with psychological empowerment and finally with employee effectiveness. To test that, we developed a survey applied to mid-level employees of Mexican enterprises in the north east of Mexico in which we used statistics of structural equation models. The results show a strong impact on these factors, except for the relationship with the variable compensation.

Keywords: Leadership, empowerment, variable compensation, mid-level employees, Mexico

Introduction

This study arises of the organizations' need to be competitive and innovative in the economically aggressive and changing context in which we live today. In order to fulfill the current requirements with a well-organized system of business management, it is essential to have organizational effectiveness. Thus, a large amount of scholars in human capital management area have worried about finding the best ways to get it. According to Estrada (2006), organizations must adapt to increasingly competitive markets, which led them to become flexible and dynamic. People in senior management level show their concern by maximizing productivity and competitiveness.

To meet these expectations new ways to motivate the human capital have arrived; today, an organization seeking to survive should focus on achieving a reasonable level of commitment among employees. Studies tell that psychological empowerment promotes an increased performance. It generates commitment and simultaneously produces benefits in the long term for the mid-level employees within the organizational hierarchy (Schein, 1973).

Taplin & Winterton (2007) mention leadership style as another variable to consider in the personnel motivation. The leadership style is considered a force that can determine the organizational competitiveness in a global economy (Bass, 1999). It has been found in different studies that there are already more organizations that include the variable compensation in its payment system, which means a part of the salary is based on achieving planned results (Mañana, 2010). Santone, Sigler & Britt (1993) comment that many researchers found evidence of the important role played by the variable compensation to align the interests of employees with shareholders. Based on the above statements, leadership style and the psychological empowerment with the variable compensation acquire increasing relevance in the organizations.

It is important to emphasize that in Mexican companies there are a few studies about it (Mollic, 2011). For example, Rodríguez & Castillo (2009) comment that the labor market has been studied through the years, but for developing countries like Mexico there is plenty to investigate. For this paper it is important to consider the following research question: *Is psychological empowerment positively related with leadership style and variable compensation as the effectiveness of the mid-level employee in Mexican large firms?*

The objective of this work is to identify whether psychological empowerment is positively related with leadership style and variable compensation in the effectiveness of the mid-level employee in Mexican large firms measured through its two components: attitudinal results and performance results. In order to answer the question the following general research hypothesis is formulated: It is proposed that psychological empowerment is positively related with leadership style and variable compensation with the effectiveness of the mid-level employee in Mexican large firms.

This study is justified due to the international environs in which these organizations work, and thus have to be effective in order to remain competitive. The organizational effectiveness should be measured, and the employee

performance level at work is essential to achieve it. Therefore, it is necessary to explore new approaches on human resources that allow sustained growth in the long term; thus, human capital represents the resource to get it. As practical justification, this research analyzes the effectiveness of mid-level employees of the companies in Mexico; because there are a few studies done in Mexico and most of them may not apply in any social context (Davila & Elvira, 2007).

Literature review

Robbins (2004) revealed that the most important reasons why people want to stay in organizations are the quality of the working environment and the design of their jobs. Hence, it is important to develop the skills to manage people for managers and organization leaders. Continuing with Pfeffer (2010), putting people first is a common characteristic of successful companies, but this is not consistent with current competitiveness. In proactive and motivational leadership, plus highly committed employees are basic, and psychological empowerment, teamwork, and an effective variable compensation system that recognizes the good performance among mid-level employees are the sources to achieve them.

1. Psychological Empowerment.

Raquib, Anantharaman, Cyril Eze & Murad (2010) assumed that new skills and experiences can be a key factor to materialize the empowerment in organizations. In previous studies, Conger & Kanungo (1988) identified four conditions of the psychological empowerment: leader influence, organizational factors, rewards system and job characteristics. Thomas & Velthouse (1990) describe the psychological empowerment as increased intrinsic motivation in the performance of the function based on four concepts: task significance, competence, self-determination and impact. Spreitzer (1995) defines it as an internal motivation that comes in four cognitions types that guide the individual approach in the performance of its duties.

Psychological empowerment is conceptualized in this study as the internal state that reaches the employee to assess its social reality in the organization. It is related to the employee effectiveness, and the psychological empowerment in a mediating role that can be considered as an administrative tool which may improve the effectiveness to generate a positive and proactive attitude in employees, according to Mendoza & Flores (2006). Liu, Chiu & Fellows (2007) comment that empowerment enhances efficacy, through commitment and motivation in mid-level employees. Psychological empowerment is also presented as a second-order factor; thus, being a general approach for representing constructs consisting of several highly related domains (Chen, West, & Sousa, 2006).

2. Leadership style.

The strong pressures of today's competitive environment generate the need for constant risks; therefore, a leadership style insisting on compliance and rules enforcement does not apply (Sapna, 2010). A key element in any company success is the motivation of the executive team to reach the staff's full potential. This team should also provide guidance to generate the ownership of problems in order to benefit the organization (Bennet, 2009). Several authors have written about the different styles of leadership. Transformational leadership being part of this study, it is defined by Pieterse, Knippenberg, Schippers & Stam (2010) as a way to change the followers' moral, ideals, interests and values, encouraging them to perform effectively. It is based on a social contract instead of an economic one (Ismail, Mohamad, Mohamed, Rafiuddin and Zhen, 2010).

The relationship between leadership style and employees has a significant impact on the level of commitment. The manager's ability to provide a strong leadership produces a positive impact on employee's job satisfaction (Danish and Usman, 2010). According to Prokopenko (2009), the efficient management and the human resources development is essential to the employee effectiveness focused on improved productivity and competitiveness.

3. Variable compensation.

Kanter (1986) commented that there was a movement encouraging companies to switch to a payment system with fixed low base salary, with a high likelihood of variable earnings controlling fixed costs and motivating good performance in order to maintain an adequate the competitiveness level. Javed et al. (2010) suggest emphasizing mixed

payment for their impact on workers morale. Madhani (2009) notes that payment is a powerful communicator of goals across all levels in the organization; therefore, firms working to be successful should share the success with their employees. Other studies of Giancola (2010) report that compensation experts have said that job positions are already considered obsolete, forcing the development of new compensation systems. The same Carpenter & Sanders (2002) suggest that if payment is linked to performance probably a change can happen in the employees' attitude by letting them produce more quality and quantity.

The variable compensation is related to effectiveness in different ways: Danish & Usman (2010) say, adequate rewards program is a key factor to maintain the high level commitment in workers (Andrew & Kent, 2007). Madhani (2009) in his paper wrote that payment is a strong communicator between an organization and its employees, and the success or failure of the payment system can affect the overall success of the organization. Ghazzawi & Smith (2009) made an annual salary survey; nearly 600 respondents said payment is the most important motivator in relation to job satisfaction.

4. Employee Effectiveness.

Several definitions were found about the dependent variable: employee effectiveness. Locke (1968) identified it as the intentions of subjects performing tasks. Treated as the objectives or goals that people seek to do their jobs are determiners of the effort level used in their performance. The formal goals increase the performance level of workers in relation to situations where no clear objectives are offered. If the goals are specific, the motivating behavior will be effective. To achieve effectiveness in organizations employee effectiveness is required in order to fulfill its goals and objectives.

There are several models that can be useful in achieving effectiveness; one of them is the goal model in which effectiveness is measured based on the compliance results (Henri, 2004); and the model systems emphasizes the ways to get results (Yuchtman & Seashore, 1967), inter alia. Continuing with the definitions of the construct, Cascio (2007) mentions that performance refers to the way an employee accomplishes the assigned tasks. Kuvaas & Dysvik (2009) establish it as a measure of the degree in which a goal is achieved. Locke & Latham (2002) define the performance by the way an employee achieves assigned tasks (meeting goals) and based on the clarity of them (Locke, 1968).

In this study, the variable employee effectiveness is defined as the degree in which goals and objectives are achieved. It is measured from the attitudinal and performance results.

a) Attitudinal results are positive or negative evaluations that employees have about certain aspects of their work environment; they could be measured by the following parameters: job satisfaction, organizational commitment and teamwork.

- **Job satisfaction.** Shahzad, Hussain, Bashir, Chishti & Nasir (2011), consider job satisfaction as the difference between what the employee thinks he deserves and what actually he gets for his work. This is an attitude response of the employee towards the organization affecting the decision to stay with the company and the effort amount applied in job performance (Ghazzawi & Smith, 2009). Sarwar & Khalid (2011) define it as the pleasurable emotional state of an employee considering its obligations, its supervisor and organization. Regarding the relationship of this variable, researchers Malik, Danish & Usman (2010) found that when workers feel that their effort and performance are recognized and valued, it increases their level of motivation and commitment.
- **Organizational commitment.** Giancola (2010) states that Towers Watson defines employee engagement as a desire to contribute to the company's success. Blau & Boal (1987) see the organizational commitment as the attitude towards work of an employee who sympathizes with the goals and the company. Zhu, Douglas & Avolio (2004) said it is the involvement of individuals with the company. Ismail et al. (2011) separate the organizational commitment into three factors: acceptance of established goals; willingness to exert effort on behalf of the company; strong motivation to stay in it. Referring to the relationship of the variable commitment, Siders, George & Dharwadkar (2001) analyzed that the employees committed to their superiors have a better performance than the less committed. Taplin & Winterton (2007) indicate that leadership style has a direct impact on employee engagement. Bycio, Hackett & Allen (1995) found that transformational leadership could have an impact on workers results to make them feel more engaged.

- **Teamwork.** Campbell (2010) defines performance management as a process that involves its employees as part of the team to improve effectiveness in organizations. To Hoyos, Restrepo & Estrada (2005) training and motivating programs should be implemented as drivers of permanent change in people, encouraging teamwork as a constant to achieve planned results. A study of human resources trends conducted by AON Consulting (2002) shows results that are of interest to this study. They relate to the new personnel profile that it is requiring: greater emphasis on productivity and teamwork.

b) **Performance results** are employees' behaviors evaluated by how well they manage tasks, considered as the achievement measure of a goal, through clarity and fulfillment of goals that strengthen job performance.

- **Approach based on goals clarity.** It is measured by defining clear and precise goals that facilitate understanding (Locke & Latham, 2002).
- **Approach based on goals achievement.** Locke (1968) states that the goals must be clear, specific, challenging, measurable, achievable, and there should be always some sort of feedback. The goals and tactical plans, that is to say plans designed to support the implementation of strategic plans are those responsible of the mid-level managers, such as functional unit heads. Tactical plans focus on the activities that must be performed to meet the strategic plan established by senior management (Chiavenato, 2001). These authors comment that employee participation in setting goals can cause favorable attitudes, such as satisfaction, performance improvement and commitment.

Considering the reviewed literature and gaps of knowledge mentioned in this article, the following graphical model is proposed ("Fig. 1"):

Methods

The population of this study is represented by the total employees working in Mexican companies located in Nuevo León state of Mexico, which is 548,587 employees classified by economic activity; 48% manufacturing industry, including construction; and 16% business services, transportation and education (IMSS, 2012), see "Tab. 1". The population corresponds to the mid-level employees according to experts representing 18% of all employees in an organization. The sample size was estimated in 136 respondents using the formula for calculating the sample size (Rositas and Mendoza, 2009).

TABLE 1: EMPLOYEES OF COMPANIES IN NUEVO LEÓN, BY ECONOMIC ACTIVITY

Economic Activity	Employees	%
Manufacturing Industry	235,177	42.9
Electric Industry	2,264	0.4
Business Services	65,966	12.0
Transportation	9,583	1.7

A questionnaire was constructed with 65 questions (items) in 8 parts using a Likert scale of 7 levels; from strongly disagree to strongly agree (Sanchez, 1998). The Cronbach's alpha of each variable by items model was calculated in order to establish the reliability of the instrument. The results shown in “Tab. 2” are above 0.70, which is the minimum level considered acceptable for the Cronbach's alpha.

Results

The Measurement Model (Outer Model)

The results of the analysis carried out are in “Tab. 3”, applying the algorithm software using the SmartPLS (Ringle, Wende & Will, 2005), it generates the average variance extracted (AVE) and composite reliability applicable to the reflective indicators (Chin, 1998). The measurement model recommends eliminating reflective indicators with smaller loads than 0.50, by doing this it allows increasing reliability without affecting the validity taking into account the criterion of Chin (1998) suggesting that the indicators must have a minimum of 0.50. Churchill (1979) recommends to eliminate reflective indicators if their charges are lower than 0.40. This happens without neglecting the fact that there are at least 3 indicators per variable (Chin, 1998; Churchill, 1979) therefore, six indicators were chosen in the development of the instrument.

TABLE 3: RESULTS FROM THE MEASUREMENT ANALYSIS OF THE ITEMS MODEL

Block	AVE	Composite Reliability
--------------	------------	------------------------------

Transformational Leadership	0.671928	0.924510
Variable Compensation	0.513482	0.892877
Psychological Empowerment	0.453293	0.932711
Attitudinal Results	0.501215	0.927502
Performance Results	0.535615	0.899172

Source: Developed by the author

The variable that contributes the most is transformational leadership with 67.19% (Tab. 3). The AVE is an indicator of reliability, a value of 0.50 or greater indicates a sufficient degree of convergent validity, which means the latent variable explains more than half of the variance of its indicators (Hair, Ringle, & Sarstedt, 2011). The analysis result shows the AVE is above the acceptable 0.50 meaning 53.51% of the variance of the indicators that form the latent variable (Chin, 1998).

Independently, psychological empowerment does not exceed this percentage by reflecting a limitation in the measurement. Additionally, we have internal consistency reliability measured with composite reliability that exceeds the value of 0.70 in all variables considered as acceptable.

Discriminant validity refers to two conceptually different concepts. They must be sufficiently different to show when the capacity of each latent variable explain their manifest variables greater than the correlations between the latent variable and the others. To measure discriminant validity in the technique of structural equation modeling, there are two criteria by Fornell and Larcker (1981) cited in Henseler et al. (2009):

a) The Fornell-Larcker criterion postulates that a latent variable shares more variance with its indicators than with any other latent variable; this means that the AVE of each variable must be greater than its squared correlation with other latent variable to test, if the criterion meets. The diagonal line of “Tab. 4” show the square root of AVE values for each of the constructs is shown. This criterion is meeting as Hulland (1999) suggests.

TABLE 4: CORRELATED LATENT VARIABLES

Variable	VC	PE	TL	AO	PO
Variable Compensation VC	0.716577				
Psychological Empowerment PE	0.177666	0.673270			
Transformational Leadership TL	0.044435	0.409460	0.819712		
Attitudinal Results AR	-0.030513	0.645883	0.541613	0.707965	
Performance Results PR	0.172602	0.517111	0.513917	0.612622	0.731857

Source: Developed by the author.

b) Cross-Loadings criterion refers that the loading of each indicator should be greater with its own variable than with any other variables in the model (Chin, 1998). The criterion was fulfilled.

The Structural Model (Inner Model)

The SmartPLS 2.0 (Ringle et al., 2005) method consists of an iterative process to estimate weights producing components of the latent variable model. In “Fig. 2” the betas of relationships and the value of R² are estimated for each of the variables. The R² represents the explanation of the independent variables on the dependent variable.

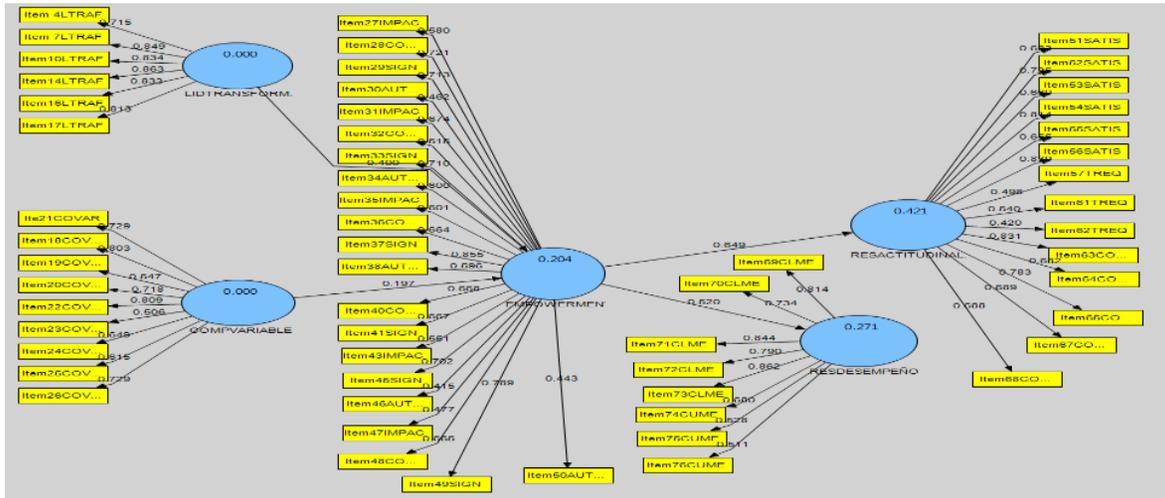

FIG. 2: STRUCTURAL EQUATION MODELS ALGORITHM (SMARTPLS 2.0)

Source: Developed by the author.

“Fig. 2” shows that the structural model the R^2 estimated average of 0.30 (Tab. 5) so the model has a relatively moderate explanation of how the independent variables explain the dependent variable confirmed in the article by Hair, Ringle, & Sarstedt (2011). They stated that R^2 values for endogenous latent variables are equivalent to moderate values between 0.33 and 0.19. The authors mention that endogenous latent variables explained by one or two exogenous variables moderate values are accepted.

Simulation analysis (bootstrapping) of the structural equation model (SmartPLS 2.0) was performed, as this model does not assume that data is normally distributed, applying nonparametric bootstrapping involves repeated random samples replacing the original sample, thus to obtain the standard error for the hypothesis test. In addition the value of the t student (p value) that helps measure the significance of the relationships is calculated (“Tab. 6”). Moreover, the individual path coefficients from the structural equation model can be understood as standardized betas. Those betas which are not significant or have an opposite sign to the direction of the hypothesis are not supported while those with significant values empirically support the proposed cause and effect. The results of the structural model show standardized betas, t student values and significance (“Tab. 6”).

For the purpose of this study PLS technique (Partial Least Square) was selected to test the research hypothesis. The analysis was conducted exploring the structural equation model using the SmartPLS 2.0 software developed by Ringle et al. (2005), presented in “Fig. 2”. In this analysis of measurements, existing validity of the constructs for the above reliability indicators can be seen (McLean & Gray, 1998). Also, it confirms the hypothesis relationships are significant as shown in “Tab. 6”, except for the relationship between variable compensation and psychological empowerment:

- Hypothesis 1, there is positive relationship between transformational leadership and psychological empowerment variables; the results of the model estimated ($b = .400$, $p < .001$).
- Hypothesis 2, there is a positive relationship between the variable compensation and psychological empowerment, with estimated result ($b = .197$, $p = n. s.$).
- Hypothesis 3, positive relationship between psychological empowerment variables with employee effectiveness through attitudinal results with estimated result ($b = .649$, $p < .001$) and
- Hypothesis 4 is presented with the performance results ($b = .520$, $p < .001$). Moreover, the values of *t student* (*p value*) that exceed the critical limit of 2.0 can be considered statistically significant (Chin, 1998).

The expectations of the objectives and contributions of this study is that the model has a predictive behavior of the endogenous construct employee effectiveness in two results: attitudinal and performance. CV Red measurement of a given endogenous latent construct should show higher values at 0.00 and in this study are greater than 0.00 confirming the predictive relevance of this research model (*Q2*).

Discussion

The results show that the research question is answered and the objective was met. Most hypothesis are supported (hypothesis 1, 3 and 4), except hypothesis 2 which found no support. These results are confirmed by research Avolio, Zhu, Koh & Batia (2004), which demonstrated that employees empowered by a transformational leadership, are more likely to respond with higher levels of commitment to their organizations. Ismail et al., (2011) also confirm psychological empowerment (PE) as a mediating variable between transformational leadership and organizational commitment, which is part of the model of this research on the attitudinal results. The PE is positively associated with the mid-level employee effectiveness through attitudinal results (hypothesis 3) and performance results (hypothesis 4). Regarding Hypothesis 2, there is not a positive relationship between the variable compensation and the PE. This hypothesis is rejected although several authors ensure that the variable compensation (VC) has a positive and significant impact in both job satisfaction, and productivity, and even appearing as a predictor of performance variable (Vlachos, 2008).

Rodriguez & Castillo (2009) state that wages respond strongly to productivity. The rejection of hypothesis 2 could arise from different reasons; among them could be the lack of adequate understanding of the concept by the participant mid-level employees. Another reason may be that the present investigation is aimed at large companies

that commonly meet the objectives; therefore, employees safely receive this compensation. A third reason may be that Mexican people prefer the security of a fixed salary, where it does not matter whether or not the goals are met, they have insured incomes, and do not pay attention to the variable compensation.

Conclusions

From an academic perspective, the hypotheses proposed by the model have been supported. The fact that the relationship of leadership with the PE shows a positive relationship reinforces the importance of studying this relationship in the Mexican context. Moreover, the relationship PE with VC was no significant, showing that the VC is not recognized as relevant by Mexican middle level employees to their work effectiveness. This research was made in context of Mexican mid-level employees as theoretical documented contribution within the fourth block of Whetten's (1989) theory development (who, where and when).

The relationship between VC and PE was rejected in this study. Although, several authors found the variable compensation has a positive and significant impact on workers performance, job satisfaction (attitudinal outcome) and productivity on a study made in Pakistan banks (Malik, Danish & Usman, 2010). In Vlachos (2008) empirical analysis on food manufacturing business in Greece, it was also found the variable compensation being a significant predictor of variable performance. According to these results, the managers in large organizations in Mexican context can promote transformational leadership as the key factor to generate psychological empowerment, or impact positive beliefs, significance, autonomy and competence in mid-level employees performing their jobs. These findings can be used as a guide to improve leadership style in Mexican organizations (Ismail et al., 2011).

Furthermore, if PE is promoted in organization, it increases the mid-level employee effectiveness in its attitudinal and performance results. Based on the results of mid-level employees working in large industries in the Mexican context, a model is proposed that can be used by Human Capital Directors to create the necessary guidelines to improve the results of employees, and upgrade the effectiveness of leadership in their organizations, among other proposals.

Knowledge transfer & development across entrepreneurial generations: Evidence from historical family-owned SMEs

Abstract

This study aimed at investigating what specific dimensions of the repeated entrepreneurial succession processes can mostly affect the mode of transferring knowledge from one generation to another. Indeed we consider this latter as a critical variable in order to foster the longevity of family SMEs.

With respect to the prevailing literature, we rather propose to extend the state of knowledge on generational transition shifting attention to a number of entrepreneurial generations, for a better understanding of what originates the longevity of the analyzed firms.

We adopt a qualitative approach. A longitudinal analysis has been conducted on six exemplary cases of small-medium sized family firms which are over a hundred years old. They belong to the industrial sector and they are situated in central Italy.

In terms of theoretical contribution, our research contributed at enriching the conceptual framework that can be used when studying the dynamics of long-lived family SMEs.

Keywords: Knowledge transfer, Entrepreneurial generations, Family SMEs

1. Introduction

Studies focusing on entrepreneurial succession within family SMEs generally circumscribe their analysis to a single generational passage. Instead, we have extended our analysis to a sequence of generational transfers, in order to better understand if and how the way the succession processes are managed impacts on the firm longevity.

In our view, a closer link between the entrepreneurial succession processes and the factors of longevity seems necessary to advance the studies on family SMEs. We therefore propose to investigate this relationship by focusing on the processes of knowledge transfer and development that occur during and after the generational shift.

We believe that successfully managing the transitions at the helm of a company is essential in order to favor the continuity of the family-firm relationship and the firm's performance. For this reason, we suggest that the integration between traditional and innovative knowledge and skills (what we call "innovation around tradition") appears to be a distinctive characteristic of long-lived companies and that this integration is affected by the modes of entrepreneurial passages.

We aim to answer the following research questions: how the transfer of knowledge and skills from one generation to another can take place? what specific mode of the entrepreneurial succession process can mostly affect this transfer?

We adopt a qualitative approach, consisting in a longitudinal analysis of multiple cases (six Italian family SMEs which have been in existence for more than a century).

The paper is structured as follows: in §2 we illustrate the theoretical background; in §3 we describe the sample and explain the research design; in §4 we illustrate the findings and we introduce some propositions; lastly, in §5, we state some theoretical and managerial implications; the current limits and the future developments of the research are also outlined.

2. Theoretical framework

The concept of longevity is inherent in the notion of the company as a "financial institution able to continue" (Zappa, 1956), but it takes on particular nuances when it comes to family SMEs becoming one of the main challenges to overcome.

The prospect of a “multigenerational study” was very scarcely supported by the managerial and organizational literature (Lussier, Sonfield, 2010): the search for factors influencing the longevity can be considered a very recent field of study.

Some authors have focused their attention upon company values and upon their influence on the longevity of family companies (Aronoff and Ward, 2000; Koironen, 2002; Le Breton-Miller, 2005; Dyer, 2006; Sharma, Nordqvist, 2008). All these contributions have recognized the existence of a clear and strong link between company values and longevity without, however, identifying which values may be recognized as key factors in this relation.

Apart from specifically conducted analyses, these contributions, as a whole, fail to unequivocally define the concept of longevity and, in any case, they argue that the most important factor in determining the longevity of family business is the way in which the succession planning is managed (Figure 1).

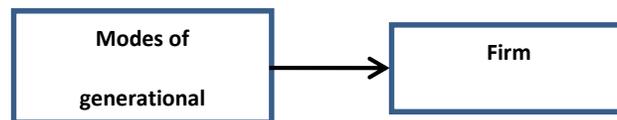

FIG. 1 – RELATIONSHIP EMERGING FROM MAINSTREAM LITERATURE

Connecting the longevity of family businesses to the generational shift leads to somehow tying the first to the success of the second, the risk being to “bring but also circumscribe” the concept of longevity to the ability, on the part of the family, to retain ownership and control of the firm.

We do not entirely agree with this view and the preliminary findings of our research corroborate our hypothesis (Bonti, Cori, 2011). Along the lines of Tàpies and Fernández (2010), we believe that the long-term survival of a family firm depends primarily on its ability to combine tradition and innovation. This means learning “the best” of the past, holding onto those values while continuing to innovate, in order to shape and build the future.

Studies on longevity form a sort of frame, in which we place our research. Our theoretical background consists basically of two strands of organization and management literature, focused respectively on the succession in family-owned SMEs and on knowledge and skills developed within the owning family.

2.1. The succession planning

The relevant literature, that is mainly focused on a single generational passage (in general that between founder and direct successor), points out some recurring features in the process of entrepreneurial succession:

- business succession is not a one-off event, but it can be interpreted as a process that unfolds over quite long period, involving a number of roles and contemplating a series of activities which can be observed simultaneously or in sequence (Cabrera-Suarez et al, 2001: 40);
- the time when the succession process begins is not unequivocally defined, while there is broad consensus on the “passage of handover” as a conclusive moment (Longenecker, Schoen, 1978; Mc Givern, 1978; Ward, 1987);
- it is possible to identify a series of phases: the first generally coincides with an awareness of the problem of entrepreneurial succession, the latter with a definitive disengagement of the outgoing entrepreneur (Gersick et al, 1999; Murray, 2003; Cadieux, 2005, 2007);
- business succession is seen as a slow, continuous, multi-staged, evolutionary process of “mutual role adjustment” (Handler, 1990) between the founding entrepreneur and members of the successive generation;
- a careful preparation and planning of the entrepreneurial transition is considered a critical issue in determining the success of the generational passage (Trow, 1961; McGivern, 1978; Ward, 1987; Handler, Kram, 1998; Lank, 2001).
- there is not a full agreement about the idea of “successful succession”; from time to time it has been associated with the maintenance of property and control in the hands of the founder’s family (Corbetta, 1995:2); with an

effective “taking over” of the company by the designated successor (Dyck et alii, 2002); with the satisfaction of all of the stakeholders (Le Breton-Miller, Miller, Steier, 2004).

A formal approach to managing the multiple aspects of the entrepreneurial succession is encouraged by the diffusion of stage-based models and of their deterministic rationale. However, the normative character of the dominant approach opens the way to a few limitations.

First, the strong emphasis on the preliminary phase highlights signs of weakness. One may argue that an excessively lengthy preliminary phase is not necessarily predictive of a higher degree of efficacy of the succession process. Time periods which are too long could in fact release latent tensions among the aspirants of succession; they could create difficulties for them to adapt to their new roles, and could prolong situations of uncertainty for the moment of, and conditions for, passage.

Further, the supposed relation between thoroughness of preparation and the success of generational exchange does not explain those cases where good results are obtained despite the fact that the passage of “handover” takes place in traumatic and unprepared circumstances caused, for example, by the early death of the founder.

Finally, the succession process itself can be regarded as a path along which “new” problems emerge for family SMEs (Del Bene, 2005). According to this view, the criticality of the phases that follow the “passage of handover” is not inferior to that of the preparatory period, and constitutes a sort of “litmus paper” for the entire process.

By considering repeated generational shifts at the helm of the family firm we try to overcome the limits associated to the study of a single entrepreneurial transition. In particular, such an approach appears to offer, among other things, more consistent elements for supporting or confuting the recurring connection between the importance attributed to planning and the success of the generational passage.

Moreover, such a perspective demands that we first rethink the meaning of the term “success” of the process we are examining.

The perspective we adopt accentuates the instrumental character of the entrepreneurial succession process in accordance with Sharma et alii (1997), while the strengthen of the firm’s ability to survive has to be regarded as the definitive outcome of that process. Thus we define “successful” those generational transition processes at the helm of the company that foster an effective balance between the transfer of the existing stock of knowledge/skills and an aware development of innovative competences. The output of this balanced dosage is what we call “innovation around tradition”.

2.2. Around familiness

The idea that the family firm develops certain idiosyncratic forms of competence linked to the proprietorial structure has gradually widespread. The recognition of such a basic element of competence, defined as “*familiness*” (Habbershon and Williams, 1999; Habbershon, Williams and Macmillan, 2003), may facilitate a unifying perspective when investigating the sources of the competitive advantage in family firms.

Cabrera-Suárez et alii (2001) bring up the concept of *familiness* and among the requirements for an effective transfer of knowledge they identify a period of “intergenerational cohabitation” in which the future entrepreneur can assimilate idiosyncratic forms of competence not otherwise transferable.

To this aim many authors stress the importance of an “early exposure” (Tagiuri, Davis, 1996, Steier, 2001; Schröder, Schmitt-Rodermund, Arnaud, 2011) to the working environment of the family firm.

Without underestimating the importance of these contributions, we cannot fail to highlight some weak points. A first limitation can be found in the excessive emphasis on the transfer of the idiosyncratic knowledge to the next entrepreneurial generation. As a consequence, the choice of particular courses of study from the designated heir, as well as work experience outside the company, are given second place. A second limitation of the studies mentioned at the beginning of this paragraph seems to be associated with the idea, often implied in the literature, that the transfer of knowledge is a matter concerning only the members of the owning family; on the contrary, employees also may present themselves at times as receivers of the historical memory of the company and its tradition (here one may think of cases of traumatic succession).

The perspective of the succession as an opportunity for development in the company appears nevertheless more consistent with actions for “enriching” the stock of knowledge and integrating the competences of the founder

with those brought by the successor. Indeed, one of the factors at the core of company longevity seems to be the ability to develop (through sharing and integration) these diverse nuclei of knowledge, adapting them to the environmental dynamics (Chirico, Salvato, 2008; Chirico, Nordqvist, 2009).

Such orientation implies the definition of a training path for the designated successor in such a way as to balance the acquisition of tacit knowledge set in the *familiness* with explicit awareness, acquired through training, exposure to different cultures and organisational models thanks to experience working in other companies (Chirico, Salvato, 2008). The knowledge gained by the new generations through university courses and other training programmes, not necessarily aligned with the distinctive competence of the company, permit a new way of interpreting the transferred experience. The knowledge acquired through work experience in other companies also allows for development of a more detached perspective concerning the way of running the company and the introduction of changes and innovations.

Along with Goto (2010: 3), according to whom “professional work experiences outside of the family provides opportunities”, Sardeshmukh and Corbett (2011: 115) also point out that training paths outside the company provide the successor with a “greater exposure to newer ideas” and pursuits of “more novel initiatives”. Therefore the external development of a successor may positively influence his ability to lead the firm in a new direction.

In agreement with them, we hypothesize that the internal development of the designated successor is important in order to deepen the industry- and firm-specific knowledge, to strengthen identification to the firm, to share the core family traditions, while external development opens the successor’s mind towards innovation.

The weaknesses of the studies examined, taken together, lead us to question any causal relationship between modes of generational passage and longevity of the family firm; they also lead us to consider the possibility of introducing some intermediate variables. The purpose is to enrich the reflections on “how to manage” the generational transfer by adding other ones, related to “what to transfer”.

3. Methodology, sample and data collection

Subject to the results of the theoretical analysis and with specific regard to the limitations identified in mainstream literature, the main aim of this research is to understand how competences have been transferred along repeated generational shifts and how entrepreneurial succession processes were managed. We carried out longitudinal analysis of six exemplary cases, following a cross-case interpretation (Yin, 1984; Alvesson, Sköldbberg, 2000). The sample consists of six long-lived family SMEs, located in central Italy.

Coherently with our research framework, we focused on family-owned SMEs, that have maintained until now the proprietorial control in the hands of the founder’s family and that have been established more than 100 years ago.

The selection of firms to be included in this study followed two main criteria: homogeneity of the sample and availability of the current entrepreneurs.

The choice of circumscribing the geographical area was dictated by the willingness to consider a territory as being sufficiently homogeneous from the point of view of business culture and paths of industrial development.

The companies in the sample were selected in such a way as to represent the main traditional industries of the Italian economy and the regions of central Italy (see Table 1).

Given the broadness of the trade market this sample presents a high level of heterogeneity. One of the businesses (Varnelli) appears on a prevalently “beyond-regional” market; with a limited share destined for exportation. For the other two (Cangioli, Pelino) the principle market of reference is the Italian national one; even with a significant weight in export. Finally for the remaining three (Giusto Manetti Battiloro, Sannini Impruneta, and L’Erma di Bretschneider) the international market absorbs a prevalent share in their turnover.

The size of firms ranges from 10 to 250 employees. In particular three companies fit in the 11-50 class of employees bracket, two to the 51-100 bracket and one to the 101-250 bracket. Three of them are placed in the turnover category of between 5 and 10 million euros; two in the €20-30 million group and one above €30 million.

All the companies are still owned by the founder's family and have maintained their own product specialisation to the present. For all these reasons, they offer interesting food for thought, thus resulting in comparison leading slowly to highlighting their similarities and differences.

The case study research was carried out by using both primary and secondary data.

Primary data were collected through direct observation and semi-structured face-to face interviews with the entrepreneurs. The interviews (two for each company) were conducted between the end of 2008 and the beginning of 2011. Each interview lasted between two and three hours. All interviews were conjointly carried out by the two co-authors. The entrepreneur was left free to reconstruct the family firm's history in such a way that a very complete picture was given, as regards: strategic-competitive position of the company, paths of productive and commercial development, knowledge/skills developed over time, meaningful organizational dynamics, the entrepreneurs who made a mark on the evolutionary events of the company. Due to the inductive nature of the study, such topics have been discussed in any sort of order and unplanned topics emerged during the discussions.

TABLE 1 – The sample

firm	Industry	geographical region	firm size (employees)	sales (ml €)	year of establishment	number of generations
Confetti Pelino	confectionery	Abruzzo	11-50	> 30	1783	7
Giusto Manetti Battiloro	gold-beating	Toscana	101-250	20-30	1820	6
Lanificio Cangioli 1859	clothing-textile	Toscana	51-100	20-30	1859	5
Distilleria Varnelli	alcoholic beverages	Marche	11-50	5-10	1868	4
Sannini Impruneta	fired bricks	Toscana	51-100	5-10	1910	4
L'Erma di Bretschneider	publishing	Lazio	11-50	5-10	1896	3

Between the first and second interview, additional and secondary information were collected through company websites and internal documents provided by the firms.

The second interview, conducted by using a semi-structured questionnaire, was aimed at focusing upon the dynamics and characteristics of repeated generational passages at the helm of the company. The entrepreneurs were asked to reconstruct the features of the repeated processes of entrepreneurial succession, to highlight the link between these processes and the dynamics of competence held to be the basis for the company's competitive edge, and to assess the degree of innovativeness of the skills passed to the next generation. On the whole, the interviews have allowed us to reconstruct 23 generational passages.

4. Findings

The longitudinal analysis of the six cases allowed us to gain some evidences about two major issues concerning the entrepreneurial succession process. We try/want to identify:

- a) some possible "logics" of transferring knowledge and skills from one generation to another;
- b) some specific mode of the entrepreneurial succession process that can mostly affect the way of knowledge/skill transfer and development from one generation to another.

Results from the qualitative data analysis are presented below.

4.1 Modes of intergenerational knowledge transfer

We got some meaningful evidences concerning the training paths for the entrepreneurs who have succeeded at the helm of the company, and knowledge and skills developed as a result of those paths. We asked our correspondents to indicate: the nature of the training paths, the distance between the competences provided by these training courses and those which at that time were considered essential to sustain the firm's competitive advantage; eventual experience in

other companies not belonging to the family; and finally the traditional or innovative nature of knowledge brought by the successor at the moment of taking the lead of the company.

First, all of the firms in the sample showed a marked orientation towards balancing tradition and innovation along an extended horizon, also in periods far back in the past. This orientation appears to be a recurring feature, especially in the last few generations, reinforcing the results that have emerged from other studies (Giaretta, 2004; Tàpies and Fernández, 2010). The analysed cases, albeit with different tones and degrees of intensity, show a clear willingness at innovating “around the tradition” by the family-owned SMEs. Innovation generally concerns the introduction of managerial and organizational practices, the development of support activities, or the outsourcing of those stages of the production processes that the firm’s top management do not consider necessary to carry out.

Secondly, the analysis of the six case studies leads us to the identification of four logical ways of transferring competences from one generation to another: integral, selective, incomplete, and lacking thereof.

Integral transfer refers to those intergenerational passages in which the stock of knowledge previously acquired and embedded in the operational routines and in the work practices remains fully utilisable after the succession. It represents an ideal condition and indicates the willingness and possibility of maximising intergenerational transfer of knowledge. *Selective transfer* refers to an aware and intentional process in which, though having conditions that would render it an integral transfer, prior knowledge and capacities are filtered by the entrepreneur in charge or/and the incumbent. *Incomplete transfer* refers to situations in which the stock of knowledge accumulated remains only partially available to the generation taking over, in a totally involuntary manner, despite the generation which takes over knowing its utility. Finally, *lacking transfer* evokes situations where the process of entrepreneurial succession takes place over time and in modes that make transfer of the knowledge gained by previous generations almost impossible.

In their respective paths of development all the companies in the sample point out at least two of the elements mentioned above. *Integral transfer* seems to be a characteristic of the first generational passage. Consistently with the emphasis on the environmental dynamics and aspects of complexity connected to company management (Padroni, 2007), *selective transfer* is continuously present in the last generational passage and in two cases during the last two alternations of the head of the company. Lastly, modalities of *lacking* and *incomplete transfer* recur much more seldom, without nevertheless definitively affecting the continuity of the business.

Furthermore, a much deeper insight leads us to identify a preferable way of transferring competences over entrepreneurial generations. While integral transfer appears to be associated with absolute continuity for the management of a company, where the successor is seen as a “custodian” of the company’s tradition, selective transfer is generally correlated to the “grafting” of innovative competence from the successor.

We therefore have recognized *selective transfer* as being the more suitable way to pursue “innovation around tradition” over time. Indeed the assessment and the subsequent selection of what is believed to give rise to the firm competitive edge can be considered a clear signal of the willingness to isolate and preserve former characteristics of products and manufacturing processes only if they generate added value. These traditions will then be integrated with some kind of innovation, resulted from new fields of competence.

Consequently, selective transfer can be regarded as the output of a generational shift that is able to guarantee the firm’s ability to survive. In our sample, selective transfer is continuously present in the last generational passage and in some cases during the last two succession processes. Finally, the analysis allow us to formulate the following proposition:

PROPOSITION 1 – *Selective transfer* of the firm’s stock of knowledge and skills can foster the firm longevity more than other transfer modes.

4.2 Modalities of entrepreneurial succession process

Some other evidence emerge about the degree of preparation/planning of the entrepreneurial succession. We asked the entrepreneurs to describe the degree of preparation for each generational passage in terms of: choice of the successor; planning of an educational path for him; planning of a period of intergenerational cohabitation; shared managerial responsibility during possible cohabitation.

Crossing the answers concerning the dynamics of competence and the characteristics of the process of the succession at the helm of the company we can observe a variety of situations (Figure 2). The degree of preparation of the entrepreneurial succession was “measured” along a continuum, ranging from the complete absence of preparation (not even the choice of the successor) to a carefully planned process (even joint decision-making), depending on the occurring of the above mentioned events.

The data we collected and processed show that when preparation for succession is lacking, it is very difficult to observe a complete transfer of knowledge; while when succession is carefully prepared the risk of “lacking” or incomplete transfer is heightened.

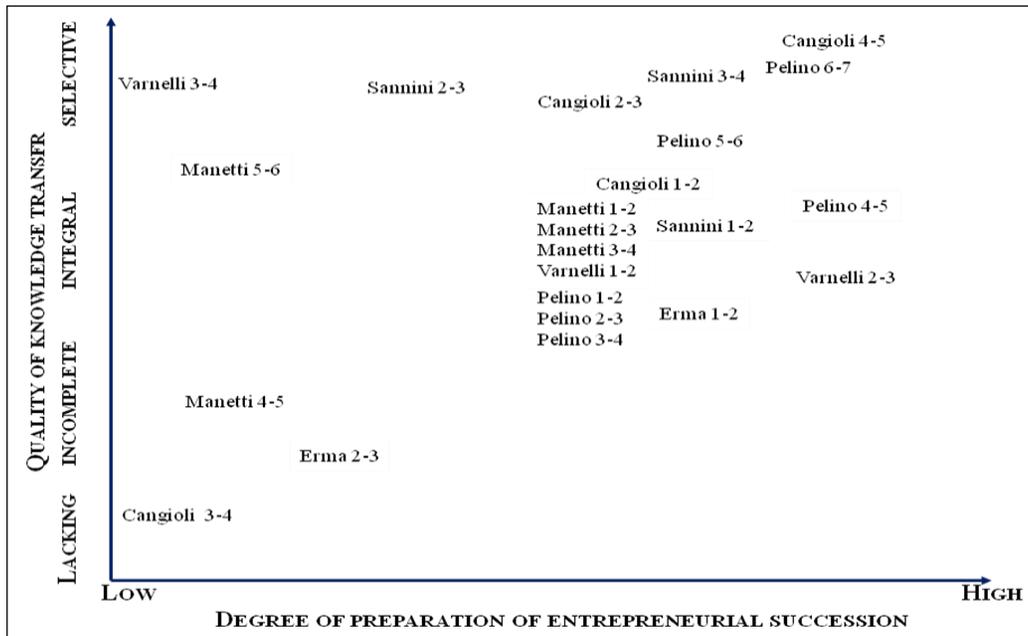

FIGURE 2: Positioning of the firms of the sample

Beyond this observation, (which would be taken for granted) a variegated scenario emerges. Integral transfer appears to be favoured by prepared succession. However, this does not necessarily mean that firms maintain the *status quo*, since transfer of knowledge is often balanced by the input of innovative competence from the successor. The contribution of skills doesn't seem to be affected much by the period of intergenerational co-habitation. It appears that a high degree of preparation influences the selective mode of knowledge transfer hardly at all, this case resorting to equal measures with or without preparation.

In the light of the present observations, the degree of preparation/planning of the entrepreneurial succession shows to have a limited impact on the choice of selecting knowledge and skills to be handed down to the next generation. The decision to “filter” available knowledge and retain only a part of it did not appear to be conditioned by the degree of preparation/planning.

In our view, this seems sufficient argument for rejecting the existence of a *best way* of conducting processes of entrepreneurial succession, identified as one with a lengthy and very thorough preparatory phase.

Supported by these findings, we suggest to introduce an additional variable to the relationship between the modes of generational passage and the ability of the firm to survive, affirmed by mainstream literature (Figure 3). This variable is represented by the mode of knowledge transfer from one generation to another, in order to pursue a balance between traditional and innovative distinctive competence.

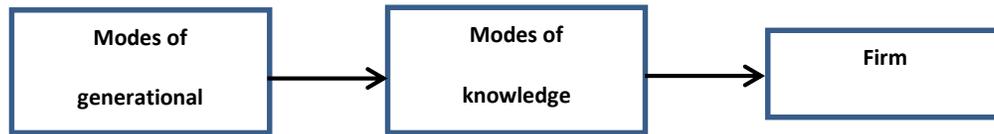

FIGURE 3 - Knowledge transfer as an intermediate variable

The early steps of our study did not shed light on the relationship between modes of entrepreneurial succession process and the pursuit of a balance between competences. It was not clear what conditions make the process of selection/retention/integration of competences easier and more effective. This led us to formulate the following proposition:

PROPOSITION 2 – *The relationship between ways of managing the entrepreneurial succession process and the ability of the firm to survive (firm longevity) is mediated by the output of the process of knowledge transfer from one generation to another.*

In order to gain a deeper understanding of what can foster a reasoned and aware process aimed at a balanced integration between “old” and “new” fields of knowledge we made a distinction between the “procedural” dimensions of the succession process (planning degree, length of the whole process, length of cohabitation) from the “substantive” dimensions (external vs. internal/external educational path, firm-oriented vs. differentiated educational path, cohabitation vs. outside work experience).

We collected such detailed information in the second interview to our informants. In particular we asked them to indicate, for each generational passage: the nature of the training path of the designated successor, the measure of how far such training was from the competence, believed, up to that time, to be a necessary source of competitive advantage; any work experience in other companies not belonging to the family.

As regards the nature of the training, entrepreneurs were asked to indicate the prevalence of school and university curricula or in-company training.

As regards instead the “distance” of knowledge and skills acquired during the training period from those already held by the company, we asked the interviewees to indicate the kind of high school and university attended (humanistic vs. technical/scientific, which technical field); this served to assess the tendency to enlarge or deepen the stock of competences held by the company at that time.

Finally, among outside experiences we considered both work contracts and internships from other companies. These were considered not only as possible chances to observe different operational approaches/practices, but also as an opportunity for “cultural contamination” from the incumbent successor.

We also asked to specify if the above mentioned features of the training paths could be considered the results of autonomous choices made by the incumbent entrepreneur or addressed by the previous generation.

We therefore propose a further enrichment of the conceptual framework. Whereas literature generally assumes consideration of the way in which the entrepreneurial succession process is managed as a sole variable, we separately consider the “procedural” from the “substantive” dimension, since we presume these latter have a significant impact on the knowledge transfer process and on the pursuit of a balanced orientation to tradition and innovation (Figure 4).

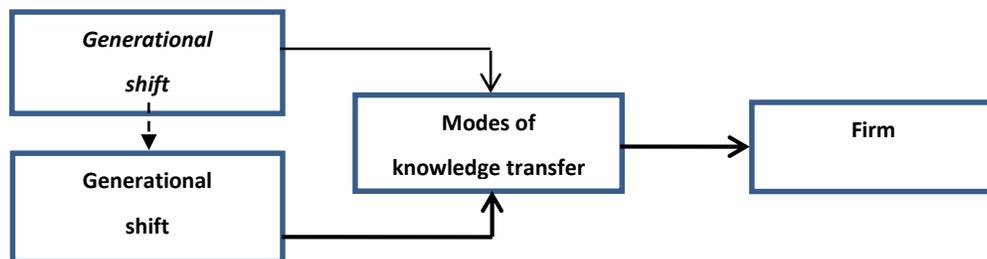

FIGURE 4 - Distinction between procedural and substantive items of the generational passage

We then focused our analysis on the impact of substantive items of the generational passage on the process of knowledge transfer from the outgoing generation to the ingoing one.

Data analysis indicate that generational passages leading to a selective transfer of knowledge are characterized by the occurrence of external or balanced educational paths for the successor, by a different orientation of the training program with respect to the firm's traditional competences, finally by the presence of work experience outside the family firm.

Consistent with Sardeshmukh and Corbett (2011), we find that non specific training and experience, developed through external paths, can provide successors with the ability to grasp different concepts, models, practices and the opportunity to catch /develop new ideas and trend.

Indeed, out of nine generational transitions of type "selective transfer", one featuring all three traits mentioned above, six show two traits, and two show one trait.

On the contrary, if we analyze generational transitions of the "integral transfer" type, only two out of nine show a balanced educational path (school/academic vs. in-company training), while there is no clear evidence that such training has been focused on skills away from those held by the company¹. Rather they show the presence exclusively or overwhelmingly of in-company training and the complete absence of outside work experience.

In summary, the analysis of the substantive dimensions of the generational passages highlights that certain characters of the training path of the successor can affect the way in which knowledge is transferred from one generation to another, and ultimately on the ability of the family firm to balance tradition and innovation.

The analysis of data obtained in this later stage of the research leads us to formulate the following two propositions:

PROPOSITION 3 - *External training path and/or differentiated training path and/or outside work experience are positively correlated to the adoption of a selective mode of knowledge transfer during a generational passage.*

PROPOSITION 4 - *Internal training path and/or training path coherent with the distinctive competences of the firm are negatively correlated to the adoption of a selective mode of knowledge transfer during a generational passage.*

5. Conclusions

This study sheds light on two major issues concerning the entrepreneurial succession process within the family SMEs. On the one hand we investigated and collected some meaningful insights about the "logics" of transferring knowledge and skills from one generation to another. On the other hand we investigated the relationships between some features of the repeated processes of entrepreneurial succession and the way of transferring and developing knowledge/skills, as well as how these connections may influence the longevity of the firm.

As regards the first aspect, the firms that have been investigated show a clear trend in pursuing a conscious integration between traditional and innovative competences over entrepreneurial generations; this means that innovative behaviours does not affect knowledge and skills that allowed the former success of the firm.

The longitudinal analysis of the repeated entrepreneurial passages has made it possible to identify four ways of transferring competences from one generation to another. Moreover it suggested us to propose the distinction between procedural and substantive dimensions of the succession process, in order to make clearer what really affects the modes of knowledge transfer.

Our research contributes to the theoretical advancement by proposing a more articulated frame of the relationships that can be observed along the entrepreneurial succession process within the family SMEs. We propose to consider the modes of transferring knowledge and skills during the generational shift as an *intermediate variable* in the relationship between the processes of entrepreneurial succession and the firm's longevity.

In terms of contribution to managerial practices, the outcomes of our analysis suggest to overcome the strictly prescriptive and sequential approaches to the preparation of the entrepreneurial succession. They also suggest to consider the opportunity of "contaminations" with fields of competence far from the firm's original ones. Furthermore, they can help entrepreneurs to pay special attention to those issues that seem to have the most significant impact on strengthening the firm's ability to survive and successfully compete.

As regards the limitations of our study, some of them could be overcome in later phases; among these, we mention the small size of the sample and some of its features, and the possibility of biases due to the perceptions of the interviewed managers. These prepossessions might relate to the description of the succession process in which those managers have been involved and to possible conflicts with other family members or branches. A limitation that is hard to consider surmountable refers to the undetermined reliability of some information concerning the early entrepreneurial generations.

Further steps of our research, in addition to trying to overcome some of the abovementioned limitations, may follow two different directions. On the one hand other possible relationships between the variables that have been included in the conceptual framework should be investigated. In particular, we believe it is important to explore the link between procedural and substantive items of the generational passage (e.g. if and how temporal and relational dimensions impact on the content of the incumbent successor's learning path). On the other hand, a quantitative analysis of a large sample of family SMEs, would really help to test our propositions which have so far emerged from the study of a limited number of firms.

End Notes

¹ We purposely do not take into account generational passages characterized by “incomplete” or “lacking” transfer since these modes are not the result of conscious choices but are suffered by the firm.

Leadership expectations ranked by different personalities

Leadership expectations ranked by different personalities

Abstract

The purpose of this study is to examine, to what degree do different personalities expect different kind of leadership. Several results were found. For example, people with extraverted, intuitive and feeling preferences wanted to see transformational behaviors even more so than the people with opposite preference pairs. All personality preferences would rather have a transactional or authoritative leader than a passive or non-leader. But sensing followers were more inclined to have an authoritarian leader than intuitive ones, and introverted followers were slightly more comfortable with laissez-faire style behaviors than extraverted.

The results implicate that personality is related to different leadership expectations. There were statistically significant results in all preference-pairs. It is important to pay attention on the individualistic needs of different personalities in leadership training programs. Leaders' and followers' relationships are crucial and unnecessary disappointments should be avoided.

Key words: Personality, expectations, transformational and transactional leadership, laissez-faire and management by exception

Introduction

Leadership exists during the relationship between follower and the leader, and it is impacted by mutual interaction. Plenty of studies have concentrated on the qualities of the leaders, and how leadership impacts on followers, but the role of the follower and their uniqueness have interested surprisingly only very few researchers. The importance of the effects of follower characteristics on the preferred leadership style cannot be overestimated. Knowing what kind of wishes followers have for leadership can help leaders to improve their understanding of different individuals and develop their leadership skills. According to Schyns et al. (2008) organizations should address the expectations followers have towards their leaders, because it could be one way to avoid disappointments in this relationship.

It has been noted that some personalities use more transformational leadership than others (eg. Brandt and Laiho, 2013; Carroll, 2010; Hautala, 2005). Additionally, there are some studies about the follower characteristics and the individual differences on the perception of transformational leadership (Brandt and Laiho, 2013; Hautala, 2005). Some studies indicate that wishes for different kind of leadership behavior can vary individually (Hautala, 2007). However, as far as we know, there is no research on followers' personality and its relation to wishes for leadership in transformational leadership context. Thus, this study concentrates on the different personalities' preferred leadership style in transformational leadership context. The current study uses the Myers-Briggs Type Indicator (MBTI) as a determinant of personality.

Background theories

Transformational leadership

Each individual has their build in beliefs of what kind of person is an effective or a good leader; implicit leadership theory investigates which traits separates leaders from non-leaders according to different individuals (Epitropaki et al. 2013; Derue et al. 2011). These mental models and leadership preferences are formed early and have been found to be affected for example by culture (House et al. 2004), personality (Hautala 2005; 2008), and sex (Brandt and Laiho 2013). More often researchers focus on explicit leadership behaviors and moreover looking into what kind of outcomes they might have (See e.g. Wang et al. 2011; Waldman and Yammarino 1999; De Jong and Den Hartog 2007; Littrell and Valentin, 2005).

Since the time of Burns' seminal research (1978) who first categorized leadership behaviors, several researchers have studied and defined Transformational leadership (TF-leadership) (Bass 1985;; Kouzes and Posner 1988) and transactional leadership (Bass 1985; Lowe et al. 1996) and operationalized the concepts (e.g. Bass and

Avolio 1990; Kouzes and Posner 1988; Roush 1992, Edwards and Gill 2012). These constructs have been viewed polar (Burns 1978) and complimentary (Bass 1985). Common elements in definitions of TF-leadership are visioning, challenging, consideration, and being an example (Bass 1985; Kouzes and Posner 1988). Behaviors of transformational leadership inspire the followers to move beyond their self-interest and increase motivation and moral (Burns 1978; Bass 1985; House 1977; as in Rahn, 2010) and the behaviors should assist organizations to change (Derue et al. 2011). Transactional leaders make the tasks clear and reward accordingly, they also actively make corrective actions to avoid anticipated problems (Antonakis et al. 2003; Derue 2011;). Common elements of transactional leadership are contingent reward and (active) management by exception. Contingent reward refers to specification of employees' goals, assessment of fulfilling and rewarding them. Active management by exception entails more involved leader who intervenes and corrects, if employee is not following the agreed standards. (Antonakis et al. 2003; Den Hartog et al. 1997; Vaccaro et al. 2010) In passive management by exception leaders get involved reactively, after the problems occurred and it correlates with non-leading laissez-faire leadership, in which leader chooses to avoid taking any actions and does not act authoritatively, avoids decision making and taking supervisory responsibility (Antonakis et al. 2003; Den Hartog et al. 1997).

The solid position of TF-leadership in research is due to it being connected to several positive outcomes regarding both follower effects and outcomes on organizational level. These include improved productivity, reduced employee turnover rates, greater job satisfaction and motivation; all of which are more strongly associated with TF-leadership than with more transactional or non-transformational leadership (e.g. Clover 1990; Deluga 1992; Judge and Piccolo 2004; Marshall et al., 1992; Masi and Cooke 2000; Medley and Larochelle 1995; Sparks and Schenk 2001). Lately, studies of TF-leadership have also focused on areas of well-being (Arnold et al., 2007), ethical sides (Bass and Steidlmeier 1999), psychological capital (Nielsen et al. 2009), cultural intelligence (Keung and Rockinson-Szapkiw 2013), and technological innovation (Chen et al., 2012).

Myers-Briggs Type Indicator

The Myers-Briggs Type Indicator (MBTI) used in this study, offers a dynamic approach to personality. The MBTI has been widely used in the field of leadership and organizations (e.g., Gallén, 2009; Storr and Trenchard, 2010). MBTI is based on Jung's (1921/1971) work on psychological types. The MBTI reveals a person's habitual preference for an orientation of energy (extraversion/introversion), a process of perception (sensing/intuition), a decision-making function (thinking/feeling) and an attitude to life (judging/perceiving).

Extraverted (E) people direct energy mainly toward the outer world of people and objects. They are energized by interaction and activity. Introverted (I) people direct energy mainly toward the inner world of experiences and ideas. They are energized by reflection and solitude. Sensing (S) people focus mainly on what can be perceived by the five senses. They are naturally interested in concrete and verifiable information about what is or what has been. Intuitive (N) people focus mainly on perceiving patterns and interrelationships. They tend to be interested in flashes of insight, abstractions, theory, and notions of what could be. Intuitive people prefer to work in bursts and wait for inspiration. Thinking (T) people tend to base their conclusions on logical analysis with a focus on objectivity and detachment. They prefer to focus on the work at hand, and do not spend much time on getting to know others and building relationships. Feeling (F) people tend to base their conclusions on personal or social values with a focus on understanding and harmony. At work, they often want to spend time getting to know others. Judging (J) people prefer decisiveness and closure. They like to live in an orderly and structured fashion. Perceiving (P) people prefer flexibility and spontaneity. They tend to be adaptable and often design flexible or innovative approaches to work (Demarest, 1997; Myers and Myers, 1990).

Several studies have concentrated on transformational leaders' personalities, using different personality measures. Most studies of leaders' self-ratings using the MBTI find that extraversion, intuition, and perceiving preferences are more related to TF leadership than their polar opposites: introversion, sensing and judging (Church and Waclawski, 1998; Hautala, 2006). Some do not include extraversion (Van Eron and Burke, 1992) in the list, and some exclude both extraversion and intuition (Brown and Reilly, 2009). The results on subordinates' appraisals of their leaders' behavior are less clear cut. Some studies did not find any relationships (Brown and Reilly, 2009), some supported similar results to those revealed by the leaders' self-ratings (Church and Waclawski, 1998; Roush, 1992), and some produced wholly opposite results indicating that sensing (Hautala, 2006; Roush and Atwater,

1992) and feeling preferences (Atwater and Yammarino, 1993; Roush and Atwater, 1992) were strongly associated with TF leadership.

Earlier one study (Hautala, 2007) has studied earlier leadership expectations of different personality types, and there were several results. Concerning expectations to leadership Clearly Set Goals were especially important to judging types. Clearly Defined Areas and Instructions were important to sensing types. Introverted types did prefer Continuous Directing. Giving Trust was favored by extraverted people. Feeling types favour Support and Directing and Empathy and Humanity. The most significant differences were in the Giving Information characteristic when perceiving types were overrepresented in wanting information from their leaders.

Methodology

The well-established questionnaires and methods were chosen as part of the research. Thus, the study is inductive by nature. The data collection took place after creating the questionnaire in September 2012, and in 2013. The data was analyzed in winter of 2014.

The data was gathered among altogether 578 Finnish university students and working professionals. The age varied between 18 and 62, and the mean age of the respondents was 24. 52,6% were male. Only 362 respondents had reported their work experience in years, amongst those the mean was 6 years. But the rest of the respondents who had not marked their work experience were likely to have very little or no work experience. Taking part in this study was voluntary. The students were explained for which purposes the study is conducted and how the results are handled. It was also possible to complete the questionnaire without taking part in this study, as in the questionnaire form there was a choice box whether the student allows his/hers answers to be included in the study. The members of the research group were present when the questionnaires were completed, and the students were given as much time as they needed in order to complete the questionnaire. The questionnaire forms were handled with care and caution, and the answers were confidential. Only the members of the research group had access to the forms and were able to see the answers.

The respondents filled a questionnaire based on Bass' MLQ, Kouzes and Posner's LPI and transformational leadership literature overall. The questionnaire featured Transformational Leadership (TF), Transactional Leadership (including Passive and Active Management by Exception), and Laissez-Faire and Authoritative leadership style. The respondents were asked to grade different statements based on different leadership style on a scale of 1-9, nine being the most desired leadership style and one the least preferred.

There were two components which described transformational leadership: Inspirational motivation and Intellectual stimulation/challenging. The Inspirational motivation was measured with 4 items such as "Supervisor encourages me", Cronbach's alpha was 0.813. The Intellectual stimulation was described with four items, e.g. "Supervisor encourages me to develop ideas", the alpha of this dimension was 0.712.

Transactional leadership was measured with Rewarding $\alpha=.56$ and Management by exception-active $\alpha=.38$ (see e.g. Derue et al., 2011). Rewarding was measured with three items, such as "Supervisor notices my accomplishments" and Management by exception-active was measured with five items, e.g. "Supervisor gives help if subordinates have already worked with problem".

Finally, passive leadership was measured with Management by exception-passive, Laissez-faire and Authoritarian Management. Authoritarian leadership could also be classified with task-orientated leadership behaviors with transactional leadership (Derue et al. 2011). These three behaviors were investigated separately. In management by exception-passive, factor analyses loaded on four items, e.g.: "Supervisor finds mistakes" $\alpha=.54$. Five questions loaded to Laissez-faire "Supervisor avoids making decisions" $\alpha=.76$, and finally authoritarian management was measured with three items, e.g. "Supervisor makes decisions" $\alpha=.54$.

Concerning MBTI the validity has been proved at the four preferences level, as well as at the type level. Internal consistency is high when both the Split-Half and Coefficient Alpha Reliabilities are measured. Internal consistency and construct validity have been proved by several researchers. (See e.g. Gardner and Martinko, 1996; Myers et al., 1998.) Gender, age, membership of a minority ethnic group, and developmental level are just some of the topics that have been researched when testing the reliability of the MBTI (see Myers et al., 1998). In this study,

the Finnish research 'F-version' was used. The construct validity and reliability of this form have been proved during a validation process lasting several years (see e.g. Järnlström, 2000). Järnlström (2000) reported an internal consistency (Pearson's correlation coefficients) of 0.65 to 0.76 and (Cronbach's coefficient alpha) of 0.79 to 0.86.

Results

Overall, transformational leadership was the most expected leadership behavior; median of all respondents was 7.06. Transactional leadership was preferred also (Mdn=5.67). Authoritative leadership behavior (Mdn=3.33) was preferred over laissez-faire (Mdn=2.60) and management by exception-passive (Mdn=2.00). Yet there were many differences between the personality preferences. The sample was divided according to personality as follows: extraversion (64 %, n=353) - introversion (36 %, n=201), sensing (60 %, n=333) – intuition (40 %, n=221), thinking (59 %, n=327) – feeling (41%, n=227), judging (55 %, n=307) – perceiving (45 %, n=247).

Transformational leadership

A Mann-Whitney U test was run to determine if there were differences in transformational leadership score between extraverted and introverted. Distributions of the transformational leadership scores for extraverted and introverted were similar, as assessed by visual inspection. Median transformational leadership was statistically significantly higher in extraverted (7.13) than in introverted (6.88), $U = 15498$, $z = 2.237$, $p = .025$, $r = 0.12$. There were no statistically significant differences in the scores of inspirational motivation between extraverted (7.25) and introverted (7.25) respondents $U = 13925$, $z = .450$, $p = .653$, but intellectual stimulation/challenging factor yielded some differences. Median intellectual stimulation/challenging score was statistically significantly higher in extraverted (7.25) than in introverted (7.00), $U = 15570$, $z = 2.322$, $p = .020$, $r = 0.13$. The effect sizes were calculated with the formula below and interpreted as suggested by Boduszek (2011) $r = \frac{z}{\sqrt{N}}$.

Next we will view the results of differences in transformational leadership score between sensing and intuitive preferences. Distributions of the transformational leadership scores for sensing and intuitive were similar, as assessed by visual inspection. Median transformational leadership was statistically significantly higher in intuitive (7.38) than in sensing (6.88), $U = 10094$, $z = -4.367$, $p = .000$, $r = 0.24$. There were no statistically significant differences in the scores of inspirational motivation between sensing (7.25) and intuitive (7.25) respondents $U = 13218$, $p = .380$, but intellectual stimulation/challenging factor yielded some differences. Median intellectual stimulation/challenging score was statistically significantly higher in intuitive (7.50) than in sensing (6.75), $z = -4.259$, $U = 10195$, $p = .000$, $r = 0.23$.

Third preference pair's, thinking – feeling, results are reported next. Distributions of the transformational leadership scores for thinking and feeling were similar, as assessed by visual inspection. Median transformational leadership was statistically significantly higher in feeling (7.13) than in thinking (7.00), $U = 12173$, $z = -2.259$, $p = .024$, $r = 0.12$. Median inspirational motivation score was statistically significantly higher in feeling (7.50) than in thinking (7.25), $U = 12014$, $z = -2.438$, $p = .015$, $r = 0.13$. There were no statistically significant differences in the scores of intellectual stimulation/challenging, between feeling (7.25) and thinking (7.00), $U = 13628$, $p = .518$.

In the last preference pair, there were no statistically significant differences in the scores of overall transformational leadership between judging (7.06) and perceiving (7.13), $U = 13231$, $p = .263$. Also the motivation factor was equally important for preferences, judging (7.38) and perceiving (7.25), $U = 14769$, $p = .558$. Median intellectual stimulation/challenging score was statistically significantly higher in perceiving (7.25) than in judging (7.00), $U = 12464$, $z = -1.971$, $p = .049$, $r = 0.11$.

To summarize, no matter what the personality preferences are, transformational leadership behaviors are expected rather than other behaviors. Still especially extraverted, intuitive, feeling and to some degree perceiving individuals expect their leaders to display transformational behavior when compared introverted, sensing, thinking, and judging.

Transactional leadership

A Mann-Whitney U test was run to determine if there were differences in transactional leadership score between different personality preferences. There were no statistically significant differences in the scores of transactional leadership between extraverted (5.67) and introverted (5.50) respondents $U = 12492, p = .237$. Also intuition (5.50) and sensing (5.67) does not appear to influence the score of transactional leadership $U = 15273, p = .155$. No statistical difference were found between thinking (5.50) and feeling (5.67), $U = 15079, p = .334$. Neither was there differences between judging (5.58) and perceiving (5.50), $U = 14694, p = .615$.

Unlike the found relationship in transformational leadership behavior expectations, personality does not play a role in transactional leadership expectations. The median is between 5.50 and 5.67 in all personality preferences; hence it is also expected from leaders.

Passive-management by exception

Three different leadership behaviors were included in the rankings in passive (or negative) leadership: passive-management by exception, laissez-faire, and authoritarian leadership. We will first view the Passive-management by exception results. A Mann-Whitney U test was run to determine if there were differences in scores between extraverted (2.00) and introverted (2.00), but there were not, $U = 13865, p = .702$.

When comparing the scores of intuition (2.00) and sensing (2.25) a statistical difference was found, $U = 16227, z = 2.498, p = .012, r = 0.13$. Distributions of the Passive-management by exception scores for intuition and sensing were similar, as assessed by visual inspection. Both preferences do not expect this of their leaders since the scores are so low, but sensing preference is more comfortable with these behaviors than intuitive.

The thinking – feeling preferences did not differ in their scores regarding Passive-management by exception both median score being 2.00, $U = 14069, p = .876$.

Finally, median Passive-management by exception was statistically significantly higher in perceiving (2.25) than in judging (2.00), $U = 12375, z = -2.078, p = .038, r = 0.11$, indicating that judging are less comfortable with these reactive behaviors.

Laissez-faire

A Mann-Whitney U test was run to determine if there were differences in laissez-faire score between extraverted and introverted. Distributions of the scores for extraverted and introverted were similar, as assessed by visual inspection. Median was nearly statistically significantly higher in introverted (2.80) than in extraverted (2.60), $U = 11936, z = -1.817, p = .069$, but the effect size indicates ($r = .10$) there might be a reason to investigate this further.

Median for both, intuition and sensing was the same 2.60. There was no statistical difference, $U = 14040, p = .967$. Also the thinking and feeling had a median 2.60, $U = 11936, p = .206$. There were no statistically significant differences between perceiving and judging either, $Mdn = 2.60, U = 15531, p = .152$. Thus on the significant level of .05 there were no differences between personality preferences in the laissez-faire leadership expectations or more appropriately acceptance

Authoritarian leadership

Lastly, authoritarian leadership expectation results are presented here. Both, extraverted and introverted had a median of 3.33, thus there were no statistically significant differences, $U = 14103, p = .514$. Median of authoritarian leadership was statistically significantly higher in sensing (3.67) than in intuition (3.00), $U = 17614, z = 4.047, p = .000, r = 0.22$. Thus sensing people expect leaders to behave in authoritative ways, when intuitive do not. Feeling and thinking preference is not relevant either when concerning authoritarian scores, both had a 3.33 median, $U = 14286, p = .933$. Perceiving had a bit lower score (3.00) than judging (3.33) but there was no statistically significant difference, $U = 15222, p = .276$.

As suggested by Coe (2002) unstandardized median differences were used because of the lower reliability of some of the outcome measures. The results are displayed below in Table 1. As can be seen of the effect sizes, the strength of the association is small.

TABLE 1: RESULTS

	Extra- version Mdn n=220	Intro- version Mdn n=123	r	Sig.	Sensing Mdn n=209	Intuition Mdn n=134	r	Sig.	Thinking Mdn n=203	Feeling Mdn n=140	r	Sig.	Judging Mdn n=202	Perceiving Mdn n=141	r	Sig.
Inspirational motivation (factor of TF- leadership)	7.25	7.25	.02	.653	7.25	7.25	.05	.380	7.25	7.50	.13	.015	7.38	7.25	.03	.558
Intellectual stimulation (factor of TF- leadership)	7.25	7.00	.13	.020	6.75	7.50	.23	.000	7.00	7.25	.03	.518	7.00	7.25	.11	.049
Transformational leadership	7.13	6.88	.12	.025	6.88	7.38	.24	.000	7.00	7.13	.12	.024	7.06	7.13	.03	.263
Transactional leadership	5.67	5.50	.6	.237	5.67	5.50	.08	.155	5.50	5.67	.05	.334	5.58	5.50	.03	.615
Authoritarian leadership	3.33	3.33	.04	.514	3.67	3.00	.22	.000	3.33	3.33	.05	.933	3.33	3.00	.06	.276
Laissez Faire	2.60	2.80	.10	.069	2.60	2.60	.02	.967	2.60	2.60	.07	.206	2.60	2.60	.08	.152
Management by Exception- passive	2.00	2.00	.02	.702	2.25	2.00	.13	.012	2.00	2.00	.01	.876	2.00	2.25	.11	.038

Conclusions

Results indicated that transformational leadership was the most expected leadership behavior and management by exception-passive the least hoped leadership style. Neither authoritarian nor laissez faire styles were preferred leadership styles, but both were more accepted than passive management by exception. Three statistically significant results occurred in E/I-dimension.

Extraverted people would like to have more intellectual stimulation and transformational leadership overall. Introverted people were more tolerant toward laissez-faire leadership. These results may be due to introverts more peaceful orientation. They are not as interactive as extraverts thus they do not necessarily demand such active leadership and can accept more passive leadership than extraverts.

The most significant results occurred in S/N dimension. Intellectual stimulation and transformational leadership was hoped more by intuitives than sensing personalities. Authoritarian leadership was clearly more accepted by sensing persons and this tendency was shown also in case of passive management by exception. In Hautala's study (2007) Clearly Defined Areas and Instructions were important to sensing types. It may be that sensing people are more frustrated in laissez-faire kind of "no rules"-leadership than authoritarian kind of leadership who can be maybe too strong and old-fashioned but makes decisions and gives instructions, which behaviors are appreciated by sensing types.

Persons with feeling preference hoped more inspirational motivation and transformational leadership than persons with thinking preference. Feeling personalities appreciate harmony and tend to give positive feedback to

others, and therefore they naturally expect this for themselves too. In Hautala's study (2007) feeling types did favor Support and Directing and Empathy and Humanity, which is in line with this study and feeling –preference's type description. Feeling types are more tender-hearted, more tactful, and more social than thinking types (Myers and Myers, 1990), so it is quite natural for them to prefer their leaders to treat them in a similar way.

Concerning last preference pair, two differences occurred: more spontaneous perceiving types wished more intellectual stimulation than more orderly judging types. Perceiving leaders have tendency to use intellectual stimulation more than judging ones, thus this is also in line with previous studies (Brandt and Laiho, 2013). Passive management by exception was tolerated more by perceiving types, and this may indicate perceiving types' flexible attitude towards passivity. It must be noted that even if those negative kinds of leadership styles were accepted more by other personality types than others, they are still not wished, because median of those were clearly low.

Implications of our results provide more information for human resource development field, especially for management training. Leaders should take personality differences more into account, e.g offer more support, motivation and harmony to feeling personalities than others. Supervisors and HR could arrange for new employees discussions about their wishes about work place and leadership style.

The Construction of Knowledge Based in Online Education: A Case Study in a Brazilian Public University

Abstract

The present study aimed to identify the perceptions of students, tutors and others involved in teaching and distance learning, on the impacts of the use of information technology and communications at the Federal University of Sergipe, in order to realize the how this use contributes to the construction of knowledge in distance education. The theme gets more space because of its specificity. In terms of its methodology, the study was described as exploratory and descriptive. Questionnaires were applied online and in person with students and distance tutors, and interviews with the ones involved with the direction and coordination of distance learning in Federal University of Sergipe. Through data analysis and perception of the sample, it was concluded that the use of information technology and communication applied in distance education contribute to the construction of knowledge, while stimulating the interaction between those involved in it; however, it was also perceived the need for clarification on this type of education so that the peculiarities of it in relation to mainstream education are identified and problems are solved.

Key words: Information technology and communication; knowledge; distance education.

Introduction

The changes taking place in the world in recent decades require constant improvement and diversified knowledge among the population and generate numerous changes in the educational context in order to adapt the construction of knowledge to the environment and its needs. The knowledge acquired through continuous learning and modern technologies of information and communication becomes a key differentiator and a key part in the development of people and organizations. Thus, the use of information and communication technology (ICT) in the educational context grows considerably, in a great rapidity and globalized form, being related not only to the access and transmission of information, but also to the process of knowledge production and training skills.

Distance Education – DE emerges as a mode of education, which tends to democratize education and learning by making information available to anyone, anytime and anywhere. Moreover, it has been considered an effective way of teaching, at what cost, time and geographical distance can be reduced without jeopardizing the achievement of knowledge.

For the objectives proposed by DE to be met, ICTs act as facilitators in the transfer of information and communication between students, tutors and educational institutions. As stated by Moré, Moritz, Pereira and Melo (2010) to be a proactive process, DE requires constant interaction between all involved, as well as a constant motivation for using the right resources and in an effective way.

In order to keep up with the increasing changes that are happening in the world, including progress towards ICTs, and make democratic forms of access to knowledge, the Federal University of Sergipe (UFS) introduced, in 2006, the Centre for Distance Higher Education (CESAD), through RESOLUTION No. 49/2006/CONSU. With the creation of CESAD, the teaching offered by the university was becoming more comprehensive, contributing to a significant portion of Sergipe population could have access to quality higher education, already known in the UFS classroom level, without the need to move from their municipalities.

Given this scenario, we sought to analyze the perceptions of students, tutors and others involved in the process of distance education (DE) in order to identify characteristics of students who seek to acquire knowledge from that distinctive form of learning, the roles of tutors in the transfer of information and the teaching institution itself, regarding the required adaptation for offering distance education courses and identify how the technologies employed contribute to knowledge building in DE.

Thus, the proposed theme, after this introduction, will be exposed as follows: the second section discusses the historical context in which distance education is embedded; the third section presents the interaction between students, tutors and educational institutions, while fourth displays aspects related to distance constructivism. The

fifth section describes the methodological procedures used and then the results are presented. Finally, in the seventh section the final considerations are listed.

Historical Context of Distance Education

Among the authors who address the background of distance education many differentiate its work on the chronology of events and the number of generations that mark the evolution of distance education. Despite the discrepancies, coincidental information among authors exists in regard to the emergence of distance education, marked by the appearance of the media and the use of these as a means of spreading information and knowledge. For Chaves (1999) writing was the first technology that involved DE: The invention of writing enabled people write down what they previously could only say, and thus allowed the emergence of the first form of distance education: teaching by correspondence. The New Testament epistles (aimed at entire communities) that have clear didactic character are clear examples of DE. Its range, however, was relatively limited - until they were turned into books.

As Moore and Kearsley (2008) said, the evolution of distance education presented so far, five generations. These generations mark its evolution over time according to the technologies used to mediate the interaction between students and teachers and construction of knowledge, through the textual interaction, via correspondence to the virtual interaction with the use of computers and the Internet.

Table 1, based on Moore and Kearsley (2008), displays the evolution of generations of distance education, dates and main characteristics of each one:

TABLE 1: GENERATIONS OF DISTANCE EDUCATION

GENERATION	BEGGINING	CHARACTERISTICS
First	1880	Study by correspondence. Instruction through distance educators, with delivery of printed materials by mail.
Second	1921	Broadcast television and radio. Radio and educational channels. Telecourse.
Third	1970	Open Universities. Universities that used communication technologies to teach adults.
Fourth	1980	Teleconference. Use in groups, unlike the open universities or correspondence courses.
Fifth	1990	Virtual classes. Use of Computers and Internet in education.

According to the information contained in Table 1, it is seen that the history of distance education starts with instructional courses delivered by mail, which characterizes learning by correspondence, where people who had an interest to study, but could not attend classroom courses, could receive instruction by teachers from distance in any environment.

The second generation was marked by the use of new technologies, radio and television, in education, initiating educational programs aired on television and telecourses, mostly for adult education and with little interaction between students and instructors. According to Chaves (1999, p. 6), "the radio allowed the sound (especially the human voice) to be taken to remote locations," but the use of this technology to support distance education did not achieve much success. In contrast, educational television got more successful, both with the use of equipment in classrooms, as the transmission of educational programs both on cable and open television, called telecourse.

The Open University has emerged in the UK as the first national distance education university, increasing the number of students and offering courses through the use of various communication technologies, and then copied in other countries. As Belloni (2006), open universities meet the specific demands of training and offer, in addition to regular courses, large variety of non-formal actions continuing education and training.

As described by Moore and Kearsley (2007), distance education emerged in the United States based on the teleconference, and because it was closer to the traditional teaching, in groups, attracted many educators. The communication by means of satellites updated the conferences, making it possible to broadcast educational programs.

During the fifth generation, the one with the most recent start, the use of computer networks and the Internet for education boost the emergence of virtual classes and promote access to distance education. With personal computers, it became possible to add sounds, images, colors, graphics, tables, among other attractions that facilitated instruction. Educational softwares began to be created as well as networks and computer conferencing in order to connect multiple computers for group instruction and more interaction between teacher and student. "The main advantage of computer instruction is to be able to offer a high quality opportunity for the student to interact with the subject under his/her full control" (MOORE; KEARSLEY, 2007, p. 92).

The emergence of the Internet in the late 90s has enabled a new field to be explored by education. Universities have started using Internet-based programs, in addition to offering online courses, which brought increased visibility to distance education.

For Moore and Kearsley (2007), the use of integrated learning systems allow for the existence of synchronous (those performed simultaneously, in real time, between teachers and students) and asynchronous communications (those in which teachers and students communicate in separate times) on a platform (in the present study, *Moodle*) as well as access to a large number of material on the *web*.

Student-Tutor -Institution Interaction

Distance education has changed and is changing the ways of interaction between students, tutors and the educational institution. Mattar Neto (2008, p. 135) states: "the classroom [...] can be seen as the less conducive place to transmission and generation of knowledge." This information can incite reflection: knowledge can actually be generated and transmitted outside the classroom?

From the point of view of Moore and Kearsley (2008), the basic idea of distance education refers to students and teachers in different locations during all or part of the time in which they learn and teach, depending on technologies to convey information and interact with, being, therefore, the enabling technologies in interaction and knowledge building in distance education. Thus, for the authors knowledge can indeed be built outside of the classroom (in different places), since the interaction between students and tutors happen through technology.

In this new context, students have more autonomy to study, choosing time, place, and time of study within their means and preferences and institutions have become more interdisciplinary, offering courses in various areas in distance, and the figure of the teacher/tutor can be seen from numerous angles, but mostly as a link between the first two and supportive of learning and construction of knowledge by students.

For Moore and Kearsley (2008), the distance learner needs to have different skills for the study and differentiated communication abilities. However, they also need different types of support and aid compared to students in traditional courses, such as learning environments, which unlike the students who attend classroom courses are not always classrooms.

Moore and Kearsley (2008) and Belloni (2006), characterize the student in distance learning courses as an adult, which can be of great importance for the understanding of the distance learner. Among the factors that favor the adoption of distance education for adult instruction, may be cited: control and autonomy in their learning, ability to define what, when, where and how the learning process will happen, greater motivation, interest in learning more about specific issues. According to Moore and Kearsley (2008) the most common reason for adults to do a distance course is "to develop or improve the knowledge necessary for employment" (p. 175).

Leal (2005) comprises the tutor's role as an academic category based on a commitment to training students to think and be able to discuss and develop knowledge, coming from him/her the power to stimulate the construction of knowledge articulated in the virtual space. It is for the tutor to create an environment where students can learn to control, manage, implement and engage with the technologies used, turning information into acquired knowledge.

Mattar Neto (2008) considers the fear that the figure of the teacher to be extinct an important issue in distance education. However, the author states that the figure of the teacher is not being eliminated and it is not losing its place

in education, but has new challenges and new tasks. Lévy (1999, cited by MATTAR NETO, 2008) states that teachers carry out the monitoring and management of learning activities, stimulating, among other things, the exchange of knowledge.

Given the foregoing, it is necessary to realize that the role of the tutor does not exclude the role of the teacher in distance education; they have different and complementary roles. While the teacher prepares the course content and seeks ways of assessing students that promote the construction of knowledge, tutors act as liaisons between teachers and students and the institution, facilitating and enhancing learning, ie, teachers and tutors are distinct characters and should, in theory, work together in building the knowledge in distance.

It is up to the institution, as quoted by Moore and Kearsley (2008), the decision about which courses that will be offered and implementation of these courses, training, monitoring and evaluation of academic and administrative staff, installation and maintenance of libraries, study centers and all technology used to inform students about the courses available and subsequent registration, admission procedures and assessment, among other decisions that can influence and assist in ensuring the success of a distance education program.

The use of various forms of technology, or learning objects, tends to create a new conception of learning through interaction between all that integrate distance education, being of great importance that the educational institutions know how to choose those that are appropriate and that can be readily used by participants of this mode of teaching and learning. It is important to note that the interaction student/tutor can occur either virtually, mediated by suitable information and communication technologies, and in presence, with strong emphasis on tutor availability and support given by him/her to the understanding of content and knowledge generation.

Constructivism in Distance

In the opinion of Todescat and Santos (2006), university is currently promoting advances in various fields, generating social, economic, cultural, environmental and technological changes that impact the development of society, through the flow of information and the creation, transfer and use of knowledge. Thus, it is necessary to find a way to adapt the university to the new economy and new society in constant change, and make it stand as a center of knowledge creation.

Gadotti (2000, p. 9) also states that "school is challenged to change the logic of the construction of knowledge, because learning now occupies our whole lives." This statement emphasizes that the need for continuous learning must exist on the part of educational institutions, media to innovate and change the ways in which knowledge is constructed.

In order to understand constructivism, it is important to know how the information differs from knowledge. To Valente (2008, p. 106), information is "the abstract representation of the facts", while knowledge is "what each individual constructs as product of processing, interpretation, understanding of information, something being built by each one, very unique and impossible to be passed."

Valente (2008) also states that the distinction between information and knowledge suggests different meanings to the concepts of teaching and learning, where learning, according to one interpretation cited by him, relates to constructing knowledge from the processing of information received. Therefore, two pedagogical approaches are up to the educator as they are seen by the authors as complementary views, the transmission of information and assistance in the construction of knowledge by students.

According to Jonassen (1996), traditional conceptions of learning assume that knowledge is an object, something that can be transmitted from teacher to student. In contrast, constructivists believe that "knowledge is a human construction of meanings that seeks to make sense of their world, to explain ideas and new phenomena in terms of existing knowledge" (p. 3). Therefore, for constructivists, knowledge is constructed rather than transmitted; however, it can be shared.

The process of knowledge construction must start from a dissonance between what is understood by the student and what is observed in the environment. Being that knowledge personally constructed, it is personally owned and assigned. Table 2 aims to point out a comparison made between the characteristics of knowledge according to traditional and constructivist beliefs/conceptions.

TABLE 2: CONSTRUCTIVIST BELIEFS CONFRONTED WITH TRADITIONAL ONES

KNOWLEDGE	
Tradicional conception	Constructivist conception
Regardless of experience	Emerges from the experience
Object possessed by learners	Built meaning
Objective, stable, fixed	Subjective, contextual, fluid
First what's elementary, then the applied	Built in action
Reflects the significance of the real world	Reflects personal meaning
Decontextualized	Built on experience
Very simplified, preconditioned schemes, rigid	Complex, flexible, integrated
Replicable	Applicable

Constructivist learning environments can be supported in distance education through a variety of technologies that are capable of improving the communication and integration and support processes of knowledge construction in distance environments, focusing education on the students and their perceptions about what is gained in terms of information, in order to assist the construction of knowledge on the pupils' part.

With that said, knowledge can be built in Distance Education, and the technologies used in the tutor-student interaction have great importance in this process, since it is from them that information that will be processed by the students are passed with the help of tutors, so that knowledge is built.

Methodology

As for its goals, the study in question was classified as exploratory and descriptive. It is exploratory, since the distance can be seen as an issue rarely addressed at the Federal University of Sergipe, in similar studies, but not in that specific context, involving a case study on the proposed topic. It is descriptive, since its purpose, as stated by Gil (2007, p. 42), is "to describe the characteristics of a given population or phenomenon using standard techniques of data collection, such as questionnaires and systematic observation."

A case study allows a broad and detailed knowledge through deep and comprehensive study of one or a few goals, as Gil (2007) explains. Thus a case study was used in order to understand and explain the problem researched in the Federal University of Sergipe.

The research in question is presented in a comprehensive manner, involving students, tutors and educational institution and the perception of each in relation to the construction of knowledge, both issues that can be quantified, as questions requiring interpretation are needed. Therefore, the research in question is defined generally as qualitative and quantitative.

Data were collected through questionnaires with multiple choice and open questions and interviews. Online and printed questionnaires to students and tutors of ODL courses, using two sampling techniques were applied. The first technique used was convenience/accessibility sampling, which according to Malhotra (2001) is left to the interviewer in the selection of the sampling units, due to its easy access, measurement and cooperation, and because

it is less time consuming. And the second, sampling snow-ball, in which, according to the author, a random initial group of respondents is selected and it is prompted to these to indicate others that belong to the same target population type.

The questionnaires were adapted by using *WebIntegrator*, a tool built in Java that facilitates the development of applications for web. After adaptation a pre-test was made and the questionnaires were made available in the online form. Two sample groups were selected for the questionnaires: one of them related to students of distance subjects/courses at the Federal University of Sergipe (UFS), whose population was located around 4400 vacancies offered in 15 centers in CESAD (Table 3); and the other, referring to DE former tutors and tutors in UFS, whose population consisted of 289 tutors.

TABLE 3: UNIVERSE AND SAMPLE

UNIVERSE AND SAMPLE		
	Universe	Answered questionnaires/Sample
Tutors	289	60
Students	4400	153

The sample of students was diverse, encompassing various courses offered in the regional CESAD centers. The distribution of courses by polis in Sergipe is shown in Table 4:

TABLE 4: OFFERING OF COURSES AT THE POLIS

* Only approved and current offerings are shown		

Data collection took place in the following: through information provided on the CESAD site 199 emails of former tutors and tutors who work/worked at UFS were collected, where online questionnaires links of tutors and students were sent, asking them to be answer and route the questionnaires to other tutors and DE students, of which 60 responses from tutors and 153 responses from students were obtained.

Another instrument used was the interview, which according to Alves-Mazzotti and Gewandsznajder (2001, p. 168), "allows to deal with complex topics that could hardly be properly investigated through questionnaires, exploring them in depth." For purposes of this study, we formulated two tiered interview scripts and these were applied by two people responsible for distance education in the educational research institution in question – a member of the leadership and a member of coordination – selected due to their performance in CESAD and their availability.

Both virtual and applied in person questionnaires had their answers stored in the web application '*Qadmin*', allowing their tab by using simple statistics. To finalize the analysis of data from the questionnaires, weighted averages, based on the intensity scale shown in Table 5 were used, drawn in base ten.

TABLE 5: RANGE OF INTENSITY

SCALE	AVERAGE	MEANING
1	0,0 a 2,0	Terrible
2	2,1 a 4,0	Bad
3	4,1 a 6,0	Regular
4	6,1 a 8,0	Good
5	8,1 a 10,0	Excelent

Tables and graphs were interpreted, generating quantitative analyzes of both tutors as well as the students. Besides that, the results from the interviews generated qualitative analysis of the perception of the course coordinator and Vice-Principal. The interviews were transcribed and responses were grouped by level of similarity, highlighting the interviewees' statements.

Analysis of Results

In this section the data obtained through the questionnaires and the contents of the interviews will be analyzed and interpreted; for this reason it will be divided into two stages. In the first one, qualitative, answers to interviews will be commented and in the second, quantitative, data obtained from the questionnaires to tutors and students will be analyzed.

Qualitative Analysis

This step addresses issues related to implementation of Distance Education at the Federal University of Sergipe and opinions regarding the organization of CESAD, teachers' interaction, tutors and students in distance learning difficulties, technologies adopted, among others, according to the interviews with people directly related to CESAD, one with a member of the board and another one with a member of coordination.

At the level of direction

The respondent holds the position of deputy director of CESAD, which he has been operating for four years. According to the respondent, distance learning implemented by UFS follows the design parameters of Open University of Brazil (UAB), within which there are gaps to formulate their own strategies. In the case of UFS, "the courses of pedagogical projects follow the same model of the presence teaching system, including the duration and the provision of objects,"; for example, the biannual curriculum of a distance learner is the same as a classroom student.

Regarding his perception of the implementation of Distance Education at the Federal University of Sergipe, the respondent asserts that it was a bold action and makes a chronological approach to the facts prior to joining the UAB project, ranging from the creation of NUCE (Center for Communication and Education) in 1996, through the creation of CEAD (Coordination of Distance Education), in the Department of Education, in 1998, and finally, the creation of the Center for Higher Distance Education, through University Council's Resolution n. 49 in 2006. According to him, "it was a long way, but it already yields good results and new challenges."

According to the deputy director, the main difficulty occurred during deployment of Distance Education at the University was "the inexperience of all parties involved with the process at its beginning", and currently it is considered that all agents are broadening their understanding of the mode and this expansion should provide education with quality to students.

Regarding the institutional aspects of CESAD, the quantities involved in the Distance Education at the time of the interview, ie, in February 2010, were: 101 UFS effective teachers, 289 tutors (202 being Distance Tutors and 87-Person) and over 82 professionals including technical and administrative staff, interns, undergraduate courses, post-graduation scholarship students, assigned technicians from other institutions, CLT and specialized service providers, totaling 472 people in the service of UFS' distance higher education. According to the interviewee, unlike teachers, tutors do not belong to the staff of the University, they undergo a simplified selection process and are hired as fellows without employment contracts and therefore do not receive salaries.

Still on the CESAD aspects of the organization, according to the respondent there is not a limit of students per teacher or course, but a limit of distance tutors, which up to the interview date was 100 students for each tutor, but there was a claim that the amount was reduced. As the provision of training for teachers and tutors, the respondent asserts that teachers receive training from the production of printed educational material, the use of *Moodle* and other media.

Regarding the adaptation of distance education students, in the interviewee's opinion it is a little more demanding when compared to regular classroom education students, since they require greater autonomy in organizing their studies, including compliance with time, and have a greater amount of material to read. Any student who has been a regular student in classroom education can adapt to distance education. What is expected is that they have the capacity to build knowledge, not only to search for information, but also the permanent performance of teachers and tutors is necessary to reinforce what is taught. Regarding the levels of evasion of students, a study was being conducted by CESAD itself, but official figures were not available.

The study tools used to distance education at the University are the class books (printed materials), virtual learning objects and video lessons (teacher and subject presentation), and the CESAD aims to increase the demand for the last two items so that they are standardized. Among the difficulties encountered in this type of education three were categorized as they follow:

- Disbelief in the positive results that can be achieved with the DE - the interviewee highlighted some prejudices that exist, such as distrust in the ability of the internet to form and generate knowledge, and the fear that it may be the end of teaching;
- Structural difficulties - some of national character were emphasized, such as the quality of broadband service;
- Students, teachers and administrators inexperience with DE - the interviewee pointed out how the adaptation challenge students and teachers accustomed to classroom teaching model with teaching relationships in distance.

According to the respondent, in order to strengthen and consolidate the contact between students-teachers-tutors there are plans for the university to organize regular face meetings. Regarding the adoption of technologies (ICT) in the educational environment as a means to promote the construction of knowledge, the respondent states:

There is no technology that by itself contributes to the teaching-learning process. It is the use that teachers and students make of the technology that generates positive results. The black board is a technology, as is chalk and cardboard. If the teacher knows how to use this instrument he will do a good job. The computer, television set, DVD player and internet are not magic wands that like a magic will turn the class better and provide better student learning. If the teacher does not hold control over the technology it will be of no avail.

At the level of coordination

The respondent holds the position of coordinator of the Public Administration course and serves on the University for thirteen years and for two years in CESAD. Regarding the implementation of DE at the University, the respondent was optimistic, since, according to him, "the new teaching method has enabled a layer of society to enhance their education and get a college degree." The respondent also pointed out that one of the difficulties, in his opinion, occurred during deployment: the acceptance by some teachers of the new teaching method.

Regarding its functions, the respondent states that there are differences between management of coordination, ie, the coordinators do not operate in a standardized manner, due to the specificities of each course; in addition, he quoted some, such as: the definition of subjects, monitoring the coordinators of subjects (teachers) and coordinators of mentoring.

Regarding the interaction between students and others involved in the teaching-learning process, the respondent contends that the interaction was not accomplished because of the physical distance itself, but considers communication between CESAD, teachers and tutors as being reasonable.

According to the respondent, the level of adaptation of students in distance is good after the student takes full knowledge of the means, because "the student will have to learn on his/her own, and in a way, knowledge is deeper." In addition, the coordinator says that there are many related DE prejudices, including the non-recognition of distance learners as students of the institution and he cited the lack of knowledge about instruments to be used by the subject coordinator as a failure in the DE mode.

Gathering the responses from the director and coordinator, Table 6 shows the questions of the interviews that were common to both respondents and a level of similarity of answers when it comes to the difficulty in the interaction between the involved, due to existing physical distance and a deeper response, due to the position held by the director when it comes to the inexperience observed in all involved, used with the classroom model.

TABLE 6: COMPARISON BETWEEN INTERVIEWS

	DIRECTOR	COORDINATOR
Implantation	Bold action; Yields good results and new challenges	Enables access to training and improvement of society
Difficulties in DE	Quality of broadband service; Inexperience of all involved	Lack of acceptance by some teachers; Non-recognition of distance learners as students of the institution
Interaction	Lack of adaptation to the pedagogical distance relationships; Actions to tighten and strengthen the contact between students-teachers-tutors	Average communication between teachers and tutors; Difficulty in interacting with students because of the physical distance
Role of ICTs	Teacher with control of the technology	Lack of knowledge of the means that can be used by coordinators

Quantitative Analysis

This step describes quantitative aspects related to perceptions of tutors and students. In relation to tutors, the profile, the functions and activities performed, the existence of performance evaluations, the use of resources of ICT, study

materials, course content and assessments to tutor-student interaction and the level of students' satisfaction were investigated. In relation to the students, the analysis also highlights their profile, followed by evaluation of the course, study materials, ICT resources, student-tutor interaction and satisfaction levels.

Tutors Analysis

Considering the profile of tutors, it was observed that most of the respondents are female (60%), single (67%), their ages range between 26 and 30 years (45%), have other gainful activity (80%), have attended online courses/subjects (47%), attended all high school in public schools (48%), have some form of post-graduation, mainly specialization (37%) or master's degree (37%). Moreover, all of them have a computer (100%) and the vast majority (97%) have Internet access in their homes and access weekly for more than 26 hours (47%), including it as their main source of information on current knowledge.

With regard to the functions and activities performed, it was found that they are trained (98%), receiving training or courses for guidance on the duties performed. It should be noted that the Edict for Selection of Tutors (2010) reported that summoned Candidates must attend the Training Program of CESAD, with dates and locations to be communicated by the Centre. The main activities of the tutors are: correcting assessments (90%), provide help to the student understand the course material (92%), motivate the student so that he/she can gain knowledge autonomously (92%), meet queries of the students (95%) and to stimulate critical reflection of students (83%).

As regards to the existence of performance evaluation of tutors, there is knowledge by the tutors (50%) about conducting a review of their handling performance, and opinions vary widely among tutors, demonstrating a lack of standardization between the procedures adopted. Similarly, 35% claim to have no knowledge about self-assessments required of students, 23% say they are never requested and the others divide opinion between always (10%), often (25%) and rarely (5%), again demonstrating the lack of standardization in procedures or difficulties in the transfer of information.

About the usage of resource information and communication technology, the vast majority of tutors (97%) stated that the materials are provided to students, such as books and handouts, which tend to facilitate the learning process. Regarding problems accessing content, it was found that 7% of the tutors said they always come across as a problem in accessing the platform, 46% responded that there is often a problem to access, while 42% said they rarely encounter some problem to access the content. Among the main problems encountered in accessing online content, the one cited as more frequent (60%) was related to content management tool, followed by problems related to connectivity (30%).

Regarding study materials, most tutors who responded to the survey (52%) state that the materials are always prepared in a clear and appropriate manner in order to facilitate understanding of the content. Furthermore, it was found that, according to the tutors (83%) of the materials used are standardized, according to requirement by the University through CESAD. However, to 43% of the tutors just some of the distance education courses/subjects are completed within the academic calendar, with 28% of the tutors saying they have no knowledge of this fact, 13% say that the courses are not completed on time and 12% claim that most of the courses are completed on time.

According to the tutors, course content or objects are often made available to students at the beginning of the semester (48%), with a significant percentage of claims that such contents are always available (43%) and some (7%) claim that the contents are rarely available at the beginning of the school year. They also consider that the courses/subjects are often completed within the dates specified in the academic calendar (62%). From the viewpoint of the majority of tutors (55%), course programs are often linked to the real needs of the students and, in relation to the feedback given to students about their grades and ratings, opinions are divided as part of them (48%) state that it is always given, other (35%) say that there is often feedback to students. To Kenski (2007), giving feedback is among the skills developed through training provided to tutors of distance courses.

Regarding the evaluations and exams, it was attempted to identify three points: embodiment, types of evaluation, and by whom the correction is made. For the first point, embodiment, 85% of the respondent tutors claim that evaluations are performed by individual students, while 10% say they can range from individual and group evaluations. For the second point, the types of evaluation vary between online and classroom evaluation (58%). Regarding the third point, correction, the results show that 96% of the tutors say the exams are corrected by the tutors, or the correction of exams is regarded as a function of the tutors.

TABLE 7: EVALUATIONS AND EXAMS

VARIABLES	ANSWER	PERCENTAGE
Embodiment	Individually	85%
Types of evaluation	Mixed (online and classroom)	58%
Responsible for correction	Tutor	96%

Regarding the interaction between tutors and students, there is a concordance (93%) that it is encouraged throughout the course, something important as the face communication is infrequent or nonexistent in some courses and tutors consider it satisfactory. Most respondents (68%) said they always solve the doubts of the students. Moreover, it was noticed that tutors (85%) believe there is a motivation for students to consult the Internet as an information source. Regarding the incentive to search in libraries, tutors (74%) stated they encourage and assist students in finding information in libraries. This incentive becomes very important because the content provided requires complement, being the tutors the ones to indicate a theoretical framework to facilitate searches by students.

A relevant data shows that none of the tutors surveyed, according to their perception, considered that students are fully satisfied with distance learning. 65% say that perceive students partially satisfied, 27% perceive a partial dissatisfaction and 5% perceive students totally dissatisfied. When asked about the existence of suggestions, complaints or comments on DE in Federal University of Sergipe, tutors had some suggestions that were listed in Table 8:

TABLE 8: SUGGESTIONS TO DE IN THE PERSPECTIVE OF TUTORS

MANAGEMENT	PHYSICAL STRUCTURE	STUDENTS
Enhance the monitoring of tutors and students	To improve the logistics related to the distribution of material	Offer more training to use the Moodle platform
Improve communication with course coordinators and tutors	Create mobile libraries and labs	Observe basic level of knowledge in computer and internet
Improve payment of tutors	Resolve Moodle system deficiencies	Need to self-guide and self-regulate the learning process
Create public examinations to make tutors permanent employees		Monthly classroom feedback
Solve problems related to application of classroom tests		More contact with teachers and tutors
Optimize administrative organization		Establish more specific guidelines about distance education

To conclude the analysis of the responses of tutors' data, averages relating to the following items were analyzed: feedback on grades and evaluations, course content, preparing materials, encouragement of searches in libraries, training of tutors, student satisfaction, completion of courses, performance evaluation for tutors and self-evaluation for students, as shown in Table 9.

TABLE 9: ITEMS AND THEIR AVERAGES – TUTORS

ITEMS	WEIGHTED AVERAGES
Feedback on grades and evaluations	7,87
Course content	7,78
Preparing materials	7,53
Encouragement of searches in libraries	7,12
Training of tutors	6,89
Student satisfaction	6,52
Completion of courses	6,26
Performance evaluation for tutors	5,17
Self-evaluation for students	4,47
OVERALL AVERAGE	6,62

The obtained overall average was 6.62, a result that shows that the perception of the tutors about the items cited is considered good, according to the intensity scale shown in Table 5 (methodology). Among the items, feedback on grades and evaluations was the one with the highest average, 7.87, also considered good, showing that, for tutors, feedback given to pupils is satisfactory. The lowest average presented was 4.47, referring to self-evaluation of students, which is considered average.

Students Analysis

Regarding the profile of distance education students at UFS, it was found that most respondents are female students (61%), they are between 26 and 30 years old (26%), they are married (45%), work more than 20 hours per week (74%), do not have children (51%), attended the regular/traditional high school (65%) in public schools (59%), within the State of Sergipe (90%) and have complete higher education (65%). It was shown that there is a high level of education, which shows that students should get in Distance Education a complement to studies. Furthermore, the majority (93%) is students of Laranjeiras, São Cristóvão and Estância polos, they have basic and medium knowledge of informatics (81%), with internet access at home (73%) and have a weekly frequency Internet use up to 12 hours (59%). Another important aspect is that most distance education students of the Federal University of Sergipe (75%) previously attended online subjects or courses, including part of them (46%) attended courses/disciplines in the university itself.

In terms of the content presented in class, students consider that they are always (27%), often (37%) or rarely (24%) made available at the beginning of the school year. Moreover, according to the students' level of agreement, the contents learned during the courses are consistent with those presented in the syllabus (77%). Regarding the online content access, 52% of students stated that there is often a problem in access and 15% say that there is always a problem, while 26% believe that there is rarely a problem in access. According to most students (35%), the courses are rarely completed within the academic year, a rate that contrasts with the percentage of students (32%) who claim that the courses are often completed in the period. Another relevant fact is that although 37% of students think the course syllabus is often linked to their needs, 34% indicated that the programs have rarely bond with their real needs.

With regard to the materials used, according to 52% of students surveyed, printed materials are provided during the course, and 31% say they often are provided and 8.5% report that they are rarely provided. Also with respect to materials, it was realized that students consider that not all materials are clear, appropriate and promote the understanding of the course. 36% believe that most materials possess these characteristics, while 33% say that only a few are clear, appropriate and promote the understanding of the course.

In terms of resources for information and communication technology, it was observed that the majority (61%) of the students think that the Moodle tool has friendly design and layout, making it easier to understand. It is worthy to notice that problems in accessing and navigating Moodle tend to cause difficulties in the learning and knowledge construction process, requiring the use of other forms of interaction between tutors and students, in order to enable students to use content management tool correctly or adopt another tool to facilitate accessibility. The majority of respondents considered that the students' tools to support distance education are adequate assistance in understanding the content.

Regarding student-tutor interaction, 39% of respondents stated that students communication often happens, while 37% claimed that there is rarely communication between tutors and students. According to most students respondents (36%), they are rarely given feedback about their grades and exams, and 16% claim to have never received any kind of feedback from tutors regarding their grades and evaluations; however, an equivalent number (30% of students) say they often are given a feedback. According to 47% of students respondents, tutors rarely respond doubts or questions in a timely manner, while for 33% tutors often respond in a timely manner. Moreover, most students (42%) say that replies submitted by tutors are rarely clear and objective, data that shows that students can be harmed by tutors not answering their questions in a timely manner and the lack of clarity and objectivity of the answers they receive. For 43% of students, tutors rarely use techniques that encourage and stimulate learning, while for 28% of the pupils, tutors often use these techniques and 16% say tutors never use techniques accordingly. Furthermore, for 34% of students, tutors rarely motivate the search for information in libraries and/or queries on the internet; for 30% of the students tutors often motivate this search for other sources of information besides the content presented. Regarding the promotion of discussions in Moodle, according to 42% of the students tutors rarely use the tool for this purpose; while 25% say that tutors often engage in discussions with students.

Aspects related to interaction between students and tutors indicate that, despite some contrasts, according to a large number of students, the interaction is rarely encouraged, as shown in Table 10:

TABLE 10: INTERACTION STUDENT-TUTOR

VARIABLE	PERCENTAGE
Communication	37%
Feedback	36%
Asnwers to questions/doubts	47%
Clear and objective answers	42%
Usage of techniques that favor and encourage learning	43%
Motivation to search for additional information	34%

Most students (32%) have no knowledge of any request for self-assessment of their performance, and item that can demonstrate both a deficiency in communication, as a variation in the methods of the tutors.

Regarding the levels of satisfaction in all variables, the students said they were partially satisfied, as it can be seen in Table 11:

TABLE 11: PARTIAL SATISFACTION OF STUDENTS

VARIABLE	PERCENTAGE
Course	61%

Moodle	50%
Relationship with the tutor	58%
Relationship with colleagues	42%
Learning	63%

The observed data show that the students are not completely satisfied with distance education, information that can be highlighted by the finding that students (58%) are not sure whether or not to enroll in other courses or subjects in the distance university, answering 'maybe' to the question, while 26% say they definitely would enroll in other courses/subjects in DE in UFS. In addition, students respondents (50%) indicate they always feel the need of classroom classes to complement the content presented in online class, 24% of students said they often feel this need and only equivalent to 1% said they never feel the need of regular classes as a complement.

When asked about the existence of suggestions, complaints or observations, students made suggestions, some of which are listed in Table 12:

TABLE 12: SUGGESTIONS TO DE IN THE PERSPECTIVE OF STUDENTS

MANAGEMENT	PHYSICAL STRUCTURE	INTERACTION	OTHERS
Greater impairment of coordination	More appropriate classrooms	More contact with tutors in person and in distance	Revision before exams
Frequent contact from CESAD to inform and clarify doubts	Improvements in Moodle platform or training of students	Formation of study groups	Field research
Align the DE academic calendar with the classroom courses	Possibility of using laboratories on weekends		Timely delivery of materials, corrections of exams and activities and the dissemination of grades
			More time between exams

In order to finalize the analysis of data on student responses, weighted averages, based on the intensity scale shown in Table 05 (methodology) were used.

The averages were analyzed regarding the following indicators: the need for classroom classes, coherence of content and teaching plans, satisfaction with colleagues, Moodle, student-tutor communication, support tools, satisfaction with Moodle, the course program and student needs, motivation to search for information, interaction - online communication, interaction - questions, feedback on grades and exams, self-evaluation of students, learning stimuli, discussions with tutor, laboratories, equipment, as shown in Table 13.

TABLE 13: ITEMS AND THEIR AVERAGE – STUDENTS

ITEMS	WEIGHTED AVERAGES
Need for classroom classes	7,9

Coherence of content and teaching plans	7,27
Satisfaction with colleagues	6,19
<i>Moodle</i>	6,06
Student-tutor communication	5,84
Support tools	5,76
Satisfaction with Moodle	5,74
Course program and student needs	5,3
Motivation to search for information	5,18
Interaction - online communication	5,04
Interaction - questions	4,82
Feedback on grades and exams	4,57
Self-evaluation of students	4,57
Learning stimuli	4,16
Discussions with tutor	4,05
Laboratories	3,8
Equipment	3,76
OVERALL AVERAGE	5,29

The obtained overall average was 5.29, which shows that the students' perception regarding the analyzed indicators is considered regular, according to the intensity scale. Among the items, those regarding the need for classroom classes (7.9) and coherence of content and teaching plans (7.27) had the highest average. Therefore, despite the coherence between content and teaching plans, students assert they feel the need of classroom classes. The items "labs" (3.8) and "equipment" (3.76) had the lowest average, ie, the perception of students is considered bad, confirming the inadequacy of the laboratories and equipment of CESAD.

Concluding Remarks

This study sought to identify the perceptions of students, tutors, coordination and direction of the Center for Higher Distance Education (CESAD) regarding the use of new technologies applied in distance education and their contribution to the construction of knowledge in the Federal University of Sergipe. The aim of the study was achieved while with its accomplishment it was possible to identify the profiles of students and tutors of distance learning courses at UFS, the functions performed by the tutors and the lack of standardization in the activities performed, the information and communication technology resources that are employed and the ones in need of settings for their usage, because it was not considered fully satisfactory. Moreover, the satisfaction of students in some aspects and information regarding the implementation of distance education at the university were investigated.

In the view of those responsible for managing and coordinating the implementation of distance education it was a bold action because it is of a deep character, but in general, they seem hopeful about the good results that can be generated by distance education, despite the difficulties and failures encountered. In the view of the students, it was found that even though they believe that DE is still incipient in the University, which has numerous flaws and difficulties, they see themselves as a key part of this teaching modality and require that teaching is geared to their needs, the realize progress and are confident that the improvements that are still needed will come to reality. The tutors perceive the distance mode as something new, a perception that tends to justify the various failures exposed by them and, according to them, will only be resolved with greater educational and administrative organization.

Regarding the features of information and communication technology, according to the tutors there is a standardization of materials provided by the university, since, according to them, these materials are always prepared in a clear and appropriate manner in order to promote understanding of content. In contrast, students consider that not

all materials have these characteristics, but the tools to support distance education are often appropriate. According to responses of tutors and students, it is noticed that in addition to materials available online, printed materials are provided for the students such as books and handouts.

When it comes to the interaction between students and tutors, tutors say that communication is always encouraged during the course, that feedback to students about their grades and evaluations are always given, that they address the questions of the students, and they often take suggestions from students into account. The students' perception makes some contrasting aspects, as these often claim that some communication happens and receive some feedback but only rarely tutors answer questions in a timely manner, provide clear and objective responses, use techniques that stimulate learning, motivate the search for additional information from libraries and/or queries on the Internet and develop discussions on Moodle.

None of the tutors surveyed believe that students are fully satisfied with distance learning, but realize that students are partially satisfied, data that coincide with the opinions of students, who were asked about their satisfaction with the course, the Moodle platform, the relationship with tutors and relationships with colleagues and they claim to be partially satisfied.

The results show the need for improvements by students themselves for greater adaptation in the distance, as by the tutors to increased motivation and learning and monitoring and by the CESAD for greater interaction with others involved in distance education as well as encouraging interaction between tutors and students and among students themselves, adaptation of equipment, materials and platform to students' needs or training for better usage of these resources. Furthermore, the results make it possible to confirm that the information and communication technologies employed for interaction and transmission of information among those involved in distance education have fundamental importance to face barriers created by physical separation of the involved in DE.

However, despite the known importance of these resources, several critical problems in distance education were found, including problems in the interaction and transfer of information, which could be remedied with the proper use of available resources. It is noteworthy that these results deal with a reality of a research institution which may be different from other institutions, thus suggesting the development of other research and comparative studies in order to improve the structure of DE in the view of all involved, mainly its prime target, the students.

Thus, the following suggestions for improvement of distance education for the researched institution and others who face the same problems may be:

- » Conducting preparatory meetings at the beginning of the academic semesters for new students to meet the specificities of this mode of teaching and learning, the platform used, the operation of DE, as well as tutors and peers with whom they will interact during the course/semester.
- » Improvements in accessibility of Moodle and/or provision of training to students and tutors to use all available tools in the virtual environment;
- » More interaction, both in distance and face-to-face, between management, tutors and students, so that problems are identified and resolved, for there to be a monitoring of the performance of students and tutors and that information can be transferred more quickly and efficiently;
- » Best preparation and greater availability of tutors for clarification of questions, so that they are resolved satisfactorily and in a timely manner;
- » Creation of libraries and laboratories, as well as encouragement from tutors for students to obtain external information (internet, libraries, videos, etc.), in addition to materials available, because even if the students are in an autonomous learning process they need motivation to continue their studies;
- » Adoption and standardization of video lessons by teachers or tutors to assist and complement fixing the content covered;
- » On-time delivery of printed materials, dissemination of materials onto the platform, correction of activities and dissemination of grades.

Although the proposed facilities are possible to be accomplished, distance education demands a differentiated student profile, with distinct capabilities to study and interaction skills; it opens space for the tutor, responsible for motivating and creating an environment where the student can, by means of ICT to transform information into knowledge received; so that communication is facilitated, feelings of isolation are reduced, the content addressed is complemented, doubts are resolved and information that will assist in the construction of knowledge is assimilated.

The use of ICT and its impact on the educational process of teaching

Abstract

The purpose of this research is to identify the relationship of the competitiveness of teachers in the use of information technologies in the educational process of teaching.

The sample was made up with professors in the academic department of Marketing and International Business on CUCEA, University of Guadalajara.

In the model we use a group of factors which were identified and used in previous researches which were discussed in the theoretical framework of this research. The educational process of teaching was the dependent variable and as independent variables automated knowledge resources, interconnection achieved through ICT tools and diversity in educational process were considered.

The use of the SPSS 20.0 program, allowed us to determine the relationship that independent factors exert in the educational process of teaching.

The investigation emerged from the need to know the impact that the competitiveness of teachers have in the use of ICT in the process of educational instruction, the results were analyzed, plotted and interpreted in order to identify the relationship of the competitiveness of teachers in the use of information technology on the educational process of teaching.

Keywords: Information and Communications Technology (ICT), educational teaching process

Introduction

Nowadays the teacher must constantly strengthen their educational performance considering they live in a society that is evolving day by day with the use of ICT; however, it is paradoxical that some teachers are not competent regarding for the use of ICT.

Teachers not trained in the use of ICT will have a high probability of being marginalized in the progress of the learning-teaching and if that happens, the problem will be profound consequences for educational quality. States that teachers are people with extensive knowledge and experience in the educational process, however some of them lack of outdated knowledge in ICT, becoming therefore an indispensable necessity that the current teaching not only know and use the ICT, but must achieve proficiency to make efficient use of them, surpassing, improving educational performance, reinforcing their knowledge and placing it in a current reality that reinforces their autonomy and critical ability. (Área, 2001).

In this research teachers of the Department of Marketing and International Business from the University Center for Economic and Administrative Sciences will be used as study subject in order to identify their competitiveness in the use of ICT in teaching and learning educational process.

Theoretical Framework

Throughout history, technological advances have changed the societies where there have been implementing different technologies (Cabrero, Lorente and Roman, 2007). There are a lot of researches into the use of ICT once in favor and other in disagreement for the use of it. Some authors state that the uses of ICT condition the didactic potential of the teacher (Weaver, García-Valcárcel and Prada, 2009).

The information and communication technologies are considered all those technological tools and resources used to communicate, create, disseminate, store and manage information (they are abbreviated with the acronym ICT). Communication and information are at the heart of the educational process, consequently the use of ICT in education has a long history. (Blurton, 1999).

In recent years there has been great interest in how computers and the Internet can be used to improve the efficiency and effectiveness of education at all levels and in both formal and non-formal settings. (Tinio, 2003).

Should not lose sight that the effective integration of ICT into education systems is a complex process that involves not only technology, but also curriculum and pedagogy, instructional preparation, skills of teachers and students, etc.

The courses based on ICT requires elements to monitor student progress in course content and to evaluate the acquisition of knowledge and skills. (Mazza & Dimitrova., 2007).

Education becomes increasingly a problem of access to networks and is sold in "instructional packages" and not in construction projects by sharing and solidarity. The individualizing trends make it more difficult the ICT use by the community, although sometimes enriches existing modes of communication and in many others, tend to replace them. Information is not knowledge and, much less wisdom; transmission of technological knowledge by itself does not solve the difficulties inherent in the process of learning or guarantee the training of citizens. (Sanz, 2006)

The use of ICT supports competitiveness in the field of educational process. ICT as Cabrero, (2006), can provide a teaching and learning environment for students and teachers, achieving competitive results in teaching.

In the new model for Higher Education brings new methodologies, demands and challenges, where the use of ICT is an essential didactic resource in the teaching / learning process. There are many advantages and contributions that digital technologies can have on the world of education today. Cabrero and Gisbert (2005) mention that some areas of human endeavor is the use of ICT to generate controversy.

Cabero (1996) has summarized the most distinctive features of the new technologies in the following traits: intangibility, interactivity, immediacy, innovation, high standards of quality picture and sound, digitization, influence, more about processes, than on products mentioned automation, interconnection and diversity.

The paradigms of new technologies are computer networks. Computers, isolated, offer a lot of possibilities, but increase its functionality connected by several orders of magnitude.

The use of these media can have both advantages and disadvantages and hence the need to try to identify what kind of technologies can be used for educational purposes in view of the skills of teaching with interactivity, innovation, digitalization and automation. Information and Communication technologies (ICT) can contribute to universal access to education, equal education, the practice of teaching and learning quality and the professional development of teachers as the management direction and administration more efficient of the educational system. (UNESCO, 2008).

New technologies (ICT) is essential that teachers are trained to teach new pedagogies and to integrate ICT in the teaching-learning process. So that teachers be evaluated by a process or certified institution granting the validity of knowledge to the teacher, if this is competent.

ICTs can help strengthen and management of democratic and transparent educational planning. Communication technologies can expand access to learning, improve quality and ensure integration. (UNESCO, 2008).

The end of the competitiveness Porter (1990), is to raise the standard of living of the population, the efforts of the countries and regions should aim to prepare their youth to be competitive. The use of ICT by teachers in the educational process of teaching and learning will contribute in achieving this competitiveness.

Justification

Most countries in the world in higher education had adopted ICT, in other levels of education have fallen behind. The use of ICT to increase access and achieve a more inclusive education, improving pedagogy and increasing both the number of teachers and their capacity, remains weak. ICT should reach people of all ages, all linguistic and cultural groups, and in all circumstances. The focus should be primarily on teachers, in the broadest sense, that is, all the people who can facilitate and expand learning opportunities for all.

Current barriers and future proposals according to research of Segura (2011), the educational landscape in the educational institution the use of ICT advances slowly, especially in countries with fewer resources, a new educational landscape is emerging that schematically, is characterized by:

- The need for continuous updating of knowledge, skills and approaches (learning throughout life).

- The most important domain of cognitive and metacognitive processes and strategies against the content (learning to learn).
- The concept of literacy has changed and expanded to new areas such as mediated communication, multimedia network or the new screens. Literacy is now recognized as a complex and evolving concept in time, as a process of learning that lasts a lifetime and whose domain and applications are constantly being revised.
- The use of Information and Communication Technologies (ICT) causes that education do not have to be conditioned by time and space, and provides, the methods of individual learning and group learning and then to community learning, where knowledge is socially constructed.
- The need to change the roles of teacher and student. The teacher should stop being a speaker or instructor who dominates knowledge to become a consultant, counselor, facilitator and mediator of the teaching-learning process. The professional profile of teachers includes powers to know the capabilities of their students, design interventions focused on activity and participation of the students, evaluate resources and materials and, if possible, create their own teaching aids or, at least, adapt existing ones from the perspective of the actual diversity of their students.

The faculty barriers refer to the lack of training and confidence in the use of ICT. This failure is directly related to the quality and quantity of teacher education programs affecting its competitiveness and use of ICT in educational process.

Most professoriate explores ICT as a tool by following a systematic approach, using them to emphasize the existing traditional practice, gradually introducing them in their scheduling teaching.

Clearly, ICTs have the greatest impact in schools with "e-maturity" and teachers with "e-knowledge", suggesting that once you have laid the foundation, the benefits will be considerable. The challenge is to train all teachers and all schools to achieve "e-maturity."

A recent study in the United Kingdom on ICT test bank schools conducted by Somekh, et al, (2006), found a "technical fall" which occurs when introducing ICT in schools, followed by a significant rise in income. This decline can last about four years, but once the center is fully e-mature, results lift off.

In Mexico very few schools use this new interactive channel as an educational tool. Some institutions have the potential advantage of the use of ICT to create virtual campuses, where students can communicate at any time, either with each other or with teachers. They achieve to attend the students in an easily way. Planellas, Marcell (1997).

The ignorance of the historical development of current developments and the lack of ICT skills and their application in today's learning environments removes competitiveness in the developing countries, leading to the following questions, objectives and hypotheses that are attended in this investigation.

Research Question: What impact on learning, into the educational process, brings the competitiveness of teachers in the use of ICT?

Objectives: To identify the relationship of automated resources, interconnection achieved through the ICT tools and diverse use of ICT tools in the educational process used by teachers in the Department of Marketing and International Business from the University of Guadalajara.

Hypothesis: The implementation of automated resources, interconnection achieved through the ICT tools and diverse use of ICT tools is related positively to the educational processes used by teachers of the Department of Marketing and International Business the University of Guadalajara.

Independent variables:

Automation (automated knowledge resources).

Interconnection (achieved through ICT tools)

Diversity (in educational process)

Methodology

"The methodology represents how to organize the process of research, monitor their performance and present possible solutions to a problem that involves decision-making." (Zorrilla & Torres 1992).

Considering the type of phenomenon that was investigated, the exploratory, descriptive, correlational and prospective approach was used. A correlation analysis of the variables was performed using the model of Analysis of

Variance (ANOVA). Research work was conducted with information obtained from SMBs in the manufacturing industry in the metropolitan area of Guadalajara. A questionnaire specifically designed to gather information to be analyzed for this research was used, with a Likert scaling type.

Type of selected research

- Exploratory research. Is performed when the objective is to examine a topic or research problem which has been little studied, of which there are many questions not addressed or before. That is, when the review of the literature revealed that there are only non-subject guides and vaguely ideas related with the study problem, or, if we inquire into subject and areas from new perspectives. (Hernández Fernández & Baptista, 2010).
- Descriptive research. Search to specify the properties, characteristics and profiles of individuals, groups, communities, processes, objects or any other phenomenon that is subject to analysis. (Hernandez et al, 2010).
- Correlational research. Its purpose is to know the degree of association or relationship that exists between two or more concepts, categories or variables in a particular context. (Hernandez et al, 2010).
- Prospective Investigation. It is that which begins with the exposure of an alleged cause, and then move over time to a specific population, until establish whether or not the occurrence of the effect.
- Statistical Model ANOVA: Analysis of Variance (ANOVA) will be applied to test the hypothesis of linear dependence between the dependent and independent variables, comparing the variance explained by the model and the residual variance. A significance level of 5% will be used.
- The analysis of variance (ANOVA) was used as a test of means for two or more populations. The null hypothesis usually states that all means are equal.
- The analysis of variance of one factor only includes a categorical variable or factor. The differences in the preference of frequent, intermediate, sporadic users and non-users can be examined with one-way ANOVA of a factor.
- The analysis of variance of a factor; one treatment equals a factor level (intermediate users constituted one treated). If two or more factors are involved, the analysis is called analysis of variance of n factors. (Malhotra, 2008).
- **Measurement of Reliability:** Reliability can be measured by applying a measuring instrument two or more times to the same group of people or applying two or more measuring instruments to the same group at different times. The split halves method requires only one application of the measurement and compares scores of both parts which must be highly correlated. Cronbach's alpha coefficient requires only a measurement management for the entire population without the need of dividing it. The method used by the characteristics of the research, will be the Cronbach.
- *Measurement of coherence or internal consistency.* These are estimated reliability coefficients:
- a) Cronbach's alpha (developed by J.L. Cronbach)
- b) The KR-20 and KR-21 coefficients from Kuder and Richardson (1937).
- The calculation method in both cases requires a single administration of the measuring instrument. Its advantage is that it is not necessary to divide into two halves to the instrument items, simply measure is applied and coefficient is estimated. Most statistical programs such as SPSS and Minitab determined this and should only be interpreted.
- It should be noted that there is no rule that says: from this value there are not instrument reliability. Rather, the researcher calculates its value, submits reports and submits to scrutiny user study and other researchers. But we can say - in general - if you get 0.25 on correlation or coefficients, this indicates low reliability; if the result is 0.50, reliability is average or regular. However if it exceeds 0.75 is acceptable, and if greater than 0.90 is high, to take into account. (Hernández, Fernández, & Baptista, 2010)
- **Measuring instrument:** The scaling method Likert type (Likert, 1976), consist of a set of items presented as statements or judgments which subjects choose one of the five points of the scale. Each point will be assigned a numerical value. Thus, the subject will get a total score by summing the scores obtained in relation to all claims. For data collection must perform the following activities: selecting a tool or method of collection, apply the selected instrument and prepare comments, records and measurement results (Hernández Fernández & Baptista, 2006).

Sample designed

- The population for this investigation, it's with 27 professors in the academic department of Marketing and International Business on CUCEA, University of Guadalajara.
- The model is formed with 27 professors, that they represents a degree of coverage of 9.87% to population.
- The polls were applied to the professors in the academic department of Marketing and International Business on CUCEA, University of Guadalajara.

N= Univers of professors in the academic department of Marketing and International Business on CUCEA, University of Guadalajara. (27)

TABLE 1. FREQUENCY OF GENRE

		SEX			
		Frequency	Percentage	Percentage available	Porcentaje acumulate
Available	Female	10	37.0	37.0	37.0
	Male	17	63.0	63.0	100.0
	Total	27	100.0	100.0	

Own elaboration.

The poll was applied on 2011 A, 2011B, 2012 A, 2012 B

TABLE2. AGE OF THE RESPONDETS (27 PROFESSORS)

		Age			
		Frequency	Percentage	Percentage vavailable	Percentage accumulated
Available	30 a 34 years	1	3.7	3.7	3.7
	40 a 44 ayears	4	14.8	14.8	18.5
	45 a 50 years	3	11.1	11.1	29.6
	51 or more	19	70.4	70.4	100.0
	Total	27	100.0	100.0	

We can see that the most percentage are between 45 to 50 years, and the second places are between 40 to 44 years

TABLE 3 ACADEMIC TRAINING

		FACADEM			
		Frequency	Percentage	Percentage válido	Porcentaje acumulado
Available	Marketing	2	7.4	7.4	7.4
	Admon	14	51.9	51.9	59.3
	Others	11	40.7	40.7	100.0
	Total	27	100.0	100.0	

We get as percentage accumulated by the academic training of the Business Administration and other careers have the most number of professors respondents

TABLE 4 DESIGNATION

DESIGNATION

		Frequency	Percentage	Percentage available	Percentage accumulated
Available	Half time	4	14.8	14.8	14.8
	Full time	22	81.5	81.5	96.3
	SNI	1	3.7	3.7	100.0
	Total	27	100.0	100.0	

When we began this project on 2011 A, only if the professors have this designation. At the end of 2013 A the change of SIN increase to 1 more having a total of 2 and the more number of professors are of full time with different designation

TABLE 5 ANTIQUE

ANTIQUE

		Frequency	Percentage	Percentage available	Percentage accumulated
Available	0 a 5 years	1	3.7	3.7	3.7
	6 a 10 years	4	14.8	14.8	18.5
	11 a 15 years	6	22.2	22.2	40.7
	16 a 20 years	2	7.4	7.4	48.1
	21 a 25 years	5	18.5	18.5	66.7
	26 or more	9	33.3	33.3	100.0
	Total	27	100.0	100.0	

Our percentage in first place is between 21 to 25 years, in second place is between 16 to 20 years and third place between 11 to 15 years.

TABLE 6 VIRTUAL COURSE

	Intra-group	38.324	22	1.742		
	Total	60.074	26			

Resources and handling of ICT was the searching of information in data bank.
It is the most used for the support of teachers.

Conclusion

This investigation help us to know and show us the relation and the importance of the use of ICT in teaching process of education in the University of Guadalajara, in universitary center of economical and management sciencies in the department of marketing and international bussiness.

In the long of the investigation was used considering the type of phenomenon that was investigated, the exploratory, descriptive, correlational and prospective approach. Because its based in the description of how the different factors influence over the dependent and independent variables, in this case the use of the resources in the smart classrooms in the university center are very used at the same time that they are used the forums to complement the help in teaching process. Complementing the use of videos and searching of information in the data bank that has the same center for support teachers in teaching and learning.

Eight years into career after business degree – Influence of gender and personality on career success

Abstract

The aim of this study is to find recent information on how different personality preferences and gender are in relationship with career success. This topic is important also because shorter graduation times and yet longer productive work years are demanded by the society, thus more strategic career planning is needed.

The graduates (N=307) of a Finnish university have worked for an average of 8.3 years. The objective career success was measured with salary and position, and the subjective career success was measured with career satisfaction, satisfaction with employer and work relations, and work-life balance. Independent variables were personality and gender.

Some aspects of personality were impacted by gender others were not. The results show for example that extraverted men were in better positions and were earning more money than introverted men; they were also more satisfied with their career than introverted. Perceiving people overall are not as stressed over heavy work load, which indicates that spontaneity and flexibility is more preferable and should be developed in business life.

Introduction

The web of science finds 1047 articles and reviews for “career success” search and the topic has been studied throughout times because individuals’ career success reflects organizations’ success, thus researchers and managers need to know how to assist employees with this (Ng, Eby, Sorensen and Feldman, 2005). The developments in the world economy after 2008 may have altered people’s views of success. Unemployment rates have increased and managers’ bonuses decreased. How is career success viewed currently by Finnish business people? This updated information is needed to guide universities in their recruiting, and to give more specific reference to educational and career advisors on how business degree has served different personality types, for example.

Career success can be defined as positive work related outcomes, and psychological accomplishments that originate from individual’s work experiences (Judge et al., 1995; Seibert, Kraimer and Liden, 2001). Career success has been traditionally divided into objective and subjective categories. Objective career success is typically measured by “external indicators of career advancement or the accumulation of extrinsic rewards” (Feldman and Ng, 2007). Objective career success measurements have historically been more used in research: it is easy to collect information of salary and promotions, preferably from companies rather than self-report (Heslin, 2005).

Typically researchers have investigated individuals’ “attitudes, emotions, and perceptions of” their personal career accomplishments to determine the level of subjective career success (Feldman & Ng, 2007). Subjective career success is only based on a personal view of the person and can be measured with questions dealing with career satisfaction; it may include intangible desires such as work-life balance and fulfillment. (Heslin, 2005).

Researchers have been studying career success and predicting factors for a long time, and Ng et al. (2005) for example categorized influencing factors as following: 1) human capital, 2) organizational support, 3) socio-demographic variables, and 4) staple individual differences. All categories were found to be positively related to career success. Organizational support (such as career support, support of manager, and training and developmental possibilities) and individual differences (such as personality and proactivity) influenced more subjective career success. Meanwhile, objective career success was more related to socio-demographic variables (such as gender, age, and ethnic background) and social capital (such as work hours, work experience, educational level, political skills and knowledge). Women had a stronger relationship between salary and education, and salary and work hours, which indicates that they have to work harder to prove their competence. Educational level was related to work satisfaction more so in case of women than men. (Ng et al., 2005.)

Ng et al. (2005) suggested more studies regarding the differences between men and women. They were especially interested in seeing what kind of situations set an advantage for men or women when compared to one another regarding objective career success. They also encouraged finding other influential variables that were taken into account in their meta-analysis. Spurk and Abele (2011) encouraged to find more details of individual differences’

impact in career success. Other factors that have been found to be related to objective or subjective career success are the size of the organization (Judge et al., 1995), career mobility (Feldman and Ng, 2007) socio-economic background and education success (Childs and Klimoski, 1986; Furnham and Cheng, 2013) and intelligence (Hartmann, Larsen and Nyborg, 2009).

Judge and Kammeyer-Mueller (2007) proposed three reasons why personality does affect career success, first one being that personality influences what jobs [or educational fields] we are drawn to and who gets selected. Secondly personality influences job performance which leads to promotions and better salary and finally, personality influences our social interactions, which help to build networks, gain knowledge and help in one's career. So we can assume that personality and gender will be related to career success, in the next section we will briefly present other previous studies related to the subject.

Earlier studies

Individual traits have found to be impact on career by several studies. Moutafi, Furnham and Crump (2007) studied the relationship of personality and objective career success amongst British managers. They found that intuition correlated positively with the managerial levels, and introversion and sensing correlated negatively. These findings coincide with previous studies (see (Moutafi et al., 2007; Rahim, 1981; Rice and Lindecamp, 1989). Proactive personality (e.g. Challenging the status quo, managing one's career) was also found to be leading to a better career success (Maurer and Chapman, 2013; Seibert, Kraimer, and Crant, 2001). Also Spurk and Abele (2011), Furnham and Cheng (2013), and Boudreau et al. (2001) found indirect and direct influences of personality (Big five traits) on career success.

Judge and Kammeyer-Mueller (2007) conclude in their review of Big five traits' relationship to career success that extroversion tends to be positively related to career success both subjective and objective. In 1996, (Melamed) found that extroverted men had a higher career success than introverted men in UK. Boudreau, Boswell, and Judge's (2001) study supported this results but also found that there no such relationship amongst American executives. Openness to experience had no relationship, and agreeableness had a negative relationship to objective success but no connection to subjective success. Conscientiousness may have a positive relationship to both but the results are inconsistent, whereas emotional stability shows bit stronger relationship to both. (Judge and Kammeyer-Mueller, 2007.) Psychological aspects, like personality and psychological capital has been found to be positively connected with individuals' career mobility and success also, when the mobility is not physical but psychological (see e.g. Brandt and Järnlström, 2013; Verbruggen, 2012). Researchers have also found a relationship between personality types and higher education success (Routamaa, Koskinen and Koskinen, 2010; Hautala and Routamaa, 2007), which implies that this specific personality indicator may be a good predictor also regarding the careers.

Methods

Personality Indicator

Personality might be considered the one dominant trait a person displays, but usually it is defined as a distinctive pattern of traits or behavior in which thoughts and emotions are included (Mischel, 1986). In this study we used Myers Briggs Type Indicator (MBTI), which was develop to measure 16 personality types based on Carl Gustav Jung's theory (Jung, 1971). MBTI reveals person's habitual preference of orientation of energy (E/I), process of perception (S/N), decision-making function (T/F) and attitude of life (J/P) (Briggs Myers, McCaulley, Quenk, and Hammer, 1998). See descriptions below in table 1.

The MBTI's "...validity is determined by its ability to demonstrate relationships and outcomes predicted by [Jung's] theory" (Briggs Myers et al., 1985: 175). The MBTI's construct validity has been proven by independent studies that investigated whether type distributions coincide with the requirements of certain professions. Correlations of other measures with the MBTI's continuous scores and studies of behavioral differences between the types have also validated the system (see e.g., Briggs Myers et al., 1985 for more detail). Gardner and Martinko (1996: 77) considered whether the MBTI is "a reliable and valid instrument for studying relationships among managerial personalities,

cognitions, behaviors, effectiveness, and situational variables” and their thorough review suggested that it is. They did recommend some “refinements of type construct and its measures.” The construct validity and reliability of the Finnish form (F-version) have been proven during a validation process spanning several years (see e.g., Järnlström, 2000). Järnlström reported an internal consistency (Pearson’s correlation coefficients) of .65 to .76 and Cronbach’s coefficient alpha of .79 to .86.

TABLE 1: DEFINITIONS OF PERSONALITY PREFERENCES

Extraversion–Introversion Dichotomy <i>(attitudes or orientations of energy)</i>		Sensing–Intuition Dichotomy <i>(functions or processes of perception)</i>	
Extraversion (E) Directing energy mainly toward the outer world of people and objects	Introversion (I) Directing energy mainly toward the inner world of experiences and ideas	Sensing (S) Focusing mainly on what can be perceived by five senses; real facts	Intuition (N) Focusing mainly on perceiving patterns and interrelationships; possibilities
Thinking–Feeling Dichotomy <i>(functions or processes of judging)</i>		Judgment–Perception Dichotomy <i>(attitudes toward dealing with outer world)</i>	
Thinking (T) Basing conclusions on logical analysis with a focus on objectivity and detachment	Feeling (F) Basing conclusions on personal and social values with a focus on understanding and harmony	Judging (J) Preferring the decisiveness and closure that result from dealing with the outer world using one of the Judging processes	Perceiving (P) Preferring the flexibility and spontaneity that result from dealing with the outer world using one of the Perceiving processes

Questionnaires

The participants were send paper and online surveys that included questions about satisfaction to career related issues. They could choose between 1-7 Likert scale, one being disagree completely, and seven being agree completely, or one being very weak, and seven being very good. Out of the 18 questions three factors were formed which described different aspects of satisfaction levels.

The *Career satisfaction* describes persons’ happiness with their career so far and also includes the confidence level of the future career. This is different from job satisfaction that focuses on the current job as suggested by Judge and Kammeyer-Mueller (2007). This factor includes 3 items: ”How has your career been so far in your opinion?”, ”How has your career been when comparing to your peers from university?”, and ”How do you estimate your career success to be in ten years when compared to others in the similar position?” Cronbach’s alpha was 0.834.

Satisfaction with employer and work relations factor includes also three items ($\alpha=.744$), ”I am satisfied with my employer”, ”I am satisfied with the actions of my closest supervisor”, and ”I am happy with my colleagues”.

In the third factor, *Work load* also three item loaded cleanly, reliability test was again satisfactory ($\alpha=.783$). This factor describes the persons’ satisfaction with the amount of work work-life balance. Items included two items that were reversed: ”My job is mentally too straining”, ”I have too much work”, and ”I am able to keep my personal life and work in balance”.

Participants

The data consists of people who graduated from a Finnish university in 2005 or 2006 and had worked in the job that fits their degree for the average of 8.3 years. Their personality types were determined during their studies, and were contacted again last year in 2013 with a paper survey and an online survey. The respondent rate was acceptable 31%, and total amount of respondents was 307. 52% of them were men. In some of the cases we did not have all the required data of them to include them in the analysis thus the number of people vary between different tests, N being between 176 and 293. The respondents have worked an average of 8,7 years after graduation of which average 8,2 years were in a job that was appropriate to their degree. They have worked for 2,5 different employer after graduation on average. Most often mentioned fields were industrial (13,9%), information and communication (15,9%), finance and insurance (10%), b2b sales (7,1%), public sector (6,8%), education (12 %), and other services (9,4%).

Data analysis

Chi-square tests were run to find any significant differences between gender and personality preferences regarding objective career success measurements. Further Cramer's V was analyzed to investigate the strength of the association. Since subjective career success variables were continuous, t-tests and one-way anova were run in those cases and Cohen's effect sizes were calculated and evaluated.

Results

Objective career success – salary

In this section we will explore the results regarding objective career success, both salary and position. First we will view the crosstabulations of salary, starting with just gender, then by personality, finally addressing the comparison between genders with similar personality preferences, for example, a comparison of woman and man introverted leaders, woman and man extraverted leaders. And within gender comparisons are made with opposite personality preferences, for example are there differences between man extraverts and man introverts, or woman intuitivist and woman sensing types. Then the same approach is taken with position.

Women are 29,7% more likely to receive a monthly salary of 3999 euros than men, while men are 36% more likely to receive a monthly salary of over 5000 euros when compared to women. A chi-square test confirms that the men are likely to be more successful than woman when considering salary, $\chi^2(3) = 42.188$, $p = .000$. All expected cell frequencies were greater than five, this was the case in all performed tests in this study except of one exception that will be mentioned later. The association is very strong Cramer's V = 0.383, $p = .000$. In a similar longitudinal study in Germany, amongst medical professionals, men were also found to have earnings much higher to women (Evers and Sieverding, 2013).

The test indicates that there is no statistically significant relationship $\chi^2(2) = 5.771$, $p = .056$ between extraversion-introversion and salary. There is however a trend indicating that extraverts earn more money. A chi-square test reveals there is no relationship between sensing-intuition and salary $\chi^2(2) = 1.115$, $p = .561$. No relationship was found between thinking-feeling variable and salary either $\chi^2(2) = 2.869$, $p = .238$. And finally there was no relationship between judging-perceiving and salary variables $\chi^2(2) = 0.779$, $p = .677$.

A chi-square test was conducted to determine if interaction of gender and personality preference (extraversion – introversion) is in relationship with salary differences. The test indicates that there is a relationship $\chi^2(6) = 25.421$, $p = .000$, and it is very strong $\phi = 0.263$, $p = .000$. As can be seen in table 2 below, extraverted men have a bigger salary than introverted men, and a similar trend is visible with women. Men earn more than women independent of this particular personality preference. Thus gender has a bigger influence on how successful one is when considering objective career success measured with salary only.

TABLE 2: SALARY * E/I*GENDER CROSSTABULATION

		E/I*gender				Total	
		Extraverted men	Extraverted women	Introverted men	Introverted women		
Salary (euros/month)	3999 or lower	Count	10	23	10	13	56
		% within E/I*gender	16,7%	38,3%	27,0%	48,1%	30,4%
	4000-4999	Count	10	17	11	10	48
		% within E/I*gender	16,7%	28,3%	29,7%	37,0%	26,1%
	5000+	Count	40	20	16	4	80
		% within E/I*gender	66,7%	33,3%	43,2%	14,8%	43,5%

Total	Count	60	60	37	27	184
	% within E/I*gender	100,0%	100,0%	100,0%	100,0%	100,0%

A chi-square test was conducted to determine if interaction of gender and personality preference (sensing – intuition) is in relationship with salary differences. The test indicates that there is a relationship $\chi^2(6) = 20.8$, $p = .002$, and it is strong $\phi = 0.238$, $p = .002$. Intuitive women earn more money than women with sensing preference, but in men this personality preference does not seem to have such a strong relationship, see table 3 below.

TABLE 3: SALARY * S/N*GENDER CROSSTABULATION

		S/N*gender				Total	
		Sensing men	Sensing women	Intuitive men	Intuitive women		
Salary	3999 or lower	Count	12	19	8	17	56
		% within S/N*gender	21,8%	50,0%	19,0%	34,7%	30,4%
	4000-4999	Count	10	11	11	16	48
		% within S/N*gender	18,2%	28,9%	26,2%	32,7%	26,1%
	5000+	Count	33	8	23	16	80
		% within S/N*gender	60,0%	21,1%	54,8%	32,7%	43,5%
Total	% within S/N*gender	55	38	42	49	184	100,0%

The relation between thinking-feeling*gender variable and salary was significant $\chi^2(6) = 20.18$, $p = .003$, and it is strong $\phi = 0.234$, $p = .003$. The test's reliability a bit questionable since one cell did not meet the requirements of expected count being more than have. The minimum expected count is 4.43. We did decide to still make careful discoveries of these results. Women who make decision based on values and feelings are more likely to earn more money when considering women with thinking preference, that is logical and objective decision making. While amongst men it is the opposite, as can be seen in table 4 below.

TABLE 4: SALARY* T/F*GENDER CROSSTABULATION

		T/F*gender			Total		
		Thinking men	Thinking women	Feeling men	Feeling women		
Salary	3999 or lower	Count	15	18	5	18	56
		% within T/F*gender	18,8%	40,9%	29,4%	41,9%	30,4%
	4000-4999	Count	17	16	4	11	48
		% within T/F*gender	21,2%	36,4%	23,5%	25,6%	26,1%
	5000+	Count	48	10	8	14	80
		% within T/F*gender	60,0%	22,7%	47,1%	32,6%	43,5%

	Count	80	44	17	43	184
Total	% within T/F*gender	100,0%	100,0%	100,0%	100,0%	100,0%

As can be seen by the frequencies cross tabulated in table 5, there is a significant relationship between judging-perceiving*gender variable and salary $\chi^2(6) = 18.603$, $p = .005$, and it is strong $\phi = 0.225$, $p = .005$. In this case the personality preference does not have any influence on salary differences but it is clearly the gender; men have higher salary women, and within gender the personality has no influence.

TABLE 5: SALARY * J/P*GENDER CROSSTABULATION

		J/P*gender				Total	
		Judging men	Judging women	Perceiving men	Perceiving women		
Salary	3999 or lower	Count	14	27	6	9	56
		% within J/P*gender	21,9%	42,9%	18,2%	37,5%	30,4%

Objective career success – position

The test indicates a strong relationship ($\phi = 0.221$, $p = .000$) between gender and position $\chi^2(1) = 13.424$, $p = .000$. In this sample 21,3 % of top and middle managers were men.

Regarding personality differences; extraverted became top- or middle managers more often than introverted, while introverted were experts or clerks more often, $\chi^2(1) = 5.918$, $p = .015$. The association is moderate $\phi = 0.183$, $p = .015$. Sensing-Intuition $\chi^2(1) = 1.229$, $p = .268$, and Thinking-Feeling $\chi^2(1) = 0.600$, $p = .439$ preferences did not show any statistically significant influence to differences in positions of the participants. Frequencies in cross-tabulation indicate that perceiving was related to Top –and middle management position while people with judging preference became expert and clerks more often than Perceiving people. Yet there was no statistical relationship between these variables $\chi^2(1) = 2.729$, $p = .099$.

A chi-square test was conducted to determine if interaction of gender and personality preference (extraversion – introversion) is in relationship with position differences. The test indicates that there is a relationship $\chi^2(3) = 11.153$, $p = .011$, and it is very strong $\phi = 0.252$, $p = .011$. Only in case of extraverted men, the bigger portion is in managerial position; all other groups have more people in expert or clerical position. Introverted women are not well represented amongst Finnish managers. Interpreting the trends, it appears that extraversion is more important than being a man when hiring managers, see table 6.

TABLE 6: POSITION * E/I*GENDER CROSSTABULATION

		E/I*gender				Total	
		Extraverted men	Extraverted women	Introverted men	Introverted women		
Position	Top/MiddleManager	Count	29	20	10	5	64
		% within E/I*gender	52,7%	33,9%	28,6%	18,5%	36,4%
	Expert/clerk	Count	26	39	25	22	112
		% within E/I*gender	47,3%	66,1%	71,4%	81,5%	63,6%
Total	Count	55	59	35	27	176	
	% within E/I*gender	100,0%	100,0%	100,0%	100,0%	100,0%	

As can be seen by the frequencies cross tabulated in table 7 there is no significant relationship regarding position $\chi^2(3) = 5.888$, $p = .117$. Intuition is highly valued personality preference in managers.

TABLE 7: POSITION * S/N*GENDER CROSSTABULATION

		S/N*gender				Total	
		Sensing men	Sensing women	Intuitive men	Intuitive women		
Position	Top/MiddleManager	Count	21	8	18	17	64
		% within S/N*gender	39,6%	22,2%	48,6%	34,0%	36,4%
	Expert/clerk	Count	32	28	19	33	112
		% within S/N*gender	60,4%	77,8%	51,4%	66,0%	63,6%
Total	Count	53	36	37	50	176	
	% within S/N*gender	100,0%	100,0%	100,0%	100,0%	100,0%	

Thinking-feeling preference interacting with gender does not seem to be in relationship with position $\chi^2(3) = 3.918$, $p = .270$. Men are in higher position regardless the personality preference. See details below in table 8.

TABLE 8: POSITION * T/F*GENDER CROSSTABULATION

		T/F*gender				Total	
		Thinking men	Thinking women	Feeling men	Feeling women		
Position	Top/MiddleManager	Count	32	13	7	12	64
		% within T/F*gender	43,2%	30,2%	43,8%	27,9%	36,4%
	Expert/clerk	Count	42	30	9	31	112
		% within T/F*gender	56,8%	69,8%	56,2%	72,1%	63,6%
Total	Count	74	43	16	43	176	
	% within T/F*gender	100,0%	100,0%	100,0%	100,0%	100,0%	

Judging-perceiving preference interacting with gender does not seem to be in relationship with position $\chi^2(3) = 6.899, p = .075$. The frequencies indicate that perceiving women do have higher positions than judging women, see table 9. But more data is perhaps needed to confirm this.

TABLE 9: POSITION * J/P*GENDER CROSSTABULATION

		J/P*gender				Total
		Judging men	Judging women	Perceiving men	Perceiving women

	% within J/P*gender	100,0%	100,0%	100,0%	100,0%	100,0%

Subjective career success

There were no statistically significant differences between men and women and how they feel about their career success subjectively. Both genders were equally satisfied with their work relation and workload, and even though men are more successful in their career when concerning objective factors, there is no difference between men and women in their career satisfaction $t(275) = 1.470, p = .143, d = .18$, men scoring only slightly higher ($m=5.06\pm.98$) than women ($m=4.89\pm.96$).

Extraverted ($m=5.12\pm.92$) are more satisfied with their career when compared to introverted ($m=4.79\pm.94$). There was homogeneity of variances, as assessed by Levene's test for equality of variances ($p = .893$). There was a statistically significant difference in mean satisfaction with career satisfaction score between extraverts and introverts, with extraverts scoring higher than introverts, 0.33 ± 0.15 [mean \pm standard error], $t(176) = 2.218, p = .028, d = .35$. There were no other differences regarding work relations or workload.

Sensing-intuition and thinking-feeling preferences did not differ from each other regarding any of the subjective career success measurements.

Perceiving people ($m=4.65\pm 1.15$) are more satisfied with work-life balance and feel that work load is not overtly heavy when compared to judging ($m=4.24\pm 1.41$). There was homogeneity of variances, as assessed by Levene's test for equality of variances ($p = .089$). There was a statistically significant difference in mean satisfaction with work-life balance score between perceiving and judging, with perceivers scoring higher than judging, 0.41 ± 0.21 [mean \pm standard error], $t(178) = -1.911, p = .058, d = .31$. No other differences were detected between perceiving and judging. A one-way anova between subjects was conducted to compare the effect of extraversion – introversion personality differences on subjective career success when gender acts as an interaction term. There was a significant differences between the groups at the $p < .05$ level in case of satisfaction with the employer and work relation [$F(3, 176) = 2.67, p = 0.049$] and satisfaction with career [$F(3, 178) = 2.76, p = 0.044$], but no differences in satisfaction to workload [$F(3, 177) = 1.50, p = 0.212$]. As stated above the only important findings regarding extraverted-introverted difference was in career satisfaction, extraverted being more satisfied than introverted. When gender is added as an interaction term, it was found that this finding is true only in case of men. Post hoc comparisons using the Tukey HSD test indicated that extraverted men ($m=5.22\pm.99$) are more satisfied with their careers than introverted men ($m=4.65\pm 1.10$). Extraverted men ($m=5.38\pm 1.09$) were also more satisfied with their employer and work relations than introverted men ($m=4.72\pm 1.08$). It is to be noted that there was no significant difference in any other comparisons, including extraverted men and introverted women.

A one-way anova between subjects was conducted to compare the effect of other personality differences on subjective career success when gender acts as an interaction term. First, regarding sensing – intuition, there was no significant differences between the groups at the $p < .05$ level regarding satisfaction with employer and work relations [$F(3, 176) = .24, p = 0.867$], or satisfaction with workload [$F(3, 177) = 1.68, p = 0.173$], or satisfaction with career [$F(3, 178) = .13, p = 0.941$]. The effect of thinking – feeling revealed no significant differences between the groups at the $p < .05$ level regarding satisfaction with employer and work relations [$F(3, 176) = .11, p = 0.952$], or satisfaction with workload [$F(3, 177) = 1.37, p = 0.255$], or satisfaction with career [$F(3, 178) = .26, p = 0.855$]. And finally, no significant differences were found between the groups at the $p < .05$ level regarding satisfaction with employer and work relations [$F(3, 176) = .37, p = 0.773$], or satisfaction with workload [$F(3, 177) = 2.52, p = 0.059$], or satisfaction with career [$F(3, 178) = .26, p = 0.854$] when judging – perceiving preference was tested.

Discussion

The results show that men were more successful in their career when looking at objective career success measurements. Yet women were just as satisfied with career when looking subjective measurements. Within gender, extraverted men were in better positions and were earning more money than introverted men; they were also more satisfied with their career than introverted. There was no statistical difference amongst women extraverts and introverts.

The results are somewhat surprising, since Finland is quite egalitarian country yet such big differences were found in these recent work entrances' positions and salary. In a Finnish business context it appears to be very important for men to be extraverted to achieve the best positions and salary. Since introverted men are less satisfied with their career we could assume that they are not in expert positions and on lower salary by choice. The results also implicate that in some cases women just have to work harder to achieve the same salary or position as men, but in some cases it is the personality that is more important when making recruitment decisions.

Based on earlier studies regarding job performance, the results regarding personality's impact in career success are not applicable across cultures. Being extraverted and/or Intuitive manager correlated positively in European sample while in China the correlation was negative (Furnham and Stringfield, 1993). Being introverted does not appear similarly in individuals or might not be evaluated in same way when promoting people in Finland as it does in U.S. or China. Then again, similar results were found amongst British managers (Melamed, 1996) regarding extraverted and introverted men, thus it may be safe to assume that this results may be relevant in other countries as well. Europe is a very distinctive area from other continents and it would be beneficial to do comparative studies with other European countries to further career research (Mayrhofer and Schneidhofer, 2009). Of course the results may be also influenced by the answering tendencies that may differ between personalities, that is one of the limitations in this study. Other limitations include the lack of other moderating variables.

Positive psychology term, psychological capital has been recently connected to career success. It has also been found that extraverted, intuitive and thinking people regarded themselves higher in psychological capital than their counterparts introverted, sensing and feeling people (Brandt, Gomes, and Boyanova, 2011). Additionally several studies indicate that the extraversion is related to many of qualities that are close to the dimensions of psychological capital, which are optimism, self-reliance, hope and persistence. For example extraversion is related to optimism (Williams, 1992), self-esteem (Briggs, Cheek and Buss, 1980; Cheng and Furnham, 2001), sense of self-worth (Cheng and Furnham, 2001) and positive self-evaluation (Cheng and Furnham, 2001). Further, several studies indicate that extraverted people have tendency to appraise themselves higher as a leaders than introverts (Brown and Reilly, 2008, Carroll, 2010; Van Velsor and Fleenor, 1997). Thus this study confirms earlier results where extraverted have tendency to overrate themselves and have positive self-evaluations. This extraverts' high positive psychological capital actually may concretize in higher positions and better wage than with introverts with lower psychological capital. As a result this is seen also in satisfaction with employer and working relations.

In practice, the career planning and educational instructors should pay more attention to the introverted men: they are far less satisfied with their career. They have done wrong education or career decisions or they need specific training

to achieve the goals they have in their career. Or perhaps they would benefit from positivity training as the findings regarding psychological capital suggest.

Perceiving people were not as stressed over heavy work load as judging types. Traditionally judging types have dominated leadership positions due to their skills to organize and make fast decisions. As the working loads are heavily growing there may be more demand for perceiving leaders. Perceiving types are spontaneous, flexible, risk-tolerant, and they are tolerant to unambiguity. These are qualities that are needed more and more in future working life.

Overall, this study indicates that personality and gender do influence career success, both on objective level and also with satisfaction in one's career. Men are more successful than women, and this is especially in case of extraverted men. Perceiving people, regardless gender, do not stress at work as much as judging types. In this more complicated changing working life with less people to contribute, it is increasingly important to have or to develop the perceiving abilities so that one is able to work with heavy work load without stressing out about it too much.

Constructing leadership with Generation Y

Abstract

The aim of this study is to examine what kind of leadership Generation Y, or Millennials, construct when referred to positive and negative outcomes of a subordinate. In the data collection process, the method of empathy-based stories (MEBS) and social media were harnessed to reach the informants. Leaning on discourse analysis, this study recognized one meta-level discourse and four sub-discourses from altogether 504 narrations from 252 Millennials. The main voice of the informants called for acknowledgement as an individual. It can be reached through knowing the subordinate and their job; respecting them; hearing them out; and helping them to develop themselves. These findings indicate that supervisors have to stay alert to the needs of their Millennial subordinates, and balance between individual preferences, equality, and, for example, legislation.

Introduction

By the year 2020, Generation Y, or Millennials as the members of this generation are often referred to as, will be the dominant generation in working life (Erickson, 2008). However, there seems to be a call for research concerning the working preferences of Millennials. Many streams of research have been involved in generational discussion and provided their own contribution. Nevertheless, contributions are scattered, and there is a need to create more understanding on the matter. (Joshi, Dencker, Franz & Martocchio 2010.) Further, the lack of empirical data and a wide variety of normative, non-academic texts (e.g. blogs, Internet sources) weaken the reliability and usefulness of this information (Myers and Sadaghiani, 2010).

The purpose of this study is to gain more understanding on what kind of leadership Millennials construct when referred to positive and negative outcomes of a subordinate. The study follows the social constructivist view (Berger and Luckmann, 1994). This study interprets Generation Y and leadership as socially constructed phenomena. Also the research design and the researcher's relationship to the data, as well as the perception of language, resembles with the social constructivist view. These are discussed more in the section of research design.

Generation Y

Regardless of the many efforts by different studies, there is no unanimous view of the definite birth years of Generation Y, or any other generation for that matter. Smola and Sutton (2002) have used the timespan from 1979 to 1994; Arsenault (2004) and Kupperschmidt (2006) on the other hand, have defined Generation Y to have been born in 1981–2000, to mention a few categories.

Generational characteristics, and thus generational differences, are tracked to the events in childhood and early adulthood that shape the generation's mind-set (Parry and Urwin, 2011). However, there are differing views when examining the generational characteristics, *i.e.* do generations differ from each other to a great extent (see e.g. Giancola, 2008), even though some scholars have identified the differences (e.g. Gibson et al., 2009; Sullivan et al., 2009; Chen and Choi, 2008; D'Amato and Herzfeldt, 2008).

Generation Y is born and raised in the times of dual-career families and protective parenting, but, on the other hand, they have also seen lives ending unexpectedly, e.g. in natural disasters, school shootings, and terrorist attacks (Welsh and Brazina, 2010). These have all shaped the beliefs, values, perceptions, and attitudes of Generation Y (Macky *et al.*, 2008; Smola and Sutton, 2002). Also the advancements in technology have shaped Millennials to be competent when it comes to using technology in various ways (Arsenault, 2002). This uniquely created mind-set is reflected in the leadership preferences as well (Arsenault, 2002).

Nevertheless, Millennials are said to appreciate social connections and social working (Myers and Sadaghiani, 2010), flexibility (Behrstock-Sherratt and Coggshall, 2010), work–life balance (Cennamo and Gardner, 2008), training and development (Sturges *et al.*, 2002) and a job description that suits their needs (De Hau and De

Vos, 2010). Further, they would like to work in a supportive environment that offers them feedback (Martin, 2005) and lets them feel appreciated (Hurst and Good, 2009). They are not afraid of seeing changes around them, on the contrary, they are afraid that things do not change (Martin, 2005). It has also been proposed that Millennials are seen as demanding and high maintenance employees (Zopiatis *et al.* 2012; Hira, 2007), although Weyland (2011) concluded that engaging and managing Generation Y requires only new ways of thinking.

These preferences are heavily affected by the actions of the supervisor, especially the closest supervisor. Jamrog (2002) has even stated that Millennials are not afraid of the supervisor being too close, and the supervisor plays an important role for Millennials (*e.g.* Smith, 2010; Hurst & Good, 2009; Martin, 2005; Jamrog, 2002). Overall generational characteristics have been neglected and underappreciated both in research and in practice (Westerman and Yamamura, 2007; Arsenault, 2004; Kupperschmidt, 2000), and Millennials in Finland have not gained too much attention. Also the normative nature of the literature on Generation Y needs to be strengthened with empirical evidence. Thus, this study seeks to contribute to generational studies and especially provide new information on the leadership preferences of Generation Y.

Research design

This study utilizes the method of empathy-based stories (MEBS) in the data collection process. Also the term passive role-playing has been used when referring to MEBS (Eskola, 1991). MEBS utilizes the same patterns people use in their everyday actions (consideration, speculation), as the method sees the informant as an active individual. (Eskola, 1997: 12–14.) By enhancing these patterns, and because the reactions of an individual are not random but based on one's own experiences, beliefs, expectations, and perceptions, MEBS is aiming to reveal how informants construe the topic at hand. (Eskola 1997: 15.)

In MEBS, the cores of the data gathering process are the scripts. Usually there has to be at least two different scripts, as one crucial factor is varied between them. However, the frame of the script and other issues that are mentioned in them should stay relatively stable in order for the researcher to be able to concentrate on the variation between the stories. (Eskola 1997: 16–18.) MEBS was a suitable choice in this data gathering process, as it has advantages in mapping out a research area or conducting more or less exploratory research (Tuorila and Koistinen, 2010; Juntunen and Saarti, 2000).

Regarding the scripts in this study, there are two that concern leadership and supervisory issues. Quite often it is justified to vary positive and negative aspects in the study (see *e.g.* Juntunen and Saarti, 2000).

Positive script: Imagine that one day Sanna comes home from work. She feels herself energetic. She is happy and glad that she has her job, just the way it is, and she is not considering applying for some other job. She feels truly engaged to her employer and it is always nice to go to work in the mornings. What has happened between Sanna and her supervisor, when Sanna is feeling like this and she likes her work?

Negative script: Imagine that one day Sanna comes home from work. She is really irritated and bored. She does not feel like working at all, and she has started to look for some other job, as it feels difficult to go to work in the mornings. What has happened between Sanna and her supervisor, when Sanna is feeling like this and her work is like watching paint dry?

The data were gathered in 2012. They are consisted of altogether 504 short stories written by 252 Millennials. In order to reach the informants, social media (namely Facebook) has been utilized. The scripts were created to an electronic platform, and the link to this questionnaire was shared in Facebook altogether three times. In addition, some e-mailing lists were used as well. The study uses also snowball method, since the link was asked to share forward. The responses took place in an external platform, hence the informants were not able to see each other's stories.

Analyzing process and background perceptions

At first and as a starting point for the analysis, the answers, which varied from one short sentence to approximately 150 words in length, were coded with NVivo and analyzed using the traditional content analysis method. Thus, the main themes and issues became apparent. At second, the longest stories were selected for closer look. This sample

included 19 positive stories and 17 negative stories. These stories were further coded and marked using different colors. Based on this phase of the analysis and careful reading and consideration, five discourses were finally distinguished from the stories (please see the next chapter).

I decided to concentrate to examine *how* the informants write about supervisor issues rather than to evaluate the level of truth as such (see Eskola 1997: 96–97 or Eskola 1991: 20–21). Further, the interest is not merely in similarities or patterns in the material, but also in dissimilarities between the informants' stories (i.e. multi-voiced view).

I lean on the social constructionism view (see Berger and Luckmann 1967), in a sense that in this study the language is seen as a part of the reality rather than only a mediator of reality or a reflection of it (Eskola: 1995: 288). Additionally, I apply here discourse analysis as a research method that is more like a loose framework or a guiding principle instead of strict regulations (Potter and Wetherell, 1990). I further relate to the views concerning discourse analysis and the use of language by Alvesson and Kärreman (2000). They call for a “*discourse-near*” approach, which they further identify as discursive pragmatism. It does not diminish the meaning of language or language use, but it takes a step towards more speculative nature of discourse analysis, which allows discussing indications and conclusions behind the discursive material. Moreover, the roots and antecedents of this particular approach are the same as in any discursive view. The authors call for pragmatism in methodological issues, and they remind that, in the end, the research interest defines the most suitable approach. (Alvesson and Kärreman, 2000.)

Adopting the views by Alvesson and Kärreman (2000) lead to interpret the possible meanings behind the actual language (text) the informants used. However, the main interest concerns the texts themselves, but I have tried to work towards interpretations and conclusions based on the material. In relation to this approach, I respect the richness of social reality and, thus, will not try to underestimate it. On the contrary, one of the objectives is to aim to capture the different viewpoints, contradictions, and tensions. This led me to reflect upon the narrations and adopt a speculative view when presenting the findings. Overall, I am giving voice to Millennials' narrations in this study, but I take the next step as well when analyzing, interpreting, and concluding. I consider this as the relationship between me as a researcher and the material for Millennials.

Discourses

In this study, I wanted to examine the perceptions of especially the closest supervisor and supervisor work as well as the relationship between Millennial and her/his supervisor, and how these are construed according to the stories. Thus, mentioning the supervisor in the scripts was intentional and considered. In fact, it was the purpose of this study to see, what kind of issues the informants attach to the supervisor and how they narrate supervisor's actions both in good and bad. All of the informants treated the scripts the way I expected them to, *i.e.* referred to supervisor and explained her/his actions, such as receiving feedback, respect, or rewards (both material rewards such as pay rises, salary, and bonuses; and non-material like career opportunities and more responsibilities) from the supervisor. Also, especially in based on the negative scripts, unevenly distributed workload was pointed out as a negative action of the supervisor. Only a few informants mentioned straightforwardly that the protagonist's feelings are a result of something other than the actions of the supervisor, for example the work itself.

In the next section I present the strongest discourses: one meta-level discourse and four other discourses that complement each other. They are somewhat overlapping, but I consider it as a natural consequence, as the themes the informants mentioned are complex, as is the supervisor work in practice, too.

Acknowledge me as an individual!

The strong meta-level discourse deals with acknowledgement. A story-line in the narrations more or less handled how feeling acknowledged was the key for the protagonist to feel herself well and happy. This was demonstrated with the supervisor's ability to offer tailor-made solutions based on the protagonist's capabilities, desire, and life situations. There is a need to feel special in the supervisor's eye, and have a feeling that the supervisor can be trusted to take care of the protagonist.

“The relationship between Sanna and her supervisor is between two adults rather than between a boss and a subordinate. They both respect each other and the other person’s viewpoints, wishes, expectations, and suggestions. Communication between Sanna and her supervisor is open and confidential; the supervisor is easy to approach and precise. The supervisor seizes on problems and keeps her/him promises, and does not diminish them. The supervisor is skillful on knowing people, recognizes Sanna’s personality and can thus give Sanna right kind of feedback and opportunities for development. The supervisor is also genuinely keen on the well-being of Sanna and other employees, and sees the personnel as one of the most important resources in the company.”

Further, the supervisor was described to be interested in the protagonist’s life and well-being, and showed that by discussing with the protagonist, encouraging her, and ensuring that everything was fine with her. Giving recognition of her efforts and being equal with all of the employees was also a matter that was relatively often discussed. In the case of the protagonist feeling unwell or being disappointed or bored with her job, it is, according to the stories, in the concern of the supervisor to provide help and some kind of solution. This was assumed rather automatically, as it was an obvious duty of the supervisor.

“Sanna feels that she is drudging and drudging, but the employer/supervisor does not notice her efforts enough. She feels she is doing useless work, “it doesn’t matter whether I’m here or not”, or she might be bitter to the employer “they don’t even realize that they couldn’t cope without me” “.

The next four discourses further develop and illustrate the meta-discourse.

Know me and my job!

Some of the narrations describe how the supervisor knows the subordinate and has personal ties with her. In these cases, the relationship is described as informal, and that the supervisor and the subordinate might even be friends. Further, the personal life and family matters are in these cases taken into account and the connection between work and private life is catered by the supervisor, or at least the supervisor is considering the individual matters (skills, family, different situations at work etc.) when making decisions. However, there are also differing views. Some of the informants write how the supervisor and the subordinate are not too close and the supervisor should take her/his position as a true leader. Nevertheless, the view that these parties are close and know each other also in a personal level is more commonly used and stronger.

In order for the supervisor to be able to allocate the resources of every individual in a fair and suitable manner, it is highlighted in the stories that the supervisor is, first of all, interested in the subordinate and, second, is willing to sacrifice some time to get to know the work, the person, and the way she/he works and performs. Interestingly, the stories describe how the supervisor has given interesting tasks to work with, and that the supervisor has targeted the skills and resources correctly. Some of the informants have mentioned that this is the responsible way to act.

According to the stories, the wrong kind of allocation might also lead to the resources and skills going to waste in case the supervisor lets this to happen. On the other hand, the informants also write about uneven workload and too many tasks and responsibilities, which may result in stress or intention to quit. In relation to knowing the subordinate not only in a personal level but professionally as well, the informants wrote relatively lot about work allocation. The tone of these stories was that the supervisor has given the tasks or has ignored this, or that the protagonist has gotten suitable tasks from her supervisor. This might indicate that the level of self-direction could be relatively low. At the same time, the informants might also mean that they consider work allocation as a task that the supervisor is responsible of. It seems that in the stories the protagonist is happy to receive help and instructions from her supervisor, and that she is not afraid of even direct orders. In fact, they have led to positive outcomes according to the stories.

“The supervisor is responsible as a boss and knows not only their own field, but has had the ability to structure Sanna’s job description clearly and has let Sanna to have an influence on her own work. In the end the supervisor is responsible. The supervisor genuinely cares about how Sanna is managing her work and knows if there is something in other parts of her life that has an effect on taking care of the work. The fine balance between the freedom of the employee and the responsibility of the supervisor or, the other extreme, neglect, is in order in this case.”

Respect me!

The informants discuss a lot about being respected, heard, and appreciated not only as an employee but also their efforts should be noted. They mention both material (*e.g.* pay rises, bonuses) as well as non-material (*e.g.* career development, new tasks) rewards, but the mainly discussed issues emphasize the meaning of thanking and encouraging feedback. In fact, thanking played a big role in this particular discourse. When considering the demands or wishes in the narrations, the informants were really modest. They were not expecting big rewards, at least not in monetary terms. They described how plain “thank you” might be sufficient. It was also a matter of recognizing the efforts and results, but they were merely expecting the supervisor to make clear that the protagonist’s work has been noted.

The informants refer to respecting on a relatively abstract level. It might also indicate that they automatically expect to receive respect from their supervisor, although they emphasize this matter heavily in their stories. For the informants, it is not enough to know in their heart how they are performing, but they want to hear and feel it from the supervisor in a genuine and honest way. Thus, this particular discourse is probably the most overlapping with the meta-level discourse.

Overall, respecting also deals with knowing what you are doing, *i.e.* that the subordinate is on the right track and is doing what is expected from her/him. The narrations imply that when the supervisor is giving feedback and showing respect in any way, it is a clear hint for the subordinate regarding her/his performance. However, this process seems problematic, as the informants were not able to concretely identify, what makes the supervisor respectful in the end, even though they mention thanking, giving feedback, but also showing genuine respect. Nevertheless, especially based on the negative scripts, unfair comments, inappropriate supervisor behavior, or treating the protagonist only as a “robot”, causes feelings of disrespect.

Nevertheless, some kind of multi-voiced view can be recognized in this discourse as well. Some of the informants mention sufficient salaries and salaries overall, as well as pay rise. However, there is another opinion relatively heavily emphasized, according to which the informants are stating that the salary or money overall does not have an effect on how person perceives her work, and that money is not an issue when considering positive and negative aspects of one’s work. However, in some cases the mentions of money had to do with, for example, pay rises that were promised but never conducted, or otherwise unfairly low salary.

“The supervisor does everything they can for Sanna and that is why Sanna feels herself precious and significant as an employee.”

“Sanna feels that she is dignified and doing an important job, the supervisor enables proper mental and physical conditions at work.”

“Employees’ strengths or skills are not being utilized, neither does the supervisor respect the employees or not at least all of them. Sanna does not feel she is receiving respect, help or encouragement, on the contrary, only negative feedback and the supervisor keeps hurrying her up.”

Hear me say!

Open and regular communication played a big role in the Millennials’ narrations. The narrations referred to both formal and informal discussions with the supervisor. There seems to occur some kind of reciprocity, where both of the parties listen to each other and try to understand the other person’s point of view, as the stories strongly described. Even though the views might not be unanimous, there is mutual respect between the parties: the protagonist is able to speak her mind and she knows that she will be heard. On the other hand, a challenging dialogical connection or an ignorant supervisor might lead to, according to the stories, a situation where the protagonist feels unhappy and this unsatisfying relationship with the supervisor results in feelings of insecurity, unreliability, and almost betrayed.

“The supervisor and Sanna have an open and free dialogical connection, and they both appreciate each other as an employee. The both trust that what has been agreed on, stays, and both of them take care of their own duties. Sanna and her colleagues have an influence on the decisions made in the work community and regarding its development.”

The informants keep mentioning being in good terms with the supervisor and having a pleasant relationship with the supervisor. However, there exists some kind of multi-voiced view. On the one hand, some of the informants

wrote about having personal ties with the supervisors and talking about private life as well. They also mentioned that the supervisor talks about her/his own life, so it is easier for the protagonist to tell about hers. As a result, these informants wish that their private life and the changing situations are taken into account in the workplace. These informants would like to see the relationship with their supervisor as an “*equal relationship*”, or “*between two adults, not with a supervisor and a subordinate*”. On the other hand, a few of the respondents are describing somewhat an opposite relationship, where the ties are not too close and the supervisor remains more distant.

Help me to develop myself!

The stories quite often mentioned opportunities for development. This might indicate that the informants reflect on their fear of stagnation. It seems that the informants see the supervisor as a coach or a personal trainer, who provides them with enough challenges and helps them to gain skills as well as opportunities for career advancement. These stories also reveal the informants’ perceptions and expectations concerning the working life. It might seem that they would like to take advantage of their supervisor’s experience and skills in leading people, and thus require more hands-on management. Moreover, in their stories the informants see the supervisor as a career facilitator, and that the supervisor should take this responsibility serious. In fact, they seem to take this for granted, as an automatic process embedded in the relationship with the supervisor. Also, according to the stories, in a situation of too much routine work and boring tasks, the supervisor should act and exploit the capabilities of the subordinate more efficiently in order to prevent too much stress or haste.

Based on the stories, assistance in development is required from the supervisor and that the supervisor takes responsibility of the development issues. The threat of getting bored with the job or getting stuck on the whole seems to be threatening. The balance between too less or too much challenges seems to be delicate, and the supervisor really has to know what the subordinates want. In the tailpieces, the protagonist was disappointed in case there were no equal opportunities to receive training or if the supervisor was not interested in taking responsibility of the development of the subordinates. The protagonist was also described frustrated when her skills and capabilities go to waste in too easy work. Concrete instructions and feedback, discussions, flexibility, and attention from the supervisor are mentioned in the stories. Based on them, neglect from the supervisor and supervisor not being keen on the development of the subordinate, are referred in the negative stories.

“Sanna’s supervisor saw potential in the employee and suggested special training for her alongside her work. It was a training that would last for a year, after which Sanna would get a special certificate for new duties. Sanna got some time to think about it, discuss about it at home and then she decided to take part in the training alongside the work as her supervisor suggested. Now the training is completed and the new duties that require this certificate seem to be very interesting and challenging”.

“Sanna feels that she is not getting clear instructions from the supervisor, no responsibilities and she is not appreciated as an expert in her field.”

Discussion

Even though the data gathering method in this study was rather innovative and somewhat experimental, the stories provided were rich and interesting. The discourses presented in this paper were expected to some extent, but the level of discussion was rather straightforward and clear. As described in the previous section, there were altogether five discourses found from the stories, out of which one was identified as the meta-level discourse. Some of the discourses are partly overlapping, as they deal with same kind of issues: the main voice from the stories repeated acknowledgement and attention. The discourses were, a bit surprisingly, relatively unanimous. Figure 1. illustrates the discourses and their relationship to the meta-level discourse. The four sub-discourses could be seen as well as overlapping with each other. However, in this study they are seen as building the meta-level discourse concerning acknowledgement.

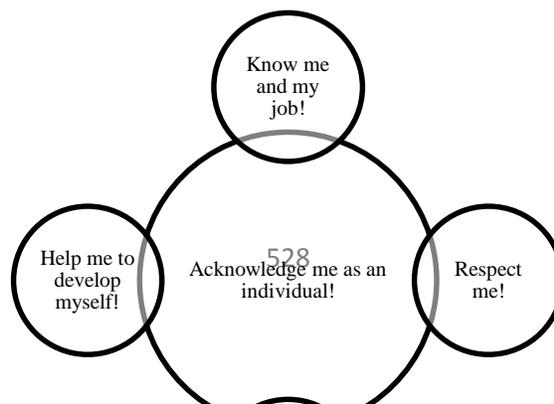

FIG 1. ILLUSTRATION OF THE DISCOURSES.

Regardless of the relatively innovative research setting when studying Generation Y, the findings were in line with previous studies. For example, recognition is important for Millennials (Gursoy *et al.*, 2008) and they value respect (Eisner, 2005) as well as personal attention from the supervisor (Gursoy *et al.*, 2008). Further, Zopiatis *et al.* (2012) concluded that while Millennials enjoy social activities and relationships, they still want to remain a high level of individuality. Further, the need for constant feedback was found also by Martin (2005).

However, there were some multi-voiced views as well. The strongest ones dealt with salary and knowing the supervisor personally. When describing motivating supervisory work, monetary issues did not gain a lot of attention from the informants, but there were some contradictory notions. A few of the stories heavily emphasized the inferior meaning of salary and money, but some single informants mentioned pay rises, monetary perks, and salaries. On the other hand, the opposite views were strongly saying that money is not an issue in motivating people, and that it does not have an effect on how one perceives her/his work. Further, there was discrepancy regarding the depth of relationship with the supervisor. On the one hand, the issues the informants discussed were in a level where the supervisor really has to know the subordinate on a personal level and regarding the performance and the work tasks as well. Without this kind of affection or interest, it is not possible to allocate the tasks in a way that would consider the skills, competences, and the situation in the personal life of the subordinate. On the other hand, some single answers pointed out that there does not have to occur this kind of deep relationship in order for the protagonist to feel good, and that the supervisor and the subordinate cannot be that close.

Further, the informants seem to write in a humble and modest way. In fact, they do not demand extraordinary solutions or extreme things. They even mention how receiving a simple recognition, such as thanks, from the supervisor is enough. Also the supervisor being in a good mood was sufficient for some. This might indicate that the informants reflect on the behavior of the supervisor, and that it has an effect on their spirit as well. Thus, the supervisor should have to be really alert to and sensitive to the messages the subordinate is sending.

The meta-discourse *Acknowledge me as an individual* might seem trivial at first. However, the material and this discourse strongly manifest that supervisors should pay attention to individual traits, efforts, experiences, and expectations. It is not an easy task, but it is what Generation Y needs. It might lead to a situation where we cannot take generational stereotypes for granted, as there is heterogeneity in the group. However, the almost collective opinion of Generation Y seems to be that they should be taken as individuals, *i.e.* as they are. The four other discourses support this view and further are in line with the meta-discourse. The different voices are relatively few but strong. This multi-voiced view inside Generation Y is highly interesting, as media, for example, has tried to put all of the Millennials in one group with several strong stereotypes.

Overall, most of the informants seem to be saying that the supervisor needs to be interested in the subordinate. Even though the views were not unanimous all the way, the message is quite clear. *Acknowledging one as an individual* is a difficult and time-consuming task. However, it leaves some room for the individual characteristics of the Generation Y, as it cannot be assumed that every Millennial would like to be treated in the same way. In fact, the supervisor needs to be really alert and sensitive in listening to the millennial subordinate: is it the pay or the amount of holidays that is in the interest of the subordinate? What is the voice of this particular subordinate? Does the supervisor have to stay distant or open up also her/his own private life in order to get close to the one of the subordinate? The voice of Generation Y is somewhat united in this discourse. In order to be fulfilled, it requires consideration, time, and efforts from the supervisor to get to a level where she/he can genuinely treat the subordinates the way they prefer. On a more practical level, it demands first of all conversations with the subordinates and careful listening and understanding, not to mention that it takes time to get to the core.

The narrations that built this paper were relatively expected. However, there was one voice that was a bit surprising, and which is scattered in different discourses. The informants were concerned about equality and fair treatment between each other. It cannot be concluded for sure whether they value even opportunities and possibilities, or are they plainly selfish and looking after their own interest or even evaluate their performance higher than anyone else's. Thus, they might feel obliged to rewards and further feel different perks as important. Interestingly, they did not describe solely the protagonist, but placed her in the wider work community. This was seen in the stories, where the informants wrote about the whole work community and how the supervisor treats all of the employees, not only the protagonist in the stories. It, on the other hand, seems very unselfish. This might be due to Millennials being very social and appreciating a pleasant work community (Eisner, 2005; Smola and Sutton, 2002). Nevertheless, they want to be acknowledged for their real efforts and do not want to suffer from someone else's mistakes or poor performance. They were not discussing a scenario, where the protagonist was underperforming or someone was saving her skin. Thus, the root cause for this view remains blurry.

Conclusions

The leadership that the informants constructed is about being interested in the subordinate and listening to her/him carefully. The supervisor as her/his best knows the Millennial subordinate personally, or more like how personally the Millennial wants to be known. It all comes down to individual characteristics and preferences that the supervisor needs to be aware of. The supervisor should take care of the development needs of the subordinate by giving encouraging and constructive feedback, and distributing duties that suit the needs of the employee. This should occur in an open and pleasant atmosphere, for which the supervisor should have a special interest in: a willingness to create a work community that is supportive, nurturing, and safe. Overall, the supervisor is sort of a catalyst or a personal trainer in the Millennial's career that the Millennial is willing to respect and appreciate. Supervisor's actions are also manifested in equal and fair treatment

This is probably the first study to take a look at how the Millennials construe leadership and how they actually describe positive and negative actions of the supervisor. The five discourses shed a light on Millennials' preferences and expectations concerning their supervisor. The discourses, based on the stories by 252 Millennials, quite clearly state that the most of all the supervisor has to build the level with the Millennial subordinate based on individualism and individual consideration. This leads to somewhat tailor-made relationship between the subordinate and the supervisor.

This meta-discourse, *Acknowledge me as an individual*, becomes even more meaningful when considering the inevitable consequences where this voice of Generation Y leads. Further, when placing this to a larger picture, the supervisor needs processes and systems that support these actions. Discussing and getting into the roots of the subordinate's behavior takes time, which is usually non-existing in today's working life. Also rewarding systems and work time allocations should leave room and flexibility for the supervisor's consideration. However, the voice of Millennials also calls for equality and fairness. Where is the balance between individual wishes and treating everyone fairly? Millennials might give the answer themselves: they clearly voice open communication and communality.

Some previous studies (*e.g.* Gursoy *et al.* 2008; Martin, 2005) have concluded that the supervisor is important for the Millennials and that they demand different things from the supervisor than older generations. As qualitative research concerning Generation Y has been scarce, future research could take a look at to which extent the Millennials pay attention to supervisor's role. However, there are no studies that map out the working life as a whole from the Generation Y's point of view. Thus, it would be beneficial to see, what are the issues the Millennials actually see important regarding working life. Also the inevitable effects on HR should be noted. This study suggests that HR should provide supervisors processes and tools that fit the organization's needs, and that supervisors should also be trained for their supervisor duties. Further, recruiting and selecting supervisors becomes even more important task and responsibility of HR.

After this mapping of the territory, more information is needed concerning the Millennials' expectations for leadership. This study could be further developed by in-depth interviews. It would also be relevant to study Millennials' supervisors and their perceptions of what they think Millennials need. This would take the field forward and offer more empirical evidence on Generation Y.

To Study the Concept of Transformational and Transactional Leadership on Employees with Special Reference to Hindustan Computer Limited (HCL) Noida

Abstract

This study evaluates that the criteria of transformational and transactional leadership which was explained by Bass (1985) earlier and how these criteria, their role have influence on select outcome variables and employee attitudes with special reference to HCL Noida. Using Multifactor Leadership Questionnaire (MLQ 5x) the data was collected from a sample of 255 employees from a large multinational organization in India. The research results show that transformational and transactional leadership have significant influence with extra effort of subordinate, effectiveness of the leadership, satisfaction with the leader and attrition rate of employees. The 2 factor active-passive model of leadership is being supported by this research which will also help to different researchers in coming time. This research has also tried to clear out the concept of transformational and transactional leadership in simple manner and how these leaderships can influence the morale of employees which can in turn lead to the overall growth of the organization.

Keywords - Transformational leadership, transactional leadership, active leadership, passive leadership, leader effectiveness.

Introduction

Transformational leadership has become the most important foundation of efficient leadership in the organizational structure. Burns (1997) gave the concept of transforming and transactional leadership was introduced for the treatment of political leadership. Furthering the concept of Burns, Bass (1985) has given an inclusive theory of leadership using transformational term, he anticipated that such leaders are change agents and they rise and change the attitudes, beliefs and motives of followers to a higher level.

But transactional leaders are different; they centered on exchange of resources for valuable results. But Bass has different view; transformational and transactional leaders are dissimilar but not mutually exclusive and the best leaders are both transformational and transactional. Full-range leadership theory (FRLT) [Bass et al. (1978); Bass et al. (1997)] was suggested after several changes in the theory of Bass (1985). Later Bass and Avolio [Bass et al. (1995); Bass et al. (2004)] together developed Multifactor Leadership Questionnaire to calculate leadership proportions and results.

In today's business scenario the need of research on leadership has witnessed the importance of transformational leadership. Research shows that retaining human resource has become a very important concern in today's business situation and the transformational leadership may initiate the development of intellectual capital required to meet organizational changes [Bass et al. (1997); Drucker et al. (1999); Herman et al. (1997); Hitt et al. (2000); Ireland et al. (1999)]

Several researches have shown that transformational leadership gives rise to higher effectiveness and thus satisfaction of subordinates than any other leadership styles Hater et al. (1988). Lower employee attrition rate comes when satisfaction factor of subordinate increases as well as trust in leadership also shows an increase Burns (1978), as a group the performance also shows an increase. Subordinates also start putting their complete efforts Seltzer et al. (1990).

In Indian context the research material related to transformational and transactional leadership model of Bass (1985) is rare. So the main objective of this paper is to analyze the relationship between transformational and transactional leadership and their effect on employees with special reference to HCL Noida.

1. The Research Hypotheses

On the basis of above statements following hypothesis have been taken as the base for the empirical study:

Hypothesis-1(a): Transformational leadership will have significant positive influence when the follower puts extra effort, the effectiveness of the leader and follower's satisfaction with the leader and negative influence on the attrition rate of the employees.

Hypothesis-1(b) The four criteria of transformational leadership will have significant positive influence on extra effort of the follower, leader's effectiveness and follower's satisfaction with the leader and significant negative influence

on the attrition rate of the employees. One more objective of this research was to illustrate the relative importance of leadership criteria to elucidate the selected outcome variables with special reference to HCL Noida

Hypethesis-2: That Transformational leadership will have significant impact of leadership criteria (extra effort of subordinates, effectiveness of leader, and satisfaction of subordinate with the leader) in controlling the transactional leadership.

Hypotesis-3: The Active leadership will have significant influence of leadership outcome variables (extra effort of subordinates, effectiveness of leader, and satisfaction of subordinate with the leader) in controlling the passive leadership.

2. Methods

Data for this study was collected from a large technology based multinational organization located at Noida, operating in India and overseas for over two decades. Respondents in the sample were selected predominantly on convenience method of sampling though attention was paid to include respondents from major divisions of the company. Data was collected from 255 employees working in different divisions of the organization. The sample consisted of 141 male and 114 female respondents with an average age of 26 years and average work experience of 3 years and 8 months. This study satisfied the rules proposed by Thorndike Seltzer et al. (1990) with regard to the sample size.

3. Measures

3.1. Leadership dimensions and outcome variable

In this research we have used the Multifactor Leadership Questionnaire (MLQ 5x-Short) which was developed by Bass (1995) and Avolio (2004). It is made of 45 items which are used to measure transformational leadership, transactional leadership and leadership outcome variables.

This Questionnaire also helped to find out the four dimensions of transformational leadership which are: Idealized Influence, Inspirational Motivation, Intellectual Stimulation, and Individualized consideration; and the three components of transactional leadership: Contingent Reward, Management-by-Exception-Active, and Management-by-Exception-Passive; and a non-leadership dimension – Laissez-faire leadership. Major part of the questionnaire consisted of those questions which tried to measure the above points. The minor part of the questionnaire measured the following outcome variables: Extra Effort of the subordinate, Effectiveness of the leader, and Satisfaction of subordinate with the leader.

The range for the reliability leadership factor scale is from 0.75 to 0.95. To maintain the internal consistency the reliability for all scales have exceeded the standard cut offs. As per the given calculations the Cronbachs alpha reliability coefficients for transformational leadership scale in this research are 0.92 and for transactional leadership it is ranged between 0.68 and 0.81, and for laissez-faire leadership it is 0.78 for the overall transformational leadership scale the Cronbach alpha reliability coefficients are 0.92.

3.2. Attrition rate criteria

Attrition rate criteria of employees were measured by a 3-item 7-point scale developed by Camman et al. (1983). For this scale this research reported a Cronbach alpha reliability coefficient of 0.88.

3.3. Analysis of the Data

To evaluate the reliability of instruments used in this study Cronbach alpha coefficient of internal consistency has been used. To understand the criteria of leadership Exploratory factor analysis was done. For studying the relationships between variables Correlation and regression analysis were used. The amplification effects of transformational and transactional leadership were analyzed by Hierarchical regression analyses.

4. Results Discussion

4.1. Leadership criteria's and their relationships

Correlation relationship between eight leadership criteria and their reliabilities and descriptive statistics are given in Table-1.

The analyzed results below show that all the transformational leadership factors and two factors of transactional leadership (contingent reward and management-by-exception-active) were having significant correlation with each other. ($p < 0.01$)

TABLE-1: DESCRIPTIVE STATISTIC DATA, RELIABILITIES AND CORRELATIONS FOR LEADERSHIP VARIABLES

S No.	Variables	Mean	S.D	1	2	3	4	5	6	7	8	9	10
1	Idealized influence	2.62	0.74	(.81)									
2	Inspirational Motivational	2.74	0.79	0.80**	(0.73)								
3	Intellectual Stimulation	2.58	0.76	0.76**	0.65**	(0.66)							
4	Individual Consideration	2.48	0.87	.78**	0.65**	0.72**	(0.69)						
5	Transformational leadership	2.60	0.71	0.94**	0.87**	0.87**	0.88**	(0.92)					
6	Contingent reward	2.66	0.80	0.81**	0.72**	0.72**	0.70**	0.86**	(0.73)				
7	Management by exception (Active)	2.66	0.78	0.58**	0.55**	0.44**	0.46**	0.57**	0.56**	(0.63)			
8	Management by exception (passive)	1.66	0.96	-0.09	-0.15*	-0.1	-0.07	-0.10	-0.05	0.07	(0.67)		
9	Transactional Leadership	2.34	0.58	0.62**	0.52**	0.51**	0.50**	0.61**	0.72**	0.76**	0.58**	(0.59)	
10	Laissez – Faire Leadership	1.38	1.09	-0.20**	-0.22**	-0.20**	-0.24**	-0.22**	-0.20**	0.02	0.70**	0.31**	(0.79)

See Cronbach's alpha reliabilities in parentheses along the diagonal.

** Note $p < .01$

From the above table it can be observed that the Management-by-exception-passive was sharing a positive correlation only with laissez-faire leadership. A positive correlation was seen between Laissez-faire leadership with the overall transactional leadership and which had a significant ($p < 0.01$) negative correlation with all the factors of transformational leadership and also with contingent reward dimension of transactional leadership whereas it was not correlated with management-by-exception-active. The reliability of all the sub-constructs is also within medium to high (0.59 to 0.81). The components of transformational leadership shared the correlation coefficients between the range of 0.65 to 0.81 and an overall reliability coefficient of 0.92 was calculated after all the four dimensions were clubbed together forming a measure of transformational leadership. Similarly after clubbing the overall transactional leadership dimensions a combined reliability coefficient of 0.59 was observed. The two dimensions – contingent reward and management-by-exception-active is not significantly correlated with the management-by-exception-passive dimension which provides an indication towards two factor model discussed in hypothesis 3. This could be the reason for the reliability coefficient not being high for transactional leadership.

4.2. Exploratory factor analysis of leadership variables

One of the objectives of this study was to evaluate the dimensionality of transformational and transactional leadership in the Indian context and accordingly hypothesis-2 was formulated and tested. In order to examine the factors underlying the eight dimensions an exploratory factor analysis of the scores of all dimensions of transformational and transactional leadership was conducted. In the common factor analysis only 2 factors had latent root or eigen value greater than 1. Since the latent root criterion generally results in conservative estimate of the number of factors to be

extracted in the case of common factor analysis in comparison with principal component analysis a scree test Harman (1976) was conducted. In the procedure of Scree test latent roots are plotted against the number of factors in their order of extraction, and the point at which the curve first begins to straighten out, giving the maximum number of factors to extract Cattell (1978). From the eight dimensions two factors were extracted out through the common factor analysis. The minimum factor loading for interpretation Harman (1976) is generally considered as absolute value of .32. On the first factor out of the eight dimensions; six dimensions (idealized influence, inspirational motivation, intellectual stimulation, and individualized consideration, contingent reward and management-by-exception-active) had a factor loading higher than 0.71. Five dimensions had factor loadings of 0.85 to 0.95 on first factor and one dimension (management-by-exception-active) had a loading of 0.71 on the first factor. Two dimensions (management-by-exception-passive, and laissez-faire leadership) had factor loadings of 0.94 and 0.93 on factor 2 and less than 0.22 loadings on factor one. The two factors that emerged after varimax rotation were labeled based on the content analysis of the dimensions and findings of earlier studies [(Bycio et al. (1985); Judge (2004); Srinivas et al. (2006))]

Active leadership was labeled on the first factor consisting of six dimensions (idealized influence, inspirational motivation, intellectual stimulation, and individualized consideration, contingent reward, and management-by-exception-active). The second factor, which consisted of two dimensions (management-by-exception-passive, and laissez-faire leadership) was termed as **passive leadership**. These two factors (active leadership and passive leadership) were used to examine their relations with outcome variables and also to test the augmentation hypothesis.

4.3. Leadership dimensions and outcome variables

Tabel-2 shows the correlations between eight leadership dimensions, active-passive leadership and outcome variables of extra effort, effectiveness of the leader, satisfaction with the leader, and intention to quit are provided in table-2 below:

TABLE-2: CORRELATIONS OF LEADERSHIP VARIABLES WITH LEADERSHIP OUTCOME VARIABLES.

Leadership Variables	Extra Effort	Effectiveness of the Leader	Satisfaction with the Leader	Intention to Quit
Transformational Leadership	0.71**	0.82**	0.74**	-0.16*
Idealized Influence	0.67**	0.76**	0.73**	-0.09
Inspirational Motivation	0.60**	0.72**	0.68**	-0.11
Intellectual Stimulation	0.63**	0.64**	0.64**	-0.16**
Individual Consideration	0.65**	0.69**	0.69**	-0.22**
Transactional Leadership	0.43**	0.52**	0.43**	0.06
Contingent Reward	0.67**	0.76**	0.68**	-0.15*
Management-by-Exception (Active)	0.47**	0.57**	0.45**	-0.02
Management-by-Exception (Passive)	-0.18**	-0.20**	-0.20**	0.26**
Laissez-faire Leadership	-0.32**	-0.30**	-0.29**	0.26**
Active Leadership	0.75**	0.80**	0.77**	-0.15*
Passive Leadership	-0.28**	-0.28**	-0.26**	0.27**

** $p < .01$. * $p < .05$.

Transformational leadership and all the factors related to it were significantly ($p < 0.01$) correlated with extra effort, effectiveness of the leader and satisfaction with the leader. From these results it can be seen that hypotheses 1(a) and 1(b) are accepted.

4.4. Relative importance of leadership variables

In order to test the hypothesis that transformational leadership is responsible for a greater proportion of variance in outcome variables a hierarchical regression analysis was conducted. In the first analysis, transactional leadership was entered as predictor in step-1 and transformational leadership in step 2. In the second analysis, the order of entry was reversed.

Table -3 represents the changes in R^2 at each step. In the three leadership outcomes – extra effort, effectiveness of the leader, and satisfaction with the leader Transactional leadership accounted for 17, 27, and 18 percent of the variance respectively – when entered first and when entered second there was no account for additional percent of variance for all the three outcome variables. Transformational leadership accounted for 52, 62 and 58 percent of the variance in the three leadership effectiveness criteria of extra effort, effectiveness of the leader and satisfaction with the leader, respectively when entered first, and when entered second an additional 33, 39 and 42 percent of the variance respectively was accounted.

TABLE-3: HIERARCHICAL REGRESSION ANALYSES: PREDICTING OUTCOMES FROM TRANSACTIONAL AND TRANSFORMATIONAL LEADERSHIP

	Extra Effort		Effectiveness of Leader		Satisfaction with the Leader	
	R^2	R^2	R^2	R^2	R^2	R^2
Order 1						
Step1						
Transactional Leadership	0.17**		0.27**		0.18**	
Step 2						
Transformational Leadership	0.52**	0.33**	0.62**	0.39**	0.58**	0.42**
Order 2						
Step1						
Transformational Leadership	0.51**		0.63**		0.58**	
Step 2						
Transactional Leadership	0.52**	0.01	0.62**	0.01	0.58**	0.01

** $p < .01$

This shows that transformational leadership variables are more significant than transactional leadership. Thus hypothesis-2 is supported and therefore steps were taken for leadership outcomes by using the explanatory power of active and passive leadership.

Table 2 shows the following:

Active leadership was significantly ($p < 0.01$) positively correlated whereas Passive leadership was significantly ($p < 0.01$) negatively correlated with extra effort, effectiveness of leader, satisfaction with the leader. Active Leadership was significantly ($p < 0.01$) negatively correlated whereas Passive leadership was significantly ($p < 0.01$) positively correlated with intention to quit.

Hypothesis: As compared to passive leadership, active leadership would contribute higher proportion of variance in outcome variables.

Hierarchical regression analyses was conducted and the results of which are presented in Table-4 below:

TABLE 4: HIERARCHICAL REGRESSION ANALYSES: PREDICTING OUTCOMES FROM PASSIVE AND ACTIVE LEADERSHIP

	Extra Effort		Effectiveness of Leader		Satisfaction with the Leader	
	R ²	R ²	R ²	R ²	R ²	R ²
Order 1						
Step1						
Passive Leadership	0.07**		0.08**		0.08**	
Step 2						
Active Leadership	0.55**	0.46**	0.69**	0.64**	0.59**	0.53**
Order 2						
Step1						
Active Leadership	0.55**		0.69**		0.59**	
Step 2						
Passive Leadership	0.55**	0.04**	0.69**	0.03**	0.59**	0.03**

* $p < .05$ ** $p < .01$

In the first analysis, passive leadership was entered as predictor in step-1, and active leadership in step-2. In the second, the order of entry was reversed.

Table 4 reports the change in R² at each step in these analyses. In the three leadership outcomes – extra effort, effectiveness of leader, and satisfaction with the leader, Passive leadership accounted for 7, 8 and 8 percent of the variance, respectively, when entered first, and on the second entry no additional percent of the variance was accounted for all the three outcome variables. Active leadership accounted for 55, 69 and 59 percent of the variance in the three outcomes of extra effort, effectiveness of leader and satisfaction with the leader, when entered first, and accounted for an additional 46, 64 and 53 percent of the variance respectively, when entered second. Therefore the active leadership explains leadership outcome variables significantly more than passive leadership. Thus hypothesis-3 is supported. These findings support prior research on augmentation effect of transformational leadership over transactional leadership [Bycio et al. (1985); Judge (2004); Gorsuch (1985)]

5. Conclusion

This research shows that there is a significant link of leadership criteria with extra effort of the subordinates, how they take the effectiveness of their leader, satisfaction of the subordinates with the leader and their attrition rate from the organization.

The research result tells that extra variance can be justified only by transformational leadership. Also transformational leadership and contingent reward criteria has significant influence on employees attitude and their extra effort.

Satisfaction of employees, extra effort of subordinate and their commitment to the organization are positively correlated with the concern, inspiration and direction received by employees from their superior.

This research establishes the significance of transformational leadership in impacting employee attitudes as well as their attrition rate, hence the two factor model of leadership may provide a better and in depth understanding this variance. These contributions have important connotation for practice and value addition to further leadership research.

6. Limitations of the Study

The limitations of the above research are:

- i. Cross-sectional design of the research due to which underlying relationships cannot be examined.
- ii. Also the causality between leadership factors and the outcome variables can not be determined by this research

- iii. There was a limited possibility of getting a totally different factor structure underlying transformational and transactional leadership in the HCL Noida.

7. Implications for the Future Research

Culture specific model of leadership can be proved helpful if future research with wider sample is done on the same. This could also help to identify and give guidance to future transformational leaders. Also a view of longitudinal research may help assess the casual relationships. In future Efforts can be made to discover more leadership criteria in the Indian context.

Perspective of American Students after the Deep Recession of 2008

*Harbans Singh, Singh@montclair.edu
Montclair State University (USA)*

Perspective of American Students after the Deep Recession of 2008

Abstract

This paper, through an opinion survey conducted in October 2012, provides a snapshot of the perspective of American college students after the great recession and the global financial crisis of 2008. Students were asked to rank six highly pertinent issues. Family obligation emerges as the highest ranking issue and career advancement opportunities comes out as a close second. Both male and female students, students of different age groups, students of different major disciplines and different political affiliation have a similar response to these two high ranking issues. Environmental issues receive low ranking among important issues. However, when asked as a free standing independent question an overwhelming proportion of students chose their response to environmental protection as very important. Students studying business, mathematics, computer science and natural sciences are more confident of getting a job in their field shortly after graduation. Two third of all students aspire to pursue graduate studies. Overall, students show a high level of confidence and aspiration.

Introduction

The deep recession of 2008, that was a result of the bust of the housing bubble and the subsequent global financial crisis, caused high rates of unemployment throughout the industrialized countries. After more than 5 years, the United States' economy was still reeling from its effects. Students seeking jobs after graduation are expected to face two challenges. First, the weak economy, with a high rate of unemployment, makes it harder to get a job. Second, the increasing inequality of income limited chances of upward economic mobility (Piketty 2014, Krugman 2014). In this harsh economic environment, what is the perspective of students as to their prospects and the issues that will affect their life, family and society?

Methodology

This research project involved an opinion survey in the first week of October 2012 just before the U.S. presidential election. 503 students at Montclair State University, New Jersey, where I teach, were the respondents. The survey was conducted by the graduate students in my Research Methods course in the program Environmental Management and Science. Care was taken to have a random sample. Students were approached to complete the survey at different sites, different times and classes at different schools and colleges at the University. A copy of the questionnaire is attached. SPSS was used to analyze survey data. Statistical results, such as, frequencies, cross tabulations and chi square were calculated for all pertinent combinations of responses. Interpretation of these results is the core of this research paper.

Analysis and Interpretation

Students were asked to rank order 6 issues on a scale of 1 to 6, 1 being most important and 6 being least important. These issues are: career advancement opportunities, sustainable resources use, health insurance cost, family obligation, environmental pollution and outsourcing.

Family obligation has the highest mean rank with a value of 2.42. Career advancement opportunity with a mean rank of 2.61 is the close second. Health insurance comes out third with a mean rank of 3.52. Sustainable resource use and environmental pollution, with a mean rank of 3.58 and 3.83 respectively, have a lower priority. Outsourcing of jobs to other countries is the least important with a mean rank of 5.04 (Table I).

The importance of these six issues can be further illustrated by the ranking value students have given to the issue. 62.4 percent of the students have ranked the issue of family obligation with a value of 1 and 2 i.e., the most important. 60.4 percent of the students have given the same two highest ranking to the issue of career advancement opportunities.

The identical 1 and 2 ranking values for other issues are: 25 percent of students for health insurance, 23.5 percent for sustainable resource use, 22 percent for environmental pollution, and 7.8 percent for outsourcing.

The issues of family obligation and career advancement opportunities emerge as the most important issues. Nearly 75 percent of students give these two issues the combined ranking of 1, 2, and 3. More than half the students, 52.5 percent, give health insurance the combined priority ranking of 1, 2 and 3.

TABLE 1: RANKING OF ISSUES

1=Highest Rank. 6= Lowest rank.							
Issue	Mean Rank	Percent Respondents Who Gave 1,2 Ranking			Percent Respondents Who gave 1,2,3 Ranking		
Family Obligation	2.42	62.4			74.6		
Career Advancement Opportunities	2.61	60.4			74.8		
Health Insurance	3.52	25.0			52.5		
Sustainable Resource Use	3.58	23.5			43.9		
Environmental Pollution	3.83	22.0			39.8		
Outsourcing	5.04	7.8			14.9		

For further explanation, the statistical procedures, the crosstab and the chi-square test, was performed on the data set selecting the most important variable family obligation with gender, with age groups and with the school or college the student is enrolled in. This analysis produced three crosstabs with chi-square values. The similar analysis was performed for the variable, career advancement opportunities, with the above three variables one at a time.

The chi-square p-values for all the six combinations were statistically insignificant. That is the p-values were higher than 0.05 levels. This reveals that both male and female students have similar responses to the issues of family obligations as well as concerns about career advancement opportunities. Different age groups have similar responses towards these two important issues. The response to these above two important issues is similar irrespective of the school or college that the student is attending. Montclair State University constitutes five major academic units: School of Business, College of Arts, College of Education and Human Services, College of Humanities and Social Sciences and College of Science and Mathematics. The analysis shows unanimity in identifying important issues irrespective of gender, age or subject discipline.

Additional Results of the Survey

In addition to the principle question of ranking the most important issues, students were asked about the health insurance they rely on, climate change, time spent on electronic gadgets, job opportunities after graduation, pursuing higher education, hours of work to earn income and the political party that reflects their personal philosophy. A snapshot of student's perspective is developed from their responses to the above questions (see questionnaire).

In the presidential campaign of 2012, health insurance was one of the major issues. Under the then prevailing law, students up to the age of 22 years were covered by their parent's health insurance plan. Among the respondents, 64 percent of the students are covered under their parents' plan. The new healthcare law extended this coverage up to the age of 27 years. A sizeable proportion of students, 18 percent, buy health insurance provided by the University. 10 percent of the students are covered by their employers. 7.5 percent of the students have to buy their own insurance.

Environmental issues have a lower importance in terms of rank order. However, 77 percent of the students responded that climate change is harmful in its impact. At present, climate change as it is interconnected with global warming, greenhouse gases and clean energies is the pressing environmental issue. The overwhelming proportions of students are aware of its harmful effect. This will certainly have a corrective impact on climate change policy in the near future.

On average students spent 3.4 hours daily using electronic devices. Median time spent is 3 hours. 44 percent of students spent between 5-10 hours daily. A sizeable 25 percent spent between 10-15 hours daily.

To the question, "How confident are you that you will find a job in your chosen field within a year of graduation?" a high 40 percent are moderately confident and 19.2 percent are very confident. Two thirds of the students want to pursue higher education. This high level of confidence and aspiration indicates a positive and optimistic attitude towards the future.

To the question, "Which political party reflects your personal philosophy?" 48 percent of the students selected the Democratic Party and 21 percent selected the Republican Party. A sizeable proportion, 27 percent, chose other.

Females are the majority of the student body at Montclair State University. New Jersey has a tradition of sending sons to out of state or distant colleges and universities but prefer that daughters to stay closer to home and attend a local college. There are financial benefits associated with nearness. The survey reflects overall enrollment by gender in the University. 55 percent of students in the survey are females and 44 percent are males.

The interpretation of chi-square test for selected pairs of variables contributes in important ways to understanding the perspectives of students. For the variable, confidence of finding a job within a year after graduation, the chi-square p-values are statistically significant (lower than 0.049) with the college that the student is attending, with age and with hours of work. Students majoring in mathematics and sciences and business are more confident of job prospects than students in other disciplines. Older students are more confident in comparison to the younger students. The higher the numbers of hours the students work, the more confident they are about their job prospects. The chi-square p-values were statistically insignificant for confidence in finding a job with gender and with political party. This is interpreted as there are no differences in the confidence in finding a job among male and female students as well as between the democratic and republican students.

One of the negative aspects of students working a high number of hours is that it takes longer to graduate than the conventional four years. The chi-square p-values are statistically significant for number of hours students work only with gender. That means there are real differences in working hours among male and female students. More female students work in each category of hours worked.

Chi-square p-values were statistically insignificant (higher than 0.05 levels) for the variable number of hours worked with the college a student is attending and with political affiliation of the student. This demonstrated that there is no relationship of working hours with the college student is attending or their political affiliation.

The survey was conducted in October 2012 during the heightened interest of the Presidential Campaign. How do students of different political affiliation and philosophy relate with other variables? The chi-square p-values are statistically significant for the variables, political affiliation with gender and with the college attended. Consistent with the national trend, more females affiliate with the Democratic Party. Similarly, students attending different colleges have different political affiliation. Students attending the Business School are overwhelmingly conservative and republican. On the other hand, students attending the College of the Arts and the College of the Humanities and Social Sciences are more liberal and democrats. However, students of different political affiliations have no difference of

attitude towards pursuing higher education, importance of family obligations, career advancement and environmental pollution.

Questionnaire

1) Please rank the following from 1-6. 1 being most important, and 6 being least important to you.

- _____ Career Advancement Opportunities
- _____ Sustainable Resource Use
- _____ Health Insurance Cost
- _____ Family Obligation
- _____ Environmental Pollution
- _____ Outsourcing

Please circle your response

2) What type of health insurance do you currently rely on?

- 1- Job Provider Insurance 2 - Montclair State University Student Insurance
- 2-Parents' Insurance 4- Privately Purchased Insurance

3) What will climate change have?

- 1-Beneficial 2- Harmful Impact 3- No impact

4) How many total hours a day do you use electronic devices?(computers, smart phones, tablets, video games, etc.)

- 1-None 2- less than 5 hours 3- 5 to 10 hours 4-10 to 15 hours 5- more than 15 hours

5) How confident are you that you will find a job in your chosen field within a year of graduation?

- 4-Very Confident 3- Moderately Confident 2-Somewhat Confident 1- Not Confident

6) After graduation, do you plan on pursuing a higher degree in you chosen field?

- 1-Yes 2-No

7) Which political party reflects your personal philosophies?

- 1-Democrat 2- Republican 3- Other: please specify _____

8) What is your age?

- 1-Under 20 years old 2- 20-24 years old 3- 25-30 years old 4- over 30 years old

9) Which Montclair State University college or school do you belong to?

- 1- College of the Arts 4- College of Science and Mathematics
- 2- College of Education and Human Services 5- School of Business
- 3- College of Humanities and Social Services

10) How many hours a week do you work to earn income?

- 1-Do not work 2- 0 to 10 hours 3- 10-20 hours 4-20-30 hours 5- Full Time

11) What is your gender?

- 1-Female 2- Male 3-Other

How Sensitive Is Schooling Achievement to Instructional Time?

Salisbury University, USA

How Sensitive Is Schooling Achievement to Instructional Time?

Abstract

Policy makers at the highest level have recently called for broad increases in instructional time to improve student achievement in the United States. Nevertheless, previous empirical research on the effectiveness of expanding instructional time has produced largely mixed and inconclusive results. This paper investigates the effects of changes in instructional hours per day and days per year (and, by extension, the distribution of instructional time) on eighth-grade student achievement using the international TIMSS Assessments. We find that the relationship between student achievement and instructional time follows a nonlinear, concave specification: student achievement is maximized at 179 days in the average American school open for 5.9 hours per day and at 7.6 hours in the average American school open for 179 days per year. Extending the length of the school day also appears to be more effective than extending the length of the school year.

Introduction

In light of recent concerns about the declining performance of American students on internationally standardized assessments, policy makers at the highest level have called for extending the amount of time that students spend learning in school. While increasing instructional time may allow students to digest more material in an academically conducive environment, doing so might also incur substantial costs without assurances that the existing level of instructional time has been optimally distributed (to maximize student test scores) and that the effects of additional time have been properly disentangled from those of other inputs.

Indeed, the empirical research done on this issue to date has not produced a consensus regarding the true effects of instructional time on student achievement, given considerable disparities in these studies' methodologies and focuses. One set of studies examines the effects of instructional time *within* countries, capitalizing on the ability to avoid cross-country variations that may lead to imprecise estimation of such effects but sacrificing sufficient variability in the independent variable and/or the capacity to generalize results to other settings and populations. Some of these earlier studies (Card and Krueger 1992, Pischke 2007) analyzed the effects of instructional time on outputs not solely restricted to student achievement, while more recent studies (Farbman 2009, Dobbie and Fryer 2011, Hansen 2011, Goodman 2014) focused attention on student achievement as the intended outcome of changes in instructional time. Another set of studies (Lee and Barro 2001, Baker et al. 2004, Lavy 2010, Rivkin and Schiman 2013) focuses on the effects of instructional time *across* countries, thereby capturing significant variations in the independent variable (and increasing their external validity) but being more prone to suffer omitted variable bias stemming from heterogeneity between countries. While most results from these studies illustrate either an insignificant or slightly positive effect of increased instructional time on student achievement, there exists little evidence of a settled consensus on this topic.

In this paper, we exploit variation in instructional time across countries and years to examine the relationship between eighth-grade student achievement on the international TIMSS (Trends in Mathematics and Science Study) Assessments and the amount of instructional time offered by a student's school. Unlike prior literature, this paper divides aggregate instructional time (hours per year) into separate indicators for days per year and hours per day to investigate the effects of how instructional time is distributed within a school. Moreover, this study merges achievement data from four quadrennial testing cycles between 1995 and 2007 (covering more than 800,000 student observations across seventy unique countries) with student-, teacher-, and school-level data gathered from background questionnaires accompanying the assessments. As school- and student-level observations within a country are randomly sampled for every testing cycle, we treat countries (which are measured longitudinally) as panel data units. Consequently, this study's empirical framework controls for country- and year-fixed effects in addition to a broad range of student- and school-level covariates.

After analyzing a number of plausible functional forms, this paper finds that the association between student achievement and instructional time is best demonstrated through a nonlinear specification. In particular, we find that student achievement can be maximized at particular levels of instructional time, with hours and days having

substitutable effects on student achievement. As a result, this study provides evidence that merely increasing instructional time – without accounting for other important factors – cannot be assumed to automatically increase student achievement.

The remainder of this paper is organized as follows. Section 2 presents a framework of empirical specification to understand the relationship between instructional time and student achievement. Section 3 describes the data, and Section 4 analyzes the results. Section 5 discusses the implications of the results and concludes.

Empirical Specifications and Hypotheses

Introductory Framework and Linear Specifications

A simple, general form of the education production function – using measures of instructional time as the primary inputs and student achievement as the output – can be formalized in the following Cobb-Douglas functional form:

$$A_{isct} = BH_{sct}^{\tau\omega} D_{sct}^{\tau(1-\omega)} \quad (1)$$

Here, A_{isct} refers to the educational outcome (represented by test score) of student i in school s and country c at year t . The function supposes that A_{isct} can be determined by the number of instructional hours per day (H_{sct}) and days per year (D_{sct}) mandated by student i 's school s in country c and time t . All other inputs that influence student achievement – including other school-level inputs (e.g. teacher quality), peer effects, and external influences – are captured within B . The inclusion of τ reflects the possibility of first-order non-homogeneity for the production function (assuming that $\tau < 1$), with $\tau\omega + \tau(1-\omega) < 1$ implying decreasing returns to scale.¹ Such an assumption is reasonable, as academic achievement depends on more than instructional time and previous empirical studies suggest that simply doubling the number of days and hours would be unlikely to actually double student achievement.

It is useful to further separate the “catch-all” term B into a constant C (representing determinants of A uncorrelated with H and/or D) as well as a variable ε (representing a vector of variables affecting A and correlated with H and/or D):

$$A_{isct} = C\varepsilon^\gamma H_{sct}^{\tau\omega} D_{sct}^{\tau(1-\omega)} \quad (2)$$

Taking the logarithm of both sides and simplifying, we obtain the following derivation:

$$\ln(A_{isct}) = \ln(C) + \tau\omega\ln(H_{sct}) + \tau(1-\omega)\ln(D_{sct}) + \gamma\ln(\varepsilon) \quad (3)$$

Rewriting some terms and letting $\alpha = \tau\omega$ and $\beta = \tau(1-\omega)$, we obtain:²

$$\ln(A_{isct}) = \text{Constant} + \alpha\ln(H_{sct}) + \beta\ln(D_{sct}) + u_{isct} \quad (4)$$

Equation (4) presents a basic linear regression model of the logarithm of student achievement on the logarithms of instructional hours and days. The error term u_{isct} in Equation (4) can be further subdivided as follows:

$$u_{isct} = \rho'X_{isct} + \theta'X_{sct} + \kappa'X_{esct} + \eta'X_{ct} + \varepsilon_{isct} \quad (5)$$

Here, X_{isct} refers to a vector of student-background controls with coefficient ρ' , X_{sct} designates a vector of school-level controls with coefficient θ' , X_{esct} denotes a set of teacher- and classroom-controls with coefficient κ' , X_{ct} indicates a set of country-level controls with coefficient η' , and ε_{isct} represents the unobserved error term. Substituting Equation (5) into Equation (4) and inserting country- and year-fixed effects denoted respectively by δ_c and γ_t , we obtain:

$$\ln(A_{isct}) = \delta_c + \gamma_t + \alpha\ln(H_{sct}) + \beta\ln(D_{sct}) + \rho'X_{isct} + \theta'X_{sct} + \kappa'X_{esct} + \eta'X_{ct} + \varepsilon_{isct} \quad (6)$$

Equation (6) thus presents our most robust linear specification.

Nonlinear Specifications

Having outlined specifications that assume a linear relationship between instructional time and student achievement, we now consider the possibility of a nonlinear relationship. In particular, we begin by estimating a generalized, trans-log form of the production function in Equation (6). Such a specification allows us to test the robustness of the linear Cobb-Douglas results and analyze the factor substitutability between hours and days by calculating the elasticity of substitution between hours per day and days per year. Thus, we consider the following trans-log specification:

$$\ln(A_{isct}) = \delta_c + \gamma_t + \alpha_H\ln(H_{sct}) + \alpha_{HH}\ln(H_{sct})\ln(H_{sct}) + \beta_D\ln(D_{sct}) + \beta_{DD}\ln(D_{sct})\ln(D_{sct}) + \lambda_{HD}\ln(H_{sct})\ln(D_{sct}) + u_{isct} \quad (7)$$

To evaluate the robustness of this nonlinear functional form against that of the strongest linear specification, one can compare the statistical significance of the coefficients α_{HH} and β_{DD} in Equation (7) against the statistical significance of the coefficients α and β in Equation (6).

Using the results of the trans-log estimation in Equation (7), we can then calculate the elasticity of substitution – denoted σ – between days per year and hours through the following formula (Sato and Koizumi 1973, Chambers 1988):

$$\sigma = \frac{\sum_{i=1}^2 x_i f_i}{x_1 x_2} \frac{F_{12}}{F} = \frac{-f_1 f_2 (x_1 f_1 + x_2 f_2)}{x_1 x_2 (f_{11} f_2^2 - 2f_{12} f_1 f_2 + f_{22} f_1^2)}$$

Here, F is the determinant of the bordered Hessian matrix and F_{12} is the cofactor of f_{12} , while σ is evaluated at the values of $\ln(H)$ and $\ln(D)$ averaged across all observations.³ Hours and days can be described as imperfect complements with $\sigma < 1$ and as imperfect substitutes with $\sigma > 1$. These designations should also correspond, respectively, with positive and negative signs on the coefficient λ_{HD} for the interaction term in Equation (7).

If Equation (7) indeed establishes a robust nonlinear relationship between instructional time and student achievement, then – assuming this relationship is continuous and concave and that the sets of hours and days are closed and bounded – there must be unique levels of hours and days for which student achievement can be maximized. Conditional on these assumptions, we introduce a final specification that eliminates logarithmic terms while adding quadratic terms for the measures of instructional time and an interaction term between hours and days:

$$A_{isct} = \delta_c + \gamma_t + \alpha_1 H_{sct} + \alpha_2 H_{sct}^2 + \beta_1 D_{sct} + \beta_2 D_{sct}^2 + \lambda H_{sct} D_{sct} + u_{isct} \quad (8)$$

Compared to the trans-log functional form, this specification provides a more manageable way to calculate both critical values and the marginal effects of extra hours and days. Taking partial derivatives of A_{isct} with respect to H_{sct} and D_{sct} , the marginal effects of an extra instructional hour and day on student achievement (holding constant the levels of instructional days and hours, respectively) are given as follows:

$$\begin{aligned} \frac{\partial A_{isct}}{\partial H_{sct}} &= \alpha_1 + 2\alpha_2 H_{sct} + D_{sct} \\ \frac{\partial A_{isct}}{\partial D_{sct}} &= \beta_1 + 2\beta_2 D_{sct} + H_{sct} \end{aligned}$$

Equating these partial derivatives to zero, one can also solve for the optimal levels of H_{sct} and D_{sct} , conditional on the respective levels of D_{sct} and H_{sct} .

As a result, while this paper assumes the possible existence of imperfect factor substitutability between hours and days, decreasing returns to scale for achievement, and a nonlinear relationship between instructional time and achievement (all of which contradict some aspects of the classic Cobb-Douglas specification with constant elasticity of substitution), we nevertheless find that the Cobb-Douglas functional form provides a firm foundation on which to build and adjust this paper's models.

The Data

The TIMSS Dataset

This paper's dataset of interest encompasses the TIMSS Assessments, which measures standardized mathematics and science achievement at the fourth and eighth grades in participating countries on a quadrennial basis and collects a wealth of background information on students, teachers, and schools (through individually administered questionnaires). Within the realm of international surveys, the TIMSS data provide a stronger foundation for analyzing the impact of instructional time on student performance than those of PISA (the other primary internationally standardized assessment program), as the measure by which TIMSS respondents report instructional time remains consistent throughout the testing cycles (unlike that of PISA). Using an international dataset like the TIMSS also circumvents several challenges that would otherwise be associated with utilizing a domestic dataset, including the dearth of nationally standardized assessments within the United States that are administered to a randomized and nationally representative subset of students.

While TIMSS uses previous assessments to inform future testing designs, it does not readily invite the consolidation of data from different testing cycles into one panel data set. As a result, the process required to assemble

a workable dataset was both exhaustive and complex, and no study before this had comprehensively compiled the TIMSS datasets across multiple testing cycles.⁴ Within each year, the data are originally stratified by country and by unit of analysis (school, student, or teacher). Thus, for each testing cycle, we append the country-level data files at the same unit of analysis before merging between units of analysis to create a student-level, year-specific dataset (with background information on teachers, classrooms, and schools). After importing country-level data from the World Bank, we merge the consolidated year-specific datasets to form the final dataset.⁵ The final dataset contains approximately one hundred variables and more than 800,000 student observations comprising four testing cycles from 1995 to 2007.

Descriptive Statistics

There seems no readily discernible pattern in how the amount of instructional hours is distributed internationally. We also see evidence of hours and days serving as both substitutes and complements. As a result, one cannot readily discern an international pattern for instructional-time distribution between such measures.

It is difficult to descriptively establish even a broad relationship between the amount of instructional time offered and student achievement. While it is true that the highest-achieving East Asian countries have the longest school years, they also have shorter school days. On the other hand, some of the countries in the Western Hemisphere with scores nearly as high as those of the East Asian countries have among the shortest school years in the world and longest school days. Consequently, one must ultimately take into account other possible confounding factors (both within and across countries) to determine the true effects of instructional time on student achievement.

To account for omitted variable bias – which potentially skews the independent effect of instructional time on student achievement – we control for variables that are correlated with at least one of the measures of instructional time (days per year or hours per day) and student test score. These covariates are broadly categorized into four levels: (1) student, (2) school, (3) teacher/classroom, and (4) country.

Table 1 lists these variables, along with their average values for schools in the highest and lowest quartiles for instructional days per year and hours per day. Schools with the most instructional time tend to have students with only marginally greater beliefs in their academic ability and expectations for applying academic learning to future jobs, with these students also more inclined to spend less time watching television. Schools with the most instructional time also tend to have fewer computers and larger class sizes (in line with the theory of a fixed budget), as well as greater problems with student absenteeism and vandalism. Nonetheless, there appears to be an ambiguous tradeoff between instructional time and both the presence of enrichment activities and college-certified teachers. Furthermore, schools with the greatest amount of instructional time tend to have more students begin homework in class (along with a smaller probability of homework per class taking less than a half-hour) as well as more uninterested students and pupils with differing academic abilities. Finally, schools with the most days per year appear to be in countries that are slightly poorer and less developed (compared to those with the fewest days), while schools with the most hours per day tend to be in countries that are slightly richer and more developed (compared to those with the fewest hours).

Results

Linear Specification

The results in Table 2 present linear OLS regressions on the main data. Column (1), which corresponds to Equation (4) in Section 2 and controls only for dummy variables specifying missing data for the instructional time measures (before imputation), indicates that a 1% increase in instructional days per year and hours per day respectively decreases student achievement by 0.05% and increases achievement by 0.007%. The effect of hours per day is both extremely small and statistically insignificant, but the negative and statistically significant effect (at the 99% level) of days per year – while tiny – seems counterintuitive at first glance.⁶

Robust standard errors in parentheses

*** p<0.01, ** p<0.05, * p<0.1

Column (2) in Table 2 expands on Column (1) by controlling for a set of student-level covariates equivalent to X_{isct} in Equation (5). A 1% increase in days per year now translates to a 0.03% decrease in achievement, and a 1% increase in hours per day is now associated with a 0.02% increase in test score (with both effects statistically significant at the 95% level). The effect of days per year on achievement in Column (2) has become less negative than in Column (1) and the effect of hours per day has also become greater, as controlling for important student-level factors removes some of the previously uncaptured bias in these coefficients. Column (3) builds on previous regressions by including school-level covariates equivalent to X_{sct} in Equation (5). The effects of instructional time have marginally decreased relative to those in Column (2), with a 1% increase in days per year and hours per day respectively associated with a 0.04% decrease and 0.01% increase in student test score.

Column (4) further controls for a vector of teacher- and classroom-level covariates represented by X_{esct} in Equation (5) – all of which are statistically significant at the 99% level. A 1% increase in days per year now results in an increase in test score by 0.006%, which – while statistically insignificant – is now positive compared to analogous effects in Columns (1) – (3). A 1% increase in hours per day has also become larger, resulting in a statistically significant increase in student achievement by 0.05%. The most robust OLS regression specification can be found in Column (5), which includes a set of country-level covariates equivalent to X_{ct} in Equation (5). Column (5) indicates that a 1% increase in days per year – holding hours per day constant – increases student achievement by 0.04%, and a 1% increase in hours per day – holding days per year constant – increases student achievement by 0.02%. Before proceeding, it is important to notice that these effects – while statistically significant – are still quite small.

Incorporating covariates into the regression specification does much to circumvent omitted variable bias, but the OLS regression models in Columns (1) – (5) cannot fully control for unobserved heterogeneity across observations, which are likely greatest between countries. As a result, Column (6) employs a fixed-effects regression model that controls for effects varying across countries but not over time.⁷ The within-country effect of a 1% increase in instructional days per year is now associated with a statistically insignificant 0.007% decrease in test score, while a 1% increase in hours per day is associated with a statistically significant 0.01% increase in test score. Column (7) adds to Column (6) by including year-fixed effects that do not vary across countries. It appears that the results change only

marginally, with a 1% increase in days per year resulting in a statistically insignificant 0.01% decrease in test score and the effect of hours per day remaining largely unchanged from Column (6).

Trans-Log Specification

To test for nonlinearity, Column (1) in Table 3 displays the regression results from the trans-log estimation in Equation (7), which illustrate positive coefficients for the linear terms and negative coefficients for the quadratic terms – all of which are statistically significant at either the 90% or 95% significant levels. These results imply a robust, concave relationship between student achievement and both measures of instructional time. Given that the coefficient on the interaction term is only marginally insignificant at the 90% significance level, the optimal level of instructional days per year – as well as the marginal effect on achievement of an extra day – may very well be dependent on the existing level of instructional hours per day (and vice-versa). Furthermore, the implication of the negative sign on the interaction term (that days and hours have substitutable effects on student achievement) is confirmed by calculating the elasticity of substitution, which is equal to 3.40 and implies that days and hours are imperfect substitutes.

Quadratic Specification

Having confirmed that the relationship between both measures of instructional time and student achievement follows a robust nonlinear relationship, we analyze the regression results of the quadratic specification – equivalent to Equation

(8) – that eliminates the logarithmic terms from the previous trans-log estimation. These results are found in Column (2) of Table 3. Substituting these coefficients into Equation (8), we obtain:⁸

$$A_{iset} = 247.4 + 0.411D_{set} - 0.000779D_{set}^2 + 9.693H_{set} - 0.374H_{set}^2 - 0.0225D_{set}*H_{set} + u_{iset}$$

Taking partial derivatives with respect to both days per year and hours per day produces the following first-order conditions:

$$\partial A_{iset} / \partial D_{set} = 0.411 - 0.001558D_{set} - 0.0225H_{set} = 0$$

$$\partial A_{iset} / \partial H_{set} = 9.693 - 0.748H_{set} - 0.0225D_{set} = 0$$

Using the second partial derivative test, we find that all critical values of this quadratic specification serve as local maxima. Because the critical value for days per year is dependent on a given value for hours (and vice-versa), we take as fixed the existing average values for instructional time in the United States. As a result, given an average school day length of 5.9 hours, we find that student achievement is maximized at 179 days per year. Coincidentally, this also happens to be the length of the average school year in the United States. On the other hand, given an average school year length of 179 days, we find that student achievement is maximized at 7.6 hours per day. This is significantly higher than the length of the average school day (5.9 hours) in the United States.

Because the marginal effects of an extra unit of instructional time depend on the original amount of days or hours, schools in different countries will experience different marginal effects of increasing instructional time. Table 4 presents these effects for the average school in a sample of countries, given the average country-level data for instructional time compiled from the most recently available source – the 2011 TIMSS dataset.⁹ As expected, the marginal effects of an extra day – holding constant hours per day – are statistically insignificant for all of the selected countries in Table 4. These trivial effects can be contrasted with the more significant effects of an extra hour per day. In the United States, an extra instructional hour per day – controlling for days per year – increases test score by 1.3 points (0.016 standard deviations), with this effect rising to 1.5 and 2.4 points (0.020 and 0.032 standard deviations) in Japan and Hungary, respectively.¹⁰ Even in Israel, with one of the longest school years in the world, an extra hour per day increases student achievement by 1.2 points (0.014 standard deviations), *ceteris paribus*.

TABLE 4. MARGINAL EFFECTS OF TIME INCREASE IN DIFFERENT COUNTRIES

Country	Days Per Year		Hours Per Day	
	2011 Avg. Level	Marg Eff: +1 Day	2011 Avg. Level	Marg Eff: +1 Hr
United States	179	-0.000947	5.9	1.256**
Japan	201	-0.0128	4.9	1.510***
Hungary	183	0.0310	4.2	2.438***
Israel	211	-0.0306	5	1.210**

Note: These marginal effects assume that the other measure of instructional time (e.g. hours when analyzing days and vice-versa) is fixed to the existing 2011 average of the relevant country.

*** p<0.01, ** p<0.05, * p<0.1

Discussion

While this study finds that increasing instructional time – in particular, hours per day – until a threshold produces small, positive effects on student achievement, it remains to be seen whether or not such results warrant the passage of policies increasing the time that students spend learning in school. Indeed, there are two broad limitations to such policies: (1) the diminishing marginal returns of student achievement to instructional time and (2) the presence of significant monetary and opportunity costs to increasing instructional time.

Studies have shown that a ten percent increase in instructional time leads, on average, to a six to seven percent increase in monetary cost (Silva 2007). There also exist substantial non-budgetary costs to increasing instructional time, as altering school schedules produces wide-ranging consequences (especially with regard to extending the school year). Parents may be unwilling to sacrifice family vacations and independent out-of-school activities, and teacher unions may also be reluctant to accept the burden of longer schedules for teachers (even if salaries are concomitantly raised).

Furthermore, there remain nontrivial opportunity costs associated with allocating more resources to expanding time in school, as spending money towards increasing instructional time might take away from funds that could be distributed towards other inputs with beneficial effects on student achievement. As a result, the effects of added instructional time should be evaluated alongside those of other inputs to properly ascertain its benefits.

In particular, the achievement impact analysis of instructional time could also be sensitive to heterogeneous groups of students. Dobbie and Fryer (2011) find that urban charter schools that add 25 percent or more instructional time (comparable to an increase of 1.5 to 2 instructional hours) have annual gains that are 0.059 standard deviations higher in math. On the other hand, research by Dee and West (2011) shows that a decrease in class size by 10 students increases test scores for urban students, on average, by 0.12 standard deviations. It has also been found urban schools providing feedback to teachers ten or more times per semester have annual math gains that are 0.038 standard deviations higher than those of other schools, while schools that tutor students at least four days a week in small groups have annual math gains that are 0.044 standard deviations higher than those of other schools (Dobbie and Fryer 2011). While slightly smaller, the effects of an extra instructional hour found in this study lie within the same general range as those of the aforementioned schooling inputs. As a result, increasing instructional time (over other inputs) may only be prudent if the target population is particularly amenable to benefiting and the costs of doing so are less than those associated with the other inputs.

Given the high costs of increasing instructional time, schools might also consider increasing the utility of available time before increasing the length of the school day or year. With research suggesting that the quality of instructional time matters at least as much as the quantity (Silva 2007, Baker et al. 2004), it is conceivable that some schools could match or exceed the academic gains from increasing instructional time merely by making their current schedules more efficient.

Consequently, there are several important policy implications that can be drawn from this paper's findings and the discussion above. First, policymakers deciding between which measure of instructional time to increase would be wise to extend the length of the school day rather than (or before) expanding the length of the school year. Furthermore, the effectiveness of instructional time reforms depends greatly on the context within which such changes are proposed. Finally, policymakers should balance the benefits of increasing instructional time against (1) corresponding pecuniary and non-pecuniary costs and (2) the benefits attained from investing in other resources and/or the utility of available time.

There are several important areas of further inquiry that future studies are encouraged to tackle. It would be worthwhile to examine the possibility of heterogeneous effects of instructional time between other groups – for instance, do students in elementary school benefit more from increased time than those in middle or high school? Furthermore, what are the effects of variations in instructional time on outcomes other than student achievement? Finally, are there ways to increase instructional time such that the quality of time is maximized in the process? Answers to these sorts of questions are important in fully understanding not just the effectiveness of policies that increase instructional time (as this paper examines) but also the measures needed to implement such policies on the ground.

End Notes

¹ However, this production function still assumes diminishing marginal returns to each parameter of instructional time, given that $\tau\alpha$ and $\tau(1-\alpha)$ are both assumed to be less than one.

² This assumes that $Constant = \ln(C)$ and $u_{isct} = \gamma \ln(\varepsilon)$ in Equations (4) and (5).

³ More precisely, the terms in this equation can be denoted – per the coefficients in Equation (7) – by the following:

$$\begin{array}{ll}
 x_1: \ln(H) & x_2: \ln(D) \\
 f_1: \frac{\partial \ln(A)}{\partial \ln(H)} = \alpha_H + 2\alpha_{HH} \ln(H) + \lambda_{HD} \ln(D) & f_2: \frac{\partial \ln(A)}{\partial \ln(D)} = \beta_D + 2\beta_{DD} \ln(D) + \lambda_{HD} \ln(H) \\
 f_{11}: \frac{\partial f_1}{\partial \ln(H)} = 2\alpha_{HH} & \\
 f_{12}: \frac{\partial f_1}{\partial \ln(D)} = \lambda_{HD} & \\
 f_{22}: \frac{\partial f_2}{\partial \ln(D)} = 2\beta_{DD} &
 \end{array}$$

⁴ Because the 1999 TIMSS testing cycle omitted fourth grade students from the study, this paper uses only eighth-grade data for purposes of data continuity.

⁵ In doing so, we had to address the following caveats: (1) Questionnaires differed in structure from year to year, (2) Answer choices followed different scales between years, and (3) Variables were often labeled differently between testing cycles.

⁶ Throughout these regression specifications, we also assume that standard errors are clustered at the school level. Because the regressions analyze the effects of school-level measures of instructional time on the achievement of each student in a particular school, one can expect the errors to be correlated within each school. Thus, given the non-independence of each student-level observation within a school, clustering standard errors accounts for the fact that the effective sample size is lower than what it appears to be.

⁷ These effects may include – among others – attitudes toward the importance of education as well as various cultural and institutional factors.

⁸ Here, the constant 247.4 essentially captures the sum of the country-fixed and year-fixed effects intercepts.

⁹ These marginal effects assume that the other measure of instructional time (e.g. hours when analyzing days and vice-versa) is fixed to the existing 2011 average of the relevant country.

¹⁰ When describing the change in student achievement in terms of standard deviations for a particular country, we divide the change in test score by the standard deviation from the achievement mean *for that country's sample*. When describing the change in student achievement in terms of standard deviations cross-sectionally, we divide the change in test score by the standard deviation from the achievement mean for the dataset's entire population.

How do SMEs appropriate the value from the innovation? An empirical analysis in medium high-tech industries

Abstract

Innovation is assuming increasing relevance in the actual economic context, but being able to complete the innovation process is not enough for firms if they could not appropriate the value of their investments. Since, the relationship between appropriability regimes and firm performance has not received the attention it deserves, the present paper aims to narrow this gap.

To this end we used a panel regression model on secondary data related to balance sheets and patent portfolios of 559 Italian SMEs belonging to medium high-tech industries, but it showed no relationship between patent portfolios and economic and financial performance. Thus, we performed a cluster analysis on primary data collected through a survey in order to gather useful insight regarding the effect that other appropriability mechanisms might have on firm ability to profit from their innovation. Results suggest that the cluster preferring informal mechanism, in particular lead time, secrecy, skilled employees and control of distribution network, over patents registers superior performance.

1. Introduction

In the present-day economy, intangible assets have become more important than physical ones to succeed (Chen and Chang, 2010) and innovation has increasingly acquired a central role in developing and establishing a firm competitive advantage (du Plessis, 2007; Eppinger and Vladova, 2013). However, being able to generate new products and process, or to improve existing ones, is not a sufficient condition to maintain a superior competitive position over time (Neuhäusler, 2012): in fact, it has long been recognized that many innovative firms face difficulties in gaining the expected economic returns from its investments in innovation due to the presence of potential imitators (Arrow, 1962; Teece, 1986). For this reason, the activities related to the management of innovation, in terms of its exploitation and protection, might have a deep influence on firm profitability (Teece, 1986). To exclude third parties from the exploitation of their innovations, firms can put in practice several mechanisms, that generally are classified into two macro categories: formal regimes, such as patents or other kinds of Intellectual Property Rights (IPRs), and informal ones, more related to firm exploitation strategic choices (Milesi *et al.*, 2013), such as keep the innovations secret or devolving them faster than competitors.

A broad branch of the literature has focused on the means that firms can use to appropriate the value of their innovations; however, despite the fact that small and medium enterprises (SMEs) are often seen as important innovators in the economy (Kitching and Blackburn, 1998), few empirical researches are addressed to study the association between the appropriability strategy chosen by SMEs and their performance (Helmets and Rogers, 2008; Leiponen and Byma, 2009; Thomä and Bizer, 2013).

This issue seems particularly relevant in the Italian context, where 35% of SMEs, more than the European average rate, have introduced product or process innovations and, in recent years, have shown a positive trend in patent registration, more than large firms do (Hollanders and Es-Sadki, 2013).

To this end our aim is to better investigate the relationship between patents and SMEs economic and financial performance of Italian manufacturing SMEs belonging to medium high-tech industries. Additionally, to gain a deeper insight on the impact that also other appropriability regimes might have on firm performance, we identify clusters of firms having different innovation behaviours with particular reference to appropriation strategies and the generation of incremental and radical innovation. This clusterization allows to test whether there is a significant difference in terms of profitability between the identified groups of SMEs.

This paper is structured as follows: section 2 presents an analysis of the literature on the influence that patent and the choice of other appropriability regimes might have on SME economic and financial performance; section 3 describes the methodology of both the analyses carried out in this study; section 4 illustrates the result obtained from the two analysis before presenting the conclusions and suggestions for future research in section 5.

2. Literature review

2.1 Patents and firm performance

In the last decades, a broad branch of scientific literature (e.g., Faems, de Visser, Andries, and Van Looy, 2010; Geroski, Machin, and van Reenen, 1993; Mansfield, Rapoport, Romeo, Wagner, and Beardsley, 1977) aimed to assess the relationship between innovativeness and firm economic and financial performance has developed. As patents can be considered a proxy of a firm innovative activities (Griliches, 1990; Haroff *et al.*, 2003; Lanjouw and Shankerman, 2004), many empirical works have focused on testing their specific association with firm economic and financial performance.

However, results of those studies are conflicting: some proved that there is no significant relationship between patents and firms performance measured in terms of Return on Assets (ROA), sales growth and market value (Griliches *et al.*, 1991; Rivette and Kline, 2000; Kretschmer and Soetendorp, 2001); instead, among those who found evidence of a significant association, a certain number of papers assert that patents have a strong positive effect on the above-mentioned firm performance (Andries and Faems, 2013; Austin, 1993; Bosworth and Rogers, 2001; Bessler and Bittelmeyer, 2007; Chen and Chang, 2010; Deng *et al.*, 1999; Ernst, 1995, 2001; Hall *et al.*, 2005; Nerkar and Roberts, 2004; Scherer, 1965; Teece, 1998), contrarily others found a negative influence (Artz *et al.*, 2010; Heimonen, 2012).

In addition, industry and nation peculiarities are claimed to influence the association between patents and firm performance (Ernst, 2001); as a consequence, some of the above-mentioned studies have been conducted in a specific country, principally U.S, U.K and Germany, and/or in a specific industry, above all the pharmaceutical (Mansfield, 1986; Narin *et al.*, 1987; Nerker and Roberts, 2004; Chen, 2011; Chang *et al.*, 2012; Demirel and Mazzucato, 2012), the mechanical (Rothwell, 1979; Ernst, 1995, 2001; Agostini *et al.*, 2013) the biotechnology (Arora *et al.*, 2008) and the nanotechnology (Fernandez-Ribas, 2010).

Within this context, the domain of SMEs is much less investigated. (e.g., Andries and Faems, 2013) Only few empirical works regarding the relationship between patenting activities and firm performance, mainly in terms of sales, have specifically taken into consideration the SMEs context, and again results are not so straightforward. Demirel and Mazzucato (2012) and Andries and Faems (2013) conclude that also SMEs benefit from their R&D activity, and in particular from patents, while on the other hand, Heimonen (2012) find that innovative small firms are less successful than non-innovative ones and Agostini *et al.* (2013) observe that for Italian SMEs, belonging to mechanical sector, there is no significant impact of patents on firm performance in the mechanical industry.

The literature recognizes that SMEs face relatively big challenges in capturing the value of their patenting activities because the patent system seems to be more appropriate for large firms, especially in the drugs industry (Brouwer and Kleinknecht, 1999). There are two main factors that might make patenting less effective for SMEs, and thus reduce their probability to obtain advantages from patents: the lack of economic resources as well as of the legal and procedural information about the IP systems (Masurel, 2002; OECD, 2004; WIPO, 2004). However, there are evidences of an increasing patent activity on the part of SMEs rather than of large firms, both in Europe and in the U.S (de Rassenfosse, 2012), and especially in high-tech industries (Burrone, 2005). For these reasons, it might be important to gain a deeper understanding of this controversial topic, trying to unveil whether SMEs can gain an economic benefit from their patents.

On these grounds, we formulate the first hypothesis.

H1: The number of patented invention is not associated with SME profitability in medium high tech industries.

2.2 Mechanisms to protect innovation

It is widely recognized that one of the main purposes when investing in innovative activities is to differentiate the firm offering and consecutively gain a profit increase. Indeed a novel product or service has few direct substitutes, and this should allow the innovator to benefit from a “quasi monopoly” position in the market (Milesi *et al.*, 2013). However, in practice, the possibility to establish a competitive advantage and gain significant economic returns from the successful innovation is reduced due to the presence of potential imitators (Galende, 2006).

The topic related to the means firms can use to capture the value of their innovations preventing or delaying imitation is broadly discussed in the stream of literature about the so called appropriability “regimes”, “mechanisms” or “strategies”, where these terms are used as synonyms.

There is general consensus among authors (i.e., Galliè and Legros, 2012; Milesi *et al.*, 2013) that appropriability regimes can be grouped into two macro categories: “formal” or “legal” mechanisms and “informal” or “strategic” ones. Legal appropriability regimes require the demonstration of the novelty/originality of the innovative output to an authorized external authority (Laursen and Salter, 2005) which, in case of approval, grants the innovator the exclusive right to exploit it (Rammer, 2002). Formal means coincide with the Intellectual Property Rights (IPRs), so they include mechanisms such as patents, trademarks, utility models, industrial designs and copyrights, that aim to protect different kind of new knowledge.

With regard to the second category of informal appropriability regimes, the most relevant are trade secret, technological complexity, lead time advantage, complementary assets and skilled employees.

- *Trade secret* consists in undisclosed knowledge that provides an actual or potential competitive advantage over firms that lack of those information (Galliè and Legros, 2012). The efficacy of this means of protection is related to the efforts to exclude third parties to capture the knowledge developed by the innovative firm in form of products, processes, techniques, methods, devices, or *formulae*; however secrecy does not protect from “reverse engineering” (Rammer, 2007; Milesi *et al.*, 2013; Galliè and Legros, 2012) or independent discoveries (Galliè and Legros, 2012).
- *Technological complexity* of goods or production processes can reduce the risk of being copied, thanks to the difficulties faced by potential imitators to put in practice “reverse engineering” and “invent-around” strategies (Rammer, 2007; Galliè and Legros, 2012). Moreover, nowadays, many products are based on the integration of different technologies and pieces of knowledge; this means that a competitor should acquire sufficient knowledge to understand and manage all of them in order to replicate a someone else’s innovation (Brusoni *et al.*, 2001). In fact, the human capital plays a fundamental role in innovative activities: having a group a of qualified and experienced technicians that embody the knowledge of the firm have a positive influence on innovations (Galende, 2006; Gonzalez-Alvarez and Nieto-Antolin, 2007), and might help to respond to specific customer needs developing highly tailored solutions that are difficult to imitate (Thomä and Bizer, 2013).
- *Lead time or “first mover” strategy* is related to the ability of a firm to routinely develop innovations more quickly than competitors (Galliè and Legros, 2012). Rapid innovation rate gives to a firm the opportunity to benefit from a “quasi-monopoly” period between the launch of its innovation to the market and the introduction of substitute goods developed by imitators (Milesi *et al.*, 2013). In addition, due to the constant accumulation of knowledge over time, the innovative firm might have achieved a more advanced technological step than its potential imitators, allowing it to achieve a position of technical leadership for a period of time in its competitive environment (Galende, 2006; Delerue and Lejeune, 2011; Gonzalez-Alvarez and Nieto-Antolin, 2007). Other potential benefits arising from the “continuous innovation strategy” consist of the possibility to acquire a significant market share, establish technological co-operation networks (Gonzalez-Alvarez and Nieto-Antolin, 2007) and rise “entry barriers” to potential imitators thanks to high imitation cost and time (Harabi, 1995; Milesi *et al.*, 2013; Gonzalez-Alvarez and Nieto-Antolin, 2007; Lawson *et al.*, 2012)
- *Complementary assets* are key factors in determining how economic benefits are distributed between the innovative firm and its imitators. In fact, they represent the set of different capabilities difficult to imitate that used together with the core technological ones contribute to appropriate the profits of innovative activities, especially when imitation is inevitable (Teece, 1986). Complementary asset have a technical, commercial and organizational nature because they comprise different resources like complementary technologies, control of distribution channels, service capacity (e.g., after-sales support) and relationship with customers and suppliers (Teece, 1986; Galende, 2006; Lawson *et alt*, 2012; Milesi *et al.*, 2013).

2.2.1 Appropriability regimes and innovative behaviour of firms

Although in the literature the definition and the description of the means for protecting and capturing economic benefits of innovative activities are quite homogeneous, the results of empirical studies about their efficacy and usefulness are not directly comparable. This may be due to the difference in the period of analysis, the characteristics of the sample, and the used methodological approach (Milesi *et al.*, 2013).

Overall, most of the empirical studies analyse how the perceived importance of appropriation regimes changes according to one or more factors among industry characteristics, type of innovation (process vs product innovation) and firm size.

As far as sector of activity is concerned, firms belonging to industries with low levels of technological opportunities tend to resort less to appropriability regimes; informal appropriability mechanisms are more used by firms in medium-tech sectors and formal ones are preferred in medium-high tech and knowledge intensive industries (Levin et al., 1987; Harabi, 1995; Arundel and Kabla, 1998; Arundel, 2001; Laursen and Salter, 2005; Jensen and Webster, 2006; Leiponen and Byma, 2009; Olander et al., 2009; Milesi et al., 2013). In particular, patents are found to be important for those firms whose products are expensive to develop but that are, at the same time, easy and cheap to imitate, like chemical compounds, mechanical equipments, electrotechnical instruments, semiconductors (Brower and Kleinknecht, 1999; Cohen, 2000; Arundel, 2001; Harabi, 1995; Kumar and Vedmani, 2007).

From the point of view of the kind of innovation to be protected, generally informal appropriability regimes seem to be perceived as more valuable, both for product and process innovations (i.e. Levin et al., 1987; Harabi, 1995; Arundel, 2001; Cohen *et al.*, 2002). Process innovations can be kept within the firm and protected through secrecy more effectively than product innovations; in addition, for process innovations, the disclosure of information required in a patent application might not be worth the legal protection offered by this kind of mechanisms (Harabi, 1995). Although informal methods are overall preferred, in case of product innovations, firms show a higher inclination towards the use of patents than for process innovations: in fact, when a product is launched to the market, it might be subject to reverse engineering (Leiponen and Byma, 2009).

Regarding the last of the above-mentioned factors, firm size, most of the studies highlight that strategic mechanisms are viewed as more valuable than formal ones both from large and small firms (Levin et al., 1987; Cohen, 2000; Arundel 2001; Neuhäusler, 2012). However, firm size could be an inhibiting factor (Leiponen and Byma, 2009; Galliè and Legros, 2012; Thomä and Bizer, 2013) particularly for patent activities due to the resource constraints, more difficulties in dealing with patent process and legal activities, non-familiarity with patent information that SMEs, rather than large firms, face (Kumar and Vedmani, 2007). Despite this issue, not all small firms follow the same patterns to protect their innovations (Olander *et al.*, 2009) and, as stated in the previous paragraph, the literature presents evidence of the increasing use of IPRs, especially patents, by small and medium enterprises.

Furthermore, most of empirical studies agree upon the fact that firms generally employ a variety of means to protect their inventions (Choen, 2000; Olander *et al.*, 2009; Galliè and Legros, 2012; Neuhäusler, 2012). In fact, as stated by Hurmelinna-Laukkanen *et al.* (2008 p. 281), it is a “combination of mechanisms that at its best enables protecting innovations and the increased rents due to R&D needs to be used strategically”.

Despite the fact that the aim of appropriability regimes is to protect and capture the value of innovative activities of the firms, and even if the literature available on this issue is extensive, little research, to the best of our knowledge, concentrates on how the choice of a specific or a set of mechanisms influences firms performance. Within the few empirical contributes that shed light on the effects that the efficacy of the appropriability regimes has on firm performance, Laursen and Salter (2005) analyse the relationship between the importance attributed by a sample of 2707 firms to legal and informal mechanisms to “innovative performance”, measured as the rate of firms sales related to new products on the global market. Results from their regression models show that the strength of both sets of approaches are curvilinearly associated to innovative performance, with an inverted “U-shape”.

Similarly, Hurmelinna-Laukkanen *et al.* (2008) tries to link the perceived strength of appropriability regimes, both formal and informal, to the percentage of firms turnover related to new products launched in the preceding three years, defined as “innovative performance”. A positive effect of the strength of the appropriability mechanisms is found when innovations are incremental, but not when they are radical.

Those results are also supported by Ceccagnoli (2009); his work concludes that the strength of appropriability means has a positive impact on firm performance, estimated as Tobin’s q value, in particular when patents are used to protect incremental innovations rather than radical ones.

Some studies focus on the moderating role that different kinds of appropriability regimes play on the association between innovation capability and business performance: Lawson *et al.* (2012) find that both legal and informal mechanisms positively moderate the relationship between innovation capability and the global business performance, measured in terms of financial and nonfinancial aspects, as customer retention, employee productivity,

market share growth and rate of return on capital. The regimes, except the ones related to technological capabilities, are found to have a positive influence on the overall firm performance.

Since most of the above-mentioned studies focus on large firm innovative performance, disregarding the economic performance, our aim is to test whether there is a significant difference in terms of SMEs profitability between clusters defined according to firm appropriation strategies and propensity to generate both incremental and radical innovation.

3. Methodology

The sample of analysis is identified according to some considerations that reflect the aim of our research. The sampling technique adopted is defined as “purposive”; it allows to draw samples including specific areas or groups identified in a population, in order to satisfy certain conditions (Kerlinger, 1986; Short *et al.*, 2002).

In particular, we select firms which match the following *criteria*:

- micro firms and SMEs: with a turnover higher than 1 million of Euros;
- belonging to manufacturing medium-high tech industries [1];
- located in the Veneto region, where, although the economic context is constituted mainly by SMEs, the mean number of workers employed in R&D (Regione Veneto, 2011) and private investment in R&D are one of the highest in Italy (Regione Veneto 2013).

Based on these conditions, a final sample of 559 firms is obtained.

To carry out the data analysis, we use a two steps methodology. Firstly, we employ a panel analysis on a set of secondary data in order to estimate the relationship between patents and SME economic and financial performance. Secondly, a cluster analysis on primary data, obtained through a questionnaire, is performed. In the following paragraphs we describe the two methodologies in deep details.

We employed the softwares Stata and SPSS.

3.1 First step: panel analysis

The impact of patents on firm economic and financial performance is investigated using a panel data set of 559 Italian SMEs belonging to the three industries described before which span the period from 2000 to 2012.

Independent variables

In this study, data for patents are drawn from Thomson innovation, a database with global coverage provided by Thomson Reuters.

In line with previous researches (Putnam, 1996; Harhoff *et al.*, 1999; Belderbos *et al.*, 2010; Agostini *et al.*, 2013), we rely upon patented invention, which refers to a patent family instead of a single patent. A patent family comprises all patents, filed in different countries, which protect the same invention disclosed by a common inventor (OECD, 2009). Technically, it represents the set of patents, or applications, filed in several countries that are related to each other by one or more common priority filings.

Patent families can be considered as a measure of firm innovative activities since, in combination with early priority date, allows to identify the original protected invention that in consecutive years, might have been filed in the patent offices of other countries, and thus, avoid the risk to count more than one time the same protected invention. For this reason the earliest priority date is considered as the reference date, because it best reflects the period of generation of the original invention (Schmoch *et al.*, 1988).

In particular, we use a stock measure instead of a flow one; this means that the iterative sum of patent families of two, three, four and five years is used to assess the impact on firm performance of the subsequent year. In fact the benefits deriving from patents are likely to persist in the future and may show a cumulative effect (Grabowsky and Mueller, 1978; Bloom and Van Reenen, 2002; Eng & Keh, 2007; Agostini *et al.*, 2013); furthermore, SMEs generally face resource constraints and might need more time to reap the benefits of their investments.

Dependent variables

The impact of patent families on economic and financial firm performance is assessed through two profitability indexes, Return on Assets (ROA) and Return on Equity (ROE).

Data from balance sheets, collected from AIDA database by Bureau Van Dijk, are used to compute the value of ROA and ROE.

Using these two indexes as a measure of firm performance, rather than sales, provides a more complete information about firm profitability: ROA represents the capacity of a firm to generate profits from its assets, while ROE shows how well investment funds are exploited in order to generate earnings growth. Table 1 reports the descriptive statistics for the initial entire sample of firms.

TABLE 1: DESCRIPTIVE STATISTICS

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
MEAN SALES [M€]	7786.4	7927.4	8645.7	9076.0	9451.9	9836.2	9250.0	9701.0	10128.2	10061.2
MEAN ROA	6.96%	7.02%	6.89%	7.90%	8.48%	6.39%	4.92%	5.41%	5.86%	4.22%
MEAN ROE	1.90%	7.08%	6.89%	6.47%	9.48%	7.56%	2.81%	4.40%	9.62%	11.80%

Control variables

Consistently with previous empirical studies on innovativeness and firm performance that used firm size (Lin and Chen, 2005; Chang *et al.*, 2012) and firm age (Demirel and Mazzucato, 2012; Kim *et al.*, 2012) as control variables, we include both of them in the first part of our analysis, in order to provide as much detail as possible.

In particular, we define SMEs size through firm total assets and firm age through the years since foundation. In our case, control variables have been log transformed because raw data were skewed.

Method of analysis

In line with our previous studies, we adopt cross-sectional time series-regression to investigate the association between patent families and firm profitability, in terms of ROA and ROE. After testing the assumption performing the Hausman test, we use the fixed effect model, instead of the random one, to remove all between-firm variance and thus controls for any time invariant unobserved heterogeneity among firms (Chang *et al.*, 2012). So, the fixed effect with firm and year dummy variables serves to control for multiple observations per firm and per year (Artz *et al.*, 2010).

Based on previous literature (Basberg, 1983; Schmoch *et al.*, 1988; Griliches *et al.*, 1991; Ernst, 2001; Agostini *et al.* 2014) which states that a time lag of up to five years is needed between first patent filing and its effect on firm performance, we use the following panel models, where each equations include four diverse models testing how different year aggregates impact on firm profitability of the subsequent year:

$$ROA_{i,t} = \beta_0 + \beta_1(\sum_{\tau} \text{Number of patent families}_{i,\tau}) + \beta_2(\text{Firm assets}_{i,\tau}) + \text{Error term} \quad (1)$$

$$ROE_{i,t} = \beta_0 + \beta_1(\sum_{\tau} \text{Number of patent families}_{i,\tau}) + \beta_2(\text{Firm assets}_{i,\tau}) + \text{Error term} \quad (2)$$

In particular $i = 1, 2, \dots, N$ represents the firm identifier, $t = 1, 2, \dots, T$ is the number of periods, $\tau = t-1, t-2, \dots, t-5$ is the year aggregates, β_0 is the intercept, while β_1 and β_2 are the regression coefficients.

3.2 Second step: cluster analysis

As underlined before, the aim of this second part of the analysis is to identify potential subsets of firms having different innovation behaviours with particular reference to appropriation strategies and the generation of incremental and radical innovation, and then test whether there is a significant difference in terms of profitability between these groups.

To this end, the 559 firms of the entire sample were invited to take part to an on-line survey that focused mainly on the overall firm approach in developing, exploiting and protecting innovations. 100 useful questionnaires were received, corresponding to a response rate of about 17.5%.

Combining part of the primary data from the questionnaires with the correspondent economic and patent information contained in the initial dataset, we then conduct a cluster analysis.

Cluster analysis represents one of the different statistical techniques that heuristically sort observations, in this case the firms who answered the questionnaire, into homogeneous sets or groups, called clusters, based on certain characteristics.

Clustering variables

The variables employed to define groups refer to the appropriation regimes and the innovation capability.

According to Ritala and Hurmelinna-Laukkanen (2013), we thus employ four variables related to the perceived effectiveness of different appropriability mechanisms: secrecy, lead time advantage, employee skills, control of distribution networks; these variables were evaluated on a 7-point Likert scale. Additionally we also use, as clustering variable, the total number of patent families own by a firm, because they reflect how much it is inclined to protect its innovations through patents. We also include the innovation ambidextrous capability (Lin and McDonough, 2011), measured as the product of the propensity of firms to develop incremental and radical innovation, since it leads to market opportunities that appropriability regimes might support to profit from (Lawson *et al.*, 2012). These last two variables are measured on a continuous scale.

Method of analysis

Since variables are measured on different scale levels, as just explained, the algorithm adopted to conduct the study is the “two step cluster analysis”, that has been specifically designed by Chiu *et al.* (2001) to handle categorical and continuous variables simultaneously. For the same reason, we use the Log-likelihood distance measure, instead of the Euclidean one.

After conducting the cluster analysis, a t-test is carried out in order to verify if the clusters of firms show significant difference in terms of profitability (ROA and ROE).

4. Results

4.1 First step: panel analysis

Tables 2 summarises the results of the panel analysis for the two dependent variables, ROA and ROE, for all year aggregates.

TABLE 2: RESULTS OF THE PANEL ANALYSIS

DEPENDENT VARIABLE: ROA				
	Model 1 (2Y)	Model 2 (3Y)	Model 3 (4Y)	Model 3 (5Y)
PAT	-0.0002 (0.768)	0.0001 (0.926)	0.0002 (0.805)	0.0008 (0.238)
FIRM SIZE	0.0677*** (0.000)	0.0677** (0.000)	0.0824*** (0.000)	0.0630*** (0.000)
FIRM AGE	-0.0018*** (0.000)	-0.0018*** (0.000)	-0.0018*** (0.000)	-0.0016*** (0.000)
R-SQUARED	0.68	0.68	0.69	0.71
NUMBER OF OBSERVATIONS	4725	4725	4360	3939
DEPENDENT VARIABLE: ROE				
	Model 1 (2Y)	Model 2 (3Y)	Model 3 (4Y)	Model 3 (5Y)
PAT	-0.0006 (0.765)	-0.0014 (0.400)	-0.0009 (0.567)	-0.0003 (0.830)
FIRM SIZE	0.0267** (0.031)	0.0268** (0.031)	0.0466*** (0.001)	0.0519*** (0.001)
FIRM AGE	-0.0063*** (0.000)	-0.0063*** (0.000)	-0.0070*** (0.000)	-0.0062*** (0.000)
R-SQUARED	0.33	0.33	0.36	0.39
NUMBER OF OBSERVATIONS	4622	4622	4268	3858

Table 2: panel regression models for the dependent variable ROE

** significance at 5% level

*** significance at 1% level

While both control variables, firm size and firm age, are positively associated to firm performance, proxied by ROA and ROE, on the other hand, results suggest that these profitability indexes are not positively influenced by patents families. Thus, H1, which predicts no impact of patents on firm performance, is supported.

4.2 Second step: cluster analysis

Then, in order to better investigate the association between firm ability to generate innovation and benefits arising from these activities, we perform a cluster analysis. The analysis highlights that, within the firm sample that answered the questionnaire, two different clusters can be identified. Some descriptive statistics of the variables used to define them are presented in Table 3

TABLE 3: DESCRIPTIVE STATISTICS OF THE CLUSTERING VARIABLES

	CLUSTER 1			CLUSTER 2		
	Obs	Mean	Std Dev	Obs	Mean	Std Dev
LEAD TIME	51.315%	5.308	1.260	48.684%	3.108	1.680
SKILLED EMPLOYEES	51.315%	4.820	1.667	48.684%	3.027	1.691
CONTROL OF DISTRIBUTION NETWORKS	51.315%	3.153	1.570	48.684%	3.513	1.938
SECRECY	51.315%	4.077	1.840	48.684%	4.729	1.557
PATENT FAMILIES	51.315%	0.487	1.374	48.684%	1.784	4.535
INN. CAPABILITY	51.315%	29.008	11.038	48.684%	23.675	10.739

Results of the analysis show that “Cluster 1” is characterised by a higher ability to develop both radical and incremental innovation than the other group of firms and rely more upon informal mechanisms of protection, especially lead time; on the other hand, “Cluster 2” although gives a certain importance to non-legal regimes, in particular to secrecy, it has a greater tendency to protect its innovations through patent than “Cluster 1”.

From the point of view of firm performance, the mean values for the two clusters are presented in Table 4.

TABLE 4: MEAN VALUES OF ROA AND ROE FOR THE TWO IDENTIFIED CLUSTERS

	CLUSTER 1		CLUSTER 2	
	Obs	Mean	Obs	Mean
ROA	53.521%	7.45%	46.479%	4.06%
ROE	53.521%	16.81%	46.479%	5.28%

Both ROA and ROE seems to be higher for the first cluster. In order to statistically verify this difference, we perform the t-test that confirms that the means of the two indexes are significantly different between the groups, as shown in Table 5 (first column).

TABLE 5. VALUES OF THE T-TEST

	T-TEST	(MEAN1 > MEAN2)	(MEAN1 < MEAN2)
ROA	2.0102*		

ROE	(0.0483)	0.0242*	0.9758
	2.4297*		
	(0.0178)	0.0089*	0.9911

*Level of significance < 0.05

Looking at the second and third columns, we understand that the mean values of ROA and ROE of SMEs belonging to the first cluster are significantly higher than those of SMEs belonging to the second cluster.

5. Discussion and conclusions

The aim of this paper was to investigate the impact of different appropriability regimes on firm economic and financial performance. Our results show that the number of patent families owned by a firm are not associated to its economic and financial performance; instead, firms characterised by higher innovation ambidexterity and relying upon time-to-market and human resource know-how register a higher profitability than firms with a higher tendency to rely upon patents and secrecy.

We argue the first evidence is mainly due to the lack of specific know-how regarding IPRs on the part of SME entrepreneurs who are too much involved in routine and operative activities, thus having no time to build a longer term strategy encompassing the IPRs. More frequently, not only entrepreneurs have time constraints, but also they would not even know how to exploit these assets, as some other authors argued (e.g., Agostini *et al.*, 2014). It must be recognized that the actual patent system is designed more for large firms than for smaller ones (Brower and Kleinknecht, 1999), which makes entrepreneurs argue whether the investment is worth doing.

On the other side, the second evidence confirms that more profitable firms have an inclination towards protecting their innovations through informal appropriability mechanisms. In particular, time-to-market and human resource know-how seem to be significantly different between the two clusters. This means that rapidly launching in the market an innovation which has been developed thanks to unique competencies of people working inside the firm leads to higher profits for SMEs. Actually, innovative SMEs are supposed to resist the pressure of large firms thanks to their high specialization and flexibility which allow them to be a pioneer/forerunner in the market and have some form of advantage in respect to larger firms (Olander *et al.*, 2007; Thomä and Bizer, 2013). These evidences are in line with Laursen and Salter (2005) stating that when firms put an over-emphasis on protection, especially through intellectual property or secrecy, rather than on the exploitation of their innovation, they might face a deterioration of innovative, and thus economic, performance. Results of this paper have useful implications both for the empirical research and management practice regarding the influence of patents and appropriability regimes on firm economic and financial performance.

From a managerial point of view, results suggest that, as patenting activity is expensive, especially for SMEs that face resource constrains, the nodal point is not to possess a patent portfolio, but to understand how to manage and exploit it strategically, in order to generate economic benefits from this kind of investment. Otherwise, the risk for SMEs is to spend large amounts of money in order to register and maintain patents, neither gaining an effective protection of their innovations, which is the primary driver towards SME patenting, nor reaping any economic benefit. Moreover, managers might face a tricky trade off, on how much disclosure or strictly protect the innovations, when defining the firm appropriation strategy (Laursen and Salter, 2005), which calls for attention and consciousness towards these topics.

From a theoretical viewpoint, our contribution builds upon previous literature in order to shed light on the under investigated issues regarding appropriation strategy and its effect on economic and financial performance in the micro and small-medium firm context. In addition, the combination of different statistical instruments proves particularly useful when addressing complex issues which need to be examined from different perspectives.

Our paper has also some limitations that could be overcome by further future research. Firstly, the little dimension of the sample used to perform the cluster analysis should be enlarged, e.g. through a new survey in other high-tech industries, in order to understand whether the results of this study can have a broader scope of validity. Secondly, the Italian context in which the analysis is embedded contains a number of specificities which prevents from generalizing our findings. Hence, the same analysis could be replicated in other countries. Thirdly, proving that

it is a multifaceted matter, this study suggests the use of case studies to explore the dynamics of SME appropriability regimes in deeper details.

Internationalization of Technology Startup Firms from Emerging Economies: Leveraging Intangible Assets in Turbulent Environments

Abstract

Rapidly internationalizing technology firms from emerging economies are a recent phenomenon. They are the result not only of efforts by governments to diversify and expand their economies, focusing on higher value added products, but also from a wider fields of technological business opportunities available to entrepreneurs. For these firms early internationalization is often not only an option, but a necessity. In those cases where technology is the foundation for developing high-value added products or services, it is frequently the case that startup firms cannot easily find domestic markets ready to pay higher prices for their products or services. In order to access more industrialized markets, technology firms from emerging economies need to be more skilled in leveraging their intangible assets. The challenge for them, however, is that usually the institutional context in which they work is not developed enough to support these efforts in the same way as they do in more industrialized economies. Emerging economies tend to present both institutional weaknesses and market failures that hamper the ability of firms to properly manage their knowledge assets. Intellectual property regimes are usually weaker, and knowledge sources tend to be scarce locally, for example. Thus, technology firms need to manage their assets wisely and with more agility, in order to survive in international markets. Knowledge management becomes a key issue for technology firms very early in their development. Using case studies from Mexico, we study the networking behavior that technology startup firms use in order to identify, assess and assimilate knowledge they need in order to succeed in international markets. For these firms, knowledge acquisition and management tends to be inextricably linked to adapting their business models rapidly in order to take advantage of local and global networking opportunities they need when entering international markets.

Research on Internationalization Processes: Where are We?

Research on internationalization processes has come a long way since the work of Johanson and Wiedersheim-Paul that has come to be known as the Uppsala Model (Johanson & Wiedersheim-Paul, 1975). Many research studies have contributed to our current understanding of the internationalization process of a firm. Some of them have established the specific traits of such a process for multinational corporations, while others have documented the particularities that it has for small and medium enterprises (Bell, Crick, & Young, 2004). Technology tends to be an important factor in internationalization processes (Gassmann & Keupp, 2007; Huan Zou, Xiaohui Liu, & Ghauri, 2010), since it enables greater ability to adapt to foreign markets, while at the same time it requires wider markets in order to recover investments in R&D that the firm makes.

Internationalization places severe demands on the firm's ability to learn and to adapt to new environments (Eriksson & Johanson, 1997), including the adaptation and reconfiguration of their business models (Casadesus-Masanell & Ricart, 2010; Onetti, Zucchella, Jones, & McDougall-Covin, 2012).

The emergence of firms that internationalize rapidly after their creation, without going through the phases that the Uppsala model posits, has been also studied, giving rise to the "born global" concept (Brännback, Carsrud, & Renko, 2007; S. Chetty & Campbell-Hunt, 2004; Knight & Cavusgil, 2004). Here, again, technological capabilities and opportunities play a strong role in shaping the rapid internationalization that these firms undergo (Freeman, Hutchings, Lazaris, & Zyngier, 2010; Lee Li, Qian, & Qian, 2012). Born global firms, however, do not operate by themselves, their internationalization process tends to depend heavily on networks of alliances that they rapidly build (Fernhaber & Li, 2013; Freeman, Edwards, & Schroder, 2006).

Technology-based Firms from Emerging Economies: A New Actor in Global Markets

Many forces explain the increase in the number of "born global" firms from advanced economies, including the increasing complexity and reach of global supply chains, the globalization of markets, and advances in transportation and communication technologies (Bell et al., 2004; S. Chetty & Campbell-Hunt, 2004; Knight & Cavusgil, 2004; Oviatt & McDougall, 2005; Shane, 2001). According to this view, international new ventures are

made possible when ownership of valuable assets, and technological assets in particular, provides a sustainable competitive advantage that is transferable to foreign locations (Oviatt & McDougall, 2005)

But these same factors do not necessarily explain the increasing number of “born-global” firms from emerging economies, particularly since resources are not as readily available to them. Since their creation, technology firms from emerging economies face competition from incumbent firms from advanced economies, and many institutional factors in their economies are much less favorable than those available to firms from industrialized economies (Zhu, Hitt, & Tihanyi, 2006). The usual explanations for the rise of technology-based new firm formation in advanced economies (Almus & Nerlinger, 1999; Collinson & Gregson, 2003; Ganotakis & Love, 2012; Shane, 2001a, 2001b) are not readily applicable to their counterparts from emerging economies, since the economic environments in both cases show strong differences.

In the last decade a growing number of start-up firms from emerging economies are entering international markets on the basis of stronger technological assets, and are finding opportunities by being highly creative in their business models, frequently relying in resources that lie in the networks they build, rather than undertaking internationalization processes on their own (Che Senik, Scott-Ladd, Entekin, & Adham, 2011; De Clercq, Danis, & Dakhli, 2010; Huan Zou et al., 2010; Zahra, Matherne, & Carleton, 2003). Particularly in Latin America, lack of international experience, and relative unavailability of technological knowledge, has had a strong impact on the business models and in the strategies available to entrepreneurs. Learning processes for entrepreneurs who venture into international markets have therefore been intensive, for they have to explore and exploit opportunities at an accelerated pace (Keen & Wu, 2011), and with relatively less resources than their counterparts from developed economies, in order to offset their late comer disadvantages (Yadong Luo & Huaichuan Rui, 2009).

In order to successfully enter international markets, startup firms from emerging economies have to contend with more resourceful competitors, and thus need to leverage their intangible assets and capabilities, adapting quickly to new circumstances. Since they do not have the same amount of R&D infrastructure (whether internally or in their immediate economic environment), they need to leverage their intangible assets by actively seeking resources and capabilities by building networks and alliances (Huan Zou et al., 2010; Zahra et al., 2003) that enable them to rapidly detect and exploit business opportunities.

Given that usually their resources (including infrastructure, financial and human capital, for example) are much fewer than those of their counterparts from developed economies, an important issue seems to be to understand the ways in which these firms identify technology-based entrepreneurial opportunities in international markets, and the ways in which they rapidly learn what they need, including the rapid adaptation of their business models, in order to successfully compete in them.

Even though there are significant differences between new technology-based firms in advanced economies and those from emergent economies, such as the availability of venture capital, the level of the technology, and R&D infrastructure, for example, it is important to understand the differences in business model design and adaptation between the two groups, and the strategies they follow as they endeavor to enter international markets.

We present results from a case study research project that aims to understand the processes through which entrepreneurs from Latin American economies search, identify, and take advantage of technology-based business opportunities in international markets, competing against firms that have access to considerably more technological resources and capital. We use case studies and in-depth interviews from twenty technology-based firms from several industries: veterinary pharmaceutical, biotechnology, food supplements, and embedded systems, in order to develop a model of these processes. Cases were selected among firms in Western Mexico that have undertaken rapid internationalization processes without having developed first a strong domestic market base. Even though in none of these cases technological assets are at the level of leading edge or disruptive technologies that are common in more industrialized economies, they have in common the fact that their business opportunities rely primarily on technological knowledge assets, rather than in production infrastructure, capital or extensive marketing capabilities.

Method

Technology-based firms are a recent phenomenon in emerging economies. Relatively few cases are available, and there is therefore little basis on which to attempt generalizations. We present results from a multiple case study research project that aims to understand the processes through which entrepreneurs from Latin American economies search, identify, and take advantage of opportunities in international markets, competing against firms that have access to considerably more technological resources and capital. We use a grounded theory approach in order to map the ways in which entrepreneurs search for technology-based economic opportunities, and the ways in which they build and adapt their business models in order to compete internationally.

We use case studies and in-depth interviews from nine technology-based firms from several industries: veterinary pharmaceutical, biotechnology, food supplements, and embedded systems, in order to develop a model of the technological knowledge space in which entrepreneurs search for opportunities, the rules they use to decide upon those opportunities and the business models they use to exploit them, and upon collaboration opportunities they encounter in their environment. Cases were also selected on the basis of their variability as to their technology sources, business models and internationalization strategies, in order to highlight the similarities and differences in the ways entrepreneur detect, realize (enact) and take advantage of business opportunities in international markets. Appendix 1 presents a summary table of the cases' characteristics.

To our knowledge, there is little prior research in this area. We therefore have decided to use a grounded theory approach (Corbin & Strauss, 1990; Glaser & Strauss, 1967), in order to constructively build a model of the process for firms from emergent economies, by identifying patterns that emerge in the data from different case studies (S. K. Chetty & Hamilton, 1993; S. Chetty, 1996; Eisenhardt, 1989).

With the objective of generating relevant theory, however, we have relied on the multiple case study approach (S. K. Chetty & Hamilton, 1993; S. Chetty, 1996; Yin, 2009). Case study design has been made with the general purpose of understanding: a) the role technology has in their business strategies, as an intangible asset; b) their motivation to enter international markets; c) the criteria they use in deciding to adapt their strategies and business models, as they face international competition and resource limitations, and d) the reasons and motivations they have for networking and collaborating with other organizations. In order to achieve this, several data sources have been used in each case: on-site visits and field observation, in-depth interviews with the entrepreneurs and their key managers (when applicable), content analysis of available documents (of business plans, websites, patents, business intelligence documents, for example), when available.

Results

Knowledge of previously existing technology as an intangible asset. A very salient feature of the companies participating in this study is that they do not work with radically new or disruptive technologies, but they rather exploit opportunities derived from available knowledge and technologies.

For firms operating in industries where the presence of MNC's has been strong in the country, it is usually a secure bet to rely on expired patents in order to develop products with reasonable presence in the market. The firms selected for this study, however, were firms unwilling to participate in such domestic markets, because profit margins are too small and successful products are usually copied very soon. These firms rather invest in rapid product improvement to the point that products cannot easily be copied, and soon realize they have a product with a viable international market.

A significant source of business opportunities is further development of commercially available technologies, frequently overcoming barriers that used to be considered insurmountable by pioneer firms (usually from advanced economies). In many instances these barriers are overcome by exploring avenues that were not considered worthwhile by companies that initially developed specific products.

"As a firm we have developed products and broken long standing paradigms. Some of the substances we work with were considered to be essentially non-soluble, and we have managed to make them soluble. Our key resource is our personnel problem-solving capabilities. We have a few people who are very adept at transforming information into knowledge in order to solve problems and in order to detect new product development opportunities. If we see an opportunity, and there are many of them, we look at the literature and find things that might not be new, but

that are not being used (...) Our main tool is information and knowledge management... to find whatever we need to go on with a project, and we collaborate with high-level university laboratories that have sophisticated equipment and researchers to do the science we need."

Entrepreneurs are well aware of scientific literature and the work at university labs in their product domains. Whether they have been able to identify a business opportunity from published research, or whether they systematically use it to develop new products, they are well aware of the economic value of specialized knowledge. Company B manufactures a product derived from agave, and initially identified the opportunity from results reported by public R&D labs:

"The original idea came from being aware of basic research reported by public R&D laboratories, in neighboring states and here in Jalisco. (...) they began to report on the existence, well the existence and some interesting effects of prebiotic substances in agave. We took that idea and applied it to our industrial project, looking to commercially exploit those products (...) but we did start from academic literature and began to make our own adaptations (...) we collaborate with them, since they do all the scientific validation that stays in publications. What we aim is to add value to scientific knowledge and to generate a value chain for industry, from the producer to the end product."

Company K has come to rely on their mastery of scientific and technical literature as their main line of business. Instead of directly commercializing its products, it has become a contract manufacturer for domestic as well as foreign markets.

"We can develop nutritional supplements to order. Our clients commercialize our products under their own brands, and request from us products with specific properties, in order to attend to needs they have identified in the market. We are able to use scientific and technical literature to develop tailor-made products, according to their specifications."

Whether working on the basis of expired patents, or directly from the scientific and technological literature, firms need to do in-house R&D. They usually resort to grants and funding from public economic development organizations. Although some of them have access to private capital, it is not venture or angel capital. Since they are not firms that already have a strong domestic market base, they operate on tight schedules and under pressure from funding agencies or private sources to deliver milestones and become profitable in the short run.

"The main problem I have had to deal with as an entrepreneur? ... to deal with our investors and get them to be patient, and maintain their confidence in our project."

"We will wait for public funding of our R&D project. We will try to advance on our own resources, but there's no way we can come up with that level of funding for the project."

Even though firms in our study do not yet have a strong domestic market base, they make extensive use of global networks and knowledge pipelines. They are able to do this mostly because of their background in multinational corporations, because of their business experience abroad, or because of having obtained graduate degrees in prestigious universities in other countries. They are able to leverage their technological assets by using their networking capabilities, both locally and abroad.

"We interact continually with researchers in other places, in other countries; we rely on communication technologies in order to maintain our contacts in other countries, and to collaborate with them. That is of the utmost importance."

Drive and strategy for internationalization. Since the sources of opportunities are technology based, and not built around traditional product or process knowledge, there is frequently no significant domestic market available, or its institutions and competition rules are not mature enough to make them worthwhile.

"We are not as interested in the domestic market as we are in the international one. Our challenge is to compete with multinational corporations. We are able to develop better products, by improving on what is available, and we have a cost advantage over them. We are not a significant threat for them, for our sales are less than one percent of theirs. They make their decisions globally, not locally. Locally we face copycats; they will copy our formulations, our products, even our labels. Sometimes they might even have stronger marketing capabilities, but we have the know-how."

"There is no significant domestic market for our product. Consumers are reluctant to change their purchasing behavior, so we have decided to better address foreign markets, where consumers are more educated as to the (health) benefits of our product, and willing to pay for it; foreign markets are much more lucrative."

“I have come to learn that organic products are heavily demanded in the world, and we have tried to learn more about it, getting information from different sources, and we have confirmed that there is no strong demand for organic fertilizers in the country, since there is little faith in organic products, so then, what we are doing is to export our product to Canada, and we are in the process of getting ready to do it, since over there they have a lot more faith in organic products, even knowing that in Mexico there will be a much stronger demand for them in one or two decades...”

Due to entry barriers being similar (because of domestic markets are being liberalized, but at the same time homologation with international regulations is taking place), or even harder to overcome, in many cases entrepreneurs prefer foreign markets, because they are more lucrative.

“We found that, in order to enter successfully in the domestic food ingredient market, we would need production and logistic capabilities far superior, by orders of magnitude, to what we have at this stage. The major market in this area is monopolistic, so their purchasing power enables them to require from their suppliers conditions that are far above those that we can deliver, so we have decided to address niche international markets, which are much more profitable.”

Entry barriers are not necessarily easier to overcome in international markets, but their attractiveness makes it worthwhile to invest time and resources in order to overcome them:

“Through our collaboration with (university institute) we began to find out that our product would be very well accepted in Europe and in the United States, if we can scientifically prove its value, which we can, but we have to wait for scientific validation of the product’s properties (...) we have partnered with a university in France and with the National Nutrition Institute, since we need that scientific publications validate the health properties of our product, because this is required by regulations in those markets (...) but we want our products to gain international recognition...”

Rather than limitations in the availability of technological knowledge, marketing capabilities tend to be the major constraints in the realization of knowledge-based entrepreneurial projects, which is only natural, given the fact that these firms do not have a strong domestic market base to use as a springboard into international markets. Since they also have little knowledge about foreign markets, they are forced to quickly change and adapt their business models in order to make their enterprises viable. Entrepreneurs quickly adapt their strategies accordingly.

“As I learned that the major domestic market for (my product) is monopolistic in the country, I also realized that, even though I can deliver a product of a much higher grade and quality, I could not possibly deliver the product in the quantities, places and financing conditions that customers demand, so I had to turn to other less profitable markets, such as animal feed producers. I decided I would do this in order to finance our growth into foreign markets.”

“We quickly found out that our product could not be nearly useful if sold on its own, since it needs to be used as part of a technological package that includes many other organic producing practices. So we learned to partner with organic produce firms, and share risks with them. Now that has become one of our major credibility sources. (...) But we found out that the product can easily be used by organic producers abroad, so exporting it has become an easy task.”

For firm C, who commercializes its product in bulk, mastering the technological aspects of its business has not been a big an issue as mastering the business aspects, and it has had to change its business model several times:

“I found out that I could easily control the technical aspects of production, being able to manufacture (the product) to specifications beyond any of my competitors (...) but I found no significant domestic market for such a product, so I began to attend fairs and exhibitions, and soon found foreign customers (...) I know they package and label (my product) under their own brand, and that they take away most of the profit, but I cannot do it. I wouldn’t know how to do it, since I do not know their market, their regulations, and so on.”

Company S started out doing contract manufacturing for domestic and multinational firms, but soon found out that it could help them to find needed technologies from local and foreign sources, so it started to change its business model in order to become a hub that connects demand and supply of innovations and technology in the veterinary pharmaceutical industry. As of this writing, it is also going into clinical research services for both foreign and domestic companies, with the aid of international partners.

It is not infrequent that opportunities are found only under the tutelage of business support organizations, that provide business and market intelligence to the entrepreneurs, and who work extensively with them in order to grow and strengthen their business networks.

Collaboration and networking

As in firms from advanced economies, the firms' limited resources are leveraged by networking and outsourcing, both locally and internationally. This is particularly true when research infrastructure is an essential tool.

As opposed to traditional firms, the possibility of forming joint venturing and partnering is not out of the question, when it is seen as convenient in order to achieve their business goals:

"In order to enter the shelf products for human consumption market, I must learn about foreign regulations on the matter, so we have turned for help to public and private organizations that help us in this matter. (...) We decided that Europe was the more attractive market for our product, so we are setting up a joint venture with European partners, in order to develop products appropriate to that market, and in order to learn about applicable regulations."

"Since we are a small company, we are not able to export on our own and have success in foreign market, so we have formed an exports consortium with firms in a situation much similar to ours (...) we like to say that here in the domestic market we are rivals and competitors, but in foreign markets we are partners."

"In order to grow our international operations we have understood that we need local (foreign) partners. They have helped us tremendously with their knowledge of local markets, frequently becoming also investors in our business."

Product development is one of the main issues in collaborating with foreign firms, and not necessarily on the receiving end:

"So we met these people from Canada and found that they were looking to develop a gel formulation of the product, and indeed we could help them with it, at a much lower cost than it would mean for them to develop it over there."

Leveraging technological capabilities through networking, partnerships and alliances is a given for those firms included in this study, as a radical departure from the typical behavior of traditional firms, where owner/founders are very oriented towards secrecy an isolation, and more akin to what happens with high technology new ventures from advanced economies:

"We still have a lot to do in new product development (...) in biotechnology (...) in bioremediation, and in other areas, because we have people who are well prepared to do so (...) there are people in the networks in which we work so that we can innovate in almost any product. Look, here in the network in which we operate there are more than a hundred people that are doing research or working to obtain their graduate degrees by developing vaccines, or biotechnology products, or new pharmaceutical products... What we do directly is very little, because we are few, but our connections with high-level researchers are extensive."

"(...) We know the best technical personnel in the country in the veterinary field, and in the R&D environments, we could say (...) we have developed the skill to connect with a group of high-level researchers, both at the national level and globally; that is what the Internet is useful for now, and what we want is to take advantage of all the resources that this makes available, right?"

These firms do not passively absorb knowledge from their partner institutions. Company B is well aware of this. The entrepreneur is very conscious about the flows of knowledge in the network, and about the roles different actors play in it:

"In terms of research protocols, our dealings with the National Nutrition Institute to bring, not to our firm, but to an institution in (our state), in this case university X, the ability to determine the presence of probiotic microorganisms. We worked as a liaison between laboratories, and now the laboratory in the state already has that capability (...) we are about to do the same with all of the protocols in development. That is to say, what we are looking for is applicable results for our product, but the research institutions we work with finally retain the knowledge, and that is fine with us."

In enacting the realization of the business opportunities they detect, entrepreneurs design their business models, and then change them in order to adapt them to newly discovered constraints and opportunities, and in order to ensure their firm's survival and growth. Opportunities are frequently discovered along the way, with many promising avenues turning out to be unsuccessful, and many good opportunities discovered and enacted. In this search, however, it is previously available knowledge itself the founding stone for the search for new knowledge. This is consistent with the much cited work of Cohen and Levinthal (Cohen & Levinthal, 1990).

The fact that many of the firms participating in the study are able to identify opportunities by being aware of the scientific and technical literature underscores Shane's assertion (Shane, 2000) that the identification of an opportunity is dependent on the entrepreneur's prior knowledge is clearly borne out in the cases studied. Many of our interviewees explicitly acknowledge the fact that it is their previous background in MNC's and their post graduate studies that have enabled them to recognize and evaluate business opportunities.

However, in the cases studied we notice a significant difference in the general pattern that opportunity discovery and enactment shows, as compared to the usual pattern that can be discerned in technology-based firms from advanced economies. In this last group, the development of leading edge and disruptive technologies is at the heart of the entrepreneurial process. Once it is at hand, the entrepreneur and his associates immediately look to global markets as a means to recoup the investments made, and those about to be made in order to ready the product or service for distribution and consumption. This process is exacerbated because time to market is of the essence, in order to maintain the first mover advantage, and because technology life cycles tend to shorten with time. This leads the entrepreneurial team to invest massively in order to shorten the time to market.

On the other hand, for the firms we have studied the option to enter international markets may not be the only one at inception. In some cases, this option appears and improves in its attractiveness as different obstacles and alternatives lead the entrepreneur to consider entry into foreign markets. In those cases where international markets are the main option from the start, resources are limited, and usually dedicated to develop technological and production capabilities, at the expense of marketing capabilities.

In the task of further developing existing technologies firms from emerging economies indeed have a cost advantage, and relatively easy access to sources of knowledge and technology, as long as they are willing to partner and network extensively. This availability of knowledge determines to a large extent the possibility of improving on existing technologies and products, by exploring avenues that world technology leaders may have left unexplored.

Conclusion

Our results provide an important step in understanding the ways in which technology firms from emerging economies leverage knowledge as an asset in order to enter and compete in international markets.

In sharp difference to technology-based firms from advanced economies, those firms participating in our study work more on the basis of knowledge availability than on the basis of large resources for knowledge generation. Whereas the time to market imperative drives up the cost of knowledge generation in developed economies, in order to forestall competition, firms in emerging economies must adapt their technology development to the availability of financial resources. They seem to follow rather an imperative of discovering profitable markets that are accessible on the basis of their limited marketing capabilities.

Internationalization processes in technology based firms from emergent economies are likely not the result of the sudden realization of opportunities, or the result of rational strategic decision making at the outset, but rather the result of a complex process of "muddling-through", where opportunities are gradually discovered, lines of action initiated and abandoned, resulting in emergent strategies and highly adaptive business models, rather than the result of a deliberate objective defined at the outset.

In using the multiple case study method, we have attempted to research and portray the interaction among variables that shape decisions made by entrepreneurs as they seek to identify, enact, and exploit opportunities, with the aim to understand causal relationships that may explain the how and why they are made. Knowledge is an intangible asset, and therefore very difficult to dissect in order to understand its origins and the ways it is used when attempting to devise strategies and internationalization efforts. We have thus attempted to map the relationships among

distinct variables, in order, at this stage, to understand their causation interactions, rather than developing far-reaching generalizations. Since we find important differences in the ways these interactions occur for emerging economy firms, as opposed to those reported in the literature so far, we expect to be able to contribute to this field as it continues to develop and track the behavior and development of these firms.

Next generation Manufacturing: the Mediterranean Fab Lab case study.

Abstract

The main purpose of the paper is to outline a new entrepreneurial horizon targeted by the raising of a new way of manufacturing that could be defined as hi-tech handicraft. Currently, the business studies have gathered up the empirical application of technology advances in the way to estimate the effect produced by the networking and crowdsourcing on to production process. The paper focuses on the growing importance of digital manufacturing and fabrication laboratory network. The proposed research model is a case study approach, looking at the Mediterranean Fab Lab of Cava de' Tirreni (SA).

Introduction

It's now common the opinion that market and industry as well are changing. From the early 2000 years, we attended to the rise up of ideas and start-up movements; ICT was the only industry that challenged the economic downturn with strength. In fact, United Nation Conference on Trade and Development [63] shows a growing ICT global spending from 2005 to 2011; in 2011 the amount was 1.2 billion dollars. Simultaneously, researcher and entrepreneurs have tried to identify a new way to foster entrepreneurship and value creation. Emerging technologies and the evolution of social behaviors generated a shift in the production model. Innovation has become a fundamental driver of competitive advantages and the aim of small businesses' strategy. An alternative model took its birth, based on networking and open innovation dynamics [16]. The way to develop this model is to catch ideas from the outside [65], starting a co-creation process, based on crowdsourcing [30, 34] and open source resource, is even better. Co-creation implies the involvement of customers, in particular end-users, in the design and development of new goods and services, a competitive imperative [56, 65] because of they are source of information, competence, whose experience and needs could participate to value creation [55, 56, 64, 66, 67]. Therefore, if customers become to be perceived as co-producers in the information era they could be considered part of the collective intelligence [43, 37, 38, 39] that actively participate to the creation of innovation and to the social innovation movement, intended as a collective creative process shared by a plurality of actors [29; 41]. According to the Schumpeter's position [58] of the individual as a source of innovation, who naturally research solution to the problems throughout new ideas creation [5]. Clearly, it draws a line to the crowdsourcing that could be defined as a participative activity, expressly on line, in which the involved actors, via a flexible open call, participate voluntarily to a process sharing their knowledge and skills, in order to obtain and utilize the advantage produced from what they participated on (Estéllés-Arolas & González-Ladrón-de-Guevara, 2012) more easily defined by Howe [30] as a web based business pattern which make best use of the individuals on internet.

Literature review

Many authors [14, 32, 46, 28,7, 18] agree on the idea that all across the years technology has been considered a tool; moreover, technology is the result of R&D activities, which are made possible thanks to the knowledge production. Knowledge is cumulative, the main resource that could produces new flows of knowledge itself and new technology. In other terms, to produce new knowledge, we need a production factor that is knowledge itself that turn technology into an evolving tool [18]. This dynamic phenomenon is the origin of innovation. Knowledge is a very important impact factor; the reason why innovation is not only an enterprise's benefit, but a positive outcome widespread through the community. This is usually defined as spill over: knowledge oversteps the bound of organization hitting, voluntarily or not, all the members of the community [59].

Clearly, knowledge and innovation needs an ideal habitat to grow, where stakeholders' co-evolutive capabilities could be expressed in order to score the target of systemic innovation and opportunity creation [53]. Networking is the key. In fact, relationship networks are the place where knowledge based resources are traded [27]. Social capital [8] is the essential cultural infrastructure to create relationship and knowledge to trade. If we take the distance to the specific

topic of this paper, looking at the industrial district and technology cluster, we could notice that they are the right places where to co-evolution process usually takes its birth. In fact, district and cluster, describe a local frame almost integrated into which assets and know-how are easily exchanged, for example, from enterprise to enterprise [35].

Proximity is a necessary condition to foster co-evolution; Boschma [9] identified five different types of proximity: cognitive, organizational, social, institutional, geographic. The main shared peculiarity of all these shape of proximity is the easiness to realize interactive learning. Cognitive proximity can be realized when several individuals share the same basis of knowledge and technology competencies; organizational proximity is defined by hierarchical mechanism that leads relationship from the inside; social proximity refers to relationship and social connection need to trade one another; institutional proximity buds from shared rules, laws, regulation, habits, mores; finally, geographical proximity depends on the distance between stakeholders [53]. But what would happen if we tried to integrate both cognitive and social proximity? Maybe we could find a new place where to innovate. Both cognitive and social proximity [9] represent the base to create a trade of knowledge and competencies; on one hand, cognitive proximity entails the share of the same knowledge and technology basis between the actors of the network; on the other hand, social proximity entails the share of relationship and trust. It means that in that kind of perimeter is easy to maximize the one another learning and takeover process.

It seems that Fabrication Laboratory (Fab Lab) , so-called “*labs for fabrication*” [25, pg. 12], represents a model that mashes up the types of proximity described above. Being born out of Massachusetts Institute of Technology’s (MIT) Medialab in the year 2003, today they’re a real international network. By now the operation is well known, Fab Lab is a laboratory where people, thanks to hi-tech tools and machine, can create, manipulate and process different kind of material in order to “produce their own ideas”, supported by a team of technicians. Some talks about quick prototyping, some talks about democracy of manufacture [46, 25, 7, 26, 44, 48, 6, 18, 15, 45, 52], but what gives force to Fab Lab development is the widespread adoption of internet and the rapid diffusion of the new innovative expression of the “internet of things” [4, 42] side by side with the economic crisis and the cultural movement of makers¹.

Fab Labs seems to make true and transform into materials fictional ideas, thanks to digital culture, digital data and “*magic machine*” (Walter-Hermann & Bueching, 2013, p.10). Personal desktop turned into personal fabricator. Formerly, fab labs were intended as places and spaces where making (almost) everything [25] was possible, today we should change this point of view because, actually, they make technology and knowledge accessible to almost anybody, empowering people.

Fathoming the literature, we could try to draw a *trait d’union* with the theories of co-production and co-creation. Both concepts are defined often, but they’re important to comprehend the fab lab mechanism. To express what co-production/co-creation usually means, is the first step to have a snapshot of fab lab. Literature use both the words as synonymous, but Voorberg *et al.* [67], referring to social innovation, tried to identify a unique definition of the above quoted concepts. Voorberg and his colleagues analyzed their data collection, even if they found a common base in the collaborative creation of value, they underline three types of co-creation/co-production policies. In service oriented organizations, the participants, treated like partners are: co-implementers; co-designer; co-initiators. Thus, co-creation and co-production are strongly related. Their conclusion are really near to the concept that, looking both at companies and industry, actors/stakeholders work together in a value-creating system [47]. The idea of a “*reconfiguration of roles and relationship among this constellation of actors in order to mobilize the creation of value in new forms and new players*” [47, pg. 66] fits really good to the structure behind the fab labs. It redefines the logic of value creation and it goes beyond, embracing the traditional production logic. The complexity of the network into which fab labs are integrated, agreed with the state that value occurs in complex constellations.

The peculiarity of openness [16] and stakeholders integration in the value chain - now value constellation - of fab labs, are justified by the latest concept of crowdsourcing [31, 10, 34, 68, 69, 19, 20, 33, 11]. In order to understand this connections, we don’t have to intend crowdsourcing as a subset of outsourcing, but it’s a process, a call to participate, an open source development [22]. As wrote in the introduction, crowdsourcing evidently identifies a wide group of activities that, summarizing, are oriented to create value thanks to the voluntary participation of individuals to the value creation, supplying ventures with their knowledge, ideas, competences, in order to use the added value they’ve contributed to create, mainly through the web an internet [30, 31, 33, 19, 22]. Sometimes, the concept of crowdsourcing is strongly linked with the open source one. Brabham [10] criticizes the connection between crowdsourcing and open source. The last one is mainly referred to the software, and defines ways to allow the access

to the essential elements of a product. There are limits mostly related to the reward for contributors. Crowdsourcing overcomes this limits procuring an *“hybrid model that blends the transparent and democratizing elements of open source into a feasible model for doing profitable business, all facilitated through the web”* [10, pg. 82].

This point of view agrees with the findings about the adoption of idea generation throughout the broadcastings of problem information [40]: to overstep the firm bound accessing to the outsiders’ knowledge allows to include different perspectives and improve the effective solution rates.

This considerations could be extended to the generic manufacture industry or to the process of production: community is undeniable source of innovation that yield ideas’ success. It was already studied by Chesbrough and explained in “OPEN” [16], the author found the reason why open a business model is fair in the possibility to access to new resources, outside the bound of firms, to be up to create/acquire value in terms of innovation. Models create value taking advantage of the idea variety that exist beyond the gate of an enterprise.

In this context, fab labs are able to create space, both physical and virtual, where is possible to trade skills and capabilities, to re-conceptualize the framework into which producers and consumers interact; are part of a network where knowledge goes open. Usually, fab labs are strongly connected to the definition of a laboratory equipped with tools that allow people to make up their own “objects” (some talks about personal fabrication) supported by a pool of technician [46]. Micelli in his piece on Nòva24 [45] tried to go over this reducing definition, talking about a new way to call the production process in the strict sense into question, ready to set up the next industrial revolution. Anyway it’s currently difficult to hypothesize that fab labs could represent the end of automation process. More plausible is to believe that it’s the leading step for a change, maybe not so extreme as Cowen [17] suppose, but it is proved that the infrastructure of the network, created starting from the MIT, is the fuel for a new productive paradigm internet-powered, crowd-accelerated and crowd-designed to lead the birth of a new generation of innovation [23].

The core of this change seems to lie under the concept of presumption, literally a *portmanteau* of the two word of production and consumption, that synthesize the transformation of the consumers’ role [36]. The concept of presumption emerged from Toffler reflections [62] about Industrial and Post-Industrial Age: production and consumption have been separated during what he calls “the second wave”, better known as Industrial Revolution. Prosumption belongs to the first wave (agricultural revolution) and to the third wave (information age) because of the recognized dominant institution². According to Toffler, prosumption revives because of the demarketization and demassification process. This means a challenge for marketers to overcome a frustrating future. Kotler [36] argues that, even if Toffler’s studies on prosumption are not systematic and based on a miscellaneous of statistics anecdotes, his point of view is quite right: people are going to play a large role in designing or producing goods they want to consume. He uses to define them “homemakers” and finds the reason why they behave so in their joy to compose, as results by the observation of daily life. Moreover, Kotler seems to make a step beyond the Toffler’s consideration trying to return the marketers’ point of view. Producing for use makes people prosumers; instead, production for exchange splits production from consumption; then marketer should treat prosumers like a new market segment, helping them to meet their need to produce. It’s possible because market is a human invention and networks are changing their face.

To be true, Toffler didn’t consider the dominant role of key enabling technologies like internet whom gave the massive involvement of consumers in the “creation” of products [57].

In the latest years, we attended to the birth of a new definition of prosumers: the “makers”. Makers are the base of an independent capitalism (Nussbaum, 2011), localized and focused on social wealth, whom take advantages from the knowledge shared through networks and community. The makers create value through the application of process coming from the do-it-yourself culture, extracting it from the “community factor”. Using the digital fabrication [46, 25, 49, 44, 48, 18, 50, Walter-Hermann & Bueching, 2013, 45, 52], makers become hi-tech artisans able to create and prototype new products [46, 25, 44, 48, 45] Their habitat is represented by fab labs, where they could meet each other and share their own ideas. In conclusion, the whole review seems to draft a new manufacturing process that, based on small contributors in large number, draft a long tail model [3, 51, 52].

Methodology

The focus of this paper lies under the target to identify new way of knowledge transfers and networking process which introduce models that foster self production and entrepreneurship, especially centered on hi-tech handicraft and small enterprises creation. The lack of certain and various data, the peculiar newness of the analyzed phenomenon on the Italian

context, the explorative nature of the research, push the authors to choose a case study approach (Yin, 2009). Eisenhardt [21] explains that one or more cases are useful to develop theories about some specific topics. Because of the current framework, it could be useful to follow an inductive development of the theory that aim to recognize and describe the existence of a phenomenon [61]. Through a conceptual exercise and a conceptual question [60] “How open source tools, crowdsourcing and international fab lab network could affect on the italian small business tissue?”, authors start a case-based research, whom empirical evidence are collected by observation of participants (Burgess, 2002), studying a single case [21].

In the way to strengthen this assumption, looking at a single case takes the start for the attempt to research a meaning and give a sense to the observed phenomenon, in a local and contextual perspective [24, 12].

After the analysis of the prior state of theory and a literature review, that can be read above, and a recognition of the current digital fabrication approach in Italy, a case is investigated.

The Mediterranean Fab Lab, one of the international network bore in Boston’s MIT, located in Cava De’ Tirreni (SA), in the south of Italy, will be briefly illustrated in the following paragraph.

FabLabs: digital fabrication laboratories.

According with fabfoundation.org, Fab Lab is an extension of MIT’s Center for Bits and Atoms (CBA), a Boston housing project, that researches in digital fabrication and computation. A technical platform for innovation and invention, created to foster local entrepreneurship throughout the connection of technologist, researchers, innovators, educators, learners and makers, building a global network, into which knowledge is freely traded. It’s not easy to imagine a factory, flexible and customized, in a living room [49]. All along the years, the ideas of digital and personal fabrication were spread, even thanks to the Fab Chart that is the fab labs’ manifesto, and fab lab became effectively an international network. Nowadays there are about 333 fab labs in the world, whereof 214 in Europe and 33 in Italy (Fabfoundation.org, 2014). The idea of creating almost everything and the open access to knowledge and technology is well chased. In Ghana, an eight year old girl made a working circuit board; in Norway, a 14 year old boy crafted a robot car. The introduction of fab labs in South Africa helped to empower both individuals and rural communities. In that case it emerged that the access to the fab labs’ resources was, effectively, dependent on the possession of a school level by the users, indicating a limit of the statement: everybody can make almost everything. Anyway, the solution to this problem seems to lie under the implementation of educational program and workshop that spread the culture of making. In fact, it’s been envisaged a program to deploy “fab schools”. Another Norwegian experience was interesting too: established in strong connection with the MIT Fab Lab and the innovation cluster in Tromsø, the MIT FabLab Norway developed a project called “Electric Shepard” in the Slovik Farm, previously started by researchers from the University of Tromsø, Telenor Research and Development and Slovik farm itself. The project uses telecom equipment to track sheeps in the mountains and overcomes the problems caused by weather, morphology and difficult of communication. The establishment of Fab Lab in that country, near to the University and the above quoted Cluster, confirm the triple helix condition and opened a wide range of opportunity for companies, entrepreneurs and Academia.

More interesting is the Barcelona Institute for Advanced Architecture of Catalonia (IAAC) Fab Lab experience, where fab lab entered the infrastructural shift of the city toward the smart city philosophy. In Barcelona, fab lab started as usual to share content, knowledge and processes online, influencing the production process; then, it shared an educational program; nowadays they’re conceptualizing the fab city, contributing to educate the smart citizens. Barcelona Fab Lab has created a network in the network, that is a set of neighborhood fab labs, representing, today, the hinges of the civic structure.

In Italy, the making culture was launched by Massimo Banzi, founder of Arduino and Officine Arduino, the first Italian makerspace established in Turin - that was born in 2012 - where he fosters the creation of innovative business models and products/services, using a bottom-up approach. In about three years this movement grew up in a stunning way, and today we can count about 43 laboratories that embrace the fab lab approach, even if some of them are not yet.

In the south of Italy, the first one was the Mediterranean FabLab, located in Cava de’ Tirreni, Salerno, the case observed and studied in this paper.

Nowadays fab labs enlarged their field of action, moving from the research to the entrepreneurship, from biology to medicine, from food to agriculture, from architecture to robotics.

Case study: Mediterranean FabLab

“Think. Make. Share.”

As you can read in the previous paragraph, Mediterranean FabLab was the first of its kind in the South of Italy and the headquarter is in Cava de’ Tirreni. The idea to embrace both the makers movement and the fabrication laboratory approach was born after the maturation of the overseas experiences by Amleto Picerno Ceraso, the founder, and his partners. Since the year 2012, Mediterranean FabLab operates within the wider Mediterranean Academy of Architecture (medaarch)³, looking at a four dimensional world: small businesses, institution, university and “community”. The least common denominator between these four dimension is “contamination”, between knowledge, individuals, innovation and technology.

To be clear, the idea of a fab lab was born in 2009 after a study and work experience, conducted by the founder, at the IAAC’s FabLab. There, the Mediterranean FabLab’s founder got the importance of digital culture, makers movement, research and innovation to start a shift from the economic and production *status quo* towards the third industrial revolution, which basis lie under the mash up of knowledge transfer, co-working, digital fabrication and learning by doing.

The startup of Mediterranean Fab Lab, was characterized by educational and instructive programs in order to spread the making and DIY⁴ culture. It was definitely a bet, in fact they found difficult to assert their presence on the territory. Through these five years they grew up, purchasing facilities and spaces that granted them the qualification of fab lab. Since 2012 it is part of the MIT’s FabLab International Network, with:

- 3d printer;
- Vinyl Cutter;
- 3-axis milling;
- Polystyrene cutter;
- Milling;
- Arduino TinkerKit – School;
- 3d printer (extrusion of plastic material).

That puts the Mediterranean FabLab as an hub for creative process of digital fabrication, through participative innovation and co-ideation.

Getting over this observation, that don’t notice great differences with other fab labs, the breakthrough is the management team composition. While fab labs are usually populated by technicians, the observed one shows a multi-disciplinary and varied team made by architects, engineers, technology transfer and startup advisors, business and economics experts, marketing experts. Evidently, this is an advantage and represent the possibility to lead better the principal drivers of the activities lowered on the four dimension environment portrayed before.

The activity drivers, fundamentally, are: early and rapid prototyping, education, research and innovation, smart cities solution, mentorship and advisory.

Each dimension is bordered by the other and the drivers are pervading across them.

Small Businesses

In order to promote innovation and the constitution of competitive advantage for companies they work with, Mediterranean FabLab established educative paths and workshop directed to reduce the existing gap between enterprises and research.

During this action, the FabLab team, first evaluate the facilities owned by the company; second, they make an analysis of the production process, thus of the products and services; then, they elaborates a path *ad hoc*. In this way they are able to update the industrial process adopted by the company, educate workers and entrepreneurs towards a new way to perceive needs and think products, ease the adoption of innovation.

The FabLab team act to foster new solution of value creation through business model innovation [2] and product innovation. Thus, small business become lean and reactive to the market changes. Two are the leading examples, two different collaboration that turned into solid partnership.

In order to mix design, architecture, recycling, smart strategies and green economy, Mediterranean FabLab collaborated with Cartotecnica CRTS to re-think the use of corrugated paper. There was born a new furniture line,

modular and sectional. From that point they create a new shape that recall biologic structure and follow parametric modeling to re-configure the final form.

The second example, is the relationship that was born with Tekla, leader in the doors and windows industry. FabLab and Tekla worked together for the creation of smart surfaces and responsive object for the interior design, using digital fabrication techniques. Then, they recoup the CRTS parametric model to build a pavilion, in etalbond⁵ - with parametric modeling techniques and exploiting machineries already owned by Tekla - exposed at the last Rome Maker Fair. The pervading trait of the activity driver was expressed, first, by the involvement, in the educational paths, of people off the Tekla bound. Second, by launching a contest called “Don’t dream it, make it” that offers to designers and makers the opportunity to measure their capabilities across the creation of new products in corrugated paper.

This way to behave represent the capacity of the FabLab to link small businesses to community and vice versa, pushing businesses to open up their model and creating new opportunity for individuals. It means that to open up a business model entail that small businesses launch outwards their bounds a call for innovative solution, gathered by the FabLab. Thus, Mediterranean FabLab, make a match with enterprises and makers’ community, thanks to the education path structure.

Creators start to test their ideas and small businesses, first, open their model, then, unbundle their process accessing to external skills via outsourcing paths.

Institution

Performing research in the smart city field, following IAAC’s model, FabLab started a collaboration with the Municipality of Cava de’ Tirreni (SA) to adopt smart and green solution for the city organization.

Part of this collaboration, considered the possibility of re-convert abandoned industrial area to create open spaces and open labs. On the other hand, in order to foster self-employment and reassess traditional handicraft in an innovative way, FabLab and PA started an incubation project addressed to craftsmanship and whoever wanted to participate to the third industrial revolution and digital fabrication, encouraging the territory richness and reemergence of crafts.

Clearly, emerged the principal role of FabLab that had to open the doors to consumers, helping them to reduce the gap with the production, supplying knowledge and technology drawing from the international network and the open source resources. The bind between the dimension through the activity drivers seems to be clear.

University

With this actor, Mediterranean FabLab use to have a biunivocal relation, because Academia represent both a source of innovation and a customers who want to implement new way of knowledge transfer. In both meaning the output is the creation of opportunities. For students, they line a road towards the experimentation of their own ideas; for FabLab, to close the circle of education, to access to more facilities, to complete (or start) the mentorship and advisory activities; for University, to follow side by side the evolution of this hi-tech artisan stores and the next generation of manufactures. In fact, Mediterranean FabLab have recently activated a partnership with the Department of Business Studies and Research – Management & Information Technology (DISTRA-MIT) of the University of Studies of Salerno, to ease the technology transfer, among other things.

Community

As well as University, community represents a source and a target. As already mentioned before, fab labs ground their force on the network and its capacity to trade knowledge and skills. These knowledge and skills traded are open source for those individuals who want to start making and test their ideas. These artisan factory 2.0, making spaces, knowledge, technology and technical skills available, foster entrepreneurial intents and exploits the ideas potential. Mediterranean FabLab does the same implementing the presumption transformation, putting in contact the digital fabrication reality with a wide audience. Throughout education and workshop would spread the entrepreneurial culture: reducing the distance between project and product, via incremental innovation, using new

technologies, contribute to the economic relaunch. Moreover, community are source of revenue, because of Mediterranean FabLab is an Association with an associative fee.

This Italian based fab lab seems to show an organizational complexity, structured like a business as we know it, but highlight an evolutive approach based on the perception of local needs.

Data Collection and Analysis

In order to understand the rising phenomenon of the next generation manufacturing, the so-called new industrial revolution, we collected qualitative data and information about the above quoted case. First data were collected through the observation of the activities of the fab lab and their relationship with university and local businesses; then through many sources like articles, interviews, papers, special issues and website.

The first step was to discover the identity of this new kind of social businesses. Subsequently we investigate the network, its story, what kind of proximity is important and how proximity is significant. After that, technology and knowledge production and transfer were observed.

The first problem was embodied by the heterogeneity of activities and their aim. Fab Labs are integrated in an international network, but operate local with global information; the end users are various and difficult to recognize. Anyway, this problem seems to be overcome by understanding the evolution of the studied fab lab.

The second problem was represented by the dimension of knowledge transfer and its strong connection to the dimension of the network and customer segments, which embody small businesses as well. This problem obliged authors to study the collaboration with local firms and how it's been evolved into partnership.

The third problem is represented by the difficulty to relate startup business creation to social outcomes: inventing something, the self-employment and the pursuit of entrepreneurial intents are not enough.

Conclusion

By the observation and analysis of the Mediterranean FabLab, emerged a design based on the long tail model [3, 51]. Mediterranean FabLab, approaching to the market, sells small quantities of products and services to a large number of niche markets. The reason why FabLab adopt this business model is the diffusion of three economic triggers [3]: the democratization of tools of production; the democratization of distribution, thanks to Internet; the costs to connect supply and demand are reducing. Moreover, FabLab is part of the international Network of MIT FabLab, so knowledge and technology skills are freely traded and crowdsource.

These condition transform the Mediterranean FabLab business model in a hybrid model, joining the open business model design [15, 51] that we can call open long tail model. Almost everybody can make almost everything, everywhere.

Summarizing, the analysis outline a business model able to satisfy the needs expressed by many different users, designers and makers, in order to make them possible to create their own products; throughout the open long tail business model [3, 51, 52] Mediterranean FabLab contributes to the success of prosumption [62, 36]. Once again, the model satisfies open innovation [15] instances by connecting ideas and innovative project to people who own the knowledge to realize them.

With Abell's matrix [1], using the data and information collected, we could identify the strategic business areas of the Mediterranean FabLab. The Abell's matrix in Fig.1 highlights a wide volume of business, but even two missing link. In fact, because of both the dimension of the lab and the facilities owned, the Mediterranean FabLab seems to haven't already reached the segment of medium business. Locally, medium businesses, are just a few and operates in the agri-food industry, if FabLab would implement a research directed, for example, to the packaging innovation or the agricultural innovation, it will enlarge their strategic business area. It's undisputed that FabLab should improve its partnership with University in order to take advantage of academic knowledge and technologies.

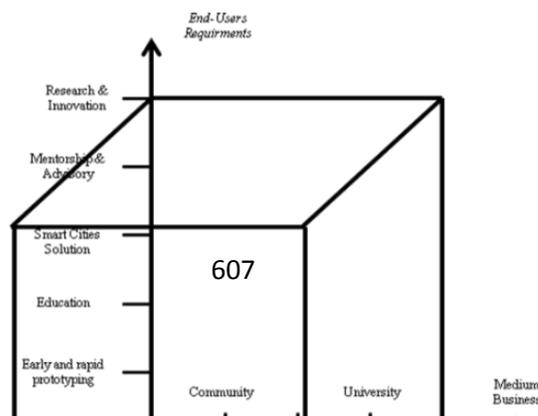

FIG. 1

Taking a step back to the observation of the model, we have to make two more considerations. FabLab, today, has a strong connection with the territory and the small businesses localized on it, through the bridging of community and businesses it fosters both the knowledge transfer and products innovation. It is possible thanks to the integration of individuals project in the enterprise throughout the education activities it conducts. The results are, first, a push to open up its partners' business model – it is even plausible that a further consequence is to adopt an unbundled business model [51], outsourcing the innovation research - that could test the advantage of an open strategic view at lowered cost; second, the creation of new business opportunity for “makers”.

The second consideration is linked to the concept of the fab lab itself: by making available spaces, facilities and collective intelligence to consumers, it spreads the making and entrepreneurial education, that is recently considered a priority target restart economy, as proved by both the last special issue of Journal of Small Business and Management, and the ICSB World Entrepreneurship Conference in Dublin.

To make it possible, proximity is the key. As we wrote before, both cognitive and social proximity [9] represent the base to create a trade of knowledge and competencies needed to create almost everything by almost everybody. Anyway, the whole model can't disregard the geographical proximity. In one hand, geographical proximity allow to clearly highlights the current social needs to satisfy and, evidently, to identify the hubs to connect each other and to integrate in the network. In fact, involving craftsmen and institutions is a way to realize the well known statement “*Think Global, Act Local*”.

This framework underline a bottom-up process that aim to transform the manufacturing into a new generation that mixes creativity, technological opportunity, innovation, making culture and territory richness. Maybe this is not the only scenario that could be considered, in fact the activity of Mediterranean FabLab highlights an interest to recoup of old manufactures that, throughout the access to collective intelligence and new technologies, could innovate both their production process and business model.

Although, the discussion seems to lead to the idea that digital culture and democratization of production represent the fuel for new venture creation and startup acceleration, focused on product and devices which benefits affects the whole society.

The collaboration with institution to implement smart cities solution and the incubation of hi-tech handicraft start-up, instead, are source of social innovation that is, by definition, as a collective creative process shared by a plurality of actors, which positive effects hits the entire society [41].

It's unveiled a question: what would it be of traditional production? The next generation are fascinating for sure, and could fill the gap existing in the market today, but the shoulder are not large enough to cause old industrial concept distress. A collaboration is more fair and probable.

Unfortunately, this case study research present some limits. The data and information weren't enough to perceive quantitatively a wider context. Open source and crowdsourcing model of Mediterranean FabLab should be tested in a more extensive manner. The test should comprehends both businesses and customers. Research, thus, have to turn from a qualitative view to a quantitative one, or both. If social benefits are conceptually identified, there's a lack of quantitative data; moreover, the observed benefits should be compared with the costs.

This is a future research target, as well as the idea to measure the customer satisfaction and the business competitive indexes.

Innovation as competitiveness factor in Guadalajara's SMEs manufacturing Industry

Abstract

The purpose of this research is to get to know the importance that innovation has in the competitiveness of the SME in Guadalajara. The method used for this job is the usage of structural equations to correlate innovation and competitiveness. In this way we are able to find out how important is innovation in the Guadalajara's SMEs. With the support of this method we found out what are the most significant factors, also which ones are most likely to be used for the SMEs sector in order to have better competitiveness.

Introduction

Innovation is nowadays considered by the SMEs as a strategy of making having a better job done by every single companies department. This is not only for company survival but is also seen as a way to strengthen the company's foundations, (Castellanos, 2003).

Companies understand that this new marketing dynamic where the companies have to completely understand what the customer wants; also it has to have the capability of adapting to their customer needs (Lafuente & Bassa, 2011). Thus is achieved by adapting to new business processes, developing and revamping their products in short continuously evolving and meeting the expectations from their customers. There are precedents where companies had work hand to hand with their providers to develop innovation projects that as a result left better techniques of developing products and services. (Nordberg, Campbell & Verbeke, 2003).

Innovation and competitiveness

The research of this factors competitiveness and innovation is not something new; they have been studied since the 1960's. Authors like Porter determined that the competitiveness of a nation was determined by the capability of innovate and improve (Aguada, Navarro & Meza, 2013).

One of the first authors that began talking about innovation was Schumpeter cited by (García, Serrano & Blasco, 2005) developed the theory of innovation as the means to explain the economic development and analyzing the technology change. He basically found the difference between invention and innovation. Invention is the creation of new things and innovation being the application of the invention of new products or processes of production and its application on commercial uses.

In 1991 the OCDE considered that the technologic innovation was only for the companies in the manufacturing sector and that it was focused only on products and technical processes. Later in 2005 the OCDE widen the concept of innovation to the service industries because that economic activity gives higher economic output and better profits in those industries.

Innovation does not only limit to the radical changes in the products it also has expanded to different company areas. Many authors agree that the term innovation takes in changes in productivity methods, supply, distribution and workforce capabilities (CE, 2003), as well as services and consumer satisfaction (Valls Pasola, Guitart. & Núñez 2007), making a change in the methodology and technology; a useful deviation on how things were done before (Bateman & Snell, 2009).

Therefore innovation can be considered as a necessary ingredient to have a better competitive advantage (Darroch & McNaughton, 2002); due to innovation (Damanpour & Gopalakrishnan, 2001), cited by Naranjo, Jiménez & Sanz, 2012 generated competitive advantages in for the enterprises. Enterprises become more flexible and are able to adapt faster to any given changes. Also they are able to exploit opportunities better than their competitors, thus getting positive effects for the enterprises making them more profitable (Prajogo, 2006; Berson, Oreg & Dvir, 2008), cited by Prajogo, (2006).

Then the technology factor along with the ability of innovation are a source of a great competitive advantage (Galende & Suárez, 1999). Nowadays companies that want to generate and acquire the latest technological advancements to better their productivity and have a higher competitiveness rate.

If the companies want to keep being competitive have to get more technological capabilities and introduce innovation in processes and products that allow them to raise the productivity and their distinction from their competitors (García, Serrano & Blasco, 2005).

Additionally when competitiveness is given by free market conditions in a given country it could produce goods and services that can exceed international standards; as well it allows maintaining the growth of the local GDP (OCDE, 2010.)

Some of the indicators that measure competitiveness are performance. Performance shows the results of different companies obtained by the competitive process and its competitive potential. Sales and exports show the growth of the participation on the market as well as profitability and some others, (Pérez & Velásquez, 2013.)

Then, that companies innovation have a great development for them and generates benefits in the sector that is being developed. It generates competitiveness between companies of the same kind generating a chain of knowledge and improvement for the companies in the same sector.

Research Method

For the analysis of the data of this research we used the method of differential equations which allows giving the type and direction of relations contained in the analysis so we can estimate the parameters specified by the relationships in a theoretical level. Structural equations are confirmatory models due to the fundamental interest is to confirm thru the analysis of the sample of the relations given by the explicatory theory that is chosen to use as a reference (Ruiz & San Martin, 2010).

Sample

In order to analyze the variables of innovation and competitiveness we applied 409 well-structured surveys to the object of study which in this case were the SME sector of Guadalajara.

Results

The method that was used is estimation ML-robust which throws very robust statistical data that allow us to verify that the theoretical model is correct which includes the scaling correction χ^2 Santorra-Bentler and corrects the possible errors according to the normality. What was mentioned before it is possible because the data comes out from surveys that contain Likert scale, which can present problems of normal distribution due to the variables which are not continuous (Alvarado, Sadín, Valdez, González & Rivera, 2012.)

After that, the model was adjusted considering as a guide the set of non-normal fit index, (Brown, 2006.) Which are NFI, NNFI and CFI, the values for those have to be between 0.80 and 0.89 and they represent a reasonable fit, (Segars & Grover, 1993.) On the following Chart 1, show that all the values go over what it's acceptable getting an NFI of .862 and NNFI of 0.845 finally a CFI of 0.861. With this data, it's corroborating that the model is acceptable. On the other hand Jöreskog y Sörbom (1986,) state that the value of RMSEA has to be under 0.80 to be acceptable but in this case the RMSEA value is 0.60 which indicates that the model is correct.

Related to the factorial loads Bagozzi and Yi, (1988,) they state that the factorial loads have to be above 0.60, and in the table 1 shown that all the factorial loads of this particular model are above this value.

The value for the reliability index IFC and the index of extracted variable IEV they should be above 0.70 and 0.5 respectively, Fornell and Larcker (1981), which is easily achieved in the theoretical model.

All the indexes and values previously mentioned achieve the previously established by the theoretical, which allows us to state that the theoretical model is correct for application of structural equations is shown by the table below.

TABLE 1: INTERNAL CONSISTENCY AND CONVERGENT VALIDITY OF THE THEORETICAL MODEL

Variable	Indicator	Factor Loading	Robust t-value	Cronbach's Alpha	CRI	VEI
Implementacion of changes	AIC1	0.644***	1.000*	0.872	0.872	0.51

* = Parameter constrained to this value in the identification process

*** = p < 0.001

The table 2 shows the validity of the theoretical model by values like IEV and it is shown diagonally from left to right and top to bottom, those values were previously mentioned, which has to have values above 0.50. Above the diagonal IEV we have the variance and then underneath the IEV we have the confidence coefficient, which we can appreciate an interval of 90% of confidence. Also we can see that none of the individual latent factors from the correlation matrix has the value of 1.0 which indicates the inferior and superior limits (Anderson & Gerbing, 1988).

TABLE 2: DISCRIMINANT VALIDITY OF THE MEASUREMENT OF THE THEORETICAL MODEL

Variables	Implementacion of changes	Barriers to innovation	Financial Performance	Costs Reduction	Technology Use
Implementacion of changes	0.51	-0.089	0.231	0.214	0.472

Barriers to innovation	-0.181 , 0.003	0.501	-0.051	0.063	-0.105

The Chart 3 indicates the result of the hypothesis from this investigation for this particular case we achieved 3 different hypothesis.

H1: The standardized coefficient is 0.531, with this data we can show that when they are changes done in companies it generates more innovation.

H2: The standardized coefficient is 0.616 were the effects of having fewer barriers of innovations it's conducive to generate more innovation

H3: The standardized coefficient is 0.420 this means that innovation affects in a positive manner competitiveness.

TABLE 3: SEM RESULTS OF THE THEORETICAL MODEL

Hypothesis	Structural relationship	Standardized coefficient	Robust t-value	Measure of FIT
H1: To a higher implementacion of changes, a higher innovation	Implementacion of changes → Innovation	0.531***	12.968	$S-BX^2_{(491)}=1206.3072$ p = 0.000
H2: To a lower barriers to innovation, a higher innovation.	Barriers to Innovation → Innovation	0.616***	17.125	NFI = 0.866 NNFI=0.845
H3: To a higher innovation, a higher competitiveness	Innovation → Competitiveness	0.420***	13.098	CFI = 0.864 RMSEA = 0.060

Source: Own elaboration

*** = p < 0.001

The conclusion that the 3 hypothesis have significant values for the theoretical model. Hypothesis number 2 we obtained a standardized coefficient of 0.616 which indicates that the factor of fewer barriers of innovation helps companies to be more innovative and this weight more in the investigation. When the standardized coefficient was 0.420 indicates that innovation affects the competitiveness of manufacturing companies, even thought it was the lowest standard it does not necessarily mean that it is something negative it just allow us to make a differentiating point between all the hypothesis.

Conclusions

Upon checking all the literature with this work we can conclude that innovation is all those gradual or radical changes in their products, means of production and commerce. And these changes can be applied in any type of industry, next it allows industries to be in a better competitive position. Mexico is one of the countries that is far behind in competitiveness technology.

There are many different concepts for competitiveness and also many indicators that measure whether a company, industry or country is competitive. But there is no universal fully accepted indicator by all authors. The most respected indicators can be determined by international institutions like WEF, in the reports that are published on a yearly basis Mexico has not performed not that well just being in the middle spots.

Thanks to the analysis of the statistical data of the SMEs in the manufacturing sector of Guadalajara, we can conclude that innovation does affect the competitiveness of the manufacturing sector in a positive

manner. The mentioned before shows a very competitive and positive correlation in the statistical analysis due that its factors are quite representative. It also shows that when there were any representative changes on implementation of changes inside of a company it generated many improvements in different areas of the companies. Then the barriers of innovation on the SMEs for the manufacturing sector of Guadalajara are very high that is why it is difficult for companies to innovate it is really hard to get financing and there is also innovation resistance inside of companies

At the end the manufacturing sector of Guadalajara is showing some level of innovation development and this allows us to get a diagnostic of market competitiveness. It allows us to see the strength and weaknesses of the manufacturing sector, once these are fixed and revamped it will allow the manufacturing sector to pay more attention to other deficiencies.

Regional Context and Academic Spin-offs: Effective or Critic Cooperation?

Abstract

Several studies have point out the importance of the infrastructural support offered by business incubators to stimulate high-tech entrepreneurship, like academic spin-offs (ASO). Other studies connect the effectiveness of this entrepreneurial action with local characteristics and proximity between incubators, universities and ASO. The paper goals are to investigate the role played by the geographical proximity of business incubators and to analyze the characteristics of the socio-economic context that influence the development of ASO. Using a sample of 405 ASO and 162 incubators we show that the presence of incubators in the geographical area of ASO alone is not enough for them to reach better performance. This aspect is well-improved by participation of financial institutions in the business incubators, which increase the financial stability of ASO. Furthermore, the results indicates that the local context features have a positive effect on the ASO performance, underlings the role played by regional settings.

1. Introduction

During the last two decades literature have shown a growing interest in the promotion of stakeholders capable of acting as facilitators in the process leading to the creation of innovative firms, as well as in their roles as privileged intermediaries in building relationships and exchanging networks between start-ups and more mature firms (Cesaroni and Gambardella, 1999; Colombo and Delmastro, 2002; Link and Scott, 2007). Though the features and functions of these intermediaries are well known, any research (Jaffe1989; Colombo and Delmastro, 2002; Squicciarini, 2009) exploring the effectiveness of stakeholders have taken different perspectives thus preventing the development of a systemic view on the phenomenon. Some scholars (Phan et al., 2005) identify several research lines on the subject depending on the level of analysis chosen, ranging from the performance of incubated firms (Ferguson and Olofsson, 2004) to the facilitators' services (Rothaermel and Thursby, 2005; Bigliardi et al., 2006), from the impact on the territory (Scilitoe and Chakrabarti, 2010; Lindelöf and Löfsten, 2003) to the competences of incubated entrepreneurs (Almus and Nerlinger, 1999).

However, there is little research which focuses on the impact stakeholders have on academic spin-offs (Olofsson and Wahlbin, 1993), a specific type of new technology venture (NTV) involving stakeholders and resources of both public and private nature and which are given the ambitious function of promoting local development by national research policies. The combination of academic spin-offs (ASO) and business facilitators should highlight the impact on innovation and economic growth both on the affected territory and the firms related to those entities. However, the trend of development, in literature, is not yet clear, that is if it depends primarily on the presence of facilitators – which are intended to support the rise and the development of local enterprises – and by the presence of performing and innovative firms in the local area or if it could be socio-economic factors of the territory to affect the growth of companies located therein and to enhance the business activity of the aforementioned facilitators. The regional economy may benefit from the growth of NTV (Pattorn and Kenney, 2010) but also may contribute to the knowledge transfer between producers and users of technology and so to the generation of specialized cluster. Therefore, the territory emerges as the best level of analysis for a systemic view of the phenomenon, for it takes all the socio-economic stakeholders into consideration. In this respect, research aims at analyzing the relationship between the development of the context and the performance of ASO located in it, in order to understand whether the former acts as a promoter or a receiver of growth. Specifically, among the characteristics of context, the role played by business facilitators regarding the performance of ASO will also be considered. To this purpose, our research is based on a sample of 405 Italian ASO surveyed by Netval and university websites, and of 162 incubators, broadly understood, recorded on the 31st of December 2013 and located in 18 regions, in relation to which some ISTAT territorial indicators have been extracted, according to important characteristics of the local productive and innovative system.

2. The role of business facilitators

Among business facilitators, literature conventionally enumerates technology and science parks and innovation poles (O'Shea et al. 2005; Link and Scott 2007; Wright et al., 2007), where incubators are identified (Mian, 1996) as entities specifically devoted to the creation of new businesses and their support in several forms. Businesses are also supported, above all in the relations and exchanges between socio-economic operators in a specific area, by technology districts, that often evolve or merge into innovation poles thus making their identification difficult. Generally, literature identifies four categories of incubators (Mian, 1996; Grimaldi and Grandi, 2005): university incubators and innovation poles, sometimes seen as regional incubators (von Zedtwitz, 2003; Hackett and Dilts, 2004), with a public nature and a non-profit focus; independent, private incubators and private business incubators, both profit-oriented. The distinction between these categories can be observed especially in the type of services offered to new firms, in the nature of their revenues and in the strategies employed by their management teams (Grimaldi and Grandi, 2005). The services usually provided concern the following elements: access to supply, capital and goods markets; support in administrative activities related to the start-up phase; formation of human capital; access to relationship networks with stakeholders critical to business processes (Hansen et al., 2000; von Zedtwitz and Grimaldi, 2006). The main advantage that literature assigns to those entities is given by cost and time reductions to start up a new venture and the added value of transferred competences, outcomes that will favor an increased survival rate of NTVs on the market and their faster growth. However, there are few confirmations of the effectiveness of this business action, especially in the long time (Ferguson and Olofsson, 2004; Squicciarini, 2009), where the effectiveness is to be understood in terms of creating performing firms that are capable of giving their contribution to the socio-economic development of the area where they operate. About the incubators, many studies estimate their effectiveness in relation to the survival and development rates of incubated NTVs; yet, some researches demonstrate that even the advantages gained against other non-incubated start-ups seem to disappear as time passes when they leave the incubator (Ferguson and Olofsson, 2004). Whereas other studies show inconsistent results on an incubator's ability to create firms that can survive on the market for a longer period (Schwartz, 2013), and underline that the characteristic of contexts are important to explain this result. Similarly, some studies demonstrate that the survival of incubated start-ups does not necessarily imply their development (Oloffson and Wahlbin, 1993), thus inviting to choose other measures to evaluate the effectiveness of incubators in their territory (Bigliardi et al., 2006). Other researches on the subject investigate the characteristics of successful incubators (MacMillan et al., 1987; Bellini and Piccaluga, 2000; von Zedtwitz and Grimaldi, 2006; Grandi and Grimaldi, 2005) and technology and science parks (Link and Scott, 2007; Wessner, 2009), by connecting them to the features of management teams, the strategies employed, the goals pursued and the resources owned. Different studies correlate the performance of incubators to the growth in employment and development at local level (Aerts et al., 2007), the investments in R&D (Siegel et al., 2003), the new ventures created (Ratinho and Henriques, 2010). In this case, the territory is chosen as an observational unity to study the effectiveness of incubators, although it is worthwhile noting that the success of incubated NTVs should be fully appreciated even outside the contexts where they are located, especially if they are able to build relations on the international level. Yet, few studies analyze the impact of incubators in converging countries or not developed economies (Marques et al., 2006; Sofouli and Vonortas, 2007). Further studies investigate the effectiveness of incubators from a comparative point of view, by comparing the performances of incubated firms to those of non-incubated ones that are in their geographical proximity (Westhead and Storey, 1994; Squicciarini, 2009). Performance measure is understood in several ways and carried out considering the following parameters: the ability of NTVs to create innovation, as resulting from the patenting activity (Squicciarini, 2009); the development of NTVs, measured by the added value and the growth rate of investments (Salvador, 2011) or by employment and profit margin rates (Lindelöf and Löfsten, 2003; Aerts et al., 2007) or by the growth rate of sales, ROA and ROE (Bigliardi et al., 2006); the ability of NTVs to reach management effectiveness of various types according to the services provided by incubators (McAdam and McAdam, 2008); the ability of NTVs to improve their positions on supply markets, as measured by their creditworthiness and trading capacity (Colombo et al., 2002). From a NTV perspective, the effectiveness of incubators is related to the specific features of NTVs, in particular to their ability to absorb the knowledge transferred by incubators through the exploitation of the patents

owned by the latter (Rothaermel and Thursby, 2005), as well as to the age of firms and the field they belong to (Monck et al., 1988).

To evaluate the effectiveness of their actions, it is important – especially in the case of public or mixed incubators – to highlight their ability to contribute to the development of a robust and innovative business background, in order to assess the suitability of public investments in this direction. Specifically, the current literature does not allow to clearly establish whether development begins from the actions undertaken by incubators toward the creation of performing firms that promote the socio-economic growth of the territory where these operators act or where the survival and growth of firms is fuelled by the characteristics of the territory (Ratinho and Henriques, 2010). Thus, it can be speculated that the development of NTVs is not geographically neutral: the geographical proximity to incubators may positively influence the performance of NTVs (Hp1).

A further issue to be considered is the different nature of the subjects involved in incubators that can have an influence on the several directions of development. While the presence of universities can increase the chances of transferring innovative knowledge into contexts with slow technological development (Colombo et al., 2010; Muscio, 2010), the participation of financial institutes and venture capitalists could improve the creditworthiness of NTVs, as well as the proximity to other mature firms, which could promote an easier access to the end markets. Based on these considerations, and focusing exclusively on the critical role that financial dimension plays, above all for the NTVs represented by academic spin-offs (ASO), it can be postulated that the presence of financial stakeholders, in the shareholding structures of incubators, allows to incubated firms to reach better financial structures (Hp2).

3. The role of territorial context in the development of university spin-offs

Academic spin-offs (ASO) play a significant role in the development of a region as they contribute to technological dissemination and, consequently, identify value-creating networks (Sternberg, 2014). The knowledge arising from a spin-off can be conveyed both locally (within the same region where the reference university is located) and long distance (Boschma, 2005). The regional context of a company start-up greatly affects start-up success. Indeed, its importance is higher than being granted any government funding (Sternberg, 2014). Actually, government funding granted to innovative companies does not necessarily ensure achieving better results. A few empirical studies (Saxenian, 1994; Wagner and Sternberg, 2005; Fritsch and Mueller, 2007) show that “the regional setting can affect individual entrepreneurial behavior”, in as much as Sternberg and Roch (2007) state that, within the same country, regional contexts can be so different from one another that significant differences also arise in the relevant entrepreneurial activities. On these grounds, several authors agree with the following assumption made by (Feldman, 2001; Sternberg, 2014): “entrepreneurship is mainly a regional occurrence”. In this regard, there is ample evidence in literature (Carlton, 1983; Bartik, 1985; Fritsch, 1997; Reynolds et al. 1994; Audretsch and Fritsch, 1994) linking new company start-up activities to specific regional characteristics and traits (Audretsch and Lehmann, 2005). There are various general environmental factors (Looy, Debackere and Andries, 2003) that allow setting off innovative start-ups, which successfully develop in a given region, such as: 1) a critical mass of specific skills and research; 2) a close connection between public higher-education institutions, learning and technological output (Blind and Grupp, 1999); 3) an enhanced “entrepreneurial” direction in research centers – including universities – which more positively affects the development of a region with a view to its innovation performance (Porter, 1995); 4) the presence of developed financial markets, especially venture capitalist and business angel ones (Looy, Debackere and Andries, 2003). Furthermore, a study on biotechnological industry in the US performed by Deeds et al. (1997) shows that the “geographical concentration” of businesses in the same sector does not only lead to competitive challenge but also greater cooperation among businesses (Stuart, 1998; Looy, Debackere and Andries, 2003). However, given the importance of both local and global business activities for new high-tech companies, an internationalization strategy is only effective if the local/regional settings offer enough opportunities to create a critical mass of both technologically- and market-oriented skills (Debackere, 1998, 2000).

In order to consider a given region as a true activator of highly performing businesses (Hp3), based on GNP, employment, competitiveness, it is necessary to remove all the restraining factors, especially, as Lehrer (2000) put it: on a national level, the absence of developed capital markets; on a regional level, evident lack of the facilities and

instruments required to create and support high-tech networks; on an individual level, a risk-averse ambience and lack of entrepreneurship, supported by a public university education system which does not stimulate entrepreneurship (Looy, Debackere and Andries, 2003). It must be noted that the presence of universities in the territory may be decisive in shaping the social and economic development of a region (Pazos et al, 2012). Several authors (Slaughter and Leslie, 1997; Shane, 2004) point out that various “entrepreneurial universities” are actively committed towards the growth of their region through the commercialization of research, spin-offs of new enterprises as well as cooperation with economic development bodies (Youtie and Shapira, 2008). Luger and Goldstein (1997) also suggested that universities may have a multidimensional impact on the relevant regional economies through research and creation of knowledge, education and training of human resources, dissemination of know-how to improve the existing industry, technological innovation for commercialization, spin-off technology, infrastructure development, information flow improvement and leadership in order to deal with regional issues, the creation of a favorable regional setting. As a consequence, the role of university in certain contexts (Youtie and Shapira, 2008) developed from common research and education functions in order to become a knowledge hub by promoting innovation. University operates as a “knowledge hub” when seeking to spur endogenous development, new abilities and innovation, especially within the relevant region (Shapira and Youtie, 2004; Newlands, 2003). Furthermore, literature (Nelson, 1959; Arrow, 1962; Fujita and Thisse, 1996; Fischer and Varga, 2003) has long recognized that knowledge-based and technology-intensive enterprises draw advantages from their location close to a university site, thanks to the knowledge spill-over created by basic research and the creation of human capital (Audretsch and Lehman, 2005; Bathelt, Kogler and Munro, 2010).

4. Research method

Sample and data collection

In order to validate the above-mentioned research assumptions, the level of analysis selected for the research is, thus, the regional area, which they are lead back the two observatories actors: business incubators and academic spin-offs (ASO). For the ASO, primary data were extracted from NETVAL database (www.netval.it) and universities websites as of 31 December 2013; from the 747 companies identified were excluded inactive spin-offs (34), those being liquidated and cancelled (193) and those for which no financial statements comparable data were available (115). Thus, we assed a sample of 405 active Italian companies, equal to 54.21% of the population identified, divided into geographical macro-area clusters (North - Central - South) and relevant administrative region. Secondary data collection was performed on the grounds of several sources and essentially consisted in the assessment of financial statements and historical corporate files (Infocamere, AidaBvdep). Second, information concerning development indexes of the regional economic context were collected by drawing the data from the records contained in the Italian National Institute of Statistics (ISTAT). Finally, additional information regarding 167 national business incubators were gathered from institutionally websites of universities, of MIUR (Ministry of Education, University and Research), of the regional authorities and business incubators.

Variable definition and measurement

The empirical study of the features of the local socio-economic context affecting academic spin-offs as well as the modes and strength of certain intermediate entities facilitating spin-out processes, together with the economic impact whereby spin-off enterprises affect their reference context, was performed through Pearson’s multivariate analysis by means of two variable sets. As far as the former set is concerned, variables were structured as macro level analysis and aim at measuring the degree of socio-economic development and entrepreneurial support mechanism on a regional level. The first set of these variables – defined as context variables – consists in a set of indicators divided into four basic groups, drawn from the ISTAT database, measuring company competitiveness degree in the local context, corporate demographics, the various aspects concerning capital markets and corporate finance and, finally, industrial innovation and research dynamism. As far as the first set is concerned, it includes three variables, namely, capital accumulation intensity (%Acc_capital) as a percentage of gross fixed investment out of GDP percentage, company service development capacity (%Busserv) as a percentage of work units in the company service sector out of total AWUs of retail services and, finally, industrial added value (Ind_VA) which expressed production and distribution capital gain at chained industry prices in million Euros. Corporate demographics was measured via two variables –

the former expressing the gross registration rate in the Company Register (%Buss_gross_enrol) and the latter expressing the net registration rate in the Company Register (%Buss_net_enrol). The third set (Capital markets and corporate finance) is expressed via a variable measuring funding risk (%Financrisk) as funding decay percentage. Three variables are further used to determine the scientific research and innovation level attained by the region being considered: as found in Di Gregorio and Shane (2003), O’Shea et al. (2005), Powers and McDougall (2005) and Pazos et al. (2012), the first is measured by the company R&D spending rate (%Buss_R&D) expressed as GDP percentage of R&D expenditures (both public and private); the second is determined by innovation skills (%Innovation_resexp), expressed as GDP percentage of intramural expenditures borne by public administration, Universities and public and private entities for R&D activities, whereas the third is measured via company R&D personnel rate (N_R&DStaff). In accordance with Vinig and Van Rijsbergen, (2010), Pazos et al. (2012), Fini et al. (2011) and O’Shea, et al. (2005), the above-mentioned variables are supplemented with data concerning the infrastructural support given to local entrepreneurial setting, expressed via the number of corporate incubators operating in each region. The said information is encoded in a set of four variables expressing the incubation rate according to the nature and features of the entity providing incubator services: “%Incub_gen” (general incubators), “%Incub_mixpublic” (mixed-public nature), “%Incub_fin” (presence of financial institutions), “%Incub_uni”, (presence of universities). As far as the latter set of variables is concerned, variables are structured on a microanalysis level (data drawn from the approved financial statements as of 2013) and are used to measure the economic-financial performance achieved by ASO, by means of the mean return on equity (Mean_ROE) as well as the mean current liquidity ratio (Mean_ILC).

5. Results

5.1. Incubators in Italy

The empirical analysis shows the presence of 162 incubators on the national territory, though they are not representative of the whole population of activated incubators since it is difficult to identify the private ones. From the observed sample, frequency distributions on the regional level (Table 1) appears to be homogeneous for those entities over the national area, even though a slightly higher prevalence can be observed in the northern regions. Most of these incubators are the result of public intervention, particularly by local authorities and regional development agencies; that indicates a prevalence of their non-profit character. In both the northern and southern areas, the role of universities in start-up and managerial activities of incubators is significant; this leads to consider universities as a preferential tool for technology transfer from public research to the market. On the other hand, there is a less prominent participation in the share capital of incubators by financial institutions, primarily represented by banks, especially in the regions of the South. The predominantly public nature of those entities and their non-profit character may act as a deterrent to the attraction of financial partners, especially in the social and economic areas that are experiencing phases of stagnation.

TABLE 6: INCUBATORS

Geographic distribution	No. Incubators	% incub_gen	% Incub_mixpub	% Incub_fin	% Incub_uni
Center	45	27.78%	77.78%	24.44%	62.22%

Sicilia	5	3.09%	60.00%	20.00%	100.00%
Tot.	162	100.00%	84.57%	22.22%	73.46%

5.2. Academic spin-offs in Italy

Descriptive statistics for the sample analyzed, divided into two spatial levels investigated – the geographical macro-area and region - are shown in Table 2 and Table 3.

Table 2 show frequency distributions (both in absolute and relative terms) of active spin-offs together with their graphic representations. It can be observed that most of the spin-offs (43%) are located in the North with a major presence in Lombardy, while the 34% of ASOs are located in Central Italy, with a largest presence in Emilia Romagna. The South of Italy includes the 23% of the national active spin-offs, which are mainly concentrated in Puglia.

TABLE 2: FREQUENCY DISTRIBUTIONS OF SPIN-OFFS BY GEOGRAPHIC AREA

Geographic distribution	Absolute frequencies	Relative frequencies
Center	137	33.83%
Emilia Romagna	48	11.85%
Lazio	14	3.46%
Marche	26	6.42%
Toscana	35	8.64%
Umbria	14	3.46%
North	176	43.46%
Friuli Venezia Giulia	37	9.14%
Liguria	13	3.21%
Lombardia	56	13.83%
Piemonte	39	9.63%
Trentino Alto-Adige	3	0.74%
Veneto	28	6.91%
South	92	22.72%
Abruzzo	9	2.22%
Basilicata	1	0.25%
Calabria	9	2.22%
Campania	14	3.46%
Puglia	37	9.14%
Sardegna	17	4.20%
Sicilia	5	1.23%
Tot.	405	

Table 3 show, on the other hand, distribution of spin-offs based on age criteria that highlights as most of the spin-offs are aged less than 10 years and, especially in the North and in the South there is a prevalence of active units that are aged less than 5 years (97 in the North and 58 in the South, respectively). The young age of the investigated spin-offs (only 7 companies have more than 15 years of age), indicates that in Italy the spin-offs phenomenon is very recent.

TABLE 3: SPIN-OFFS AGE BY GEOGRAPHIC AREA

Geographical area\ seniority	1-5 ages	6-10 ages	11-15 ages	> 15 ages	Tot.

5.3. Incubators and academic spin-offs performance

The correlation analysis (Tab. 4) between the nature of the incubator and the spin-off performance measured on the rate of return on equity (Mean ROE) shows positive and significant correlations when banks are present in the group (0, 33). On the other hand, a negative correlation (-0.24) can be noticed when incubators of a public or mixed nature or where university is a partner are involved (-0.32). Given that most of Italian incubators are of this type, this evidence raises concern on the actors' ability to positively contribute to the corporate performance. Indeed, an overall positive and significant but very low correlation (0.12) can be noticed between the ROE and the presence of several types of incubators on the regional level, thus confirming, at least in part, the positive role those actors can play on the revenue-generating performances of spin-offs (Hp1). In fact, descriptive statistics show higher levels of ROE (12.10%) in northern regions, where the presence of incubators is noticeably larger, too. However, the negative result of ROE for spin-offs located in southern regions is ambivalent as the presence of incubators in those regions is considerable. This leads to an in-depth analysis of the social and economic aspects of the local context. Similarly, it is interesting to study the correlation between the characteristics of the incubators and the financial position of the ASO considered

TABLE 4: CORRELATION ROE AND ILC VS INCUBATORS

	Mean ILC	Mean ROE
Mean ILC	1	--
Mean ROE	--	1
% Incub_gen	0.205708905	0.120200969
% incub_mixpublic	0.13597866	-0.35939615
% Incub_fin	0.578005557	0.334020376
% Incub_uni	0.055525397	-0.32261528

In order to confirm Hp2, a positive correlation (0.57) between the participation of banks in the share capital of incubators and the current liquidity ratio (Mean ILC) of ASOs associated to the incubator has been found. This would confirm the positive contribution offered by these actors to the financial stability of ASOs. A positive yet very low correlation (0.13), has been observed in the presence of public and mixed incubators and university incubators (0.06). The result should be further investigated in the future by gathering information relating to the public funding obtained by national and international research programs, in order to evaluate the role played by universities in resource attraction. On the whole, as regards the financial situation, a positive though very low correlation (0.20) can also be noticed between the current liquidity ratio and the presence of several types of incubators at the regional level, although again public-university incubators or regional incubators do not seem to promote the financial performances of the incubated firms included in the sample. Unlike the ROE, the best levels of current ratio on a regional basis are observed in central areas (3.63) where, nevertheless, the presence of banks is not higher than in the other areas (24.4%). Once again, this result needs to be associated to the peculiarities of the context.

5.4. Regional context and academic spin-offs performance

In order to investigate how determinants related to the local environment affect the performance of academic spin-offs, and therefore validate the Hp3, we use regression analysis between variables expressing the corporate financial performance (ROE and ILC) and variables expressing the characteristics of the regional context (see section 4 for details).

The correlation analysis between the aggregate values assumed by return on equity (ROE) of academic spin-offs at the regional level and context variables (Tab. 5) shows a positive and significant correlations between the ROE and industrial value added (0.50), as well as with R&D personnel rate (0, 49), emphasizing the role played by innovative processes and industrial surplus that are generated in the local context to stimulate the ASO activities. Positive correlations, although less stronger, are found also between the ROE and the capital accumulation intensity (0.29), as well as with the company R&D spending rate (0.29) Vice versa, negative correlations are found between ROE and the gross registration rate in the National Companies Register (although decreasing, going from -0.59 in 2011 to -0.24 in 2012); the same account for the net registration rate in the National Companies Register (-0.48). There is also a negative correlation between ROE and the funding risk (-0.30), a symptom of an unhealthy entrepreneurial context that has a negative impact on business performance.

TABLE 5: CORRELATION ROE AND ILC VS LOCAL CONTEXT

	Mean ROE	Mean ILC
Mean ROE	1.00	--
Mean ILC	--	1.00
%Acc_capital	0.29	-0.48
%Busserv	0.08	0.34
Ind_VA	0.50	0.26
%Buss_gross_enrol	-0.59	0.11
%Buss_net_enrol (2011)	-0.24	0.53
%Buss_net_enrol (2012)	-0.48	0.28
%Financrisk	-0.30	-0.16

%Buss_R&D	0.29	0.19
%Innovation_resexp	0.12	0.32
N_R&DStaff	0.49	0.25

Results of the correlation analysis between the aggregate values assumed by current liquidity ratio (ILC) of ASOs at the regional level and context variables (Tab. 5), instead, show a positive and significant correlation between the ILC and the net registration rate in the National Companies Register (0.53 in 2011 and 0.28 in 2012), highlighting how the number of firms in the regional area affect ties between ASOs and the entrepreneurial context and through them performer better, but also the greatness of the ASOs market by increasing their marketability. Other positive correlation, although less significant, are found between ROE and other context variables (company service development capacity, industrial value added, company R&D spending rate, innovation skills and company R&D personnel rate) underling the same positive considerations show by the correlations analysis with ROE. Contrary, there is a negative correlation between the ILC and the capital accumulation intensity (-0.48), as well as, although not more significant, with the funding risk (-0.16), highlighting how greater financial risks in the local context inhibit business investment and affecting the academic spin-offs performance.

From the empirical evidence gathered it can be inferred that the Hp3 results to be accepted, because the correlations show reasonable evidence of how the features and determinants of the local context positively influence the spin-offs performance.

6. Conclusions

The analysis highlights that the presence of incubators, here intended in a broad sense, is not sufficient to guarantee a good economic and financial performance of incubated ASOs. For that purpose, the contribution of public incubators, that is the regional and university ones, is even less effective, although they represent most of the business facilitators activated in the context observed. First of all, it can be concluded that the geographical proximity between business facilitators and firms meaning to create innovation on the territory is not a sufficient condition to guarantee the establishment of relations capable of contributing effectively to the economic and financial outcomes of the firms involved. A better result can be observed, on the other hand, in the presence of financial institutions that participate in the share capital of the incubators, which takes on both a public and a private nature in the cases under consideration. The nature of the partners of an incubator acts, therefore, as a predictor for the effectiveness of the action performed by the stated entities; hence, it can be deduced that the choice made by a private investor, in this case by banks, to keep on investing in an incubator can be said to be is often driven by the expectations of the return on investment, here intended in a broad sense, which is related to them. However, in the context under consideration, the presence of private sponsors for incubators is not significant, especially in southern regions, where public entities are still predominant. This leads to further explore the type of services, processes and managerial structures that characterize the several categories of incubators in the future. Some of our empirical investigations focused on the role played by the features and sizes of regional contexts as crucial factors in the performance of ASOs. The results of our analyses show how these factors play a major role in allowing ASOs to reach better economic and financial performances and in explaining the differential emerging in territorial contexts. Specifically, it can be noted that in those contexts where the industrial network generates a higher surplus in terms of competitiveness (both on the level of added value and in the ability to develop business services), spin-offs show higher performances due mainly to quantitatively and qualitatively better connections found between ASOs and the industry thanks to their cooperative activities that increase the synergistic potentials so promoting the transfer of technology from universities (through spin-offs) to industry. Moreover, the connections between university and industry are underlined by the higher performances obtained by academic spin-offs located in contexts where firms invest larger resources in R&D (both in terms of expenditure and staff employed), an aspect that highlights the importance of applied research. Furthermore, this also points out how influential entrepreneurial culture is on the territory for, where a certain tendency of firms to invest in research and innovation is reported, a full development of academic spin-offs is also possible. In addition, is revealed as the degree of funding risk of a region reduces the capital accumulation by firms, also due to lower bank borrowings, impacting negatively on the financial performance of ASOs because the fewer resources for growth and development.

The results of this paper offer some cues to reflect on the implications in terms of public policy. In particular, regional governments – through national-based policies – should promote the relationships between territorial contexts, universities and academic spin-offs in those areas characterized by poor infrastructures and facilities and where key resources for the innovation and development of firms are lacking. Finally, local governments should be stimulated, by tax incentives and subsidized loans, business investment, especially those key to innovation, as it plays a key role in the full development of academic spin-offs and the socio-economic scenario.

Knowledge Management & Generational Change: the impact on local SME

Abstract

The paper wants to analyse the role and the impact of knowledge management in the development of local SME's specifically linked to the stage of business succession and generational change. In SME'S the generational transition is critic and often become a real and complex situation to overcome. The aim of the work is to understand if knowledge management can be a lever with which it is possible to support the generational transition and what are the empirical mode used in some different organizations investigated, all of them engaged in this critical stage.

The work in progress research is focused on the different actors and methods involved in the generational change. In this way different figures are investigated like entrepreneur and his/her next generation and management engaged, but otherwise the role of practical methods, guidelines, values and culture like specific forms of knowledge used in order to manage the business process.

1. Introduction

In the current business environment, knowledge is a crucial competitive factor for the firm's success. Even in the system of SMEs, with a strong work intensive approach, the value of knowledge is clear, but often it's difficult to recognize all the different components involved (Takeuchi, 2001); in this way it's easy to underestimate the real effects and lead the businesses to the crisis. But in the dynamic markets with a high rate of innovation it's essential that the entrepreneur points to the development and management of different aspects of knowledge (Spender, 1996). On the other hand, in a country like Italy - with a large presence of SMEs, internationally known for the quality of their Made in Italy (CNA, 2008) – it's necessary to work on the development and transfer of knowledge, not only as a prerequisite for the continuity of the business, but also for the growth of the national economy at all. Thus, the paper aims to identify and analyse - through an empirical approach - what are the principle tools for sharing, dissemination and use of knowledge present in SMEs, as fundamental elements for the survival and development of firms (Durst, Edvardsson, 2012), particularly in the difficult step of generational change. In fact this is a crucial moment in the firm's life because it involves the transfer from one generation to the next to a real assets of know-how and management expertise, acquired through years of experience. So regarding this particular stage of the firm, specific role could have the knowledge management like a strategic tool to overcome the generational crisis and support the enterprise in the way of development and growth.

2. Methodology

The present work was imagined and projected from the desire to deepen – in the complex process of "generational succession" of SMEs - the role of knowledge and management tools suitable for its management. Aim of this paper is to bring out and discuss the main issues faced in this particular moment of business life, between those who represent the outgoing generation and those that represent the incoming generation.

There are about 80,000 Italian entrepreneurs who each year are involved in the generational transition and 80% of them is in a particularly delicate and difficult stage to manage. According to research of INFOCAMERE (2012) only 31% of family businesses get through to the second generation and only 15% in its third generation. In Italy, 71% of employers plan business succession between 61 and 70 years old; 67% of them organizes the generational transition over 71 years. Therefore it follows an entrepreneurial people with high seniority registry. Based on these premises, the paper represent a work in progress research, organized to deepen actors and methods typical of the process of generational succession, by analyzing how role, guidelines and values end up to impact on the effectiveness of inheritance. The methodology adopted is embodied in the following phases: A first step on the desk it's finalized to the exploration of the main literature on generational succession and knowledge. A second step on the job it's directed to explain and highlight what forms of knowledge and organizational tools have been fully implemented in a

selection of SMEs in the Province of Catanzaro. Specifically, the Firms investigated was n°3, selected and become from Industrial Association of Catanzaro's district (Confindustria Catanzaro). A specific check list of semi-structured interview was used was used to collect information from the entrepreneurs involved.

3. Theoretical framework: generational transition in the family business

In recent years, the issue of inheritance or succession planning in SMEs remained constantly a specific topic in management studies. In response to a question already manifested, but in part still latent, this argument of the generational shift had over time significant encouragement from European Commission¹ to deepen in different ways and with different approaches the theme. In the following table (Table n°1) are identified a selection of contributions of particular interest to define the characteristic features of family businesses.

TABLE 1: DIFFERENT DEFINITIONS FOR FAMILY BUSINESS

Source: our elaborations by Vallone (2009)

Author	Definition
Channon (1971)	An enterprise may be said to be familiar when it is controlled by a family for at least two generations
Bork (1986)	A family business is a firm founded by a family member and who has been transferred or is in the process of being transferred to the descendants. The descendants of the founder will own and will control the company. In addition, work and participate in company activities and they stand to profit.
Churchill e Hatten (1987)	For family business means the event or the expectation that the youngest member of the family takes or take control of the company from the older generation.
Upton e Sexton (1987)	Define a business like family when they are at least two generations, and when at least two family members are employed daily in the management.
Donneley (1988)	Consider a business like family when she was closely identified with at least two generations of a family or when this bond had a mutual influence on the policies of the company and the interests and goals of the family.
Ward (1990)	Family is a firm where the management and control will be passed on to new generations of the family.
Schillaci (1990)	The family business is a business that can intimately identify with a family (or several families), for a generation or more. The influence of the family on the company is entitled from the ownership of all or part of the venture capital and exercised also through the participation of some of its members to management.
Gallo (1992)	The characteristics of the familiarity of a business are to be considered related to the permanent union between the two institutes (family and business). This link must be based on values and assumptions that members of a generation consider more correct to conduct the business and the family and strive to pass it to future generations.
Raymond (1994)	Defines the family business as a firm in which the family is able to control the succession to the Chief Executive Officer and his direction.

Astrachan e Kolenko (1994)	They write that is familiar business in which the family controls the capital, more than one family member is involved in the company and that there is the prediction of the transfer of ownership to the members of the emerging generation.
Heck e Scannell Trent (1999)	In accord with this approach, the authors stress that there must be the intention to transfer or a generational shift in managerial control. If it does not intend potential means that the company could become a Public Company or may have the intention to take professional managers.
Rouvinez e Ward (2005)	For the authors a family business is a company that is substantially affected by one or more family members. Family includes a group of people descended from a couple, their related and the couple itself. Influence of the family is basically generated by the ownership of the entire capital or in their absence, it is balanced by the influence of the governing body and management.

The different contributions submitted in the table, showed that the succession in family business became over time a particularly sensitive topic, so that all the actors involved are called to redefine roles and relations.

In fact, often, the founder of the business family tends to ignore the demands of succession planning, resulting in conflicting reports and critics with the potential successor in an unfinished sequence that puts at risk the survival of the same family firm (Kets de Vries, 1993). Following matrix (table n°2) explicit and summarizes the possible types of transition obtained, as a result of different relationships / behaviors activated between outgoing and incoming contractor in the generational change.

TABLE: TYPES OF TRANSITION

Source: our elaboration by piantone, 1990; miglietta, 2009

	Physiological Succession	Pretension Succession	Enthralling Succession	Traumatic Succession
Succession without abdication	Easy	Easy	Easy	Easy
Succession with abdication	Problematic	Problematic	Problematic	Problematic
Succession delayed or evaded	Problematic	Problematic	Easy	Problematic

The matrix demonstrates two different transactional models, the critical one, where the entrepreneur tries to escape to the succession, while the successor has a strong and immediate claim to take over; that smooth, in which the propensity of the entrepreneur to promote the transition of knowledge skills and compare it with the availability of the successor to a process of gradual involvement in the business. So, the generational shift ends with the brand themselves as a very complex process, being influenced by many variables, some attributable to the contextual features of the business (competitive environment, growth rate, the legal system, etc ...), all other company (organizational dimension, systems of roles and positions, technology, culture and values, etc ...), and others linked to the characteristics of the parties involved (owners and entrepreneur involved in the succession of generations, culture and family values, etc...), other influenced by the operating procedures adopted in practice (systems of transfer of knowledge and skills, education and training, organizational models, etc...). The process of

entrepreneurial succession can take place in conditions of presence or absence of heirs; therefore, the sequence can be effective if there are the heirs of the company, whether derived - even in the presence of heirs – when these are considered as incapable of running the company and so to manage the same transition.

The process of transition in generational change can occur in the condition of the absence or presence of the heirs that can be effective when there is an absence of heirs, when derivatives even if you are not considered suitable for the succession. In some cases there is the presence of a multiplicity of heirs and this brings forth a series of conflicts in family relationships that, in some cases, determine the assignment of the company. In other cases, even if there is the figure of the heir this may prove unsuitable to the direction of the company and therefore we resort to an external figure. When the founder out by the firm shall not his knowledge, skills and characteristics considered important for the development of the company, so the one who will replace him must have adequate knowledge to continue to run the business. Therefore, the entrepreneur \founder must have the ability, during the process of development of relations with the successor, to lead the training of specific skills for the continuation of the business, taking care not to restrict the freedom of self-determination of the future, because the opportunity to develop a personal vision to the successor enables the so-called "innovation intergenerational" (Litz and Kleysen, 2001). On the other hand, the same attitude of the successor can be conservative (attachment to the past), rebellious (rejection of the past), fluctuating (incongruity between past and present), and this situation can influence the chances of the process of succession (Miller, Steiner and Le Breton - Miller, 2003); so the same successor may have different characteristics:

- does not possess the required skills and consequently adversely affects the management of the company;
- has an adequate supply of skills but without any innovative trend, therefore the management is affected by the inability to adapt the successor;
- has a very wide knowledge management that allows it to efficiently manage the company, directing the development and growth in accordance with the opportunities offered by the competitive scenario.

Therefore, precisely with regard to the items reported in the generational succession specific role have internal relations within the family, the opportunity to increase their knowledge on the processes of the business, communication processes adopted, taken for granted, but often sources of misunderstandings and surprises are not easily circumvented. That is why, once identified actors and context, specific study concerns - the purpose of the present study - the processes that knowledge transfer can be implemented in order to support and enable a less traumatic transition of the business among the generations involved.

4. The role of Knowledge in the process of generational succession

After clarified the scope and the different elements influencing the time of succession, the planning process of generational change can be decomposed into its main phases emerging (Sharma, 2004; Miglietta, 2009). The start-up phase and / or preparation can often be supported by use of the appropriate organizational units that are responsible for preparing the succession plan and its monitoring (Carlock and Ward, 2001). The next stage regards the formation of the heir that begins after the definition of the minimum requirements needed for entry into the family business. This training is to be adjusted according to the needs related to business roles (Cabrera-Suarez, De Saà-Perez, Garcia-Almeida, 2001). The phase of the choice of successor is quite delicate, as it should prefer people who have the most appropriate skills to the management of the business. Nevertheless this phase is characterized by the propensity to choose a family relying on emotional and not on the objective one, making it more complicated the resulting process. Therefore often the presence of external consultants to the family is considered more effective in achieving organizational objectives. The complex process of generational succession ends with the transfer of company and with drawl from the scene of the founder (Fleming, 2000). The real result of the planning of generational process depends on the degree of interdependence that binds “Family, Property and Business”, conflicts that may arise in the distribution of the charges, and the relationship between predecessor and successor. Tagiuri and Davis (2004) identify the different relationships that arise from the superposition of the three systems, represent in the FIG. 1.

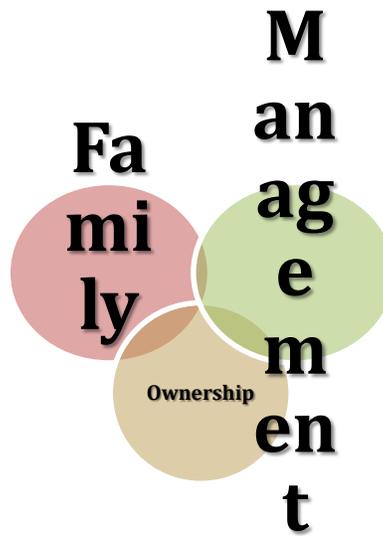

FIGURE 1: RELATIONSHIP IN TRANSITION: F - M - O
Source: our elaboration by tagiuri and davis, 2004

The interdependence between the three sub-systems, identifies how each one has its own identity and strength, as well as the objectives and rules of action, but at the same time it relates to and interface with others by contributing to the success in the transition from one generation to the next. As explained above, at the time of the transfer sequence and the support of the values rooted in the culture of the family becomes important because without the force generated by these process continuity and growth may be interrupted. Thus, recovering and schematizing phases characterizing the process of succession planning (FIG. 2), it is necessary to find the right balance between recognize and internalize the values of the past, with their appropriate reinterpretation in order to enable new applications.

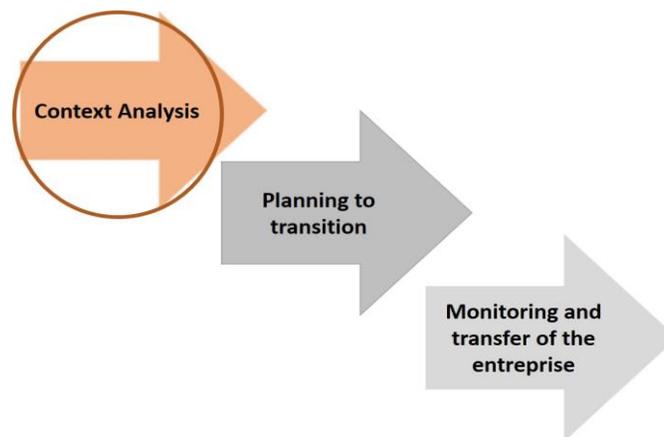

FIGURE 2: FIRST STEP “ANALYSIS OF THE BUSINESS ENVIRONMENT”
 FOR THE GENERATIONAL SUCCESSION
Source: our adaptation by gallucci and gentile, 2000

Thus, the analysis of the business environment allows to identify the environment of the family, whose focus on common heritage, will start the planning phase of succession. In fact, in family businesses the company's assets is made not only by the productive assets, from all those issues of value that can strengthen the identity of the business such as:

- Identification of the firm as Public good, to be managed with great responsibility towards all stakeholders (customers, suppliers, partners of the supply chain);
- The meritocracy that helps to make clear choices in the selection of personnel;
- Entrepreneurship that sees every generation involved in contributing to business growth.

Often, we think of the succession only in terms of contracts, capital charges, but it is difficult to think of the body of knowledge that are likely to be lost during this process. A company that is based on knowledge, acknowledging the fact the strategic importance and the value represented by the people and their knowledge, giving a key role, especially in a crucial phase as that of the generational shift. Thus, the transfer of the knowledge leads to the possibility to reduce the effects caused by the loss of expertise that may occur when the founder leaves the company (Botti, 2006). Only a few years ago, the continuity and sustainability of the enterprise is linked to the transfer of knowledge, that matter planning organizational solutions facilitating the successor in understanding the context.

Thirteen years ago McAdam and Reid (2001) wrote that Knowledge Management (KM), like other management practices, was invented and developed in large organizations to be applied later on in small and medium-sized enterprises (SMEs). From 2005 there seemed to be an increasing interest in the topic. Knowledge management became an emerging field that has commanded attention and support from the industrial community. Many organizations currently engage in knowledge management in order to leverage knowledge both within their organization and externally to their shareholders and customers. Knowledge management involves the creation of value from an organization's intangible assets (Rubenstein-Montano, Liebowitz et al., 2012). So even with reference to SMEs, over the past few years, there has been felt the need to develop a system of management skills / knowledge in the company by defining, in this way, an overall strategy capable of producing longer lasting effects than those traditionally oriented to exploitation of market opportunities (Camuffo 1996; Sbrana, 1996). This will enable businesses to increase responsible capabilities and organizational flexibility, focusing on the ability to manage the processes and tools through which knowledge can be created, disseminated and shared in the company (Hunt, 2008). The theme of knowledge has long been addressed by scholars of organizational disciplines, developing and enriching in parallel to what happened in firms with reference to business studies, enriching the implications flow from IT to Management² (De Nito and Reina, 2003). A key aspect to deal with when it comes to knowledge is related to the nature of knowledge and its size. As for the size, the knowledge must be analyzed from two aspects both ontological and epistemological. The former refers to those who create knowledge moving from the individual to the organization, it can be said that knowledge is a product of the individuals in an organization because without them it could not create knowledge (Monzani, 2005). From the epistemological point of view, however, the concept of knowledge has always been a place of comparison and interpretation within the scientific community: from the classical distinction between tacit and explicit knowledge to the leaky / steaky (Polanyi, 1966; Nonaka, 1994; Brown and Duguid, 2001). Tacit knowledge is personal, context-specific and difficult to be formalized, while explicit is coded and transmitted through a formal and systematic language. Also, while tacit knowledge is highly subjective and difficult to define, explicit on the other hand can be expressed in words and numbers and, once organized, can be distributed in the form of data, formulas and manuals. The distinction between tacit and explicit knowledge, then, is the starting point for any cataloging of the concept of knowledge and just starting from the famous distinction of Polanyi, Nonaka is a remake of this distinction in order to formulate a new model of knowledge conversion. It must also be pointed out that despite the differences between tacit and explicit knowledge, it is still two complementary dimensions because knowledge can not be decomposed into two separate entities since it is composed of a tacit and explicit by another that "can be divided sharply" (Polanyi, 1988). Compared to the further distinction, the leaky size considers knowledge as a resource to be spread within the organization and focuses on the ways in which the organization must act to encourage the creation, growth and dissemination of knowledge. The steaky size, however, identify knowledge as a resource which share must be limited and therefore bother to make sure that the knowledge is not transferred to people who may take advantage of it. Obviously, these insights refer and are interwoven with reflections on the types tacit / explicit knowledge and the potential opportunities "to identify defensive mechanisms to limit the escape" (De Nito and Reina, 2003) (see FIG. 3).

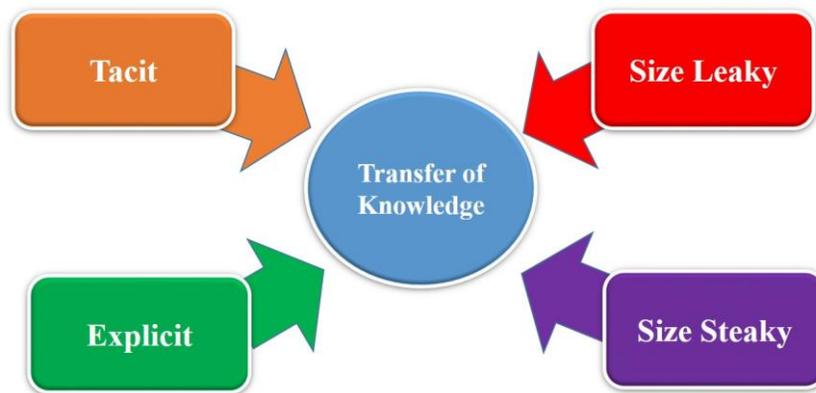

FIGURE 3: SIZE AND TYPOLOGY OF THE KNOWLEDGE
 Source: our elaboration by nonaka 1994 and polanyi 1988

KM research tended over time to focus on processes and structures within organizations, able to transform knowledge from tacit to explicit, organizational culture and learning, and technologies for knowledge storage and sharing to enhance productivity and sales, reduce cost, or increase innovation and quality (Kluge et al., 2001; Quintas, 2002; O’Dell et al., 2003; Edvardsson, 2009; Jashapara, 2011). The subject of knowledge management implementation is another KM topic relatively widely examined. The findings illustrate that the SMEs reviewed use different ways to handle the aspect of knowledge management implementation. This raises the issue of heterogeneity (Curran and Blackburn, 2001) which must be taken into consideration when researching and discussing SMEs. Furthermore, some studies imply that SMEs are involved in KM activities, especially in business succession. The passing of the baton in the succession of a family business represent in fact some peculiarities, already identified above with reference to the actors involved. The communication flows can be facilitated through communication between people who already know each other because there is a family relationship, which eventually leads to connote the relationship and closer trade relations, compared to the other obstacles already identified and related to the management of the relationship between employer and successor (Botti, 2006).

5. Empirical Analysis: Reference Context

The data at European level on Small and Medium-sized Enterprises show that 99% of companies fall into this bracket, and 9 of 10 are micro firm with a staff of fewer than 10 people. So, the European economy is based, therefore, on a group of micro companies employing an average of 2 or 3 people. The passing of the baton within the enterprise is a phenomenon that affects a considerable number of business realities operating in our country especially SMEs. The situation of dimensional data of Italian firms - shown in the table below – regard the year 2010, in which it’s possible to highlight the diversity of different companies, by sector, size, ownership structure, propensity to export and innovation.

TABLE 3: TOTAL NUMBER OF SEPARATE ENTERPRISES³ BY SECTOR OF ECONOMIC ACTIVITY (absolute values)
 Source: ISTAT, Statistical Archive of Active Companies, 2011

Employees Range	Industry	Construction Industry	Trade, Transport, Hotels	Other Services	Total Industry	Total Employees
1	153.224	342.897	840.488	1.319.159	2.655.768	2.480.178
from 2 to 9	211.912	221.354	697.990	446.798	1.578.054	5.341.753
from 10 to 19	45.215	19.013	48.900	24.084	137.212	1.795.963

from 20 to 49	21.809	5.783	15.783	10.843	54.218	1.613.195
from 50 to 249	9.496	1.361	5.268	5.914	22.039	2.125.788
from 250 e più	1.416	83	909	1.238	3.646	3.520.706
Total	443.072	590.491	1.609.338	1.808.036	4.450.937	16.877.583

If we consider, finally, the number of firms by geographical (for thousand inhabitants) it can be seen that in the area of the North - East there is a greater concentration of businesses in the area and the bottom of the South (Table n°4). In addition, from 2010 to 2011 there was a decrease in North-East regions.

TABLE 4: BREAKDOWN BY COUNTRY (for thousand inhabitants)

Source: ISTAT, 2013

Country	2010	2011	Change
North-west	69,6	69,7	0,1
North-east	71,6	70,9	-0,7
Central	68,5	69,8	1,3
Central-North	69,8	70,1	0,3
South	51,4	51,5	0,1
Italy	63,5	63,6	0,1

On 31 December 2013 there has been a stream of registrations amounted to 384.483 businesses, against a stream of terminations, to the net of cancellations of office, of 371.802 businesses. The demographic balance was positive and amounted to nearly 13.000 new businesses. The best growth rates of the companies in 2013 were recorded in the northwest and south of the country (table 6).

TABLE 5: EVOLUTION OF ENTERPRISES REGISTERED BY GEOGRAPHICAL AREA

Source: Unioncamere- Infocamere - Monvimpresa (2013)

Geographical Area	Registrations	Closures	Growth rate 2013
North-west	100.197	96.457	0,23%
North- east	70.660	77.385	-0,56%
Central	86.507	76.895	0,74%
South- and Islands	127.219	121.065	0,31%
Italy	384. 483	371.802	0,21%

Going specifically, the same source points out that the rate of growth of enterprises in Calabria in 2013 was 0,35% with a positive balance of 625 new companies.

6. Empirical Analysis: case studies & reflections on theme

Given the assumptions outlined, the future of the Italian passes, more than ever, through the ability to enhance the contribution of the human factor within the system of business. All family businesses, for the same process of genesis that characterize them are rooted in a heritage of values handed by the family that owns and updated through the different generations. Without the force generated by the values rooted in the culture of family ownership, the process of continuity and growth of the company would stop. The theoretical model suggested (Fig. 4) is, as an example, the following.

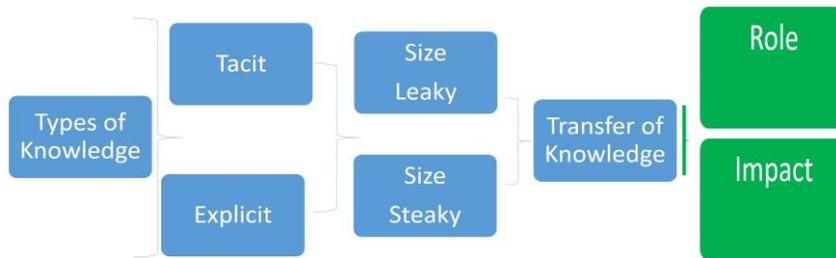

FIGURE 4: THEORETICAL MODEL

Source: our adaptation by Nonaka 1994 and Polanyi 1988

On the theoretical model discussed above, the surveys developed on the field have explored whether and how knowledge is seen as a strategic tool used by the entrepreneur in the complex process of generational succession. Specifically, the companies under study were No. 3, selected in companies associated with Confindustria Catanzaro, on the basis of specific situations; in fact, both are characterized by being SMEs, both are family businesses, both are living the coexistence of both generations proprietary, that parental outgoing and new incoming entrusted to the children. Thus, a check list of semi - structured interview was submitted to the entrepreneurs interviewed, designed with the aim to explore the theme and entrepreneurial positions relative; the research team therefore conducted these interviews - separately - than the two entrepreneurial generations, reporting the first results in the following table.

TABLE 6: FIRST RESULTS ON ANALYZED CASES

Source: our elaboration on questionnaires administered

Firm	Foundation year	Sector	Generation	Type of Knowledge transfereed	Methodology and Tools
Costruzioni Zinzi srl	1960	Construction company building	II°	Tacit and explicit	Intuitive component, observations, participation, mentoring, regular meetings
Destra Industrie srl	1984	Production & Trade of ecclesiastical robes and vestments	II°	Tacit	Intuitive component, observations
Cotto Cusimano spa	1972	Production and sale of building products, bricks, tiles	II°	Tacit and explicit	Intuitive component, observations, participation

While the first three columns describe briefly the types of companies involved, in the other columns (in the table above), are reported the most relevant data related to the object of analysis: moment generational lived, type of knowledge used in the process of entrepreneurial succession, awareness tools and methodologies useful to improve organizational performance. In fact, the objective of the survey was directed to explain and highlight what forms of knowledge are transferred and what tools are used in the organizational phase of generational change. From the taxonomy reported shows that the surveyed companies are all involved in the generational transition from the first to the second generation, and in all three contexts, there has been a transfer of both tacit and explicit knowledge. This transfer is done using tools such as mentoring, participation, intuitive components that significantly affect the wealth of knowledge of his successor.

What has been achieved, it seems clear to respondents highlight how the role of knowledge in its various phases of the acquisition, preservation and dissemination, and application of the transfer, is considered one of the key points on which it's necessary to face the challenge of growth and recovery of productivity for Small and Medium Enterprises. Another result of this first phase of the research, is the positive feedback - compared to the change in the style of leadership, management processes and organizational structure – related to a perspective that focuses on knowledge - especially at the stage of generational transition - that the enterprise produces through the consolidation of knowledge and value of the firm.

Next step of research will try to broaden the analysis respect other business sectors (services, food, etc ...) and compared with other territories (provinces and regions) in order to verify the comparability of the data and study on them.

A FRAMEWORK FOR FRUGAL INNOVATION IN MEDICAL DEVICE INDUSTRY

Arvinder P. S. Loomba, arvinder.loomba@sjsu.edu
San José State University, San José, USA.

A FRAMEWORK FOR FRUGAL INNOVATION IN MEDICAL DEVICE INDUSTRY

Abstract:

With ever-increasing globalization in the new century, the world is becoming more closely interconnected, more densely populated and more urbanized than ever before (Anderson, Cavanagh, & Lee, 2005). Plus, omnipresence of Internet across the globe is facilitating universal access to information, shaping consumer preferences and acquisitiveness, thereby affecting demand for technology, products, and services (Haferkamp & Smelser, 1992). Increased demand for products has led to increased job opportunities and higher wages, albeit this proliferation is not equitable across the globe.

An unintended drawback of globalization is that diseases and health complication are also proliferating on a global scale. Gentrification is permeating unevenly in developing countries with poorer pre-gentrification residents, who are unable to pay higher cost of living, are forced to migrate to more cost-effective geographical regions (Lees, Slater, & Wyly, 2008). These macro trends lead to increased polarization of population demographics and unintended discrimination in access to health care, among other public goods (Bardhan, 2005). As the resulting burden of disease is becoming far too severe for governments of low resource countries to bear, the criticality of addressing unmet healthcare needs of populace in the bottom of the pyramid is being brought to light.

While governments of low resource countries fail to deliver improved healthcare access to the poor, entities in developed countries often try to send medical technologies through charitable channels. However, many such well-intended efforts aimed at world's poor often prove futile. The fact remains that about 90 percent of medical devices reaching low resource countries are, in fact, hand-me-down equipment designed for use in first-world facilities (Miesen, 2013). Although, basic medical technologies, such as X-ray machines, diagnostic equipment, and incubators, are desperately needed in clinics in low resource economies, these same devices often fail few months later—or are even dead on arrival—because they are neither designed to operate in these environments nor repurposed for new working conditions. Consequently, strategies for delivering 'usable' medical devices in emerging markets need to be reconsidered with a low-resource perspective (London & Hart, 2004).

Where state agencies in low resource economies fail to deliver on the healthcare front, social enterprises and resourceful locals are making considerable inroads through 'frugal innovation' (Ahuja, 2012; Tiwari & Herstatt, 2012). The purpose of this paper is to introduce the framework of frugal innovation in healthcare and initiate a discussion of how it contrasts with other innovation types, its antecedents, its process, and its contextualization. Few case studies of frugal medical innovation low resource economies are reviewed and implications for business practitioners for institutionalizing it to develop and market viable medical goods and services for world's poor are discussed.

**Complementary and Synergistic Competencies in Technology Transfer:
A New Model of a Spin-off Creation Program**

Complementary and Synergistic Competencies in Technology Transfer: A New Model of a Spin-off Creation Program

Abstract

Knowledge transfer aims at promoting and fostering the transformation of ideas with high innovation content emerging from university research into various innovation vehicles, among which start-ups and (university) spin-offs. One of the major obstacles that hinder the success of this type of firms is the scant level of entrepreneurial competencies possessed by the academic and technical team. Drawing from the complementary competencies perspective of the RBV theory of the firm, the present study describes the spin-off creation program implemented at the University of Florence Incubator. The purpose is to investigate how the synergistic integration of business students' managerial skills and scientific-based business projects can bridge the gap between entrepreneurship education and technology transfer within the university environment. We conclude that the joint presence of technical and managerial competencies may be favored by specific methods and must also be supported by an appropriate strategic orientation concerning the implementation of the third mission of the university.

Keywords: technology transfer, university spin-off, venture creation program, entrepreneurship education program, university incubator, complementary competencies, resource-based view, team building, university scientist, academic entrepreneurship

Introduction

Gaining a position of competitive advantage is often difficult for companies in today's complex, turbulent world. Identifying the factors that determine the improved performance of firms allows us to better exploit their specific resources and competencies and to make strategic choices that improve their ability to take advantage of future opportunities. Knowledge-based resources are among the most important determinants of institutions, business and industry performance.

Given the difficulties of established firms in bringing new technologies to the market, universities are increasingly viewed as a source for the creation of high-tech firms (O'Shea, 2005). As a result, there is a growing need for universities to develop stronger linkages and leaner channels between science, technology and utilization and serve a "third-mission" to the development of the wider social and economic community (Etzkowitz, 2002). While it is widely recognized that teaching and research are the two missions of a university through which knowledge is preserved, created, applied and disseminated, knowledge transfer is defined as its third mission and refers to the transfer and application of knowledge to the community (Unesco Workshop, 2007).

In order to significantly reduce the gap between knowledge creation and knowledge use, knowledge transfer aims at promoting and fostering the transformation of ideas with high innovation content emerging from university research into high-technology and knowledge-based innovation vehicles, among which patents, joint research laboratories and projects, research contracts, and university spin-offs. The start-up of business venture is an important channel that universities can use to transfer the knowledge generated beyond the narrow confines of the academic community itself to the economic system (Mansfield and Lee, 1996).

Unfortunately, for many institutions, efforts to make universities more entrepreneurial have not had sufficient impact. Recent findings, especially regarding Europe, suggest that many universities are not experiencing a significant increase in spin-off behavior dynamics (Wright et al., 2003). In addition, several empirical investigations show that the majority of public-research spin-offs perform rather poorly (Mustar et al., 2008). Clarysse et al. (2005) stress the fact that there is a distinction between the creation of spin-offs per se and the start-up of spin-offs that create significant wealth. From an academic standpoint, identifying and analyzing the obstacles that limit the success of this type of high-tech start-ups appears an important research topic to better understand and, where possible, leverage their potential contributions in terms of innovation and growth.

In the goal of transforming scientific knowledge and research outputs into marketable products or services, university spin-offs face both market and scientific-technological uncertainties (Fontes, 2005). As suggested by Barr et al. (2009), in order to have economic impact, technology ventures have to bridge institutional, financial and skill gaps, labeled the “valley of death”. One of the major obstacles that potentially hinder the success of university spin-offs is the scant level of entrepreneurial competencies possessed by the academic and technical team. New venture creation, and entrepreneurship in general, seems to be not readily compatible with the traditional role of the university researcher (Louis et al., 1989). Indeed, according to Lundqvist and Williams-Middleton (2013), the majority of academic scientists seem not to prioritize the dissemination of their research through business and wealth creation.

It is clear that high-tech ideas per se are not enough to set up a business. Academic research wouldn't have much effect without committed and competent persons to develop and manage new firms and new business activity (Rasmussen and Sorheim, 2006). Therefore, the success of a spin-off necessarily implies that two opposite concepts of science become closer, namely, the “scientific” conception, which considers science as an end in itself, and the “economic” conception, which considers it as a means to making money (Ndonzuau et al., 2002). Most authors claim that team building is crucial for start-ups' success, by bringing complementary competencies and knowledge together (Lundqvist, 2014). There still exists a gap in the literature, where entrepreneurial education is not included as a contributing stream of research to the field of university entrepreneurship (Olilla and Williams-Middleton, 2011).

Drawing from the complementary competencies perspective of the resource-based view theory of the firm, the aim of the paper is to fill this gap and investigate how introducing spin-off creation programs at university incubators can bridge the gap between entrepreneurship education and technology transfer within the university environment. The overall purpose of our research is to contribute to the existing debate on spin-off creation weaknesses by analyzing extant literature, and to offer an operational idea to improve universities' strategies for dealing with the challenge of academic entrepreneurship by illustrating the spin-off creation program implemented at the University of Florence Incubator (IUF).

The program is grounded on the collaboration between the IUF and the School of Economics and Management of the University of Florence. Following the most successful venture creation/entrepreneurial learning programs around the world, the spin-off creation process would benefit from the synergistic integration and transfer of complementary specialized competencies. Business students preparing for their second-level degree are appointed as surrogate entrepreneurs to develop promising early-stage technology transfer ideas, connecting their managerial skills to scientific-based projects of innovation start-ups with low organizational, marketing, and administrative skills. The core design of the program is matching business students with technology-based ideas in order to build the team.

Results show that spin-off creation programs can effectively augment the university technology transfer in developing and growing successful start-ups. Incubators, business schools and laboratories concerned with entrepreneurship and action-based education are key resources allowing university scientists to engage in venture creation. The research findings will provide a better understanding of the knowledge transfer process in education, and enable evidence-based recommendations for researchers as well as for managers and policy-makers.

The structure of the paper is as follows. In the theoretical framework section we review the relevant literature on the third mission of universities, the link between university scientists and venture creation, the RBV theoretical framework on complementary competencies, and venture creation programs. The following section illustrates the methodology. Next, an in-depth description of the IUF program is presented. The discussion relates case findings to our understanding of academic entrepreneurship through venture creation. Finally, the last section draws conclusions and presents possible implications and opportunities for future research.

Theoretical Framework

The Third Mission of Universities

The main missions of universities have long been the higher education and the universal advancement of knowledge and culture (Carayannis et al., 1998). More recently, a third mission is being considered of as increasing importance, that is the direct involvement of universities with society: the valorization of the results of academic research and

knowledge transfer for innovation (Unesco Workshop, 2007). The notion of “valorization”, “transfer”, “third stream” or “third mission” is connected with the new concept of “entrepreneurial oriented university” (Etzkowitz, 1998).

From the mid-1970s to the mid-1980s, a progressive transformation occurred as regards the nature of knowledge and the process of innovation. The main implication was that in high technology sectors, it was important for firms to develop strong connections with academic labs if they wished to be in a position to master new knowledge (Roberts, 1991). On the other part, there was a growing need for universities to disseminate the knowledge generated beyond the narrow confines of the academic community itself (Mansfield and Lee, 1996). The pursuit of the third mission goals involves a series of processes and tools aimed at transferring the products of research to the market and the society (Visintin and Pittino, 2014).

At the policy level, combining the importance of tacit dimensions in knowledge production with the heterogeneous composition of innovation networks drove to a shift in the acknowledgement of the role of universities in regional and national innovation systems. Assuming to hold important economic and social benefits, this political understanding progressively put on the agenda of all countries and universities the organization of the knowledge and technology transfer (Etzkowitz, 2003). With the Bayh-Dole Act (1980), the USA defined a landmark in the national regulation of technology transfer activities.

The increasing importance of the third mission has resulted in the enlargement of the public-private cooperation, also in the form of spin-off firms (Lerner, 2004). In practice, this capitalization of knowledge takes different forms and is sustained by an ever-growing array of policies and organizational structures including technology transfer offices, incubators, spin-off firms, science and technology parks, patenting, fiscal incentives for business angels and seed capital, policies for venture capital, and so on (Leitch and Harrison, 2005).

University Scientists and Venture Creation

Visions of research universities expanding into the third mission have added to the image that university scientists are also increasingly confronting with entrepreneurial roles (Etzkowitz, 2003). Jain et al. (2009) describe academic entrepreneurs as spanning from the “pure academic” pursuing entrepreneurial endeavors to the “hybrid individual” with both science and business qualifications.

However, Louis et al. (1989) argue that new venture creation, and entrepreneurship in general, is not readily compatible with the traditional role of the university scientist. The majority of university researchers seem not interested in championing their ideas in the market place as the entrepreneur, because they already have a career path within academia. In many cases, the university scientist’s main ambition when commercializing research is to illustrate the discovery of new knowledge in order to gain recognition within the scientific community, with financial gain as a secondary objective as a means to securing more funding for research (Lundqvist and Williams-Middleton, 2013). Lockett et al. (2003) find that the more common roles for university scientists in a venture based on their research is as senior manager, advisor, or technical director, while the role of managing director or lead entrepreneur is less common and often not encouraged by the university.

Moreover, university scientists may face barriers such as lack of knowledge or skill in recognizing and exploiting opportunities stemming from their research (Mosey and Wright, 2007). As suggested by Ndonzuau et al. (2002), the success of a spin-off necessarily implies that two opposite concepts of science become closer, namely, the “scientific” conception, which considers science as an end in itself, and the “economic” conception, which considers it more as a means to achieve other goals (in particular making money). Due to their peculiar nature, they need to properly balance scientific orientation with business orientation: scientific orientation is necessary for the process of discovery and early technology development, whereas business orientation is required for the effective commercialization of the products and services which incorporate the technology (Cetindamar et al., 2009).

In order to have economic impact, technology ventures are often seen as having to transcend different institutional, financial and skill gaps labeled the “valley of death” (Barr et al., 2009). They are archetypical cases of companies which need to effectively manage the intersection between academic research and industry in order to be successful (Etzkowitz, 1998).

Resource Based View Framework

The resource-based view (RBV) is used as a theoretical framework model from the field of strategic management for identifying the complex, intangible and dynamic resources of an enterprise and assessing its competitive advantage (Penrose, 1959; Rumelt, 1984; Wernerfelt, 1984). Following Prahalad and Hamel (1990), the real source of advantage are to be found in management's ability to consolidate corporate-wide technologies and production skills into competencies that empower individual businesses to adapt quickly to changing opportunities.

As stated by Lockett and Thompson (2004), it is the heterogeneity, not the homogeneity, of resources and competencies that give each firm its unique character. Resource-based theory claims that complementary resources and competencies may enjoy synergistic performance impact (Teece et al., 1997). Complementary competency is an enhanced resource or asset that arises when a resource produces more value in the presence of another resource than by itself.

A core issues in the field of innovation management is the synergy between the technological and non-technological elements (strategy, marketing, culture, organization, and institution) of innovation (Xu et al., 2007). Business and managerial competencies in general refer to the skills and knowledge (technical as well as cognitive) of the top management to craft a strategic vision and communicate it, problem solving and resource allocation, leadership, and competences to create and stimulate enabling environment for change, and continuous improvement through learning (Lado et al., 1992).

A combination of technological and marketing (entrepreneurial) resources and competencies are key for achieving superior performance in environments with high technological turbulence and creating a sustainable competitive advantage for innovative firms (Song et al., 2005; Wang et al., 2004). Technological-related competencies have been shown to enable firms to achieve superior performance (Pisano, 1994). Likewise, marketing-related competencies have been recognized in the innovation management literature as complementary for the appropriation of research results (Teece, 1986). A firm with strong technological competencies is capable of using scientific knowledge to promptly develop products and processes that offer new benefits and create value for customers (McEvily et al., 2004). A firm with strong marketing competencies is able to use its deep understanding of customer needs to foster development of new products and organize marketing activities that provide a unique value to consumers (Day, 1994; Vorhies, 1998).

Following theoretical arguments drawn from the RBV perspective, it has been suggested that one of the main factors that may affect growth and success of new business ventures is the quality and heterogeneity of the entrepreneurial/managerial group (Visintin and Pittino, 2014). Compared to single founders, entrepreneurial teams are more likely to possess the competencies needed to achieve a fit between technology and business (Chowdhury, 2005; Colombo and Grilli, 2010).

Venture Creation and Entrepreneurial Education Programs

As stated before, one of the major obstacles that potentially limit the success of university spin-offs is the scant level of entrepreneurial competencies possessed by the academic and technical team. An economy that allocates a large portion of its resources to R&D development without a reciprocal portion of entrepreneurial capacity cannot be said to be utilizing its designated resources in an effective manner.

Universities can contribute to entrepreneurship both directly by the commercialization of research and by being the seedbed for new ventures, and indirectly through education of candidates as future innovators and entrepreneurs (McMullan and Melnyk, 1988). According to Klofsten (2000), there are three basic complementary activities aimed at stimulating entrepreneurship that should be found at a university. First, activities to create and maintain an enterprising culture on the whole at the university, serving as an integrated part of all courses, research, and external activity. Second, the provision of separate courses in entrepreneurship to students. Third, the offer of specific training programs for individuals who wish to start their own enterprise. Issues concerning resource constraints on the development of spin-off ventures has links to a parallel debate on the role business schools can play in the development of entrepreneurship in universities (Wright et al., 2004).

Drawing from the complementary competencies perspective of the RBV, team building and networking are crucial for start-ups' success, by bringing complementary competencies and knowledge together, and helping to bridge the valley of death (Barr et al., 2009). Successful universities around the world in creating spin-offs are characterized by clear strategies towards the engagement and commitment of multiple stakeholders (both internal and

external to the university) to achieve new ventures and support the spin-offs' entrepreneurial orientation. Some universities establish or create stronger links to incubators and technology transfer office, others have integrated technology transfer activities with entrepreneurship education, still others recommend the use involvement of surrogate/external entrepreneurs (Vohora et al., 2004).

The incubators and the technology transfer offices play a key role with respect to engendering academic entrepreneurship. First, they may engineer synergistic networks between academics, venture capitalists, advisors and managers who provide the human and financial resources that are necessary to start a company. Second, they provide services such as training and tutoring in evaluating markets, writing business plans, raising venture capital, assembling venture teams and obtaining space and equipment (Etzkowitz, 2002).

One of the major challenges of university incubators is precisely that of combining entrepreneurship education and university technology transfer (Lackeus, 2013). Bringing entrepreneurial education together with incubation at the university and letting students create a venture as a part of their entrepreneurial education is proposed to be a successful way to develop entrepreneurs as well as technology transfer and to bridge the gap between inventors with ideas and the marketplace (Olilla and Williams-Middleton, 2011).

An important question underlying venture creation and entrepreneurial education programs concerns whether it is possible to help the emersion of latent entrepreneurial attitude and the learning of complementary managerial competencies through different specific educational policies and programs (Erikson 2003; Sanchez, 2013). Many argue that there is enough evidence that entrepreneurship can be taught (Kuratko, 2005). Others state that entrepreneurs are primarily born, not made (Nicolaou and Shane, 2009). Some opt for a middle way, claiming that certain aspects of entrepreneurship cannot be taught, such as self-confidence, persistence and energy levels (De Faoite et al., 2003).

On the whole, consensus among scholars is that the only way to become entrepreneurial is through direct experience (Lackeus, 2013). Related methods range from case-based teaching, to matching with real start-ups, and finally support to start a company (Erikson and Gjellan, 2003). Learning-by-doing and direct observation can be put to use in entrepreneurial education through action-based approaches, often labeled "learning through entrepreneurship" (O'Connor, 2013; Rasmussen and Sorheim, 2006).

External entrepreneurship has been suggested as a way of adding complementary entrepreneurial competencies, attracted to and integrated with early technology ventures to increase the venture creation rate and bridge the valley of death (Fontes, 2005; Vohora et al., 2004). The joint presence of academic and non-academic members is an important dimension that may enhance the integration of the "scientific" and "economic" conception of science (Beckman et al., 2007; Druilhe and Garnsey, 2004). But also students or recent graduates in management and entrepreneurship courses can play as external entrepreneurs in early-stage technology ventures (Franklin et al., 2001; Lundqvist, 2014). Since both product/technology competencies and more business oriented market and managerial competencies are important in success cases of technology ventures, such surrogacy should complement rather than replace the entrepreneurial contributes from science- and technology-based teams (Lockett and Wright, 2005).

Methodology

On the basis of the information collected through the literature review, the aim of the present study is to illustrate the venture creation/entrepreneurial education program developing at the University of Florence Incubator (Italy). The main objective of the program lies in trying to bridge the gap between entrepreneurship education and technology transfer within the university environment.

This paper is based on an in-depth analysis that may be characterized as a case study (Yin, 1994). The case study method allows for study of a phenomenon within a real-life context, when boundaries between the phenomenon and its context are blurred, and multiple sources of data are utilized. In general, case studies are the preferred strategy when "how" or "why" questions are being posed, when the investigator has little control over events, and when the focus is on a contemporary phenomenon within some real-life context.

Case evidence is gathered through interviews, documentation, participant observation, and archival material. Data is triangulated where possible in order to determine replicable information and falsify inconsistent information in an attempt to minimize the subjectivity of the data presented (Flick, 2006).

The IUF Spin-off Creation Program

The University of Florence aims at promoting and fostering the transformation of ideas with high innovation content emerging from university research into spin-offs and innovative start-ups. In recent years, it has established a number of tools to facilitate the link between its research facilities and external parties. To take on this challenge, at the beginning of 2010 the University of Florence Incubator (IUF) was established. It is managed by CsaVRI (Centre of academic services for the valorization of research and the management of the University Incubator), which is the central Technology Transfer Office of the University of Florence.

The IUF support or provides pre-seed and seed services: scientific/business ideas scouting, training, mentoring, tutoring, networking, fund raising, and logistic support. It has a general vocation and aims to promote the valorization of the results of research even beyond the traditional technological and biomedical fields. Access to IUF services is open to applicants inside the University of Florence, or even to external applicants if they show strong links with university research. The IUF offers its services to those intending to join a spin-off project or propose an innovative start-up, to those who want to know more about the activities of the IUF start-up businesses with a view to purchasing the patents or products developed, and to those looking for collaboration with university spin-offs.

It has been understood from the beginning of the IUF activities that one of the major obstacles that potentially hinder the success of the University of Florence high-tech spin-offs is the scant level of entrepreneurial competencies possessed by the academic and technical team. The IUF managing staff recognized the need for stimulating entrepreneurial activity and bridging the gap between inventors with research-based innovations and the marketplace; even if core of entrepreneurial attitudes cannot be taught, but only helped to emerge when already resident in academic or students bringing ideas for new business ventures.

Following the most successful venture creation programs (US and Sweden above all), the IUF has been developing a mixed venture creation/entrepreneurial learning program based on team building, by bringing complementary competencies and knowledge together. A special project enacted in such perspective has been the “IUF Spin-off Creation Program”, precisely with the aim to try to connect undergraduate business students (in the future also graduates and young researchers in management) bringing entrepreneurial and managerial skills to scientific-based projects in the pre-seed or start-up stage with the aim to manage a synergistic integration and transfer of complementary competencies. The program is grounded on the collaboration between the IUF and the School of Economics and Management of the University of Florence. Business students preparing for their second-level degree have been selected and matched with teams bringing projects of new spin-offs based on science and technology research.

In order to obtain a synergistic effect between economic-managerial competencies and technological ones three main activities have been identified and organized. Firstly, students bring within scientific-based projects organizational, marketing and administrative capabilities, in order to support the development of business models and business plans. Secondly, business students support scientific-based projects in presenting their ideas through an elevator pitch and participating at various business competitions. Lastly, they analyze and develop the economic-managerial aspects of the project as a case study for their graduation thesis.

The matching mechanism to build the team is based on a brief presentation of the students and the projects and on a further stage of job interview between the two parties under the supervision of the IUF managing staff. The formed teams are supported by educators, practitioners, coaches, investors and business advisors, collaborating to fill the needs of both student and venture.

The first test of the program started in 2011 and was managed jointly by the IUF, the Laboratory of Innovation of the University of Florence School of Economics and Management, and the main association representing industrial companies of Florence (Confindustria Firenze). The pilot project was organized as a three months intensive program. The final goal was to present the technology-based projects pre-incubated in the IUF as real business opportunities

through an elevator pitch developed in the entrepreneurial subjects by the student to an audience of business angels associated to Confindustria.

After the first and the second edition of the program there was a follow-up phase dedicated to highlight the results obtained. Thanks to the support of 45 business students, 40 ideas were presented to the business competition, 3 were financed by business angels, 3 students were employed in the start-ups and 1 became shareholder.

Overall, in the short run, the program has been a good opportunity both for business students and academic inventors. Business students have had the opportunity to train their managerial and entrepreneurial skills on a real business case and to get involved in the spin-off as manager or as a co-founder being part of the entrepreneurial team. Academic inventors have had the opportunity to develop the economic and commercial side of their projects and to test their sustainability and competitiveness. In the long run, the synergistic integration and transfer of specialized complementary competencies fosters a virtuous circle of knowledge and technology transfer which helps the start-up of successful spin-offs.

Future implementations of the program will allow students to work voluntarily under a contractually secured incentive which stipulates how they will become shareholders if the venture is successful. The work for equity model allows spin-off to reduce their financial requirement for professional services in the start-up stage and to undertake a useful professional collaboration. The IUF management team experience suggests that becoming co-founders is for students and technical team the best way to share their competencies and obtain successful synergies.

Discussion

In 2008, the European Commission remarked that the teaching of entrepreneurship was not yet sufficiently integrated in higher education institutions' curricula and that far too little of existing entrepreneurship education efforts targeted students engaged in technical and scientific studies. The IUF spin-off creation program confirms the importance of entrepreneurship centers and incubators at universities. It illustrates venture ideas emerging from university engaging a much larger network and resource base, and extending beyond the border of the university. Furthermore, as suggested by Glassman et al. (2003), it confirms a view of universities acting as "gateways" for innovations, thus deviating from an "ivory tower image".

Combining business students and research-based ideas as a strategy for entrepreneurship education and technology transfer might be a daunting task, but if carried out successfully, several objectives are obtained. First, this approach leads to a further development of ideas that otherwise might have been neglected. Second, students who wish to start their own company get access to better ideas than they would normally come up with themselves. Third, it offers action-based entrepreneurial learning to business students and gives the students training in developing high-growth businesses. Finally, this approach may lead to cross the valley of death and to establish successful and long-lived spin-offs.

The primary goal of the program is not to turn the greatest number of students into entrepreneurs (Boyd and Vozikis, 1994). It is, instead, to get students to understand that entrepreneurship is an option for them and to increase their confidence and self-efficacy in regard to making this career choice (Chen et al., 1998).

The IUF management team has worked from a basic theoretical perspective largely consistent with the five critical factors described by Van Burg et al. (2008) in their science-based design approach to creating university spin-offs as a framework for crossing the valley of death. Two framework factors include the development of university awareness of entrepreneurial opportunities and the creation of a university-level culture to motivate and reward entrepreneurial behaviors. A third major factor is that the mix of technology knowledge and venturing skills (marketing, financial, intellectual property) must be provided through coaching and training. A fourth factor is the development of a collaborative network of mentors, advisors, managers and investors. The program violates only the last factor, which suggests that spin-off processes should be separated from academic research and teaching.

Moreover, following the framework suggested by Lackeus (2013), the IUF program helps bridging the gap between entrepreneurial education and technology transfer hinging on five pillars. First, it offers action-based learning, giving students the opportunity to interact with technical and entrepreneurial environment motivated by value creation. Second, the program fosters team building, fostering interdisciplinary and complementary competencies. Third, the

educational process includes networking events such as elevator pitch competitions to boost the technology transfer process. Fourth, the teams are supported by the incubator network, working together to fill the needs of both student and research-based ideas. Finally, the program is strictly connected with the local business context.

Conclusions

Our study has explored changes in the role of the university scientist towards academic entrepreneurship through venture creation, while adding to the understanding of the influence of university initiatives towards knowledge and technology transfer. Previous research had positioned venture creation as the type of academic entrepreneurship least compatible with a traditional role of the university scientist. The IUF spin-off creation program, a mixed venture creation/entrepreneurial learning program based on the complementary competencies perspective of the RBV framework and on team building, contributes to a more collaborative perspective on venture creation, in which university scientists play multiple and compatible roles, but not necessarily have an exclusive responsibility in leading the spin-off.

The article contributes to extant research showing that venture creation can be more compatible with the role of the university scientist due to an organized collective entrepreneurial activity at universities. Involving students together with scientists in venture creation is proposed as one important line within this perspective.

Our research has some implications for theory, practice and policy makers. On the theoretical side, it suggests that university spin-offs, due to their peculiar nature, need to properly balance their scientific and business orientations. It also contributes to the general literature on entrepreneurial teams in new ventures, and suggests a way to reconcile some inconsistent results of the literature on demographic homogeneity/heterogeneity and company performance. Core competencies are an asset growing from collective learning in a firm; the same is for university spin-offs aiming at achieving performance superior to the competitors in turbulent environments which must feature a harmonious and dynamic combination of marketing, technological, and integrative competencies.

Concerning the implications for academic management, our research supports the vision of universities' increasingly important roles in entrepreneurship and economic development, and in encouraging the provision to students of the skills they need to create and lead technology-rich entrepreneurial ventures. In the design and implementation of their scouting, coaching and consulting activities, the managers of university knowledge transfer offices should spread and promote some key messages among the potential academic entrepreneurs. First of all, academic founders should recognize the need to include people with business and commercial expertise in the team in order to develop the business model and to create the business plan. Then, non-academic members should be selected among those who exhibit entrepreneurial and managerial competencies, in order to promote an effective integration and synergistic knowledge exchange. The managerial implications are in the confirmation that university spin-offs should be encouraged from the beginning of their entrepreneurial path, to incorporate all the major constituents of core competencies into value creation and focus on the dynamics of competence development as a whole.

Finally, policy makers and university governance players are asked to intensify their activities to implement educational, research and resource programs, in the challenge to enable a culture of academic entrepreneurship to emerge within universities. This study has revealed intriguing aspects related to the importance of local networks when setting up an action-based entrepreneurship program.

The current research is of course limited to a single case study thus leaving open many questions. Future research will have to verify the real results obtained in the long run by the spin-offs who have benefitted from the IUF venture creation program. Another future research challenge is to compare similar programs around the world, from both the performance and the value creation standpoint.

SEGMENTING, TARGETING AND POSITIONING OF MOBILE PAYMENT SERVICES

Abstract

New technology companies only maintain a leading role, if their innovations are adopted by a majority of consumers. Due to an increasing mobility of today's society and progress in technological infrastructure, the mobile phone technology has been quickly adopted worldwide. The technological advances in the field of near-field contactless communications and the development of sophisticated mobile applications have enabled mobile phones to become a potential means of payment.

As part of its business strategy and strategic management process, a technology firm has to develop a strategic marketing plan (strategic marketing plan process) which includes: Segmentation, Targeting, Positioning (STP paradigm) – in this very order.

The purpose of this paper is to suggest strategic management recommendations for STP the mobile payment services (MPS) – based on drivers and barriers of MPS adoption that were identified both in literature review and empirical research related to MPS. Hence, the managerial implications of this study: to help managers to improve their longer run decisions and keep them focused on the launch of a new payment product.

Introduction and Definition of Mobile Payment Services

Successful companies in the technological field only maintain a leading role, if their innovations are adopted by a majority of consumers. Due to an increasing mobility of today's society and progress in technological infrastructure, the mobile phone technology has been quickly adopted worldwide. The technological advances in the field of near-field contactless communications (NFC) and the development of sophisticated mobile applications have enabled mobile phones to become a potential means of payment.

The notion of Mobile Payment Services (MPS) refers to making payments for goods, services and bills authorized, that are initiated and realized by using mobile devices independent from a bank website connection (Schierz *et al.*, 2009). The transaction can either be remote (SMS-based for instance) or processed locally via contactless technologies such as Near Field Communication (NFC). Overall, according to a study from Arthur D. Little (2012) so-called "mobile payments" represented a transaction volume of \$250 billion in 2012. Based on new technologies, MPS are currently diversifying. However, they have so far developed slowly, except in a few countries. In developing countries, where mobile telephony is also widely adopted, mobile payments are seen by the governments as an opportunity to improve access to banking services for the unbanked population. The launch of the M-Pesa service by Vodafone in Kenya, which reached a total of 7.5 million subscribers in 2009, has also generated hopes to reduce financial exclusion in these countries (Bourreau and Verdier, 2014). As Venkataraman (2008) shows, not all mobile payment implementations are successful: one of the reasons behind the slower growth is a lack of suitable guidance or planning for a successful mobile payment adoption; he addressed this issue - from both technical and business perspective - by proposing a reference framework (roadmap) for mobile payment implementation. However, a close analysis of these cases reveals that success stories cannot be easily generalized and demonstrates that several ingredients are needed for Mobile Payments to succeed (Bourreau and Verdier, 2014).

Research Objective

At the heart of the management problem lays the question how could the involved companies make sure that the newly launched payment products will subsequently lead to new and to steady income streams.

The authors will start by presenting the main criteria for consumers to adopt or to reject Mobile Payment Services. The objective of this article is to suggest strategic management recommendations that follow the beaten path of the Segmenting-Targeting and Positioning (STP Paradigm) and are based on drivers and barriers of MPS adoption that were identified in empirical research related to MPS.

Drivers and barriers of Mobile Payment Services' consumer adoption

Mobile Payment Services (MPS) is a dynamic and growing market segment, regarded as strategic business field (Bauer, 2012) and thus, potential providers and retailers aim for a competitive advantage if they start offering MPS to their consumers. The overall aim is to position the services from the consumer perspective to ideally realize a strong position in the market (Abell, 1980, 1999) as reflected in the Market-Based View (MBV). In this logic the value proposition of the product is a result of how an innovation is accepted by the consumers in comparison to comparable products from the competitors (Day, Montgomery, 1999).

Pousttchi and Hufenbach (2013) proposed a mobile payment reference model that provides not only theory background but it is also a tool for marketing research – to be used for data collection and customer preferences analysis. “Discovering preferences transparently means that the marketer learns the customer needs without actually involving them. When marketers learn customer preferences collaboratively, they engage in a dialogue to help customers to articulate their needs and identify how to meet those needs.” (Kahn, 2000, p. 14)

With the aim to identify the drivers and barriers of MPS consumer acceptance and adoption, the author selected empirical explorations, each with a different focus, but all contributing with unique insights. The meta-study by Tornatzky and Klein (1982) on innovation adoption provides a fundamental understanding of influential variables of the intention to use innovations in general. The study by Schierz et al. (2009) explored acceptance determinants of MPS. Mallat (2006) identified MPS drivers and barriers of consumer adoption and together with Tuunainen (Mallat and Tuunainen, 2009) barriers of merchant adoption. Yang *et al.*'s (2012) exploration conducted among Chinese and Americans is not limited to the “intention to use” but includes results from the post-adoption stage of MPS usage. Research results of consumer acceptance in e-commerce (Pavlou, 2003) and m-commerce (San-Martin and Lopez-Catalan, 2012; also see Bauer, 2012) have been incorporated to examine the role of trust for adoption.

Based on the Technology Acceptance Model (TAM) by Davis (1985; 1989) and the Innovation Diffusion Theory (IDT) by Rogers (1983) and with the scope to determine drivers and barriers across opposite cultures, the authors of this article developed an own research model (Wurster, 2013) and conducted a qualitative study among German, Romanian and Chinese Bachelor students aged between 21 and 24 years (Figure 1).

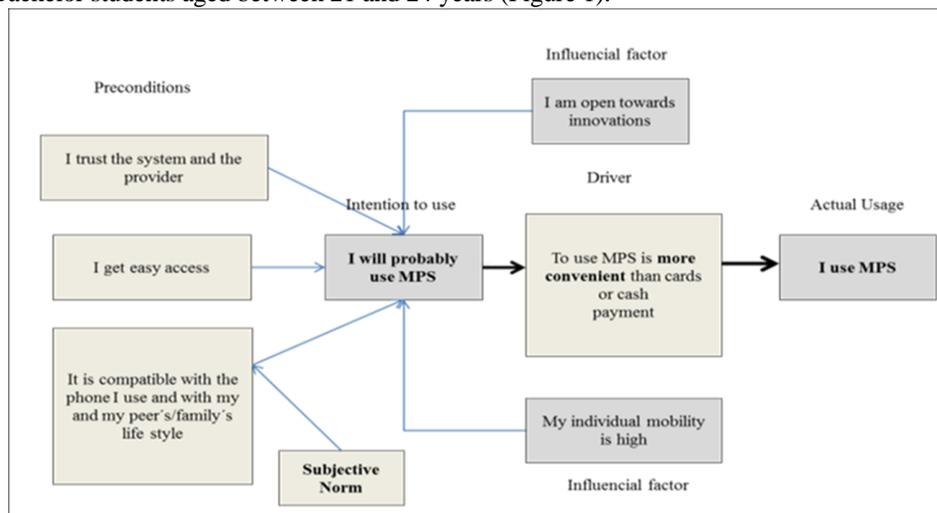

FIG.1: RESEARCH MODEL (WURSTER, 2013)

All participants in the study were born during the internet and mobile communication area and without any fears of using technology in their daily lives. Most of the students still lived with their parents or shared their apartment with other students. While the Chinese were technologically the best equipped with the latest Apple iPhone and Tablet PC and Lenovo computer and had the highest income available of all students (the majority had a budget available of 1000-

2000 €/month), half of the Romanian students not even possessed a smart phone and the majority had to exist on a monthly budget of 500 €. The German students all possessed a smartphone, either an iPhone or a Samsung and had an lived on an average budget of 1000€.

Common behavioral variables were a high degree of mobility in life and the predisposition to be open towards innovations; however, the majority was hesitating being the first to try innovations (“I would only try new technology after others tried it first and approved it.”). A remarkable insight was that the majority of the Chinese believed that money led to a happy and a satisfied life, while for most German and Romanian students money was “important, but not essential for happiness”. The Chinese were also very conscious to avoid debts. The majority did not possess a credit card as it would possibly lead to making debts. The majority of the Chinese used the cash disposal machine only once a month. Germans did not have an issue with making debts or using credit cards. Romanians preferred cash, except for e-commerce purchases and for the booking of hotels and flights.

The majority preferred stationary shopping to online shopping, except for very few male students. If they went online for purchases, all students preferred to use a computer and a W-LAN access at home as it was perceived as safer and more convenient than m-commerce via mobile device.

Convenience was very important to all interviewees. The main benefit and reason for using the latest technology is convenience as it “makes life easier”. Other reasons are “status” and higher acceptance within the peer group. As could be seen in the clear preference for the brand Apple, for the Chinese students, “conformity” might still play a role and might possibly root in decades of communism. The authors came to the conclusion, that following variables are driving MPS acceptance and adoption, which was also confirmed by previous research:

- Trust into the system and the provider(s) (Pavlou, 2002; Mallat, 2006; Mallat and Tuunainen, 2009; San-Martin and Lopez-Catalan, 2012; Bauer 2012; Fingerhut, 2014, Wurster, 2013).
- Compatibility of the system (Tornatzky and Klein, 1982; Mallat, 2006)
- Accessibility to the system (Wurster, 2013; Fingerhut, 2014)
- Convenience (Wurster, 2013)

While the first three variables (trust, compatibility and accessibility) became pre-conditions in the ongoing worldwide adoption process of this payment method, the providers of MPS can deliver a real benefit to potential consumers by offering *more convenience than* alternative payment options (Wurster, 2013) or “*value added services*” (Fingerhut, 2014). According to the primary qualitative research conducted by the authors, MPS was perceived as “convenient alternative” to pay, especially vs. cash money; thus, the relevant competitive reference should not be debit or credit card payment, but cash payment; another important insight was that “convenience” means *fastness and simplicity* of the financial transaction via mobile phone.

The primary research also confirmed what has been identified as individual influence factors for MPS adoption by previous researchers (Yang *et al.*, 2012; Schierz *et al.*, 2009) as

- Individual mobility
- A positive attitude towards technological innovations
- Experience with technology usage in daily life
- Subjective norm, as for example, the consumer’s attitude towards money and banking and opinions of his/her family, peer group and social net community
- Personal risk or control perception

Identified barriers of MPS consumer adoption are

- The absence of trust into security dimensions of a payment system. Most authors and researchers agree upon the dominant role of security issues for the acceptance of online and mobile payment services (Pavlou and Chai 2003; Bauer, 2012; Wurster, 2013; Fingerhut, 2014).
- Complexity as the opposite of convenience (or simplicity), but in the sense of too many different procedures to accomplish the payments on POS and long lasting registration procedures (GfK, 2011; Ondrus and Pigneur, 2009; Wurster, 2013).
- All factors that hinder merchants to adopt mobile payment systems and thus, prevent from making the services accessible for the consumer (Mallat and Tuunainen)

Strategic management options for Segmenting, Targeting and Positioning MPS

As a framework to strategically positioning MPS, the authors chose the Segmenting-Targeting-Positioning Paradigm as it plays a central role within the Market Based View (MBV), which is the Strategic Management stream that is focusing on consumer needs and acceptance within a certain competitive surrounding (Figure 2, Figure 3).

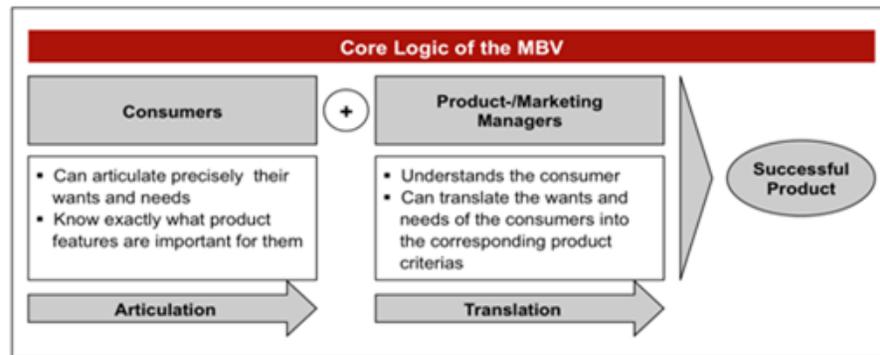

FIG. 2: CORE LOGIC OF THE MBV

Of all established strategic management streams, the Market-Based View (MBV) plays a pivotal role for the launch of a new payment product. As the name of this view already implies the market-based considerations are at its core and it thus correspond highly with the Marketing concept. The rationale behind the MBV is that - based on an intelligent definition of the relevant market – an attractive market segment will be identified which in turn will be secured and developed by an adequate positioning strategy (Kotler, 1989, 1997). The overall aim is to position the products and services as idiosyncratic as possible from the consumer perspective to ideally realize a strong position in the market (Abell, 1980, 1999).

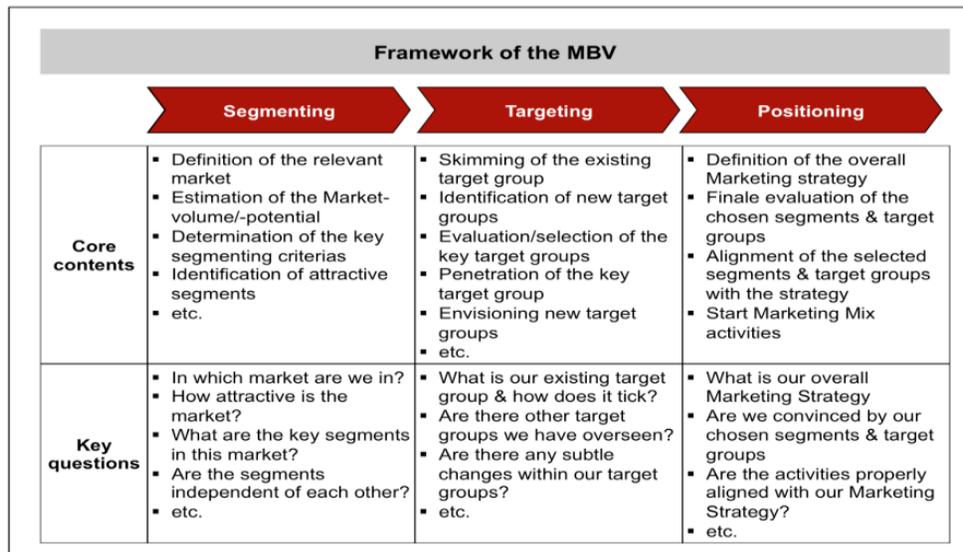

FIG.3: FRAMEWORK OF THE MBV

Segmenting and targeting

“Market segmentation is concerned with a classification of customers and consumption and when enacted, market segmentation usually turns to or is based upon the relationships, which follows” (American Association of Marketing, 2014); it is a creative and iterative process to satisfy customer needs more closely and, in doing so, to deliver sustainable competitive advantage for the company (MacDonald, 2012).

Taking the discussion to a strategic and tactical level, the idea of a strategic window as outcome of the market segmentation efforts gives companies the opportunity to increase their profits and allow them as new competitors to challenge and attack traditional market leaders (Abell, 1978). However, this strategic window is reduced to limited periods when the key requirements of a market and the particular competencies of a company competing in the market are at an optimum (Proctor, 2000). On the tactical side this means, until competitors copy a firm’s segmentation routine, the firm has a competitive edge; if the product or service is specific to the segment then this competitive advantage is multiplied (McBurnie, Clutterbuck, 1988).

Although segmenting is perceived on the theoretical level as an “objective” and straightforward activity one has to point that there is an array of issues and challenges when it comes down to successfully implement the identified and selected segments. Indeed many concepts and approaches do exist to segment a market but when it comes down to identify the key criteria’s like measurability, accessibility, the strength of the segment as such and last but not least the non-interference within the segments especially in terms of buying behavior, the scope of the differentiating variables are considerably reduced.

The identification and selection of the differentiating variables is further complicated as their preferences keep on changing at a much faster rate and that the behavior of the consumer is increasingly difficult to predict since it is getting more and more hybrid meaning that the consumer cannot be associated with one segment but rather with many. As a result of fast changing markets and a consumer behavior which is enormously difficult to predict the non-interference within the different segments can be hardly granted which in turn questions the overall segmentation of the company. Due to the increased turbulence of the environment the companies are literally forced to question themselves in terms of their key target segments like: Are our segments properly aligned with our strategy or are they contrary? Since the consumer behavior does not take into account artificial the segments the company has defined in the light of an adjusted strategy due to new trends in its environment. Most researchers (e.g. Schierz *et al.* 2009, Mallat, 2006, Mallat and Tuunainen, 2008, Yang *et al.*, 2012) suggested that companies should specifically target and position their MPS solutions to well suit individual behavioral patterns and prior experience.

There is a variety of research upon dividing the mobile communication market into different target groups. Yang *et al.* (2012) suggest segmenting the potential users according to their personal traits, especially to their degree of pre-disposition to adopt innovations and to their degree of individual mobility (Yang *et al.*, 2012).

Schierz *et al.* (2009) found out, that it is crucial to identify the early adopters of MPS as they are likely to adopt innovations first (Schierz *et al.*, 2009, p. 215). The positive influence of the early adopters has its origin in the IDT construct (Rogers, 1983) and has been positively confirmed by the qualitative study conducted by the authors: those who describe themselves as early adopters of technological innovations are all willing to try MPS.

Nearly every adult owns a mobile phone and carries it with him; however, this would imply to be owner of a smart phone, which accounts for 25% of the worldwide population and approx. 40% of the German population. Those who possess a smart phone and go online with their mobile phone on a daily basis are much more likely to use mobile payment services in the future than those whose use the internet less frequently (Kreimer, Rodenkirchen, 2010).

Therefore, a valid segmentation option would be to take the mobile internet usage behavior of consumers as a basis, as for instance done in the Austrian Mobile Communication Report 2013 (MCR, 2013). Although Austria is a small country, its location between East and West Europe is ideal to integrate insights from both, Western and Eastern European consumers as well. The MCR research revealed three target groups, Digital Natives (36%), Digital Immigrants (52%) and Digital Outsiders (12%).

Consumers who cannot reject a certain addiction to their mobile phone belong to the “Digital Natives” who have been brought up with mobile phones and the internet and account for 36% of the sample. Their usage rate of mobile web services is 96%. For these people, the mobile phone is essential for their communication, even for online

purchase, they prefer using a mobile phone. This was relevant for the majority of the *male* Chinese and German students, interviewed by the authors.

The “Digital Immigrants” include a wide age range and are regular users of mobile web services (76% usage rate), but their usage is selective and goal-oriented. Their hesitation is grounded in “security and data protection” issues they have with web services their education level and income is the highest of all three target groups (MCR, 2013). The majority of the Chinese and Romanian students interviewed by the authors would be related to this target group denomination.

The “Digital Outsiders” are the ones with most skepticism. Their mobile internet usage rate is only at 8%; 34% of them are older than 50 years and the majority of them (81%) have only discovered the web during the last two years. The majority of the “Digital Outsiders” rejects using the mobile phone for other communication activities than to make calls because the display seems to small for them which reduces the convenience and they are technically too poorly skilled to go online with their phone, even if is a smart phone (MCR, 2013).

Gender-segmentation, age-related or segmentation according to the individual risk disposition of consumers would be additional feasible segmentation strategies for MPS. Men (78%) and consumers younger than 30 years (89%) are the heavy users of mobile Web services. A large percentage as 88% use the mobile phone to gather information about products and services and their benefits or to search for certain brands and offers. The reason for the high attractiveness of these consumers is that they go online on a daily basis and rather have trust in mobile payments than those who go online less frequently. Dividing the potential users in risk-averse and risk-friendly users and targeting them individually as Mallat suggested would be an alternative variant (2006). 30% of the mobile shoppers think that payments in mobile commerce are not secure enough (MCR, 2013; Francis *et al.*, 2010). 56% that have downloaded an App from an App store, pay attention to which features the App has possibly access on.

Especially in payments, MPS providers need to make sure to increase transparency and information for those users who are risk-averse with special programs individually targeted to them with the aim to make them overcome their fears (MCR, 2013).

One possibility to increase the efficiency of the targeting activities considerably is the implementation and deployment of Customer-Relationship-Software-Tools since one of the central value these systems have for companies is that all customer data is centralized and that new target groups can much more easily identified when customer behavior patterns are at the basis of the analysis (Sheth, Sisodia, 1999).

Positioning of MPS

What does successful positioning in the MPS market imply? Those providers of MPS will succeed that offer customers the highest degree of convenience and value-perception.

Companies that opt to engage in MPS should fulfill their promises, exhibit an ethical behavior and inform the audience, taking into account individual user needs and preferences of their target groups, in order to achieve trust (San-Martin and Lopez-Catalan, 2012). PayPal demonstrates that strategies built on trust are successful in the long-run.

Confidentiality, data integrity, authentication and non-repudiation are the most important requirements for e-commerce and mobile payment transactions to build trust among risk-averse consumers (Dahlberg *et al.*, 2007; Mallat, 2006). Other aspects that are significant for trust-building are anonymity and privacy, which consumers rather associate with banks than with telecom providers (Kreimer and Rodenkirchen, 2010). Practical implications would be to offer following benefits and communicate them to the relevant target group:

- security aspects in software and hardware
- technical security standards at technical construction of the service
- insurances covering possible losses
- reliability as brand benefit in the communication strategy

Influences from friends and social networks have to be considered as critical, especially in the pre-adoption stage, but “this is especially the case among highly collective-culture countries as China, where individuals are more easily influenced by other’s opinions than those, living in the low collective-culture countries as USA, Great Britain, Australia etc” (Yang *et al.* 2012, p. 137).

Recent attempts of mobile service providers to promote special fares and flat rates targeted at “Digital Natives” by asking their friends to participate and installing a bonus system for new contracts (“Friends gain Friends” by Base/Eplus) are going into this direction.

MPS providers can positively influence the consumer perception:

- by improving the conditions for retailers to perceive MPS as attractive enough to adopt it and
- Showing in their communication executions different situations for MPS usage to influence the value perception of MPS being more convenient and adding value than alternative payments
- Reducing the payments to maximum €50 spending per buy.

Ideally MPS providers adopt to consumer’s needs and offer NFC technology in places where time is a critical factor, as for example in airports, train stations or bus/tram stops, taxi-cabs, but also in staff canteens or in public libraries, university cafeterias etc. But time saving also implies the expectation, that the payment process is as short as possible. Consumers are not willing to queue up longer in supermarkets, if the mobile payment procedure takes longer than card payment would take.

Thus, for successful mass-marketing of MPS, providers would need to develop advertising to emphasize the value of MPS service vs. cash payments. They should communicate the benefit “convenience” by demonstrating how compatible the method is with daily life situations, if MPS are accessible everywhere, where the consumer is, independent from a bank branch or cash disposal. Service providers need to extend their services and offer, apart from convenient and fast payment, saving tickets, price comparisons or search functions to find the closest shop with the lowest price for instance (Fingerhut, 2014).

To reject negative perceptions service providers would need to

- design various assurance procedures
- “Easy to understand “ design of the verification process during an NFC transaction
- offer a long term user preferential plan
- provide a packaging cost scheme

San-Martin and Lopez-Catalan (2012) questioned, whether it would prove beneficial for mobile service providers to encourage impulse buying via promotions etc. since they found out, that

- it may reduce satisfaction
- it may lead to a greater number of complaints, refunds and returns
- it probably sparks negative word-of-mouth concerning the provider and regarding m-commerce as a whole.

In the post adoption-stage, the factor “satisfaction” with MPS might play a more dominant role for consumers and on the provider’s side, the ability of the providers to cope with system errors (Yang *et al.*, 2012). However, MPS providers should not be over-enthusiastic as only a minority of the Bachelor students that were interviewed by the authors believed that MPS would entirely replace the existing payment methods, but rather that it will become one of the ways to pay in a few years.

Conclusions

With regards to the overall objective to derive management recommendations from empirical research on MPS acceptance and adoption, the theoretical research streams and the empirical research were able to give fruitful insights.

If one analyzes the success of disruptive technologies and applications, these main parameters have to be seamlessly working together: A reliable technology behind the product, transparent communication, data security measures and a high acceptance rate of retailers.

If MPS providers and retailers start to create the preconditions for usage intention i.e. wide access and compatibility – most preferably in offering the most convenient and secure solution – the mobile payment method could receive more attention. But, it needs a clear positioning, a transparent information policy by banks and credit card companies and more intense sales activities by the respective technology providers to convince consumers and retailers that this technology is worth investing as it will help them increase the retailer’s sales significantly and build long-term consumer relations.

However, it is almost a fact that only a smaller group of dominant platforms and technologies will emerge from the array of confusing standards competing in the market today – an ecosystem of players who are all building trust and can plausibly explain that their services offer more convenience than conventional payment methods will demonstrate enough value to consumers to replace cash payment in the long term.

Analysis of operations in the context of manufacturing, and its impact on the competitiveness of SMEs in Guadalajara, Mexico

Abstract

This research is motivated by the importance of SMEs in the current work of the world and our country in particular. It is appropriate to understand the important social role played by SMEs to be an instrument of social cohesion and stability, creating employment opportunities for people with no professional education (Enríquez, Adame, Camacho, 2012). The analysis was done to manufacturing SMEs in Guadalajara, analyzing the mechanisms that SMEs become increasingly competitive, globalized, entrepreneurial vision with entities that have the resources to acquire the technology they will streamline processes.

We propose an approach where competitiveness is the dependent variable and independent variable operations, each variable is related to certain factors such as financial performance, technology and costs of the dependent variable as well as other factors by the independent variable, such as: reliability, administrative control, staff development and automation.

The results relates the operations (manufacturing), with competitiveness using Structural equations.

Keywords: Competitiveness, Operation, Business vision, technology

Manufacturing in Mexico 2013

Currently, the monthly reports from the National Institute for Geography and Statistics (INEGI) indicate that industrial activity in Mexico decreased (-) 1.67% in the fourth month of 2013 compared to last March based on seasonally adjusted figures. Manufacturing decreased (-) 1.16% during the month of April. But compared to the annual rate, manufacturing increased 5.6%. (INEGI, 2013)

The manufacturing industry in Jalisco

In June 2011 the production of the domestic manufacturing industry recorded an increase of 0.8% over the same month in 2010. The level of manufacturing output grew 1.7% in Jalisco during June 2011 at an annual rate. In the accumulated January-June 2011 grew 4.9% the manufacturing industry at national level for the month of September 2010, while in the state of Jalisco was growth of 7.7%.

Manufacturing SMEs in Jalisco

According to SEIJAL, (2012) Jalisco is the fourth at national level economy contributing 6.6% to the PIB in 2010. The main economic activities are manufacturing 42%, further highlighting the electronic industry

The metropolitan area of Guadalajara (ZMG) is one of the main tourist destinations in the country, out in Puerto Vallarta beach centers, strengthening the service sector. This has allowed it to stand out in the international arena both foreign trade and investment, contributing to the development of the entity (SEIJAL, 2012).

TABLE 1: EXPORTS AND IMPORTS OF MANUFACTURING ZMG

Manufacturing Industry	Exports Jan-Mar 2013	Imports Jan-Mar 2013 (USD)
Food industry	\$624,298,670.94	\$756,898,225.75
Textile industry	\$64,139,268.82	\$273,633,584.05
Footwear industry	\$11,104,970.00	\$53,776,079.83
Manufacture of rubber and plastic	\$194,404,329.31	\$624,325,828.51
Metal mechanical industry	\$433,536,079.39	\$686,404,676.84
Chemical industry	\$472,211,539.83	\$1,214,136,594.01
Furniture industry	\$67,859,260.24	\$75,256,617.43
Jewelry industry	\$133,099,360.67	\$18,049,896.21

Operations

Within operations, one of the factors that highlight most is the research on the human resources of the company. The knowledge, skills and attitudes of workers and how they are working, are increasingly important issues for companies, because traditional sources of success, as the technology and products, markets, financial resources and economies of scale are increasingly less relevant.

Although in the modern age the industry organization does not rely only on the organization of human labor but also on various factors that affect their operations, such as technology, capital, access, knowledge, proximity to logistics / market, etc., creating more competition. Therefore, industries are increasingly flexible in their manufacturing operations and their supply chains / distribution. However, industrial operations are inevitably exposed to a variety of risks arising from market conditions, technological changes and the disappearance of the benefits over a period of time. This makes industrial operations, obsolete or reduce the period of time with good benefits. Moreover, economic and financial factors and government policies play an important role in the prosperity of the industries and their disappearance (Nallathiga, 2010).

Therefore, for the development of operations personnel, we suggest considering the following skills in production, divided into two categories: intellectual control capability (to memorize the order of placement of parts or work procedure correctly) and skills motor and sensory (being the visual, auditory, tactile sense, and limbs) (Mori and Kikuchi, 1995). The latter being difficult to remove through interviews (Doyo, D., Ohara, A., Shida, K., Matsumoto, T., & Otomo, K., 2009).

It is important that the level of competition that a company projected, as there are several industries that are engaged in the same thing and sometimes that makes it more outstanding than the other is the performance and development of all staff it works. For that reason an institution or company should be able to compete with both domestic enterprises and global, whatever its rotation and size, but the best competition is with herself, as to be better every day is a goal that all industry should be set, as it is important to improve oneself to be better than the thousands of skills that surely exist in the market.

An important point for such purposes is industrial automation, serving much within a firm, as it is a primary tool for efficient management in enterprises, it can reduce time and increase productivity.

It should be noted that automation is not only the fact be changing machines and tools but is an entire project to be carried out to verify that it is profitable to automate the whole plant or part of it, this is based on painstaking research taking into account the history of the industry to subsequently reach the best conclusion (Télliez, 2008).

The automation process has now been successfully impact the software development, as these may become, in many cases, cheaper than conventional machines, one can speak of those programmable (PLC programmable logic controller) that sometimes you only ever need one operator, which reduces costs in payment for labor that is directly related to the process (Télliez, 2008).

Problematization

At present the issue of competitiveness for SMEs has expanded significantly in any business environment where these businesses are operating, leading to the conclusion that the economies of the regions where these organizations operate are constantly growing and important indices of competitiveness (Gardiner et al., 2004 Strambach, 2002)

Small and medium-sized enterprises in countries with a low industrial development have serious limitations, such as inadequate infrastructure and limited government support, hindering the implementation of innovation and the lack of financial resources in small and medium enterprises as essential for the development and growth because, due to deficiencies in the marketing and no specialization of human resources, as well as design and implement appropriate for new market development strategies, they impede the performance and implementation of the innovation. Similarly, several studies establish that barriers to innovation among business organizations are usually associated with the strategies, costs, human resources, organizational culture, information flow, and government policies (Baldwin & Lin, 2002; Mohen & Roller, 2005). In this sense, the barriers to innovation SMEs directly affect the limited resources they have (Hadjimanolis , 1999, Hewitt -Dundas, 2006).

The current situation presents small and medium enterprises in Mexico is the result of a gradual deterioration and results in the loss of competitiveness due to the lack of support to maintain growth and development; this has resulted in job losses and the closure of companies in this sector, due to international competition and globalization of markets (INEGI, 2004). The importance of SMEs in the environment, both for their contributions to the creation of jobs and wealth in the country, covering 95.5% of the total national companies, and generate 45% of GDP.

The fundamental problem with the Mexican manufacturing industry is the low labor productivity growth, due in part to the low investment in training, research and technological development "budget cuts in research and education that violate our future".

Given the current state of manufacturing in Mexico urges a new industrial strategy that is inclusive, sustainable, long-term, so far away, and with a free market that has not yielded the expected positive results.

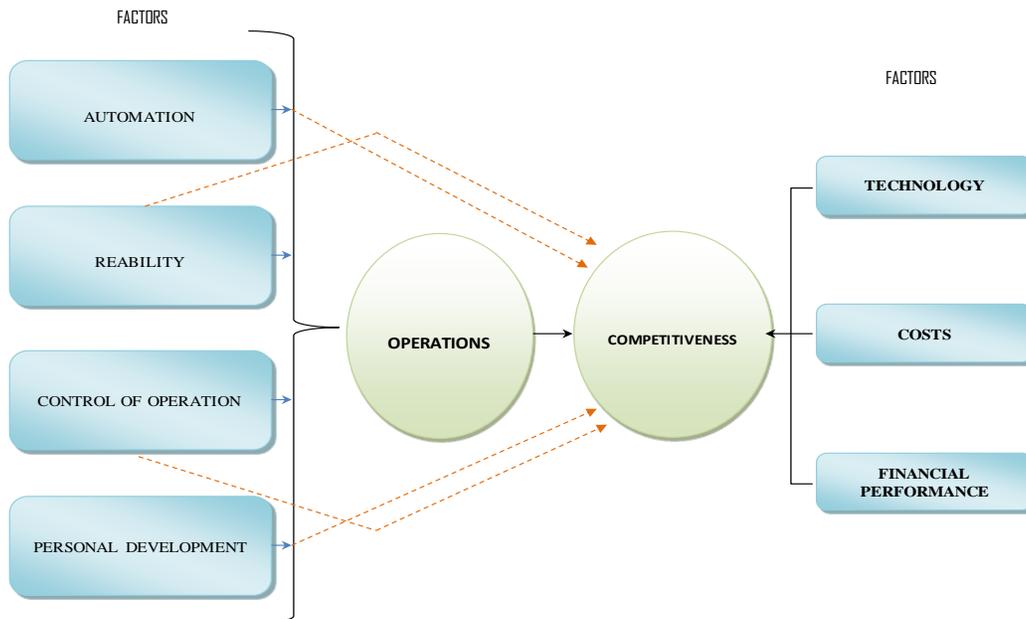

A strategy for the development of industry, value-added services and innovation, required to incorporate emerging issues in the new industrial policies on education and training, enhancing productivity, competition in domestic markets, internationalization of companies, research and technological development, energy efficiency, sustainable development and use of the purchasing power of government and big business to the development of suppliers of domestic goods and services.

Urges also define policies for industries and products that are facing new global competition or technological paradigms that detonate faster growth and more balanced regional development with significant impacts on employment, sectorial coordination and production chains.

Methodology

Research model of competitiveness with respect to operations of manufacturing SMEs in the ZMG.

Spatial and temporal delimitation

The delimitation of this study was done for manufacturing SMEs in the Guadalajara metropolitan area consists of the municipalities of Guadalajara, El Salto, Tlaquepaque, Tlajomulco de Zuñiga, Tonalá and Zapopan, in the period 2012-2013 being the cross questionnaire and this phenomenon was studied in a specific period (Münch & Angeles, 2009).

TABLE 2: NUMBER OF MANUFACTURING SMES IN THE METROPOLITAN AREA OF GUADALAJARA

Township	Manufacturing SMEs
1. Guadalajara	1, 417
2. El Salto	114
3. Tlajomulco	112
4. Tlaquepaque	317
5. Tonalá	155
6. Zapopan	732
TOTAL	2, 842

Source: INEGI (2013).

The sample

$$n = \frac{Z^2 \cdot N \cdot p \cdot q}{i^2 (N - 1) + Z^2 \cdot p \cdot q}$$

$$n = \frac{2.17^2 \cdot 2847 \cdot .50 \cdot .50}{(0.05)(.05)(2847 - 1) + 2.17^2 \cdot .50 \cdot .50} = 404 \text{ surveys}$$

TABLE 3: TECHNICAL DETAILS OF THE RESEARCH SAMPLE

features	survey
¹ universe	2 847 SMEs in the manufacturing industry.
Scope of Study	regional
Sampling Unit	Manufacturing SMEs with 11 to 250 workers
Method of data collection	survey staff
Sample Type	Simple random
Sample Size	400 companies
Margin of sampling error	± 4% at a global level, to a confidence level of 97% (p = q = 0.5)
Date of fieldwork	September 2012 to February 2013

Source: Authors' calculations based on data from INEGI (2013)

General purpose

To analyze the relationship between operations management and Competitiveness of SMEs in the manufacturing industry in the metropolitan area of Guadalajara.

Specific objectives

- To present the most relevant aspects of operations management and the importance of competitiveness as key to higher profitability in market share relative to its competitors.
- Identify the factors involved in the management of operations within the SMEs.
- Identify and relate aspects of operations management to competitiveness in organizations.

Hypotheses

- H1: A greater automation, lower production costs.
- H2: A greater control of operations, the greater the financial performance.
- H3: A better management of operations improves the competitiveness of the organization

Research question

What are the elements of the correlation between variables and Operations Management Competitiveness of SMEs in the manufacturing industry in the metropolitan area of Guadalajara?

Additional questions

What factors intervene in the management of operations in manufacturing SMEs in the central-western part of Mexico?

Is it possible to identify key processes for optimal management operations in the organization and deal with the changing environment to be competitive?

TABLE 4: INTERNAL CONSISTENCY AND CONVERGENT VALIDITY OF THE THEORETICAL MODEL

Variable	indicator	factor loadings	t-Robust value	A de Cronbach	IFC	IVE
Automation	PA1	0.776***	1.000*	0.807	0.808	0.583
	PA2	0.776***	18.768			
	PA3	0.739***	15.472			
Reliability	PCI_A	0.639***	1.000*	0.818	0.820	0.604
	PC2_A	0.839***	15.179			
	PC3_A	0.792***	14.951			
Control of Operations	PO1	0.749***	1.000*	0.877	0.876	0.542
	PO2	0.796***	18.707			
	PO3	0.648***	12.958			
	PO4	0.797***	17.911			
	PO5	0.748***	15.777			
	PO6	0.667***	13.527			
Personal Development	PD1	0.709***	1.000*	0.887	0.897	0.688
	PD2	0.832***	17.305			
	PD3	0.933***	19.612			
	PD4	0.828***	14.626			
Financial Performance	FP1	0.782***	1.000*	0.914	0.915	0.729
	FP2	0.895***	19.825			
	FP3	0.883***	20.492			
	FP4	0.851***	18.844			
Costs	PC2	0.747***	1.000*	0.843	0.845	0.580
	PC3	0.793***	13.501			
	PC4	0.847***	17.925			
	PC5	0.644***	12.192			
Technology	TE1	0.775***	1.000*	0.913	0.914	0.638
	TE2	0.817***	22.461			
	TE3	0.817***	18.706			
	TE4	0.826***	18.905			
	TE5	0.746***	15.540			
	TE6	0.809***	18.157			
S-BX ² (df373=894.9570 (p < 0.000), NFI=.888; NNFI=.919; CFI=.931; RMSEA=.059						

Parameter constrained to this value in the validation process*** = p < 0.001

Therefore, the results of applying the AFC are presented in Table 4.4 and show that the model provides a good fit of the data (S-BX²= 894.9750; df = 1321; (p < 0.0000); NFI = .888; NNFI = .919; CFI = .931; RMSEA = .059). Also, Cronbach's alpha and IFC exceed the value 0.70 recommended by Nunally and Bernstein (1994), which

refers to the rate of the extracted variance (IVE) was calculated for each pair of constructs, resulting in a higher than 0.50 IVE (Fornell & Larcker, 1981). And for evidence of convergent validity, the results indicate that the AFC all items related factors are significant ($p < 0.001$) and the size of all standardized factor loadings are greater than 0.60 (Bagozzi & Yi, 1988).

Regarding the indicators most relevant factor or more we have to load into the variable indicators include automation as automation (PA1) has automated production processes (PA2), has machinery that uses some software, which infer that the fact of having an automated process directly impacts the cost, increasing the reliability of the product as well as adhere to the planning in the preparation thereof.

Related to other indicators, administrative control of operations, note that the factor loading more records are: (PO1) has a statistical process control of production; (PO2) has a letter of process control; (PO3) has a plan for maintenance of machinery and equipment, we infer that directly affect respect to financial performance, once the projected financial statements have reliable support, whether it is possible to fulfill commitments with customers and deal with the volumes of production, both in quality and delivery times. For as regards the maintenance, it will not become a cause for backwardness.

TABLE 5: DISCRIMINANT VALIDITY OF THE MEASUREMENT OF THE THEORETICAL MODEL

Variables	Automation	Reliability	Control of operations	Personal development	Financial performance
Automatización	0.583	0.671	0.777	0.640	0.210
Reliability	0.501,0.841	0.604	0.851	0.751	0.2610
C. Operations	0.593,0.961	0.665,1.037	0.542	0.9140	0.3360
P. development	0.466,0.814	0.573,0.929	0.716,1.112	0.688	0.3060
Financial P.	0.096,0.324	0.157,0.365	0.222,0.45	0.194,0.418	0.729
Costs	-0.053,0.171	0.059,0.259	0.018,0.23	0.018,0.23	0.172,0.356
Technology	0.382,0.682	0.346,0.618	0.446,0.746	0.391,0.683	0.193,0.401

Regarding the evidence of discriminant validity, the measurement is provided in two forms that can be seen in Table 5. Since, with a confidence interval of 90% of confidentiality, none of the individual elements of the underlying factors of the correlation matrix contains the 1.0 (Anderson & Gerbing, 1988). Another point to note is extracted variance between the two constructs is greater than 0.50, taken from Table 4 that references the index variance extracted (IVE) (Fornell & Larcker, 1981). And based on these criteria it is concluded that the different measurements to model demonstrate sufficient evidence of reliability and convergent validity

Results

Finally to obtain the results statistics research hypotheses, a structural equation model (MEC) was performed using the same variables to check the model structure and get the results that allowed contrasting hypotheses, using for this the software and above EQS 6.1 (Bentler, 2005, Byrne, 2006; Brown, 2006).

As well as, the nomological validity of the theoretical method was analyzed by the Chi square test is the fundamental measure, where the final value of the adjustment function or minimization measure is the chi-square (Lévy et al . 2005); whereby the theoretical model was compared with the adjusted model. And the results indicate that no significant differences are good theoretical model in explaining the relationships observed between the latent constructs (Anderson & Gerbing, 1988; Hatcher, 1994). These results of the application of MEC are presented in Table 6.

TABLE 6: RESULTS USING STRUCTURAL EQUATIONS

Hypotheses	Estructural relationship	Factors loadings	T-robust value	Measure of the FITs
H1: A greater automation lower production costs	Automation → Competitiveness	.288***	.1711	S-BX ² ₍₃₇₃₎ = 894.757 P=0.000 NFI=.888
H2: A greater control of operations increased financial performance	Control → Financial development	.279***	.1577	
H3: A greater management operations increased competitiveness	Management → Competitiveness	0.736***	.3288	NNFI=.919 CFI=.931 RMSEA= 059

In the results table of the application of MEC appreciate where we refer to the hypothesis H1 regarding the results ($\beta = 0.288$, $p < 0.001$) indicates that automation has significant positive effects on competitiveness. Assuming H2 results ($\beta = 0.279$, $p < 0.001$) indicate that control of operations have significant positive effects on competitiveness. And finally with the latter hypothesis H3 results indicate ($\beta = 0.736$, $p < 0.001$) than the management of operations have significant positive effects on competitiveness. In the above table the results of the application of MEC appreciate where we refer to the hypothesis H1 regarding the results ($\beta = 0.288$, $p < 0.001$) indicates that automation has significant positive effects on competitiveness. Assuming H2 results ($\beta = 0.279$, $p < 0.001$) indicate that control of operations have significant positive effects on competitiveness. And finally with the latter hypothesis H3 results indicate ($\beta = 0.736$, $p < 0.001$) than the management of operations have significant positive effects on competitiveness.

Analysis and discussion

Automation currently plays an important role in business, because, once the processes are automated or support in software support activities, the goals can be met with regard to: quality, on-time delivery and the quality of the finished product, which directly impacts costs.

Since, compared to the results obtained in the statistical and factor analysis corroborated the views expressed by the various authors in the theory experts in the variables investigated; where manufacturing SMEs in the Metropolitan Zone of Guadalajara, consider that automation has significant effects on the implementation of cost reduction. With this budgeted reaffirms H1: a greater automation lower production costs.

In regards to the administrative control of operations, all attributes of this variable were accepted by the interviewees as elements to consider that the product met in terms of contributing to increase the profit margin. Identified as key elements were: statistical process control, have a preventive maintenance program, as well as exceed the expectations of customers in terms of quality. A further important point is the fact of working with suppliers to meet the input requirements of quality. With the above complies with H2: a greater administrative control of operations increased financial performance.

H3: the higher management operations increased competitiveness. If by definition, operations management refers to the control of resources flowing into a process properly structured, with the idea of adding value to fulfill the goals of the organization and make it happen in an environment that generates higher profits competition, this study reveals that, at least in manufacturing SMEs in the Guadalajara metropolitan area itself is true.

Branded apps for high-involvement products: the results of an empirical study

Abstract

In the ecosystem of digital environments, the new communication policies of Inbound Marketing allow companies to reach their customers in a more effective way (Halligan and Sheh, 2010). A common feature of those policies is the pull-type consumption model of messages.

Among the wide range of communication channels available for disseminating these messages, the mobile plays an important role since cell phones have by now become 'an extension of the consumer'.

In particular, branded mobile applications enable companies to implement pull-type communication, by offering customized content that also helps to create brand engagement. Bellman et al. (2011) define branded apps as *"software downloadable to a mobile device which prominently displays a brand identity, often via the name of the app and the appearance of a brand logo or icon, throughout the user experience"*.

The aim of this paper is to investigate the propensity of firms to use branded apps in their communication policies. The studies conducted thus far on branded apps are still in their infancy and further research is needed to gain in-depth understanding of how applications can be implemented and used in marketing strategies (Mobile Marketing Association, 2009).

Given the aim of the study, a qualitative method will be adopted; it will consist of two steps: an analysis of the state of the art of branded apps in a sample of Italian industrial firms and an analysis of some meaningful case studies, through in-depth interviews. In particular, the focus will be on high-involvement products, such as furniture.

Introduction

Internet has changed the way consumers interact with brands and the diffusion of mobile devices has contributed to this trend. Smartphone penetration on total mobile audience has reached 64% in the EU5, with a maximum of 74% in Spain and 71% in the UK (ComScore, 2013), and 60% in the United States (ComScore, 2013).

Mobile channels have provided the market with the connectivity and context-aware search capability, which enables brands to target and interact with consumers on the go, as well (Deighton and Kornfeld, 2009; Crosett, 2012). Mobile channels have a unique target potential, as mobile devices are personal, location-aware, interactive, and always with the consumer (Khan, 2012). This enables brands to reach their target market anywhere, at any time with a tailored message (Vernali and Toker, 2012; Khan, 2012).

Research on mobile marketing is in its early stages (Persaud and Azhar, 2012). The conducted research is still very scattered across disciplines (management, marketing, information technology, finance, etc.) and fragmented; also, our understanding of mobile marketing is lacking (Varnali and Toker, 2010; Shankar and Balasubramanian, 2009).

Among the different mobile marketing formats there are branded applications that can be used by firms to implement a pull-based marketing communication. The mobile applications market is growing¹, but most of the branded apps prove unsuccessful (Dredge, 2011). How and why brands implement branded applications is therefore of interest and more research is needed to gain an in-depth understanding of how applications are and can be used in the marketing strategy.

Moreover, much of the research is still focused on push-based mobile marketing, such as SMS and mobile advertisement (Holland, 2010; Drossos et al., 2007) and there is still a lot to explore regarding pull-based mobile marketing, such as branded applications. The latter are still in their infancy and further research is therefore needed to explore best practices (Mobile Marketing Association, 2009) and to gain insight into the phenomenon and its concepts (Ghauri and Gronhaug, 2005).

So, the aim of this paper is to contribute to filling this gap by investigating both the propensity of firms to use branded apps in their communication policies and the strategies behind their implementation.

Given the explorative and descriptive nature of this study, a qualitative method will be adopted; it will consist of two steps: an analysis of the state of the art of branded apps in a sample of Italian industrial firms and an

analysis of some meaningful case studies, through in-depth interviews. In particular, the focus will be on high-involvement products, such as furniture.

Customer involvement in a product category is widely recognized as a major variable affecting a firm's advertising strategy and its effectiveness (Dahlen et al., 2010). For high involvement products, a customer searches for more information, engages in more active behavior, is more interested in evaluating alternatives, and devotes more attention to the advertising messages.

Branded apps can be an effective tool when used to meet the customer's informational needs and to stimulate more interaction with the brand.

This paper is structured as follows: after a brief review of the literature on mobile marketing and branded apps in particular, the empirical research findings are presented and some managerial implications highlighted; finally, some ideas for future research are proposed and the limitations of the study discussed.

The rise of mobile marketing and branded applications: a literature review

Nowadays the spread of mobile devices (laptops, tablets and smartphones) has reached a level that cannot be ignored by marketers and firms. People view their mobile phones as extensions of themselves (Bellman et al., 2011): something they cannot live without and which allows them to be in contact with anyone, anywhere, and at any moment. So, mobile devices have become a powerful tool which firms could use to create a constant connection with the customer.

Consequently, the amount of academic research on mobile marketing has grown very rapidly in the past few years, the majority of which is focused on the following issues (Varnali and Toker, 2010):

- the mobile consumer's behavior (Persaud and Azhar, 2012), the objective being to explain the adoption of mobile marketing, starting from individual-level characteristics;
- the conceptualization of mobile marketing and m-commerce from a theoretical point of view;
- the strategy of formulating a mobile business model.

Mobile marketing is defined as «a set of practices that enable organizations to communicate and engage with their audience in an interactive and relevant manner through any mobile device or network» (Mobile Marketing Association, 2009). This type of interactive communication is provided by four aspects which characterize mobile devices:

- *Location specificity*: a GPS system inside mobile devices could define the physical location of the user. This aspect allows marketers to target location-sensitive promotional offers to mobile device users (Shankar and Balasubramanian, 2009).
- *Portability*: the ultra-small size and the ease with which it can be carried make a mobile device a constant companion to the user and allows it to be used on a continuous basis (Shankar and Balasubramanian, 2009).
- *Untethered/wireless feature*: the typical mobile device is not tethered or connected by wires for the majority of the time that it is in use (Shankar and Balasubramanian, 2009).
- *Customization*: they are extremely adaptable to the customer's tastes. Users can choose what content and what functionality to download to their device (Boaretto et al., 2011).

These features offer great potential for understanding a customer's preferences and quickly advertising customized products or services (Tang et al., 2013).

Mobile marketing can be implemented using different tools:

- SMS, MMS;
- mobile advertising;
- mobile site;
- QR code;
- mobile applications.

Some of the characteristics of these formats are summarized in Table 1.

TABLE 1: DIFFERENCES AMONG MOBILE MARKETING FORMATS

Format	Type of communication	Objectives	Advantages	Disadvantages
SMS, MMS	Push	<ul style="list-style-type: none"> - Lead generation - Conversion - Customer retention 	<ul style="list-style-type: none"> - Little planning effort required - Extremely viral 	<ul style="list-style-type: none"> - Must opt-in - Perceived as intrusive by users
Mobile advertising	Push	<ul style="list-style-type: none"> - Awareness - Reputation - Conversion 	<ul style="list-style-type: none"> - High visibility on the small screen of the mobile device - High rate of click through 	<ul style="list-style-type: none"> - Perceived as annoying by users - High level of accidental mobile clicks
Mobile site	Pull	<ul style="list-style-type: none"> - Customer experience - Conversion - Brand awareness 	<ul style="list-style-type: none"> - Visibility in mobile search engines - Compatibility across any device - Flexibility of upgrading 	<ul style="list-style-type: none"> - Internet connection always required - No integration with all the mobile device features (camera, GPS, address book)
Branded app	Pull	<ul style="list-style-type: none"> - Engagement - Customer experience 	<ul style="list-style-type: none"> - Unique user experience - No Internet access required - High level of integration with all the mobile device features 	<ul style="list-style-type: none"> - Not accessible on all devices - The app updates must be submitted and approved by the app store every time
QRcode	Pull	<ul style="list-style-type: none"> - Lead generation - Engagement - Customer experience 	<ul style="list-style-type: none"> - Integration between traditional offline communication and online communication 	<ul style="list-style-type: none"> - Download of a QRcode reader required - Lack of awareness by the user

Among these tools, mobile applications present some distinguishing characteristics that can create a new realm of possibilities in mobile relationship marketing and in the engagement of the consumer (Chiem et al., 2010). Bellman et al. (2011, pp. 191) defined branded apps as *software downloadable to a mobile device which prominently displays a brand identity, often via the name of the app and the appearance of a brand logo or icon, through the user experience*. They implement a *pull-based mobile communication* in contrast to other tools (such as, SMS, mobile advertising) that implement a traditional *push-based mobile communication*. Push-based mobile communication consists of any content sent by, or on behalf of, marketers to a mobile device at a time other than when the subscriber requests it. On the contrary, pull-based mobile communication refers to any content sent to the mobile subscriber upon request, or shortly thereafter, on a time basis. So, with branded applications the firm doesn't need to get the user's permission in order to send the marketing content. It's up to the customer to talk to the brand, not the firm which contacts him through his device. In this case, customers are only exposed to the apps they opt into by downloading them and they are also able to control what personal information they want to reveal when customizing the app (Bellman et al., 2011).

It has been shown that companies can use apps to create personalized content, thus promoting brand engagement and giving the device an actual and sustainable utility (Chiem et al., 2010), rather than simply creating brand awareness by sending text messages to the customer (for example, with an SMS). This last practice is totally inappropriate as a way to engage the user who not only perceives mobile communication by text-messages as annoying and irritating, but also sees it as an intrusion of his/her privacy. As Watson et al. (2013) have demonstrated, users consider mobile handsets to be extremely private, something they use for their own personal reasons, so they don't like to be contacted by companies this way. Users have a positive attitude, instead, towards brands that offer useful and entertaining apps. In contrast to the other forms of advertising, branded apps are welcomed by customers because

they are useful and it is they who choose to download them (Bellman et al., 2011). In fact, both smartphone and iPad users spend the majority of their time (respectively 87% and 76%) using mobile apps (Nielsen, 2013).

Branded apps are an effective form of advertising that influences the customer's attitudes and purchase intentions. In addition, branded apps also increase interest in whole categories of products. Therefore, they can be a useful medium for educating people about new categories which they have not yet tried (Bellman et al., 2011).

Nevertheless, branded apps do not have all the same effectiveness. For example, apps with an informational style are more effective at shifting purchase intention, compared to apps with an experiential style (Bellman et al., 2011). This happens because the informational style focuses attention on the user and encourages him/her to make a personal connection with the brand, while the experiential style focuses attention on the phone. Furthermore, a recent study by Kim and Lee (2014) investigates how subjective characteristics, such as beliefs, values, attitudes, evaluations, preferences, and tastes of smartphone users, influence the preferred type of mobile communication. They found four different groups of mobile users: *The Business Partner* prefers cross media ads and mobile web banners, but hates Social Network ads; *The Skilled Enthusiast* fancies in-apps, QR, Localization Based Service ads and mobile web banner ads, but does not like streaming, e-book and coupon ads; *The New Experience Seeker* prefers coupon ads and streaming media ads, but hates mobile web banners or map ads; *The Close Buddy* prefers Social Network, coupons, map ads, cross media ads, but dislikes QR.

Recently, some authors have also turned their attention to the branding design elements that must be present when developing a mobile application, namely brand name, brand logo, brand design (including typeface, layout, colors, stimuli), brand content (including imagery, copy, relationship feature, sound and video). Visual design elements strengthen the brand image, resulting in the improvement of brand loyalty, brand satisfaction and brand equity (Magrath and McCormick, 2013). It is suggested that these four elements act as a pillar of information and help the consumer to recognize the brand values linked to the mobile app. Thus, all brand channels should be consistent and utilize, for example, the same font, colors and presentation style in order to form an identifiable entity (Okonkwo, 2007).

Finally, it is important to underline the differences between a mobile branded app and a mobile site, which are often confused. The choice for a company is whether to develop a mobile branded application or to create a corporate website that is optimized for smartphone views. These two formats differ in four main areas (Boaretto et al., 2011):

- *dependence on device*: branded apps are totally dependent on the operative system they are designed for; mobile sites are device-independent, they are available on the Web and accessible from all devices;
- *presence of Internet connection*: in contrast to mobile sites, branded apps do not need an Internet connection in order to be used;
- *interaction with the device*: mobile sites are not supposed to interact with all the functions of the device. On the contrary, branded apps can have complete access to the hardware components of the device, such as camera, address book, etc.;
- *visibility of the brand*: mobile sites benefit from the visibility provided by keyword advertising and search engine optimization (SEO), while branded apps are less likely to be seen by the customer. Their promotion has to follow different rules, connected to visibility inside App Stores.

As stated in the introduction of this paper, the type of product being marketed can influence the communication strategy's effectiveness and the choice of the most appropriate tools to carry it out. For example, more Internet users click on banner ads for high involvement products than do on banner ads for low involvement products, because they then search for more information and clickthrough increases positive brand attitude and brand purchase intention for high involvement products (Dahlén et al., 2010). By contrast, attitudes and buying intentions are less favorable when an SMS is used to advertise a high-involvement product compared to one for a low-involvement product, because of the limited quality and quantity of information that an SMS can communicate to the user (Drossos et al., 2007).

In general, for high involvement products (such as furniture) customers search for more information, engage in more active behavior, are more interested in evaluating alternatives, and devote more attention to the firm's content. The purchase process is longer and they perceive more risk. In this context, the aim of the firm's communication strategy should be to provide useful information as well as service, and to educate the customer, rather than simply

creating brand awareness (Dahlén et al., 2010). A good app can convey a lot of relevant and timely content to the customer, in an original form and so, help the users to best appreciate the product and brand. In addition, an app that satisfies the expectations of its target would encourage a more frequent interaction with the brand and thus, more engagement.

Mobile apps in the Italian furniture industry: an empirical analysis

Research methodology

The research can be divided into two different steps.

Step 1) A descriptive and quantitative analysis of the existing situation of the mobile branded applications market in the Italian furniture industry.

In order to measure the level of adoption of this marketing tool by the selected sample, a longitudinal analysis was conducted, consisting in a comparison between two different time periods, December of 2012 and February of 2014. The aim of this phase was to monitor the mobile branded applications market and record its changes from a quantitative point of view. The sample consists of the one hundred companies with the highest turnover in the Italian furniture industry. In order to create the sample, the AIDA² database was used and companies identified according to the ATECO³ 2007 codes.

The analysis included the following variables.

a) *The number and the type of applications developed by each firm.* The search was limited to the two main App Stores on the market nowadays, in terms of shares of revenues and number of applications: iTunes and Play Store⁴. Since there are no consolidated models at present, the app classification was based on two different dimensions, the function and the content of the app (Figure 1).

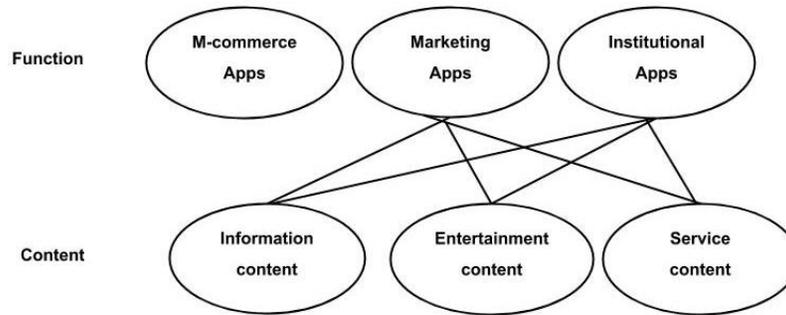

FIG. 1: CLASSIFICATION OF APPLICATIONS

The first dimension identified three different categories of applications:

- *M-commerce applications*: apps with clear commercial objectives that allow the user to purchase directly from his/her mobile device;
- *Marketing applications*: apps designed for the promotion of the brand, the product or the service and directly related to the final user;
- *Institutional applications*: apps developed to communicate the company's values to all the stakeholders. They include applications relating to the company's profile, mission and initiatives.

The latter two categories were subjected to another characterization based on their content and they were divided into:

- *Apps with information content*: the application provides useful information about the company, the brand, the nature and the use of the product or service. The level of interaction with the customer is low or, in some cases, totally absent. This category includes, for example, apps which describe the product, display catalogs, show company services, and so forth;

- *Apps with entertainment content*: apps which use activities, games or other entertainment tools in order to engage the user in an active and unconventional way. The relationship with the customer reaches high levels of interaction, motivated by the pursuit of leisure;
 - *App with service content*: the application aims to provide varying degrees of usefulness to the customer. The level of interaction with the user is generally high and it could be for anything from simple services, such as the Store Locator, to more complex services, such as product customization by the user .
- b) *The operating system chosen*: iOS and/or Android.
- c) *The mobile device* for which the application was made: smartphone (iPhone or Android Phone) and/or tablet (iPad or Android Tablet).
- d) *Integration with the corporate site*, measured by the presence in the company's web site of a link (or something similar) referring to the mobile application.

In addition, for each of the 100 companies of the sample, the creation of an optimized website for mobile use was verified. The *optimization of the site* refers to a website that is perfectly viewable and navigable from any type of device (mobile or desktop).

Step 2) A qualitative study carried out through the analysis of three case studies.

The analyzed cases are included in the sample of the 20 companies operating in the sector, that have developed at least one mobile application⁵. They are three medium-sized and large firms in the Italian furniture sector, with different positioning and target markets. Company A and Company C are designed for a niche of high-income consumers, by offering high-quality and hand-crafted products; they are historical Made in Italy brands. Company B, instead, is positioned transversally, with products that appeal to a wider market which also includes less well-off consumers; the brand has a high reputation in the Italian market, where it made 80% of its turnover, thanks to widespread distribution throughout the territory. The other two firms are more export-oriented, with a percentage of turnover generated abroad exceeding 50%. Their product is different, too: the core business of companies A and C lies in the manufacture of upholstered furniture (plus other complementary goods) while Company B's core activity is kitchen and bathroom furniture. As a final point to note, Company C is part of a group of companies which includes other furniture brands.

The people in charge of communications for these companies were interviewed about the firms' digital communications strategy and mobile marketing. The interviews were conducted following a semi-structured design based on open questions. All the interviews were recorded so the authors could transcribe the material.

Results of the descriptive and quantitative analysis

The results of the first step are presented in Table 2.

TABLE 2: RESULTS OF THE DESCRIPTIVE ANALYSIS

	2012	2014
no. of companies with at least one app	13 (13%)	20 (20%)
Total no. of apps	19	28
no. of iPhone apps	11 (57.9%)	17 (60.7%)
no. of iPad apps	17 (89.5%)	26 (92.8%)
no. of Android Phone apps	4 (21%)	6 (21.4%)
no. of Android Tablet apps	5 (26.3%)	7 (25%)
Total no. of iOS apps	18 (94.7%)	27 (96.4 %)
Total no. of Android apps	7 (36.84 %)	8 (28.57 %)
no. of companies with at least one app among the top ten	1 (1%)	2 (2%)
no. of companies with at least one app among the latest 15	4 (26.7%)	4 (26.7)
integration with the corporate website	10 (52.6%)	12 (42.9%)

Between 2012 and 2014, the number of companies that have developed at least one application has risen from 13 to 20, while the total number of apps has grown to 28, an increase of seven. Despite the slight increase, the numbers are

still quite low (only 20% of companies have developed an application). From these findings, we deduce that *companies are still reluctant to incorporate this tool into their mobile marketing strategies.*

Regarding the choice of operating system, in 2014 there is a clear prevalence of iOS (96.4 %) over Android devices (28.57 %). This gap is greater than the surveys for 2012 showed, when the percentages amounted to 94.7% and 36.84 %, respectively. The new applications, in most cases, were carried out only for Apple devices. This data appears to be in contrast to the evolution of the OS market, since Android has by far surpassed iOS in both number of sold devices and market share⁶.

Many companies today are probably using the iOS platform for two reasons:

1. iOS is more “traditional” and companies are more aware of how it works and how to use it;
2. iOS allows them to identify a certain type of target population; in fact, it is known that iOS is used mostly by people of the upper-middle class. Android, instead, is used on both up-market and low-market smartphones and it is used by people of many different classes. This gap is probably also due to the fact that the process of technology adoption is different between consumers and companies because of the lack of competences and investments in terms of budget by the latter.

The number of applications developed for tablets is greater than for smartphones, and this hold true both for iTunes and Android. This aspect of mobile marketing highlights how the furniture industry can reap the benefits of the bigger screen of a tablet, since it can provide a much clearer visualization of products and catalogues, compared to the small screen of a mobile phone.

Another important aspect that emerged from the study is that among the top ten companies classified by turnover, only one (in fifth place) has its own app, while the company ranked first in the industry still does not offer any app. The situation changes for those ranked lower in the sample where there are four companies with at least one app; so, it appears that smaller companies are more aware of an apps’ potential than the biggest ones are.

Moreover, only 12 out of 20 companies have integrated the app with their corporate site, where there is a space dedicated to the promotion of the application, sometimes through a direct link to download it from the Store.

Finally, 19 out of the 100 companies were able to achieve full optimization of their website, in order to be viewable from any mobile device. They are not the same ones that developed a mobile application. Therefore, it appears that the two formats are considered either/or options by businesses.

The findings of the study concerning the characteristics and functions of the applications are presented in Table 3. There is no m-commerce application for either year and there is only one institutional app. Therefore, companies opted for a marketing app with an information content. The catalogue-viewing function is predominant among all applications and it appears to be an alternative to downloading the brochure from the company’s corporate website. This means that mobile branded apps can have important implications as far as delivering information to the user in every touch-point with the company and in every stage of his/her relationship with it.

TABLE 3: CLASSIFICATION OF APPLICATIONS

	2012	2014
no. of marketing apps	18 (94.7%)	27 (96.4%)
no. of institutional apps	1 (5.2%)	1 (3.6%)
no. of m-commerce apps	0	0
no. of information content apps	16 (84.2%)	25 (89.3%)
no. of service content apps	2 (10.5%)	2 (7.1%)
no. of entertainment apps	1 (5.3%)	1 (3.6%)

This could be a consequence of the high involvement nature of the furniture product, which is not purchased very often and implies high prices. In order to reduce the complexity and the perceived high risk, customers require a lot of information before completing the purchase. For this reason, it is important to offer them the right tools to ensure an adequate level of information from both the quantitative and qualitative point of view. The nature of the product also partly explains the absence of m-commerce apps; in fact it is rather unlikely that the consumer will purchase a

kitchen or a bathroom from his mobile device. In this case, the contact with the retailer becomes essential and is directly connected to the complexity of the product.

Results of the three case study analyses

Digital communication and mobile strategy

The three surveyed companies are different in both the adopted digital communications strategies and in the level of integration and importance of the mobile communication strategy within the firms' communication policy.

Companies B and C can be placed in two opposite positions, while company A is located in an intermediate situation.

Company B is still tied to a traditional type of communication, where web and mobile play a marginal role; it prefers the offline channel and traditional advertising, such as print, radio, billboards, TV, that still carry a heavy weight in communication investments. This is the result of an involution in the digital policy of the company, which entered the Web in 1990, with the creation of the corporate website and the use of different banner and display campaigns. Nevertheless, it gradually reduced investment in online channels, because of some unsatisfactory results obtained. The site is optimized for mobile devices; however, this choice is not linked to a particular strategy or designed to achieve specific goals or targets, because the site itself it is not one of the corporate communication strengths.

On the opposite side, company C is strongly embracing the new means of communication and makes the mobile the main strongpoint of its strategy. In its sector it has been an early mover for online and mobile communication. This is coherent with its competitive positioning, based on innovation as well as on quality and the design of its products. The digital and mobile strategy of the company has changed over the last year as a result of the strategic decisions made by the Group; they went from a common and integrated Group-wide strategy, which aims to enhance the identity of the group rather than any single brand, to a more individual strategy which aims to restore the identity of each of the three brands in the Group; as a consequence, now every brand site and every branded mobile application has a distinctive language, content, look and feel.

In addition, last year, significant changes to the mobile strategy were also made; the core of this strategy is no longer the branded app but the responsive website optimized for mobile devices. This choice is due to the fact that, at the end of 2013, for the first time the accesses to the website from mobile devices (60%) exceeded those from desktops. The creation of an optimized mobile site has become a necessity derived from the request of the consumers, the operators, the agents and the retailers who use the site both as an informational and a business tool. The company has therefore decided to continue to serve the Apple channel, through the application, but focusing its mobile strategy on the website, viewable from any device.

For company C the mobile has become the main tool for creating a connection between offline and online channels. In fact, in its showroom and in all other exposures it just started to use NFC tags and QR codes on its products; these codes allow anyone to download a data product sheet onto their phone and share it on social networks.

Company A is in an intermediate situation, somewhere between the previous two. As stated by the interviewee, the company has always carried Print advertising campaigns, centering around newspapers and public relations, but they have recently started using the Web: corporate website, presence on social networks (Facebook, Pinterest, GooglePlus, LinkedIn, YouTube) and a mobile application. Hence, the mobile strategy is part of a larger process of opening up to digital communication, which began with the redesign of the corporate website structure, constantly updated and whose main objective is giving information. Furthermore, the site structure has been made more fluid and responsive to viewing from any type of device. Even in this case, just as for company C, the choice to create an optimized site was made based on the big growth of accesses recorded from mobile devices.

Characteristics of the applications

Companies B and C have developed only one mobile application, while company A is present on the market with two apps. However, only one of these apps has been the subject of the study, because the other one was designed for the showroom in 2012 and will soon be taken off the market.

The characteristics of the three applications are presented in Table 4.

TABLE 4: MAIN CHARACTERISTICS OF THE ANALYZED APPS

	Company A	Company B	Company C
Release date	2011	2012	2009
Operative System	iOS, Android	iOS	iOS
Device	Tablet Smartphone	Tablet Smartphone	Tablet Smartphone
Technological nature	Native	Native	Native
Target	BtoB (sales force and agencies)	BtoB (agencies)	BtoC (consumers) BtoB (agencies, sales force, retailers and architects)
Classification	Marketing app with information content	Marketing app with information content	Marketing app with information content

Motivations, objectives and targets

Table 4 shows that companies A and B have developed applications for BtoB users, while only company C has expanded its target to consumers and architects.

In the case of Companies A and B, the app development was driven by the demands of their sales force and agents who needed an efficient and practical working tool which would enable them to consult the catalog at any time without physically carrying it and regardless of the availability of an Internet connection. The objective was therefore to provide an effective tool to support sales. However, in the case of company A the app is usable and downloadable by anyone, including the consumer, from the Apple and Play Store.

Company C differs substantially from the others; its target is a lot wider:

- sales network, which requires a responsive and inexpensive tool for the presentation of products and the updating of catalogs;
- architects and interior designers, who require support for their design work in terms of access to product information and images;
- consumers.

The main objective of the application developers was twofold: on one hand, they wanted to meet the demand of various company customers, from a service point of view, by offering a tool with high added value that would facilitate their work and the product sale; on the other hand, they wished to enhance customer engagement through the use of an innovative tool, and then make him want to come to the store. The decision to develop a mobile branded app was also supported by the company's desire to be perceived as "innovative". The communications team member interviewed said in this regard: "we are strongly oriented towards innovation, with a pioneering communication; so we wanted to convey the idea that we are also leaders in the digital industry."

Contents

All three apps have been categorized as marketing applications with information content because of the predominance of information related to the product and the brand, rather than to other content.

However, it must be underlined that Company C is a particularly complex case, as its app also delivers, in addition to the purely informative content (for example, the product catalog), an entertainment and especially, a service type of content, albeit in a lesser amount. The entertainment content is supposed to emotionally involve the final customer through the use of some engagement tools, such as virtual factory tours, while the service content is associated with the presence of the Store Locator and the 3D configurator. The app created by Company C, compared to the two other company apps, appears much richer in order to adapt to its three different targets. Nevertheless, the company is trying to streamline the contents and transfer them to the optimized website.

In Company A, the branded application and the website have the same content, except for the Store Locator which is only implemented on the site but not in the app: the purpose of the company is essentially informative. In

particular, the application contains sections related to products, designers, news, photo gallery and allows the user to create his own 'wish list'. The strength of the application, as the interviewee says, is to be constantly updated in terms of content so that users are able to know all the news concerning the products, their technical specifications, and the communication policies promoted by the company. The company B's app is similar in terms of content characteristics in that there is a product catalog, brochures, video tutorials, etc. The strength of the app, however, is its ability to provide customized content to agents, including official communications from the company.

Operative System and Technological nature

Of the three cases, company A is the only one to release a mobile application for both Android and iOS. The choice is clearly explained by the digital communications manager: "Making a choice to serve some users and not others is a wrong choice. Moreover, looking at our customers and our markets, we noticed that Android is the most popular one. Especially in our sales force, a lot of agents don't have an Apple device but they own a Samsung. Not to mention that this brand is highly preferred in China and Android seems to dominate throughout the East. For this reason we decided to make a double effort at the beginning of the development process, but once you make this initial effort, it is something that remains with the company forever."

For Company B, the choice was imposed by the web agency itself, which developed the application only for Apple devices.

Company C, also, decided to make an application for the iPhone and iPad only, and has so far not shown any desire to enter the Android market. The choice in this case is solely derived from the consistency between its target and the Apple target, which in both cases is composed of people with a high income, often foreigners (non-Italians) and people who appreciate innovation and high end technology.

All three apps are native apps which allow access to all of the functions of the mobile device to which they are downloaded. These types of apps could also work offline and, unlike the web app, ensure a higher quality of user experience, since they are optimized for a specific platform and device. On the other hand, they imply a much higher initial investment in their development.

In all three cases, the app implementation was delegated to a web agency, while the company maintained the internal control over the content and the possibility of updating the app. This is possible thanks to the use of CMS systems (content management system). However, it is worth pointing out that Company B displayed a more passive attitude towards the app development process; the external web agency was predominantly in charge of the initiative.

Results of applications

As it emerges from the three interviews, there are some difficulties inherent to measuring the results of the branded application. Due to the fact that apps are a communication tool and that none of the three companies has an e-commerce channel, it is difficult to establish quantitative metrics that can associate the increase in sales with the growth in downloads. However, the results deriving from the use of this mobile instrument have been judged satisfactory by all three companies.

Main findings, managerial implications and limitations of the study

The objective of this research was twofold: 1. to analyze the propensity of firms to use branded apps in their communication strategies; 2. to explore the reasons why and the way some firms are already using them. The research was focused on Italian furniture firms which are characterized by the sale of high-involvement products.

From the quantitative analysis it emerged that companies are still reluctant to incorporate branded apps into their marketing strategies, as shown by the fact that only 20% of the sample has developed at least one branded app. This could probably be due to the nature of the industry, which is not web-oriented and still connected with traditional push-based communication. From the three analyzed cases it emerged that commitment to mobile communication goes hand in hand with commitment to digital communication in general: mobile and digital communication are seen as integrated and complementary. As a result, Company B, which prefers a traditional type of communication, attributes a marginal role to both digital and mobile communication. The opposite happens for the other two companies and in particular, for Company C.

The limited role assigned to the new means of communication by Company B could be due to its different market target, from both a geographic and strategic point of view, as it is more focused on the Italian market and addresses a wider (mass) market. On the other hand, Companies A and C are more export-oriented and aim to reach a global niche of high-spending consumers who, compared to Italian customers, are more likely to use these new technologies and are more sophisticated in their use. Smartphone and iPad are becoming the primary tools that foreign users adopt to search for products and make purchases. The use of branded apps could become an effective tool for companies that want to reach international markets. The nature of this research does not allow the Authors to draw definitive conclusions about this aspect and so, future research could verify the existence of a relationship between export intensity and propensity to use mobile apps (or mobile sites) through a quantitative survey.

The conservative orientation of Italian furniture firms is confirmed by the choice of the Operating System: 96.4 % of the total apps are designed for iOS devices, while only 28.57% for Android. The fact that this trend has increased over the last two years is one of the most important findings of the research. Firms continue to not consider the Android target in their mobile marketing strategy, even if nowadays it represents the widest app market in the world. From the three cases analyzed, it emerges that the preference for iOS derives from the increased knowledge and experience of use that companies have for iOS compared to Android. Moreover, the process of technology adoption is different between consumers and companies. While from the consumer's point of view the OS market is changing faster, from the firm's point of view the process is slower, because of the need to develop new competences in the emerging technologies. In the specific cases we have analyzed, the iOS preference is also due to the correspondence between the Apple target and the companies' target. The choice of Operating System is strategically important and management must be aware of the target users' preferences.

The study has brought to light that firms look at branded apps and the mobile site as alternative choices. In fact, in the majority of the cases, firms which developed the app did not make their website optimized for mobile viewing. However, these two formats have different characteristics and they allow the firm to reach different goals. Therefore, for companies it would be better to implement both formats. However, this strategy requires high investments and a choice is often forced by limited available resources; in this case, the decision makers have to identify the firm's objectives early on and then, choose the right formats in order to achieve them. This was the case in Company C which changed its focus from app to mobile site in the last year.

A useful contribution made by this paper is the app classification model which is based on two different dimensions, i.e. the function and the content of the app. This model makes it possible to identify the characteristics of the branded apps. The results show that the companies opted for a marketing app with an information content. This result is in line with Bellman's (Bellman et al. 2009) findings, i.e., the informational style of app is more effective at shifting purchase intention than are apps with an experiential style. Branded apps could be used to deliver useful information to users in every touch-point with the company and in every stage of the relationship. This is true, in particular, in high-involvement products, for which the decision process is complex and risky. Branded apps could become a useful tool when adopted to vehicle company and product information to the customers who would now be able to access the information anytime and anywhere. This way of using branded apps would ensure that the company can improve the customer experience and decrease the perceived risk. Actually, in the three analyzed cases the apps are designed to facilitate the company's relationship with the customer in the pre-purchase stage, rather than in the transactional and post-purchase phase. This is evident in the case of Company C, whose app intentionally addresses BtoC users but also in the other two cases, in which the app's target is clearly BtoB. In these latter two cases, the objective is to provide those who must interface with customers (intermediate and final) with the most effective tools and materials to present products and to influence the consumer's selection process. The results of the study confirm that for the high-involvement products the app's goal is not to create brand awareness, but to provide information and services, and to educate the customer. It might be interesting to investigate low-involvement products in order to identify different strategies and different uses of branded apps compared to high-involvement products.

The research also drew attention to another type of branded app, business-to-business apps. The past literature concentrated primarily on mobile applications for the consumers. This study, instead, shows how apps could also be an effective support tool for the sales force. First of all, the catalogue function solves the problem of space which affects the furniture industry; with a digital catalogue, retailers and agents could show the entire range of products to

the customer, without having to physically carry or display them in the store. Secondly, the app is a means of direct communication which allows the company to send tailored messages to their sales force and constantly update them.

A problem related to the use of branded apps emerged from the qualitative analysis, however, and that is the lack of quantitative metrics to measure the apps' return on the investments. In fact, even if companies could know the number of downloads of their app, nowadays there is no established method that allows firms to monetize this type of strategy. Therefore, further research is required in order to define a pool of quantitative metrics that can help managers to measure the results, especially in the case of apps other than m-commerce apps.

As regards the limitations of the study, the research method does not allow the generalization of the findings, but this was not the aim of the paper. It was to explore the current situation and the role of branded apps in firms' marketing strategies, in order to contribute to filling the gap in the literature, which is scarce and mostly focused on push-based mobile formats.

End Notes

¹ According to Gartner (2013), in 2012 annual downloads of mobile apps reached 64 billion, with a total revenue of \$18 billion. This trend is not expected to stop in the future: mobile app stores will see annual downloads reach 268 billion in 2017, with a total revenue of \$77 billion, growing at a rate of 27% a year between 2012 and 2017.

² AIDA is a database which contains comprehensive information on companies in Italy, with up to five years of history.

³ ATECO 2007 is the classification of economic activities, adopted in January 2008 by ISTAT. This classification is the national version of the European nomenclature, Nace Rev. 2, published in the Official Journal of 20 December 2006 (Regulation (EC) no. 1893/2006 of the European Parliament and of the Council of 20 December 2006).

⁴ Google and Apple with their operating systems (respectively Android and IOS) cover 70% of the European market and 93% of the US market (ComScore, 2013a).

⁵ For privacy reasons, the companies' names will not be mentioned.

⁶ According to the latest IDC report (February 2013), Android and iOS together made up around 95.7% of all smartphone shipments in the last quarter of 2013 (up from 91.2% in the year ago quarter). Android has grown more rapidly than iOS. As of last quarter, Android reached almost 80% of that 95.7% and shipped close to 800 million of the billion smartphones shipped during 2013, compare to iOS which held 15.2% of the market share and shipped 153.4 million units in 2013.

Analyzing Brand Values with a Semiotic Approach

Analyzing Brand Values with a Semiotic Approach

Abstract

In the current competitive context consumers wish and exchange signs rather than objects, thus the trade and the exchange of products are being progressively replaced by the trade of signs, symbols and messages, intangible brand benefits that exceed the goods value in use. From this point of view, consumption becomes a language with its rules and its syntax. In order to favor the dialogue between different disciplines interested in the study of brand, this paper proposes a structural semiotic approach to investigate the coherence of a brand communication mix. Different studies on brand share a tendency to emphasize the symbolic and intangible aspects of the brand. We believe that semiotics, a discipline that extends the laws of structural linguistics to the analysis of verbal, visual, and spatial sign systems and focuses on the intangible dimension of texts, will contribute to the study of the brand and the “possible worlds” communicated.

Introduction

In the last fifty years, branding has become a core aspect of marketing and business strategy¹. As a modern concept, branding can be applied to everything from products and services, to companies, countries and even individuals, to produce an emotional and a psychological attachment with consumers and a financial value for the brand owner. Many studies on the topic have appeared in several disciplines and the concept has been progressively stretched beyond the product or service to emphasize the symbolic and intangible aspects of a brand. There is now a consensus that the brand occupies a strategic position between the issues that companies need to manage daily (Semprini and Musso, 2000: 439). The most innovative aspect is nevertheless the growing importance of the intangible elements such as references, symbolic paths, effects of meaning evoked by the brand. Indeed every brand possesses the characteristics of identity, promise, value and differentiation, features that create a relationship between the consumer and the brand. This stems from the consumption context, where the *symbolic value* overrides the *value in use* of the objects. Consumption becomes increasingly communication, image, and less and less function (Marrone, 2007). Brand-owners aim to exploit the symbolic content of their bid, charging it with added meanings to communicate with a consumer very different from the past, who considers products as means to express his identity. Products become signs, symbols and convey multiple messages.

The brand is a central element in the new competitive environment. From simple tool to ensure the product reputation and credibility, it becomes the absolute protagonist of the economic scene, the “intangible asset par excellence”² (Semprini and Musso, 2000: 65). It constitutes a framework of meaning around the product, gives him a cultural and social thickness, and at the same time makes it unique and multi-dimensional (Semprini, 1993: 59). The brand no longer has the tasks of presenting the product and convincing about its qualities: on the contrary, it gradually dissociates itself from the product and starts telling narrations, “based on the staging of *possible worlds* able to attract consumers” (Semprini, 2003: 105). These worlds are often configured as true parallel worlds, woven of values which consumers can decide to join, as the “solitary manliness of Marlboro, the discreet elegance of Armani, the conviviality of Buitoni, the seduction of Levi’s”³ (*ibidem*). The competition between products is therefore enriched with the competition of brands worlds, each of one has the aim of achieving customer loyalty. The crucial problem of the company is to establish a strong, distinctive, seductive brand image. The brand produces worlds, specific universes of reference, and these ones animated and gradually expanded over time (*ibidem*: 26).

In particular, with the advent of postmodernism brand emphasizes its emotional characteristics to establish a new type of bond with the consumer. In this regard Fabris and Minestrone (2004), in their work devoted to the brand, speak of the sensory and emotional values of the brand and their significance in building a lasting relationship with consumers. Marketing Aesthetics, Experiential Marketing, Emotional Branding, are new kind of marketing indicating the reorientation towards the emotional and affective contents of the brand. The experience, senses and imagination channels becomes new paths to access people wishes, transcending the mere materiality of the object and its tangible benefits. The mere functionality of a brand is not sufficient if it is not always enriched

with a *sensory experience* (Ferraresi and Schmitt 2006). Consequently brands should be able to provide consumers with highly emotional experiences, able to create a deep and immediate interaction and to relate effectively to the market (*ibidem*: 82).

Consumption as a language

In parallel to the increasing importance of the brand in corporate strategies, communication and sense gradually become part of the brand-core, giving centrality to semiotics and other disciplines interested in the study of communication. From a semiotic perspective, objects have communicated a universe of meanings since ancient times: we can think of the expressive value of a dress, of body decoration, but also of a sword, helmet or armor. Through the selection or the use of an object, people expressed moods, desires, hopes and identities. However in postmodern society the product performance is exceeded by the semiotic meanings of objects (Semprini, 2003) and “the space that goods have in the semiotic universe is no less important than that they occupy in the shelves of sale”⁴ (Fabris, 2003: 49). The world of objects, for consumers, becomes a reservoir of symbols, a possible narration of their identity, thus an “engine of belonging”. The food, a dress, a cosmetic have partly lost their primary function (their *value in use*) to become communication. For example, behind the purchase of a sports car there can be the promise of youth or manhood; behind the purchase of a perfume there can be seductiveness, and so on. In this perspective, advertising has a role that goes beyond its traditional marketing function because, compared to a virtual polymorphism of objects, it helps to narrow the field of possible meanings, to select those most culturally current and desirable and to fix them on the object.

An example of how the value in use of an asset tends to be progressively obscured by a symbolic value is given by the motorcycle: in this regard Fabris (2003: 80) highlights how the traditional motivation for using this means of transport has given way to symbolic nature gratifications, such as courage and individualism. Riding a motorcycle takes on the meaning of conventions challenge because through this means people can go away from the usual paths, passing motorists slowed by traffic queues. Only those who have courage and quick reflexes can ride a motorcycle: with a motorcycle a man wins admiration and respect without entering into direct competition with others, and becomes a free man, for whom the rules and the common laws don't work. In the new scenario the motorcycle becomes a real cultural symbol, a myth fed by a vast filmography focused on extraordinary characters, like Steve McQueen in *The Great Escape* or Marlon Brando in *The Wild One*.

Another example done by Fabris is about the jeans that emphasize, in addition, the continuous process of *de-semantization* and *re-semantization* that accompanies the use of certain products. Initially, jeans were the uniform of the miners, railway workers and all those who were in need of a practical, economical and durable garment: they didn't wear jeans for ideological reasons, but only for working. Over time, then, jeans began to take on different meanings depending on the changing historical periods: the primacy of free time, sexual liberalism, as opposition to the clothing models of the time, the statement of informality, and so on. In the eighties jeans changed meaning and are integrated into the system and normalized, remaining strongly associated with youth culture. Even high fashion designers begin to draw jeans, presenting them in a highly customized and branded version, or as an inter-generational means, worn by men and women of all ages and repurposed in a myriad of versions which, in some cases, become a real cult product of mass consumption (for instance Levi's 501).

At the base of the new interpretation of consumption there is a process of *dematerialization of society*. What was once called the consumer society is becoming the less materialistic society never existed, where the value in use of an asset tends to be progressively overshadowed by its symbolic value (Fabris 2003: 68). On one side we see the increasingly miniaturization process of the products, ever lighter and smaller and smaller, and the shift to a service economy; on the other in postmodern society products become signs, a form of language that has its own internal rules and conventions. This implies that we can communicate even making use of the new alphabet of objects: we consume signs before products, and we prefer to invest in new forms of sociality, structured around emotions, passions and feelings to live together in the space of consumption.

Semiotics and Marketing

Because of the growing complexity of consumer behaviors, brand-owners look for new analytical tools, as the phenomena of consumption become more symbolic and cultural and the traditional tools of investigation tend to be less effective (Semprini, 1990: 39). As a result of changes in the competitive environment contacts between semiotics and marketing have become more frequent and systematic. On one hand, semiotics plays an increasing important role within marketing as a guide to intangible and social aspects of communication. On the other semiotics shows a renewed interest in disciplines such as sociology, marketing and ethnography, confirming its operational as well as theoretical nature.

The first semiotic approach to the marketing research was carried out by Jean-Marie Floch in the Nineties. Floch (1990) analyzed a number of cars advertisements and tries to understand the different ways in which the object machine can be enhanced. Four types of possible valorizations emerge from his analysis:

- *Practical valorization*: corresponds to the values of use, conceived as opposing the existential ones, also possible to be designated as “utilitarian values” (Floch, 1990). Its aim is eminently concrete and utilitarian and the product will be appreciated for being practical, functional and adequate to its function;
- *Utopian valorization*: corresponds to the basic values, conceived as opposing the practical ones, also possible to be designated as “existential values”: identity, life, adventure, etc. (Floch, 1990). According to this valorization, the product will always be the accomplishment of something, touching expectations such as self-fulfillment or identification;
- *Ludic valorization*: corresponds to the denial of practical valorization and centers itself on values of gratuitousness (of pleasure or aesthetic) such as luxury, refinement, impulsive act or “small act of madness” (Floch, 1990: 120). It lays at an emotional and sensorial level, the product having to provide pleasure, amusement;
- *Critical valorization*: corresponds to the denial of the utopian valorization, seen as a withdrawal from the existential values through the logic of calculation and interest, characterized by separation and comparison (Floch, 1990). Quality/price, economy, innovation/cost will be important criteria, frequent in critical evaluation.

These fundamental values are projected on the semiotic square as portrayed in Fig. 1:

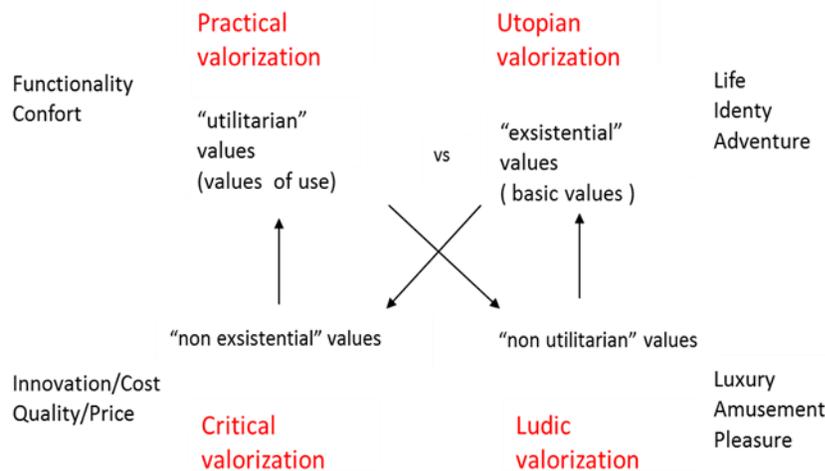

FIG. 1

The positioning of these valorizations in the “semiotic square” allows one to obtain a typology of the relative positions and, even more importantly, of its relationships. This produces four classes which represent all the possible
