TABLE 2: MAJOR MANUFACTURED PRODUCTS.

Main products	number of companies
Electronic Components	20
Auto Parts	6
Tools and electrical and electronic materials	4
Computer equipment	1
Medical Instruments	1
Total	32

Source: Authors.

Most of the companies involved in the production of electronic components, representing 62.5% of the total sample, followed by the industries that produce parts for the automotive industry with 18.8%, in third place are the industries that engaged in the production of electrical and electronic accounting for 12.5%.

On the other side and to know the situation of companies in terms of organizational development to the stage of progress in its administration system, they were questioned about the existence of methods and software used. According to (Lilia Domínguez, 1999), she defines three levels of corporate culture: high, which houses the companies with the following systems, total quality, Material Requirements Planning (MRP), Statistics process control, continuous improvement program and supplier development program.

In the middle lie those with two or three of the previous programs and the level under which they have implemented only one or none of them (see Table 3)

TABLE 3: LEVEL OF CORPORATE CULTURE.

Company size	Number of enterprises according to their level of business culture			
	Large	Small	Total	Average

Large	15	0	15	3
Medium	10	0	10	3
Small	2	4	6	1.66
Micro	1	0	1	3
Total	28	4	32	2.66

Source: Authors.

The electronics industry average is above the average, very close to the high level, this is because the vast majority of companies surveyed are large or medium and all of them with a high level of corporate culture, due to market demands and the competitiveness that is handled within the media, thereby completing the first objective of this particular work.

The company and the environment

The use of natural resources is a fundamental part in the production process, hence the importance of their management. In this sense, water resources and waste management represent significant environmental aspects in companies in the electronics industry, so it is important to know what happens to the water they use and what happens to the waste generated. In this regard, water is an important element of e-business in its production process as this vital fluid is used as a solvent or mixture directly and indirectly in the washing and cooling processes (see Fig.No. 2).

FIG.NO.2: MAIN ROLE OF WATER IN PRODUCTION PROCESSES.

Source: Authors.

As shown the three major water uses are as a continent or means of transportation, in operations such as washing and cooling processes, the magnitude of the discharge varies with the size of the company, and in some cases such as operations cooling water does not undergo any chemical or biological contamination so that it can be reused in another process. In the case of using water as a continent or in the washing operation is necessary that these processes are carried out as efficiently as possible to avoid waste, it also requires that some form of water treatment to reuse. In this regard, the business activities carried out in order to maximize the use of water, with the following systems (see Table No.4).

TABLE 4: WATER TREATMENT SYSTEMS USED IN COMPANIES.

Systems used	Number of companies	Average
Recycling system	3	9.4
Water recirculation system	5	15.6
Water Treatment System	9	28.1
System has no	13	40.6
Using the 3 systems mentioned	2	6.3
Total	32	100.0

Source: Authors.

Treatment systems reduce water pollution, once the activity has been the water is discharged to drain. Recycling systems treat water and allow reuse in companies in their production processes or the irrigation of green areas.

As shown in Table 3, the most widely used system is the water treatment, as just over 28% of companies indicated that they have this system. 40% of the industries do not have any water treatment systems or water recycling, however a large portion of them do not use water in their production processes. It is important to know the relationship between the companies if they use any of the above systems and the size of the company which according to the results of the survey was obtained as follows (see Table 5)

TABLE 5: SYSTEMS USED TO MAKE MORE EFFICIENT USE OF WATER BY COMPANY SIZE.

Systems used	Company size			
	Large	Medium	Small	Micro
Recycling system	1	2	0	0
Recirculation system	3	2	0	0
Water Treatment System	6	3	0	0
System has no	3	3	6	1
Using all the above schemes	2	0	0	0
Total	15	10	6	1

Source: Authors.

The large and medium enterprises are those with some system that allows them to maximize the use of water, only two companies have made investments that enable them to have all the required systems and is known as small and micro industries do not engage in any activity and carry out investments that reduce water use.

To determine the intensity of care of the water was analyzed based on the results of the questionnaire and providing an idea of what has been the environmental performance of industry in Jalisco. Are three ranges of intensity of care: high with three points that correspond to the companies that have reduced water consumption by reducing their cost and have more than two programs or systems in place to improve efficiency in water use within this range are only two companies, representing eight percent of the total sample surveyed. In the middle two points are located the company that have at least one program and also gained economic benefits due to the investment, they account for 40.0%. And finally in the lowest level are firms that do not have systems to maximize water use and these are the 52% of all industries surveyed (see Table 6).

TABLE NO.6: INTENSITY OF CARE IN USING WATER EFFICIENTLY.

Intensity of care	Number of companies	average	Score
Slow	13	52.0	13
Medium	10	40.0	20
Added	2	8.0	6
Total	25	100	39
Average			1.56

Source: Authors.

The average of all firms surveyed by the number of points obtained is 1.56, indicating that on average maquiladora electronics industry industrial corridor of El Salto, not even have a medium level in terms of intensity care in the

efficient use of water, so it is necessary to implement actions to improve this situation. However, despite the low average score, it is pertinent to note that it is undertaking a major change in business and that some of them have been conducting activities to promote the rational use of water, which indicates an improvement in culture business already mentioned.

On the other hand, in the process of production of the electronics industry generated among other liquid wastes such as solvents, sludge, processed water, paint and ink and wash water. For purposes of this analysis, questioned the companies selected in the sample if liquid waste generated and what was available to them (see Fig.No. 3).

FIG. 3: ARRANGEMENT OF LIQUID WASTE.

Source: Authors.

As noted, just over half the companies surveyed did generate liquid waste, most of the latter, 37.5% are sent to a detention facility, to contract these services companies were detached from the responsibility to adequate treatment of waste and they are handled with greater control of pollution by the contractor. 9.4% of the companies reuse their waste in other processes, holds 6.3% of water treatment and then be discharged to the drain and only 3.1% directly discharged to drain.

According to company size, are large and medium who generate liquid waste, but they who are responsible both to treat, recycle or send a company authorized this waste. Small and micro businesses do not generate waste and only one of them replied downloaded directly to the drain as shown below (see Fig.No. 4).

FIG. 4: ARRANGEMENT OF LIQUID WASTE BY FIRM SIZE.

Source: Authors.

As mentioned, the electronics industry is a major source of water pollution, however, the use of this resource in their production processes and waste generated from them, they become significant environmental aspects, thus giving effect to the provisions of the second specific objective of this work.

The company and compliance with environmental legislation

It is necessary for companies to become aware of environmental problems that generate the whole production process, for it is required to know what the law is demanded of these economic units. In this sense, the survey yielded information about the regulatory framework for companies located in the GMA electronic, almost 60% said yes, 19% said he was unaware of these standards and 21% of companies did not answer, some argue that because they do not pollute, do not know what the regulations, and does not apply to your industry.

Of the companies that know the environmental standards, 13 companies replied that they consider reasonable standards, four of them seem vague and only two companies believe the regulations imposed by the government is demanding. In this regard, the authority makes periodic visits to evaluate the environmental performance of companies and monitoring that they are giving to the rules imposed. The results are as follows (see Table 7).

Answer	Number Os Companies
yes	24
No	7
Did not answer	1
Total	32

Source: Authors.

The vast majority of companies if an environmental nature are visited by government institutions, however, they are not regular or constant, in some cases they "visit" is solely in filling forms and not a review depth of production processes. This can be advantageous for both parties, but is deteriorating environment, therefore, necessary that government intervention is more efficient in this area, and otherwise does not comply with current environmental regulations. Regarding environmental training programs, that enterprises had questioned them, the results are very encouraging as shown in the illustration (see Table 8).

TABLE 8: COMPANIES THAT HAVE ENVIRONMENTAL TRAINING PROGRAMS.

They have a training program	Average
Yes	53
No	47
Total	100%

Source: Authors.

As shown in the table above, just over half the companies if they have an environmental training program, the rest has not been doing any activity that allows employees to know what actions could be done to help protect environment and prevent deterioration. Regarding the knowledge that companies have on the potential sources of pollution that might eventually generate in the water, it was found that the majority, 62.5%, if they have an inventory or known pollution sources, the rest (37.5%) have not made or are in the process of doing, some argue that it is not necessary because within their production processes are not performed polluting actions.

For all the above, the degree of compliance with existing environmental legislation is poor and the authority is partly responsible for this failure, a situation that requires both the government and the company meet this requirement of law for the benefit of society. With the above points are answered in the third specific objective of this work.

Environmental Outlook

An important point of analysis is to determine which companies are doing today to preserve and improve the environment. For this they are asked about some variables and perspectives that they had in the future. Questioned about it on the main environmental problems of a future, interestingly, most companies (53.1%) said not to provide any (see Fig.No. 5).

FIG. NO. 5: VISION OF THE FUTURE ENVIRONMENTAL PROBLEMS.

Source: Authors.

In this question, it's interesting that most companies do not provide for any kind of problem in the future, this is because the vast majority of respondents who answered this option are thinking only of your company as production unit, have no an overview of what happens in your environment, if your company pollutes or uses too much water, then, respondents felt that there will be no major problem in the future.

This point is important because the company apparently has not become aware of their role in the surrounding environment, and though while every economic manufacturing units are responsible for their own actions, should also be aware that belong to a economic group, and that their participation in this group must be active, and that the actions of one affect the other, and if others are not doing anything for scarce natural resources, this short-term impact on all companies .

31.3% of companies surveyed expected to require more control by government authorities, this is very important because if you work efficiently, can help solve environmental problems and the need for natural resources, besides awareness among businesses about the damage caused due to the production process, trying to make the change due to a change of culture and not only for meeting standards imposed. For 6.3% of companies indicating a problem, and which can be very serious, is the fact that there are few options for disposing of waste, this may jeopardize the improvement of waters in the state, and that media companies may opt to be avoided, so the participation of both industrial and government seems to be urgent. Another problem is that companies must absorb the cost of implementing technologies that allow them to efficiently use water or any other natural resource.

With regard to the future prospects of the companies on pollution control investment was found that the vast majority of respondents, ie 65.3%, felt that tend to improve or increase, to 15.1% investment will be equal, ie only large companies will be those who make the bulk of investment in pollution control equipment and programs and only 3.1% believe that investment will be lower in the future. The remaining companies do not know what will happen (see Fig.No. 6).

FIG. NO. 6: PROSPECTS FOR POLLUTION CONTROL INVESTMENT.

Source: Authors.

According to the results obtained by the survey, the companies anticipate that the relationship between government and business will continue as now good overall, according to the following (see Fig.No. 7).

FIG.NO. 7: PROSPECTS FOR THE RELATIONSHIP BETWEEN BUSINESS AND GOVERNMENT

Source: Authors.

Although for 75% of companies surveyed (24 companies), the relationship for the future between them and government institutions will be good, only 15 companies replied that the standards imposed are reasonable, for the 9 remaining companies are demanding standards and imprecise. Which indicates that companies would be hoping for an improvement in their relations, so it is compulsory for the government both federal and state and municipal plans are developed to enable them to work together with industrialists in order to achieve change corporate culture, and if

the state of Jalisco vocation is to belong to the manufacturing industry, then it must carry out actions that have clean industries in harmony with the environment, ie that development is sustainable for the benefit of all .

In this last and how compliance with the provisions of the fourth specific objective of this work, we recommend that the electronics industry located in the industrial corridor of El Salto, a holistic approach to environmental management and uncompromising commitment to social responsibility, which have the infrastructure necessary for the preservation of the environment, which simultaneously boost economic growth in the region but will include stakeholders with subsidiarity and strategic vision, relevant aspects of sustainable development.

PROPOSALS

No activity is free to generate environmental impact or arouse criticism from environmental groups, why the concern for the environment is a social and legal requirement that every company must address. In this sense and according to the results, the relationship is established between the electronics industry located in the GMA and environmental management which allows then to propose strategies for improving performance under a sustainable framework, as stated the overall goal of this research.

- According to information obtained and compared to the first specific objective of this work, it has good corporate culture, environmental management information placed in a prominent place, but be aware that this is not relevant if not used in solving problems, hence the company has the inescapable ethical obligations to dispose of it for society as a whole. The products and goods that are designed, will have to consider much more seriously its recycling capacity or revaluation at the end of its life cycle, ie the life cycle analysis must increasingly become a standard tool. In this regard, and given that these organizations have the right tools to influence an environmental culture both internally and externally, should adopt a proactive attitude of respect and care for the environment that allows you to make all parties concerned are their allies and carry out conservation efforts of nature, which undoubtedly will be the backbone of the company's future interaction with their environment.

- We identified two significant environmental aspects of water use and waste generated in production processes as noted in the second objective of this work, is you must have a social attitude bent on saving and conserving water for which must go beyond legal compliance in this area. Authorities are required for regulating water consumption, if it exceeds a certain amount every month should be forced to the ground to try and reuse this resource in order to avoid waste. It is necessary that both industrial society and consider that water is an economic good that must be used efficiently and rationally. The wastewater treatment is another alternative that should continue to promote more broadly for all companies in the industry. Wastewater recycling is saving support in every way, since the possibilities of use of treated water are very broad and can be used by the sector in its processes such as cooling and cleaning and irrigation of green areas. Similarly, there must be a constant search for innovation and development that would reduce its maximum waste generation.

- The questionnaire used, information was obtained on the third objective of this work in establishing a poor compliance with environmental legislation, the construction of a new model of growth of Jalisco, should promote a comprehensive and sustainable regional development primarily engage the industry to fully comply with current legislation, and promote the engagement of all sectors in specific tasks to ensure its realization for the environment. In particular territorial policy must go beyond a strictly regulatory approach and must become a process of promotion and induction of private and public investment in infrastructure and financing sustainable development in the region of El Salto de la ZMG in particular, which is one of the hardest hit state. This vision must include all municipalities, especially the least developed, for the purpose of having greater financial and administrative capacity, enabling them to aspire to higher standards of welfare and progress. That is, the state administration should build a management system that promotes inter-sectorial coordination, social participation and intergovernmental

competition for society as a whole. For this, it plans to establish environmental policies that protect and ensure the sustainable development of natural resources of the state and especially the GMA and that public opinion, ie the citizen, requires companies to act properly and in compliance with the law.

- Finally in the fourth specific objective of this work establishes the environmental commitment to be getting the electronics industry to be socially responsible in a sustainable framework; In this regard it must be recognized that environmental problems are externalities that must be corrected, this amounts to achieve those who generate environmental damage costs the bear, which can be achieved through various means including the establishment of regulations and their enforcement, persuasion and cooperation or through economic instruments. The latter are meant that officers receive appropriate signals from the price system to incorporate in its objectives or functions of well-being permanent motivation for sustainable management of natural resources and reduce pollution and waste generation, so that This will decrease the inherent negative environmental effects. It is therefore proposed to develop a new tariff system which pays more than the most consumed, even if it exists, it is desirable to review and amendments thereto providing for environmental pollution, which encourage the different sectors to use if the process allow treated water or treat water used and of course meet the waste generated by giving them a proper and sustainable disposal.

CONCLUSIONS AND RECOMMENDATIONS

Conclusions

Industrial development has resulted in the depletion of natural resources and pollution of air, water, soil and biodiversity of the planet, a situation that was raised at the summit meeting of the United Nations held in 1972 in Stockholm, Sweden and recognized until 1987, when through the Brundtland Commission established the concept of sustainable development, defined as development that meets the needs of the present generation without compromising the needs of future generations.

On the other hand, development and environment are not only not opposed but are two different aspects of the problem and acquire a new dimension to sustain that economic growth is fundamental to social welfare only when it is extended under the framework of development sustainable. In this regard, the maquiladora is a significant development in countries and regions of the same venues and Jalisco is no exception, but of course, keeping a strict respect for the environment.

In this sense, this paper presents the relationship between executive management in the electronics industry located in the GMA and the receiving environment, which met four main aspects and the present situation that each saved due to the continuous physical exchange . In this exchange are used primarily natural water resources with its various uses including various types of discharges and waste generated during the production process of these companies.

An important result is the fact that there is a regulatory framework which should be adjusted industrial and has enabled them to somehow give a partial fulfillment for the environment.

As I can see, the electronics industry does not significantly contaminate the water used in their production processes; however, these companies use a large quantity of this vital liquid, a situation that should be considered as a relevant factor in environmental management to propose immediate solutions thinking sustainability as a way of life and future. In this regard, and as a result of this study, we propose strategies that lead to efficient resource use and waste reduction. That is, they must take concrete actions to increase efficiency in the environmental management and it is immersed in the overall management of the company, because according to (Mercado García, 1999, 221) "To the extent that reflects a waste pollution raw materials and energy, we can say also that a company

that has systematized his accounts and has launched programs in production management with continuous improvement and training programs designed to reduce wastage and improve quality of life of the goods produced, have a greater technological and administrative capacity to identify and solve environmental problems "

Recommendations

Knowledge of environmental management that are electronic companies established in the GMA, is a topic of interest, since it will depend on the measures to be taken into account by businesses and by the authorities in the field, to the effect that will continue with the state's economic growth without damaging the Santiago river basin and therefore compliance with the foundations of sustainable development meeting the improvements that impact on the harmony of the environment and hence on the quality of life of citizens.

An important point which has drawn attention, is that most respondents do not foresee any future environmental problem, because your company does not pollute or do not know. In this regard, employers in the electronics industry should be aware of their social responsibility and future, therefore it is essential that government intervention will generate information and lead the company's relationship with universities and schools of the place, course involving society in general.

As noted, the preservation of the environment by employers depends on a number of factors not only internal to the company, but some of them are external, such as stakeholders. While it is true that their actions such as improving their production systems to prevent waste is essential, and largely solves the problem, also the role of government is essential to promote this change in environmental management and there must be clear rules and consistent with the objectives that were intended to reach and all that is completed.

It should be emphasized that environmental management must be an aspect of business and must be integrated into the daily practice of company management, environmental management must be part of the overall business system that includes organizational structure, responsibilities, practices, procedures, processes and resources that determine the performance and company policy.

Questionnaire administered to the electronics industry located in the metropolitan area of Guadalajara, Jalisco, Mexico with regard to management and environmental policy.

1. ORGANIZATIONAL PROFILE AND DEVELOPMENT

1.1 Name of company:

1.2 Business Size : ___ Large ___ Medium ___ Small ___ Micro

1.3 Main line products manufactured

1 _____

2 _____

3 _____

1.4. Indicate whether the company has:

a) Quality Systems total _____

b) _____ MPR Systems

c) Statistical Process Control _____

d) Continuous improvement programs _____

e) Supplier Development Program _____

f) Other (specify) _____

1.5. Does the company have a formal job training program?

Yes ___ No _____

2. BUSINESS AND THE ENVIRONMENT

2.1. Processes to nest where they use more water

Product 1 Product 2 Product 3

Cooling ___ Cooling ___ Cooling ___

Continent____ Continent____ Continent____

___ Middle Settlement Middle Settlement Middle Settlement ___ ___

Mixtures____ Mixtures ____ Mixed____

Washes ____ Washes ____ Washes ____

Other_____ Other_____ Other_____

2.2. Does the company with an inventory of potential sources of contamination?

Yes___ No_____

2.3. What is your current water consumption (monthly, yearly, per unit of product, etc.)

2.4. Total volume of water discharge (average daily, monthly, etc.).

2.5. Has this consumption from the company had to comply with environmental standards?

Yes_____ No_____

2.6. Have you made any investments to make changes in consumption?

Yes___ No_____

2.7. Did you get any advantage in terms of cost reduction?

Yes___ No_____

2.8. The company have:

a) A recycling system _____

b) Recirculation _____

c) _____ Water Treatment

2.9. Liquid wastes are generated:

Yes___ No_____

2.10. How to have them?

3. THE COMPANY AND COMPLIANCE WITH ENVIRONMENTAL LEGISLATION

3.1. Does the company have a training program on the environment?

Yes_____ No_____

3.2. Please state environmental standards or other environmental regulations in their field:

3.3. As regards these rules: Reasonable_____ Exegetes_____ inaccurate or confuses_____

3.4. Does the plant meets the requirements beyond the environmental standards of its industry? Yes_____ No_____

3.5. "The plant has received regular visits for environmental?"

Yes_____ No_____

4. ENVIRONMENTAL OUTLOOK

4.1. How is your biggest problem of environmental impact in the future?

4.2. What is your opinion about the future of pollution control investment in your industry?

4.3. How expected to be the future relationship between the company and the authorities responsible for environmental policy?

4.4. Do you consider that compliance with environmental standards affect competitiveness?

Comments

Appendix No.2

Simple random sampling method

Is to select a sample of size n from a population of N units, where each element has a probability of inclusion and known as n / N . This method has the advantage of being simple and easily understood, for it was used the following formula, which is useful to calculate the sample size in finite populations. For its calculation we have the following equations:

$n' =$ provisional sample size = sample variance

population variance

Corrected later with other data, in line with population size

$n = \text{Sample size} = n'$

$1 + n' / N$

Where:

n: Sample size

N: Population size

Z: Value for the Gaussian distribution for $\alpha = 0.05$ 1.96

In this case we find that the standard error (I) was 15% and an occurrence Probability 50%

Then:

$I = 0.15$

$P = 0.5$

Through the Maquiladora Industry Association of the West, were able to confirm that in the Guadalajara metropolitan area was established until 2008 approximately 126 companies engaged in electronics production. Therefore took this as our universe. Then with the total population size (N) of 126 companies. The data were taken into account to obtain the sample size are:

Variable	Data
Z	1.96
A	0.05
P	0.5
Q	0.5
$I^{(IV)}$	0.15
Sample size	32

$n' = n' = 43 = 43 = 32 \text{ sample size}$

$1 + n' / N = 1 + 43/126 = 1 + 0.3413$

Governance and Design in Infrastructure Public Private Partnerships: The Indian Experience with the Bangalore International Airport

*Kalpana Gopalan, kalpanag07@iimb.ernet.in
Indian Institute Of Management, Bangalore, INDIA*

Abstract

Public Private Partnerships are attracting attention in both scholarly and policy discourses. Politicians, policy makers and researchers the world over are talking about them. The growing demand of a vocal public for better infrastructure services, coupled with constrained government budgets, has made PPPs an attractive public policy option. If PPPs are here to stay, we need to learn how to make them work. Academic scholarship has not addressed this imperative, and praxis is still grappling with it. My research proposes to use an integrative framework along with a case study approach to explore the characteristics and issues relating to an infrastructure public private partnership, and the policy processes and institutional structures that will make PPPs an effective and appropriate policy instrument.

My case study of the Bangalore International Airport involves three levels of analysis, national, local and project level. The study will cover three broad thematic areas of PPPs: public interest and accountability, private efficiency and profitability, and organizational and policy design. Borrowing concepts from public policy, economics, organization theory and finance/law, and a practical understanding of policy processes and political realities, i propose to prepare an integrative framework of critical issues relating to PPPs, using the experience of Bangalore International Airport.

PPPs are still a nascent phenomenon in developing economies; this is an area where, “theory is yet to catch up with practice” (Allan, 2001); PPPs have evoked interest in several disciplines, including economics, public policy, law, finance and organization theory. As PPP literature developed separately along conceptual and empirical traditions, with little cross-fertilization between the two, research became less grounded and more speculative in consequence. Though PPPs have evoked interest from several disciplines, each disciplinary tradition examines through its own lens and vocabulary, often resulting in a blinkered vision which ignores vital issues. The fit between theory and practice becomes elusive as the literature continues to follow these independent trajectories. Extant literature largely relates to developed economies, though PPP implications for developing economies are critical. Research which marries the theoretical concept of PPPs to the practice and process on the field, with a developing country focus and an integrative cross-disciplinary framework is therefore essential. This is the gap we propose to fill.

In doing so, we pose the following questions:

- How can we use governance and organization design to achieve public interest and private efficiency in a public private partnership in the Indian context?
- What is the context, actors and institutions and how do they interface with one another?
- How can design and governance elements be used to achieve the desired objective?

Using a qualitative paradigm and embedded case study design using data from archival sources and interviews, the study presents the following conclusions.

- The effective implementation of PPPs requires a shift of focus - from project to process
- PPPs require a second shift of focus-from the firm (SPV) to the partnership,
- PPPs require a broadening of our notion of governance-from the dyadic engagement between the public and private partners to domain-based governance and engagement with society and citizenry.\

I. INTRODUCTION.

Public private partnerships are attracting considerable attention in both scholarly and policy discourses. Politicians, policy makers, bankers, scholars, researchers the world over are talking about them. The growing demand of a vocal public for better infrastructure services, coupled with constrained government budgets, has made PPPs an attractive public policy option. As Greve & Hodge state “PPPs are now an increasingly relevant and popular public policy option throughout In spite of PPPs attracting widespread media attention, there is very little clarity in the public mind about what is a public private partnership. There is certainly no consensus about what outcomes we can expect from a successful PPP, or how we can execute them successfully, not just in the popular or policy discourse but even in scholarly debates about the subject If PPPs are here to stay, we need to learn how to make them work. Academic scholarship has not addressed this imperative, and praxis is still grappling with it.

Hammersley states that all qualitative research should be “relevant to some legitimate public concern” (1992). The purpose of my study is to examine two critical issues in the experience of Bangalore International Airport (hereinafter BIAL). These are (a) the decision relating to the location of the airport and (b) the controversy that broke out to retain the former HAL airport as a civilian airport even after opening of the BIAL. Though divided in time, these interlinked episodes give us an insight into the kind of issues that can arise while implementing large infrastructure PPPs in the Indian context. My approach helps to explicate the contemporary dilemmas that governments face in the changing economic globalized scenario today- balancing the traditional workings of political and bureaucratic practice and tested systems of public accountability to the new, at times conflicting and contradictory, demands of private foreign systems. My work involves three levels of analysis, the national context, the sub-national local context and the project level. Borrowing concepts from public policy, economics, organization theory and finance/law, as well as a practical understanding of policy processes and political realities, I utilize an integrative framework and a case study design to highlight the interplay of forces, actors and arguments in megaprojects such as BIAL.

II. Mapping the terrain: a review of literature.

Scholarly literature on public private partnerships can broadly be categorized into two groups: (a) conceptual pieces that deal with ppps as an economic, and/or organizational entity (b) contextual descriptive case studies of particular projects or policies. The evolution of ppp literature was influenced by three factors: ppps are still a nascent phenomenon in most countries, in particular developing economies; this is an area where “theory is yet to catch up with practice” (Allan, 2001); ppps have evoked interest in several disciplines, including economics, public policy, law, finance and organization theory, but with little cross-fertilization. Taken together, the literature gives us an intelligent and varied perspective on public private partnerships. However, as PPP literature developed separately along conceptual and empirical traditions, with little cross-fertilization between the two streams, research became less grounded and more speculative in consequence. The fit between theory and practice becomes more and more elusive as the literature continues to follow these independent trajectories. Research which marries the theoretical concept of PPPs to the practice and process on the field is therefore essential.

III. The context.

“Understanding the context, political, economic and cultural, in which the case study is embedded, is vital in a world where cultural barriers are becoming permeable” (Kamath, 2006). Around the 1980’s, winds of change swept over the way governments conducted their business. Nicknamed ‘Thatcherism’ and ‘Reagonomics’ after the political leaders who spearheaded it, the new wave was most powerfully felt in the UK and the USA, but left its mark on most countries of the world. India, anxious both to retain its socialist heritage and yet not lose out on the gains of capitalism, adopted a gradualist approach, liberalized its economy in 1991, bringing the public sector down a notch or two from the ‘commanding heights’ of the economy. A growing focus on infrastructure provision to cater to

corporate demands also characterized the new liberalized state. While national policy set the parameters within which growth occurred, sub-national governments began taking advantage of those opportunities for growth. Karnataka in early-2000 was symptomatic of this trend. The new congress government that came to power in 1999 emphasized governance reform, attracting investment and marketization, with primary focus on the corporate sector. A new idea of 'brand Bangalore' began to make the rounds in the 1990s, nationally and internationally.. The creation of a new urban landscape was characterized by certain flagship projects, which "are the material expression of a developmental logic that views megaprojects and place marketing as means for generating future growth and for waging a competitive struggle to attract investment capital" (Swyngedouw, 1989) (Ferguson, 1990) (Swyngedouw *et al*, 2002) (Short *et al* , 1993) (Hall & Hubbard, 1996) (Kamath, 2006).

IV. THE BIAL STORY.

The idea of a new airport for Bangalore was mooted in 1989 by a former director of the state owned national aeronautical laboratories, to meet the growing aviation needs of the city. From 1989 to 2008, the project has seen many changes in elected governments at the government of India and government of Karnataka. The story of BIAL is not over. The project still draws bouquets and brickbats, and litigations relating to the project are pending, this maiden effort at a Greenfield airport for Bangalore is truly rich in its political economy and public policy implications. In the ancient Indian language of Tamil there is a proverb that says: "the elephant alive is worth a 1000 gold coins, an elephant dead is also worth a 1000 gold coins". So also, this project is a repository of lessons, both in its achievements and its mistakes. For a researcher and policy maker, it offers an endlessly fascinating study.

V. PROCESS OF SITE SELECTION.

The Valluri report of 1989, based on a study of air traffic growth in Bangalore and the plans of several international airports, recommended four alternatives to build a new domestic airport. The Civil Aviation Ministry set up a committee in March 1991 under the chairmanship of a former Secretary to Government of India and Chairman of International Airport Authority of India "to examine alternative sites for construction of a modern and futuristic civil airport of international standards of international standards and make suitable recommendations". The committee, which comprised technical members from nal, hal, iaf iaai ,dgca and Indian Airlines; state government secretaries from pwd and Revenue departments, and industry representatives from cie, fkcci, Travel Agents Association of India and Air Cargo Association of India, submitted its report to the centre in June 1992. The contents of the report become especially important in view of latter day allegations in the media that the location decision was made casually and without much thought.

In the period between March 1991 to June 1992, the committee held five sittings in Bangalore on 19th/20th April 1991, 19th December 1001, 19th February 1992, 15th June 1992. In addition, a meeting was convened on 4th July 1991 and attended by members stationed in Delhi. A meeting of the special core group was held on 24th march 1992 in Bangalore to study issues of integrated airspace management. A detailed narrative in the report details the process followed by the committee. Its first step was to lay out the norms for site selection. Broadly, the criteria invoked during deliberations included: the capacity to meet both domestic and international traffic, safety requirements, operation of B-747; constraints of airspace management due to the existence of three airport in Bangalore, a runway length of 14500 ft suitable for airbus -300 and occasional landing of B-747; adequate provision of land area for construction of a parallel runway, taxi-tracks and additional passenger terminals, adequate space for all infrastructures such as 4 to 6 lane express highways, rapid mass transportation systems for access to airports, residential colony for workforce, terminals for international and domestic cargo, provision of water supply for airport and colony, location of oil terminal, a site dimension capable of accommodating a strip 6kmx2.5km, site should meet traffic growth for next thirty years. A formal document of technical parameters was prepared by NAA and provided to the state government

Different site options in the north of Malur, Kengeri-1, Kengeri-2, Vijayapura, south of Devanahalli and Yelahanka, and Kanminike village, near Mysore road, Bangalore south were proposed to the committee, of which two-

Vijayapura and Devanahalli- were shortlisted for inspection. While the committee members conducted ground inspection of the proposed sites-“the entire team walked around these areas”, the HAL member Capt. Ashok conducted aerial. The committee also formed a core group of officials of the NAA (resume of second meeting) to examine the sites in detail after receipt of data from the state government. The core group met on 03.07.1991 and prepared a detailed comparative statement. In pursuance of a suggestion from Dr.Valluri, who was apprehensive of the distance of Devanahalli from Bangalore, the Core Group of Director (Planning), Director (Operations) and Assistant Director (Planning), NAA visited air headquarters on 25.10.1991 and examined the feasibility of Yelahanka aerodrome.

The final evaluation therefore relied on the following: The deliberations of the committee;The spot inspection of committee members;The comparative statement of sites by the core group;Aerial survey by Captain Ashoka;The core group spot inspection and feasibility report on Yelahanka aerodrome site ;NAA’s Proforma for selection of site;The details furnished by the state government;The report on cargo handled at Bangalore air cargo complex;Perspective plan prepared by Indian airlines . The options narrowed down to Devanahalli. This site was 15 km north, north east from Yelahanka air force airfield on highway-7. It was 5 km south of Devanahalli, which was the taluka HQ, commencing in the revenue limits of Yarataganahalli village as its western boundary near the national highway and stretching east-west. The distance from the Vidhana Soudha, the state secretariat building in Bangalore was 29 km. This land was found suitable for an airport of international standards. It had enough land for a terminal building, runways, associated facilities and for cargo, engineering and maintenance base. There was also room for expansion in view of the availability of land. The site was only 29 kms from the central line connected by the National Highway 7 and also served by a narrow gauge rail line which almost ran parallel and adjacent to the national highway at the point where the western boundary of the proposed site ends. It was possible to provide the direct rail links to the terminal building in the proposed site after discussions with the ministry of railways and the state government. If this was done, the feeder services from the airport could be run connecting both the Bangalore cantonment and the city railway stations. This would eliminate to a great extent the need for commuting by cars and coaches to the airport, thus resulting in tremendous savings in fuel.

This is the story of the location decision, the selection and location of the new Bangalore airport in Devanahalli. As we saw, this process took place between 1989-92, and was approved by the government of India in 1994. Now let us fast forward to 2008, the new airport construction is almost complete, and the city and the airport readies for the inauguration after a twenty year wait.

VI. **The HAL airport: to close or not to close?**As the construction progressed and the aod was approaching, opinions came to be expressed through the media, seminars and debates that the HAL airport should not be closed for commercial operations. The union civil aviation ministry gazetted a notification on 16.5.2008 stating that the HAL airport would be closed down on 22.5.2008 midnight simultaneously with the opening of the new international airport at Devanahalli . This became the trigger for the “**Save HAL**” campaign.

Unions and employees associations.Substantial resistance came from the employees union of the airports authority of India. What began as a ‘non-cooperation’ drive became an indefinite nationwide strike of an estimated 18000 employees working at 135 airports across the country. Airport operations across the country came to a halt after talks between the Airport Authority Employee’s Joint Forum and Secretary, Civil Aviation failed and their demand to continue operations of the existing Bangalore and Hyderabad airports was rejected. Though the employees’ union protested privatization of airports in general, it also focused specifically on the development of new airports at Hyderabad and Bangalore by private players, which would eventually result in the closure of existing ones run by AAI. One of the union representatives stated; “our agitation is also in protest over the ongoing privatization of airports by the AAI”.

Corporates. If the unions were the hard muscle, the corporate sector was the suave voice of the protest. Information technology companies in the city represented by Nasscom president, Infosys Vice President, Chief Executive Officer, and Wipro CEO, appealed to the Karnataka chief minister to retain the HAL airport even after the opening of the Devanahalli international airport. In a memorandum to the chief minister during a breakfast meeting, they felt

that retaining the present airport would be appropriate instead of closing down of commercial operations. The federation of Karnataka chambers of commerce and industry president was quoted as saying the “road commuters will be the first to feel the heat. It doesn't make sense to travel for two hours to the airport to catch a 30-minute flight” and that some flights should be retained at the HAL airport, at least till a rail link or a dedicated road is established between the city and Devanahalli .

Private airlines. The media reported that leading private airline operators called upon the state and central governments to re-examine the decision to close the HAL airport to commercial traffic once the Devanahalli airport became functional. Their contention was that not only many global cities have more than one airport; certain flights are best operated out of a facility closer to the city. Managing Director, Air Deccan, apparently representing the private airlines’, confirmed that he was in talks with the government. “Bangalore is a global city, and all global cities have multiple airports. London has five. I met the chief secretary a few days ago, and he indicated he's open to the idea”.

- **Parliamentary and legislative committees.** At this juncture the parliamentary standing committee on transport, tourism & culture was requested to submit a report on privatization and modernization of airport of India. The committee visited Bangalore international airport on 15.9.2008, and conducted wide ranging discussion with various stakeholders including representatives of airport authority employees union. Subsequently it submitted its 142nd report to the parliament titled “functioning of private airports and related issues” which discussed exhaustively the demand for keeping the HAL airport open. The report highlighted several issues: The closure of the HAL airport was not mentioned in the tender for Bangalore greenfield airport and making an offer of closure of HAL airport, after notice inviting tender appears to be a clear violation of the due process; granting permission start a greenfield airport within a radius 150 km of the existing HAL airport, without a passenger sharing formula prima-facie seems to be in violation of the govt. Policy on airport infrastructure; the continuance of the Bangalore HAL airport with the consent of the management of BIAL and govt. Of India shows that if the govt. wants they can operationalize the old airport with notwithstanding the concession agreement; sec.5a of aircraft act 1934 under which HAL airport was notified to be closed talks of danger to the aircraft / country which reason is totally irrelevant for the instant case; the NOC for setting of Bangalore greenfield airport by the ministry of defence made it amply clear that the operations at HAL airport will continue even after BIAL becomes functional and the choice of airport to be utilize should be left to the operators / commuters / general public; there are examples of more than one airport coexisting in cities to cater to various types of passengers requirements. For all the above reasons the committee recommended that the HAL airport should be made functional.

Civil society. Ramesh Ramanathan, of Janaagraha, largely representing the voice of the residents of Bangalore south , wrote in a daily as follows: “so, a few weeks in advance, here’s a greeting to Bangalore’s air travelers: welcome to the most under designed, under connected, woeful piece of infrastructure that is the face of new India to the world. Maybe we can harness a new source of renewable energy in India: “angry citizen energy”. It’s available in plenty, and being replenished every day by our governments.” The first legal challenge to the goi notification in the high court of Karnataka also came from a Bangalore resident on the grounds that the provisions invoked by the civil aviation ministry for closing down the HAL airport, that is, section 5a of the aircraft act, 1934 and rules 11 and 78 of the aircraft rules 1937, and clause 5.5 of the concession agreement dealt with the opening of a new airport and not its closure; sufficient notice had not been given to the parties before the notification was issued

The arguments put forth by the advocates of the save HAL campaign were as follows:

- **Capacity constraints.** A team of AAI officers undertook the study from 16th June to 18th June 2008 at New Bangalore International Airport. The study was not released to the public and the details in it have not been corroborated by BIAL, but portions were leaked to the press and gave a fresh twist to the controversy. The study maintained that new airport has been built to handle 9.78 million passengers much less than the 11.4 million passengers claimed by BIAL; and at least 10% less than the capacity of the old HAL airport. The AAI study also recommended that the old airport, run by Hindustan aeronautics ltd, or HAL, reopen until such time additional capacity is added at the new airport on Bangalore’s outskirts.
- **The exclusivity clause.** When BIAL was conceived, a concession agreement was entered into with the government of India, wherein the latter granted the exclusive right and privilege to BIAL to carry out the development, design, financing, construction , operation and management of the airport for a period of thirty years from opening date with

an option to extend the concession for another 30 years. A number of other agreements were also in place to support the concession agreement. At the time of the concession agreement it was the policy of the government of India that airports serving the large metropolitan areas shall have monopolistic rights of carriage; that is they were assured that no competing airports would be permitted to operate within a 150 km radius from them. In line with this, BIAL too was assured in the concession agreement that no new or existing airport will be permitted to operate as a domestic or international airport within 150 km. But there were variations in the way this was implemented in different cities, Bangalore, Hyderabad, Pune, Mumbai, due to local considerations. Notwithstanding these, it was agreed in the concession agreement that when BIAL became operational, the old HAL airport would be denotified for commercial passenger traffic.

- **Access and connectivity.** As the deadline to switch airports drew near, there was increasing consternation among certain sections of the public that the new airport may be ill-suited to serve a portion of the existing demand. During the last decade or so, Bangalore witnessed rapid development of its southern and south-eastern suburbs, whereas the new airport lay far to the north of the city.. Mysore also lay to the southwest, and there was development along mysore road. As a result, a population, numbering over 2.5 million in the larger metropolitan region from south-west to south-east, including Hosur in Tamilnadu, faced the prospect of having to drive forty kilometers or more to reach the new airport, and sometimes through congested city areas, to reach Devanahalli. Given Bangalore traffic, it was estimated that travel from majestic city centre to the new airport would take two hours; and an hour more from Bangalore south; including the three hour advance time for international travel, a resident would need six hours to catch an international flight, the same as going by road from Bangalore to Chennai!
- **A rival airport?** In Delhi, it appeared that the one-airport policy would be discarded as the area under the exclusivity clause intruded into a second state, and the government of Uttar Pradesh was planning a new airport in greater Noida, only seventy kilometers from Indira Gandhi international airport. In Bangalore too plans for commercial operations were on in Puttaparthi airport in Andhra Pradesh. BIAL argued that a new airport in Hosur would be precluded by the concession agreement, but judging by the example of the new proposed airport at Noida, it was likely that neighboring states that were not party to the agreement would not feel bound by it. In that case Tamilnadu or Andhra Pradesh could insist on their independent right to develop an airport within their borders without being constrained by a concession agreement between BIAL and Karnataka. To forestall that, it would be more efficient to retain the economic benefits linked to HAL airport and even to try to draw traffic from the growing twin city of Hosur, giving less room for the development of an airport outside the state.
- **Dual airports as an international phenomenon.** It was pointed out that more than 25 cities, including New York, Washington DC, Paris are served by two or more airports each carrying several million passengers a year. The average catchment area of such is typically 300-400 square kilometers each, roughly half the size of the current municipal area of Bangalore. Major metropolitan airports of the country, Delhi, Mumbai and Chennai all have firm plans for the establishment of new airports. Whatever the merits of an exclusion zone granted to BIAL, it appeared that other metros were able to demand and obtain exceptions to the single airport policy of the civil aviation ministry. Therefore, if the 'one airport per metro' policy was applied only to Bangalore, and if the centre itself abandoned the policy in its new aviation policy it would be advisable for Bangalore to be certain that it suffers no discrimination among metros on account of this policy. (CPP, IIMB, 2008, p. 16).
- **Hub for domestic, low-cost, short-haul traffic.** Prophesying that "fears are coming true", supporters of save HAL claimed that BIAL would discourage travelers flying on short-haul routes -those that have a flight time between 30 minutes and an hour. "Those who are travelling before March 30, when the new airport opens, and plan to come back after march 30, are booking onward flight tickets but are wary about booking their return tickets. Passengers having to fly out of the city from the new airport are thinking twice if their chosen destinations are on the short-haul sectors". The argument was that the distance and the expense made rail and road options more attractive to the visiting-relatives-and-friends segment of passengers who formed over 70% of short-haul destination flights. "if people find train and bus travel to be a smarter option, then airlines will have to discontinue certain short-haul routes or rationalize their frequency on some". Short-haul routes are unlikely to increase despite the new airport's capacity a 26% increase in domestic flights compared to what HAL airport currently handled.
- **Economic activities linked to an airport.** Inevitably, a range of businesses come up around any airport directly linked to the travel industry, but also to serve the secondary needs of establishments. It was argued that over the

course of its operation in east Bangalore, HAL airport has created a large eco-system in the tourism, travel, software, engineering, services and other industries that critically rely on the connectivity it provides to other cities and the rest of the world. The likely economic impact of disrupting this ecosystem was highlighted. A number of large firms have made huge investments in south and southeast Bangalore, and would not like their choice of Bangalore as an investment destination disrupted by the closure of HAL airport. The air traffic now originating from the southern suburbs would cease or diminish its use of air travel itself as a result of the increased distance to the new airport. Would such firms relocate some of their key offices within Bangalore metropolitan area itself, or prefer to locate significant operations in other cities? Economic disruption was also anticipated for the thousands of other businesses that indirectly relied on HAL airport traffic. Whether these too would find alternate sources of revenue, or move their operations, or face closure was a question.

- **Monopoly profiteering.** One reason for the debate over HAL airport was that past estimates of demand for air travel in Bangalore proved to be severe under-estimates, as the city had grown dramatically. The early negotiations for the establishment of a new airport took place during a period of low growth in air travel; the concession agreement was finalized during a period of moderate growth, and the construction of the airport took place during a period of unprecedented growth. Given the growth in traffic volume, there was no question that BIAL would make out even better than the returns that it projected when it won the tender, even if HAL airport were kept open.

- **The options explored.**

Building public opinion. Based on its capabilities and pursuant to its interest in actively engaging policy questions in government, the CPP organized a half day seminar on 3/3/2008 to discuss questions pertinent to the looming closure of the HAL airport. The seminar's objective was to create a meaningful discourse between the stakeholders about an infrastructure project that could irrevocably affect the future of the city and the citizens of Bangalore and Karnataka. In addition, the CPP proposed to develop recommendations for the government on the choices available at the time.

A negotiated outcome. To explore these options, the government could engage in a consensus building exercise to determine whether a satisfactory middle ground between the various contending positions can be found. How viable this option was, and whether the various stakeholders remain open to a consensus building exercise to find a middle ground, was uncertain. The government could invite the participants to a second meeting, this time in a closed to the public format that would permit such an eventuality to be explored.

Litigation. Several individuals and citizen forums filed public interest litigations in the high court of Karnataka against the decision of closing HAL airport for commercial operations after opening of the new airport. The closure of the old airport was challenged in court by a citizens' group. Citizens groups and top companies in Bangalore lobbied for reopening the old airport complaining commute to the new airport takes up to two hours from the city and the union government is encouraging a private monopoly by letting it be the only one open in the city.

ANALYSIS

The controversy that broke out and the public campaign to retain the HAL airport is symptomatic of the dilemmas that governments face in implementing PPPs in the India context. The crux lies the balancing of the mandate contractual governance with the compulsions of popular politics. In most instances of Indian electoral politics, the general consensus is that the compulsions of populism override those of principle, law or even ethics. However, in the case of HAL, the governments of India and Karnataka chose to keep their contractual obligations above that of considerations of popularity. Despite mouthing sentiments in favour of keeping HAL airport open, they ultimately chose to take the legal rather than the political route towards resolving the issue. This is an unusual, at least in the light of popular perception about the polity of India. The implementation of long gestation megaprojects with 25-30 year timelines requires a stability of policy structure and political and bureaucratic decisionmaking. Shifts of popular sentiment, on the other hand, need display no such restraint. This leads states to display inconsistencies in its stand, compounded when there is a change of the ruling political combination or party. In BIAL's case, there was a change from the congress when construction began to successive coalition governments midway and finally the Bharatiya Janata party when the airport was launched. Foreign investors are ill-equipped to handle policy shifts,

particularly on critical issues such as exclusivity. The theme that any modification may affect future investment sentiment is reiterated again and again in the discourse of BIAL.

As we have seen, the location was selected after a careful comparative evaluation. It was by no means a casual or easy choice. From all available evidence it does not appear that there has been any political interference at any stage at the point of site. On being questioned on this aspect, the interview respondents who were involved in the site selection emphatically stated that there was no political interest or interference at that point of time. Nor was there any competition between different locations for being chosen for the purpose. To that extent, the committee was free to select an appropriate site, based on operational constraints only.

The question arises whether the committee itself could have been blind to the distance between the city and the Devanahalli site? It is clear that the committee had to keep in mind several parameters, physical conditions, type of terrain, surrounding obstructions; availability of utilities such as power and water, accessibility to ground transport, availability of land for future expansion, technical factors such as the presence of other airports in the vicinity, so distance was only one item among the multiple factors to be considered. Notwithstanding this, it is clear that the committee, particularly Dr. Valluri, was alive to the distance factor, motivated as much by fuel savings than passenger convenience.

From inception, industry associations were participants in the exercise, and completely privy to decisionmaking, again giving lie to later accusations of opaqueness and lack of transparency.

One development that the committee could not have foreseen at the time was the tremendous growth of the IT sector in Bangalore and its concentration in the south of Bangalore city. As we saw in chapter 4, this was the consequence of a series of policy and circumstantial factors. By the time BIA was constructed in 2008, the golden crescent of Whitefield, Hosur-Sarjapur and Koramangala had emerged as the main feeder to the airport, and it was this group that was most inconvenienced by the relocation to Devanahalli. As the IIMB report states: “during the last decade or so, Bangalore has witnessed rapid development of its southern and south-eastern suburbs, extending all the way upto Hosur in Tamilnadu, whereas the proposed new airport is far to the north of the city. Mobility patterns clearly indicate high concentrations of employment-related movement in the southern suburbs, and as newer establishments keep coming up in the area, this is likely to mount even further. And Karnataka’s own second city, Mysore, is to the south-west, and there has been plenty of development along Mysore road, which may accelerate once the infrastructure corridor project to that city is sorted out”. But this was certainly not something that could be foreseen in 1992. Aside from the public policy perspective, there is an interesting legal issue here. Non-contractibility, the incapacity of negotiating parties to completely anticipate and prepare for all contingencies, is a recurrent theme in PPP literature (Hart, 2003) (Besley & Ghatak, 2006) (Stewart-Smith, 1995) the exclusivity clause which became the focus of debate was in fact a demand that had been agreed upon much as early as the 1990s, much before the Siemens consortium entered the fray. It is obvious that the contingency of reworking the contract on such a critical point was not envisaged, leading both the union and the state governments to lay the onus of alteration on BIAL management. The power of an intelligent articulate section of society to rally around a demand was an important aspect of this episode. But the shifts of perspective and popular sentiment was manifest. The new airport for Bangalore was championed largely by the new IT economy and the middle-classes that formed the bulk of its workforce. For a period in BIAL’s early history an industrialist who epitomized the new economy in Bangalore, held office as its chairman. The need for a new airport is reiterated in popular middleclass discourse of the Bangalore south. But, when faced with the prospect of travelling 30 odd kilometers to the new airport, this group effected a complete turnaround, and began to criticize not just the distance, but almost every aspect of the airport’s design and features. This group was also able to intelligently articulate their views through a variety of devices, chiefly newspapers and blog spots. The fickleness of public opinion was nowhere more in evidence. Through the entire drama, the media had a field day. Dailies such as times of India tracked the save HAL campaign day after day. Headlines screamed: for several months this was a regular feature, until the improvement in connectivity, the familiarization of the new airport to passengers, and the litigating of the issue in the court removed it gradually from the forefront of public interest.

Conclusion.

The ultimate fate of the HAL airport will be decided in the courts. Yet the save HAL episode forms an important chapter in BIAL's history. For all the heat that it generated, the campaign was not successful in persuading either BIAL or governments to reopen HAL. This was for several reasons: the mandates of contractual governance proved greater than the compulsions of political popularity. Thus, even while mouthing sentiments such as: and exploring options, the governments ultimately joined the chorus rather than determining its direction. In itself, this was an important instance of political will in action, though not in vocabulary. Also, the campaign failed in its purpose also because the cause it propounded ultimately only a small section of Bangalore's population. The users of Bangalore south were only a small section of Bangalore's population, albeit prosperous and voiced. Most users who hailed from other parts of the city were either indifferent, or frankly relieved at escaping the obnoxious traffic of the old airport road. This, rather than the firmness of governments or the clauses of the concession agreement, have proved decisive so far.

Abstract

The company’s annual letter to the stockholder attempts to set stakeholder expectations of the financial reports for both this year’s report and, perhaps, next year’s. What is included in the letter is not a matter of chance but the result of a great deal of deliberation on each word, each phrase, and each sentence. For this reason, content analysis may be quite revealing of values and strategies.

Earlier studies (including Bowman, 1984; Subramanian, Isley, & Blackwell, 1993) have shown that there are significant differences in the language used to convey negative news in a company’s “Letter to the Stockholders” as compared to conveying positive news. For example, the impact of negative news is tempered by the use of long sentences and passive voice. But, this level of analysis is, in a sense, at a “gross” level and does not get to the finer details of the language strategy used in corporate communication. These finer details are trapped in the arduous task of “decoding” the language in a consistent and valid way. DICTION (Hart, 2000), a computer-aided content analysis software program, allows us to explore common themes at the word level in corporate communication and therefore, is a deep grained analysis.

In this research we seek to identify measures of statistical difference between the language used by companies reporting positive financial results vs. companies reporting negative financial results. Our focus is on Fortune 500 U.S.-based companies. The analysis includes all of the available DICTION measures listed above with emphasis on the occurrence of the five “master” words in DICTION’s functionality – certainty, optimism, activity, realism, and commonality. We identify differences in the text of the two sets of Letters and offer explanations for these differences. We suggest follow-up studies to further refine the content analysis approach.

Keywords: Letters to stakeholders, text analysis, content analysis

Introduction

Analysts and investors intently wait for and pounce on any bits of information on a company of interest with hopes of discovering facts that will lead to a better investment decision. Among the more important and influential sources of such information is the company’s annual report due to their wide coverage and availability (Hooks, Coy & Davis, 2002; Marston and Shrivess, 1991) and also because its content is somewhat regulated by government agencies. Annual reports, these state-of-the-company disclosures, were first required by the Securities and Exchange Commission in 1934 (Flanigan, 1993). Today, annual reports are required for companies with more than \$10 million in assets whose securities are held by more than 500 owners. Federal regulators require that disclosures be “accurate and complete so as not to mislead”. Sarbanes-Oxley regulations extended this commitment by making CEOs and CFOs legally accountable for the veracity and integrity of their financial statements (Goodman, 2004).

While the annual report may be read by stockholders, stockbrokers, employees, regulatory agencies, customers, financial analysts, the press, general public, and investors, the primary audience is considered to be stockholders (NIRA, 2004; Kohut and Segars, 1992). Accordingly, the financial sections of the annual report affords all readers a common point of reference. The narrative sections, while somewhat regulated, offer investors a window to the company.

The Management’s Discussion and Analysis (MD&A) usually follows a pattern of an overview of performance followed by in-depth discussion of changes and trends in sales, expenses, and selling and administrative expenses. The Letter to the Shareholders, also called the president’s letter or the CEO’s letter, is

generally used to expand upon the MD&A and provide an overview and interpretation of the firm's financial position. It is generally written and signed as a personal letter from an executive. The MD&A is required (The SEC, 2004) while the Letter to the Stockholders is not.

While generally receiving less analyses than the financial sections, the narrative is an interesting opportunity to learn more about management's interpretation of company performance, the prospects for the company, and the underlying message(s) management wishes to convey to stockholders. It is in the narrative, especially the Letter to Stockholders, that senior managers have an opportunity to shape the perceptions of stockholders that cannot be accomplished in the financial sections. Executives are free to explain past, present, or future performance; free to divert attention away from financial performance in favor of broader, softer themes (e.g., social responsibility, company recognition, change in management, etc.); and, free to offer any spin they feel will benefit the company—especially its stock price. Plus, the narrative offers a rare opportunity to hear directly from those in key management positions in the company. These executives are deciding the direction of the company and their messages offer clues to future performance.

The importance of the narrative portion of annual reports is well documented and there is evidence that companies use the narrative strategically. The messages in these annual reports frequently offer a description of the company's managerial priorities. Research has indicated that the market responds to the quotes of officers in earnings press releases (Hoskin, Hughes & Ricks, 1986) and influence analysts' forecasts (Barron, Kile & O'Keefe, 1999). We see this managerial "manipulation" in the research by Kohut and Segars (1992) and their discovery that the messages hidden in annual reports differ in terms of the subject emphasized as the company's performance worsens. This might explain the Subramanian (Subramanian, Isley & Blackwell, 1993) finding that companies that perform well produce annual reports that are easier to read. Or, as another strategy, Letters to the Stockholders follow the Pollyanna Hypothesis and the language is predominantly positive (Thomas, 1997). This strategic use is prevalent as it is certainly more difficult to enforce "accurate and complete" information in the context of language usage in the Letter to the Shareholders. Even though the authorship of Letters to the Stockholders is uncertain, there is widespread agreement that executives are heavily involved in their preparation (Barr, Stimpert & Huff, 1992).

Studies of narrative texts produced by companies also allows the unobtrusive study of beliefs and cognitions of top-level executives that are hard to obtain (Bettman and Weitz, 1983, Morris, 1994; Duriau, Reger & Pfarrer, 2007). While the information in the financial section may be added, subtracted, multiplied and divided in ratios that allow comparisons to other companies, no such tools have existed for standardizing the narrative, or, more accurately, the tools have been rare, hard to use, and/or inaccurate.

Given the strategic salience of the narrative sections of an annual report, it is important that research examines the approaches used by companies. While content analysis has been the lens through which this has been done in extant research, prior studies have been limited in their depth due to the availability of content analysis tools. The purpose of this study is to offer a fine grained analysis of the strategic orientation of "Letter to the Stockholders" using an advanced content analysis software.

Content analysis in strategic management

Content analysis of text is a research methodology that uses a set of procedures to analyze and categorize communication (Weber, 1990). The methodology offers a number of potential benefits including the identification of individual differences among communicators (Weber, 1990), avoidance of recall biases (Barr, Stimpert & Huff, 1992), and the ability to obtain otherwise unavailable information (Kabanoff, Waldersee & Cohen, 1995). In the business disciplines content analysis has been used in accounting (Rogers, Dillard & Yuthas, 2005), management (Fiol, 1989), marketing (Simon and Houghton, 2003), and corporate strategy (Merchant, 2004; Yuthas, Rogers & Dillard, 2002). The source of the text being analyzed may be shareholder letters, transcripts from interviews and speeches, or other corporate communications. The selection depends on the extent of the match between the research question and the intended audience and intent(s) of the communication. In the strategic management area, content analysis has primarily been of shareholder letters and annual reports (Duriau, Reger, & Pfarrer, 2007). For example, Kloptchenko (Kloptchenko, Elkund, Back, Karlsson, Vanharanta & Visa, 2002) used text mining methods

to compare the financial ratios of quarterly reports to the quantitative sections for consistency of the message. They conclude that the two sections do not coincide; the quantitative section reflects past performance while the qualitative portions holds hidden indicators about the future financial performance.

There are three types of approaches to language analysis (Morris, 1994): human-scored procedures, artificial intelligence systems, and individual word count systems. With the first approach, coding rules are established, human coders are trained, and then the coders classify selected aspects of the text. Artificial intelligence approaches consider the lexicon, syntax, and semantics of text (Rosenberg, Schnurr & Oxman, 1990). With respect to individual word count methodology, individual words in the text are counted and the frequency of each word is compared to the frequency of these same words in other communication samples. Word frequencies outside of the range of frequencies in these comparative samples are an indication of differences between the samples.

DICTION (Hart, 2000a) is one of a number of word frequency programs. In DICTION the frequency of word usage in the analyzed text is compared to the frequency of word usage across various genres studied by Hart (Hart and Jarvis, 1997; Hart, 1984a; Hart, 1984b; Hart, 2000b; Hart, 2001). The genre(s) to which the analyzed text is compared may be selected from business, daily life, entertainment, journalism, literature, politics, and scholarship. Hart (Hart, 2003) analyzed from one to six sub-genres to derive word frequency norms for each genre. In total, the norms are based on the analysis of 22,027 texts of various genres written between 1948 and 1998.

The words from these genres are arranged in 33 dictionaries or word lists ranging in size from 10 to 745 words. No word appears in more than one dictionary. Brief descriptions of each dictionary may be found in Appendix A.

In addition to the absolute frequency counts, DICTION calculates four variables based on word ratios. These calculated variables are:

Insistence, a measure of “code-restriction” that indicates a “preference for a limited, ordered world”;

Embellishment, a measure of the ratio of adjectives to verbs;

Variety, a measure of conformity to, or avoidance of, a limited set of expressions (different words/total words); and

Complexity, a measure of word size based on the Flesch (Flesch, 1951) method.

Frequency counts from the various dictionaries along with the four calculated variables compose five master variables. Hart’s (Hart, 2003) master variables, intended to capture the tonal features of the text, are defined and formulated from the individual dictionaries as follows:

Certainty is a measure of language “indicating resoluteness, inflexibility, and completeness and a tendency to speak ex cathedra.”

$Certainty = [Tenacity. + Leveling. + Collectives. + Insistence] - [Numerical Terms + Ambivalence. + Self Reference + Variety]$

Activity is a measure of “movement, change, [and] the implementation of ideas and the avoidance of inertia;

$Activity = [Aggression. + Accomplishment. + Communication. + Motion] - [Cognitive Terms. + Passivity. + Embellishment]$

Optimism is a measure of “language endorsing some person, group, concept or event or highlighting their positive entailments.”

$Optimism = [Praise + Satisfaction + Inspiration] - [Blame + Hardship + Denial]$

Realism is a measure of language “describing tangible, immediate, recognizable matters that affect people’s everyday lives.”

$Realism = [Familiarity + Spatial Awareness. + Temporal Awareness. + Present Concerns. + Human Interest + Concreteness] - [Past Concern + Complexity]$

Commonality is a measure of language “highlighting the agreed-upon values of a group and rejecting idiosyncratic modes of engagement.”

$Commonality = [Centrality. + Cooperation. + Rapport] - [Diversity + Exclusion + Liberation]$

Researchers have noted the potential of DICTION for the study of leadership (Bligh, Kohles & Meindl, 2004a, 2004b), image management (Rogers, Dillard & Yuthas, 2005), communicative action (Yuthas, Rogers & Dillard, 2002), and the content of mission statements (Short and Palmer, 2010). Bligh (Bligh, Kohles & Meindl,

2004a) used DICTION to create a construct of tangibility for measuring levels of executive charisma (Concreteness + Insistence – Variety).

Davis (Davis, Piger and Sedor, 2006) used content analysis based on DICTION to measure levels of pessimistic and optimistic language in earnings press releases. They find that optimistic and pessimistic language in earnings reports reliably predicts future firm performance. Yuthas (Yuthas, Rogers & Dillard, 2002) , using DICTION, found that firms anticipating large earnings surprises use the narrative of the annual report to communicate information about managements' veracity and trustworthiness. They conclude that these narratives violate the Habermasian (Habermas, 1984, 1987) principles for communicative action for understanding which include norms for comprehensibility, truthfulness, sincerity, and legitimacy (Forrester, 1985).

Advantages of DICTION include freedom from coder bias as the search rules and algorithms pre-exist, development based on political discourse that would seem similar to the narrative disclosures of executives, and analysis of large sample sizes. A limitation of DICTION is that words are taken out of context and this omission of context likely leads to a noisy measure of the intent of the message. However, Bligh (Bligh, Kohles & Meindl, 2004b) reported a high degree of comparability between DICTION measures and human coding.

Specific research questions

In this exploratory investigation we were interested in understanding more about how managers wrote about their financial performance. Specifically we want to determine whether there were significant differences in the Letters to the Stockholders as written by companies reporting a positive financial performance year-over-year versus companies reporting a negative change year-over-year when both sets of Letters were compared to the language of the general business population as defined by the dictionaries included in DICTION. Specifically, the questions addressed were:

- Are there significant differences in the Letters provided by companies reporting positive financial change (“Positive Reporters”) versus those companies who were reporting negative financial change (“Negative Reporters”) with respect to the master variables (i.e., Certainty, Activity, Optimism, Realism, Commonality)?
- Are there significant differences in the Letters provided by Positive Reporters versus those Negative Reporters with respect to the four content-analysis master variables (i.e. Insistence, Embellishment, Variety, and Complexity), ?
- Are there significant differences in the Letters provided by Positive Reporters versus Negative Reporters with respect to the four content-analysis calculated variables?

For the Master variables of DICTION, we hypothesized as follows:

Certainty. As a measure of resoluteness, the group of Negative Reporters will be more certain in their language than Positive Reporters. This certainty will be revealed in higher scores for tenacity, leveling, collectives, insistence, numerical terms, ambivalence and self-references. Negative Reporters will also show this certainty by a reduced variety of words.

Activity. This measure of movement will show Negative Reporters with greater activity. Words of aggression, accomplishment, and communication will be higher for this group. They will also use more terms of passivity, and more embellishments.

Optimism. Positive and Negative Reporters will reflect their ratings in their choice of words in their comments. Positive Reporters will use more terms of praise, satisfaction, and inspiration. Negative Reporters will do the opposite; fewer terms of praise, satisfaction, and inspiration. In addition, while Positive Reporters will not avoid blame, hardship, and denial, Negative Reporters raters will use more of these terms than would be usual.

Realism. There will be no significant differences in the frequency of word use in any dictionary making up this master variable either for Positive or Negative Reporters.

Commonality. Positive Reporters will use above average numbers of words of centrality, cooperation and rapport while Negative Reporters will use fewer of these words. These raters will indicate their feelings of exclusion and liberation by more frequent use of these terms.

Methodology

For this exploratory study we restricted the data set to a random sample of companies listed on the Fortune 500. Since not all companies would have reported their fiscal 2010 results as of the time this research was conducted in late 2010, we used fiscal 2009 annual reports. Using a table of random numbers, we picked companies, categorizing each in terms of their year-over-year result as having a positive or a negative change as determined by their annual financial statements. We continued this process until we had identified approximately fifty companies in each category. There were instances when the randomly picked company was not usable: no annual report (13 times), no Letter to the Stockholders (3), the 2009 annual report was not yet available (1), extensive changes to the company made comparing year-to-year financials difficult (1), and a text coding problem where the Letter to the Stockholders could not be copied (1). In each case we returned to the table of random numbers and selected the next company. In total, we selected 47 companies with negative financial changes to report and 53 with positive changes to report.

The Letters to the Stockholders for each of these 100 companies was captured as a text file from annual reports downloaded from Investor Relations Information Network (IRIN). All files were then cleaned to correct misspellings and abbreviations that would impact the word frequency counts. No other changes were made to the corpus. A single, combined text file of all the Letters from Positive Reporters was created and submitted to DICTION. Similarly, text files of Negative Reporters and a Combined Positive + Negative Reporters were created and submitted to DICTION. All words were processed (DICTION allows sampling of the corpus) and no custom dictionaries were created for the analysis.

An exploratory analyses of specific research hypothesis

Table 1 displays the DICTION reported results for the two groups of ratings, Positive Reporters versus Negative Reporters, for each of the five master variables and their corresponding component variables. Also indicated in the right-hand column is our hypothesis for negative vs. positive reporters. A “<” symbol indicates that we hypothesized that those with negative growth to report would display this text characteristic significantly less than would those Letters reporting positive results. A “>” means just the opposite, we would expect the negative messages to include this text characteristic more, while “=” is a hypothesis that both groups would be significantly different from the business norm offered by Hart. A blank indicated that we hypothesized no difference either between the Positive and Negative reporters and both sets of reporters compared to the business norm. All results that are significant are identified by bold font and are underlined.

In a private email communication on February 8, 2011 Hart shared the means and standard deviations of the norm group on each dictionary and on the master and calculated variables. We noted that a number of standard deviations were larger than their means, an indication that the scale has many low values but a very wide range from very, very low to some highs. From the data it is easy to see which variables are quite skewed and which approach symmetry and perhaps even a normal curve. To get a sense of symmetry we calculated the average of the minimum and maximum (the midrange) and noted that when the average was close to the mean then the data set may be close to symmetrical. For those data sets that may be symmetrical, if then calculated the range and divide by six. Results close to the given standard deviation indicated when the data set was approximately normally distributed. For the majority of variables this did not happen.

It must be pointed out that Hart used one standard deviation from the norm as statistically significant. He rationalized this decision as the need to account for lack of precision in the ability of the dictionaries to capture the nuances of the language sample. We used this one standard deviation rule but prefer to call it “practical” significance to distinguish it from the more rigorous “statistical” significance.

TABLE 1 – DICTIONARY, CONSTRUCTED, AND MASTER VARIABLE RESULTS FOR
“NEGATIVE” AND “POSITIVE” REPORTERS

Variable	Freq. Negative	Freq. Positive	Mean + 1 SD	Mean – 1 SD	Hypothesis Neg v. Pos
CERTAINTY =					
+Tenacity	<u>10.53</u>	18.7	36.62	12.35	>
+ Leveling Terms	2.96	5.19	16.94	-0.90	>
+ Collectives	5.08	6.23	13.38	0.96	>
+ Insistence	30.55	31.70	182.19	0.27	>
- Numerical Terms	20.62	9.88	53.23	-4.38	>
- Ambivalence	2.75	2.14	17.96	1.69	>
- Self-reference	1.07	2.60	16.69	-8.13	>
- Variety	0.64	0.60	0.70	0.42	<
TOTAL CERTAINTY	24.04	46.60	160.55	23.08	>
ACTIVITY =					
+ Aggression	3.11	2.14	7.23	-0.36	>
+ Accomplishment	<u>38.46</u>	23.49	30.38	5.35	>
+ Communication	1.94	4.40	10.53	-0.30	>
+ Motion	1.40	1.97	13.13	-6.99	
- Cognitive Terms	4.56	10.43	15.95	1.46	
- Passivity	<u>23.70</u>	4.72	8.79	0.36	>
- Embellishment	0.97	2.38	4.11	-2.26	>
TOTAL ACTIVITY	15.69	14.84	25.26	-2.96	>
OPTIMISM					
+ Praise	4.48	6.95	12.40	0.01	<
+ Satisfaction	1.52	<u>8.37</u>	7.59	-1.47	<
+ Inspiration	<u>11.70</u>	6.62	9.80	-1.11	<
- Blame	1.79	1.80	3.63	-0.97	>
- Hardship	3.12	0.52	7.87	-1.38	>
- Denial	0.81	6.23	12.89	-1.26	>
TOTAL OPTIMISM	<u>12.32</u>	<u>13.39</u>	5.40	1.04	=
REALISM					
+ Familiarity	109.80	121.28	142.22	91.37	
+ Spatial Awareness	5.05	9.15	14.79	0.21	
+ Temporal Awareness	<u>30.68</u>	12.31	25.87	2.40	
+ Present Concerns	3.68	12.78	21.75	2.83	
+ Human Interest	39.21	<u>46.61</u>	41.28	2.02	
+ Concreteness	12.13	14.20	35.27	8.47	

- Past Concerns	3.42	3.62	6.51	-0.82	
- Complexity	5.18	4.90	5.34	4.34	
TOTAL REALISM	191.93	207.80	269.33	103.78	=
COMMONALITY					
+ Centrality	2.61	3.76	10.11	0.10	<
+ Cooperation	3.21	8.04	11.71	-0.14	<
+ Rapport	2.09	0.66	4.18	-0.61	<
- Diversity	0.51	1.59	4.70	-0.81	
- Exclusion	3.69	0.19	5.60	-1.23	>
- Liberation	0.42	0.90	5.17	-1.61	>
TOTAL COMMONALITY	3.29	9.78	10.53	3.00	<

The results indicate that for the five master variables of DICTION our combined hypotheses were confirmed for one master variable and inconsistently confirmed for the component variables. The first surprising result occurred with the master variable Certainty where our hypothesis for a difference from the negative reporters was not confirmed. In fact, only one of the eight component variables, Tenacity, was “practically” significant with negative reporters using this text characteristic significantly less than the norm. We had hypothesized they would use it more.

The second surprising result occurred with the master variable Activity. There was no difference in overall indication of Activity in the messages. However, negative reporters were practically different in having more Accomplishment terms and more Passivity terms.

For the master variable Optimism our hypothesis was confirmed. Both negative and positive reporters were practically different from the norm. In addition, negative reporters used more inspiration terms than either the positive raters or the norm group. Those reporting positive growth used more terms of Satisfaction than either negative reporters or the norm business group.

For the master variable Realism we did not hypothesize any difference in direction of results for the master variable. Those reporting negative growth used more terms of Temporal Awareness while those reporting positive results used more Human Interest terms.

For the master variable Commonality our hypothesis was not confirmed and, opposed to our hypotheses, none of the sub-variables was significantly different from the business genre norm.

Discussion

From Table 1 it is observed that our hypothesized results were only confirmed once for the five master variables. It is interesting that this one master variable, Optimism, not only was used more in the text of these Letter to the Stockholders than would be normal in business genre, but also that both groups observed here used features signaling optimism, regardless of the results being reported. Given that a purpose of the Letter narrative is part cheerleading, it seems consistent that these messages would be filled with optimism. It seems to be the case that optimism is built into the text in different ways depending on the growth results. Those reporting negative growth seek to paint a picture of a management with attractive virtues that will serve the future shareholder well. Those reporting positive results seems to point out their moment of victory.

It is of some concern that only nine of the 70 possible sub variables (35 variables for each message type) were of practical significance. The question that must be pondered is why such unexpected results? A few possibilities must be thoroughly examined.

- 1 – Is it the case that Letters to the Stockholders are less strategic than previously thought? Or, as a corollary, maybe more credit for message manipulation is being given to those crafting these narratives than is deserved.
- 2 – Could it be that narrative authors resort to the language of other genres besides business (e.g., politics)? To make this determination we may need to analyze the language of these Letters by comparing them to other genre norms in DICTION.
- 3 – Although much has been written about the DICTION program in various articles by Hart (Hart, 1984a; Hart, 1984b; Hart, 1987; Hart and Jarvis, 1997; Hart, 2000a; Hart, 2000b; Hart, 2001) and others who have used it for research one must question its validity and reliability which have not been reported. Furthermore, there is no readily found description of the computation of mean and standard deviation, or computation of the standard Z scores and Hart fails to demonstrate why he breaks with long-held convention and describes absolute Z scores greater than 1.0 as outside the normal range and thereby significant.
- 4 – Hart's (Hart, 2001) five master variables appear to be independent constructs arising from a factor analysis – there is little to no correlation among these constructs. The component variables comprising the five master variables did not seem to consistently display the direction of difference expected by our hypotheses, perhaps a misunderstanding on our part of the definition of the involved terms?
- 5 – It is impossible for us to determine how the DICTION program searches for discrepancies in various Letters that could result in misclassification. For example, it is not known whether the DICTION program can properly classify a comment as it was intended. If the DICTION program cannot properly distinguish among language nuances, both its reliability and validity, as a measuring instrument can be questioned.

Further exploration will provide answers to the above.

Conclusions

In this exploratory study we sought to identify textual distinctions between Letters to the Stockholders written by companies reporting negative year-over-year growth versus those reporting positive growth. We were able to identify some differences between groups in the component variables of optimism and a difference between both groups and the norm for business genre. This evidence supports the contention that writers of annual report narratives do attempt to manipulate optimism in these messages and, interestingly, manipulate optimism in different ways, depending on the negative or positive news.

Despite the surprising findings which indicated discrepancies with several of our hypotheses we remain encouraged by the results of this exploratory study. Once we satisfactorily address the aforementioned dilemmas described in the Discussion section we plan to extend the study and address additional questions of message intent.

Appendix A

Descriptions of the Dictionaries and Scores

Accomplishment: Words expressing task-completion (establish, finish, influence, proceed) and organized human behavior (motivated, influence, leader, manage). Includes capitalistic terms (buy, produce, employees, sell), modes of expansion (grow, increase, generate, construction) and general functionality (handling, strengthen, succeed, outputs). Also included is programmatic language: agenda, enacted, working, leadership.

Aggression: A dictionary embracing human competition and forceful action. Its terms connote physical energy (blast, crash, explode, collide), social domination (conquest, attacking, dictatorships, violation), and goal-directedness (crusade, commanded, challenging, overcome). In addition, words associated with personal triumph (mastered, rambunctious, pushy), excess human energy (prod, poke, pound, shove), disassembly (dismantle, demolish, overturn, veto) and resistance (prevent, reduce, defend, curbed) are included.

Ambivalence: Words expressing hesitation or uncertainty, implying a speaker's inability or unwillingness to commit to the verbalization being made. Included are hedges (allegedly, perhaps, might), statements of inexactness (almost, approximate, vague, somewhere) and confusion (baffled, puzzling, hesitate). Also included are words of restrained possibility (could, would, he'd) and mystery (dilemma, guess, suppose, seems).

Blame: Terms designating social inappropriateness (mean, naive, sloppy, stupid) as well as downright evil (fascist, blood-thirsty, repugnant, malicious) compose this dictionary. In addition, adjectives describing unfortunate circumstances (bankrupt, rash, morbid, embarrassing) or unplanned vicissitudes (weary, nervous, painful, detrimental) are included. The dictionary also contains outright denigrations: cruel, illegitimate, offensive, miserly.

Centrality: Terms denoting institutional regularities and/or substantive agreement on core values. Included are indigenous terms (native, basic, innate) and designations of legitimacy (orthodox, decorum, constitutional, ratified), systematicity (paradigm, bureaucratic, ritualistic), and typicality (standardized, matter-of-fact, regularity). Also included are terms of congruence (conformity, mandate, unanimous), predictability (expected, continuity, reliable), and universality (womankind, perennial, landmarks).

Cognitive Terms: Words referring to cerebral processes, both functional and imaginative. Included are modes of discovery (learn, deliberate, consider, compare) and domains of study (biology, psychology, logic, economics). The dictionary includes mental challenges (question, forget, re-examine, paradoxes), institutional learning practices (graduation, teaching, classrooms), as well as three forms of intellection: intuitional (invent, perceive, speculate, interpret), rationalistic (estimate, examine, reasonable, strategies), and calculative (diagnose, analyze, software, fact-finding).

Collectives: Singular nouns connoting plurality that function to decrease specificity. These words reflect a dependence on categorical modes of thought. Included are social groupings (crowd, choir, team, humanity), task groups (army, congress, legislature, staff) and geographical entities (county, world, kingdom, republic).

Communication: Terms referring to social interaction, both face-to-face (listen, interview, read, speak) and mediated (film, videotape, telephone, e-mail). The dictionary includes both modes of intercourse (translate, quote, scripts, broadcast) and moods of intercourse (chat, declare, flatter, demand). Other terms refer to social actors (reporter, spokesperson, advocates, preacher) and a variety of social purposes (hint, rebuke, respond, persuade).

Complexity: A simple measure of the average number of characters-per-word in a given input file. Borrows Rudolph Flesch's (1951) notion that convoluted phrasings make a text's ideas abstract and its implications unclear.

Concreteness: A large dictionary possessing no thematic unity other than tangibility and materiality. Included are sociological units (peasants, African-Americans, Catholics), occupational groups (carpenter, manufacturer, policewoman), and political alignments (Communists, congressman, Europeans). Also incorporated are physical structures (courthouse, temple, store), forms of diversion (television, football, CD-ROM), terms of accountancy (mortgage, wages, finances), and modes of transportation (airplane, ship, bicycle). In addition, the dictionary includes body parts (stomach, eyes, lips), articles of clothing (slacks, pants, shirt), household animals (cat, insects, horse) and foodstuffs (wine, grain, sugar), and general elements of nature (oil, silk, sand).

Cooperation: Terms designating behavioral interactions among people that often result in a group product. Included are designations of formal work relations (unions, schoolmates, caucus) and informal associations (chum, partner, cronies) to more intimate interactions (sisterhood, friendship, comrade). Also included are neutral interactions (consolidate, mediate, alignment), job-related tasks (network, détente, exchange), personal involvement (teamwork, sharing, contribute), and self-denial (public-spirited, care-taking, self-sacrifice).

Denial: A dictionary consisting of standard negative contractions (aren't, shouldn't, don't), negative functions words (nor, not, nay), and terms designating null sets (nothing, nobody, none).

Diversity: Words describing individuals or groups of individuals differing from the norm. Such distinctiveness may be comparatively neutral (inconsistent, contrasting, non-conformist) but it can also be positive (exceptional, unique, individualistic) and negative (illegitimate, rabble-rouser, extremist). Functionally, heterogeneity may be an asset (far-flung, dispersed, diffuse) or a liability (factionalism, deviancy, quirky) as can its characterizations: rare vs. queer, variety vs. jumble, distinctive vs. disobedient.

Exclusion: A dictionary describing the sources and effects of social isolation. Such seclusion can be phrased passively (displaced, sequestered) as well as positively (self-contained, self-sufficient) and negatively (outlaws, repudiated). Moreover, it can result from voluntary forces (secede, privacy) and involuntary forces (ostracize, forsake, discriminate) and from both personality factors (small-mindedness, loneliness) and political factors (right-wingers, nihilism). Exclusion is often a dialectical concept: hermit vs. derelict, refugee vs. pariah, discard vs. spurn.

Familiarity: Consists of a selected number of C.K. Ogden's (1968) "operation" words which he calculates to be the most common words in the English language. Included are common prepositions (across, over, through), demonstrative pronouns (this, that) and interrogative pronouns (who, what), and a variety of particles, conjunctions and connectives (a, for, so).

Hardship: This dictionary contains natural disasters (earthquake, starvation, tornado, pollution), hostile actions (killers, bankruptcy, enemies, vices) and censurable human behavior (infidelity, despots, betrayal). It also includes unsavory political outcomes (injustice, slavery, exploitation, rebellion) as well as normal human fears (grief, unemployment, died, apprehension) and incapacities (error, cop-outs, weakness).

Human Interest: An adaptation of Rudolf Flesch's notion that concentrating on people and their activities gives discourse a life-like quality. Included are standard personal pronouns (he, his, ourselves, them), family members and relations (cousin, wife, grandchild, uncle), and generic terms (friend, baby, human, persons).

Inspiration: Abstract virtues deserving of universal respect. Most of the terms in this dictionary are nouns isolating desirable moral qualities (faith, honesty, self-sacrifice, virtue) as well as attractive personal qualities (courage, dedication, wisdom, mercy). Social and political ideals are also included: patriotism, success, education, justice.

Leveling: Words used to ignore individual differences and to build a sense of completeness and assurance. Included are totalizing terms (everybody, anyone, each, fully), adverbs of permanence (always, completely, inevitably, consistently), and resolute adjectives (unconditional, consummate, absolute, open-and-shut).

Liberation: Terms describing the maximizing of individual choice (autonomous, open-minded, options) and the rejection of social conventions (unencumbered, radical, released). Liberation is motivated by both personality factors (eccentric, impetuous, flighty) and political forces (suffrage, liberty, freedom, emancipation) and may produce dramatic outcomes (exodus, riotous, deliverance) or subdued effects (loosen, disentangle, outpouring). Liberatory terms also admit to rival characterizations: exemption vs. loophole, elope vs. abscond, uninhibited vs. outlandish.

Motion: Terms connoting human movement (bustle, job, lurch, leap), physical processes (circulate, momentum, revolve, twist), journeys (barnstorm, jaunt, wandering, travels), speed (lickety-split, nimble, zip, whistle-stop), and modes of transit (ride, fly, glide, swim).

Numerical Terms: Any sum, date, or product specifying the facts in a given case. This dictionary treats each isolated integer as a single "word" and each separate group of integers as a single word. In addition, the dictionary contains common numbers in lexical format (one, tenfold, hundred, zero) as well as terms indicating numerical operations (subtract, divide, multiply, percentage) and quantitative topics (digitize, tally, mathematics). The presumption is that Numerical Terms hyper-specify a claim, thus detracting from its universality.

Passivity: Words ranging from neutrality to inactivity. Includes terms of compliance (allow, tame, appeasement), docility (submit, contented, sluggish), and cessation (arrested, capitulate, refrain, yielding). Also contains tokens of

inertness (backward, immobile, silence, inhibit) and disinterest (unconcerned, nonchalant, stoic), as well as tranquility (quietly, sleepy, vacation).

Present Concern: A selective list of present-tense verbs extrapolated from C.K. Ogden's list of "general" and "picturable" terms, all of which occur with great frequency in standard American English. The dictionary is not topic-specific but points instead to general physical activity (cough, taste, sing, take), social operations (canvass, touch, govern, meet), and task-performance (make, cook, print, paint).

Past Concern: The past-tense forms of the verbs contained in the Present Concern dictionary.

Praise: Affirmations of some person, group, or abstract entity. Included are terms isolating important social qualities (dear, delightful, witty), physical qualities (mighty, handsome, beautiful), intellectual qualities (shrewd, bright, vigilant, reasonable), entrepreneurial qualities (successful, conscientious, renowned), and moral qualities (faithful, good, noble). All terms in this dictionary are adjectives.

Rapport: This dictionary describes attitudinal similarities among groups of people. Included are terms of affinity (congenial, camaraderie, companion), assent (approve, vouched, warrants), deference (tolerant, willing, permission), and identity (equivalent, resemble, consensus).

Satisfaction: Terms associated with positive affective states (cheerful, passionate, happiness), with moments of undiminished joy (thanks, smile, welcome) and pleasurable diversion (excited, fun, lucky), or with moments of triumph (celebrating, pride, auspicious). Also included are words of nurturance: healing, encourage, secure, relieved.

Self-Reference: All first-person references, including I, I'd, I'll, I'm, I've, me, mine, my, myself. Self-references are treated as acts of "indexing" whereby the locus of action appears to reside in the speaker and not in the world at large (thereby implicitly acknowledging the speaker's limited vision).

Spatial Awareness: Terms referring to geographical entities, physical distances, and modes of measurement. Included are general geographical terms (abroad, elbow-room, locale, outdoors) as well as specific ones (Ceylon, Kuwait, Poland). Also included are politically defined locations (county, fatherland, municipality, ward), points on the compass (east, southwest) and the globe (latitude, coastal, border, snowbelt), as well as terms of scale (kilometer, map, spacious), quality (vacant, out-of-the-way, disoriented) and change (pilgrimage, migrated, frontier.)

Temporal Awareness: Terms that fix a person, idea, or event within a specific time-interval, thereby signaling a concern for concrete and practical matters. The dictionary designates literal time (century, instant, mid-morning) as well as metaphorical designations (lingering, seniority, nowadays). Also included are calendrical terms (autumn, year-round, weekend), elliptical terms (spontaneously, postpone, transitional), and judgmental terms (premature, obsolete, punctual).

Tenacity: All uses of the verb "to be" (is, am, will, shall), three definitive verb forms (has, must, do) and their variants, as well as all associated contractions (he'll, they've, ain't). These verbs connote confidence and totality.

Intellectual Property Rights and Corporate Governance challenges- a case of Britannia and Danone

*Padma Srinivasan, bpadmasrinivasan@yahoo.co.in
Manipal University, India*

Abstract

The intellectual property rights issues have emerged between Britannia Industries and French Dairy and beverages giant, Group Danone regarding the ‘Tiger’ brand of biscuits. Simultaneously, corporate governance issues on stakeholder management and corporate disclosure policies have arisen.

Britannia’s chairman Nusli Wadia resigned on 19 September 2008 from the IPR panel to ensure there was no argument of interest in dealing with Tiger IPR matter and talks between Wadia Group and Danone over shareholder issues. Danone wants to go for arbitration on the issues.

Key words: Corporate Governance, IPRs, Britannia, Corporate Finance

1. Introduction

Mr. Nusli wadia had resigned from IPR panel to ensure no conflict of interest in dealing with IPR matter. The difference of opinions between Britannia Industries and Danone over intellectual property rights of Tiger brand of biscuits had initiated proceedings in the courts with the Indian firm initiating legal action against the French food giant in Singapore. Britannia has obtained legal advice and IPR experts’ support on the premise of brand ‘Tiger’ against the Danone group.

Danone had wanted a third party judge to arbitrate and settle issues amicably. When contacted, a Danone spokesperson said it had a different position from Britannia regarding the IPR of Tiger. “We have tried to find a solution harmoniously. So a third party as a judge will be great to arbitrate,” the Danone spokesperson said.

2. Britannia IPR Committee

The IPR committee was created in May 2006 to deal with all IPR matters of the company and for the last year had been meeting to decide the issue of use and registration of Tiger brand by Group Danone in several countries without the consent of Britannia Board.

Recently, Danone had sold its global biscuits business to Kraft foods except in India, where it is one of the promoters of Britannia. Now the Britannia IPR committee will now be headed by Vijay Kelkar, an independent director and will consist of Britannia managing director Vinita Bali and two other sovereign directors Nimesh Kampani and Keki Dadiseth. Wadia and Danone hold almost equal stake in Britannia through UK-based Associated Biscuits International Holding.

3. Company Backgrounds

French dairy giant Group Danone, was waiting in the wings for regulatory approvals to make a big bang entry into India, has decided to sell its 25.1% stake in domestic biscuit company Britannia Industries, subject to Britannia allowing Danone to operate separately. Danone which used to blend Britannia’s revenues in its financial results has ceased to do so since the first quarter of the financial year ie April-June 2006.

Now, Britannia is only accounted for as a financial investment in Danone's books. The French company is currently negotiating with Indian partner Nusli Wadia to resolve issues related to the Indian joint venture, Wadia BSN India Ltd. The Wadia BSN joint venture, which was set up in 1996, has been practically obsolete, with no business for the past 11 years. But the Indian partner has been up in arms over the foreign partner's endeavor to ride alone in India. Wadia has so far refused to issue a no objection certificate to Danone. The French company is also very clear that its India strategy will be limited to fresh dairy products, essentially yoghurts and beverages (bottled water). Britannia Industries has refrained from sharing its results for the quarter ended September with Group Danone in a surprising move that could further widen the gap building up between the Wadia group and the French foods giant.

The Bangalore-based maker of Tiger and Pure Magic biscuits is believed to have cited corporate governance issues in support of its decision. A Britannia board meeting on August 6 is said to have approved the move.

As a result, Danone's financial figures for its third quarter ended September do not include Britannia's performance. This is the first time in the joint venture's 12-year-old history that such a development has taken place. The exact reasons behind Britannia's sudden decision is not known. Indian stock exchange regulations forbid prior revelation of price sensitive information to any one particular shareholder group. However, it is not known if the prohibition applies to joint venture partners and parents of domestic subsidiaries. Many firms are known to share their financial performance with the parent to enable consolidation in the global accounts if the parent is also a listed company overseas. However, in the case of Britannia, Danone is only a joint venture partner and not the owner. The firm owns about 25% through Associated Biscuits International Holdings which in turn is owned jointly by Danone and the Wadia group.

Group Danone is also in talks with the Indian government to clarify its stand on various issues. Danone, which has an FIPB sanction to invest in India, is now in discussion to reactivate that approval. Group Danone is likely to take on a mass-market strategy for its fresh dairy products. India is one of the largest markets for fresh dairy products, but a lot of it is limited to the unorganized sector.

The intellectual property rights conflicts between Britannia Industries and French Dairy and beverages giant, Group Danone is heading for an early breakthrough. Sources close to the development said that the matter is likely to come up for hearing in Singapore early next week.

Britannia Industries dragged Danone to a Singapore court last year seeking a immediate redressal of the Tiger brand issue. Both parties have been locked in a dispute over the trademark of Britannia's mass market biscuit brand Tiger. Danone which holds 25.5% indirect stake in Britannia through a holding company Associated Biscuits International Holdings (ABIH) has been accused by the management of Britannia Industries of registering the Tiger Trademark globally without the approval of Britannia.

The case which was filed by Britannia last year has reached the critical pre-trial stage at the Singapore court according to sources if the parties reach a settlement at the pre-trial conference (PTC) stage, they would not need to go for a full trial. Danone applied for registration of the Tiger trademark in over 70 countries. It had made an application to register the Tiger trademark in Singapore way back in November 1999 and received a certificate in July 2003, according to the Intellectual Property Office of Singapore.

Britannia Industries discovered that its trademark had been registered in nearly 35 countries by Danone only a couple of years back when the company aggressively pursuing its International expansion. Britannia submitted its trademark application for tiger in Singapore only in April 2007 and the same still pending. Danone is fighting the case through its wholly owned French subsidiary generate biscuits. Its trademark registration at Singapore however will expire by November 2009.

The Tiger trademark contains an animated image of the tiger and the word tiger is a key component of the ongoing tussle between the Indian textiles to airlines conglomerate Wadia group and Danone. Both of them have an equal stake in ABIH which in turn holds 51% in Britannia. The management of the companies said that sources are in discussion to hammer out the terms of Danone to sell its stake in ABIH to the Wadias. Danone would have to exit the biscuits business in India and dissolve its partnership with the Wadias. This move will pave the way for its solo entry into the marketing yoghurt and beverages in India.

4. Taxability of IPRs¹

Service tax has been imposed on intellectual property services rendered by holder of an intellectual property right by the Finance Act, 2004 with effect from 10th September, 2004. The gross amount charged to any person in relation to intellectual property services is chargeable to service tax, i.e. services provided by holder of intellectual property rights to any person.

Intellectual properties are the creation of the human mind and human intellect and that's why such assets are called intellectual property. Intellectual properties help to sustain the leadership, initiative and investment of holders with technical know-how and successful marketing ideas that foster huge commercial returns. On legislative framework, in a country like India, intellectual property finds its recognition in entry No. 49 in the Union List of Seventh Schedule under

Article 246 of Indian Constitution. The entry finds place as patents, invention and designs, copyright, trade marks and merchandise marks. To regulate these intellectual properties, we have following legislations -

. Patents Act, 1970

. Copyright Act, 1957

. Trade & Merchandise Marks Act, 1958

. Trade Market Act, 1999.

5. Meaning of Intellectual Property Right

Section 65(55 a) defines "intellectual property right" to mean any right to intangible property, namely, trademarks, designs, patents or any other similar intangible property, under any law for the time being in force, but does not include copyright".

Intellectual property rights (IPRs) are intangible property rights arising out of intellect. Intellectual property refers to the results or benefits arising out of application of intellect which may be in the form of any design, patent, trade mark, invention, formula, goodwill, etc. IPRs refers to the rights arising out of creation of intellectual property enjoyed or owned by its owner. The rights can be relinquished, delegated, shared, sold, assigned or transferred, whether temporarily or permanently. IPR's do not include copyright which are covered under Copy right Act. Intellectual property rights are the rights granted by state to provide parties or persons to encourage creativity of mind like artistic or literary work, invention, marks, symbols etc. IPRs provide creators with certain rights which in turn have commercial value. Ideas, knowledge, processes, invention, designs etc. are today important part of trade. IPRs could relate to following -

Patents - New technical concepts, inventions

Copyright - Text, graphics, software, data compilations, art, music

Trade marks - Brands (Product/Service) image and reputation

Confidential Information - Ideas, information, know-how etc.

Design Rights - Form and appearance, decoration

Trade mark has been defined under Section 2(zb) of the Trade Marks Act, 1999 as under -

"trade mark' means a mark capable of being represented graphically and which is capable of distinguishing the goods or services of one person from those of other and may include shape of goods, their packaging and combination of colours; and -

(i) in relation to Chapter XII (other than Section 107), a registered trade mark or a mark used in relation to goods or services for the purpose of indicating or so as to indicate a connection in the course of trade between the goods or services, as the case may be, and some person having the right as proprietor to use the mark, and

(ii) in relation to other provisions of this Act, a mark used or proposed to be used in relation to goods or services for the purpose of indicating or so to indicate a connection in the course of trade between the goods or services, as the case may be, and some person having the right, either as proprietor or by way of permitted user, to use the mark whether with or without any indication of the identity or that person, and includes a certification trade mark or collective mark".

Mark has been defined under Section 2(m) of the Trade Marks Act, 1999 as under-

"mark' includes a device, brand, heading, label, ticket, name, signature, word, letter, numeral, shape of goods, packaging or, combination of colours or any combination thereof".

Design has been defined under Section 2(d) of the Designs Act, 2000 as under-

"design' means only the features of shape, configuration, pattern, ornament or composition of lines or colours applied to any article whether in two dimensional or three dimensional or in both forms, by any industrial process or means, whether manual, mechanical or chemical, separate or combined, which in the finished article appeal to and are judged solely by the eye; but does not include any mode or principle of construction or anything which is in substance a mere mechanical device, and does not include any trade mark as defined in clause (v) of sub-section (1) of section 2 of the Trade and Merchandise Marks Act, 1958 (43 of 1958) or property mark as defined in Section 479 of the Indian Penal Code, 1860 (45 of 1860) or any artistic work as defined in clause (c) of Section 2 of the Copyright Act, 1957".

"Brand name" or "Trade name" has been assigned meaning under Chapter Note 12 of the Chapter 71 in Central Excise as:

'Brand name' or 'trade name' means a brand name or a trade name, whether registered or not, that is to say, a name or a mark, such as symbol, monogram, logo, label, signature, or invented word or writing which is used in relation to such specified services for the purpose of indicating, or so as to indicate a connection in the course of trade between such specified services and some person using such name or mark with or without any indication of the identity of that person.

Patent has been defined under Section 2(m) of the Patents Act, 1970 as a patent granted under the Act. Dictionary meaning of patent is a license to an individual or an organization conferring a right or title for a set period, especially the sole right to make, use or sell some invention. Patentee is a person or organization that obtains or holds a patent for something. Copyrights are governed by the Copyright Act, 1957. Copy rights subsists throughout India in certain classes of works i.e., original literary, dramatic, musical and artistic works; cinematograph films and sound recording. Intellectual property right, thus implies the following basic ingredients -

- (a) it is a right
- (b) right should be to intangible property
- (c) intangible property could be a patent, design, trademark or any other intangible property
- (d) such intangible property should be recognized under any law in force
- (e) IPR excludes a copyright.

Meaning of Intellectual Property Services

Section 65(55b) defines "intellectual property service" as under -

"intellectual property service" means -

- (a) transferring, temporarily; or
 - (b) permitting the use or enjoyment of,
- any intellectual property right".

IPR services would cover both - permitting the use or enjoyment of IPR or temporary transfer of IPR. IPR service would, therefore, include both - transfer of an IPR on temporary basis and allowing the use of an IPR or right to enjoy IPR to some one else, other than the owner or holder of an IPR.

IPR service would mean -

- (a) permanent transfer of IPR (only prior to Finance Act, 2005)
- (b) transfer of IPR, which may not be a permanent transfer (say, assignment of an IPR for a fixed term)
- (c) permitting the use of IPR
- (d) permitting to enjoy the IPR.

Meaning of Taxable Service

Taxable Service has been defined under Section 65(105)(zzr) to mean any service provided or to be provided to any person, by the holder of intellectual property right, in relation to intellectual property service.

A taxable service should meet the following conditions -

- (a) service should be provided to any person
- (b) service should be provided by the holder of IPR
- (c) service should be any service in relation to IPR.
- (d) IPR should be transferred temporarily or permitted to use without transfer.
- (e) IPR should not pertain to copyright.
- (f) Such IPR should be recognised under Indian laws.

According to Circular No. 80 dated 10th September 2004, a permanent transfer of intellectual property right does not amount to rendering of service. On such transfer, the person selling these rights no longer remains a "holder of intellectual property right" so as to come under the purview of taxable service. Thus, there would not be any service tax on permanent transfer of IPRs. The definition also stands amended by the Finance Act, 2005 w.e.f. 15.06.2005.

According to clarification issued vide Circular No. 80 dated 10th September, 2004, intellectual property emerges from application of intellect, which may be in the form of an invention, design, product, process, technology, book, goodwill etc. In India, legislations are made in respect of certain Intellectual Property Rights (i.e. IPRs) such as patents, copyrights, trademarks and designs. The definition of taxable service includes only such IPRs (except copyright) that are prescribed under law for the time being in force. As the phrase "law for the time being in force" implies such laws as are applicable in India, IPRs covered under Indian law in force at present alone are chargeable to service tax and IPRs like integrated circuits or undisclosed information (not covered by Indian law) would not be covered under taxable services.

In *Araco Corporation v. CCE, Bangalore* (2004 - TMI - 221 - CESTAT (BANGALORE)) where the appellants had transferred the technical know how under the licence, it was held that the service falls prima facie, under the category of intellectual property services and not under consulting engineer's services.

In *Aviat Chemicals Pvt. Ltd. v. CCE (ST)*, (2004 -TMI - 145 - CESTAT, NEW DELHI), it was held that right to use trade mark is a transaction in property and not consultancy or advice and that no consultancy or advice is involved in lease or sale of trade mark as it is a transaction in intangible property.

In *India Pistons Ltd. v. CCE* (2007) 8 STJ 276 (CESTAT, Chennai), it was held that telegraph transfer is distinct and separate from engineering consultancy service. The royalty paid to foreign collaborators in terms of technical assistance agreement entered between them was not exigible to service tax as service received was different from engineering consultancy service. [Also see *Prudent Communication System Pvt. Ltd. v. Commissioner of Service Tax*, (2007 -TMI - 1008 - CESTAT, BANGALOR); *Colgate Palmolive Company v. CCE & C, Goa* (2007) 6 STT 169 (CESTAT, Mumbai); *Shore to Shore MIS Pvt. Ltd. v. CCE, Chennai* (2006 -TMI - 837 - CESTAT, CHENNAI)]

Supply of technical know-how and royalty paid for technical know-how was not taxable as consulting engineers service. [*Hindustan Hardy Spicer Ltd. v. CCE, Nasik* (2006 -TMI - 1528 - CESTAT, MUMBAI)] [Also see *Bharat Electronics Ltd.v. CCE* (2007) 7 STT 206 (CESTAT, Bangalore); *Hero Honda Motors Ltd. v. Commissioner of Service Tax* (2007) 8 STJ 429 (CESTAT, New Delhi)]

In *Hero Honda Motors Ltd. v. CCE* (2008) 13 STT 193; (2008), 10 STR 185; (2008) 13 STJ 59 (CESTAT, New Delhi), it was held that right to use trade mark on containers for lubricant oil for a consideration would be prima facie covered under IPR service and as such pre-deposit was not waived fully.

In *Bharat Heavy Electricals Ltd v CCE, Bhopal* (2008 -TMI - 30075 - CESTAT, NEW DELHI), it has been held that transfer of right to use patented technology and brand name is taxable from 10.9.2004.

In *Modi Mundipharma Pvt Ltd v CCE, Meerut* (2009 - TMI - 34273 - CESTAT, NEW DELHI) , where goods were manufactured in own brand name by appellant and royalty was paid by way of deferred payment for know how received in 1990, it was held that service was rendered in 1990 when it was not taxable and payment made as per agreement only. Therefore, no IPR service was rendered in 1990 so as to be called a taxable service [Also see *Switzer Instruments Ltd v CST, Chennai* (2009 -TMI - 75120 - CESTAT, CHENNAI)

In *R.M. Dhariwal (HUF) v CCE, Pune -III* (2009 -TMI - 75867 - CESTAT, MUMBAI), it was held that royalty as a consideration for transfer of trade name and formulae for manufacturer of pan masala, gutka etc was covered by intellectual property service rather than scientific & technical consultancy service .

So far as service tax is concerned, transactions involving temporary transfer of IPR and grant of licence to use IPR, whether on exclusive or non-exclusive basis, are exigible to service tax. Service Tax is not levied on IPRs recognized under the Plant Varieties Act, the IC Design Act, the GIG Act, the Bio Diversity Act and Copyright Act. Service Tax is also not levied on the IPR not recognized under the Indian law.

6. Value of Taxable Service- In the event of holder of intellectual property rights assigning an intellectual property right without any consideration, the value of taxable service will be nil.

The value of taxable service would be determined by holder of IPR who provides the service based on his own valuation and criteria. There cannot be any benchmark to the valuation.

In case a transfer or use of an IPR attracts cess under Section 3 of the Research and Development Cess Act, 1986, the cess amount so paid would be deductible from the total service tax payable. The value of taxable service will not include the amount of cess paid towards the import of technology under Section 3 of the Research and Development Cess Act, 1986 in relation to any intellectual property right. (vide Notification No. 17/2004-ST, dated 10th September, 2004).

7. Specific Exemption-The value of taxable service will not include the amount of cess paid towards the import of technology under Section 3 of the Research and Development Cess Act, 1986 in relation to any intellectual property right. Vide Notification No. 17/2004-ST dated 10-9-2004.

8. Person Liable- A holder of an intellectual property right shall be liable to pay service tax and shall be treated as an assessee for service tax purposes.

Way Forward and Arbitration

An arbitration case between the two parties is also pending at the Bombay High Court if the talks between the managements fail, arbitration could take place in London where ABIH is officially registered. Danone recently formed a joint venture with Yakult Honsha of Japan and launched a probiotic drink called Yakult in the country.

Board Room to Battlefields of Family Wars- Learning From Reliance- Mtn Deal

*Padma Srinivasan, bpadmasrinivasan@yahoo.co.in
Manipal University,INDIA*

Abstract

RCom and MTN deal was a simple share swap but it fell apart due to family dynamics. It brought about the thinking and governance beyond board rooms.

The deal between MTN and RCom to form a \$70 billion world's largest Telecommunication Company has led to significant corporate governance challenges when RCom and MTN had initiated talks. The deal focused on swapping shares of RCom and MTN. RCom decided to sell 66% of shares to MTN¹. The merger would lead to making RCom the biggest shareholder and the subsidiary of MTN. The opinion differences between the two brothers Anil Ambani and Mukesh Ambani owner of Reliance Communication and Reliance Industries respectively led to legal hurdles resulting in the unsuccessful merger. Mukesh Ambani was of the view that Reliance Industries had the Right of First Refusal (ROFR) especially, for the deals that have a direct effect on the control structure of the Company. RCom was threatened of the challenge in the court by RIL for any transfer of equity. Anil Ambani thought of restructuring the deal in such a manner that his controlling stake is not affected in RCom. This research case looks the governance challenges arising during corporate deals that may have succeeded had there been consensus among the business families and the clause 'First Right of Refusal' duly, appropriately invoked.

Key Words: Corporate Governance, Family Businesses, Reliance Group, First Right of Refusal, Ownership Structure, Family wars, Media and Telecom sector

JEL No- G32, G34

1. Introduction

It was 18th July 2008 morning when Vashist saxena, opened the day's English Daily to read the business column after a brief search for his glasses. He was following RCom and MTN deal because he has just purchased 1000 shares of the company. He, being a conservative, office executive to analyse how cross border transactions will enrich his small kitty of shares and other investment. He was shocked to see that the deal was given in the front page simply as "deal called off". He felt peeved and could not comprehend- "why does a good deal gets flushed down the drain?" and started looking into the small library collection of books on stock investing. He found the company background and performances too.

2. MTN - RCom Company details

MTN is a South African telecom giant and Africa s biggest wireless company with over 68.2 million subscribers and operations in South Africa, Nigeria and Iran. It has a market capitalization of \$33 billion, operates in over 20 countries across the world. The news came in the early April 2006 that MTN is willing to sell of a part of its stakes

and this attracted a lot of telecom giants all across the world and in the list were Reliance, Bharti Airtel and Vodafone from India.

RIL claim is legally untenable and baseless as said by RCom officialsⁱⁱ. RIL also threatened MTN of exemplary charges for procuring a breach of agreement, if it enters into a deal with RCom. The intensification of the issues would lead to further complex legal challenges which are yet to be solved.

Talks were taking place in full stretch, but at the end it was RCom who got the lucky number. But, things didn't go well as everyone thought it would be. The proposed deal between Reliance Communications (RCOM) and MTN may involve an open offer by MTN to the shareholders of RCOMⁱⁱⁱ. The deal, results in a transfer of Anil Ambani's two-third equity stake in RCOM to MTN shareholders, against his acquisition of one-third equity in the foreign company. Also under Indian laws, any acquisition above 15% triggers an open offer for a further 20% stake for minority shareholders. In the two-step structure as discussed, MTN will become the holding company of RCOM and in return, Mr. Ambani will have a direct one-third equity stake in MTN and an indirect holding of nearly 20% in RCOM. In effect of this deal, Anil Dhirubhai Ambani Group (ADAG) will become the largest shareholder of the combined entity^{iv}. The deal would also need approval from the Indian and South African authorities as well as from 21 other countries where MTN operates all across the world.

Just within five hours after MTN called off talks and broke off from a proposed alliance with Bharti Airtel, Reliance moved into the fray and achieved what Bharti, India's largest telecom provider was not able to do a 45 days exclusivity period with MTN. If the deal was to happen, it would have created one of the world's largest emerging-markets telecom operators with 115m subscribers spread across the world^v. MTN would have entered the Indian dynamic market.

3. The deal

Both companies had the opportunity of expanding their business all across the world. For RCom, MTN would have definitely offered its experience in running GSM networks and it would be very important for RCom since, it had plans to launch a pan-Indian GSM network which is a CDMA operator. MTN is also expertise in offering 3G services in South Africa that RCom could have leveraged in India^{vi}. MTN, on the other hand, had the chance to leverage Reliance's non-mobile business enterprise and its large submarine cable network across 60 countries around the world^{vii}. The coming together of MTN and RCom would bring benefits to 115 million customers of 23 countries and will edge out the Airtel deals with MTN. Airtel is a worthy competitor having 62 million customers in comparison with RCom that has a customer base of 45 million.

The combined Balance Sheet in 2008 of MTN-RCom would have indicated a \$14.4 billion or Rs.58000 crore companies and have been very profitable next to the Chinese telecom giant, China Mobile in the entire world. RCom's market capitalization also would have soared from \$28 billion, taking the stake value in MTN to \$12 billion. MTN also stands to gain as the single largest shareholder in RCom in addition to the management rights. RCom's shareholding pattern has been consistently changing since 2006 when it was first listed in stock exchange.

4. Proposal for Deal between MTN and RCom

RCom has proposed an acquisition with South African telecommunication MTN. In order to finance for the same it is planning to raise a part of the capital \$5 - \$6 billion from the banks. As in reply to the same, many international banks, Indian banks and also some European banks like HSBC and Barclays, have offered an underlying commitment for the purpose of the deal. Given an overall equity holder's contribution of \$4 billion and an extra \$7

billion to \$8 billion by RCom would cover the financial constraints of the deal. MTN Group was to issue as much as 20 per cent fresh equity to Anil Ambani's Reliance Communications (RCom) as part of a multi-stage merger deal^{viii}. The fresh equity will have special voting rights helping Ambani gaining authoritative control over the company and make them the largest stakeholder of MTN. MTN also will be part of RCom to assist reverse merger process.

Mr Mukesh Ambani-backed RIL sent a letter to RCom claiming first right of refusal [ROFR], if Mr Anil Ambani decides to sell equity to South African telecom company MTN. AAA com, company of Anil Dhirubhai Ambani Group (ADAG) which has a share of 63.38% of the paid up capital in Reliance Communication Ltd (RCOM) has charged Mukesh Ambani's Reliance Industries with causing it substantial damage. AAA Com claimed that RIL's unwanted interference had derailed merger negotiations between RCOM and MTN and has created confusion between the two companies.

The statement came a day when both RCOM and MTN mutually called off their talks. In the letter to RIL, AAA Com said that it was not part to any non-compete agreement, dated January 12, 2006 between RIL and RCOM and said that the agreement was not binding on AAA Com's shareholding, that its shares cannot be subjected to right of first refusal by RIL, that it was claiming at the time of negotiation between RCOM and MTN^{ix}. But, on the other hand, RIL claims that RCOM had entered into a non-compete agreement under which RIL has right of first refusal on Anil Ambani's holding in RCOM - when the Reliance empire was divided in January 2006. Negotiations between RCOM and MTN on the day after RIL moved to start arbitration proceedings on its right of first refusal on RCOM shares and it was publically announced by both companies that "due to certain legal and regulatory issues, the parties are presently unable to conclude transaction".

5. Right of First Refusal (ROFR) - a contractual right

Right of First Refusal is actually an agreement with the property owner that gives another person the right to buy or rent the property before it goes to the open market^x. It is a contractual right which gives the property owner the option to enter a business transaction with others, strictly according to specified terms, before the owner is entitled to enter into any sort of transaction with the third party. Right of first refusal is similar in concept to a call option^{xi}.

A call option is much of a financial contracts between two parties or persons- the buyer and the seller^{xii}. The buyer of the option has the *right* to buy an agreed quantity of a particular financial instrument or a commodity from the seller of the goods at a certain time within the expiration date for a certain price^{xiii}. The seller is obligated to sell the commodity or financial instrument should the buyer so decide. An ROFR differs from a Right of First Offer (ROFO, also known as a Right of First Negotiation), even though both of them are similar. In ROFR, the owner undergoes exclusive good faith negotiations with the rights holder before negotiating with other parties or persons^{xiv}.

A ROFR gives us an option to enter into a transaction on exact or approximate transaction terms on the other hand ROFR can be merely an agreement to negotiate. For example, if X owns a house that he plans to sell to Y for 10 lakhs. However, Z holds a right of first refusal to purchase the house. Therefore, before X can sell the house to Y, he must first offer it to Z for the exact amount of 10 lakhs. Y can only buy the house if Z declines the offer at the proposed 10 lakhs price. An ROFR can cover almost any sort of assets which includes personal property, real estate, a screenplay, a patent license or an interest in a business^{xv}. It can also cover business transactions which are not strictly assets, for example the right to enter a joint venture or distribution arrangement^{xvi}. Since ROFR is a contract right, the holder's remedies for breach are mostly limited to recovery of damages^{xvii}.

6. Challenges and Issues- An analysis

Mukesh Ambani, the owner of Reliance industries (RIL) asked for first right of refusal and requires the South African giant MTN to stop the deal till the family issues are resolved. The series of aggressive statements made by RIL have put a stop on the deal. This was going to be one of the largest merger and acquisition telecommunication deal by an Indian company. In a complex share swap agreement, Reliance communication (RCom) owner Anil Ambani was to part with his portion of stake in RCom.

According to MTN dialogues are still under process as said by MTN spokes person Nozipho Bardill. The RIL stands say that the RCom has to be offered to Mukesh Ambani before being sold to anyone. The family settlement was signed in august 2005 after informal discussion between the two brothers. The ownership settlement clearly divided the two businesses. Anil was given the telecomm business and Mukesh Ambani was given the lucrative petroleum and petrochemical business. RIL didn't reply on this but according to RCom group "RIL is hampering one the biggest telecomm deal which would have made billions of Indian proud".

The Anil Ambani group claimed that RIL has talked to MTN group and have made a false claim of stakes in RCom. RCom was served with copy of letter send by RIL to MTN^{xviii}. For RCom, (Anil Ambani) MTN deal is very important. If deal is on than telecomm network will spread from the Cape of Good Hopes to Himalayas. This merger will create a telecomm giant with the base of 100 million customers and further growth of telecomm sector. This has to be seen whether the RIL claim will hamper the merger and acquisition between the two giants^{xix}. But according to analyst any seller would go back if there were controversial statements and disputes. According to the RCom, RIL is claiming on the agreement made on January 12th, 2006 which was unilateral signed by only RIL officials^{xx}. RIL claim is out of frustration and envious because of the continuous success of RCom. RCom has informed stock exchange on May 26th 2008, regarding the negotiation with MTN for a potential combination of two businesses. Also an agreement was signed between brothers according to whom family should be kept informed of any majority stacks is any of the group companies.

7. The collapse of the deal

MTN communicated that the deal was mainly called off due to unfavorable regulatory issues that had terminated the birth of world's largest telecom company \$70 bn telecommunication company with 120 mn customer base. RIL was of the view that the merger would not help the shareholders RCom and would only benefit Anil Ambani. Mukesh Ambani further added that most of the shareholders of RCom were also shareholders of RIL and that it was hid duty to protect their interests and rights. As per RIL, the benefit received by RCom should be returned to RIL.

Corporate know that both the groups have spanners kept in the other company to keep a track of activities undertaken by the other but none knew that the spanner would actually work as it has in the MTN case. This also led to the sliding of price of RCom. The market capitalization showed a meltdown of nearly a third to reach a level of \$18 bn. Before the deal was called off, ril had claimed the right of first refusal over sale of RCom shares to MTN^{xxi}. The ADA group however scraped the claim. In order to protect the deal, two of the ADAG companies had filed caveats in the Bombay high court to ensure that no ex-parte order is issued if RIL goes for RoFR^{xxii}.

However RIL had proposed for mutual conciliation before the commence meant of formal arbitration. Rcom believed that mutual conciliations was just a way of ril to remove its frustration. The younger sibling warned the elder brother by threatening to retaliate if RIL goes legal. It would vigorously defend and would also claim for the cost and damages from RIL. It also added that RIL's claim was baseless, legally and factually untenable^{xxiii}. RIL

sending letters to intermediaries, banks and MTN without even communicating to RCom was reflecting the unfair and mala fide motives of the Mukesh Ambani led group^{xxiv}.

Terming RIL's threats as "false bogey of litigation and damages," the RCom sources expressed surprise that without knowing of the nature of a possible transaction between RCom and MTN, how RIL has jumped to the conclusion that it would be covered by the alleged agreement of January 12, 2006^{xxv}. RIL also threatened MTN of exemplary charges for procuring a breach of agreement, if it enters into a deal with RCom. Anil claimed that Mukesh was jealous of younger brother's success and was trying to sabotage the deal and that the combines entity would be operating at a profit of Rs 50,000 cr which was higher than Mukesh Ambani's group, RIL was trying to curb the formation of the world's largest telecom giant. RIL's communication to MTN was based on a 'unilateral' agreement of January 12, 2006 signed by RIL officials, ADAG replies that the agreement for effecting the family settlement was held "unfair and unjust" by the Bombay High Court later the last year itself^{xxvi}.

RIL has referred to arbitration to solve this issue on 'First right of Refusal'. All the companies MTN did not want to enter into a legal tussle of the two brothers. The collapse of the deal has intensified the battle between the two brothers. This case speaks about how RIL claimed its first right of Refusal and RCom in turn fought back heavily by claiming that the agreement (which was made during demerger of reliance industries in 2005) was mala fide. Of course, because of Legal and regulatory hurdles RCom failed to save the deal. The case also talks about opposing views speculating in media and about possible solution and the corporate governance issues arising out of the dispute. This corporate war would see a lot of legal aspects coming into picture over the coming years.

Vashist Saxena, after an extensive study of the newspaper, found many opposing views speculating in media and about possible solution and the corporate governance issues arising out of the dispute. He also wondered aloud if Kokila Ben should Step in to solve the problem as she did in 2006 and intervene to silence corporate India's worst bitter battle between brothers on a single issue. He, finally raised hands and said 'God save the companies' and turned to browse the share quotations for the day.

The widening horizons of commercial corruption in developing countries – A case study

George Shenoy, georgeshenoy@smu.edu.sg
School of Law, Singapore Management University, Singapore

Abstract

Commercial corruption in developing countries appears in different stages. The first stage involves petty bribery with payment of bribes to public officials and bureaucrats as grease or facilitation payments. Then as the economies develop it moves on to the next stage involving the purchase of big ticket items and the award of infrastructure development projects. These involve immense amounts of money where even a small fraction or a percentage in bribe or kickback adds up to enormous amounts. With the advent of the revolution in information technology a third type of corruption has now emerged. This involves the telecoms sector with mobile phones and broadband services and the outsourcing of information technology services. This paper seeks to examine some aspects of commercial corruption in this context with a case study involving a recent scam concerning the issue of 2G telecom licenses in India.

Introduction

What is corruption

There is a correlation between power and corruption. Good governance is the essential requirement for human development in any society. Sadly, in developing countries good governance is generally known by the lack of it in varying degrees. The two plinths of good governance are competence and integrity on part of those who govern the country. Power is entrusted to those who govern to achieve a defined and socially desirable end so that it can benefit the governed. Power exercised corruptly and without integrity makes good governance impossible. Power can be and is abused for personal ends or for ends that have nothing to do with their intended purpose.¹

The abuse of power and corruption covers a wide spectrum that may be difficult to describe but not difficult to recognize. One definition of corruption states that it is the ‘misuse of public office for private ends or private gain’. The bribery, the most common form of corruption was described by the Privy Council in the case of *Attorney General of Hong Kong v. Reid* as “an evil practice which threatens the foundation of any civilized society”. It described the bribe as any “gift accepted by a fiduciary as an inducement to him to betray his trust”. The World Bank has defined corruption as the ‘abuse of public power for private benefit’. The actors involved are public figures, civil servants, politicians, bureaucrats and bribe-givers such as companies or individual business persons. Whatever the context, the notion of corruption connotes a betrayal of trust and a misuse of power, resulting in unfair advantages or illicit enrichment.² Most people intuitively know the broad meaning of corruption by seeing a link between power and its abuse. In most countries both the taking and the giving of a bribe is a crime.

Commercial corruption thrives in the absence of good governance. It is a fact of life especially in the developing countries. It has the ability to adapt to the growing economies where it appears in different stages. The first stage would be petty bribery. This involves payment of bribes to public officials and bureaucrats as grease or facilitation payments. Then as the economies develop it moves on to the next stage which involves the purchase of big ticket items like ships, aircraft and the defense supplies, as well the award of projects for infrastructure developments such as the building of highways, ports, and airports. These involve immense amounts of money, where even a small fraction or a percentage in bribe or kickback would amount to enormous amounts. These amounts can be spirited away into foreign bank accounts, or can be held for the benefit of the bribe taker by his relatives or nominees. For example shares can be issued to a relative which results in a bonanza to the bribe-taker when the enterprise makes a public issue of shares. A third type of corruption has now emerged where technology is involved. The stakes are high as the world is taken in by a technological revolution spurred by information

technology. This involves growth of the telecoms sector with the use of mobile phones and of broadband services and the outsourcing of information technology services.

This paper seeks to examine some aspects of commercial corruption in the context of a case study involving a recent scam concerning the issue of 2G telecom licenses in India. But before we go to the case proper it would be advantageous to consider some aspects of corruption to put the case in perspective.

What is wrong with corruption?

Where criminal conduct becomes a practice in any society, something which is routine and tolerated as a fact of life with little prospect of disclosure and punishment, such a society becomes a dysfunctional or a failed society. Such a society has no place for the rule of law and other features that distinguish it from a civilized society.

Corruption has been described as an 'evil practice' because of the severe effect it has on the poorest and most vulnerable segments of society as well as society at large. In poor societies, there is but one complaint that is common to their citizens and it is that the people in power are corrupt, that they are rogues who steal public money, and these sentiments are accompanied by feelings of disempowerment, shame and rage.³

From the earliest times, bribery and corruption have been regarded as vile. Most societies regarded them as vile because, next to torture, they are the most oppressive abuse of power of the state over its citizens, who are usually poor and powerless. The opposition to corruption in all forms is therefore closely linked to justice and the citizens' conception of what makes a society just and worth living in.

It has been pointed out, citing a report by the Stanford University's Graduate School of Business, how corruption breeds inefficiency, which means lower profits. The report found that corruption in its various forms, leads to inflation of employee ranks and drags down efficiency. This in turn slows the growth of a nation's wealth. Corruption is associated with lower per capita gross national products and lower rates of investment, which damages national economies by making businesses inefficient. Specifically, corruption adds extra costs to businesses and consumers, which in turn deter investment. Many capital exporting countries now have laws that prohibit their companies and nationals from giving bribes to foreign officials. As a result, the big players that are subject to laws prohibiting overseas bribery will avoid countries where giving bribes is a requirement for doing business. It has also been observed that bidders for projects will go for big ticket items like roads and airports that cost tens of millions of dollars where the percentage of the costs paid as bribe amounts to a large sum of money. Often in such cases the contract is over-priced and the quality of the finished product is inferior. Accordingly the officials will shun smaller projects like schools and hospitals, even though these are desperately needed, because there is little or no payment in bribes.⁴

Case study of 2G Licenses in India

Scandals of all types occur in India with unsurprising regularity. Some of the more recent scandals include those involving Satyam Computer Services, the Commonwealth Games, and the Adarsh Housing Society, to name a few. While the issues relating to these are yet to be resolved a new scandal has emerged relating to the issue of 2G telecom licenses that has been making the news headlines. India is the world's second-largest cellphone market, with over 700 million subscribers and the profits of private operators depend on licenses for spectrum. In 2008 the telecom ministry issued 2G spectrum licenses at below-market prices causing the national exchequer a loss of US\$39 billion. The scam has now come to head and is currently still in the process of unraveling. *The New York Times* (NYT) aptly summed up the scandal as "Tycoons with friends in high places. Public tenders conducted by irregular rules. Tens of billions of dollars in potential losses for the national treasury. Allegations of government ministers on the take, and of a respected prime minister too aloof to notice."⁵ The scam has spotlighted the dangerous nexus between the government officials and big business houses. The corruption problem has been blamed upon "crony capitalism" where everyone did favors for and received favors from dominant corporations.⁶

The unfolding of events

The issue came to light in November 2010 when India's Comptroller and Auditor-General (CAG) in a report, based upon the amount of money collected from the auction of 3G licenses, found a loss of over US\$39 billion to the national exchequer due to under pricing of the 2G spectrum. As a consequence the Union Cabinet Minister for Telecommunications and Information Technology at the time, Andimuthu Raja resigned from his ministerial post on 14 November 2010, was arrested for corruption⁷ and lodged in Tihar Jail along with a number of corporate figures.⁸ Raja who is a politician from DMK, a regional party in Prime Minister Manmohan Singh's national Congress-led coalition, has denied any wrongdoing. An Indian parliamentary panel questioned several business leaders including industrialist Ratan Tata of the Tata Group and Mr. Anil Ambani of the Reliance ADA Group in connection with the alleged irregularities.⁹

Raja's trial commenced on 13 April 2011. Earlier the police laid charges in the corruption scandal, said to be the biggest in independent India's history. Raja, who is accused of abuse of power, cheating, forgery and criminal misconduct appeared in court with eight senior company executives and bureaucrats.¹⁰ Subsequently Ms Kanimozhi, the daughter of DMK Chief M. Karunanidhi, the No.1 coalition partner of the Congress party was also arrested for corruption charges for her alleged role in the scam and lodged in the same jail.¹¹ The charge sheet filed by the CBI before the Supreme Court establishes how Rupees 200 crore connected with the scam traveled from a partnership firm of businessman Shahid Balwa of Swan Telecom to the Karunanidhi family-owned Kalaingar TV.

The scam involved the issue of 122 licenses of the 2G spectrum to 85 companies including many new telecom companies with little or no experience in the telecom sector at prices set in the year 2001. The scam involved allegations regarding the under pricing of the 2G spectrum resulting in a loss to the exchequer and illegal manipulation of the spectrum allocation process to favour select companies. The scam came to public notice when the Supreme Court of India admitted the writ petition filed by the President of the Janata Party, Mr. Subramaniam Swamy.¹²

Disregard of rules and established procedures

The CAG report highlighted how the telecoms ministry under Raja circumvented the established procedure and disregarded repeated warnings to use the auction mechanism to ensure transparency and equitable distribution of licenses. Instead licenses were sold on a first-come-first-served basis to benefit a select few bidders at 2001 prices contrary to government directives and rules. The ministry's actions were not in tune with the policy decision of the Telecom Regulatory Authority of India (TRAI) to replace fixed license fees with a pricing mechanism that would more accurately capture market prices with a combination of a nominal fee and a market-determined spectrum fee through competitive bidding. The 2001 prices reflected a totally nascent market and Raja's ministry also ignored efforts to bring in transparency through actions and updated spectrum valuations by the prime minister, the ministries of finance and law & Justice, TRAI, the telecom commission and a ministerial group and others.

Even though the telecom ministry professed a first-come-first-served policy in allocating 2G spectrum there was something wrong the way it was administered. This actually favoured a few bidders who seemed to have been privy to advance information. The ministry's Department of Telecommunications (DoT) issued a press release on 24 September 2007 saying it would stop accepting spectrum applications a week later on 1 October 2007, effectively putting an artificial cap on the number of licences. But it later advanced the cut-off date to 25 September, or 24 hours after the press release. The telecom ministry issued 121 licenses on 10 January 2008. It had received 575 applications, 408 of which were filed after the 24 September press release. A notice through another press release gave applicants less than an hour to collect the licenses, for which they had to submit bank guarantees. CAG noted that some licensees "who could proactively anticipate such procedural changes were ready with the demand drafts and could avail of the benefit of the first right to allocation of spectrum, having jumped the queue." It added, "the entire process lacked transparency and objectivity and has eroded the credibility of the DoT." According to the report, it turned out that 85 licensees did not meet basic eligibility conditions; some had provided incomplete

information and submitted fictitious documents. The new telecoms minister, Mr Kapil Sibal has said that he will issue show-cause notices to the 85 licensees for violation of the eligibility criteria, and also to 69 licensees that have failed to meet spectrum rollout obligations.¹³

Role of the Political Opposition and the Media

Mr. Subramaniam Swamy, the President of the Janata Party, had filed a petition in November 2008 seeking permission to prosecute Raja but that was ignored, leading the Supreme Court of India to ask the Prime Minister's Office, after Raja was arrested, to explain why it took 11 months to respond to the petition. The Government's answer was that it was premature to sue Raja and that Swamy should wait for the outcome of an ongoing investigation. The other petitioners include Paranjay Guha Thakurta, a journalist who was among the very first to write on the irregularities in awarding the 2G spectrum; Prashant Bhushan on behalf of the Centre for Public Interest Litigation; Anil Kumar, on behalf of the civil society organization Telecom Watchdog; and others among whom are the former chief election commissioner and former central vigilance commissioner (CVC). Following the allocation of the 2G spectrum in 2008 the media had highlighted its flaws but nothing came out of it. However, the CAG report in November acted as a catalyst to spur the opposition parties to make a concerted effort to remove Raja. Meanwhile there were reports in the media of secret phone recordings implicating Nira Radia, a high-profile corporate lobbyist whose clients included the big names in the industry including the Tata Group and Reliance Industries, of using top journalists to help secure the appointment of Mr Raja as the telecoms minister. The main source of these leaks are over 100 tapes of 5,000 recordings made by India's Enforcement Directorate and Income Tax authorities as part of their surveillance of Ms. Nira Radia. Radia lobbied government ministers and politicians on behalf of India's business elite.¹⁴

Companies and Individuals Charged

Mr Raja resigned as the Telecoms Minister in November 2010. In mid November the Comptroller issued show-cause notices to the companies involved, Unitech, S Tel, Loop Mobile, Datacom(Videocon), and Etisalat to respond to his assertion that all of the 85 licenses granted to these companies did not have the up-front capital required at the time of application and were in other ways illegal. However it is speculated that these companies will receive large fines but not have their licenses revoked. The CBI conducted raids on Raja and four other telecom officials in December 2010.¹⁵

The CBI will charge India's top conglomerates the Essar Group and Reliance ADAG with criminal conspiracy and cheating. This corruption scam was brought directly under the control of the Supreme Court of India as the government failed to move against powerful businessmen and politicians. The CBI has said that the two companies Loop and Swan Telecom were used as front companies by established telecom operators Essar and Reliance Communications to get more licenses. It is noted that this defeated the entire exercise and there is ample circumstantial evidence to prove that the telecom minister Raja and his cronies connived with the companies to give precious spectrum for a song. Massive kickbacks were given through real estate companies like DB Realty whose top billionaire owners are under arrest.¹⁶

The CBI filed its first 80,000 page chargesheet on 2 April 2011 before a Special Court in Delhi naming nine individuals and three companies. The nine accused individuals are: (1) A. Raja, the former Telecom minister, (2) Siddharth Behura, former Telecom secretary, (3) R.K.Chandolia, Raja's former personal secretary, (4) Shahid Usman Balwa, former Director of Swan Telecom (now Etisalat DB), (5) Sanjay Chandra, Managing Director of Unitech Limited and Unitech Wireless, (6) Gautam Doshi, Group MD, Reliance Anil Dhirubhai Ambani Group, (7) Hari Nair, Senior Vice-President, Reliance Anil Dhirubhai Ambani Group, (8) Surendra Pipara, Senior Vice-President, Reliance Anil Dhirubhai Ambani Group and Reliance Telecom Ltd, and (9) Vinod Goenka, Director, Swan Telecom and Managing Director of DB Realty. The three companies are: (1) Swan Telecom, (2) Unitech Wireless, and (3) Reliance Telecom. In the first chargesheet the CBI had named lobbyist Nira Radia and 124 others as witnesses. The CBI filed a second charge sheet on 25 April 2011 wherein it named five more accused individuals: (1) Kanimozhi, Rajya Sabha Member (DMK) and daughter of M. Karunanidhi, Tamil Nadu Chief Minister, (2)

Sharad Kumar of Kalaingar TV, (3) Karim Morani of Cineyug Films, (4) Asif Balwa of Kusegaon Realty and (5) Rajiv B. Agarwal of Kusegaon Realty.¹⁷

The Charges

All the accused have been booked under sections 120(b) (criminal conspiracy), 468 (Forgery for purpose of cheating), 471 (using as genuine a forged document or electronic record), 420 (cheating and dishonestly inducing delivery of property) and 109 (abetment if the act abetted is committed in consequence, and there is no express provision is made for punishment) of the Indian Penal Code. Kanimozhi has been charged with sections 7 and 11 of the Prevention of Corruption Act.¹⁸

Aftermath of the Scandal

It has been observed that among the many corruption scandals that India has been reeling under the telecom scandal may beat the rest in shock value, brazenness, arbitrariness and size.¹⁹

India's new telecom minister, Kapil Sibal, has proposed a slew of changes to the country's telecom policy in an attempt to streamline the industry. There are currently 15 service providers catering to nearly 800 million subscribers. As the subscriber base continues to grow the companies will look to consolidate. He has said that the merger and acquisition rules will be relaxed to allow consolidation of the sector. Mr Sibal also indicated that as part of the new policy, the government will separate mobile licences from spectrum fees.²⁰

The Fallout

As *Time* has pointed out "The impact of any irregularities in spectrum allocation – if such irregularities are ultimately proved – may, in fact, be felt in other institutions. Corruption has become the No.1 concern in public conversation in India, according to a recent poll by the BBC, and opposition demands for a probe have disrupted the functioning of the legislature in the world's biggest democracy. The press, too, has come under fire, with several prominent journalists featuring in the Radia tapes as power brokers and go-betweens. Repairing the damage to - India's reputation may take much longer."²¹

It has been suggested that the telecom scandal may just be the tip of the iceberg. A broader and more serious independent inquiry is now required to find any evidence of widespread corruption as powerful Indian businessmen like Ambanis and Tatas use their power, influence and cash to garner resources or projects. The role of the media is also under scanner. Instead of playing their role as watchdogs in a democracy, many in the Indian media have chosen to collaborate with corrupt politicians and greedy businessmen to enrich themselves. Indian media are guilty of manufacturing consent in favor of a powerful few against the interest of the vast majority of India's population that is among the poorest and the most deprived in the world.²²

Beyond the political infighting, the scandal has broad implications for India, the world's second-fastest-growing economy. Growth depends increasingly on turning large swaths of the state-controlled sector over to the private sector, whose capital and expertise are critical as India embarks on plans to build roads, bridges, ports and power plants. But analysts say that the telecom scandal is just one indicator of crony capitalism and inadequate oversight that fuel public skepticism about capitalism and slow down reforms. The scandal has reinforced the perception of an Indian economy dominated by a small, tightly connected elite. NYT quoted Eswar S.Prasad, a professor of trade policy at Cornell University and an advisor to India's Finance Ministry, as saying "Even as government cedes control over large parts of the economy, its graft-ridden approach to privatization could leave long lasting scars that hold India back from reaching its potential. Open corruption and rising disparities in wealth are a volatile mix that could affect social stability if benefits of growth don't filter down."²³

Wharton's Professor Jeetendra Singh feels that foreign investors may view corruption in India 'as the cost of doing business' undermining the business confidence. There is a need to rebuild confidence in India as a destination for foreign capital. India would attract more foreign investments and business interest if it had a stronger

reputation as being non-corrupt. Singh says that corruption is “heterogeneous and multifaceted”, ranging from a simple bribe to systemic corruption, where retrograde cultural norms get well-established in specific settings, such that non-corrupt newcomer may well find it impossible to survive”. According to him inferior cultural norms are the toughest to tackle, and those values could prove very difficult to unhinge. “In its abstract form, the gains in a transaction get disproportionately appropriated by actors in relation to their role in the creation of this value,” he says, “This distorts incentives and ultimately, values in a society and leads to inequitable distribution of income and wealth, and inefficient allocation of capital”. He warns of “collective consequences such as institutionalization of inferior cultural norms [for example, ‘in order to succeed, you have to be dishonest, because everyone else is dishonest’] may take generations, even centuries, to sort out meaningfully.” Unfortunately, there is no solution with a silver bullet, but he says that the citizenry have the right to vote out of power forever all corrupt leaders and elect better replacements.²⁴

Need for Good Governance and Transparency

The ongoing scandals involving corruption will only confirm the lingering doubts about doing business in India. Though India’s economy has been growing at a respectable rate in recent years and attracting foreign investors, the ongoing corruption scandals would have discouraged many more from investing in India. A recent survey by KPMG on bribery and corruption in India makes for a dismaying reading. A full 100% of the survey respondents said that “Corruption skews the level playing field and tends to attract organizations with lesser capability to execute projects.” Only real transparency and swift, effective prosecution of corruption charges will change that, and India has a long way to go. For every well-publicized set of arrests, there is another behind-closed-door session and another round of rumors.²⁵

India makes a dismal showing in the 2010 Corruption Perception Index rankings issued by Transparency International, a premier non-governmental organization devoted specifically to corruption, where it takes the 87th spot among 178 countries listed.²⁶ The top rank is shared by Denmark, New Zealand and Singapore with 9.3 points out of 10. India scores a meagre 3.3 points, but this ranking was compiled before the telecom scandal erupted.

Transparency International has identified several factors that generally exist in an environment conducive to and associated with bribery. Some of these factors are (a) low public-sector salaries; (b) immunity of public officials; (c) secrecy in government; (d) worsening public procurement practices; (e) the privatization process; (f) increase in foreign investment and trade; (g) restrictions on the media; (h) financial liberalization; and (i) multiparty elections. It would be observed that most of these factors are relevant in India’s case and India would have to tackle these issues in a serious manner in order to extricate itself from the current sorry state of its affairs.

Legal framework to fight corruption

As India plugs into the global economy owing to its new-found role as one of the two economic drivers of the world economy (the other being China), India needs to come on par with international standards. This is because India cannot afford to have third world standards in its domestic setting while it seeks to take on global role for which it must adopt international standards. While this assertion is valid for all fields across the board it is particularly relevant in the context of this paper, that is, to begin with it has to set its house in order with regard to its legal framework and enforcement in criminalizing corruption on par with international standards.

India does have a legal framework for criminalizing corruption. As indicated above the charges were brought against the accused in this scam under various sections of the Indian Penal Code, and under the Prevention of Corruption Act. The problem however is perhaps not the lack of laws but the enforcement of them. Nevertheless there is plenty of scope to update the legal framework and the enforcement of the laws.

This is where India can take a leaf from other countries and organizations that have enacted legislation and other measures to fight corruption. Some of these notable examples include USA which was the first country in the industrialized world to pass a law against corruption, the Foreign Corrupt Practices Act (FCPA). This statute applies to all companies that are listed on the US stock exchange. UK passed the Bribery Act in 2010 which is a comprehensive statute that criminalizes bribery which is due to fully come into effect on 1 July 2011.²⁷ It imposes

criminal penalties on companies and other organizations on whose behalf bribes have been paid. To escape sanctions, the burden rests on the company or organization in question to prove that it had in place adequate procedures designed to prevent persons associated with it from undertaking the conduct that was forbidden. Singapore and Hong Kong have earned the reputation as the top corruption-fighters in Asia with their legislation and excellent infrastructure in fighting corruption.

In addition there are regional and international Conventions on corruption. The Organization of Economic Cooperation and Development's (OECD) Convention on Bribery obligates its members to pass laws criminalizing bribery. OECD countries have enacted legislation to give effect to this Convention. For non-OECD countries including large countries such as India and China, there is the UN Convention Against Corruption (UNCAC). There is also the UN Global Compact whose Principle 10 requires the businesses to work against corruption in all its forms, including extortion and bribery.

India will do well to take a serious look at and implement the provisions of a UN Convention Against Corruption that it ratified on 1 May 2011. The UN General Assembly approved the text of the United Nations Convention Against Corruption (UNCAC) in October 2003 and it came into force in December 2005. To date more than 140 countries have signed the UNCAC and more than 60 have ratified the Convention. India signed the Convention on 9 December 2005 and ratified it on 1 May 2011.²⁸ To note a few salient features, Article 8 requires that countries promote integrity among their public officials, inter alia, by considering the establishment of codes or standards of conduct; Article 9 provides that countries shall establish transparent, competitive and objective systems of procurement and shall promote transparency and accountability in the management of public finances; Article 12 requires countries to take measures to prevent corruption and to enhance accounting and auditing standards in the private sector; Article 23 mandates the criminalization of the laundering of proceeds of crime; Article 26 requires countries to establish the criminal, civil, or administrative liability of legal persons for participation in the offences established in accordance with the UNCAC. These are but a few random examples, but needless to say that it is evident that they are all so strikingly relevant in the context of the subject matter of this paper. India needs to seriously abide by the principles contained in this Convention that it has now ratified.

Conclusion

India is at the crossroads where the forward thrust of its economic development is undermined by rampant corruption. Admittedly there is a dire need to tackle corruption. The ongoing saga of 2G Telecom scandal has called into question the government's willingness and the ability to do it. India's image has suffered nationally and internationally. There is not the slightest doubt in everyone's mind that India needs to clean up its act. Whether it will take up the challenge and rise up to the occasion in this regard remains to be seen.

Methodology of determining the basis of corporate social responsibility towards employees

Anna Remišová, anna.remisova@fm.uniba.sk
Zuzana Búčiová, zuzana.buciova@fm.uniba.sk
Comenius University in Bratislava, Slovakia

Abstract

Paper deals with framing corporate social responsibility (CSR) in the European business environment. The authors introduce the *Integrative model of CSR*, which is created in accordance with European theoretical fundamentals of CSR. The model presents a unique way of measuring and evaluating CSR level towards different stakeholders. The basis of CSR is set in terms of economical, legal and ethical responsibilities towards all stakeholders and the methodology of measuring CSR level is described. *The Integrative Model of CSR* is later on concretized for a selected stakeholder – employees to outline the process of evaluating CSR level towards a particular stakeholder.

The main aim of the paper is to present the methodology of determining the basis of CSR towards employees and to provide a guideline according to which it is possible to concretize CSR towards different stakeholders.

Key words: corporate social responsibility, Integrative model of CSR, business ethics, stakeholder theory.

Introduction

Corporate social responsibility (CSR) is a topic that has been widely discussed for almost six decades. Scholarly literature on the subject dates back to at least 1950s though according to Crane *et al.* (2008, p. 3) commentators on business have written about the subject for considerably longer. At the beginning it was discussed only by American authors and since 1980s it has spread to Europe as well as other parts of the world.

For a subject being discussed for such a long time it is not usual to lack a generally accepted definition or a common set of core principles but that exactly is the problem with CSR. Researchers still do not share a common definition or set of core principles and they still argue about what it means to be socially responsible (Crane *et al.*, 2008, p. 4). For example, Carroll (1999) reviews and discusses over 25 different conceptual definitions of CSR within the academic literature. According to Lockett *et al.*'s conclusion from a study of the CSR literature over a ten-year period “CSR knowledge could best be described as in *continuing state of emergence*. While the field appears well established ... it is not characterized by the domination of a particular theoretical approach, assumptions and method” (Lockett *et al.*, 2006, p. 133).

The main reason why it is so complicated to agree on a single definition, is that understanding CSR is determined by different cultural, historical, political, legal and social conditions of individual countries as well as different subject fields of scholars discussing the issues. Crane and Matten state that, “CSR as a view of business responsibility in society has been particularly strong as a concept in the USA, from where much of the authors, literature, and conceptualization have emerged. In Europe, however, the concept of CSR has never been quite as influential” (Crane, Matten, 2004, p. 46). We can say the opposite about business ethics. After business ethics was established as an independent scientific discipline, European authors have intensely engaged in the issues. According to Búčiová (2010, p. 34) it can be assumed that European scholars did not take an interest in CSR during the first four decades of its existence as it originated from different cultural, legal and historical background that was not close to the European culture. Until 1980s CSR addressed issues that did not reflect European business situation. Raising the question of corporate ethical responsibilities caused that European scholars got interested in the issues and joined the discussion on core principles of CSR. For European scholars it is business ethics what matters and thus it represents the bottom line of CSR. “In the USA from where CSR has emerged, business ethics is viewed as “alternative” or “complementary topic” to CSR. On the other hand, in Europe business ethics was broadly

accepted by scholars and developed over years. It has also become an integral part of understanding CSR” (Búciová, 2010, p. 35).

An important attempt to define CSR was made in 1979 by Carroll (1979, p. 500) stating that “the social responsibility of business encompasses the economic, legal, ethical, and discretionary expectations that society has of organizations at a given point of time.” According to Wood and Jones (1996, p. 45) Carroll’s four-domain framework for defining CSR has “enjoyed wide popularity among SIM (Social Issues in Management) scholars”. Carroll’s definition has been broadly accepted by scholars, but its interpretation significantly differs in Europe. Stakeholder theory is an integral part of the CSR notion, which means that accepting social responsibility towards all stakeholders is seen as a must. Ethical responsibility is very important part of CSR and encompasses a lot of CSR issues. CSR in Europe is seen as economic, legal and ethical responsibility towards all stakeholders as the reevaluation of the role of corporations in society is more evident. Philanthropic responsibility is seen as a complementary issue. To be socially responsible a corporation does not have to “pay part of its profit back to society” but to make certain that the profit is being achieved in a socially responsible way.

According to Teach (2005, p. 31) quoting Lyndenbergs perspectives to CSR, “the European influence will be very hard to resist over the long run.” These words are underlined by a recent article by Peter Knight, the president of Context America. He has commented on the criticism of some observers claiming corporate social responsibility in the USA has been falling as the corporations are not giving enough back. In his opinion “this criticism displays a lack of understanding about the responsibilities of business. Corporate responsibility is about integrity and ethics, rather than choosing to give away shareholders’ money” (Knight, 2011).

In Slovakia as well as other European countries there is an increasing number of corporations claiming CSR and reporting it on the basis of some CSR guidelines or standards or without using any. The problem occurring in practice is that since there exist neither common definition of CSR nor a common system for measuring it, corporations may misuse the situation and claim CSR for marketing purpose only without deeper interest in CSR activities and practices. On the other hand, corporations that are seriously interested in CSR may become confused as they are not familiar with the precise extent and complexity of the issue (Búciová, 2010, p. 32) Therefore we find it very important to create a new model for measuring CSR in accordance with European theoretical fundamentals of CSR – *The Integrative model of CSR*. As the evolution in CSR thinking worldwide seems to approach European understanding of CSR, the model will be applicable not only in Europe but also in the other parts of the world.

The main aim of the paper is to introduce *The Integrative Model of CSR* and to present a unique way of measuring and evaluating CSR level towards different stakeholders. Our partial goal is also to explain the methodology of measuring CSR level towards different stakeholders. On the example of one selected stakeholder (employees) we will outline the methodology of determining the basis of CSR. The article provides a guideline according to which it is possible by analogy to concretize CSR towards other stakeholders.

Theoretical foundations of the *Integrative Model of CSR*ⁱ

The Integrative Model of Corporate Social Responsibility is based on the notion of a corporation being a „corporate citizen” who is obliged to meet its legal and ethical commitments and at the same time has some specific responsibility based on its status of an economic entity. Furthermore, it is based on an integrative approach to business ethics developed by a Swiss professor P. Ulrich (1997; 2002) being also accepted by A. Remišová (2004; 2011) and her school of business ethics.

Description, analysis and comparison of individual approaches to CSR, simulation, and textual analysis of relevant CSR guidelines and standards have been used to develop *The Integrative model of CSR*.

Theoretical foundations of *The Integrative Model of CSR* are as follows:

- (1) Generally accepted definition of CSR by Carroll according to which “the social responsibility of business encompasses the economic, legal, ethical, and discretionary expectations that society has of organizations at a given point of time.” (Carroll, 1979, p. 500)
- (2) The notion of an organisation being an entity with social responsibility (i.e. accepting the idea that a corporation can act and acts as a subject of social responsibility which means that CSR cannot be understood merely as a sum of individual employee responsibilities). Understanding an organization as a subject of social responsibility, CSR should be understood as an institutionalization of certain principles and rules into everyday life of an organization.
- (3) The Stakeholder Theory according to which an organization should take responsibility for all relevant stakeholders in both its internal and external environment.
- (4) Emphasis on ethical responsibility of an organization as an integral part of all corporate activities.

Principle 1: Definition of CSR generally accepted by the authors all over the world states that the social responsibility encompasses 4 components – economic, legal, ethical and philanthropic responsibilities, with the first three components being an integral part of corporate activities, whereas philanthropic responsibility is being understood as desirable behaviour of corporations from the side of society. On the grounds of the above mentioned we have come to the conclusion that corporate social responsibility must inevitably include ethical, economic and legal responsibilities. Without being economically, legally and ethically responsible towards its stakeholders, an organization cannot be considered socially responsible entity. Accordingly, it is **necessary to set the basis of corporate social responsibility** which would define fundamental requirements for socially responsible behaviour of organizations in the area of economic, legal and ethical responsibilities. Moreover, in case an organization has accepted philanthropic responsibility towards its individual stakeholders it will, according to *The Integrative Model of CSR* increase the level of its social responsibility. However, if an organization carries out philanthropic activities without simultaneously being able to meet essential requirements for economic, legal and ethical behaviour towards its stakeholders, it cannot be considered socially responsible. The model does not accept the possibility of “compensation” of the criteria of CSR basis that have not been met by other activities beyond the core principles of economic, legal and ethical responsibilities.

Principle 2: *The Integrative Model of CSR* is described by Venn diagram (Fig. 1). Venn diagram is used to describe CSR also by Schwartz and Carroll (2003) in *the Three-Domain Model of CSR*. However, the interpretation of their model is different from the interpretation of *The Integrative Model of CSR*. The fact that in *the Integrative Model of CSR* the Venn diagram is used merely to describe the three basic components of corporate social responsibility and not to assess intentions of individual corporate activities makes significant difference. In our opinion, **corporate social responsibility should be assessed on the basis of the rate of institutionalization of economic, legal and ethical responsibilities into corporate activities** and not on the basis of the intention of the actions (as it is in *the Three-Domain Model of CSR*). It is important to bear in mind that even if the intention is of significant importance in the assessment of ethical conduct, it is in fact very difficult to reveal the true intention of an organization. The intention is thus not included as an indicator in *The Integrative Model of CSR*. The real intentions of corporate actions do not have to be obvious at the time of the assessment and thus we find the assessment of the intention of corporate activities very difficult and inaccurate. However, in case the rate of institutionalization of social responsibility principles is assessed, it is possible to come to accurate conclusions about the level of CSR within the given organization.

FIG. 1: THE INTEGRATIVE MODEL OF CORPORATE SOCIAL RESPONSIBILITY

Principle 3: In our opinion, it is only possible to talk about CSR **in the case an organization consciously accepts responsibility towards all relevant stakeholders**. An organization should consciously accept responsibility towards these groups at least to the extent stated by the *basis of CSR*. Provided that an organization has excluded even the only one of its stakeholders towards which it fails to meet the CSR basis (e.g. an organization sells harmful products, does not pay taxes, exploits its employees or suppliers, does not follow the rules of economic competition, significantly pollutes the environment etc.) it cannot be regarded as socially responsible.

Principle 4: Corporate ethical responsibility should be viewed in a broader context – in the way it is presented by a great number of European authors. Organizations should accept the responsibility and commit themselves to follow these moral rules and the essential condition of business ethics “*Do not harm others!*”

Defining the basis of corporate social responsibility

Defining the basis of corporate social responsibility appears to be the main contribution of *The Integrative Model of CSR*. CSR basis includes three areas – economic, legal and ethical bases of corporate social responsibility.

The basis of legal responsibility results from compliance with the law in force governing the relations of an organization to a particular stakeholder. Compliance with the basis of legal responsibility shall be demonstrated by acting in compliance with the law in force in relation to all stakeholders of a corporation. A corporation fails to comply with the basis of legal responsibility in case the relevant authority has taken final decision and definitely found an organization guilty of violation of law in force in at least one case in relation to one or more of its stakeholders in the period concerned.

The basis of economic responsibility is specified for each stakeholder on an individual basis and reflects minimum requirements of individual stakeholders for corporate economic responsibility (e.g. the basis of economic responsibility in relation to employees constitutes liability to pay salaries/wages to its employees and pay all mandatory contributions to insurance companies and funds). A corporation fails to comply with the basis of economic responsibility in case it has broken whatever requirements specified within the period concerned.

The basis of ethical responsibility represents specification of ethical principle “*Do not harm others!*” in relation to individual stakeholders. Compliance with the basis of ethical responsibility shall be demonstrated by the

institutionalization of specific ethical processes and procedures. The basis of ethical responsibility is met as long as there is demonstrably both strategic concept and functioning system of the execution of this concept in every area specified for each individual stakeholder. Provided that there is no defined strategic concept in some of the above mentioned areas and/or a company fails to demonstrate functionality of the execution system the company fails to comply with the basis of ethical responsibility.

As was already shown in Fig. 1, organization can be considered socially responsible just in case it accepts economic, legal and ethical responsibilities towards all its stakeholders in both the internal and external business environment i.e. only the organization **which complies with the basis of economic, legal and ethical responsibilities** towards all these groups. Philanthropic corporate responsibility is not depicted in the picture as it is not considered an essential requirement for corporate social responsibility.

Considering that companies achieve different level of social responsibility, it is important to continue monitoring the extent and content of socially responsible corporate activities beyond the basis of CSR they have met (i.e. to take in account all additional philanthropic activities and other activities of a company not covered by the basic requirements for corporate responsible behaviour). The given model is fully applicable in practice when measured by CSR. The following chapter deals with a brief description of CSR measurement based on CSR basis.

CSR evaluation and measurement based on the *Integrative model of CSR*

In *The Integrative Model of CSR*, the need to define the basis of corporate social responsibility towards its individual stakeholders is accentuated, compliance with which is a prerequisite for the basis of socially responsible business practices. CSR evaluation system based on this model distinguishes activities forming the basis of corporate social responsibility and activities an organization carries out beyond the essential requirements for socially responsible behaviour.

CSR towards each stakeholder is measured on an individual basis and it is important to create two categories of specific indicators of socially responsible behaviour – indicators identifying particular requirements arising from CSR basis and indicators for evaluating corporate activities beyond the scope of minimum economic, legal and ethical requirements. Based on the results of CSR measurement, an organization may fall into one of the following three categories: non-achievement of CSR (an organization is below the CSR line), CSR achievement and CSR enhancement (Fig. 2).

CSR measurement should be carried out in two separate steps. Compliance with CSR basis should be evaluated first, followed by an evaluation of activities beyond the CSR basis. A corporation scores no points for compliance with CSR as the CSR basis represents the minimum of corporate social responsibility. However, in case a corporation has failed to meet whatever requirement of CSR basis, it is awarded a minus point (one point for each requirement that has not been met). As long as a corporation achieves a negative value (this happens if an organization has failed to meet even one criterion of CSR basis), it gets below the line of CSR and thus cannot be regarded as socially responsible in relation to a given stakeholder. In such case the organization cannot be given any points for additional activities it has been carrying out in favour of a given group of stakeholders beyond the CSR basis. In corporation which have been found to comply with CSR basis (and thus are found above the CSR limit) the second part of CSR measurement – evaluation of other activities an organization has been performing towards a given stakeholder – shall follow.

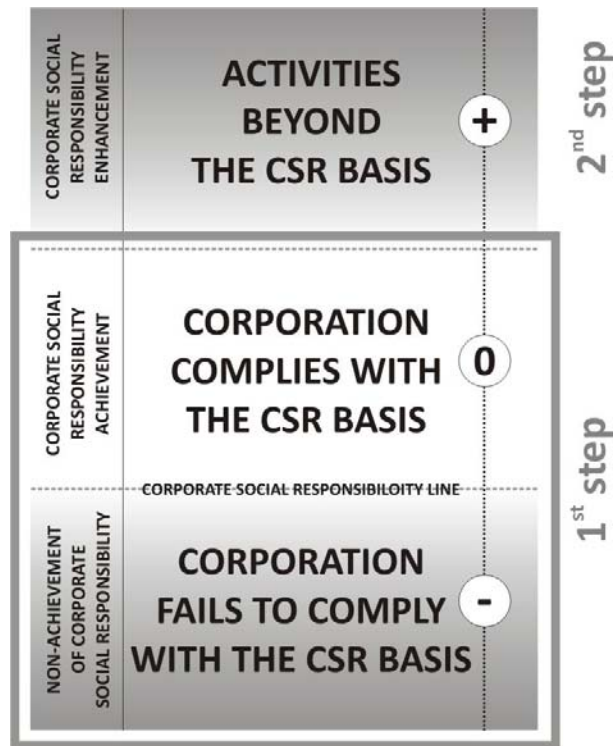

FIG. 2: CSR MEASUREMENT BASED ON THE INTEGRATIVE MODEL OF CSR

The Integrative Model of CSR includes specific indicators, for achieving of which an organization is given positive points. The final total score an organization has achieved determines the **range** of socially responsible activities of a company in relation to a given stakeholder. **Content** and **quality** of those activities are described in a final evaluation report on corporate social responsibility of a particular company.

Concretizing CSR towards employees

The authors have carried out a theoretical research to concretize *the Integrative model of CSR* towards one selected stakeholder – employees to prove its functionality and validity. Based on the analysis of the most frequently used guidelines and standards in the area of CSR, seven main areas of CSR towards employees were identified: (1) compensation issues, (2) health and safety, (3) work conditions and corporate social politics, (4) labour relations and collective bargaining, (5) work dignity and protection against discrimination, (6) individual work relations and internal communication, (7) enforcing employee rights. In these areas indicators for measuring CSR were set in both categories – indicators identifying particular requirements arising from CSR basis and indicators for evaluating corporate activities beyond the scope of minimum economic, legal and ethical requirements.

The basis of economic responsibility towards employees was set in terms of paying employees on time and paying all taxes and other legally required payments to social and health insurance funds, etc. If a corporation fails to pay its employees on time in at least one case in the period concerned or/and if it fails to make all the necessary payments resulting from employment relationship, the basis of economic responsibility is not met.

To meet the basis of legal responsibility towards employees means to comply with the labour legislation of a particular country in the above mentioned areas. If the final decision was taken by the relevant authority that the

corporation violated law in force in at least one case in the period concerned (usually a year), the basis of legal responsibility is not met.

The basis of ethical responsibility presented concretization of the ethical minimum in the employer – employee relations. Sixteen different indicators were identified within the seven basic areas of CSR towards employees. In order to meet each of the indicators, a corporation must prove the existence of a strategic concept as well as a fair policy to implement the strategy into everyday life.

For the second step in measuring CSR fifty other indicators signalling CSR towards employees beyond basic requirements were identified. The indicators were tested on two large companies conducting business in Slovakia and proved to be applicable for measuring CSR towards employees.

Conclusion

Corporations form an integral part of society in which they operate and without which they could not exist. The role of business in society is to contribute to a common good, not to harm it. Therefore corporations are obliged to analyse consequences of their everyday activities in order to minimize the negative impact on each of their stakeholders.

The Integrative model of CSR makes it possible to measure CSR in a completely new way that respects the European theoretical fundamentals of CSR. CSR is viewed and measured in terms of economic, legal and ethical responsibilities towards all stakeholders. According to the model it is not possible to limit CSR only to philanthropic responsibility. To be socially responsible means to act economically, legally and ethically responsible in day-to-day business towards all stakeholders.

Defining *the basis of CSR* presents a shift in understanding and measuring CSR. The authors argue that without complying with basic economic, legal and ethical requirements towards each stakeholder, the corporation cannot be viewed responsible regardless of its philanthropic activities. Compliance with CSR basis is a prerequisite for further CSR evaluation of activities an organization carries out beyond the essential requirements for socially responsible behaviour.

According to *the Integrative model of CSR* it is possible to concretize the content of socially responsible practices towards each stakeholder separately. Concretizing the responsibilities helps in intentional achieving and developing CSR as it enables the corporations to grasp the issue in a more complex and systematic way.

Change Management: The Inspirational Role of a Change Leader

*Yaseen, Zahi, eibfs@yahoo.com
AL Ghurair University, UAE*

Abstract

Today the world has become a global village and markets have expanded to the extent that now firms are competing on a global level. This on one has provided firms with a massive opportunity and on the other hand it also demands more hard-work and effort from the workers. The challenge therefore is how to tackle the ever-changing work-environment. Today's companies are struggling to remain competitive, mainly due to the tough global competition, uncertain environments, cutbacks in personnel and resources, and massive worldwide political, social and economic shifts. The growing diversity of the workforce brings new challenges: maintaining a strong corporate culture while supporting diversity; balancing work and family concerns; coping with conflicts brought upon by the demands of women and ethnic minorities for increased power and responsibilities. Workers expect their managers to share power rather than the other way round. Organizations have become flatter in structure, forcing the flow of power and information to be pushed amongst the few lower layers. This allows the formation of teams whose front line workers play new roles as decision makers. Thus, today's business world is highly competitive. One needs to reshape and react to the rapidly changing and evolving needs of the world if they are to survive and thrive. Resistance to change would mean the end of the road, both for the leader himself and the organization. Today customers are demanding more than an excellent service. If one doesn't supply it, the competitors will. Organizations are therefore aiming to reshape themselves to change quickly, so that in the long-run they may be able to meet the needs, and honor the demands, of their customers. The organization's top leaders know that in order to attain their long-term goals they would require highly skilled, trained and committed workers.

Keywords: leadership, change management, change agent, leading people.

Forces of Change

More and more organizations today face a dynamic and changing environment. This, in turn, requires these organizations to adapt. Hence, it is important to consider the changing nature of the workforce. Most organizations, today, have to adjust to cope up with a multi-cultural environment. Human resource policies and practices have to change in order to attract and keep this more diverse workforce motivated and willing to work. And many organizations have to spend large amounts of money on training to upgrade various skills of the employees.

Also another important factor that is responsible for bringing about change in the global business environment is the technology. The substitution of computer control for direct supervision, for instance, is resulting in wider spans of control for managers and flatter organizations. Sophisticated information technology is also making organizations more responsive. Companies like Ford, AT&T, Motorola, General Electric can now develop, make and distribute their products in a fraction of time it took them a decade ago (Luecke, 2003). Also individuals doing narrow specialized and routine jobs are being replaced by work teams whose members can perform multiple tasks and actively participate in team discussions.

Competition is also changing. The global economy means that the competitors are as likely to come from across the ocean as from across town. Heightened competition also means that the established organizations have to defend themselves against both traditional competitors that develop new products and services and small entrepreneurial firms with innovative offerings. Successful organizations will be the ones who can change themselves in response to the competition. They will be fast on their feet, capable of developing new products rapidly and getting them to the market quickly. They will, in turn, require an equally flexible and responsive workforce that can adapt to rapidly and even radically changing conditions.

Resistance to Change

There is a definite downside to the resistance to change and that is hindrance to the process of adaptation and progress. It doesn't necessarily surface in a standardized manner. Resistance can be overt, implicit, immediate, or deferred (Robbins, 2004). It is easiest for the management to deal with resistance when it is overt and immediate. For instance, a change is proposed and employees quickly respond by voicing complaints, engaging in a work slowdown, threatening to go on a strike, etc. The greater challenge is managing change when it is implicit or deferred. Implicit resistance efforts are more subtle, like, loss of loyalty to the organization, loss of motivation to work, increased errors or mistakes, increased absenteeism, etc (Robbins, 2004). Similarly, deferred actions cloud the link between the source of the resistance and the reaction to it.

A change may produce what appears to be only a minimal reaction at the time it is initiated, but then resistance surfaces weeks, months or even years later. Or a single change that in and of itself might have little impact becomes the straw that breaks the camel's back. Reactions to change can build up and then explode in some response that seems totally out of proportion to the change action it follows (Luecke, 2003). The resistance, of course, has merely been deferred and stockpiled. What surfaces is a response to an accumulation of previous changes (Luecke, 2003).

Resistance to change may actually exist at two separate levels, individual level and organizational level (Luecke, 2003). If we look at the individual sources of resistance to change, they mostly emanate from basic human characteristics such as perceptions, personalities and needs.

Habit is one of the reasons why individual resistance to change may exist in employees. As human beings, we are creatures of habit. Life is complex enough; we don't need to consider the full range of options for the hundreds of decisions we have to make everyday. To cope with this complexity, we all rely on habits. But when confronted with change, this tendency to respond in our accustomed ways becomes a source of resistance. Also, another factor is security, as people with a high need for security are likely to resist change because it threatens their feelings of safety.

Economic factors also are a strong source of building up individual resistance. As changes in job tasks or established work-routine can also arouse economic fears if people are concerned that they won't be able to perform the new tasks or routines to their previous standards, especially when pay is closely tied to their productivity. Also, the fear of the unknown may hamper employee morale and result in resistance to change.

The other level of resistance is the organizational resistance. Organizations, by their very nature, are conservative. They actively resist change. Government agencies want to continue doing what they have been doing for years, whether the need for service changes or remains the same (Robbins, 2004). Organized religions are deeply entrenched in their history (Robbins, 2004). Educational institutions, which exist to open minds and challenge established doctrine, are themselves extremely resistant to change (Robbins, 2004). The majority of business firms, too, appear highly resistant to change.

From a Leadership Perspective

Today the world has become a global village and markets have expanded to the extent that now firms are competing on a global level. This on one has provided firms with a massive opportunity and on the other hand it also demands more hard-work and effort from the workers. The challenge therefore is how to tackle the ever-changing work-environment.

When one speaks of the dynamic work environment one has to realize the importance of Good Leadership in such a scenario. So, the leaders of today's companies have a lot to care about and a lot of responsibilities to take care of. Therefore, it is totally up to the leadership to make most of the human skills at hand and motivate them in order to make sure that they adapt quickly and easily to the work environment and thus maximize efficiency.

Today's companies are struggling to remain competitive, mainly due to the tough global competition, uncertain environments, cutbacks in personnel and resources, and massive worldwide political, social and economic shifts. The growing diversity of the workforce brings new challenges: maintaining a strong corporate culture while supporting diversity; balancing work and family concerns; coping with conflicts brought upon by the demands of women and ethnic minorities for increased power and responsibilities. Workers expect their managers to share power rather than the other way round. Organizations have become flatter in structure, forcing the flow of power

and information to be pushed amongst the few lower layers. This allows the formation of teams whose front line workers play new roles as decision makers.

Thus, today's business world is highly competitive. One needs to reshape and react to the rapidly changing and evolving needs of the world if they are to survive and thrive. Resistance to change would mean the end of the road, both for the leader himself and the organization. Today customers are demanding more than an excellent service. If one doesn't supply it, the competitors will. Organizations are therefore aiming to reshape themselves to change quickly, so that in the long-run it may be able to meet the needs, and honor the demands, of their customers. The organization's top leaders know that in order to attain the long-term goals they would require highly skilled, trained and committed workers.

Leaders need to ensure a transition amongst workers from change avoidance to change acceptance, which can then be observed throughout periods of change. According to Donald Clark, there are 5 steps accompanying change. The first is Denial, where the employee has a traditional mindset where he cannot foresee any change occurring in his work, then comes Anger, when he realizes that he has been forced into changing, but he still cannot face the reality and is not in favor of the change, then comes Bargaining, where he finally accepts the fact that he'll have to do things differently now and he tries to keep himself and others happy, however, this is soon accompanied by Depression, where he keeps comparing his older job parameters to the new ones and he doesn't find the new way of work easy and interesting. The final stage comes after the depression phases out, and this is called Acceptance, where he finally gets used to the new way of work (Roberto and Garvin, 2005).

This probably explains why a worker's first reaction is always to resist change. Workers tend to feel comfortable performing the same tasks and processes in a particular and timely manner. This comfort helps them by providing them the security and forcing them to believe that they are the masters of their environment. So it would be obvious for them to fear a disruption in their lives, as they fear that if they aren't able to adapt and learn, their jobs might become harder, and they might lose control over their jobs.\

When one speaks of change management and the role leaders tend to play in bringing about the change necessary for an organization to perform, leaders skill come into account, especially emotional intelligence. There are 5 main components to emotional intelligence (Goleman, 1998). Self-awareness is the trait where emotional intelligence actually begins, such leaders are never hesitant to talk about and discuss their weaknesses and it is this attitude that later brings upon a positive change in them as they are able to improve upon such weaknesses with time. This helps a leader in bringing about change as he is someone who knows his limitations and he knows when and where he can actually stand-up and deliver for the rest of the workforce and be a motivator for them, i.e. when can he lead by example. Thus he knows which tasks and changes can actually be brought about in an organization and which ones cannot be.

The second trait is self-regulation, and that leaders with this trait can control their emotions and impulses better and channel them for good purposes (Goleman, 1998). This brings about openness to change in their attitude and behavior, and increases their trustworthiness and integrity, and also helps them remain comfortable in ambiguous situations and scenario. And this is what subordinates try to see in their leaders, especially in times of change.

Motivation is perhaps the most important trait and the most obvious one that a leader is judged upon. It's the motivation abilities of a leader that gives the sub-ordinates the notion that the leader has a strong drive to achieve. It portrays the optimism of the leader to the followers, such that they know that their leader would still be optimistic when facing failure, so it has to do more with the mind than anything else. It is the positivity of the mind; it emanates from the mind of the leader and leads its way to the minds of the followers (Roberto and Garvin, 2005).

Empathy is the ability to understand the emotional makeup of other people. Empathy is the trait that enables a leader to be an expert in building and maintaining talent. It enables him to treat people according to their emotional reactions. This is why he can be successful in getting the most out of the talented people that work under him; it thus makes him a better man manager. He is able to manage and lead people from various different backgrounds and cultures, belonging to various social and economic classes, i.e. it increases the cross-cultural sensitivity of the leader himself. With the businesses and economies globalizing, leaders have to lead and manage people belonging to different cultures which is the major reason why change management in such a scenario is very difficult, however, if only a leader can empathize with his followers, it makes the job half as difficult as before.

The last trait that comes under emotional intelligence is the social skills of the leader. A leader needs to be proficient in managing relationships and constructing networks that lead to effectiveness in change management.

Such a leader is able to find common ground between individuals and situations and scenarios and is able to build rapport. It also improves his persuasiveness and the ability to build and lead teams.

Bringing about change in an organization is a very hectic task and it requires dedication from both-ends, the leadership and the followers. Leaders need to be aware of what is the current situation of areas and departments where changes have taken place by involving persons who will be in charge of the results. Analyze the conditions with the representatives. Indulge in strategic planning that leads towards success after change in organization. Continue activities with involvement of employees that will help in solving problems and also in improvement of change process. Finally measure, examine and estimate the change.

Another important tool in ensuring effective transformation is collaboration and good communication, which is essential and plays a vital role in process (Kotter, 1995). All processes, practices and functionalities give more values to customer, goals and performance for achievement of goals. There should be internal solutions. Horizontal, Vertical and multi directional interaction must be carried out before change in organization.

For a leader, it is important to study the present culture of the organization and to know where one is. It is also necessary for a leader to identify employees who want change and those who are not happy with change. Take examples from existing model that has effectively implemented change and also communicate with them regarding their experience with change. Don't be immediate at trying to completely change existing culture, but take advice from people about ways to implement change and methods to solve the problems while implementation. Vision may help you in change, but this is not the only way.

Creating a Learning Organization

What Total Quality Management (TQM) was to the 1980s and reengineering was to the 1990s, the learning organization has become today (Luecke, 2003). It has helped managers develop and look for new ways to successfully respond to a world of interdependence and change.

A learning organization may be defined as an organization that has developed the continuous capacity to adapt and change. Just as individuals learn, so too do organizations. In order for an organization to exist sustainably, they all have to learn, it is a fundamental requirement. However, some organizations such as Xerox, Ford, General Electric, Wal-Mart, Corning, and Federal Express just do it better than others (Robbins, 2004).

Most organizations engage in what has been referred to as single loop learning, in which errors are corrected using past routines and present policies. Learning organizations, in contrast, use double loop learning (Kline and Saunders, 1997). When an error is detected, it is corrected in ways that involve the modification of the organization's objectives, policies, and standard routines. Double loop learning challenges deep rooted assumptions and norms within an organization. In this way it provides opportunities for radically different solutions to problems and dramatic jumps in improvement.

Some of the main characteristics of a learning organization, include, a shared vision of the entire workforce to which everyone agrees and believes in (Kline and Saunders, 1997). Also people part of such an organization discard their old ways of thinking and the standard routines they use for solving problems or doing their jobs. The members also think of all the organizational processes, activities, functions and interactions with the environment as part of a system of inter-relationships. Learning organizations also permit their employees to openly communicate with each other (across vertical and horizontal boundaries) without fear of criticism or punishment.

A Study on the Relationship of Market Orientation, Quality Orientation and Business Performance

*Peng Du, dragondoggyao@yahoo.com.cn
Zhongnan University of Economics and Law, China*

Abstract

Studying the impact of market orientation on business performance has been a popular research topic in recent years. However, there seems to be a lack of empirical studies that measure the relationship of market orientation and quality orientation and their impact on business performance, even though marketing and quality management are considered complementary business approaches. Based on 110 samples of Chinese enterprises, this research indicates that the quality orientation correlates positively with market orientation; market orientation of a firm affects positively its business performance. However, quality management alone does not appear to have a direct effect on performance success.

Keywords : market orientation, quality orientation, business performance, empirical study

Introduction

A number of studies have been conducted to examine the impact of quality management, particularly TQM (e.g., Hendricks and Singhal, 1997), and the impact of marketing (e.g., Narver and Slater, 1990)^[1] on business performance. However, the literature is short of empirical studies on the combined effects of quality management and marketing, although they have been considered complementary business approaches for performance improvement. The objective of this study is to explore whether quality management and marketing are complementary business approaches in organizations and, if so, the extent of their performance impact.

Theoretical Framework and Hypothesis

Quality is an abstract concept depending on the desire of the individuals involved with a primary emphasis on the satisfaction of customer's needs and wants. One important point to note about the meaning of quality is the multidimensional nature of the concept (Garvin, 1984)^[2]. To direct employees' efforts towards the goal of customer satisfaction, a common understanding of the term quality is required. Viewed from this perspective, quality has become a critical strategic issue rather than an operational one. What a quality management system emphasizes is the organizational ability to satisfy customer needs precisely and profitably involving all members of an organization. The marketing concept centers on the management of market "exchange" between customers and organizations. It helps organizations to achieve exchange-determined goals more effectively (Houston, 1986)^[3]. The marketing concept requires firms to take a proactive attitude to do business and be responsive to customer needs and market changes.

Quality management can potentially contribute to the effectiveness of marketing implementation in three aspects as it plays the role of internal integrator, external integrator, and efficiency enhancer. On the other hand, marketing can add substantial value to quality management implementation through its functions as customer window and quality leader.

Quality Management as Internal Integrator

The most severe criticism about the marketing concept concerns its tendency to be practiced as a set of functional activities rather than an organization-wide approach. If this should happen, it would hinder the voices of customers to be translated into internal improvement processes and filtered throughout the organization for the benefits of customers, thus yielding the risks of losing, misinterpreting, and distorting the voices of customers generated from marketing to other internal functions. The holistic nature of quality management, particularly TQM, together with its set of management tools and techniques, are of potential use for effective marketing implementation (Day, 1994)^[4] and breaking down functional barriers. The consequence of teamwork, as prompted by the team-base quality

management approach, is penetration of the marketing concept that permeates the whole organization. The total involvement aspect of quality management and its related tools ensures congruency between the voices of customers and the voices of processes for the delivery of customer satisfaction.

Quality Management as External Integrator

In addition to managing relations among organizational functions, relationships with customers and the network organizations such as suppliers, distributors, and advertising agencies should not be neglected for effective marketing implementation. One important note about quality management is its emphasis on establishing mutually supportive forward relationship with customers, and backward relationship with the network organizations, particularly suppliers that have significant impacts on customer satisfaction. The relationship emphasis of quality management complements marketing, particularly the relational marketing approach to the cultivation of long-term relationships with customers and the network organizations.

Quality Management as Efficiency Enhancer

Marketing as a business approach is dedicated to both the achievement of effectiveness, i.e., the ability to create and keep customers, and the achievement of efficiency, i.e., the achievement of maximum output from minimum input. While marketing plays the role to ensure “doing the right things,” quality management complements marketing with an emphasis on continuous process improvement for “doing the things right” across the whole organization. From the standpoint of efficiency, this emphasis is of great value to marketing, particularly at the tactical level involving a series of operational activities, which needs understanding of such process variables as cycle time, capacity, yield, waste, and flexibility.

Marketing as Customer Window

Although quality gurus, such as Deming (1986), have discussed the importance of customer wants, they give little practical advice on how to assess wants so that appropriate product/service specifications could be established. Marketing, particularly through its role in promoting listening to the voices of customers in organizations, has too often been ignored in quality improvement often has had no clear connection to customer needs, for instance, producing products/services that customers do not want. The role marketing plays is critical to quality management implementation, as organizations must ensure that their quality improvement efforts are focused on improving customer satisfaction rather than on management’s own perceptions of quality requirements.

Marketing as Quality Leader

For successful quality management implementation, it is important that all involved employees understand the customer definition of quality and the needs of other functional areas to meet the customer requirements. Viewed from this perspective, marketing links requirements from the external environment with the relevant functional areas within the organization and contributes to developing priorities of quality improvement and providing a road map for utilizing company resources. This creates an environment where employees at all levels understand how priorities are set and connected with customer needs, and the network organizations are informed of the customer requirements.

The above discussions highlight that quality management and marketing share the concepts of customer orientation, interventional coordination, and continuous process improvement for successful implementation. The compatibility of quality management and marketing implementation for organizational performance improvement is manifested. Thus, we hypothesize the following relationships.

Hypothesis 1: The quality orientation of a firm correlates positively with its market orientation.

Hypothesis 2: The quality orientation of a firm affects positively its organizational performance.

Hypothesis 3: The market orientation of a firm affects positively its organizational performance.

Research Design and Results

Data Collection

We draw a sample of 500 companies from the Chinese Enterprises' Database. We solicit not only one response from each sample company. Measures are taken to cross-check the sample to avoid double mailing. We send out the questionnaire twice. The two mailings of the survey questionnaire yield 124 returns with 110 of them valid for data analysis, representing a usable response rate of 22%. The sample consists of 33 manufacturing companies, 44 service companies, 25 construction companies, and 8 public utilities. We conduct a test on nonresponse bias using the t test, with the respondents in the first and the second mailings as the proxy "respondents" and "nonrespondents," respectively, to determine if there are significant differences in the mean scores of the quality orientation, market orientation, and organizational performance constructs between the two groups (Armstrong and Overton, 1977)^[5]. The results show no differences between the groups at $P > .05$ level (quality orientation, $t = -0.32$; market orientation, $t = -0.24$; organizational performance, $t = -0.36$), suggesting that nonresponse is not a problem in this study.

Measures

We adopt Black and Porter's (1996)^[6] 10-dimension, 32 item instruments to measure quality orientation. The instrument represents literature-based and empirically tested elements of quality management implementation. We find seven potentially confusing items, each asking two questions in the Black and Porter's (1996) instrument during the panel review of the study. We split each of those items into two, resulting in a 10-dimension, 39-item instrument measuring quality orientation. The 20-item MARKOR instrument developed by Kohli et al. (1993)^[7] is used to measure market orientation. To increase the content validity of both the quality and market orientation measures, we add illustrative examples to most of the items to facilitate respondents' understanding of the items. While both quality management and marketing emphasize satisfaction of different stakeholders, many extant studies about their performance impact are confined to financially related indices only. To overcome the limitations of these studies, we define organizational performance using the Weerakoon's approach (1996)^[8] to address the interests of various stakeholders rather than those of stockholders only. We use perceptual measures on a five-point scale (1=strongly disagree to 5= strongly agree) because of their high level of convergence with objective measures

Validity and Reliability

Validity and reliability of the three constructs are initially assessed using coefficient alpha and item-total correlation analysis. CFA is then performed to evaluate the three constructs at both first and second-order levels. The results show that all the construct items have a reasonably high loading on their first-order factors in item-total correlation analysis, ranging from the lowest loading of .42 to the highest loading of .80. All the alpha values of all first-order factors of the three constructs exceed the .70 cutoff level, except two (teamwork structures for improvement, $\alpha = .67$, and corporate quality culture, $\alpha = .69$), which are just a shade below the benchmark level.

Measurement Model Estimation

In CFA, we allow all the first-order factors to correlate freely in their respective measurement models. All the construct items, load significantly, i.e., $\lambda > .30$, $t > 2$, onto their first-order factors in the analysis with the loading in the range between .69 and 1.0, thus establishing the convergent validity of the items. The three items are retained as other measures such as item-total correlation coefficient and alpha value in their first-order factors suggest that there is sufficient internal consistency among the items in their first-order factors despite inclusion of those items in the measurement models. Table 1 provides the means, standard deviations, and intercorrelations of the 17 first-order factors of the three constructs. We test discriminant validity with phi estimate, i.e., intercorrelation among first-order constructs. All phi values shown in Table 1 are significant at $P < .01$ level. Discriminate validity is not achieved in some cases as some of the first-order factors are highly correlated. This is expected as the first-order factors are components of the second-order they are measuring.

Using composite scores of the first-order factors by taking the arithmetic mean of the items, we perform CFA to assess the measurement models of quality orientation, market orientation, and organizational performance. Table 1

presents the CFA results with lambda loadings, standard errors, t values, and error variance estimates at the second-order level. Table III displays the means, standard deviations, and intercorrelations among the three constructs.

Table I shows that all alpha values for all three second-order constructs exceed the .70 cutoff level, yielding satisfactory evidence of internal consistency, with the highest being .95 for quality orientation, and the lowest being .86 for market orientation. Furthermore, all first-order factors have large and significant lambda loadings, i.e., $\lambda > .30$, $t > 2$, on their corresponding a priori specified second-order factors. Thus, these measures display adequate convergent validity. The loadings range from the lowest of .65 to the highest of .91 for the quality orientation construct, and from .52 to .69 and from .58 to .60 for the constructs of market orientation and organizational performance, respectively. In addition, we evaluate discriminant validity among the three second-order constructs using pairwise tests by comparing a model with the correlation constrained to one with the unconstrained model. Results in Table IV show that discriminant validity is achieved among the three constructs because of the significant differences between the constrained models and the unconstrained models. Nomological validity is also supported by the positive, significant intercorrelations among the three constructs as shown in Table III. Having determined that the latent constructs and their observed indicators possess acceptable measurement properties, we proceed to estimate the structural model.

E Structural Model Estimation

Table V shows the results of individual paths in the structural model. The overall fit of the structural model is considered adequate with the results (Model 7) displayed in Table VI. The structural model is estimated and a reasonable fit is obtained, where $\chi^2=300.1$, $df=116$, $P=.00$, although the chi-square statistic is significant. This is to be expected, given the large number of variables in the model. However, other indicators suggest that the model fits well: goodness-of-fit index (GFI)=.90, comparative fit index (CFI)=.96, normed fit index (NFI)=.93, root mean square (RMR)=.022.

The estimates of the loadings of the first-order constructs on the second-order constructs are also tested through t values, and all lambda parameters are found to be significant, i.e., $t > 2$. As all of the goodness-of-fit criteria demonstrate good “fit”, the structure of the model is considered reasonably accurate. To provide greater confidence for the proposed model and to check for better-fitting, more parsimonious models, we test the propose model (M7) against a set of alternative models (M1-M6). The null model in M1 is used as the baseline model in this study. The baseline model implies that the relationships among the three constructs are independent, i.e., parameters restricted from free estimation to zero. The estimates of the proposed model and the goodness-of-fit comparisons with the alternative models are shown in Table VI.

Comparison of the proposed model with the six alternative models shows support for fitness of M7. Although

all seven models have a significant chi-square value, we find that M7 has the best fit to the data as

TABLE VI
COMPARISONS OF THE GOODNESS-OF-FIT OF THE PROPOSED MODEL WITH ALTERNATIVE MODELS

	M1	2 M	3 M	4 M	5 M	6 M	7 M
χ^2	974.8	708.2	648.6	356.2	300.9	616.5	300.1
df	119	118	118	117	117	117	116
GFI	0.76	0.84	0.85	0.88	0.90	0.85	0.90
NFI	0.79	0.85	0.86	0.92	0.93	0.87	0.93
CFI	0.81	0.87	0.88	0.95	0.96	0.89	0.96
RMR	0.26	0.20	0.25	0.025	0.022	0.21	0.022

indicated by a smaller chi-square value, $\chi^2=300.1$, $df=116$, $P=.00$, a higher value in $GFI=.90$, $CFI=.96$, $NFI=.93$. A comparison of the RMR among the models also shows that M7 has a smaller value, implying that it has an adequate fit to the observed data comparing with the other six alternative models. However, many of these goodness-of-fit indicators in M5 are close to those in M7. The latter is preferred to the former in model comparison because M7 has a smaller chi-square value. Since the proposed model is found to be better than the alternative models for examining the relationships among quality orientation, market orientation, and organizational performance, the proposed model is accepted and used for hypothesis testing.

An examination of the path coefficients among the higher order constructs and their associated t values shows that, except for the quality orientation to organizational performance path, the completely standardized path estimates are all significantly different from zero at $P<.01$ level, with the value of the parameter estimates, standard errors, and t values shown in Table 5. We also find that the models with quality orientation and market orientation intercorrelation, i.e., M4, M5, M7, have better model fitness to the observed data than those without, i.e., M1, M2, M3, and M6. This provides support for the complementary nature of quality management and marketing in organizational performance improvement.

Analysis and Implications

Hypotheses testing

Hypothesis 1 is supported, as the value of $\phi(2, 1)$ is positively high and significant with a completely standardized path coefficient of .89, a standard error of .04, and a t value of 9.76. Hypothesis 2 is not supported as the value of $\gamma(1, 1)$ is positively low and insignificant. The path coefficient is .04 with a standard error of .10 and a t value of 0.33. An inspection of the measurement model of the quality orientation construct reveals that only two components, i.e., people and customer management and customer satisfaction orientation, directly address the customer-oriented aspect of quality management. Other components of the construct tend to focus on internal improvement of the quality management systems. For instance, it is possible that many quality improvement efforts do not deliver the desired results because of their inward focus. Indeed, the impact of quality orientation on organizational performance is explained by the other construct in the model, i.e., market orientation, as the two exogenous constructs are highly intercorrelated in the model. This implies that the performance impact of quality orientation has to be complemented with market orientation. This is consistent with the arguments of Kordupleski et al. (1993) that quality management needs to be outward-looking with a focus on market needs to drive performance and the role that marketing plays as a customer window to assure a market focus in quality improvement efforts. The

result suggests that quality management requires a market focus, while internal improvement alone is less likely to drive improvement in organizational performance. Hypothesis 3 is supported as the value of gamma (2, 1) is positively high and significant. The path coefficient is .88 with a standard error of .11 and a t value of 6.80. This supports the notion that firms have to be market-driven for improvement of organizational performance.

Discussion

In general, we provide empirical evidence that quality management and marketing are complementary business approaches for improved organizational performance. However, the former needs to be market-driven to drive the performance impact of quality improvement efforts. The results are in line with the argument of Kordupleski et al. (1993) that awareness of customer needs and marketing are required for successful implementation of quality management. The role of marketing serves as a customer window to assure a market focus in quality improvement efforts.

The findings suggest that quality management alone does not appear to have a direct effect on performance success. In fact, the lack of a positive direct relationship between quality orientation and organizational performance would imply that firms should not simply focus on internal improvement. Rather, it may be appropriate to develop an outward-looking improvement focus on market needs, driving organizational performance through a market-oriented culture. It is evidenced in companies A and B where their quality management practices are driven with a focus on the market, but not on internal procedures and documentation processes as in the case of companies C that a market orientation is required for quality management to drive organizational performance.

The results, however, do not signify that quality management is unimportant. On the contrary, quality management may be just as important, or even more so, in driving organizational performance. Our results indicate that quality orientation and market orientation in organizations are highly correlated and complementary, and that organizational performance is improved when market orientation is high. Furthermore, models with quality management/marketing complementarities display better goodness-of-fit than those lacking it. By employing the two business approaches as management implementation and marketing implementation alignment are conducive to achieving a high level of organizational performance. It is important to pay attention to the philosophical elements and the complementary nature of quality management and marketing to ensure their alignment in implementation.

Data Collection: Managerial Implications

The results suggest that simply implementing a quality management system such as the ISO 9000 series alone does not appear to be comprehensive enough to gain competitive advantages. In contrast, formulating a quality strategy with the participation of the whole organization for continuous improvement, with the interests of the customers put at the very heart of the business operations, should provide a more coherent and comprehensive road map for effective marketing implementation. An organization-wide focus on both business approaches of quality management and marketing should be addressed, and the ways that quality management and marketing can and should guide the values and attitudes, and ultimately the activities and performance of the whole organization, should be recognized.

Marketing must work with other functional areas to enhance customer value and increase customer satisfaction. It should act as a window to discern customer needs in the intelligence will be of utmost importance in guiding organizational response to customer needs and market changes. Alternatively, quality management provides the structure, techniques, implementation, and control mechanisms required by marketing for its effective implementation. The need to develop an outward-looking focus on market needs rather than an inward improvement focus for quality improvement must be stressed, and the ways quality management complements marketing in the delivery of customer satisfaction must be appreciated.

In addition, the achievement of customer satisfaction requires organizational-wide efforts. Not only should the quality management/marketing interface in organization be understood, but it should constantly be reinforced in the workplace in light of the fact that quality management and marketing performance for customer satisfaction are the responsibility of every organization member, instead of confining it to some specialized departments. The

philosophical elements of quality management and marketing need to be communicated to both quality and marketing specialists and other organizational members to discourage “departmental focus” to broaden the appreciation of quality management and marketing in business operations.

Directions for Future Research

First, cross-sectional data are used to test the research model and the hypotheses that capture the perceptions of managers at a point in time. The cross-sectional data do not capture any continuous transformations that might affect the hypothesized relationships. A longitudinal study is desirable in determining the effect of quality management and marketing on organizational performance in future research.

Second, the research model includes only the major latent constructs of quality orientation, market orientation, and organizational performance. To examine the interrelationships among them, other important macro variables such as business an economic environment, national culture, and technological intensity are not considered.

Furthermore, studies of the quality management/marketing interface in different cultural and social contexts will not only help to generalize the findings, but also contribute to determining how differences in cultural and social contexts influence the effectiveness of various systems and practice.

Talent Management Philosophies and Practices in the Chinese Multinational Corporations: An Empirical Study

Yi Liu, Yi.Liu@curtin.edu.au

Cecil A. L. Pearson, Cecil.Pearson@cbs.curtin.edu.au

Samir Ranjan Chatterjee, Samir.Chatterjee@cbs.curtin.edu.au

Curtin University, Perth, Western Australia

Abstract

A legacy of a centrally planned economy with a strong traditional bound culture, coupled with the dynamism injected by the arrival of international multinational corporations (MNCs), and even the rise of Chinese MNCs has created strong demands for talent in all spheres of China's economic life. As Chinese companies extend their global reach, they increasingly face the complexities of personnel acquisition, including severe shortages of domestic managerial talent, international brain drain of educated Chinese youth, and migration of managers from domestic Chinese companies to global MNCs. Against this background, the present study explores ways in which Chinese MNCs strategically integrate resources at the international level to attain global business success. The study finding indicated there is a crossvergence of talent management practices in Chinese MNCs, and such finding has potential to contribute to understanding how to overcome the identified barriers to the internationalisation process, especially in locating managerial talents.

Key words: Talent Management, Chinese Multinationals, Internationalisation, Strategy

Introduction

As China emerges as a significant economic force the shortage of well trained and experienced managers has become the key impediment in corporate success. An earlier prediction by McKinsey in 2005 documented that the international expansion of Chinese firms would need 75,000 senior managers with global competency in the next ten to fifteen years (Farrell & Grant, 2005), and this estimate appears to be very conservative in the emerging, growing economies. For instance, it has been predicted a number of emerging economies, such as Brazil, Russia, India, and China are likely to "... overtake the USA, Japan, Germany, France, the UK, Italy, and Canada by 2040." (Fan, 2008, p.354). The increasing strength of this phenomena is evidenced in the rise of a new group of MNCs in the Fortune Global 500, which has increased from 20 in 1995 to 70 in 2007 (Fan, 2008). Specifically, China had a total of 29 firms on the Fortune Global 500 in 2008 (Jonsson, 2008), and by April 2010 in the lists of the world's top 2000 companies, a total of 113 Chinese MNCs has been listed (DeCarlo, 2010). Notable are the international expansion of Chinese MNCs, such as the efforts of Lenovo's acquisition of IBM PC in 2004, and the acquiring of France's Thomson Electronics. The spectacular economic reformation of the Chinese economy is compelling institutions in the MNCs to reassess their architectural identities in terms of managerial practices and the forging of linkages in cross cultural landscapes. Hence, a departure point for understanding talent management strategies and cultural priorities in MNCs is beginning to attract serious attention.

Recently, the phenomenon of MNCs overseas investment from China has gained significant momentum (Rajan, 2009). For instance, the number of Chinese manufacturers has expanded rapidly around the world to become increasingly important competitors in the global marketplace (Ge & Ding, 2008). Furthermore, Chinese MNCs have not only entered the global market as exporters, but also as foreign investors across an array of industries, including manufacturing, natural resources (i.e., gas, oil and minerals), trade and services, and Information Technology (IT) (Guillén & García-Canal, 2009). In particular, the manufacturing of electrical appliances and electronics by Chinese MNCs, such as Haier, Lenovo, TCL, Gree Electric Appliances, Galanz, as well as Huawei Technologies has led to the successful development of their brands in the global marketplace. A specific example is the overseas expansion of Huawei Technologies in electronics to be widely recognised as a successful Chinese IT enterprise on a global scale. Interestingly, these Chinese MNCs did not exist 20 years ago, but today they are challenging some of their competitors and have gained well known reputations in overseas markets. The substantial level of overseas investments and acquisitions being undertaken by Chinese firms at a

relatively robust pace is facilitated by institutional transformations requiring a diversity of managerial talents (Bhatnagar, 2007). Indeed, the diversification in assets in terms of managerial capacity, business acumen competencies, knowledge networks and financial resources obliges a different type of human resources to effectively leverage the transformation processes (Mellahi & Collings, 2010).

Despite the increasing engagement in the global arena, firms throughout the world are facing difficulties in locating and retaining suitable managerial talents to manage international operations (Gregersen, Morrison, & Black, 1998; Scullion, 1994; Scullion & Collings, 2006; Sloan, Hazucha, & Van Katwyk, 2003; Suutari, 2002). Among the reinvigorated reform initiatives the acquisition of talented personnel remains a high priority issue for many Chinese MNCs (Chuai, Preece, & Iles, 2008; Mäkelä, Björkman & Ehrnrooth, 2010). For example, Burke and Ng (2006), Cappelli (2008), Iles, Chuai and Preece (2010) as well as Ready and Conger (2007) indicate MNCs are facing the biggest human resource (HR) challenge in the shortage of talented employees. Subsequently, the primary objective of the present study is to examine how Chinese MNCs address their talent management concepts and practices. More specifically, do Chinese MNCs share some common features in the operational level of talent management related issues (e.g., selection)? The findings of this study are likely to add value to understanding the processes that have been undertaken by these MNCs in tackling issues that relate to talent management practices.

This paper is presented in seven parts. Following the Introduction (the first part) the second part of the study discusses the triggers of internationalisation of Chinese MNCs. The third part of the paper presents the concept of talent management, which incorporates the barriers and challenges that Chinese MNCs face in HR related issues such as selection. The fourth section describes the research method, which outlines the study site and subjects, the employed procedure, the measurement and the analysis. In the fifth part of the study the results of the assessments are documented. A discussion component is delineated in the sixth part of the paper, which highlights talent management philosophies and practices that were employed by the Chinese MNCs. The seventh part of the paper concludes with indications how the study findings contribute to the understanding of the talent management concept, and in particular implications for contemporary organisations in Asian contexts in general; and specifically, in the Chinese context.

Triggers of Internationalisation

Legislative reforms and economic liberalisation have accelerated the internationalisation process of Chinese firms. Cheng and Ma (2008), Child and Rodrigues (2005) as well as Warner, Ng and Xu (2004) have suggested the internationalisation process of Chinese firms is largely affected by the Chinese government. Cheng and Ma (2008) stated that Chinese government promotes

“ ... national firms during official visits by government officials and state leaders, to incorporating business negotiations into inter-governmental cooperation frameworks, to building databases on investment environment and opportunities in specific host countries, to providing consultancy services to Chinese firms that consider investing overseas.” (p.8).

This notion is further supported by Ge and Ding (2008), who also indicated the Chinese government plays a key role in MNCs' involvement in business activities outside their home market. The initial policy, which was proposed in 2001 encouraged MNCs to 'go overseas'. Outward foreign direct investment (FDI) approval process was loosened by the Chinese government, and incentives such as financial support were given to MNCs in targeted industries and countries (Cheng & Ma, 2008). Overall, the Chinese government has created a supportive policy environment, which provides a platform for MNCs to 'go out' (Ge & Ding, 2008).

A number of other motives push the internationalisation process of the Chinese MNCs. The economic reform within China has attracted a large amount of FDI inflows (Li, 2005), and in turn intensified the domestic competition among firms (Goldstein, 2007). For example, Chinese firms that are involved in industries, like mobile phones, electronics and white goods have to face fierce domestic and international competition from their counterparts (Child & Rodrigues, 2005). Such competition and over capacity may result in a lower profit margin for some Chinese firms, and many of them had to seek opportunities overseas. Another potential motive is the level of government interference in China. Several researchers (Huang, 2003; Meyer & Lu, 2004; Nolan, 2001) have noted domestic mergers and acquisitions were tightly controlled by the central authorities, and these types of institutional restrictions may pose uncertainties and complexity of the legal system, that force Chinese

firms to invest overseas in order to escape institutional restrictions (Child & Rodrigues, 2005). Although these motives have contributed to the internationalisation of Chinese MNCs, the notion of the Chinese diaspora cannot be ignored.

The Chinese diaspora has been considered as an important factor in facilitating the integration of China into the world economy (Buckley, et al., 2007). Since 1979 the level of inwards FDI made by overseas Chinese from Singapore, Taiwan and Hong Kong has indicated a positive influence on outward FDI from China to the rest of the world (Henley, Kirkpatrick & Wilde, 1999; Ng & Tuan, 2002; Sikorski & Menkhoff, 2000; Yeung, 1999). Furthermore, Luo (1997), Standifird and Marshall (2000), and Tong (2003) suggest the well linked economic and financial connections among overseas Chinese and the importance of *guanxi* in Chinese business dealings may assist a number of MNCs to engage in the global arena. Indeed, Braeutigam (2003), Erdener and Shapiro (2005), and Sung (1996) pointed out the ethnic and family *guanxi* or networks created a firm specific advantage in the reduction of the level of risks, and transaction costs associated with identifying global business opportunities overseas. Consequently, such strong economic connections and networks gathered, from the overseas Chinese, have the potential to promote the internationalisation activities of the Chinese MNCs.

The internationalisation strategy taken by many Chinese MNCs could be summarised in three main levels (Child & Rodrigues, 2005). The first level, exporting has been considered as an important component of China's outward economic expansion, which is a strategy not necessarily involving any form of direct investment or active organisational presence overseas. For the second level, a number of Chinese MNCs have engaged in the international market through the route of original equipment manufacturer, and joint venture partnerships. Deng (2004) indicated the internationalisation of Chinese firms is largely driven by seeking natural resources, advanced technology, markets and strategic assets, which are unavailable in the domestic market. Due to the shortage in resources, Chinese MNCs prefer to build linkages through strategic alliances or forming joint venture with foreign companies to enter the international market. In addition, acquisition (e.g., Lenovo) is another internationalisation strategy that provides a fast expansion route for many Chinese MNCs. The physical and organisational expansion to an overseas market has formed the third level of internationalisation strategy for the Chinese MNCs. This route of internationalisation involves the Greenfield establishment of subsidiaries and facilities within targeted markets. Overall, the outstanding internationalisation strategies exercised by the Chinese MNCs have demonstrated the important role that they play in the global marketplace. Regardless of whether the Chinese MNCs is engaged in exporting, joint partnership or Greenfield establishments overseas quality managerial competencies are critical for the success of international organisation.

Talent Management

Despite the dominant role that Chinese MNCs play in the world stage these organisations are facing challenges in the shortage of managerial talents. Stahl, et al. (2007) defined talent management (TM) as an emerging business strategy, that enables an organisation to identify, develop and redeploy key talented employees. Such a strategy may assist organisations to minimise the impacts of managerial shortages, and consequently, TM is significant to the success of an MNC's international operations. Collings and Mellahi (2009), Lewis and Hackman (2006) as well as Hartmann, Feisel and Schober (2010) indicated organisations throughout the world have realised one major source of competitive advantage is created through knowledge, skills and abilities of their talented employees. Often, internationally competent managers have been identified as a key component of an organisation's global business success (Becker, Fineman, & Freedman, 2004; Black & Gregersen, 1999; McDonnell, Lamare, Gunnigle & Lavelle, 2010; Scullion 1994, 2001; Shen & Darby 2006; Stroh & Caligiuri, 1998). Paradoxically, the concept of TM is not yet well understood, and while the importance of the phenomenon is recognised relatively few studies have been undertaken to systematically ascertain the effectiveness of implementation (Cappelli, 2008; Cohn, Khurana & Reeves, 2005; Mäkelä, et al., 2010; Scullion & Collings, 2006; Sparrow, Brewster & Harris, 2004). Therefore, a more strategic and broad based analysis of TM is required (McCauley & Wakefield, 2006).

Globalisation has increased the demand for skilled labour worldwide (Collings, Scullion, & Morley, 2007; Scullion, Collings, & Gunnigle, 2007). "The acceleration of China's integration towards the global economy" (Nie, 2008: p.131) has inevitably onset a search for TM. Hechet and Ruet (2009) indicated that "... Chinese groups suffer from a lack of internationally trained managers, limited knowledge of the European and American legal and administrative environments, and a lack of flexibility to compile complex financial

operations for mergers and acquisitions...” (p.195). Moreover, Lou and Tung (2007) point out that Chinese MNCs not only suffer from a lack of global experience, but also from a lack of managerial competence and professional expertises. Recently, the McKinsey survey (2008) of Chinese executives has further demonstrated Chinese companies are challenged by lack of managerial talents and insufficient understanding of the legal and reputational risks as well as lack of financial resources. As a result, talent shortage is predicted to be one of the greatest barriers to the current and future growth of an organisation (Ma &Trigo, 2008; Taylor, 2007).

A number of recent studies has highlighted the changing mindsets of Chinese managers brought about by the economic resurgence (Cooke, 2010, Nankervis &Chatterjee, 2011). These authors indicated a shift towards willingness to accept performance based pay, demographic value shift away from collectivism to risk taking, and a subjugation of traditional Confucian culture to material gain. Alleviation of talent shortage by poaching staff from other companies with alterative packages has been a widely used tactic employed by both Chinese owned as well as global MNCs (Cooke, 2008; Walsh& Zhu, 2007). The key theoretical argument being that the adoption of an uniform global (integrated) HRM strategy is not possible in China without accommodating local practices and policies. This crossverging mindset is generating an unique challenge for Chinese managers in understanding and negotiating not only managerial, organisational and institutional forces, but also the strong traditional culture underpinning their philosophies.

Research Method

Site and Subjects

The study sample was 30 executive managers of MNCs in Qing Dao city, of mainland China. A convenient sampling method was employed through personal relationships (guanxi) to obtain a unique sample of respondents, who were business owners or senior managers of 24 Chinese business organisations. Among the 30 respondents were six participants, who worked in the same organisation, which has more than 1,000 employees. Each of these six managers holds different executive positions. All of the 30 managers are engaged in strategic business decision making. An important feature of this group of people lies in the fact that they are involved in strategy formulation and implementation processes. In other words they are not only information rich individuals, but they are frequently engaged in decision making processes of internationalisation strategies as well as global investment directions.

Procedure

A three stage process was used to evaluate the study constructs. First, the study questionnaire was generated by back translating (English to Mandarin to English) a set of Western instruments. This procedure involved three independent groups of bilingual assistants, who are professional translators employed in Qing Dao, China. Members of the first group translated the questionnaire items from English to Mandarin, the second group of assistants translated the questionnaire from Mandarin to English, and the third group played an important role in assessing the translated (English) items for correspondence with the initial English version of the questionnaire. Second, the distribution of the finalised questionnaire either in Mandarin or English, which was preferred by the participants, was undertaken through personal networks (guanxi). According to Chatterjee and Pearson (2002), and Ananthram (2008) data collections from Eastern business contexts would be greatly assisted when networks or guanxi (i.e., in the Chinese context) is involved. The questionnaires were delivered by either the first researcher or a third party to the agreed study companies in Qing Dao, China, along with a letter introducing the researcher, and explaining the purpose of the study. In addition, ethical consideration for conducting this research, including participation was voluntary, and respondent anonymity was preserved, two features that were carefully addressed in the letter to the managers. A total of 30 questionnaires were distributed, and collected from the study companies.

Measures

The research instrument is designed to measure quantitative elements. Personal information, such as demographic dimensions was obtained in the first part of the survey. For example, managerial position, length of service in the company and industry, the level of formal education of the respondents as well as global market entry modes of the company were measured with nominal data. This information is presented in Table

1. Quantitative data were obtained with interval scales to assess aspects of TM acquisition as perceived by the managerial sample.

A total of five variables related to TM was identified. These constructs include 1) selection, 2) recruitment, 3) training and development, 4) promotion, and 5) reward. Six items, which were frequently mentioned (evaluated by percentage), were adapted from Hsu and Leat (2001), and El-Kot and Leat (2008) to measure *selection*. The variable of *recruitment* was assessed with nine items, that were adapted from Chang, Wilkinson and Mellahi (2007), and Lockyer and Scholarios (2007). The most frequently used techniques for recruitment were employed and recruitment can be done both internally and externally. *Training and development* was measured with eight items, and two items were reverse scored (Altarawneh, 2009; Fisher, Bibo, Youngsamart&Chomjunroone, 2001). *Promotion* was scored with seven items, which was an adaptation of scales from Fisher, et al. (2001), and Hsu and Leat (2001). *Reward* was assessed with five items (Entrekin& Pearson, 1997). These variables were assessed with data that were captured from the administration of seven point Likert scales, which have responses range from 1 = ‘Strongly disagree’ to 7 = ‘Strongly agree’. Arithmetic means were generated from the responses.

Analysis

The data captured with the questionnaire survey were examined with several statistical tests. Firstly, the responses generated through the questionnaire survey were examined for outliers. This process enables the researchers to ensure that no data entries exceed their interval range. Secondly, exploratory factor analysis employing the Varimax option was performed so that the interval validity could be evaluated. These statistical procedures were conducted with SPSS software (SPSS, 18).

Results

Demographic of the Respondents

Table 1 summarises the demographic characteristics of the respondents. It is shown in Table 1 the respondents have been engaging in their respective industries for more than 10 years, and indeed, over one third of them had been active for 15 years or more. In addition, most respondents have been working in their current position for more than five years to demonstrate respondents have extensive working experience. A second feature of the sample was that two third of the participants’ companies were involved in the manufacturing sector. This finding is aligned with the existing study findings that a large number of the Chinese MNCs are engaged in the global marketplace to take home cost advantage in manufacturing (Jonsson, 2008). A third feature of the sample was that more than 90 per cent of the respondents are younger than 45 years old, which indicates that seniority in leadership promotion has become less important, as these organisations have placed emphasis on a young well training and skilled workforce. Indeed, 66.7 per cent of the participants had Bachelor degrees, and 16.6 per cent of the respondents have been awarded Master degrees. A fourth feature of the sample was that a one third representation of female managers (33%), which may suggest that male dominant leadership is weakening in Chinese companies. These results are consistent with previous studies findings conducted by Ananthram and Pearson (2008), Ananthram, Pearson and Chatterjee (2010), Nie (2008) as well as Chatterjee and Pearson (2002; 2006). A fifth feature of the sample was that most of the study organisations have employed exporting, joint venture or strategic alliance as their investment type for entering foreign markets. However, there is a shift in employing more risk type of entry mode to engage in a foreign market, in fact 23.4 per cent of the study companies have expanded overseas through establishing foreign subsidiaries.

TABLE 1: DEMOGRAPHICS % (N = 30)

Management position		Age (years)	
Executive	6.7	25-35	23.3
Middle	86.7	36-45	73.3
Supervisory	6.6	More than 45	3.4
Length in industry (years)		Gender	

Less than 6	6.7	Male	66.7
6-10	23.3	Female	33.3
11-15	33.3		
More than 15	36.7	Education	
		College/technical	16.7
Industry type		Bachelors	66.7
Manufacturing	73.3	Masters	16.6
Services	26.7		
		Entry	
Length in organisation (years)		Export	30.0
Less than 6	3.4	Joint venture	33.3
6-10	33.3	Strategic alliance	13.3
11-15	33.3	Subsidiary	23.4
More than 15	30.1		

Factor Components Assessments

Tables 2 to 6 present two types of results. Firstly, the factor scores, which show a distinct separation of the managerial responses for the employed TM processes of the Chinese MNCs, are presented. Secondly, in the asides are shown the average aggregated (i.e., mean) scores for each of the measured TM processes, which were determined with seven point Likert scales. These data (of Tables 2 to 6) show two important features. First, the data were relatively robust; and second, the perceived mechanisms adapted by the study organisations were generally Western oriented TM techniques with a Chinese flavour.

Selection

Table 2 shows the most frequently used selection techniques. Conveniently, the employment processes of the Chinese MNCs study firms have been partitioned as formal and informal techniques. For instance, the selection procedures of interview panel, application form as well as medical examination are considered to be formal selection methods, while external reference, curriculum vita, and reference have been nominated as informal methods.

The factor correlations and the mean scores reflect the study organisations are moving away from a traditional system of patronage to the endorsement of contemporary standard selection processes, that have been designed to provide assessments of the applicant quality. This result is consistent with existing study findings that have been largely documented in the Western literature (Hsu &Leat, 2001; Kersley, et al., 2005). Thus, the results indicate that Chinese MNCs show a strong interest in formalising their selection processes by adapting Western techniques. This notion is particular evident as the informal selection methods, such as references, which are less frequently employed by these Chinese organisations. Arguably, the selection criteria are dominated by the notion of ‘*what you know*’ rather than by the ‘*who you know*’ phenomenon. This study finding is supported by Shen (2010), who suggested that Chinese enterprises, particularly privately owned firms, tended to pay attention to selection criteria of education, skills, experience as well as performance.

TABLE 2:SELECTION (N = 30)

	Factors	
	Formal	Informal
Interview panel	.876 (6.48)	.061
Application form	.779 (6.31)	.050
Medical examination	.652 (6.03)	.279

External reference	.139	-.827(5.07)
Curriculum vita	.233	.654 (6.38)
Reference	.273	.652 (3.52)

Notes. a. Values in the brackets are mean scores.
b. The negative factor correlation value for external reference is a response to the reverse of the questionnaire item.

Recruitment

Table 3 presents the outcomes of managerial recruitment sources, that were employed by Chinese MNCs, and two types of recruitment sources (i.e., external and internal) were identified. The first finding is partly in line with Zhu, Warner and Rowley (2007), whose study identified personal relationships as very important hiring practice, employed by firms from East Asia. Also, Han and Han (2009) found that network based recruiting practices were prevalent among Chinese firms, especially large companies and Indigenous state owned enterprises. In contrast, Zhu and Dowling (2002) demonstrated that external recruitment sources such as advertising have been largely used by Chinese firms, and this observation is also consistent with the findings shown in Table 3. A key feature of Table 3 is that Chinese MNCs seldom used network related recruitment source. In fact, the predominant recruitment channels are national press advertisement and recruitment agencies. Consequently, the study finding also illustrates that Chinese MNCs appear to be interested in adapting HR practices developed and used in advanced market economies. At the same time, however, unique Chinese HR features or characteristics are being maintained.

TABLE 3: RECRUITMENT (N = 30)

	Factors	
	External	Internal
Quanxi (connection)	-.753 (3.00)	.005
Connection is seldom done	.734 (5.45)	.211
National press advertisement	.662 (3.76)	.405
Job centre	.609 (4.83)	.086
Government agencies	.587 (2.38)	-.368
Internal referral is not common	.171	.749(4.45)
Internal appointment	.046	-.659(5.00)
Referral from existing manager	.019	-.647(4.10)
Recruitment agencies	.263	.643(4.59)

Notes. a. Values in the brackets are mean scores.
b. The negative factor correlation value for external reference is a response to the reverse of the questionnaire item.

Training and Development (T & D)

The findings in relation to training and development (T & D) practices that have been exercised in the Chinese MNCs are presented in Table 4. Table 4 demonstrates that the respondents believe a high level of T & D programme investment by their organisations. This finding is partially contradicting to the observations documented by Cooke (2005) and Zhu (2005), who argued an inadequate training was provided in Chinese enterprises during the economic transition period. More interesting is the finding reported by Shen (2010), who revealed that private owned Chinese enterprises show a lack of commitment to T & D. Nevertheless, the study finding indicated there is an equal opportunity between male and female managers when it comes to T & D participation in the study Chinese MNCs. Another predominant feature of Table 4 is that evaluation (e.g., feedback) for participation in T & D is compulsory, and often managers who hold a post-secondary qualification

are required for T & D. Accordingly, T & D opportunities were regarded as adequate in the Chinese MNCs, and such programmes provide for managerial personal development.

TABLE 4: TRAINING AND DEVELOPMENT (N = 30)

	Factors		
	Favourableness	Equity	Evaluation
Availability	.909 (5.87)	-.046	-.083
Evaluation	.818 (5.03)	-.081	.121
Managerial T & D is provided	.769 (6.45)	.042	.140
Regularly work relevant T & D	.767 (6.07)	-.153	.119
Less T & D opportunity for women	-.001	.904 (2.41)	.081
Not encouraged to improve T &D	-.154	.845 (2.00)	-.190
Lack of T & D evaluation	.045	.110	-.790 (3.47)
Post secondary qualification is required for T &D	.232	.031	.711 (5.87)

Notes. a. Values in the brackets are mean scores.

b. The negative factor correlation value for external reference is a response to the reverse of the questionnaire item.

Promotion

The empirical results revealed that Chinese managers are promoted based on three factors including superiority, professionalism as well as competence, and this information is presented in Table 5. It is indicated in Table 5 that '*who you know rather than what you know*' is unlikely to be the underpinning in managerial promotion. Furthermore, female managers and male managers were given equal promotional opportunities. It is also shown in Table 5 that loyalty and managerial skills are important indicators of managerial promotion. In addition, Table 5 shows that past performance as a measure of competence is used as a managerial promotion criterion for the study Chinese MNCs. This observation is different from Shen's (2010) finding, who demonstrated that good performance did not significantly result in promotion in the Chinese privately owned enterprises of that study. Moreover, the present study indicated as a competence promotion guideline, length of service, that can be interpreted as show loyalty to the organisation was a relatively important indication in the Chinese MNCs. A strong influence of the content of Table 5 is the study managers perceived promotion in their organisations was substantially depended by professionalism (e.g., managerial skills and past performance).

TABLE 5: PROMOTION (N = 30)

	Factors		
	Superiority	Professionalism	Competence
Who you know rather than what you know	.808 (2.20)	-.082	.142
Male managers are promoted ahead of females	.766 (3.20)	.020	-.206
Female managers are more likely to be promoted	.650 (3.30)	.227	.028
Loyalty	.028	.845 (5.60)	-.096
Managerial skills	.068	.843 (6.10)	.122
Past performance	-.176	.142	.857 (5.07)
Length of service	.466	-.244	.602 (3.30)

Note. Values in the brackets are mean scores.

Rewards

Table 6 presents the results on the reward criteria being employed by the study Chinese MNCs. It is presented in Table 6 two types of main reward exercises as attached and detached have been practiced by the participated Chinese organisations. ‘*Annual red package or red envelopes*’ and ‘*Seniority*’ that have been identified as two forms of traditional rewarding exercises have been utilised in the studied companies. This observation provides foundation for the claim that Asian organisations tend to use seniority as an important factor for reward (Chang, et al., 2007; Zhu, et al., 2007). In addition, one of the major findings of the quantitative results (Table 6) was the emphasis placed by the Chinese organisations on financial rewards based on annual performance. Another key feature in Table 6 is that Chinese organisations rely heavily on team and group related performance to reward their managers. Indeed, the mean score (e.g., 4.83) further indicated Chinese MNCs focus more on group performance as a rewarding criterion. Such a finding supported the viewpoints that there is a high level of collectivism in Chinese organisations. Furthermore, Table 6 shows that Chinese organisations tend to use ‘*A document and a fixed tangible item*’ to reward their managerial talents. Overall, it could be argued the reward criteria used by Chinese MNCs provide a platform for the claim there is a gradual transformation in their HR practices that is crossvergence HR, to form a hybridisation of management system.

TABLE 6: REWARDS (N = 30)

	Factors	
	Attached	Detached
Annual red package or red envelopes	.787 (4.47)	-.098
Seniority	.672 (2.67)	.454
Financial rewards based on annual performance	.648(5.60)	-.275
Group performance	-.045	.828 (4.83)
A document and a fixed tangible item	-.068	.458 (4.13)

Note. Values in the brackets are mean scores.

Discussion

In spite the relatively small sample size the presented data are exceptionally rich. The quality of the data is underpinned by the responses of managers, who had considerable influence on the strategic decision making in their firms. These decision processes were pervasive in the selection of TM. Robustness of the data is also demonstrated by the factor scores shown in the Tables. Except for the item (*A document and a fixed tangible item*) in Table 6 all factors scores are greater than 0.5, which is considered to be an acceptable loading.

The study analysed the TM philosophies and strategies that are employed by the Chinese MNCs to locate managerial talents. The study results demonstrated that the TM practices of selection, recruitment, T & D, promotion as well as reward adapted by the Chinese MNCs are becoming crossvergent. The crossvergence approach was developed by Ralston, et al., (1993), who argued a hybridisation of management systems would occur when two cultures meet. Indeed, this hybrid condition would result “... when an individual incorporates both national culture and economic ideology influences synergistically to form a unique value system that is different from the value set supported by either national culture or economic ideology.” (Ralston, et al., 1997, p.183). Hence, the emerging trend toward crossvergence in the adaption of TM policies and practices in the Chinese MNCs was evident in a number of areas.

One of the evident areas is that managerial selection criteria have become more decentralised in the studied organisations, and the focus on candidates’ work experience is valued. Indeed, the use of *Curriculum Vita* had the mean score of 6.38, which indicated Chinese organisations put more emphasis on ability and education background when selecting managerial talents. Although the traditional HRM practices such as references are used as a screening tool, the job interview has been considered as a predominant selecting criterion when choosing potential managerial talents. Ultimately, it could be argued that while Chinese MNCs are increasingly engaging in the global marketplace the transformation towards crossvergent TM strategies are more likely to dominant the Chinese management systems.

The findings of the study with managers, who were considered to be exceptionally information rich individuals and involved in strategic decision making, revealed four salient features. First, a dominant feature that arises from the study finding is the managerial talents were mainly recruited through external sources such as job centres or national press advertisements. On the one hand, this observation is in line with the work conducted by Zhu and Dowling (2002); and on the other hand, this outcome is partially contradicted with several existing studies. These researchers (Chow 2004; Han & Han, 2009; Zhu, et al., 2007) found that referral (i.e., internal or external) or internal appointments are considered important recruiting methods used by Chinese firms. The second major feature is that T & D programmes are provided to both female and male managers. Arguably, given the experienced current shortage of managerial talents Chinese MNCs are making significant progress in developing HR through T & D. Indeed, Cooke (2008) has demonstrated "Raising the nation's education and skill level has been increasingly high on the Chinese government's agenda." (p.66). This agenda has been supported at micro level as companies across different industries to provide T & D programmes in order to acquire better quality managerial talents (Chow, 2004). A third feature of the study results is the notion that promotions were largely based on professionalism and competence of the managers. In other words, the traditional promotion criterion based on seniority rather than performance is fading as many Chinese MNCs have realised a sufficient promotion system is a key to the development, motivation as well as retention of skilled staff. Indeed, the relative importance of managerial skills in promoting managerial talents is underpinned by the high mean score (6.10). Clearly, managerial skills and performance became increasingly important determining factors for promoting managerial talents in the Chinese MNCs. The fourth attribute obtained from the study findings is while the traditional rewarding system places emphasis on seniority, performance related rewards are also used to a large extent in many Chinese MNCs. More specifically, a high tendency is revealed as the studied Chinese MNCs have endorsed the importance of a performance based rewarding systems (Chow, 2004; Zhu, et al., 2007).

The study findings may have boundary conditions in making generalisation. A particularly interesting extension of this study is to consider the effects of ownership on the TM practices in Chinese organisations. Although this study has offered insightful information for both researchers and Chinese business owners or managers to understand the notion of TM, the study sample is relatively limited as it did not incorporate the ownership dimension. In fact, Chow (2004) had reported that HRM practices are strongly affected by the forms of firm ownership. For example, Chow (2004) argued that traditional HRM practices such as staffing through one's connection are still employed by Chinese state owned enterprises. According to Chiu (2002), Shen (2010), Zheng, et al. (2006), and Zhu, et al. (2005), the privatisation in China also plays a significant role in employment relations. Due to workplace dynamics and business ownership structures a deeper understanding of the ownership dimension in relation to TM practices in the Chinese organisations has the potential to offer additional information to business managers or owner to advance their knowledge. Hence, the orientation towards a comprehensive examination by incorporating the notion of ownership may further enhance the understanding of how Chinese MNCs practice TM in their respective organisations. This approach may offer fruitful ground for further exploration.

A substantial revelation revolution of the evidence presented in this paper is the perplexity in perceived homogeneity of recruitment and associated HRM practices employed by Chinese firms. Prior to the economic reforms Chinese organisations practiced the dominant ideology of patrimonialism, which shaped managerial behaviour flavoured with familism, paternalism, mutual obligation and connections. Coupled with the planned economy people were organised in a form of personnel management in a framework termed the 'iron rice bowl' with centrally administered wages, stage controlled appointments and promotions as well as lifetime employment. Today an evolutionary process is entrained as China moves to become a powerful socialist market, which has onset significant shifts in institutional architectures. While there is a divergence from the earlier arrangements the newer management perspectives, which are inexorably linked to the international economy, will homogenise as a different set of social values and work ethic when HRM is integrated into the core business operations.

Conclusion

This paper generated research evidence likely to assist scholars and practitioners during this complex period of economic and social transformation in China. The paper reveals a significant crossverging trend in HRM

practices adopted by MNCs rising from China. As the paper points out, China is perhaps one of the most culturally and institutionally distinct societies from the central focus of contemporary managerial precepts and practices. Therefore, local adoption still remains a high priority for all managerial philosophies in China. Interestingly, these crossverging ideas are now used as the basis of competitive advantage as Chinese MNCs spread their wings abroad. In order to sustain and improve their global ambitions, Chinese MNCs will need to actively promote a developmental oriented talent retention HRM strategy. The ad-hoc HRM philosophies prevalent in domestic Chinese firms, where decision making is concentrated at the top need to give away to global imperatives of differentiation. Additionally, the industry characteristics of these MNCs also play a significant role in shaping talent management philosophies. For example, Chinese MNCs in high tech sector have already demonstrated their proactive engagement in obtaining, retaining and developing talents around the world.

The Study of Job Satisfaction and Organizational Citizenship Behavior (OCB) in the Thai Retail Industry

*Wanee Saepung, wsaepung@hotmail.com
Sununta Siengthai, s.siengthai@ait.ac.th
Asian Institute of Technology, Thailand*

I. Introduction

Human resources are intellectual capital to an organization because they are embodied with abilities, talents, skills, personalities, motivation, and organization cultural value which lead to various demonstrated behaviors and performance. The different individual behaviors result in varying organization outcomes. Organization would prefer employees who are committed and exhibit certain desirable work behaviors and those beyond their work roles that are considered positive to organization effectiveness. However, what influence employee to exhibit the latter type of behaviors at work? This study aims to investigate the relationship between job satisfaction and its facets and organizational citizenship behavior (OCB).

II. Literature Review

“A sense of citizenship translates into a readiness to contribute beyond the literal contractual obligations, just as a good citizen in the civic sense does more than simply not violate the law, A good citizen does not rest upon mere compliance, he or she does something more to promote the community. But to feel like a citizen, one must feel that one is treated like a citizen and accorded rights, privileges, and respect” (Organ, 2006, p.52).

Organizational Citizenship Behavior (OCB)

Katz and Kahn (1966) suggested three different basics of behaviors that contribute to the effectiveness of an organization. According to them, personnel should involve and support organization systems; should demonstrate dependable role performance, achieve established work standards; and should exhibit innovative and spontaneous behavior: performance beyond role requirements for accomplishments of organizational functions (Katz and Kahn, 1966). The last category comprises such cooperative actions with other members, actions that promote a favorable climate at workplace, actions that improve organizational system which is broadly considered organizational citizenship behavior (OCB).

OCB is a multi-dimensional concept. It is defined by various researchers such as: “willingness to cooperate” which contributes to an attainment of organizational goals (Barnard, 1938); “dependable role performance” and “innovative and spontaneous behaviors” (Katz and Kahn, 1966); “prosocial organizational behavior” (POB) (Brief and Motowidlo, 1986); “an individual behavior that is discretionary, not directly or explicitly recognized by the formal reward system’ and that in the aggregate promotes the effective functioning of the organization” (Organ, 1988); “behaviors which are not formally prescribed, but yet desired by an organization” (Schnake, 1991); “extra-role behavior” (ERB) (Van Dyne et al., 1995); “discretionary behaviors that directly promote the effective functioning of an organization, without necessarily influencing employee productivity” (MacKenzie et al., 1993). This type of discretionary behavior is a matter of personal choice, such that its omission is not generally understood as punishable. As OCBs have been defined in different ways by various researchers, therefore the taxonomy of OCB seems to be problematic.

Job Satisfaction and OCB

Job satisfaction is “a pleasurable or positive emotional state resulting from the appraisal of one’s job or job experience” (Locke, 1976 cited in Luthans, 2002, p. 230). Job satisfaction evaluation is a significant indicator as it is communicating employees’ attitude about their perception/satisfaction relating to job aspects and organization’s treatment. The work motivation theories underly the fundamental understanding of employee job satisfaction. The extent they are satisfied with their job is contingent upon how much they recognize that their needs/ desires are being fulfilled; or their values and expectations are being responded.

The manifestation of OCB arising from job satisfaction is theoretically supported by the social exchange theory of Blau (1964 cited in Organ 1988 and Organ et al., 2006). When employee perceives well treatments, given resources or opportunities from an organization, by the norm of reciprocity they will be obliged, in return, to exert extra efforts or perform non-required behaviors within an organization environment such as cooperative and helping behavior, or supportiveness of the supervisors (Organ 1988, and Organ et al., 2006). In addition, when people gain experience in the positive mood state, they tend to associate with prosocial behavior which is about behaving as “a good citizen”; therefore “an organization with a highly satisfied work force benefits from the goodwill in the community that satisfied worker help foster” (Organ, 1978, p.121).

Bateman and Organ’s study (1983 cited in Schnake, 1991) find that all dimensions of job satisfaction have a significant and positive relationship to citizenship behaviors ranging from 0.19 to 0.25 (p-value < 0.05) while satisfaction with supervision and with promotional opportunities reported the strongest correlation to OCB at over 0.30. They assert that motivation can stimulate the good citizenship behavior of individuals perceiving the fairness of organization treatment, in conjunction with one’s personality. So if an individual views an organizational treatment positively and fairly, one is inclined to be motivated to express certain good behaviors or attempts towards an organization. Organ (2006) notes that individual underlying motivations which are determined by individual dispositional characteristics can drive one to engage in OCBs and subsequently one might want to display for various personal reasons; for one’s own sake, for the sake of others (colleagues, supervisors) or for one’s organization. Blalock (1971) proposes four antecedents to citizenship behaviors, namely, job satisfaction, environmental variables, personal variables and demographics while Podsakoff et al. (2000) propose individual characteristics, task characteristics, organizational characteristics and leadership behaviors to influence OCB level. In the meta-analysis of Organ and Ryan (1995), job satisfaction, in combination with fairness and commitment show the rigorous and comparable correlations among them which yield a good composition of OCB determinants. However, Organ (1988a) notes that when considering only job satisfaction and perception of fairness together, the latter one would explain more variation in OCB. While in some studies (George and Jones, 1997; Jehn et al., 1999; MacKenzie et al., 1998; Ackfeldt and Coote, 2005) claim both job satisfaction and organizational commitment as the key job attitudes to be the good predictors of employees’ OCB level. Smith, Organ and Near (1983) have found job satisfaction correlated positively and significantly only with altruism but not with generalized compliance (Organ, 1988 and Schnake, 1991). Bolon (1997) finds that overall job satisfaction including its sub-dimensions of work itself, pay, supervision and coworkers has significant direct relationship with citizenship behaviors ($r = 0.22, 0.20, 0.31, \text{ and } 0.17$ respectively at $p\text{-value} < 0.01$). Also, the research findings of Murphy, Athanasou and King (2002) reveal the job satisfaction-OCB relationship of Australian human-service professionals ranging from medium to strong correlations which ranged from +0.40 to + 0.67. William and Anderson (1991) investigate the relationship between job satisfaction and organizational commitment to the performance of OCBs. Based on the regression analysis of the data collected from a sample size of 127 participants from various organizations, the results connote that affective variables (job satisfaction) and organizational commitment were not significantly related to any form of the three OCB performances, while both job satisfaction cognitions (intrinsic and extrinsic) remained significant correlations with different forms of OCBs. The researchers note that different forms of OCBs may have different antecedents as appeared in the study of Brief & Motowidlo (1986) or Smith et al. (1983). However, these different findings between two job cognitions and OCBs are not predicted by the existing theory (William and Anderson, 1991). Pornpongsuriya (2001) finds that correlations between all attitudinal variables and OCB are significant and positive ranging from 0.155 to 0.316. Based on multiple regression analysis, all given job attitude variables can

account for the variance of nurse's OCB displayed at 13.5%. Job satisfaction with work itself and interactional justice variables are predictors of nurse's OCB.

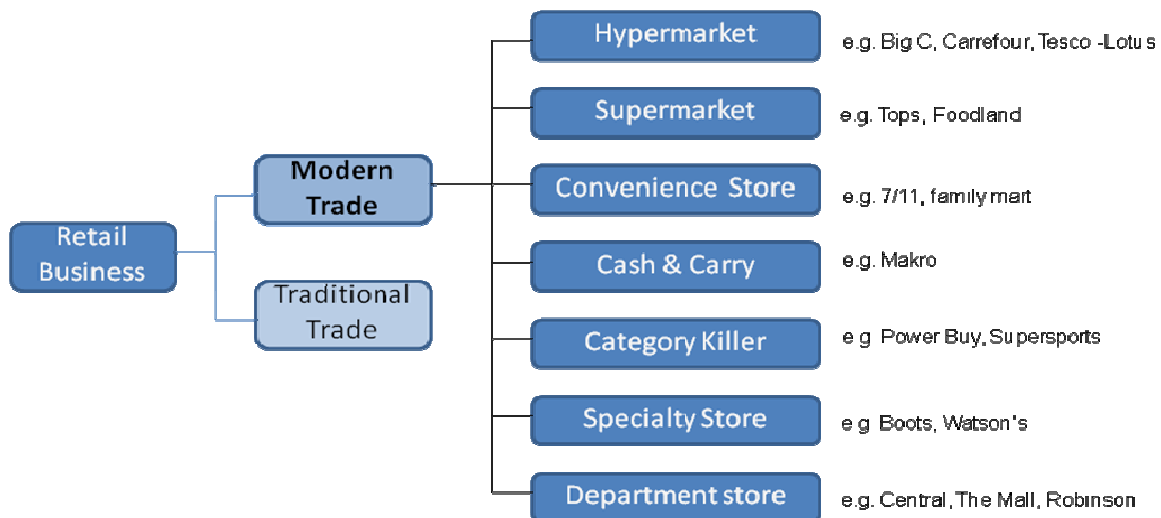

Based on the literature review, this study postulates that job satisfaction has a positive relationship with OCB of retail employees in Thailand.

III Research Methodology

Context of the Study: Retail Business in Thailand

In Thailand, retail business can be divided into two major groups, i.e. traditional trade and modern trade by Thai Retailers Association; (1) Traditional retail is seen as large number of mom and pop shops and modern trade retail mostly come from direct investment from foreign countries. Both types as illustrated in Figure 1 according to Kittiwachpokawat (2008, p. 11-17).

FIGURE 1: THAI RETAIL BUSINESS STRUCTURE

Sampling Procedures and Research Instrument:

The sampling frame of this research is composed of operational employees who work in 13 retailing companies where similar responsible jobs or functions may differ based on their retail organizational structure or type (i.e., size, breadth of operations, product assortment and so forth). These include employees who have attained at least high school level. They also must have worked at least one year as a full-time employee at the operational level who perform tasks both in the front office (direct customer-contact employees) and in the back office (indirect customer-contact employee).

A sample size of 30 units is drawn individually from 13 retailing companies so the total sample size is 390 operational units (Table 1). HR executives at the head office of these 13 companies were contacted to get permission for the self-administered questionnaire survey. The questionnaires and self-addressed envelopes were distributed to respondents working in the front-and-back office in an equal amount of 30 sets to cover retail employees in all functions in each sampling unit.

The research instrument is developed in Thai language and composed of 3 sections concerning with demographic information of respondents and two sections containing items measuring employee job satisfaction based on the work of Smith, Kendall and Hulin (1996) and Kannasoot (1999) and items measuring employee organizational citizenship behavior based on the works of Podsakoff and MacKenzie (1994) and Kannasoot (1999). A pretest of the survey was undertaken with 30 salespersons at the several shopping malls who possess the same required criteria of sampling selection. The actual survey was conducted during Feb. 2009 – March 2009. Of the total of 390 questionnaires distributed, about 372 completed and usable questionnaires were returned which is about 98% response rate. The data were analyzed using SPSS version 17.0

IV. Findings and Discussion

Based on the analysis, it is found that most of the sample respondents (i.e., 60.8%) are female. Many of them (i.e., 46.5%) are within the age group of 26 – 30 years old. About 44.1% have high school or equivalent education and about 36.3% have attained a bachelor's degree. The majority of them (i.e., 61.6%) have about 1-5 years of work experiences.

Retail Employees' Job Satisfaction and Organizational Citizenship Behavior

Table 2 suggests that retail overall employee's job satisfaction level is high. Of all the job satisfaction facets, the sample employees are found to be satisfied with the following aspects: coworkers at their workplace, i.e., 4.33; the nature of the work, i.e., 4.22; supervision, i.e., 4.12; promotional opportunities, 3.84; feeling close together, i.e., 3.87. This suggests that retail employees are likely to engage in discretionary gestures or helping contributions, beyond what are required by their job descriptions, towards other people, a group or an organization. This result is similar to what Pornpongsuriya (2001) has found based on samples of 380 Thai nurses in 15 hospitals reporting a high tendency of OCB displayed in this sector.

With respect to OCB level, Table 2 also suggests that apparently retail employees' OCBs level is quite high with the average score at 4.04. When considering the details of each OCBs' dimensions, retail employees' helping behavior shows considerably high mean scores at 4.07. Civic virtue is also reported high at the mean of 4.06. Employee's sportsmanship is high with the mean score at 3.97.

When asked whether and to what extent employee job satisfaction has a relationship with OCB, using the regression analysis, it is found that overall job satisfaction, based on the composite of five job's components, has a moderately direct relationship with OCB ($r = 0.494$) with the 0.01 significance level. When considering individual construct of job satisfaction predictors; work itself, pay, promotional opportunities, supervision and coworkers correlate positively with OCB (p -value < 0.01) ranging from the low to moderate level ($r = 0.458, 0.296, 0.411, 0.297$ and 0.383 respectively). Each of five job satisfaction variables shows a significant relationship to OCB so when retail employees perceive positively about each of all job aspects; they will be more likely to perform citizenship actions towards other people or an organization. This finding is consistent with those found in similar studies (Bateman and Organ, 1983; Smith et al., 1983; Organ, 1988; Murphy, Athanasou and King, 2002; and Bolon, 1997 and Pornpongsuriya, 2001). Thus, the current finding supports that a composite of job satisfactions and overall OCB are positively and significantly related .

Noticeably, when looking at the findings of Pornpongsuriya's and this study's findings, what has found similar is that the correlation magnitude of satisfaction with work itself is ranked the strongest among other predictor variables for the both studies, while that of pay shows the weakest correlation as the same for both studies, and indeed both studies are conducted in Thai context. This seems to suggest that if an organization wishes to promote OCB among employees, one may primarily enhance their satisfaction with the work by, for instance, providing a clear job description or scope of their accountability, providing opportunities for employees to learn new skills, making them feel comfortable to handle with their tasks and so on. However, satisfaction with pay aspect (at the least strong) should never be overlooked or paid less attention since it is a delicate and important issue to an organization and employee side.

In sum, the job satisfaction-OCB relationship in Thai retail industry has revealed the consistent finding with the past empirical studies. So, it reconfirms that job satisfaction has a significant and direct connection with citizenship behavior.

Factors Determining OCB in the retail industry

Based on the multiple regression procedures; there is a significant linear-relationship between the five job satisfaction predictor variables and OCB, taken together into the overall model. Approximately 26% of the variance of the retail employee's OCB can be accounted for by job satisfaction with work itself, pay, promotional opportunities, supervision and coworkers with the 0.05 significance level (Table 3). The three significant predictors of work itself, promotional opportunities and coworkers jointly contribute in predicting OCB among retail employees in Thailand. Their standardized regression coefficients (Beta) show at 0.28, 0.17 and 0.18 for satisfaction with work itself, promotional opportunities and coworkers respectively. It appears that the change in satisfaction with the work aspect has the strongest impacts on retail employee's OCB among the other two. It is in fact interesting to find that this model explain the OCB level of retail employees more than what has been found by Bolon (1997) and Pornongsuriya, (2001) where respectively about 10% and 13.5% of the variation are accounted for job satisfaction. In nursing organizations, only satisfaction with work itself is an important contribution for OCB prediction, whereas it is found in this study of retail employees, satisfaction with work itself, promotional opportunities and coworkers can jointly contribute to employee's OCB prediction. The findings of this study also supports Herzberg's Two Factor Theory which asserts that job satisfaction and job dissatisfaction are caused by two different groups of factors, namely, motivation and hygiene factors. Herzberg, Mausner and Snyderman (1959) assert that when motivation factors as intrinsic factors are being fulfilled; they will bring about true satisfaction to a person. Whereas the hygiene factors act fundamentally to prevent job dissatisfaction or unhappiness from arising at work. So, if these factors fail to be responded, worker's unhappiness and dissatisfaction will definitely emerge. In addition, as previously having mentioned about boundary spanner characteristics in the retailing, multi-roles in carrying variously retailing tasks and dealing with both internal and external boundaries are inherently needed in retailing employees' attributes; being social, spontaneous, flexible, cooperative, or friendly at workplace (Hassan and Yacub, 2009). Retail employees may view the coworker aspect very important in their employment and appreciate those people who have high level of these attributes.

As the results of the multiple regression analyses show that about 26.2% of the variance of the retail employee's OCB (adjusted $R^2 = 0.262$) can be accounted for by job satisfaction with work itself, pay, promotional opportunities, supervision and coworkers with the 0.05 significance level, there are other variables or factors influencing OCB which needs further investigation.

V. Conclusion and Recommendations

This research study examines job satisfaction-and-OCB relationship among employees in the modern retail industry in Thailand based on the collected samples of 372 subjects from 13 retailing firms. Questionnaire in Thai version was verified for its construct validity. The Cronbach's alpha coefficients are overall about 0.89.

The multiple regression analysis suggests that five facets of job satisfaction taken together can explain about 26.2% of the variation in citizenship behaviors demonstrated by retail employees in Thailand at 0.05 significance level. Three significant predictors (satisfaction with work itself, promotional opportunities and coworkers) are found to influence on the OCB variable over and above that of others.

Managerial Implications

Retail employees reflect their job satisfaction level in the highly positive consequences in all of five job aspects although slightly lower on the pay and promotional opportunities aspects. Thus, retailing firms perhaps can further develop and emphasize on the "career path" scheme within an organization so that employees will be well aware of

their progression throughout their working life and be able to envision where to aim to in their profession. Moreover, this application could also effectively relate to other HRM practices, e.g., individual training & development plan or succession plan, etc.

Regarding the pay aspect in retail business, based on fieldwork discussion with some HR executives, certain retailing firms have linked between performance management (or appraisal) and pay just for several years. However, in practice, the subtle issue is that if employees perceive unfavorable to their pay which is indeed related on the unclearly rated performance by their line manager, they would want to react their negative feelings in certain actions but would not risk their employment and one possible reaction is that they will withhold all sorts of discretionary gestures contributing to their supervisors or an organization since these extra-role performance is not connected to any organizational punishment or rewards system. Avoiding confrontation of the performance reviewing meeting does not contribute any good to both sides. However, as Thai culture prefers a smooth social interaction avoiding confrontation/conflict, line manager should clearly establish the performance standards agreed by all concerned at the beginning so that people know what they have to do or learn to improve their ratings. This is the purpose of developmental aspect of the performance review and also reduces misunderstanding and negative sentiments among employees.

Yet, the OCB concept is very new to Thai context and it has not yet been strategically linked to HRM practices in organizations. It would be useful to investigate a wide range of employee behavioral forms contributing to organizational effectiveness, not only just the traditional or specific role requirements, but also a desirable set of work behaviors beyond formal job description which act as a catalyst for task activities and process. 1988). With the OCB related- HR practices, it would help bolstering citizenship performance of employees in organizations.

Sound Labour Relations at Enterprise Level in Thailand

*Vichai Thosuwonchinda, vichai_tho@hotmail.com
Kasem Budit University Thailand*

Abstract.

The objective of this research was to study the pattern of sound labour relations in Thailand in order to reduce conflicts between employers and workers and create cooperation. The research was based on a qualitative approach, using in-depth interview with 10 stakeholder groups of Thai industrial relations system. They were employees of non unionized companies at the shop floor level, employees of non unionized companies at the supervisor level, trade union leaders at the company level, trade union leaders at the national level, employers of non-unionized companies, employers' organization leaders, human resource managers, members of tripartite bodies, government officials and labour academics.

The findings were presented in a model identifying 5 characteristics that enhance sound relations in Thailand, i.e. recognition between employer and workers, good communication, trust, data revealing and workers' participation. It was suggested that all parties, employers, workers and the government should take part in the promotion of sound labour relations. The employer have to acknowledge labour union with a positive attitude, have good communication with workers, create trust with workers, disclose information, create culture of mutual benefits as well as accept sincerely the system that include workers' participation. Workers need a strong labour union, good and sincere representatives for clear communication, trust, mutual benefits and seek conflict solutions with employer by win-win strategy. The government has a supporting role in adjusting the existing laws in the appropriate way, by creating policy for sound labour relations, and putting the idea of sound labour relations into practice.

Keywords : Conflict, Negotiation, Sound Labour Relations.

Introduction

Labour relations is the relationship between employers and employees in the enterprise, which affects business management, working conditions and life of employees as well as economics social and political stability of the country. It concerned also with employers' and employees' organizations such as labour union and employers' association. The government also has its' role to create social order and to support good relationship between the two parties for industrial peace and stability.

In common circumstance, employees are in a disadvantageous position vis-a-vis employers, in that they have to accept working condition and wages determined by employers. In early stage, employees were working under bad working condition and unsecured employment which gave them the pressure to organize their organization to increase their bargaining power. In many countries, employees or workers are recognized to have the right to organize labour union or trade union to act as collective bargaining agent with their employers. They also have the right to strike if the negotiation fails to reach the agreement.

Under the Labour Relation Act B.E. 2518, employees in Thailand have the right to organize labour union in the same enterprise or in the same industry. Up to 2008, there were 1,229 unions organized in private industries, many of them exercise their power in collective bargaining process as well as strikes and lock-out were always occurred from time to time in the last 34 years. For example, in the year 2008, there were 122 conflicts in 99 enterprises with 51,843 employees involved. These conflicts ended with 10 strikes and 8 cases were brought to labour court.

Labour disputes with strikes and lock-out have negative effects to all sides. Employers lost their sales volume, customers and market share, expenses of fixed cost legal action and public image. Employees lost their income and welfare. The trade union lost their membership fee and have to spend for the strike expenses. Moreover, the society and the country also lost income from production, export as well as investor's confidence. Many countries have tried to introduce appropriate labour relations system in order to create industrial peace in their own

countries, such as co-determination system in Germany, consultation in Japan, work council in Australia, collective bargaining with mutual benefits in U.S.A, Joint consultation in Singapore. For this reason, it is interesting to look for the model of sound labour relations system which is appropriate for Thailand as the main purpose of this study.

Objectives of the Study

This research aimed to study the understanding of stakeholder on the concept of sound labour relations, to investigate the similarities or differences of stakeholders' perceptions of sound labour relations, to identify practical problems and difficulties encountered in establishing sound labour relations from and to reveal best practice on sound labour relations as expressed by stakeholders. Its scope is labour relations practice at the enterprises level in private industries under Labour Relations Act B.E.2518(1975)

Concept of Sound Labour Relations

The concept of labour relations started by the idea of Karl Marx, that workers were disadvantaged compare to employer then he suggested workers to have collective action against employer (Hyman,1975). However, Dunlop showed the workers organizing as trade unions could have their roles in collective bargaining with employers under the rule of the law (Dunlop,1958) . Clegg also confirmed that in pluralism economy, collective bargaining could be done among interest groups. (Clegg,1970) By this concept, labour unions were recognized and play their roles in collective bargaining. Webbs pointed out that collective bargaining would guarantee job security and wage increases for worker but Marshall (1920) warned that, with the introducing more unskilled workers in the employment, these workers had to organize their union to strengthen their bargaining power and strike would be used for negotiation. Mulvey (1987) suggested that if the union had the capacity to organize strike, it would create negative economic benefit to employer , at the same time, it was a cost to union too. However, with the capacity to strike, the union might make a strike threat effectively. Jackson (1988) explained that causes to strike may come from economic, institutional , social and political factors. To avoid strike, Harbison and Coleman stressed that both employer and union needed working harmony and labour-management cooperation. Mill (1994) pointed out that good labour relations comprised recognition and equal relations between employers and workers. De Silva (1996) suggested that workers and employers had to negotiate with the recognition of each other and bargain in good faith, make a compromise for solution with effective communication without misunderstanding. Morishima (1991) explained sound labour relations in Japan by the system of joint consultation and information sharing between workers and managers. Inoue (1991) added that sound labour relations need good communication of workers and employers, and the union should participate in the process of decision making of the organization. . De Silva (1998) added that factors of sound labour relations were worker participation, employee involvement and good communication.

In Thailand, even though many workers' organizations took place since the end of second world war, the concept of labour relations was formally introduced by Labour Law B.E.2500, in the part of labour relations which allowed worker to organize trade union under the same employer or the same industry. However, that law was abolished in the next year due to the investment promotion policy of the government. When the Labour Relations Law was enacted again in B.E. 2518, Thai workers enjoyed their right to organize trade union and make collective bargaining with the result of many strikes and lock-outs in the last 35 years. Many Thai academics tried to do many researches to provide suggestions for peaceful labour relations in the country such as Suttawet (1996) proposed the reformation of the Thai industrial relations to international standard and in a creative way. He suggested that Thai labour relations should be based on consultation and negotiation within the Thai cultural context. In his another research, (Suttawet ,2002) he suggested the creative labour relations that employer has to recognize the trade union, create good communization and introduce mutual decision and participation. Piriya-rangsant (1997), gave the idea to develop labour relations at enterprise level by giving enough information, data for consultation and create cooperation as well as reasonable negotiation to each other. He emphasized that the senior managers had to have

open communication to employees with sincerity. With these concepts, this research tried to find out factors leading to sound labour relations at enterprise level in Thailand.

Methodology

The qualitative research was used in this study, with a descriptive approach. Research questions were posed to seek the understanding of the stakeholders' perspectives on sound labour relations, under the framework of a grounded theory. When the data were collected, it would be coded through open coding to represent an utterance or piece of meaning. After that, the researcher would form initial categories of information about the phenomenon being studied. Within each category, there were grouped by similar constructs, opposing constructs, negative or positive dimensions of construct, all depending how the information emerges. Axial coding was used to identify central phenomenon, explore causal conditions, specify strategies, identify the context and intervening conditions and delineate the consequences. In selective coding, the researcher identified a story line and wrote a story that integrates the categories in the axial coding model. (Strauss&Corbin,1990).

In-depth interviews were used to get data from key informants. The procedure started by identifying key informants of stakeholders in each group, making approaches and conducting the interview and recording the interview. When the data completed, the researcher started to analysis and wrote a report. (Creswell,1998)

The stakeholders of Thai industrial relations system were categorized into 10 groups. They were employees of non unionized companies at the shop floor level, employees of non unionized companies at the supervisor level, trade union leaders at the company level, trade union leaders at the national level, employers of non-unionized companies, employers' organization leaders, human resource managers, member of tripartite bodies, government officials and labour Academics. As to the suggestion of Creswell (1998), in-depth interview should be done through 20-30 key informants until the data completed. In this study, there were 3 key informants in each group, made 30 key informants all together. The names of those key informants were suggested by senior experts in the field of labour relations from Department of Labour Protection and Welfare, Ministry of Labour, and experts in academic field. Consultations were also made with some member of expert panel who are able to recommend appropriate interviewees from each stakeholder group.

The guideline questions for in-depth interview were concerned with opinions about the characteristic of sound labour relations, benefits to stake holders, problems or obstacles that may occur, how to overcome those problems and obstacles, and the best practice of sound labour relations?

The interview were made during March-May 2009 and data analysis was done during June –December 2009. The researcher also used audit trail for the relevant data as well as triangulation method to ensure the consistency of information.

The researcher concluded the final transcription in 5 themes., which were the meaning of sound labour relations by the understanding of stakeholders, the benefit of sound labour relations to stakeholders, the problems and difficulties encountered from practicing sound labour relations, the way to overcome those problems and obstacles and the best practice on sound labour relations as expressed by stakeholders

The result of the study

The result of the study showed that all 10 groups of stakeholders agreed on the meaning of sound labour relations that the labour relations where employers and employees have recognition to each other, mutual trust, cooperation, data revealing, compromise on conflict, fair benefit distribution and look for mutual benefits.

The benefits of sound labour relations would occur to all people concerned. The employees will have good working condition, career path, fairness at work and high standard of living. The employer would have uninterrupted production, get good quality product, high profit and productivity. The unions recognized the problem of employer, get mutual benefit, have steady growth, get support from employer. The society got peace, kept good recognition for investment of the country.

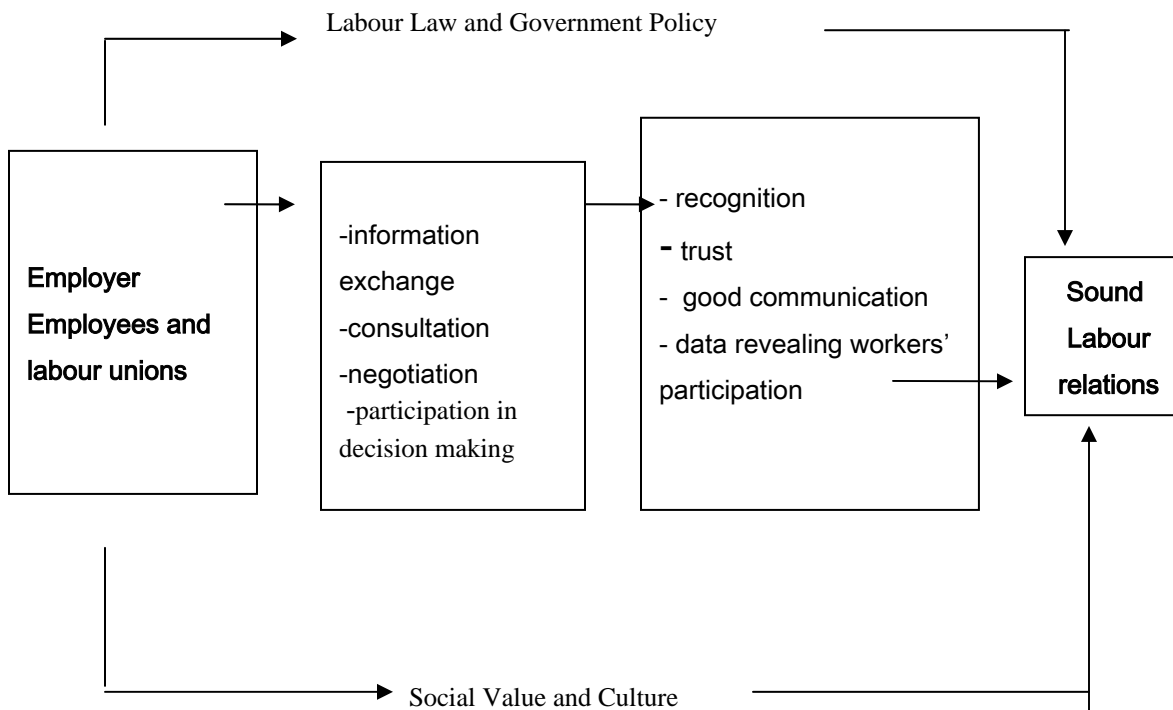

The problems and difficulties encountered from practicing sound labour

relations as expressed by stakeholders were lacking of sincerity, no union recognition, conflict of interest, employers' selfishness, no commitment, no loyalty of employees, no working participation, negative attitude and interfere from outside.

The way to overcome such problems and difficulties should start from the employer side by recognizing the workers and their organization, having positive attitude toward trade union, organizing regular conversation and meeting both formal and informal, keeping good communication, giving data revealing especially on business outcome, accepting negotiation process and introducing workers' participation to the enterprise. Employees, in addition need the strong union and capable representatives for communication with employer. Moreover, the union also has its role to accept the employer' rights in management, make negotiation on reasonable basis and keep the spirit of mutual benefit.

The best practice of sound relations has occurred when both employers and employees have recognition to each other, as well as positive attitude, compromising, good communication, data revealing, trust making and create culture of mutual benefits as well as accept workers involvement at all level. The government also has the role to adjust the labour relations law in the proper way, create policy for sound labour relations, and putting the idea of sound labour relations into practice.

As a result of the study, the researcher created a model identifying 5 characteristics that enhance sound relations in Thailand. They are recognition between employer and workers, good communication, trust, data revealing and workers' participation. The model can be presented as follows.

The result of the study, especially factor of recognition is consistent with the suggestion of Harbison and Coleman (1951) that both employer and union need working harmony and labour-management cooperation, an the

idea of Mill (1994), that good labour relations comprised recognition and equal relations between employer and workers. Factor of good communication was also suggested by De Silva (1996) that workers and employers had to make an effective communication without misunderstanding. Factor of data revealing is similar to the suggestion of Morishima (1991) on information sharing between workers and managers but the result showed that both sides need trust between them too. Factor of worker's participation was suggested by Inoue (1991) on union's participation in the process of decision making of the organization, De Silva (1998) also stressed on the factors of sound labour relations of worker participation and employee involvement.

The result of the study also go along with the researches of Chokechai Suttawet , (2002) that employer has to recognize the trade union, create good communication and introduce mutual decision and workers' participation and Sangsit Piriyaangsant (1997) that employers need to give enough information for consultation, open communication and create cooperation. .

Conclusion.

In conclusion, sound labour relations in Thailand can be created by the cooperation among employer, workers, trade unions and the government. For such a purpose, the 5 characteristics that enhance sound labour relations at the workplace level include recognition between employer and workers, good communication, trust, data revealing and workers' participation, should be enhanced. Having been created, sound labour relations will give benefit to all parties concerned even the government. However, it should be done under the proper legislation, appropriate culture and with the strong support of the government.

Real Option Value Effects Of Cross-Border Acquisitions By U.S. Multinational Enterprises

*Dong-Kyoon Kim, kimd@mail.montclair.edu
Montclair State University*

Abstract

This study identifies two real option motivations for foreign direct investment (FDI): Market-related growth options and flexibility options. This study further posits that the real option benefits are better realized by service multinational enterprises (MNEs), which are operationally less encumbered by hysteresis than manufacturing MNEs, and that flexibility option benefits are scant among soft service MNEs but better utilized by hard service MNEs than manufacturers. Our sample of 235 cross-border acquisitions announced by U.S. MNEs during 1999 and 2000 support the predictions. Flexibility options have a positive effect on shareholder value especially for the hard service acquirers, which are less subject to the muting effects of hysteresis. Market-related growth options seem to increase shareholder wealth for manufacturing and soft-service MNEs but the value impacts disappear in the total sample regression, probably because the 'liability of foreignness' offsets the growth option benefits.

KEYWORDS: Foreign direct investment (FDI), multinational enterprise (MNE), real option, growth or platform, flexibility or switching option, hysteresis

Introduction

The theory of internationalization holds that firms expand operations internationally to exploit labor, factor, product and financial market imperfections or to internalize markets for proprietary assets (e.g., Buckley and Casson 1976; Dunning 1973, 1980; Lee 2010). This thread of study suggests that expanding internationally has a positive impact on firm performance and value, particularly when the firm has a portfolio of proprietary assets.

Agency theory posits that the motivation for Foreign Direct Investment (FDI) is driven by management self interest, even at the expense of shareholder value. For example, Jensen (1986) contends that managers are motivated to develop large, complex international organizations because in doing so power and prestige are given to them. Management also can benefit from multinational organization by reducing its personal portfolio exposure through asset diversification. Management can reduce the volatility and risk of the firm's stock price by diversifying cash flows across business segments and/or markets (Amihud and Lev 1981; Kim 2004).

Real options theory posits that multinational enterprises (MNEs) can increase shareholder value in exploration and flexibility opportunities (Amram and Kulatilaka 1999; Brabazon 1999). In particular, growth options capture the uncertainty of platform investments, which can serve as distribution platforms from which subsequent products can be introduced into the new market, knowledge platforms through which the MNE can acquire product, technology or market-specific information and knowledge, or market development platforms from which the MNE can expand across product lines in developing country presence, brand equity and political leverage. Flexibility option hypothesis posits that a MNE with a strategic network of global operations will achieve excess profits as the firm shifts production from country to country in the face of labor, factor and financial market interruptions and significant systematic changes in currency exchange rates or tax rates.

The literature regarding the value effects of real options in cross-border investments is narrow in scope and fragmented, calling for more comprehensive work. This study contributes to the literature by developing a framework for evaluating the potential platform growth and switching flexibility benefits for U.S. MNEs and comparing the value effects among manufacturing, hard service and soft service MNEs. We posit that the real option benefits are better realized by service MNEs, which are less operationally encumbered by hysteresis than manufacturers, and that flexibility option benefits are scant among soft service MNEs but better utilized by hard service MNEs than manufacturers.

For 235 cross-border acquisitions announced by U.S. MNEs during 1999 and 2000, we found that the regression results are consistent with the predictions. Flexibility options have a positive effect on shareholder value especially for the hard service acquirers, which are less subject to the muting effects of hysteresis. Market-related growth options seem to increase shareholder wealth for manufacturing and soft-service MNEs but the value impacts disappear in the total sample regression, probably because the 'liability of foreignness' offsets the real option benefits.

In the next section, the theories of internationalization, real options, multinational network and hysteresis are reviewed, and testable hypotheses are developed. Data and research methods are presented in the third section. The test results are presented in section four, and section five concludes this study.

Theories and Hypotheses

Real Options Theory

Myers (1977) noted that the principles of Black and Scholes' (1973) financial option pricing theory could be applied to non-financial or real assets, and the term "real options" was originated. Certain business decisions are similar to a financial call option, which gives the option holder the right to buy the asset at a certain price within a time period. For example, if the company begins an uncertain research and development (R&D) project, the firm has in effect purchased an option. At different stages in the future development of the project, the firm's managers will be able to respond to incremental results of the project. They will have the option to continue, abandon, scale up or scale down the project. The value of these options is not included in typical capital budgeting decision processes.

Options value in FDIs takes on two major forms, among others (Amram and Kulatilaka 1999; Brabazon 1999). First, growth options often take the form of platform options when an investment can be increased if favorable information or conditions occur (Kogut and Kulatilaka 1994b). The growth option is particularly valuable for proprietary asset firms like hotel and restaurant chains and pharmaceutical manufacturers with protected products and processes.

Secondly, switching or flexibility options exist when an MNE can switch production from one geographic location to another in responding to foreign exchange rate changes, labor price changes or disruptions, material price changes or disruptions, changes in government regulations, or financial market changes (Kogut and Kulatilaka 1994a; Trigeorgis 1998).

Multinational Network: Value and Cost

Kogut and Kulatilaka (1994a) argued that the across-country growth option has value because it provides operating flexibility to management. The value is in the network through which management can coordinate flexibly multinational activities and can respond profitably to the realization of unexpected events. Kogut (1985) argued that multinational networks can effectively serve to match buyers and sellers in product markets. Secondly, MNEs are able to disseminate process and product technology from one location to another. Thirdly, government regulations often create financial incentives for corporations to produce in and export from their home countries. The MNE is positioned to consolidate export activities in the host country that provides the greatest export incentives. Similarly, host governments provide tax relief and loan guarantees which the MNE can arbitrage within its network through transfer pricing, remittance policy and parallel loans (Kogut 1985). Because of this financial flexibility, the MNE is able to transfer low-cost loans that are intended for local markets throughout the world. The fourth benefit is the physical shifting of production in response to price differentials. The multinational network allows MNEs to shift production in response to exogenous shocks like exchange rate changes, natural disasters, labor strikes and government actions (Belderbos and Zou 2007). It also allows the MNE to manage factor and labor prices in the short term through bargaining power (Kogut 1983). Kogut (1985) contended that the MNE network also creates leverage with regard to managing political risk because of dispersed international operations and global economic power.

Kogut (1983) viewed the initial costs of establishing a multinational network as sunk costs. The relevant sequential costs include the direct costs associated with maintaining excess capacity, the indirect costs incurred with

loss of economies of scale, and the direct and indirect costs attributed to network management, coordination, and information asymmetry within the MNE. In certain industries, the loss in economies of scale or the cost of maintaining excess capacity might be sufficiently high to offset the benefits of operating flexibly through the multinational network. Kogut and Kulatilaka (1994a) also identified switching costs as a deterrent to production flexibility.

Manufacturing vs. Service MNEs

Zeithaml, Parasuraman and Berry (1985) summarized the extensive literature that establishes differentiation between service and manufactured products on the basis of four, unique macro-product characteristics: Perishability, intangibility, inseparability, and heterogeneity (Table 1). Along these characteristic dimensions, a number of researchers have developed classification schemes to categorize manufactured and service goods when considering international market entry (Boddewyn, Halbrich and Perry 1986; Contractor, Kundu and Hsu 2003; Erramilli 1991; Javalgi, Griffith and White 2003).

TABLE 1. PRODUCT CHARACTERISTICS BY PROVIDER TYPE

	Manufacturer	Hard Service	Soft Service
Perishable	No	No	Yes
Intangible	No	Yes	Yes
Inseparable	No	No	Yes
Heterogeneous	No	No	Yes
Growth option	Yes	Yes	Yes
Flexibility option	Yes	Yes	No

Erramilli (1991) segregated internationally traded services into two groups: Hard and soft services. A *hard service* has a manufactured component and a service component. It is separable in terms of production and consumption. That is, the service can be manufactured in a location separate from the consumers and thus can be exported across geographical boundaries. Hard services are similar to manufactured products with the exception that hard services are intangible products. Examples include musical CDs, life insurance, and software. The hard service provider can internationalize through export, licensing, franchising or FDI. Similar to a manufacturing MNE, the sources for the hard service provider's motivation for internationalization may be expanding into new markets, shifting production in low-cost locations, following domestic customers into foreign markets, or developing geographically dispersed operating nodes to facilitate an internationally coordinated strategy.

Both growth and switching options are available to many hard service providers. The hard service MNE can realize platform growth option value by entering a new market with sales of a proprietary service. Also, the hard service provider can develop strategically located production facilities around the globe, creating a multinational production network with switching option value. As long as there is volatility and uncertainty with regard to factor and labor prices, exchange rates, government regulations and taxes, the multinational production network has switching option value.

By comparison, *soft services* are not separable (e.g., lodging and food services, and project management). Production and consumption are spontaneous. The consumer must be in close proximity of the service provider for consumption (Erramilli and Rao 1990). The soft service provider can internationalize through FDI, IJV, licensing and franchise, but not through export. Soft service providers are relatively limited in their ability to obtain real options through international expansion because production and consumption are concurrent. The soft service MNE's real option potential is limited to acquiring platform (growth) options through exploiting new markets with Hymer (1960)-like assets. For this investment to have growth option value there must be an advantage for early investment (Kogut and Kulatilaka 1994b).

Even though a soft service MNE may have a physical presence in numerous countries, it does not have a multinational network that allows it to operate flexibly in the face of uncertainty. It merely has enjoyed growth through expansion into new geographical markets; this does not provide it with a multinational network advantage or sustainable flexibility option value (Kogut 1983).

Market-Related Growth Option

Many cross-border acquisitions by MNEs are motivated by the geographical market in which the target firm is located or has operations. The MNE is potentially acquiring both growth and flexibility options with an investment into a foreign market in which it has no presence. Through cross-border acquisitions, the MNE is able to acquire a growth platform from which the MNE can learn about the target country's markets, and can develop and distribute subsequent products. Flexibility options are also acquired in certain cross-border acquisitions. The dispersed global locations allow the MNE to arbitrage between country price differentials in labor, factor and financial markets. To the degree a cross-border acquisition adds to the growth platform or flexibility of the multinational network, the acquisition carries real option value.

H₁: When *market-related growth* options are acquired, shareholder wealth changes around the announcements of cross-border acquisitions will be greater for *service* MNEs than for *manufacturing* MNEs, *cet. par.*

Hysteresis

The primary value of operating flexibly depends on the MNE's ability and costs to switch production among locations within its network. Switching is often costly due to shut-down costs, start-up costs, labor and material contracting and managerial efforts. Hence, the firm must compare the present value of the switching costs to the present value benefits, and may determine that the costs outweigh the benefits and therefore decide not to switch production. This inaction is called a condition of *hysteresis*. Dixit (1989) defines hysteresis as "the failure of an effect to reverse itself as its underlying cause is reversed. For example, the foreign firms that entered the U.S. market when the dollar appreciated did not exit when the dollar fell back to its original levels" (p.622). Dixit (1989) contended that if there were no sunk costs, there would be no hysteresis. Conversely, the greater the investment (i.e., sunk cost) in an operation or location, the greater the hysteresis or wider the band of inaction is. When tangible and intangible assets are not used, some assets "disintegrate quite rapidly and must be rebuilt should it decide to reenter" (Dixit 1989: p.621). The business loses its going concern value and market position when it mothballs its operations.

MNEs will be reluctant to switch operations if factor prices or exchange rates revert quickly (Kogut and Kulatilaka 1994a; Christophe 1997). Similarly, the greater the switching costs, the less likely the firm will switch production locations. Switching costs include the costs of mothballing current operations, startup costs at new locations, higher inventory and working capital costs, and the loss of economies of scale. If switching costs are excessively high, the MNE will not operate flexibly by switching production among geographic locations, and there will be no switching option value to its multinational network (Baldwin 1988; Belderbos and Zou 2009).

Flexibility Option

Not all MNEs are able to exploit the flexibility option equally. For some MNEs, the ability to switch operations between countries is limited by labor supply or utility contracts. For other MNEs, the ability to shift may be inhibited by the start-up and shut-down costs of the operation. The width of the hysteresis band is determined by sunk costs, switching costs and cost advantage duration (Kogut and Kulatilaka 1994a).

For manufacturing firms, switching costs include the direct costs of mothballing the physical operations in the current location plus start up costs for operations in the next location (Dixit 1989). The indirect costs include depreciation of the physical assets and loss of going concern benefits (e.g., distribution system, trained labor, and brand recognition). When a firm switches production from one location to another, it must also determine the direct and indirect costs of switching back to the current location weighted by the probability that such occurrence would occur. The present value of these costs is compared to the estimated present value benefit of switching between locations. The benefit is determined by the cost advantage, the value of which is a function of duration. In sum, while the flexibility provided by a multinational production network appears to be advantageous to the

manufacturing MNE, utilization of the network is practically difficult because of sticky labor and material input markets, and high sunk and switching costs.

By contrast, service MNEs' assets are predominately intangible and can be easily moved from location to location. Service MNEs have limited physical assets, and they rely extensively upon relatively mobile labor as the input variable. Thus, the service MNE has a more fluid and responsive operating network than manufacturing MNEs. For the service provider, the relevant shutdown and startup costs are comparatively low, and the switch in production from one location to another is relatively quick. The corresponding benefit as measured by cost advantage duration can correspondingly be low for the service provider to realize net total benefit in switching operations. For these reasons, flexibility real option value in cross-border acquisitions tend to be greater for service MNEs.

H₂: When *flexibility* options are acquired, shareholder wealth changes around the announcements of cross-border acquisitions will be greater for *hard service* MNEs than for *manufacturing* MNEs, *cet. par.*

Data and Methodology

The base sample of the U.S. acquirers of foreign firms is generated from the Securities Data Corporation (SDC) Platinum database. SDC collects data from publicly available information sources, including SEC filings, news and wire sources, and trade publications. The acquisition data from 1999 and 2000 are chosen to generate a manageable, in-depth study sample. The initial SDC list of publicly traded U.S. corporate acquisitions of foreign firms during the sample period includes 743 transactions.

To clean the SDC data, private acquisition groups and private U.S. companies are eliminated. Also eliminated are the transactions for which press releases in Lexis-Nexis or acquirers' stock ticker symbols via EDGAR Online are absent. Third, the accuracy of acquisition announcement dates is verified. Anand and Khanna (2000) found that SDC data on the date of alliance events are often misstated. Also, to isolate the acquisition event's potential value effect, firms with concurrent major corporate events like stock repurchase, securities offerings and other acquisitions/alliance investments for three days prior to the announcement are excluded.

The final sample consists of 235 acquisition announcements made by 126 manufacturer MNEs (SIC codes 1000-3999) and 109 service MNEs (4000-8999). This primary classification of manufacturer MNEs includes basic manufacturer (n=34), electronics and instruments manufacturer (n=41), consumer products manufacturer (n=15), and computer and peripheral equipment manufacturers (n=27). The primary service MNE classification includes 70 hard service and 39 soft service firms. Hard service in this study includes banks, insurance, advertising agencies, engineering services, and computer programming. Soft service firms include transportation, communication, and security services.

Then, Lexis-Nexis announcements and SEC filings are examined to determine the exclusive option character of each acquisition. If the acquisition is motivated by the target's proprietary technology, product, brand, operations or distribution, the acquisition is characterized as having exclusive option benefits. Also, each transaction is examined to determine if the acquisition is in a new country or first time entry into a new industry or product category.

From the Center for Research in Security Prices (CRSP) database, stock returns for 250 trading days around announcement are obtained. Standard event study is employed to compute the abnormal returns with the estimation period of day -250 to -50, and the CRSP value-weighted index returns.

Variables and Research Methods

Growth and flexibility options are generally unobservable within the context of cross-border acquisitions. Therefore, a number of variables are used to measure the latent option effects. In this paper, two variables are introduced to measure the option effects: MARKET and NEWCURR. If an MNE acquires a target firm in the location where the acquirer already has an operating presence, the acquisition should add little growth or platform value to the multinational network (Doukas and Travlos 1988). New markets, therefore, have the potential to carry growth

and/or flexibility options. MARKET takes a value of one if the target firm is located in a country in which the MNE acquirer does not already have a presence and zero otherwise. NEWCURRE is a measure to capture the acquisition of a flexibility option and takes the value of 1 if the target country currency is different from U.S. dollar and 0 otherwise.

NETWORK measures the value effects of the acquirer MNE's existing multinational network. The variable is the log of 1 plus the number of foreign countries in which the acquirer has subsidiaries. Following JV studies by Hennart (1991) and Baek (1999), DEALSIZE is the acquisition price in \$US over the acquiring firm's total assets in the acquisition fiscal year. Following Markides and Ittner (1994) and Morck and Yeung (1992), we assign 1 to CASH when the acquisition is an all-cash transaction and zero otherwise. Like Markides and Ittner (1994), log of sales is used to control for firm size (SALES). Doukas and Travlos (1988) found that there is positive relationship between acquisition in an undeveloped country and shareholder wealth effects. ECONDEV denotes the host country's level of economic development and is measured as the target country's per capita GDP divided by the U.S. one for the calendar year prior to the acquisition. HARDSERV and SOFTSERV indicate that a firm belongs to hard and soft service industries, respectively. Table 2 shows the correlation among the variables. The coefficients do not show signs of severe collinearity for this sample.

AR_i = Announcement date abnormal return for the ith acquirer's common stock; MARKET_i = 1 if the ith acquisition is a first time investment in the host country by the acquiring firm, 0 if the acquirer already has an investment in host country; NEWCURRE_i = 1 if the ith acquisition is a first time investment in new currency, 0 otherwise; NETWORK_i = log (1 + number of foreign countries in which the ith acquirer has subsidiaries); DEALSIZE_i = Acquisition price in US\$ over the acquirer's total assets for the most recent fiscal year; CASH_i = 1 for cash payment of ith transaction, 0 otherwise (Stock and mixed payment); SALES_i = log of net sales of the ith acquirer; ECONDEV_i = (100* target country per capita GDP / U.S. per capita GDP for most recent calendar year of ith transaction); HARDSERV_i = 1 if the ith acquirer is a hard service MNE, 0 otherwise; SoftSERV_i = 1 if the ith acquirer is a soft service MNE, 0 otherwise.

To determine the variations in the ARs, the following cross sectional regression analysis is used for each of manufacturing, hard service and soft service subgroups:

$$AR = a_0 + b_1*MARKET + b_2*NEWCURR + b_3*NETWORK + b_4*DEALSIZE + b_5*CASH + b_6*SALES + b_7*ECONDEV + e$$

Another regression analysis for the total sample includes the industry dummy variables (HARDSERV and SOFTSERV) and their interaction variables with MARKET and NEWCURR.

TABLE 3. DESCRIPTIVE STATISTICS

	N	Min.	Median	Max.	Mean	Std Dev
AR _i	235	-0.258	0.001	0.479	0.013	0.070

ECONDEV	235	1.296	65.683	116.210	63.073	20.388
HARDSERV	235	0	0	1	0.298	0.458
SOFTSERV	235	0	0	1	0.166	0.373

AR_i = Announcement date abnormal return for the ith acquirer's common stock; MARKET_i = 1 if the ith acquisition is a first time investment in the host country by the acquiring firm, 0 if the acquirer already has an investment in host country; NEWCURR_i = 1 if the ith acquisition is a first time investment in new currency, 0 otherwise; NETWORK_i = log (1 + number of foreign countries in which the ith acquirer has subsidiaries); DEALSIZE_i = Acquisition price in US\$ over the acquirer's total assets for the most recent fiscal year; CASH_i = 1 for cash payment of ith transaction, 0 otherwise (Stock and mixed payment); SALES_i = log of net sales of the ith acquirer; ECONDEV_i = (100* target country per capita GDP / U.S. per capita GDP for most recent calendar year of ith transaction); HARDSERV_i = 1 if the ith acquirer is a hard service MNE, 0 otherwise; SOFTSERV_i = 1 if the ith acquirer is a soft service MNE, 0 otherwise.

Empirical Results

Table 3 presents the descriptive statistics of the variables. 39.6 percent of the acquirers entered a new country (MARKET) and 37.4 percent made acquisitions in a country whose currency is not U.S. dollars (NEWCURR). 46 percent of the acquirers are service companies. The range of ARs on the announcement date was -25.8 to 47.9 percent with average ARs of 1.3%, 1.7% and 2.6% being significantly positive for whole, hard service and soft service groups, respectively. Both hard service and soft service firms show an average AR statistically higher than that of manufacturing MNEs (not shown in Tables). The range of sales for all acquirers varies from zero to \$162 billion, with an average of \$5.0 billion. The number of foreign country subsidiaries range from 1 to 171 with an average number of about 15, and about 55 percent of acquisitions were cash transactions. The transaction price ranges from \$300,000 to \$7.66 billion with an average of \$273 million.

Table 4 presents the results from the regression analyses. In the first regression for the sample of manufacturing MNEs, MARKET growth option variable is positive and statistically significant but NEWCURR is insignificant. Control variables including NETWORK have the predicted signs but statistically insignificant.

The second column shows the results of the regression for the hard service MNE sub-sample. The coefficient for MARKET growth option variable is insignificant but that of NEWCURR flexibility option variable is statistically and economically significant. Both NETWORK and DEALSIZE have significantly positive coefficients.

In the third column for the soft service sub-sample, MARKET growth option variable has a significant positive coefficient (.056**) as predicted, and supports H₁. NEWCURR variable has a significant negative sign. Given that soft service firms cannot utilize switching options, added risks in operating in a different foreign currency seem to be the reason for the negative wealth effect. NETWORK variable is insignificant for the soft service sample due to the limited value of such firms' multinational network. Other control variables are insignificant except that DEALSIZE has a positive effect on shareholder wealth changes.

In the last regression model for the total sample, indicator variables HARDSERV and SOFTSERV, and their interactions with MARKET growth option and NEWCURR flexibility option variables are added. MARKET or NEWCURR *per se* is not a significant variable, but the coefficients for NETWORK and DEALSIZE are significant positive as predicted. The coefficient (.073***) for HARDSERV times NEWCURR interaction variable is positive and significant, statistically and economically. It supports H₂ and indicates the multinational flexibility option is most valuable for hard service MNEs, which are less subject to the hysteresis.

White heteroskedasticity-adjusted standard errors are in parenthesis. *, ** and *** denote statistical significance at 10%, 5% and 1% levels, respectively. AR_i = Announcement date abnormal return for the ith acquirer's common stock; MARKET_i = 1 if the ith acquisition is a first time investment in the host country by the acquiring firm, 0 if the acquirer already has an investment in host country; NEWCURR_i = 1 if the ith acquisition is a first time investment in new currency, 0 otherwise; NETWORK_i = log (1 + number of foreign countries in which the ith acquirer has subsidiaries); DEALSIZE_i = Acquisition price in US\$ over the acquirer's total assets for the most recent fiscal year; CASH_i = 1 for cash payment of ith transaction, 0 otherwise (Stock and mixed payment); SALES_i = log of net sales of the ith acquirer; ECONDEV_i = (100* target country per capita GDP / U.S. per capita GDP for most recent calendar year of ith transaction); HARDSERV_i = 1 if the ith acquirer is a hard service MNE, 0 otherwise; SOFTSERV_i = 1 if the ith acquirer is a soft service MNE, 0 otherwise.

Conclusions and Discussions

The purpose of this study is to investigate the shareholder value effects of growth and flexibility real options around cross-border acquisition announcements by 235 U.S. MNEs. The value effects of market-based growth option and currency-based flexibility option are operationalized by manufacturer/service differentiation. This study finds the significantly positive shareholder wealth changes around the foreign acquisition announcements for the whole and service MNE samples. ARs are positively related to the extent of the multinational network; the results are statistically significant for hard service MNEs and the full sample.

The relationship between shareholder wealth creation and the presence of real options is mixed. First, for growth options represented by new market platform, the relationship is positive and statistically significant for manufacturing and soft service MNEs. In the regression for the total sample, neither MARKET *per se* nor its interaction with HARDSERV or SOFTSERV is significant. In particular, there is a non-negative relationship between shareholder wealth changes and the presence of market-related growth options at the announcement of cross-border acquisitions especially for soft service MNEs. So, Hypothesis 1 is fairly supported by the data.

Nonetheless, the results are consistent with Kogut and Kulatilaka's (1994a) position that growth or platform options are available to both MNEs and purely domestic firms and that growth options have no unique value to the MNE. The results are also consistent with agency theory that posits that the cost of managing in foreign countries and cultures is high and that management makes cross-border investments to diversify their personal asset holdings which are concentrated in the firm's common stock.

Secondly, flexibility options represented by a new currency have a predicted positive effect on shareholder value for the hard service firms, which are less subject to the muting effects of hysteresis. H₂ is also supported by the data. It is noteworthy that soft service firms are heavily constrained to utilize flexible switching options and investment in a country that uses a currency new to a soft service MNE means additional risk rather than an expropriation opportunity; hence, liability of foreignness offsets the real option benefits for soft service MNEs.

This study examines the real option value effects of cross border acquisitions by US MNEs, and the results are quite consistent with the predictions, particularly for hard service MNEs. This study, however, is not free from further improvements. Because the time period for this study's data covers 1999 and 2000, the return data may be inflated, which would be consistent with the "dot com bubble." This may be particularly true for the service MNE data which have many technology related acquisitions embedded within the dataset. Conducting the study during a less robust equity market time period would address the potential service return bias from the sample period.

Finally, studying the effects of cross-border investments from a real option vantage might be well served through case study analysis. An in-depth, longitudinal study of particular transactions might stimulate research that uses real options in what Tong, Reuer and Peng (2005) described as "more bounded ways."

The Internationalization of Religious Organizations: Expansion Strategies in Africa

Bernard Korai, bernard.korai@fsa.ulaval.ca
André Richelieu, andre.richelieu@fsa.ulaval.ca
Laval University, Québec, Canada

Abstract

"Religion has to be marketed." These words from sociologist Berger (1967, p.137) justify the growing interest in marketing at the heart of religious activity. In recent years, many studies have been conducted in order to understand its different implications and research topics. Religion remains a large research area to explore, simply because the studies that have been conducted are mostly applications of marketing mix to the religious "offer", and are often limited to a geographically restricted framework (Abreu, 2006; Lee, 2010). In the context of globalization, it is surprising that the internationalization of religious organizations remains an uncovered subject because religions have a biblical mission to be international (Holy Bible, Mark 16v.15). In recent decades, Western evangelist Christian communities in West Africa have flourished. In this paper, we will focus on the phenomenon of the internationalization of religious organizations in an effort to understand the preferred expansion modes in Africa.

Introduction

In this millennium of great social turbulence, the intensification of religious conflicts (Chechnya: Muslims and Orthodox; Middle East: Jews and Muslims; Ireland: Protestants and Catholics; Iraq: Coptic Christians and Muslims; Nigeria: Christian and Muslims; Tibet: Buddhists and Atheists) shakes the whole of humanity and makes the study of religion current and extremely relevant for research in social sciences. The importance of religion in modern societies is not only social, but also political (the impact of the evangelist lobby in the re-election of President George W. Bush in the USA) and commercial. Regarding the commercial sphere, recent statistics released at the World Halal Forum (2009) indicate that the European market for Halal consumption is estimated at over \$67 billion and is growing at an annual rate of 15%. Moreover, the U.S. Office of Travel and Tourism Industries estimated that more than one million religious trips outside of the United States were taken in 2008.

For some sociologists, these figures are not surprising. Religion has always been an ideological ferment that enables individuals to acquire the ability to accept adversity and give meaning to their lives (Du Pasquier, 1988). With over two billion followers around the world, Christianity (and its denominations) is emerging as the most practiced religion in the world, above Islam (about 1.5 billion followers) and Hinduism (approximately 1 billion followers) (Atlas of Globality Christianity, 2010; Chellini-Pont, 2005; Mongin, 2007). However, these numbers seem to hide a quite disturbing reality. Indeed, many studies in the religious world in recent years show a sharp decline of Christianity in modern societies. In 2000, Christians (all denominations) represented only 23% of the world's population compared to 1980 when they accounted for 33% (Thual, 2003).

The decline of Christianity can be explained by several factors, the most relevant are the rise of other religions such as Islam and the decline of religious practice, especially in Western societies. A survey by IFOP (2009) revealed that the percentage of French who say they go to mass every Sunday dropped from 27% in 1952 to 4.5% today. A study conducted in 2005 by Wolfe, demonstrated that two-thirds of Americans are unable to recite half of the ten biblical commandments.

For scholars interested in religious change in contemporary societies, the decline of faith must be understood from apostmodern perspective. In their view, advances in technology, rising standards of living, and the development of liberalism and individualism have encouraged the emergence of an era "*indifferent to the Gods and*

Prophets" (Weber, 1959, p.92) and characterized by a progressive "disenchantment" with the world. This idea is reflected in the words of theologian Pierre Gendron (2006, p.X, preface) in his thoughts on the relationship between religion and modernity: "God is dead and disappearing with him the sacred, religious rituals and ecclesiastical institutions."

Stark and Finke (2005) largely contradict the argument that Christianity is in decline worldwide. According to the findings of their study, there is a real resurgence of Christian spirituality throughout the world due largely to the emergence of new trends such as charismatic evangelicals (Protestant, Pentecostal, Methodist, etc.). For Stark and Finke, the decline of Christianity is really a decline of Catholicism; a religion struggling because of its inadequacy in meeting the spiritual needs of a modern society in search of meaning, depth and experiential relationships with the divine (Hervieu-Léger Cited in Caulier, 1996). At the same time, evangelical movements are experiencing an increase in members worldwide—over 20% of the population of Caribbean and Central America (Ruano-Borbalan, 2001).

In the United States, the number of evangelicals increased from 41% in 1906 to 70% in 2007 (over one-third of the total population) (Schwindt, 2007). In South Korea, they accounted for 20% of the population in 2006. In China, the number of Protestants (one of the evangelical denominations) was estimated at over 70 million for the same period. The rise of evangelical movements is so rapid in the evolution of modern Christianity that in 2005, the journal *Hérodote* devoted an entire section to it, entitled "Evangelicals to storm the world."

According to several scholars, the success of evangelical movements is explained by two main factors: their ability to offer a different religious experience and their ability to build strategies for international expansion that meet the challenges of globalization. During the last decade, Western evangelical religious organizations have strongly internationalized and are regarded as new symbols of globalization, just like Coca-Cola and McDonald's (Fath, 2006). A prospective analysis conducted by Chellini-Pont (2005) indicated that the new centre of gravity of this massive internationalization is now in the Third World and emerging countries, particularly in sub-Saharan Africa where today one in two Africans are Christian compared to one in ten in 1900. In a recent study, Dorier-Aprill and Ziavoula (2005) stated that the number of places of worship for Protestants in sub-Saharan Africa increased from 12,000 in 1988 to 25,000 in 1999.

Despite this increasing phenomenon and although it is very relevant to the fields of marketing and consumer behaviour, it must be noted that no in-depth study has been conducted on the topic yet. Moreover, if the literature on internationalization is one of the most abundant in marketing, it was mainly addressed from a commercial perspective (Hollensen, 2010). In recent decades, there has been a rise of non-profit organizations (particularly religious organizations), which in the exercise of their mission through the world seem to follow a similar internationalization procedure like profit organizations. By focusing on the case of Western evangelical religious organizations, we would like to see how the internationalization process for both profit and non-profit organizations is similar and to what extent we can conceive an internationalization framework which is specific to a non-profit context.

Regarding the religious organizations expansion that we study, the only reflections to our knowledge on this topic have been made by sociologists Geoffroy and Vaillancourt (2004) who have devoted a special issue on "Religion and Globalization" in the *International Journal of Politics, Culture and Society*. This study is a continuation of the reflections of these authors and strives to understand what are the preferred expansion modes and strategies of Western evangelical Christian communities into Africa.

With particular attention to the case of Côte d'Ivoire (a French-speaking country in West Africa), we will investigate the following research questions:

- What are the key factors that motivate the choice of Côte d'Ivoire as a missionary field in West Africa for Western evangelical communities?
- What are the different stages of the internationalization process and the different actions at each stage?
- What are the main limiting factors of the internationalization process?
- What are the marketing efforts undertaken to successfully implement a religious organization on the local ground?

Literature review

Who are the evangelists?

Currently, there is no precise definition of what constitutes the evangelical movement. The difficulty in defining the concept of "Christian evangelists" is mainly due to the extreme heterogeneity of practices, doctrines and styles that characterize each of the entities belonging to this religious charismatic family (Baptists, Methodists, Congregationalists, Pentecostals, Assemblies of God, Fundamentalists, etc.).

Despite some small differences, evangelical movements are all characterized by a set of traits that are summarized by the comments of Dorier-Apprill and Ziavoula (2005, pp.131-132):

They advocate a return to the biblical writings as a referent and the simplicity of the original Gospel, which passes through liberation from clerical institutions deemed unnecessary and formal (...) They value change of heart, spiritual experience in a strong affective charge (the public expression of personal conversion are important) (...) The doctrine is based on the belief that early return of Christ, but especially on the importance of "awakening" or "Holy Spirit's baptism" that is experienced by some charisma (gifts): miracles, the "speaking in tongues," healings, intercessions and visions.

According to some genealogical studies, these evangelical movements originate primarily in the United States and Great Britain, although they are now concentrating in new areas such as Asia and Africa, in the early 21st century in a context marked by a paradigmatic dissent against the religious practices of Catholicism. While the Catholic Church is based on a set of rigid and institutionalized liturgical structures, the evangelical movements advocate for a "de-institutionalization" of the belief in God that results in the possibility for the faithful to be the main actor of its religious identity in the context of intimate relationship with God (Hervieu-Léger, 2001).

Referring to many religious theorists, the evangelical movement's great success can be attributed in large part to the fact that it offers a new spiritual experience, rich in meaning, fulfillment, and happiness and that provides some answers to people's confusions and spiritual quests (Jaffrain, 2009). This way of rethinking the relationship of individuals to spirituality fits perfectly into a logic of experiential consumption where the faithful finds a new religious meaning in order to live a self-transformational experience with Jesus Christ (Camus and Poulain, 2008, Holbrook, 1999). Evangelical services are celebrated with exuberant musical performances and emphasize emotion in the Christian faith experience, unlike the silent and monotonous Catholic masses. This strategic differentiation seems to be the crux of the promise they offer to potential followers in the competitive environment of religious consumption (Abreu, 2006; Lee, 2010). The words of Cardinal Walter Kasper (cited in Kuzmanet al., 2009, p.5), senior adviser to the Pope and head of Vatican's council for promoting Christian unity around the world, confirm this competitive tension: "*We (Catholics) must not ask what is wrong with Pentecostals (or Evangelists) to ask what our pastoral failings are and come to a spiritual renewal*".

Africa: Destination for Western evangelical religious organizations

The recent remarks of Pope Benedict XVI from the book *Light of the World: The Pope, The Church and the Signs of Times* (Seewald, 2010) are sufficient to express the dynamism with which the evangelical phenomenon is spreading, particularly in Third World countries. Chellini-Pont (2005) confirmed this trend when she said that the centre of gravity of world Christianity by 2050 would no longer be Geneva, Rome, Paris or New York, but Kinshasa, Buenos Aires, Addis Ababa and Manila.

According to the Pope, "*(...) in Third World regions where there were 90% of Catholics, or even more, their share fell to 60%*" (p.154) because of the massive expansion strategies implemented by the evangelical communities. If we analyze the geographic development, we realize evangelical communities are heavily concentrated in Africa where social, political and economic conditions are very favourable to growth.

For Hellis and Harr (2004), evangelical movements thrive in Africa firstly, because religion is the most important way for Africans to keep interacting with the world. Secondly, because the evangelical churches have built their "offer" on their ability to solve the existential problems of individuals (through conversion, miracles and

exorcisms) struggling with poverty, unemployment, disease, wars and disappointments of democracy (Mayrargue, 2004). In recent years, many evangelical communities were responsible for building schools, hospitals, income-generating activities and micro-financing in several African rural areas. For example, the Redeemed Christian Church of God in West Africa has dozens of primary and high schools, a university and health centres where it develops programs for AIDS patients. Evangelical churches thus become "*places of healing and compensation for those who are unsettled by their difficulty in finding a professional or social status*" (Dorier-Apprill and Ziavoula, 2005, p.137).

Methodology

Method

We adopted a constructivist approach from exploratory design, based on the case study method. The choice of this research strategy is justified by Yin (1989, p.23): "*A case study is an empirical inquiry that investigates a contemporary phenomena within its real-life context; when the boundaries between phenomena and context are not clearly evident and in which multiple sources of evidence are used.*" Indeed, the internationalization of evangelical religious organizations is a new phenomenon of study in marketing and consumer behaviour, despite having been addressed in sociology, anthropology and theology. We intend to shed light on how Western evangelical religious organizations plan, implement and manage their expansion projects in Africa. In addition, given the novelty of this research theme, we used a multi-method approach for data collection combining both secondary data (government records) and recorded interviews from leaders of religious organizations.

This study focuses mainly on evangelical religious organizations operating in Côte d'Ivoire. The choice of this country, located in West Africa, responds primarily to some important methodological considerations in the understanding of the phenomenon being studied. First, Côte d'Ivoire is a strategic centre of evangelical development initiatives because of the great religious freedom and evangelical dynamism that exists (more than 4,000 evangelical churches, many evangelical radio stations and bookstores); and second, it represents an intersection from which major Western evangelical organizations can prepare and begin their expansion into other African countries. Côte d'Ivoire has one of the strongest evangelical annual growth rates in Africa at 14.5% (the highest in West Africa) and the highest number of foreign missionaries (about 1100 missionaries from 31 countries) (Coef, 2005). For these reasons, Côte d'Ivoire is a preferential area to study in order to better understand the various procedures of the most significant Western religious organizations in the African evangelical world.

Participants

The study focused on seven active Western evangelical missions in Côte d'Ivoire. This sample size was determined by the desired degree of relevance and validity in our data analysis and methodological requirements related to the chosen research method (case study). Although there is no unanimity, Creswell (1998) recommends a minimum of 4 cases to conduct a case study. In addition, we conducted preliminary studies to ensure the relevance of our sample size. By consulting secondary data archives and meeting with staff of the Ivorian Ministry of Religious Affairs, we identified a set of eleven Western evangelical organizations, which are the largest in terms of awareness, reference and presence, on the Ivorian religious scene. These results were also confirmed on the ground by thirty evangelical Christians of different denominations (Methodists, Baptists, Assemblies of God, and Pentecostal) who were asked to give us the most imposing evangelical organizations on the religious scene in their country.

These various Western religious organizations were contacted for interviews. Ten of them responded positively to our request. Based on interviews with leaders of the first seven largest organizations (comparing our secondary data with the evangelicals Christians interviewed), we noted a redundancy of information from the eighth interview, reflecting a theoretical saturation of data. The seven organizations selected for the study are presented in Table 1.

TABLE 1: SAMPLE CHARACTERISTICS

Organization	Country of Origin	Establishment in Côte d'Ivoire	Contact (Leader)
Baptist Church of Côte d'Ivoire	USA	1975	Rev.Tiécoura
Foursquare International Church of Côte d'Ivoire	USA	1995	Rev. Marius Gnépé
World Assembly for Restoration	USA	2004	Rev.JerômeKakou
International Methodist Church John Wesley	USA	2000	Rev. Aka
The New Alliance Missionary Church of Côte d'Ivoire	South Korea	2005	Rev.Silué
MEGVIE	France	2000	Bishop Kodja/ Rev. Koudou
International Pentecostal Church of Côte d'Ivoire	England	1990	Rev.Kambiré

Data collection

Interviews were conducted during the period of June 15 to July 20, 2010 with leaders of the evangelical organizations identified in the sample. Interviews were conducted at the headquarters of these churches or their leaders' homes and lasted on average 1h30. Interviews were conducted in a semi-directive manner from a structured interview guide composed of four main sections, each corresponding to one research question.

The choice of this data collection technique is justified by the fact that it allows a lot of interaction between the researcher and the informants therefore, leading to a more precise understanding of the phenomenon studied. The questions included in the interview guide were made from an extensive literature review on the expansion of religious organizations. Their relevance was validated by a researcher specialized in international marketing.

As stated by Abreu (2006, p.140), any marketing initiative affecting the religious sphere “*is regarded as manipulative and desacralizing religion.*” Thus, we avoided the use of the term "marketing" and other words that could refer to it. In addition, a copy of the interpretation of data was sent for approval to each religious leader we interviewed. Some quotes have been incorporated into the analysis to better support our interpretations and conclusions (Corden and Sainsbury, 2006).

Main results

During our conversations with the staff of the Ministry of Religious Affairs of Côte d'Ivoire and some leaders of religious organizations, we realized that the evangelical religious landscape in Côte d'Ivoire was characterized by extreme confusion. Many national and international religious organizations claim their membership in the evangelical movement but do not share nor practice its values, ideals and dogmas.

This can be a serious problem for the validity of the study sample. To control this potential bias, we introduced a filter question in the interview guide that invited informants, at the beginning of the interview, to present the overall vision of their religious organization. After analysis, the description given by each of the religious leaders corresponded to the characteristics of evangelical churches as described in the literature by Dorier-Appril and Ziavoula (2005).

The internal validity of our study assured, the first research question we investigated was the identification of factors that motivate organizations to internationalize in West Africa, specifically in Côte d'Ivoire.

Influencing Factors

It is important to mention that the internationalization process is considered mandatory for evangelical organizations. Indeed, according to the religious leaders interviewed, the church's primary mission is to spread the Gospel of Christ to the ends of the Earth (Holy Bible, Mathew 28 v.18-20). The expansion should be directed at people considered weakly penetrated by the Gospel. From this spiritual imperative and comments from the leaders

interviewed, it is possible to identify four main factors behind the choice of Côte d'Ivoire as a missionary settlement area: *structural, strategic, political and competitive*.

Structural factors

The choice of a missionary settlement area meets the requirements of efficiency in achieving the divine mission of the Church. Contrary to what one might think, the internationalization of religious organizations does not arise by chance. The choice of a country is conditioned by several upstream reflections based on an analysis of needs and evangelization priorities. According to Rev. Silué, the choice of Côte d'Ivoire is primarily motivated by the interest of West Africa as a missionary conquest. Unlike other regions of Africa, West Africa has the distinction of being a weak area penetrated by the Gospel, thus representing a challenging missionary region.

For example, for the religious organization led by Rev. Silué, a geographic area is considered a potential field of expansion when it includes countries whose rate of Christianity is below 30%. Côte d'Ivoire has a rate of evangelical Christianity below this threshold. Its selection compared to other countries in the region reflects the fact that although it has a low rate, it still has the highest Christianity rate among the West African countries. The importance of structural factors seems better reflected in the words of Rev. Silué: "*For us, a country in need is a country where the Christianity rate is below 30%, which means that this country cannot self-evangelize. Clearly, Côte d'Ivoire is in a position where it cannot self-evangelize because the number of evangelical Christians is low(...)*."

Strategic factors

In addition to structural factors, the choice of Côte d'Ivoire as a missionary area follows a logic of strategic growth and development of the religious organization in neighbouring countries. Indeed, Côte d'Ivoire occupies a prominent place (more than a third of GDP of all the wealth of West African countries) in the ECOWAS (Economic Community of West African States). It is a model of economic development that attracts people from neighbouring countries.

It is estimated that foreigners, mostly from neighbouring countries, represent over 25% of the population of Côte d'Ivoire. By choosing this country, the religious organization aims to maximize its efficiency in transmitting the Gospel directly to the high proportion of foreign populations living in Côte d'Ivoire, who in turn, once converted, will spread the evangelization in their respective home countries. It is this strategic role of Côte d'Ivoire that the Rev. Kakou emphasizes: "*Côte d'Ivoire is well chosen because all nationalities are represented (...) it is a platform for evangelization. Indeed, when evangelical churches in West Africa want to grow, they come first to Côte d'Ivoire.*"

The choice of Côte d'Ivoire is also motivated by a desire to overcome the many religious barriers to entry for neighbouring countries. The majority of countries in West Africa are mainly Muslim, with Christianity rates approaching 1%. It is therefore difficult to penetrate them directly although they are potential "markets" for the evangelical movement. Hence, Côte d'Ivoire is an attractive alternative to win immigrants of those countries so that when they go back to their homeland, they can facilitate the penetration of the evangelical movement. Rev. Silué effectively corroborates our conclusions on this role of ambassadors people can play: "*When we look at Côte d'Ivoire, the countries from which immigrants come are countries where the rate of Christianity is sometimes less than 1% (Niger, Senegal, Mali, Guinea) and more than 90% of the population is Muslim (...) We believe that God allowed them to come to know the Truth and then return home to continue the missionary work (...) In these nations, work is sometimes impossible, and when you send a missionary, he cannot move easily. So we must think about the strategy of encouraging local people to be missionaries in their homeland.*"

Political factors

Following the comments of various leaders, we were interested to understand why Côte d'Ivoire was a preferred destination compared to other countries in the region such as Nigeria that has interesting potential for international evangelical religious organizations (a large market of non-Christians, a vital crossroads in West Africa and also a popular destination for immigrants from other countries in the region).

The fundamental difference is that unlike Nigeria, which is constantly plagued by religious violence between Christians and Muslims, Côte d'Ivoire is characterized by a peaceful religious climate in which several

denominations co-exist in harmony. It is therefore easier for a religious organization to develop. It is precisely this particularity stressed by Rev. Kambiré: "*All the North of Nigeria is opposed to the Gospel. Therefore, we very often expect conflicts between Christians and Muslims (...) In Côte d'Ivoire we did not find this kind of conflict, which is a good ground for the blossoming of new missionaries.*"

Competitive factors

In recent years, Western evangelical churches have been increasingly faced with the emergence of new evangelical organizations that are the result of purely local initiatives. These are highly concentrated in West Africa, especially in countries such as Nigeria and Ghana where they are very well-established. Mayrague (2004) insisted on this new phenomenon that seems to change more and more the denominational mapping in West Africa.

Evangelization in Africa is beginning to be approached with a polycentric order characterized by several places of production and distribution (from Western countries to African countries but also from African countries to other African countries). Thus, for strategic purposes, Western evangelist churches willing to penetrate West Africa find doing so through Côte d'Ivoire a more fertile and less competitive area. This, in turn, allows the churches to better prepare and increase their awareness for conquering a more competitive religious "market."

Contrary to what one might have thought, cultural factors do not seem to be relevant in choosing the expansion destination of Western evangelical organizations. None of the leaders interviewed mentioned this factor as an important element in the process of internationalization. This lack of cultural importance can be explained in part because of globalization, whose ideals and values began to increasingly invade the religious world (Thual, 2003).

We are witnessing the emergence of a new class of God's servants speaking more and more languages and have been, for the most part, (especially those in our sample) trained in the Western evangelical churches that they are represented in Africa. These servants are at ease with the language of their parent church and their own local language which allows for a certain control of linguistic influence and facilitates relationships between local and Western officials. In our sample, several churches located in Côte d'Ivoire (French-speaking countries) are from the USA. However, they are able to thrive because they are headed by Ivorian pastors who were trained in the USA.

Our first research question helped to highlight the major factors considered in choosing a destination/location. Although the findings are restricted to the case of Côte d'Ivoire, they give insight into the most important factors because the process of internationalization of a religious organization in Côte d'Ivoire is not entirely different from that used to conquer other countries in Africa.

In the collective mind, the expansion of the churches was seen as guided by the Holy Spirit of God. From this first research question, it seems that the process of internationalizing religion is very structured and follows several strategic considerations that are quite similar to those undertaken by profit organizations. Using the same logic, it is now appropriate to ask ourselves about the different steps and activities that constitute the process of evangelical expansion.

Stages of Evangelical Expansion

In these stages, the process of internationalization of Western evangelical churches is very similar to the process used by profit organizations (Hollensen, 2010; a special section, prior to the conclusion, will reflect on how we could apply the internationalization model to the Western evangelical organizations expansion process). Four main stages characterize the process before religious organization implementation: *identification of potential expansion areas or countries, exploration, choice of targetcountry and expansion mode(s)*.

Identification of potential expansion areas or countries

This first step is the most important according to the religious leaders interviewed. Each religious organization develops a denominational mapping which shows a geographic expansion of the Gospel worldwide. From this, areas or countries "in need" are identified. The choice for internationalization is focused on geographic areas or countries with the most important deficiencies in terms of evangelical presence. It is precisely the case with the Foursquare International Church of Rev. Gnépé: "*Internationally, the evangelical churches are more motivated by Western countries that have not yet been touched by the Gospel because the objective is to bring more people to hear the good news of salvation in Jesus Christ.*" Two approaches of identification can be considered: direct and indirect.

The direct approach occurs when the religious organization is in its first international experience or has no religious contact abroad. Expansion areas or countries can also be determined indirectly. This is the case when the Western religious organization has contacts outside their country of origin. From this perspective, the external contacts of the religious organization may inform the latter of the value of their respective countries as a potential area for setting up a mission because of evangelical needs which are expressed.

Exploration

This step consists of assessing the practical needs of the potential expansion countries. It can be done in two ways: by sending missionaries to the target countries or by using local contacts in these countries, reports and "market" studies sent to the parent organization in Western countries. The Foursquare Church of Rev. Gnépé uses this mode of exploration: "*Before the selection of areas or countries, some exploration studies are done. Often there are missionaries who have done studies on which to rely, or simply the parent church (Western religious organization) decides to send new missionaries in the field to assess the concrete needs of each country.*"

Choice of target country

The expansion country of choice is determined by structural, strategic, political and competitive factors. However, according to the religious leaders interviewed, it seems that the political and structural factors are the most important. Strategic and competitive factors will greatly influence the selection process when the church must choose a key country to penetrate, an unexplored (by the Gospel) geographic area. This is the case of Côte d'Ivoire, which is a strategic country for religious organizations to first achieve entry in French-speaking countries of West Africa, and then enter English-speaking countries of the same geographic area.

These strategic factors were taken into account by Foursquare International Church of Rev. Gnépé when it decided to go to Guinea Bissau after Côte d'Ivoire. According to Rev. Gnépé, the choice of Guinea Bissau was motivated by the desire to quickly penetrate the Portuguese-speaking countries in Africa, such as Cape Verde, Angola and Mozambique.

Expansion modes

In the words gathered from religious leaders, two modes of expansion are favoured by Western religious organizations: the direct mode (classic) and the indirect mode. The direct mode consists of personal initiatives of the Western religious organization to establish itself in countries abroad on the basis of identified needs. This is the traditional model used by the first Western organizations that established themselves in Africa. This mode is operationalized by sending Western missionaries directly to the host country. These missionaries are responsible for the initiation of the representation of the Western church. The churches in our sample created between 1960 and 1990 were all established using the traditional model. According to data from the Ministry of Religious Affairs, this 30-year time period effectively corresponds to the beginning of the boom in evangelical movements in Côte d'Ivoire. Increasingly, we see that this traditional approach is modernized by sending national missionaries trained in Western churches. Instead of sending white missionaries as was the case in the early days of the evangelist movement in Côte d'Ivoire, religious organizations frequently send black national missionaries who have lived in the West. This is the case of Rev. Silué who resided in the United States and South Korea. The parent church in South Korea wanted to open a subsidiary in Côte d'Ivoire, and he was chosen to be the parent church representative because he hails from that country, and as such, is aware of everyday realities because of his natural cultural empathy (Hollensen, 2010).

The indirect expansion mode can be done in two ways. In the first case, the Western organization relies on its contacts in the target country and selects a local pastor to undergo its internationalization process. This is the case of Rev. Kakou who was contacted by the parent organization in the USA to open a church in Côte d'Ivoire, for which he would become the representative. In the second case, it may be a local pastor who seeks a Western church for which he wishes to be the representative in his country of origin. In both cases, the partnership between the Western religious organization and the local pastor is made on the basis of similar religious visions advocated by both parties. The type of expansion mode has an influence on the duration of the implementation process.

According to Rev. Gnépé, the internationalization process is faster with the direct approach. Using the indirect approach, the process can take up to five years. This length can be justified by the fact that the religious organization wants to gradually ensure reliability and efficiency of its local partner on the ground. Leaders interviewed were

unanimous that today the indirect approach is most privileged in world of evangelical expansion. The reasons for this are mainly economic and cultural. Indeed, sending missionaries from the West is excessively expensive in terms of maintenance costs. Moreover, these Western missionaries are not accustomed to the cultural realities of the host country (dialects and languages, food, climate adaptation, etc.). These problems lead to some expensive training and adaptation costs and slow the dynamism of evangelization in the country.

For these reasons, Western religious organizations are increasingly opting for the nationalization of missionaries abroad. The words of Rev. Aka justify this new turn in evangelical internationalization: *"There are less and less white Western missionaries. Western missions prefer to take Africans to operate as missionaries at home. They are assisted by a strict evangelical training and are more likely to work better because they know their own realities."*

Although there is a strong presence of flourishing Western evangelical organizations in Africa, it is clear that their impressive growth often occurs in difficult circumstances because of the many limiting factors to which they are exposed throughout the expansion process.

Limiting factors of Western evangelical organizations

The main limiting factors faced by the Western religious organizations studied are of three kinds: political, cultural and human. At the political level, it is essentially the religious barriers to entering some countries. Indeed, the religious organization may feel a great need to locate in a particular country for spreading the Gospel to its people. However, the political and religious measures taken by a country can make access difficult for an evangelical mission.

The informants gave us the example of countries whose constitution is Islamic (e.g. Mauritania, Sudan). When you are known as a missionary, you will automatically be expelled from the territory. For this reason, the Western evangelical missions prefer to expand in secular countries. However, some strategies are employed to overcome these barriers. Rev. Tiécoura gives us an example: *"A religious organization may involve methods of camouflage by sending missionaries in these Islamic countries as professionals (mostly teachers). On this basis, the missionaries are registered for immigration as teachers. And from that status, they could gradually do their missionary work."*

Cultural factors are related to adaptation difficulties experienced by Western missionaries when they are sent to Africa and high maintenance costs attached to them. However, we note that these cultural factors are increasingly controlled by the use of nationals as missionaries in their own country.

The final factor is human resources. In some cases, Western religious organizations cannot find a local organization that meets their needs or shares their gospel vision. In the latter case, internationalization may be difficult or even impossible.

The internationalization process can only be effective after the implementation step in the selected country has taken place. For this step to be successful, the religious organization must implement strategies to recruit followers, and keep them loyal. From this perspective, marketing plays a vital role as religious organizations use it to develop and propose a marketing/communication plan around a religious "offer" that meets the spiritual needs of their public (Abreu, 2006).

Marketing activities implemented by Western evangelical organizations

The use of marketing in the religious sphere has long been seen as something shameful. Many people see it as a tool of manipulation and conditioning. In a study by Wrenn (1993, cited in Newman and Benchener, 2008, p.2) on the perception of marketing by religious leaders, we note the following comments: *"(...) it strips the sacred significance from religion, it is at odds with biblical views."*

There is now, however, a marketing comeback in the evangelical communities in particular since they see marketing as a tool allowing religious leaders to know the intentions and needs of their various "markets" and to act more efficiently (Peycelon, 2009). In his book, *Marketing the Church*, Barna (1988), "The Man Who Brought Marketing to Church" claimed precisely: "the fastest growing churches are those which have learned to effectively apply marketing techniques" (cited in Newman and Benchener, 2008, p.1). In a recent study, Vokurka et al. (2002) showed that the explosive growth of evangelical churches happens in large part because they take advantage of marketing techniques in their strategies for winning religious market shares.

Marketing also occupies an important place in the heart of the strategies of the Western religious organizations interviewed. In this regard, the Rev.Koudou said: *"The Gospel must be preached in the era of its time, with the means of its time. This implies that we must use the most current marketing techniques to spread the Gospel of Christ."*

Indeed, the leaders surveyed rely heavily on marketing communication tools to bring their messages to the faithful. In the Ivoirian evangelical "market", there are two categories of church when it comes to the use of marketing techniques. On the one hand, we have the old religious organizations which have been established for several years and on the other, young organizations that have been established for only a few years. For older ones, the communication techniques used are generally traditional (roadshows, displays, radio, television spots, outdoor and door-to-door evangelization). This is explained by the fact that these organizations are very well-established and enjoy a good reputation and a very wide pool of followers. For the younger organizations, marketing efforts are more important when increasing market shares. Thus, they employ aggressive techniques through a strong presence on television and radio. In addition, they use new media including the Internet.

The MEGVIE, for example, has an online television project and associates itself with Christian websites to promote its image among Ivoirian Christian internet users. These newly established organizations are playing heavily on differentiation strategies by offering an experiential religious "offer". The case of MEGVIE is a good example. This organization is perceived in Côte d'Ivoire as "the church of stars." Indeed, most political and show business personalities belong to this church.

This positioning causes many word-of-mouth effects. In addition, this church is also distinguished by an emphasis on dress code (those who go there are required to dress in a jacket during the celebrations) and the Bishop's preaching are focused on personal achievement, entrepreneurship and prosperity. This folklore attracts many curious people who come to pray to God and to build professional and business relationships.

Furthermore, there is a great interest in social work as a means to build the church reputation. To this end, organizations finance micro-projects, fight against poverty, create hospitals and provide health care assistance. This social strategy has an enormous impact as Rev. Tiécoura said because it has allowed his religious organization to be easily accepted in Senegal where it is one of the fastest growing evangelical missions. Also, the communication tools are adapted in rural areas where literacy rates are very low. In these areas, organizations are using communications media such as Christian films presented in different dialects and outdoor evangelization campaigns.

Can we apply the internationalization model to the Western evangelical organizations expansion process?

The different stages of internationalization for Western evangelical organizations that we have detailed appear to have strong similarities with the internationalization theories developed by some researchers in the context of profit organizations. Indeed, in their seminal work, Johanson and Vahlne (1977) proposed the Uppsala model. According to these authors, internationalization is presented as a sequential process organized around different stages through which companies gradually increase their level of international involvement based on two main variables: the degree of market knowledge and the learning or mastery level of international operations.

As we noticed during our interviews, the idea of internationalization in Africa and specifically in Côte d'Ivoire is driven from the parent church already operating in the West, which seems to confirm stage 1 of the Johanson and Vahlne model (begin internationalizing with ad hoc exporting). In addition, we saw that the choice of internationalization in the target countries is motivated by a principle of caution. This caution explains why both profit and non-profit organizations (Western evangelical organizations in our case) prefer to follow stage 2 of the Johanson and Vahlne model (formalize entry through deals with intermediaries, often agents, who represent the focal companies in the foreign market) by using intermediaries (local pastors already settled in the target country are contacted) in order to minimize risks due to uncertainty, cultural adjustment, as well as financial risks related to potential changes in missionary staff management.

In many ways, however, the process of internationalization for evangelical organizations differs from the model proposed by Johanson and Vahlne (1977). Indeed, the authors consider that companies, before moving to step 2 of the internationalization process (export via independent representatives (agents)), must first make sure to have

control of and learn greatly from their local market. This idea does not apply to religious organizations because they are essentially deigned to be international if we refer back to their biblical mission (Holy Bible, Mark 16 v.15). So, they are born “international” and thus, unlike companies, they do not require a prior period of preparation before starting their international operations. Johanson and Vahlne(2009) also suggest that companies must choose markets that are similar to their local market on political, cultural, social and economic levels. The evangelical organizations studied here illustrated that the choice of target country is driven primarily by the existence of a great spiritual need regardless of its congruence/incongruence with the parent church country of origin on cultural, social, political or economic levels. Furthermore, we note that steps 2 and 3 are not really sequential, but rather interchangeable: religious organizations have the choice to opt for independent intermediaries (partnerships with pastors already installed in the target country) or to use their own intermediaries or representatives abroad (pastors trained in their church in the West).

Conclusion

This paper has allowed us to explore an emerging research area in marketing and consumer behaviour: religion. By focusing on the internationalization process of Western evangelical churches in Africa, we are responding, in part, to a research problem long studied by researchers in sociology and religious studies. The conclusions of this paper allow us to understand that the process of religious expansion is not the result of an accident or divine inspiration, but rather a result of strategic reflections supported by marketing tools and communication (Table 2). This confirms the growing importance of marketing as a helpful tool for profit and non-profit organizations.

This study is relevant at managerial and theoretical levels. From a managerial point of view, it shows the different steps that a religious organization can take for successful internationalization. It also presents the potential limiting factors that need to be taken into account and how to circumvent them. In the era of globalization, evangelical religious organizations need to ensure their growth abroad particularly in the so-called emerging spiritual countries of Africa, Asia and Latin America. The results of this study provide a good basis for the selection of modes of expansion. From a theoretical viewpoint, this study makes a contribution to the knowledge in marketing as it is one of the first studies to look at the internationalization of religious movements in the context of globalization. It is also an early contribution to a reflection on the development of an international-specific model or theory for non-profit organizations.

Despite its relevance, the study has some limitations. We used an exploratory approach and a case study method that restricts the conclusions of our study to Côte d'Ivoire and West Africa. However, given that internationalization of religious organizations in Côte d'Ivoire is not very different from internationalization in other African countries, this does not hinder the actual relevance and validity of our findings. It might be interesting to conduct a comparative study of the internationalization process of the Western churches to African countries versus Asian countries, Latin America and even European countries (e.g. Eastern Europe).

In this study, we witnessed the emergence of a new phenomenon of evangelization in Africa, characterized by the rise of local initiatives that are not only expanding in African countries but also in Western countries. It may be profitable to conduct a study on this form of religious globalization and to compare these two types of internationalization: the internationalization process of Western churches in developing countries, and developing countries' churches in Western societies. We have initiated some reflections on the non-profit organizations' internationalization process. Future studies might explore this research area by proposing a model more suitable for non-profit organizations at large (churches, NGOs, etc.).

TABLE 2: SYNTHESIS OF OUR MAIN CONCLUSIONS

Research questions	Main conclusions
What are the key factors that motivate the choice of Côte d'Ivoire as a missionary field in West Africa for Western evangelical communities?	The choice of Côte d'Ivoire as a missionary field in West Africa is motivated by four main factors: <i>structural</i> (existence of spiritual needs to be fulfilled in the target country), <i>strategic</i> (the country's geographic and economic importance in the Western evangelical organization expansion), <i>political</i> (the country's political stability and openness) and <i>competitive</i> (other evangelical organizations' competitive intensity).
What are the different stages of the internationalization process and the different actions at each stage?	The internationalization process of Western evangelical organizations is organized around four main stages which precede the implementation stage: <i>identification of potential expansion areas or countries</i> , <i>exploration</i> , <i>choice of target market</i> and <i>expansion modes</i> .
What are the main limiting factors of the internationalization process?	The limiting factors are mainly of three kinds: <i>political</i> (the country's religious openness to accepting evangelical organizations), <i>cultural</i> (adaptation to local climate and dialects/languages) and <i>human</i> (availability of local contacts to support the Western evangelical organization expansion).
What are the marketing efforts undertaken to successfully implement a religious organization on the local ground?	In the context of Western evangelical organizations in Côte d'Ivoire, some <i>traditional marketing tools</i> (road shows, displays, radio, television spots, outdoor and door-to-door evangelization) and <i>modern marketing tools</i> (experiential marketing techniques, Web communications via websites and social marketing activities) are used.

Crisis of habitus: the experiences of South Asian migrant managers and professionals in Australia

Syed M. Mohyuddin, syed.mohyuddin@postgrad.curtin.edu.au
David Pick, d.pick@curtin.edu.au
Curtin University, Australia

Abstract

The aim of this paper is to examine the career experiences of managers and professionals who choose to migrate from South Asia (India, Pakistan, Sri Lanka and Bangladesh) to Australia. Using a combination of phenomenology and analysis of narratives, data was collected from 21 migrants through in-depth face-to-face interviews. Analysis of the data reveals a 'crisis of habitus' that leaves the participants with a sense of disembeddedness that prompts them to reconcile this crisis through processes of acculturation and sense-making. The analysis suggests that participants tended to make assumptions about their environment that often hindered their adaptation and career progression. While the research is limited to Australia, the results have wider significant theoretical and practical relevance. Applying the concept of habitus contributes to current understandings about the career challenges faced by migrants. This brings to light new and significant insights and have the potential to raise awareness amongst policy makers and business organisations.

Introduction

Every year Australia receives skilled migrants from different regions of the world to fulfil the Australian labour shortage. According to the statistics of the Australian Department of Immigration and Citizenship (DIAC, 2010a) for the financial year 2008-09, the number of skilled migrants that came to Australia from the region of South Asia was 17,320. The regions from where skilled migrant arrivals are mainly sourced are the nations of Bangladesh, India, Pakistan, Sri Lanka and Nepal. Among these nations the largest group of migrants arrived from India with 12,304 skilled migrants. India was ranked second after United Kingdom from where 15,803 skilled migrants arrived and China was ranked third with 8,189 skilled migrant arrivals (DIAC, 2010a). Highly skilled managers and professionals were among the top ten in the list of skills recognized by DIAC (2010b).

In a broader sense the aim of Australian migration policy is that these individuals will become a productive part of a multicultural nation – a nation which until 1975 had a strict 'whitesonly' policy that excluded non-European immigrants with the aim of achieving racial and cultural homogeneity (Jupp, 1995). This policy enjoyed community support as political leaders provided them with assurance that the numbers and types of immigrants would be strictly controlled by the government and thenation's core Anglo/Celt ethnic identity would be preserved (Tavan, 2005). Despite the abolition of this policy and the advancement towards multiculturalism 'White Australia' still retains a residual appeal (Tavan, 2005). Therefore, gaining professional recognition and breaking social barriers can still be challenging for skilled migrants from non-European backgrounds. According to Beck (2002) migrants can be treated as 'excluded others' in host nations creating a situation where they live in two frames of reference, being at the same time 'here' and 'there', located in and in-between different incompatible framings of social inequalities and political conflicts. This raises interesting questions about whether migrants living in this situation find a path to resolution as they rewrite their biographies in their new environment. The purpose of this paper is to attempt to address this issue and bring to light the challenges faced by highly skilled professionals and migrant managers from South Asia as they try to build a new career in Australia.

Highly skilled professionals are individuals who possess tertiary qualifications as well as spend years of studies to gain experience to certain formal qualifications in order to gain acceptance by professional bodies (Crook & Waterhouse, 1995; Koser & Salt, 1997). Professionals can be managers; it depends upon the environment in which they exist, in as much as management is a general activity and managers are those people who achieve tasks themselves or create environments where others can work effectively (Crook & Waterhouse, 1995). Discrimination against highly skilled migrant professionals and managers especially those of Asian origins is a common research theme in the extant literature (Bhattacharya & Schoppelrey, 2004; Varma, 2002; Ward & Masgoret, 2007; Watson,

1996). The research pertaining to Australia suggests that the local managers felt more comfortable hiring locally-born employees as they were of the view that overseas qualified managers and professionals have not lived here long enough to understand the Australian management psyche (Watson, 1996). In addition, some research evidence suggests that discrimination is experienced within the system rather than as a barrier to entry; for example, discrimination that mitigates against promotion (Mellor, 2004). A similar gap between the immigration policies and job recruitment was also identified in New Zealand by Ward and Masgoret(2007). Some literature also points out that as a consequence of non-recognition of the skills migrants possess, host nations experience a phenomenon of 'brain waste'(Salt, 1997).

Researchers also point to the role of gender in the settlement skilled migrants. Froroutan(2008)examines the experiences of South Asian female migrants finding that family and religion plays a vital role in their employment status. He further explains that specifically Muslim women are at an additional disadvantage if they follow their religious values such as dress code, etc.Iredale(2005) explains that cultural attitudes have a great impact on female skilled migrant's employment and settlement. She argues that attitudes to employment, career, and family and societal values affect the position of females in society and their ability to migrate.

Although culture and gender have an impact on the migrant experience, other factors are also at play.According to Syed (2008) previous research done on migrants to Australia, USA, UK and other Western industrialized countries focus on looking at skilled migrants as a factor of production flowing across international borders. He further explains that skilled migrant experience cannot be not just confined to either human capital or socio-cultural perspective. Their employment experiences are more complex and are shaped by not only skills and economic factors but also by perceptions and experiences of the host society and its occupational opportunity structure. Taking Syed's argument as a point of departure, this paper will explore the complex phenomenon of being a highly skilled South Asian migrant professional and manager in Australia. To this end, the theories of habitus (Bourdieu, 1986),disembedding/re-embedding (Giddens, 1990), acculturation (Redfield, Linton, & Herskovits, 1936) and sense-making (Weick, 1995)will be used as a framework for analysis.

Every individual possesses a habitus that is formed through different forms of capital that is cultural, social and economic (Bourdieu, 1986). Cultural capital can exist in three forms in embodied state that is about a person's accent race or accent etc., objectified state which can be a person's way of dressing or some art collection etc. and finally in the institutionalized form that is a person's qualifications or degrees earned (Bourdieu, 1986). Since the highly skilled migrant professionals are up-rooted from their inherited social conditions they are dismembered(Giddens, 1990). Their different forms of capitals are altered in the host country and this alteration puts them in a crisis of habitus (Zipin & Brennan, 2003). This prompts them to reconcile this crisis in order to get re-embedded in the host country's work and general environment. The process of reconciliation is explored by utilizing theories of acculturation (Redfield, et al., 1936) and sense-making (Weick, 1995). Firstly, acculturation is characterized by integration, assimilation, separation and marginalization of the migrants in their new environment (Sakamoto, 2007). Secondly, sense-making is described as a process in which individuals make sense of their environment and rationalize their behaviour based on the interpretation of the environment to which they belong (Weick, 1995).

Methodology

A qualitative mixed method approach is used to collect and analyze the data of this research. According to Johnson, Onwuegbuzie, and Turner(2007) the reasons behind mixing methods are to provide a full picture and a better and deeper understanding as well as meaningful more useful answers to the research questions and to improve the validity of the findings.In this study phenomenology and analysis of narratives have been employed.A phenomenological study describes the meaning of lived experiences for several individuals about a concept or a phenomenon (Creswell, 1998). According to Sanders (1982) it is the study of a conscious phenomenon that is an analysis of the way in which things or experiences show themselves. This paper describes the lived experience of being a highly skilled migrant professional from South Asia as expressed by the participants in their narratives.

A narrative is defined as a spoken or written text giving an account of an event /action or series of events or actions chronologically connected (Czarniawska-Joerges, 2004 ,17). A story in a narrative research is a first person oral telling or retelling of events related to the personal or social experiences of an individual , often these stories have a beginning, middle and an end (Ollerenshaw & Creswell, 2002). As this study is using the interviews of highly skilled migrant professionals and managers and the interviews are about their experiences. These experiences have a time line from arriving in Australia as a migrant to time when interview was conducted. Furthermore it involves their personal and social experiences.Ezzy(1998) emphasized that it is a mistake to assume that lived experience is in some way separate from narration, as if reality from fiction. Furthermore lives and texts are not configurations rather; they become completed compositions in their reading. A clear example of this is the way in which events become episodes as part of the plot of the story Ezzy(1998).The phenomenological and narrative analysis techniques complement each other as the world of the migrants of this study is their reality and that reality is a phenomenon. The narratives of the migrants of this study are the stories which reveal the process which brought them to that reality, which gave them their new identities in their new home country Australia. Twenty one participants were interviewed for this study belonging to different countries of South Asia. The participants included both males and females. NVIVO8 software was used for the analysis and examination of the different themes emerging from those interviews.

Findings

Analysis of the interview data revealed that the capital possessed by the participants of this study that included cultural, social and economic, was altered upon immigration to Australia. This led them to disembedding and consequently a crisis of habitus. This crisis of habitus is firstly cultural; in this case the cultural capital upon which the participants relied alters to the extent that embodied cultural capital (related to his or her ethnicity and cultural background) becomes far more important than institutionalized cultural capital (education) that was previously of primary importance. Secondly it is social in that participants did not have a local network to socialize within and make contacts resulting in a loss of social capital. Finally it is economic, in that the savings of participants became depleted resulting in a loss of economic capital.

The participants of this study experienced a shift from institutional to embodied cultural capital. As they arrived in Australia they were confident that their overseas qualifications and skills (institutional cultural capital) would get recognition in Australia.Contrary to these expectations they faced non-recognition of skills and qualifications even though they were in accordance with the requirements of their chosen occupation. The only conclusion they could reach therefore was that their rejection had more to do with their ethnicity (embodied cultural capital).As participant 6 from Sri Lanka stated:

I expected that I will give some of these skills to this country. I expected that this country would be able to make use of them recognize them and put me at an appropriate level but to my surprise this did not happen.....My experience was ignored and I found it very frustrating so I would attribute that to some kind of prejudice based upon my background or colour or it could be through fear that my experience and my past background would be a threat to the senior management.

The above respondent believed that he had the right qualifications therefore the only reason he was ignored could have been his ethnic back ground. The analysis of the data also revealed that the crisis of cultural capital can be encountered even after successfully stepping into an organization or getting a job related to ones profession. For example participant 20 from India stated that:

But the expectations that you see from your own colleagues are still higher then you question yourself that how much more do...what I get reminded, very well said by Mohammed Ali the great boxer when he came to Australia in an SBS TV interview that in his time he thought it was so unfortunate that every black man has be Mohammed Ali to get any respect from the white people.

This participant also stated that the expectations of his colleagues in the organization are higher just because he was a migrant and he has to work harder to prove himself. Therefore the migrants like this person can face a continuous state of crisis of cultural capital.

While the experiences of the participants did not vary according to cultural and national diversity, gender appeared to play a role in the crisis of cultural capital. The females in this research reported having to conform to certain cultural norms that were different from the males. These norms added to their cultural capital crisis. As participant 15 from Pakistan expressed:

Although I am working and although my husband is very supportive everything is ok. But there are a few.....being a Muslim I cannot go beyond this limit or I would not try to cross these limits. But if I am a male for example.....I can still socialize with them or talk to them and try to be more communicative with them.

This participant believed that the male counter parts from her cultural background have less cultural barriers as compared to females in the organizational environments. Summing up the crisis of cultural capital the shift in between the embodied and institutional cultural capitals was a very critical event in the lives of the participants of this study.

The participants of this study also faced the crisis of social capital due to lack of understanding of the organizational socialization and cultures in Australia. The participants in this research fully understood that leaving behind their social capital was the very first compromise in their lives as migrants. This understanding is very simple and straight forward and can be considered quite realistic, for example participant 1 said:

I was mentally prepared that I might not work in Australia on the same status and I might not come back to Pakistan for years and I will lose 80 percent of my social contacts.

Some participants did not realise however, the difficulties they would have building up their new contacts and networks (social capital) in Australia. They seemed to underestimate the importance of becoming the part of the organizational socialization cultural pattern that could help them in networking. However some participants also had a late realisation of this social capital crisis. For example participant 10 from India stated:

I suppose in career you expect when you come here and do your job and you automatically get recognition and you automatically sort of rise up the ladder in the organization ... but I think that probably organization are already top heavy and may be not going that fast may be you have to market yourself a bit more may be because of those things it didn't automatically happen as I expected.

The above quote represented a realisation that working hard is not enough a person also needs to market him or herself in the organization. Some participants also remained in a state where crisis of social capital can remain unresolved as they believed that cultural barriers between them and locals would always remain. As participant 3 from Pakistan mentioned:

I realized that as migrant if you want to succeed in your profession there are a few things you need to keep an eye, the first is networking you cannot go stronger on that because of the social aspect we cannot integrate socially too much and the other is language barrier not the academic or Grammatical but the accent and the third one is cultural. So these are the three four points which segregates you among the mainstream and you are not able have the networking.

The above quote represents a feeling of always being side lined because of the migrant cultural identity. The crisis of social capital was somewhat different for the females in the sample. Coming from male dominated societies the expectations for them were quite different. The females interviewed did pursue a professional career but were also expected to be good homemakers. Even migrating to Australia was a choice of their husbands and they also needed their husband's approval for organizational socialization. For example participant 16 stated:

I came to Australia from Pakistan three and half years ago. It wasn't really my choice I had migrated because my husband was migrating to Australia so I had to move along with him. I want to move forward and I have to make more friends.....don't know if it happens with others. That's how it happens in my organization if you want to progress you have to know the right people at right time. I still feel reluctant to go to these parties.... my husband said don't feel shy just go there and if you want to move forward.

As the societies from where the females interviewed originate, if the husband would not approve of them going to a social event she would have to withdraw from such events. Therefore it can be concluded that role of cultural background cannot be ignored in the context of the crisis of social capital. As the participants of this study faced the crisis of cultural and social capital they also faced the crisis of economic capital. The reason behind this crisis was that they were not able to convert their institutional cultural capital into economic capital through their earnings. Secondly, they also lacked any social networking due to which they did not have suitable referees who

could support them in their applications for jobs. As a result periods of unemployment and underemployment led to a gradual decline and economic capital. For example respondent 1 mentioned in his interview:

When I came here I had only A\$ 5000 in my pocket in the very first week I was able to realize that I might not find job in accordance with my qualification and experience..... When I came to Perth I even had less money than my initial arrival in Australia.

The analysis of the data reveals that the participants of this study did make an effort to resolve this crisis of habitus. The conclusions which they reached illuminated the way they attempted to resolve this crisis. During the resolution phase some participants enhanced their cultural capital, some enhanced the social capital and some made efforts to enhance both. The result of this effort could lead to some re-embedding in their new career environment through sense-making and acculturation. Sense-making is a process that can explain the resolution of the crisis faced by the participants with respect to the efforts of re-embedding. The basic idea of sense-making is about the construction of a reality which is an ongoing accomplishment that emerges from efforts to create order and make retrospective sense of what occurs in the environment (Weick, 1993). One of the findings of this study was that the sense-making properties of identity, retrospect, social, extracted cues and plausibility played a role in the crisis resolution.

Identity is about the discovery of a person's thought process based upon who he is or what is his actual identity (Weick, 1995). In the case of the highly skilled migrant professionals and managers, they were able to make sense that they were carrying an embodied cultural capital with them which gave rise to their new identity in their new home land Australia and this identity also had a deep impact on how they thought and made sense of the situations and the work environment around them. The feeling of this identity was very strong among them and it existed no matter what stage of their career they belonged at a certain point of time. For example participant 15 expressed:

The main thing is that the general example they give that if you are sitting among two other Australians and you three are going for same specialization although you have got all the credentials you have got experience you have got interest everything is there but still they don't know you because your skin colour is different because you are not from here and because you haven't worked with them.

The above quote is an example that how a participant from the medical profession felt that she could not get into the choice of her specialisation because of her identity. Therefore her resolve would be to choose a specialisation where her identity would not become a stumbling block. The participants of this study have gone through a learning process when they evaluated and compared their earlier views and their current conditions with respect to their professional attainment. In the sense-making process retrospect is to learn about one's own thinking from what you said earlier (Weick, 1995). One resolution about which skilled migrants thought or acted upon after looking at their experience in retrospect was to start their own business. For example participant 3 concluded:

I have started to think to develop or start my own business. For the last few months I have not applied for any job because I am a bit reluctant go again into an employee employer relationship. For my own business I don't think its negative I feel I can do much better for the profession and the society with my own business rather than just working for someone.

The reason behind this kind of resolution was a feeling to achieve a professional attainment where a person could never be side lined because of being a migrant. The skilled migrants' professionals and managers who did not want to work for local boss might as well be reluctant to socialise with their local colleagues. However socialization is a very important property of sense-making process. As in the sense-making process a person's conclusions very much depend upon who that person socialized with and how that socialization process took place (Weick, 1995). This socialization did help the participants in the resolution of the social capital crisis but the extent of this resolution could be different. There is one category of people who have rejected the idea of socialization as their resolution. . To further understand the process of social resolution of the crisis it will be useful to look at quote of participant 20 he stated:

Somehow unfortunately I have never been able to build up any rapport except for professional pure working relation only as and when required beyond that there is hardly any relation. I don't know whether it's got something to do with what I see every day being done to my junior colleagues the overseas doctors or don't know what it is but I think that subconsciously it has affected me.

On the other hand another participant recognised the importance of social contacts and reached a different resolution participant 7 stated that:

I had good contacts with the persons who worked with me and who even left our company and are with other companies now through email etc. In a way that's very good for what I am doing as an expert.

Sometimes selective perceptions of the participants also had an impact upon their resolution process. This is explained by the property of extracting cues in sense-making which is about what a person singles out and embellishes as the content of the thought is only a small portion of the utterance that becomes salient because of context and personal dispositions (Weick, 1995). This property was also about some personal experience which stays with a person for example participant 9 said:

I think once I got the Australian citizenship I really felt that I was an Australian and soon after that I was flying to US and this American lady sitting next to me asked me that where did I come from and I said to her I am Australian. She said yes you come from Australia but what you are just looking at my face and that jolted me that you can change your nationality on paper but people do want you to have another label.

The above quote represented a link to the embodied cultural capital. As a result of considering their cultural and ethnic attributes as their weakness skilled migrants turned to plausible sense-making. Plausibility is a thought process in which persons believe that what they think is enough for them to carry on with their work (Weick, 1995). For example participant 1 made a comment about his accent, he said:

I was very confident my accent had also slightly changed. I still believe that by living here for years you can brush up your English language skills but you cannot change your accent. When I talk to someone he might say that I was talking to an Indian guy it is not an abuse to me any more I know that it can be refined it cannot be changed.

This represented a very plausible concept as born Australians still recognize him as an Indian male and he still believed that his accent is refined. Secondly, the above respondent has used the word 'abuse' for being recognized on basis of one's embodied cultural capital. This represented a very strong sentiment but the person is saying that he has learned to live with his cultural attributes this part represented the resolution and the part in which he said that my accent is refined now represents plausibility associated to this resolution. As being a first generation migrant he was just using plausibility in the process of sense-making by saying to oneself that it did not matter if one got recognition or not it was a milestone that the accent was refined. In the context of sense-making the resolution of the crisis is about coming to terms with the switch of the different forms capital with certain conclusions. The next step for the participants after reaching those conclusions was to find ways to integrate in the Australian work environment. The acculturation process will help in understanding the extent of integration of the participants of this study in the Australian work culture.

The process of acculturation is divided into four categories integration (accept old culture, accept new culture), assimilation (reject old culture, accept new culture), separation (accept old culture, reject new culture), and marginalization (reject old culture, reject new culture) (Sakamoto, 2007). An in-depth look into the experience of the participants using acculturation process theory revealed that the participants of this research integrated to some extent, there was also evidence of separation and marginalization but there was no evidence of assimilation. Some of the participants of the study separated because they felt that they could not adapt the local culture. As participant 1 said:

I liked to socialize with my colleagues in my previous job but due to some cultural constraints for example I might fund an after hour's party and not attend it as if drinking (alcohol) is the main part of celebration I can't be a part of that, in my culture the concept of celebration is different. The cultural gap always existed it is not created by the management but it is always difficult to overcome that one.

Some participants of the study also tried to find middle grounds where they can accept both home and host cultures to have an integration experience. For example participant 12 mentioned:

What I have realized is it's an important part of Australian life when you are working on Friday evening you go with you mates and have a few drinks and there are things that are discussed and shared during those sessions. Coming from Muslim back ground we are not part of those discussions..... I always joined them, to have some non-alcoholic drinks.

Since alcohol is prohibited in the above participant's religion but he found a way to integrate in the work place socialization by keeping his culture as well as adapting to certain aspects of the local culture. Evidence of

marginalization was apparent in the experience of one participant. This experience will provide an insight that how a person can reject both host and home country cultures.

Due to problems that I faced in the public schools when I was working there from my bosses, colleagues and students and sometimes from the community, everywhere did face some sort of problems so after working for three years I decided that I cannot continue this way and that's going to affect even my professional carrier..... I moved back to Perth and started looking for a job in this sector first I got job in a different school it had completely different atmosphere. The people dealing with me had a totally different attitude. I felt that I am in a different planet may be so that's the difference that I felt, that was before this school that was also an Islamic school.

The respondent before coming to Australia worked in supervisory position in his home country. His entire career before coming to Australia was in the main stream of his profession so the organizations he worked in were part of the culture of the majority in his nation that is without any religious affiliation. However after facing discrimination and the realization that he would never be able to gain a high position in any main stream Australian organization he joined an Islamic organization that was not main stream but that was the only place where he could get such a high position.

From the above discussion it can be noted that being a highly skilled South Asian migrant professional and a manager is not just about having skills and qualifications recognized by the immigration department; this is just the first step. Launching a successful professional career is a completely different story. The reality is more a story of continuing and sometimes grim struggle to find a new career identity. The issues raised in this research are significant in looking at issues of successful integration into the Australian work environment. The acculturation process for participants in this research is a journey of resolving a crisis of habitus.

Conclusion

This paper has attempted to provide a window into the challenges faced by the participants of the study and the efforts to resolve them. Although the main focus of this research was the professional lives of the skilled migrants and managers from South Asia, this research also successfully revealed the consequences of the struggles of everyday professional life. The use of theories of habitus and disembedding helped in explaining the phenomenon of being a skilled migrant from South Asia in Australia. The theories of sense-making and acculturation successfully explained that the how these migrants resolved the crisis of habitus and re-embedded themselves in the Australian work force. However, there are also implications for the employers or the potential employers of the highly skilled migrant professionals. It seems that non recognition of the overseas skills, qualifications and experience can create an air of distrust between the migrant employees and local employers. Secondly, the indifference of the local employers to the struggles of highly skilled migrant professionals adds to this atmosphere of distrust. Despite this, there is a need for more research into the process of accommodating highly qualified and skilled professional migrants into Australian organizations. Attention should be paid at both the technical and social levels as looking at only technical skills is just as looking at a portion of the whole picture. For policy makers and the organizations research that takes into account the broader scenario of flaws and loopholes in the system of skilled migrant settlement as identified in this paper will help them make better use of the skills, experience and qualifications of migrants in the task of meeting the challenge of filling the ever-increasing skills gap in the Australian economy.

The Influence of Cultural Differences on the Perception of a Web Site. A Comparison between Mexico and Spain

*Juan Antonio Vargas-Barraza, corporacion.sintetica@gmail.com

Universidad Autonoma de Madrid, Spain*

Abstract

The cultural background in the development of the Website is important to avoid mistakes that may cause bad image to the customer. (Nantel and Glaser, 2008) have found that language, a major cultural factor, is less important when the quality of the offered products is attractive to the buyers. The native language of the site does not have a big impact on the perception of the usability of a site and purchasing decisions.

This paper examines if the cultural background of the website is perceived when using English language in the design. The Website was designed and developed specifically for this research, using usability principles, trying to access to a multicultural buyers market. So far the relationship between usability and Hofstede's cultural dimensions has been an important factor in cross-cultural work. Based on this, we analyzed the data collected by a survey in Spain and Mexico to verify our research question.

Background

The first studies about the implementation of a Web site used to focus on the development and the technical aspects of the site, which has led most research on web site design to analyze technical aspects of it. Thus, it has generated a large number of design elements that will apparently make a web site to be successful: usability, use of images, aesthetics, navigation and search, site interactivity, elements such as brand power and the degree of site customization (A°berg and Shahmenhri, 2000).

According to Falk et al. (2007), not only the technical design of a Web site is the key to success. Also it should be considered other important factors such as the culture of the users that the site is focused on. It is not about adapting the company sites to attract customers from different regions, something that many companies do just by switching the language (Lynch et al, 2001). For example, designing a Web site made for entertainment or educational purposes may not be compatible with the same approach as it is done in the design of a commercial site (Cook and Finlayson, 2005). Therefore, it should be always included the cultural analysis and, as well, to establish standards that bring together the preferences and expectations of a community that is intended.

Companies that offer their products in different markets are willing to improve the usability of their sites to attract more visitors. Examples of some pieces of work are those of Ferreira (2002), that examines topics related to language besides to the metaphors used, the attitudes and preferences that weigh in the cultures to which the site aims to reach (Nantel and Glaser, 2004), which also focus on the use of language to improve the usability of a site and thus attract more visitors, offering create sites oriented to each culture rather than a universal one. In sum, most of these works are based on understanding the cultural differences and from there designing a specific site.

The models proposed so far come from computer science. However, we believe that you cannot leave out the cultural and organizational factors affecting the development of the site (Ogbonna and Harris, 2007). Thus, cultural issues and dynamics faced by organizations are a very important factor that impacts the design, development and implementation of a site. What if the site is oriented at a different market to the cultural background of the designer? Nantel and Glaser (2008) have found that a cultural factor as relevant a priori, as is the language, it is less important when the quality of what is offered is attractive to the prospective buyer. Hence, sometimes the native language of the site seems to have no impact on the perception of usability and in the purchasing decision taken by the user. While there are various models for analyzing the cultures from different perspectives, some of the dimensions and their interpretations of how a culture behaves under those values is equivalent between the different

authors. Models, regardless of whether they are related to areas such as politics or business agree mostly in two dimensions: Individualism vs. Collectivism and risk aversion. Many of the studies that have been made about culture and the Internet are related to the reduction of uncertainty or risk at the time of a commercial transaction, or tried to model sites that may be perceived the same way by different cultural groups (Hofstede, 2002; Trompenaars and Hampden-Turner, 1998; Chaney and Martin, 2005; House et al., 2002).

Marcus and Gould (2000) made an analysis of several Internet portals where they assess and classify different groups defined according to the dimensions of Hofstede and found that different cultures affect the design of their sites. Their conclusion is that culture, expressed through the dimensions of Hofstede affects the design of Web pages. In the study by Matei and Ball-Rokeach (2001) it was found that among the ethnic communities living in Los Angeles the groups of the most collectivist societies (in this case Korea and China), make from three to two times more on-line friends than the groups of European origin (while Hispanics were the ones with the lowest percentage at the time to make friends on-line). Kim and Yun (2007) attribute this to that in collectivist societies is easier for users to express their emotions in an environment where it would be impossible to communicate face to face, as is the case of Korea. In the work of Miura and Yamashita (2007) we observe that the same applies to Japanese users of blogs. They are more sensitive to the negative responses on their sites, concluding that this is due to the collectivist mentality of Japan, where they perceive less risk to say something negative when it is not say face to face. The work of Nath and Murthy (2004) shows that issues such as community, income level, the country's innovation, risk aversion and masculinity of a culture have a significant impact on Internet penetration. As far as differences regarding gender, countries with a high level of masculinity value productivity and try to be the best (Alberts-Miller and Gelb, 1996), and advertising shows how effectiveness of a product emphasizing on all the capabilities of site performance.

Studies have found that much of the risk perception is influenced by the culture of a country, since this is one way of interpreting the world (Ueltschy et al, 2004). Traditionally it has been perceived as a higher risk purchasing services than goods, due to the intangible nature of the former. Regarding on-line sales is practically saying that all sold products are intangible, so that the perceived risk increases among consumers and users (Ueltschy et al, 2004). The same applies for the Internet adoption in economically undeveloped countries, where users represent less than 1% of the population like in countries such as Bangladesh, Nigeria, Vietnam and Zimbabwe (Nath and Murthy, 2004). Yeniryut and Townsend (2003) found that the lower acceptance of new products can be supported with power distance and risk aversion, finding that technological innovations are high in countries with small power distance, low risk aversion and higher individualism. While Linjun et al. (2003) show that power distance is a key element in the e-mail acceptance in China. The use of color can also reduce ambiguity for cultures with high levels of risk aversion, or it can be used to maximize information without redundancy, for cultures with low levels of risk aversion (Zahir et al, 2002). Starting from this point, for the specific case of this research, it has been worked on a site previously designed with usability principles developed by Nielsen (1994), relating these to indices of Hofstede's cultural values. Thus, the hypotheses have been developed for each cultural value related to Web design as it is indicated below (TABLE 1).

TABLE 1. SUMMARY OF THE FORMULATED HYPOTHESES

Hofstede's values	Relationship of usability	Hypotheses	Element of usability
Risk aversion	H1a: (-)	The higher the risk aversion index from a country, the lower the perception of Web site security.	Security
	H1b: (-)	The higher the risk aversion index, the lower the perception of navigation easiness of the site.	Navigation Efficiency
	H1c: (-)	The higher the risk aversion index, the lower the perception of control on the site.	Control
	H1d: (+)	The higher the risk aversion index, the greater the importance of the site content	Content
Collectivism	H2a: (+)	The higher the index of collectivism, the lower the perception of control on the site.	Control
	H2b: (-)	The higher the index of collectivism, the lower the perception of freedom of navigation on the site.	Navigation Efficiency
	H2c: (-)	The higher the index of collectivism, the lower the interest in the site.	Emotion
	H2d: (-)	The higher the degree of collectivism, the lower the perception of a site as safe.	Security
	H2e: (-)	The lower the index of collectivism, the greater the importance of the site content.	Content
Masculinity	H3a: (+)	The higher the masculinity index, the greater the importance in the performance of the site and its products (easiness of use.)	Easiness of use
	H3b: (+)	The higher the masculinity index, the greater the importance of taking control of the Web site.	Control
	H3c: (+)	The higher the masculinity index, the greater the importance of the navigation easiness of the Web site.	Navigation Efficiency
Power distance	H4a: (+)	The higher the power distance, the greater the perceived need for security features on a site.	Security
	H4b: (+)	The higher the power distance index, the greater the importance in the site content.	Content
	H4c: (+)	The higher the power distance index, the greater the importance in the language used on the site.	Language

Taken into account the principles of usability of Nielsen (2002) for the design of Table 1, in the case of this variable there are reduce the number of actions that the user must do in order to avoid losing it, being necessary to convey a sense of security and credibility on the site. FIG.1 shows the proposed full model with all the hypothesis listed.

Sample characteristics

For the sample college students from Mexico and Spain were selected discretionally and by convenience. The countries were chosen because: 1) they represent a wide difference between their range for risk avoidance, power distance, and individualism / collectivism, being the dimension of masculinity / femininity which has a narrower range of disparity between the participants from those countries. Besides the fact that Mexico is a natural neighbor of the U.S. and the cultural influence in this country is evident by the verbal communication of Mexicans. Spain plays an important role in the Spanish language, since it is the country of origin of this idiom and its Anglophones inhabitants are more familiar with British English than with the one from the U.S. Some authors recommend at least 200 visitors to obtain a reasonable sample size (Swearingen, 2009). Data collection was performed during the period from April to June 2010, so it has been possible to achieve an appropriate size for the test statistics. For technical reasons, the survey had to be answered in one session; therefore it could not be interrupted. In order to approximate the sizes of the different subsamples, 206 questionnaires from Spain and Mexico were taken. In order to obtain the test results and all statistical models SPSS version 18 and AMOS 18 were used.

The site and its user interface are based on a model of e-commerce distribution and sale of music in order it matches with the four elements that Postava-Davignon et al. (2004) mentioned: a feeling of confidence, sense of security, sense of interest in the site and desire to return to the site. It was decided that the criteria of usability of Nielsen (2002) was the main basis to design the site and also were taken into account the categories of usability from the Microsoft guide described by Keeker (2004), including those areas identified by Agarwal and Venkatesh (2002) and Postava-Davignon et al. (2004). The site is in English and sells independent music, as a consequence the language does not have a representative impact on the perception of usability as the quality of what is offered is attractive to the consumer (Nantel and Glaser, 2008). While CD sales have declined, it is still a major source of online sales. Independent music labels have survived through the sale of formats that are believed missing -such as vinyl- and a target market consisting of an informed public, which continues to consume music in traditional formats (Hidalgo, 2009). Using a portal designed in English will also help to find whether the application of usability elements in site design effectively reduces the cultural impact of it, fulfilling a major premise that a Web site allows: it serves as a knowledge distribution channel for both providers and users of a site (Fang and Holsapple, 2007).

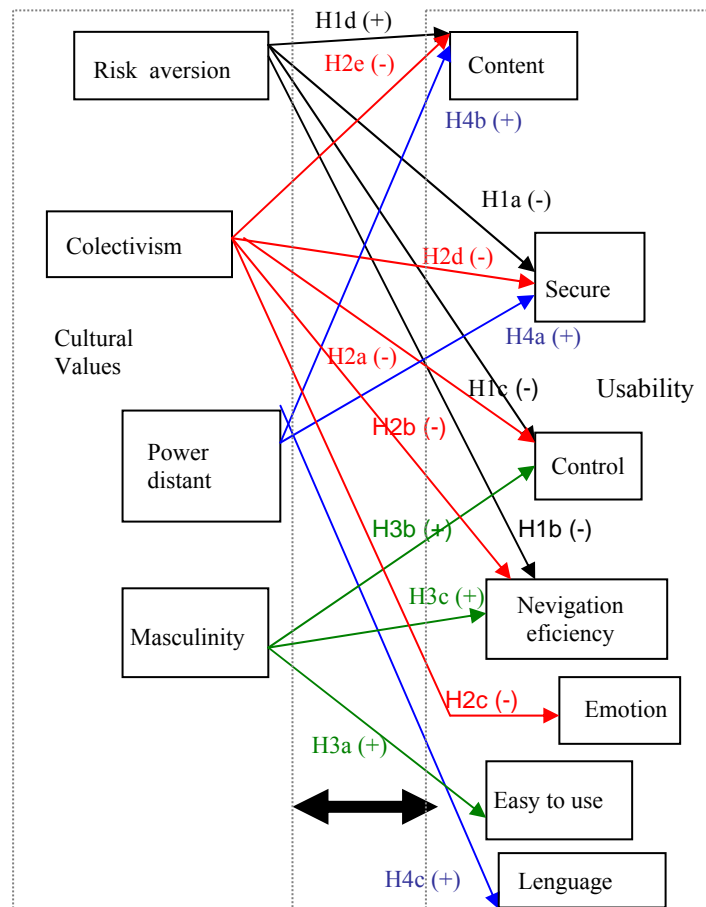

FIG 1. MODEL OF THE RELATIONS BETWEEN USABILITY AND CULTURAL VALUES AND THEIR HYPOTHESIS

The online design and implementation was carried out by a Mexican company that has experience in Web sites, even at a governmental level. The Web site design was the most "culturally neutral" as possible, considering

that there are users whose cultural values are opposite. The model is based on the Visibility Graph Usability Center at Georgia Tech (Fang and Holsapple, 2007), that suggests raising a series of instructions for the participants in order to explore and then execute a series of tasks, which are: seeking for information or for a particular object. Part of the demographic information and prior experience, appears in most of the usability studies and perception of a site, as well in analysis on Internet usage and satisfaction (Roy et al., 2001, Palmer, 2002; Ferreira , 2002, Agarwal and Venkatesh, 2002; AMIPCI, 2004). The culture dimensions are shown in TABLE 2.

Several authors use the site navigation to assess perceptions of usability (Nielsen, 1994, Agarwal and Venkatesh, 2002; Palmer, 2002, Hall et al., 2004). The effects on the usability dimensions are restricted to site navigation tasks such as selecting an item, obtain personal data and product selection of a music sales company. The dimensions of culture are shown in TABLE 3

TABLE 2. DESCRIPTION OF THE DIMENSIONS OF CULTURE

DIMENSION	ITEM	DESCRIPTION
Risk aversion RISK	RISK1	Safety is an important concern in my life
	RISK2	Life is so uncertain that I must be in constantly alert to not be in disadvantaged
	RISK3	It is important to consider different points of view when I take personal and social decisions
Collectivism / Individualism COLECTIVISM	INDIVIDU1	I like to share little things with my neighbors
	INDIVIDU2	Being an unique person is important to me
	INDIVIDU3	The decisions achieved in group are better than those achieved individually
	INDIVIDU4	Usually I sacrifice my own interest for the benefit of my group
	INDIVIDU5	I prefer to rely on others
	INDIVIDU6	It is important for me to be useful for others
Power distance POWER	POWER1	El jefe de uno es una persona igual a cualquier otra My manager is a person like any other
	POWER2	Managers are always inaccessible and distant
	POWER3	The way to change society is to make everyone equally powerful
	POWER4	Other people are a threat to my power of one and I cannot trust them
Masculinity/ Femininity MASCULIN	MASCUL1	Having a career is more important for men than for women
	MASCUL2	Men usually solve problems with logical analysis, women generally are more visceral
	MASCUL3	Solving difficult problems usually require a strong and active approach, which is typical of men
	MASCUL4	There are some jobs that a man can always do better than a woman

TABLE 3. USABILITY DIMENSIONS DESCRIPTION

Dimension	Item	Description
Security SECUR	SECUR1	The site is secure
	SECUR2	I trust in the site
	SECUR3	I relied more on the site as it has social networking (myspace, twitter, facebook)
Navigation Efficiency	EFICIENCY	The site is simple to navigate
Control CONTROL	CONTROL1	It is easy to do what I want to do
	CONTROL2	The performance of the site was excellent
Content CONTENT	CONTENT1	The site provides good information about products
	CONTENT2	The image quality is great
	CONTENT3	The site produces purchase wishes
	CONTENT4	I identify with the images of the site
Emotion EMOCION	EMOCION1	The site is interesting
	EMOCION2	The site is fun
Easiness of use	EASY	Obtaining information is easy
Language	LENGUAGE	I identify with the language used on the site

Covariance structure model (CSM)

In order to formulate the covariance structure model there were carried out two stages proposed by Anderson and Gerbing (1988): 1) To analyze the goodness of the psychometric properties of the measuring instrument used, performing a confirmatory factor analysis (CFA). 2) After the goodness acceptance of the measuring instrument, this is modified including the theoretically proposed structural relationships that are analyzed by a Structural Equations or Covariance Structure Model (CSM). Before using these tools, prior analysis was required, such as inspecting the homogeneity of the standard deviations and doing multicollinearity and normality testing of variables. Subsequently it was conducted an exploratory factor analysis that allowed to observe the structure of relationships among variables.

Preliminary analysis: homogeneity, multicollinearity and normality

It was found that there is consistency among the variables due to the observance of averages and standard deviations. Thus, we ensure good adjustment goodness in later models; it is advisable that there are no variables in the model with a lot of variability and others with few. The multicollinearity test of the tolerance statistical values are above 0.1 and the inflation variance factor (IVF) is below 10; therefore it is not perceived a possible problem of multicollinearity for any variable. Thus, the variables of the model met the requirements for their use.

Exploratory factor analysis

To assess the unidimensionality of the latent concept, we performed an exploratory factor analysis. The extraction procedure has been the Principal Component Analysis (PCA) for the dimensions of cultural values and usability. Regarding the results of the usability dimensions, the measure of sampling adequacy Kaiser-Meyer-Olkin (KMO) has a value of 0.873, higher than the acceptable value of 0.7, while the Bartlett's sphericity test has a p-value inferior than the significance level (0.05) to reject the null hypothesis that the correlation matrix is an identity one; therefore it is concluded that the factor is adequate. Concerning the test for the variables of culture, the measure of sampling adequacy Kaiser-Meyer-Olkin (KMO) has a value of 0.720, higher than the acceptable value of 0.7 and the Bartlett's sphericity test has a p-value lower than the limit of level of significance (0.05) to reject the null hypothesis that the correlation matrix is an identity matrix, so we conclude that the factorial is adequate.

Model applied to Spain

The model for Spain (FIG. 2) consists of ten variables. Masculinity only has impact on the efficiency of navigation, but with a negative sign ($\lambda = -2.347$) in an approach contrary to the expectations. Collectivism also influence this variable ($\lambda = 2.044$), which is also reflected in emotion ($\lambda = 2.052$), control ($\lambda = 2.052$), content ($\lambda =$

2.947) and security ($\lambda = 2.028$).

Of these, the greatest influence of this construct is produced on emotion. For Spain, the variable of perceived risk emerges, which is reflected in the content ($\lambda = 3.100$). In addition, power distance, measured only by the indicator "Security is a major issue in my life" influences the language positively ($\lambda = 3.818$), however the content ($\lambda = -1.654$) is influenced negatively.

Verification of the hypothesis (TABLE 4) was carried through the analysis of each of the standardized coefficients and their significance level. Regarding risk aversion, no relationships were found between safety and efficiency or easiness of use. The five hypotheses for collectivism are accepted, while for the dimension of masculinity / femininity only one hypothesis was accepted. In terms of power distance, the only hypothesis not proved was the one related to its influence on safety.

TABLE 4. VERIFIED HYPOTHESIS FOR SPAIN

Variables	HIP.	Verification
Risk Aversion	H1c: (-)	YES. With opposite sign
Collectivism	H2a: (-)	YES. The measured variable is individualism, in opposition to collectivism, the sign changes
	H2b: (-)	YES. The measured variable is individualism, in opposition to collectivism, the sign changes
	H2c: (-)	YES. The measured variable is individualism
	H2d: (-)	YES. The measured variable is individualism
	H2e: (-)	YES. The measured variable is individualism
Masculinity	H3c: (+)	YES. With opposite sign
Power Distance	H4b: (+)	YES. With opposite sign
	H4c: (+)	YES

FIG. 2 STRUCTURAL EQUATION MODEL FOR SPAIN

Model applied to Mexico

The model for Mexico only comprises two cultural variables: Sex ratio vs. femininity and collectivism. The two appear as latent variables and all enclose their reflex variables (Fig. 3).

In terms of usability variables, four of them are exposed as latent variables and two as observable variables. The observable variables are efficiency and easiness of use, which are influenced by the masculinity variable $\lambda = \lambda = -2.929$ and -3.224 respectively. It can be noticed that values have negative signs. There is a latent variable that influences also masculinity, control ($\lambda = -2.016$). The three variables have a different weight, being the ones with the greatest influence easiness of navigation followed by the navigation efficiency. The three variables are significant at 1%. The estimators for the collectivism variable are: efficiency of navigation, which is an observable variable with $\lambda = -2.968$. The other four appear as latent variables, being content the one with most significance ($\lambda = 3.166$), followed by excitement ($\lambda = 3.110$), control ($\lambda = 3.045$) and finally safety ($\lambda = 2.693$), all with positive signs. Again, it is collectivism the cultural dimension that best represents cultural differences. These values are consistent with what has already been shown in other studies (Yano and Seo,2003; Zandapour and Harich, 1996; Matsumoto et al., 1998) on these dimensions, which also explains the behavior and characteristics of many countries and are also key parts to deduce the origins of cultural differences that cause problems to achieve success with a website.

FIG. 3 STRUCTURAL EQUATION MODEL FOR MEXICO

TABLE 5 shows the assumptions that have been demonstrated for each cultural dimension regarding the variables of usability

TABLE 5 VERIFIED HYPOTHESES FOR MEXICO

Variables	HIP.	Verification
Collectivism	H2a: (-)	YES. The measured variable is individualism
	H2b: (-)	YES. The measured variable is individualism
	H2c: (-)	YES. The measured variable is individualism
	H2d: (-)	YES. The measured variable is individualism
	H2e: (-)	YES. The measured variable is individualism
Masculinity	H3a: (+)	YES
	H3b: (+)	YES
	H3c: (+)	YES

Results and conclusions

Structural equation models have helped us to propose and analyze a complete model of analysis about cultural perception and demonstrate that the site's users perceive the existing cultural differences since the web site was developed by a person of a particular national culture. The resulting models were different for each country; this is that users from Spain perceived differently the site designed by Mexicans. These results are consistent with authors such as Barber and Badre (1998) that had already pointed out: there are elements prevailing in the interface design within a given culture, known as cultural markers.

Only the model of Spain validates the four constructs of culture, although "power distance" is perceived as a reflecting variable. Stronger relationships between culture and perception of a given site are present on the "collectivism / individualism" level, construct present in two models with the five variables of usability that were proposed in the cultural model. Indeed there is a relationship between culture and usability for the dimension of collectivism / individualism. The positive and direct influence from collectivism to usability is given for the dimension of "content" for both Mexico ($\lambda = 3.166$) and Spain ($\lambda = 2.067$). As these two nations are more oriented toward collectivism, these results agree with the importance attached to the site's content, as Gibbs et al (2003) mentioned in their work. The dimension of collectivism has been consistent. This hypothesis is confirmed in its entirety to this cultural dimension, as a consequence the higher the degree of collectivism of a society, the lower the perceived safety of a site. As the site has been designed in English, but considering the collectivist culture (Mexico), issues related to security had to take into account to increase the control on the site, prioritizing the site content as well as limiting the freedom of navigation.

Relationship between Web design and cultural differences has been being discussed since the early years of the World Wide Web, where it begins to emphasize that culture plays an important role in the design of information systems (Gallupe and Tan, 1999). Despite the facts that a site can be written in a language such as English and can be directed to an international market, it must have a design that emphasizes the quality of the offering, to create interest in the prospective buyer. Nevertheless, many companies create multicultural designs or different versions for distinct markets but with an ethnocentric view, which is detrimental to the success that the site may have (Becker and Mottay, 2001). Again, is the consideration of cultural issues a key to the successful design of a site and avoid

that if it will be translated, it is transformed with mistranslations and grammatical inconsistencies that are not appropriate to the culture.

Not only should the limitations of a national culture also be considered, but also the technological infrastructure and economic development that may affect the development of electronic commerce (Jungles and Watson, 2004). The lower the country's economic development is, the implementation of successful models in other countries with economic development does not mean it will succeed in a country with less economic development, consequently users' concerns about safety should have to be taken into account. This is the reason of why a good design of a site that comprises good information about the site or products, etc., can help to reduce that risk perception (Zahir et al, 2002; Graeff and Harmon, 2002; Cunningham et al. , 2005; Pollach, 2006).

The issue of designing influences the reduction of uncertainty in a site, when it allows confidence and enables the navigation to be more accessible. It is precisely in the study of culture that has been confirmed that designing forms vary according to cultural values of a country (Marcus and Gould, 2000), in this case, using Hofstede's cultural dimensions to test the hypothesis it was proved that there are indeed different appreciations on a site, according to the culture that visits. The usability-engineering design of a site helps to make it more efficient and reduce any potential fears, but this is not enough. Once more it is emphasized that cultural differences should be considered (Nielsen, 1994; Quesenbery, 2001; Agarwal and Venkatesh, 2002; Gray and Salzman, 1998). While there have already done work on cultural differences and usability, these have been focused on making a site optimal and it has not found any of them in the test for various nationalities.

The models emerged from this study indicate that indeed, not only is necessary to make use of usability, but also allow for cultural considerations. Moreover, it is demonstrated that a universal site cannot exist because the cultural significance is such that, although the origin of the designer is not detected, the appreciation differs slightly by users from distinct nationalities. It is especially important to note that one of the cultural dimensions that represent a weighty role in cultural issues is individualism / collectivism (Ferreira, 2002).

Limitations of work and future research

The most important limitation of this work comes from its exploratory nature and foremost from the source of data collection. The survey was based on a sample of convenience that cannot be regarded as homogenous. Firstly, because although it has been distributed mainly among university students in Mexico and Spain, other users have had access the Web and therefore have produced biases related to age or educational level, mainly. Therefore, in subsequent studies it will be considered conclusive this limitation by designing a sample that, although it could be convenience, has the same amount for socio-demographic variables that may produce a higher bias in relation to the cultural dimensions or the principles of usability. Second, the participants are not necessarily music buyers and collectors of records, consequently the user characteristics of collectors are not reflected in the site preferences. For further studies, we believe mandatory to use samples that truly represent the people who visit such sites. Another limitation regarding the chosen sample is that although the web is the model actually used by several companies, it does not represent one of the major industrial markets. Although sales of vinyl records in formats have increased, it is a fact that the music industry is in crisis and buyers of such products are a very definite segment with their own characteristics in the industry.

The Mexican sample is basically formed by students from Guadalajara, making it fairly homogeneous, while the Spanish sample has been more dispersed and for that reason more heterogeneity, but it was mostly held in the Community of Madrid. Besides the future lines already pointed out in regard to the limitations, another possibility is to make a real investigation into only one of these countries, with samples representing the whole population and not just the university sector. Given that the U.S. is a country where many people live from different national origins, also it could even be perform a segmentation in which the Hispanic market is compared with other segments. Even if research is conducted again in the analyzed countries, results from the U.S. Hispanic segment could be compared with the market in Latin America and Spain.

Despite all these limitations, our study represents a starting point that corresponds to a clear contribution in the field of electronic commerce. Therefore, we intend to develop further research where more cultures become

involved. These future studies will incorporate cultures that do not have a Western origin, including emerging markets like China and India. Other countries where Internet is already well established and developed but they belong to cultures other than the Western world can be also incorporated, such as Korea and Japan. In addition, Brazil also will be contemplated since it is an emerging country and Latin America, but also has a historical background and current development different from its Latin American neighbors.

The Mediating Effect of Knowledge Sharing Behaviors on Employee Job Satisfaction in the Context of Learning Organization

Monthon Sorakraikitikul, monthon.sor@gmail.com

Sununta Siengthai, s.siengthai@ait.ac.th

Asian Institute of Technology, Thailand

Abstract

Recent research suggests positive association between learning organization and various outcomes on employee's attitudes and behaviors including job satisfaction, organizational commitment, motivation to transfer learning, and turnover intention. In the context of learning organization, knowledge sharing behaviors play a critical part in leveraging and generating the new knowledge for solving problems and improving organizational performance. The primary purpose of this research is to investigate the mediating effect of knowledge sharing behaviors in the context of learning organization on the employee job satisfaction. Based on analysis of 2,419 sample respondents from various organizations/industries, the structural equation modeling (SEM) analyses were conducted. The results reveal that knowledge sharing behaviors are positively and significantly associated with employee job satisfaction. The research results also confirm the practices of the learning organization in Thailand.

Introduction

Today many organizations are faced with more competitive, complex and dynamic environment as a result of globalization (Lopez, Peon, & Ordas, 2004). Learning organization that focuses on managing organizational knowledge (Kelloway & Barling, 2000) is the strategic management tool that is widely adopted to ensure that organizations could sustain their competitive advantage and hence survival (Afiouni, 2007). In a knowledge-based economy, organizations inevitably turn their focus onto human resources in the organization as well as knowledge sharing activities (Kelloway & Barling, 2000).

The results of previous studies suggest the relationship of organizational learning capabilities with key desired factors in human resources development in term of learning transfer, turnover intention, and organizational commitment. Many studies provide strong supporting evidences on the relationship between learning organization and job satisfaction (Egan, Yang, & Bartlett, 2004; Wang, 2007).

This research aims to investigate the mediating effect of knowledge sharing behaviors between organizational learning capabilities and employee job satisfaction.

Literature Review

Learning organization could be considered relatively new concept in the field of management and organization theory (Lien, Hung, Yang, & Li, 2006), especially in the field of human resource management (Kontoghiorghes, Awbrey, & Feurig, 2005; Lien, et al., 2006; Song & Kolb, 2009; Yang, Watkins, & Marsick, 2004). Learning organization is the accumulative function of creating, acquiring, transferring knowledge as well as modifying the behavior to reflect the new knowledge (Garvin, 1993). It is potentially a path way for change especially for the evolution of organizational culture (Senge, 1990). One of the major objectives in building the learning organization is to enhance the capacity to learn, adapt and change (Gephart, Marsick, Buren, & Spiro, 1996).

Organizational learning concentrates on the processes or activities in organizations (Aggestam, 2006; Nevis, Dibella, & Gould, 1995), especially those with the processes of change (Cook & Yanow, 1993; Lien, et al., 2006). Organizational learning involves the experiences and actions of members in the organization, the integration of structures, strategies, and processes need to exist in order to provide adaptive learning environment (Goh, 2003). In this regard, learning organization is supported by organizational learning culture as a bundle of mechanisms of

tangible and intangible resources allocation (Bhatnagar, 2006) especially to bind knowledgeable or valuable workers to the desired changes.

Findings from previous empirical studies show that organizational learning capabilities are related with the organizational financial performance measures and innovation aspects (Ellinger, Ellinger, Yang, & Howton, 2002). Organizational learning capabilities are also found to be related to human related issues in term of motivation to transfer knowledge, turnover intention, organizational commitment and job satisfaction (Egan, et al., 2004; Wang, 2007)

Loermans and Flink (2005) proposed that organizational learning capabilities or learning organization acts as enabler processes or fosters culture mechanism in creating changes that yield some particular useful knowledge for people in the organization to further apply for their work to meet the desired organizational objectives and vision (Loermans & Fink, 2005). Supporting this notion with the idea proposed by Liao (2008) which emphasized that in order to encourage interaction and communication among knowledge workers within and across business units, organizational culture or policies could promote or facilitate these actions to happen as the way in pursuing for competitive advantage (Liao, 2006, 2008).

As organizational learning capabilities are an enabler factor for knowledge workers sharing and exchanging of their particular knowledge toward work (Liao, 2006, 2008; Song, 2008; Song & Kolb, 2009), then knowledge sharing behaviors seem to be the proactive behaviors as well as key output from the processes of change in the learning organization. Adopting the theoretical concepts developed in the Western culture, this research addresses the main research question on what is the mediating role of knowledge sharing behaviors in the context of learning organization in creating employee job satisfaction? Our hypothesis for this research is formulated as follows:

Research Hypothesis: Knowledge sharing behavior mediates the relationship between organizational learning capabilities and job satisfaction.

Methods

Instruments

This research employed the self-reporting questionnaire survey to assess the individual employee perception in an organization. This research adopted many available and well-tested instruments, i.e., DLOQ, KSB and MSQ.

Dimensions of learning organization questionnaire (DLOQ) developed and used by Watkins and Marsick, 1993 and later validated by many other studies such as Marsick & Watkin (2003), Yang et.al. (2004), Song, Joo, & Chermack (2009). Based on the original short version of 21 items, this research measured the learning organization as multidimensional construct (Yang, et al., 2004) and named this construct as organizational learning capabilities (OLC) which still assessed the important of seven dimensions of the learning organization : continuous learning (OLCL), inquiry and dialogue (OLDI), team learning (OLTL), share learning system (OLSL), empowerment (OLEM), external connection (OLCE) and supportive leadership (OLLL). Each sub dimension was measured by three items, then total of twenty-one items were measured to assess the organizational learning capabilities (OLC) in this research.

The second instrument is knowledge sharing behavior (KSB),based on the knowledge sharing process proposed by Van den Hoof and Van Weenen (2004). The knowledge sharing process is divided into two different variables: knowledge donating and knowledge collecting (Bart. Van den Hooff & Van Weenen, 2004). As knowledge donating and knowledge collecting could be found both within and with other working units and according to procedure from previous studies, this research applied four constructs to assess the knowledge sharing behaviors (KSB): knowledge donating within department (KSDO_IN), knowledge donating with other department (KSDO_OUT), knowledge collecting within department (KSCO_IN) and knowledge collecting with other department (KSCO_OUT) (Bart Van den Hooff & De Ridder, 2004; Bart. Van den Hooff & Van Weenen, 2004; Bart Van den Hooff, Vijvers, & De Ridder, 2003). Two sub-constructs of knowledge donating were measured by three items, and two sub-constructs of knowledge collecting were measured by four items, resulting in total of fourteen items and all were incorporated to one construct as knowledge sharing behaviors (KSB).

To assess the job satisfaction, this research adopted the short version 20 items of Minnesota Satisfaction Questionnaire (MSQ) as it was frequently used in many research to assess employee's job satisfaction (Wang, 2007; Weiss, Dawis, England, & Lofquist, 1967). This research divided job satisfaction into three sub constructs: general job satisfaction (JS_GEN), intrinsic job satisfaction (JS_IN) and extrinsic job satisfaction (JS_EXT).

All items of three main constructs in this research were measured by a six-point Likert-scale, organizational learning capabilities and knowledge sharing behaviors constructs range from 1 = almost never to 6 = almost always, while items in the job satisfaction were ranging from 1 = completely false to 6 = completely true.

All of the instruments used in this research were originally developed in English. Thus, an English-to-Thai translation and back translation from Thai to English was performed carefully. Then, the conceptual equivalence was checked to reach the final version for the survey

Sample and Data Collection

The convenience sampling from different organizations and industries was applied, targeted at individual employees who work in an organization from various positions. The researcher approached the HR manager or person in charge at the organization in order to get the permission and asked for further distribution of the questionnaire to interested employees who would like to participate in this research. Initially, 2,900 questionnaires were distributed. About 2,634 were returned and 2,419 are usable, which is about 83.41 percent response rate.

Most of the respondents are female (65.52%) holding a bachelor's degree (57.79%) with permanent employment (93.51%). Most are working at non-management level (74.65%). The majority of the respondents also work in the for-profit organizations (74.53%) in various functions such as in the marketing and sales (18.60%), administration and supporting staff (15.30%), in financial and accounting (13.31%) and in the operation and production (10.21%). The data were obtained from 146 different organizations.

Data Analysis

In this research, about 2,419 sample responses are analyzed. Normal distribution test, scale reliability, construct validity, discriminant validity, correlation analysis, and structural equation modeling (SEM) were conducted to examine the proposed relationships among three constructs. SPSS 17 and LISREL 8.72 were utilized in this research for data analysis. In addition, to test the mediating role of knowledge sharing behaviors between organizational learning capabilities and job satisfaction, this research followed the procedure proposed by Holmbeck (1997), which is also widely used in many research (Holmbeck, 1997; Prajogo & Sohal, 2006)

Results

The results of normal distribution analysis by Kolmogorov-Smirnova show that all fourteen factors under three main constructs are not normally distributed. In addition, skewness of the variables varies between -0.357 and -0.09; and the kurtosis varies between -0.438 and 0.046, which indicate that there is no substantially non-normal distribution. In this regard, the estimation with maximum likelihood (ML) could still be performed as the skewness below 2 and kurtosis below 7 (Curran, West, & Finch, 1996). Reliability test based on sub-dimensions of each construct were performed by the item internal consistency. The results of Cronbach's alpha shown in TABLE 1, all are above the criteria at 0.70 except extrinsic job satisfaction (JS_EXT) at 0.64 and Continuous learning (OLCL) at 0.68.

To ensure the construct validity of each sub-measurement construct, the confirmatory factor analysis (CFA) was performed with all three proposed research constructs. Even Chi-square is the most fundamental measure but it tends to reject the model when investigating with large sample. Hence, several fit indices were used in this research to examine model fit to the collecting data including root mean square error of approximation (RMSEA), root mean square residual (RMR), goodness of fit index (GFI), comparative fit index (CFI) and non-normed fit index (NNFI). RMSEA value less than .05 indicates good fit, and from .80 to .10 indicating moderate fit. RMR values less than .05 or less indicate well-fitting model, while GFI, CFI and NNFI value approach 0.90 providing the acceptable model fit

(Byrne, 1998). The results of an overall CFA analysis, the measurement model of three proposed constructs provides the model fit to data [χ^2 (df=71,n=2419) = 1060.18, p=0.00; RMSEA = .076; RMR = .05; GFI = .94; CFI = .98; NNFI = .98] with values of all factor loadings above .68. This indicates that each set of measurement items under the three investigated constructs reflecting the theoretical latent constructs. In other words, CFA results confirmed the construct validity of the three conceptual models within the Thailand context.

Then, the discriminant validity test was performed to establish the distinction between organizational learning capability and knowledge sharing construct, which test procedures adopted from Ahire et al.(1996) and Prajogo and Sohal (2006), (Ahire, Y.Golhar, & Waller, 1996; Prajogo & Sohal, 2006) . In this approach the two models were analyzed by confirmatory factor analysis (CFA). The first model allowed the correlation between two constructs to be estimated and the second model the correlation was set to one. Each model provides the Chi-square (χ^2) with different of degree of freedom at 1. The different of Chi-square (χ^2) values then were compared with critical value from Chi-square table. The results is $\Delta \chi^2$ of 198.41 with Δ df of 1, as higher than the value from Chi-square table (6.64, p<.01), so this is verified as significant. This evidence suggests that organizational learning capability and knowledge sharing are different constructs.

The results from the correlation analysis provided in TABLE 1 assess the interrelations among the internal dimensions of these three constructs. All of the correlation coefficients were significant. Then, the relationships among the three constructs were further explored according to the proposed hypothesis with a two-step approach of SEM. First, to assess the model fit to the data of the proposed structural equation, several fit indexes were estimated including Chi-square, χ^2 /df, RMSEA, RMR, GFI, CFI and NNFI. Second, to measure the magnitudes of the causal relationship among the hypothesized constructs, structural equation analysis was conducted.

Furthermore, the procedures proposed by Holmbeck G.N. (1997) to assess the mediating role of knowledge sharing behaviors also adopted, two models were compared and tested for their significant difference (Germain & Spears, 1999; Holmbeck, 1997; Prajogo & Sohal, 2006; Rupp & Cropanzano, 2002).

The two models show the relationships among organizational learning capabilities (OLC), knowledge sharing behaviors (KSB) and job satisfaction (JS). The model 1 (Fig. 2) assumes that knowledge sharing behaviors fully mediate the relationship between organizational learning capabilities and job satisfaction, so no direct path is presented from organizational learning capabilities to job satisfaction. The model 2 (Fig.3) adds another path from organizational learning capabilities and job satisfaction. This model presents partial mediation role of knowledge sharing behaviors. The results from testing SEM with LISREL suggest that all standardized path coefficient between any constructs as well as all factor loadings in each construct from both tested models also show the significant level at p<.01.

TABLE 1: CORRELATION ANALYSIS AND DESCRIPTIVE STATISTIC

Construct	Mean	SD	1	2	3	4	5	6	7	8	9	10	11	12	13	14

FIG 1: THE STRUCTURAL RELATIONSHIP WITH A FULLY MEDIATION MODEL BY KNOWLEDGE SHARING BEHAVIORS

χ^2	Df	χ^2/df	RMSEA	RMR	GFI	CFI	NNFI
1396.71	72	19.3988	0.087	.12	.92	0.97	0.97

FIG 2: THE STRUCTURAL RELATIONSHIP WITH A PARTIAL MEDIATION MODEL BY KNOWLEDGE SHARING BEHAVIORS

χ^2	Df	χ^2/df	RMSEA	RMR	GFI	CFI	NNFI
1060.18	71	14.9321	0.076	0.05	0.94	0.98	0.98

The model 1 as full mediation by knowledge sharing behaviors provides $\chi^2 (df = 72, n=2419) = 1396.71$, RMSEA = .087, RMR = .12, GFI = .92, CFI = .97 and NNFI = .97. The model 2 as partial mediation by knowledge sharing behaviors provides $\chi^2 (df = 71, n=2419) = 1060.18$, RMSEA = .076, RMR = .05, GFI = .94, CFI = .98 and NNFI = .98. The results is $\Delta \chi^2$ of 336.53 with Δ df of 1, higher than the value from Chi-square table (6.64, $p < .01$).

This concludes that these two models are significantly different and the model 2 indicates the better fit by providing higher goodness of fit.

The results of total effect from organizational learning capabilities to job satisfaction between the two tested models provide the satisfactory sign, model 1 shows total effect at 0.66 and model 2 at 0.75. Even though there is some portion of variance that could not explain on job satisfaction by organizational learning capability with or without being mediated by knowledge sharing behaviors, the result of total effect in model 2 provides the higher value. This suggests that knowledge sharing behaviors affect employee job satisfaction in the organization.

Then, for mediating role, the result suggests that knowledge sharing behaviors only partially mediate the relationship between organizational learning capabilities and job satisfaction.

Discussion and Conclusion

This research aims to extend the finding of the existing studies in the area of learning organization and human resources development by incorporating a new variable as knowledge sharing behaviors into the study. Item reliability and construct validity were found to be statistically acceptable for the three investigated constructs in term of model to data fit. The simple correlation among sub dimensions of each construct also suggested statistically acceptable. Importantly, the discriminant analysis found the distinction between organizational learning capabilities and knowledge sharing behaviors. The results from standardized path coefficient presented that organizational learning capabilities and knowledge sharing behaviors both impact on job satisfaction.

Importantly, the results from the analysis found the mediating role of knowledge sharing behaviors on organizational learning capabilities and job satisfaction, which support the notion from previous studies that the learning organizations are more concerned with human or interaction of the workers in the organization (Marsick & Watkin, 2003). This shows that employees have satisfaction on their job from performing the sharing behaviors in the context of learning organization. Then, the findings from this research could emphasize the important role of knowledge sharing behaviors in term of increasing job satisfaction and as an important or proactive part of learning practices in the organization.

HRD practitioners should consider the benefits of knowledge sharing as one of the mechanisms to enhance the job satisfaction level in the organization. As well as treating as one of the important strategies for transferring knowledge among workers in the organization. In addition, knowledge sharing could support the traditional training program in helping to exchange both tacit and explicit knowledge of the workers which result in across the board competencies level improvement.

The findings of this study are consistent with previous studies that emphasize the important role of learning organization as the supporting context in the organization. Then, maintaining the aspect of learning organization as well as creating management stimulus also needs to establish, both in order to encourage employees to share work-related knowledge and to drive employee performance to meet various desired organizational performance measures as well as sustain the competitive advantage.

In this study, all variables were measured by the self-reported on individual perception, with cross-section survey, so a longitudinal quantitative approach with more objective measure may pursue for further study. In addition, as the proposed framework was developed from theoretical assumptions, some other alternative models could be considered possible based on data analysis.

Only a few studies investigate the role of knowledge sharing in the context of learning organization, this study also investigates the relationship with only the prominent variable in the field of human resource development which is job satisfaction. More studies also should investigate role of knowledge sharing with other important variables such as turnover intention, organizational commitment and self-esteem. Other possible moderators and mediators such as leadership, employee attitudes, organizational culture or policies as well as management strategies also should be investigated.

Implementation of Lean Principles to Non-Manufacturing Processes Introducing Case Study with Focus on Human Factor

*Milan Fekete, milan.fekete@fm.uniba.sk

Comenius University Bratislava, Slovakia*

Abstract

Lean management in non-manufacturing processes is a topic gaining still more and more attention in professional literature and practice. Literature sources offer wide range of tools, instructions and recommendations for successful implementation and sustainability of a newly-created system. However, it is practical experience with introduction of lean principles to offices, which reveals that every organization needs its own approach, adjustment of the general principles to particular conditions and special care devoted to employees. Often the companies encounter very unique problems.

The paper elaborates project of implementing a lean system to a real organization in Germany between 2001 and 2006. Though the company is of manufacturing character, lean initiative started in departments other than production. After identifying imperfections in the way the orders were handled, the company gradually expanded implementation to other departments as well. A three-level model of implementation was developed, starting with self-organization of each employee and workplace, defining standards of a work team on the second level up to standardization of processes on the third level.

A main problem the company had to tackle was the trust of employees and their engagement in the project. Therefore each level of the model was accompanied by a set of workshops in order to secure understanding and support of the workforce. Though the achieved success can be expressed in terms of financial indicators (EBIT increase by more than 16%) it can be mainly observed in satisfaction of employees and other capabilities.

Introduction

The need for the creation of lean management was identified decades ago; both scholars and practitioners dedicated extensive amount of time and effort into in-depth research and into formulation of new concepts. Even though lean management has been originally introduced into the manufacturing aspect of the business world, a recent trend emerging all across the world is applying lean management principles within non-manufacturing organizations and thus benefiting from reduced costs and increased effectiveness. The importance and suitability of this new approach has become evident due to the recent crisis raging through economies throughout the world. This paper addresses lean management in relation to human resources and presents a case study from a German organization that reveals several issues that can arise when applying lean management methods on real people. The paper introduces, step-by-step, a unique model which reflects the experience of the company with lean implementation acquired over years, and shows how any company can achieve great results by giving its workforce the power to make changes.

The company Alpha AG was established in 1899 as a family company. For over 110 years, it has been concentrating on the development, production and distribution of turbo machinery - steam turbines, compressors and turbo-blowers. It is a middle-sized company with five operations in Germany and other scattered throughout Europe and in USA. In 2001 the company started implementing the improvement system (never really calling it "lean" system as this term was considered to be de-motivating for the employees). The company managed to achieve great results in financial terms. The profitability increased more than sevenfold from original 2.7% in 2001 up to 19% in 2006 with 2006 EBIT at the level of €34 million. Sales reported in 2006 reached €270 million, which means there was a 125% increase compared to 2001. Total number of Alpha AG employees was 1,400 (580 in the factory that is analysed in this text) in 2006. In autumn 2006 100% shares in Alpha AG were acquired by a supranational corporation.

Starting points

The main goal of any entity is to make money. Achievement of this goal is usually expressed through margin. To say it simply, here we refer to the profit from turnover, which is calculated at the end of the accounting period. Internationally, this parameter is labelled as EBIT (earnings before tax and interest). Thus, the business success can be defined rather easily - each entity has to make money. But why only

few companies manage to keep their profit above the level of 5% and even fewer above 10 or even 15%? This is a simple question to answer. The success cannot be achieved by a single or few individuals at the top of the organizational structure; everyone's involvement is a key to success and this is an objective, which cannot be only mentioned here and there at regular company meetings. In order to really achieve significant profit growth, every employee has to be interested in doing so.

So how we do this? How can we motivate the employees and thus to achieve goal of any business? The hint is rather simple here. Let the employees to improve the processes themselves. Almost every employee gets motivated by being fully responsible for his/her own work and majority of companies wish to employ these individuals. Therefore responsibility should not be a barrier for forming the right company culture. Though this may sound easy, the process of forming adequate company culture with a defined and accepted responsibility is rather long and at the very beginning the company has to decide what has to improve.

3-Level Model

The machine components produced by Alpha AG are highly capital-intensive, custom-made products. In order to produce them, the company has to purchase expensive input materials, which were originally financed by loans provided by the financial institutions. The number of orders, entering the process through the sales department, was large. The sales department needed several weeks just to process the order and soon enough, it got overwhelmed by incoming orders. The more orders the sales department processed, the more borrowed funds were invested into purchase of expensive material. The company got to the point, where its cash-flow was not sufficient to cover the expenses. It was obvious that something had to be done. In order to solve the problem, the company avoided changing the number of employees at the sales department (which was later on identified as the "bottleneck"), but rather concentrated on creating such structure, where the employees would communicate and cooperate together and would be aware of each other's work. The results were faster order processing and increased satisfaction of employees. This is how the company developed its 3P system for improving processes within organization, with products, personnel and process representing its main core. The 3-level model is a result of efforts of the company aimed at involvement of employees in 3P system.

In order to engage all employees, the company developed and gradually improved the model of workshops consisting of three levels. The main goal of this model is to make sure that the information flows within the company continuously, to the right place, in the right volume, and to the right persons. The first level of the model focuses on self- organization of every employee at every workplace. The second level concerns improvement of information and material flow in every process in every department of the organization and the third level simply emphasizes improvement of team work at the workplaces. To sum it up, at the first level the employees are trained to work next to each other, at the second level they are encouraged to work with each other and at the third level to work for each other. The entire concept was introduced at an initial workshop, which lasted two days at the beginning; later it was cut just to one day as employees were more familiar with the concept. Upon introduction of the concept, the company was ready to work with all three levels. Here it is important to note that in compliance with the principles of continuous improvement, neither of levels is ever completed or closed. During the initial phase the company had to deal with the fact that the employees were willing to accept only partial responsibility; especially supervisors and middle managers did not want to delegate responsibility to their subordinates.

Despite the fact that Alpha AG was reporting profitability of 3% in 2001 and was a market leader with very good position worldwide, the company still had to face several internal problems, which became the reasons for seeking for new solutions.

- First of all the workplaces were in mess; no one really cared about keeping them neat and tidy; access to information and tools was complicated.
- The company kept high inventory of in-process items. The flow of information and material was inhibited and had to wait for further processing.
- The storing spaces in offices (for data) did not have any structure, which would be unified throughout the plant.
- Especially in the offices many processes were made twice.
- The throughput time of any item was significantly long.
- Collection of information took a long time and it was not delivered to a person responsible for making decisions in time.
- Despite implemented ISO managerial system, the standards were often not followed and the leaders let their employees to apply their own standards.

- At several workplaces the standards were missing completely.
- The processes were not set correctly and they prevented a single piece flow.

Through improvement the company endeavoured to achieve at least three general goals: quality improvement, shortening the individual working processes and shortening the overall throughput time. As a result of introduced changes, the company was able to reduce time needed for construction of nuclear power plant components (starting with an order up to payment for finished goods) from 3 months to only 5 days despite the fact that even the 3-month period was a goal hard to be achieved by many competitors. Out of all types of waste, such as overproduction, unnecessary transportation, inventory, motion, defects, over-processing and waiting, the company identified 2 types to be critical for the company: time spent on searching information and inventory. The survey showed that an employee spent in average 6 weeks per year by searching for information. One has to add another 6 weeks of vacation enjoyed by the German workforce and by a simple calculation the company found out that there are only 9 months in a year when an employee really creates value. Thus, there emerged an obvious need to cut the time necessary for collecting information. It was not possible to reduce this time to zero, while even in perfect system it takes a little time to acquire needed information, even when one knows where to find it. For example, after one year of workshops, the employees removed the doors from their cabinets as the act of opening and closing the door does not add any value; they rearranged the cabinets so the information could be found easily, and thus, they saved almost 20% of the time needed for searching information. The main point here was to present the need to reduce searching time to the employees and let them find their ways to do that. During the process of reducing waste, Alpha AG came to a conclusion, that significant improvement of the entire process can be achieved not only through improvement of discrete processes, but rather through synchronization of partial processes.

Level 1

The first level of the 3-level model of Alpha AG consists of the rearrangement of the workplace; at least that is how the employees perceive this at the beginning. However, by passing this level, more is achieved than just neater workplace. This step represents basis for improvement of information and material flow. In this phase the mobile walls between the workplaces are removed¹¹ so to avoid “cell-thinking” and the employees learn how to arrange their workplaces so to work efficiently. Simply to say, the working environment is rearranged so it enables continuous, barrier-free information flow and high efficiency of work. In order to implement this phase correctly, all obvious waste has to be removed. In offices this means to discard outdated documents and remove or sell useless furniture. Office supplies and devices are stored centrally and are accessible by all. In Alpha AG 30 to 50 employees working in the offices discarded up to 2 tons of paper, reused 300 to 500 paper files and removed 20-50 pieces of furniture from their workspace. It clearly shows what great results can be achieved when all employees look together at their workplace in order to remove what they do not need. In this step Alpha AG also collected 2-year worth volume of office supplies. One challenge the company has to face in this phase is to find the way of how to motivate the adult workforce to clean their workplace as they believe that their desks are their private territory. The company decided to reward its employees by giving their department 1 Euro for every 10 kilograms of shredded paper, 1 Euro for every reused file and 50 Euros for a piece of furniture. The response turned out to be very positive. Generally speaking the first level is usually met with excitement and it is of key importance for the company to maintain this excitement on its way to improvement.

Workshop at this level requires detailed preparation. Ideally, the group should consist of 40 employees and 2 moderators, who lead the workshop. The moderators have to be well prepared for their role and familiar with the concept. Before the workshop starts the moderators introduce goals of the entire workshop and tasks to be completed at the 1st level workshop, namely the principles of so-called 5S concept. Especially important is the first impression moderators give at the beginning of the workshop. Their attitude has to signalize that employees have nothing to worry about, the changes will affect their work only in a positive way and everyone should cooperate on achieving the required results. It is great for moderators to show their sense of humour. For example, a little joke always told at the workshop of the 1st level: “If this plant was about to get buried and found by archaeologists not sooner than after 1000 years, what would they think this company produced? Obviously paper!” always works in Alpha AG. This joke refers to huge amount of useless documents stored not only in Alpha AG but more or less in every company. The workshop at the 1st level also makes the change agents to realize whether the change will be easy to implement with the employees’ attitudes or not. The first workshop always finishes with the common breakfast for all participants. The idea is that if the participants experience something together, it will strengthen their relationships.

And then the work at actual workplace starts. In this phase the moderators have to make sure that every employee participates in the activities of cleaning and organizing the workplace. At first, the employees are kindly asked to “help” sorting the material in the offices. One may face certain resistance and therefore in Alpha AG the moderators at the workplaces directly encourage employees to clean their workspace by asking whether the items on their desks are really important and if so, what for. When a moderator is a new comer, he/she can use the chance to ask dummy questions, letting the employee explain or neglect necessity of a certain material. Experience with 1st level activities is as various as the employees themselves are. Even after 5 years 30% employees of Alpha AG were fully convinced about concept’s importance and supported it; 60% were cooperating willingly, but the remaining 10% resisted any attempts to change the ways the things had been done in the company. In this phase it is important to excite as many people as possible since they have the drive to turn other people to what they think is the best for company.

At the end of the first day of Level 1 workshop it is essential to receive feedback. The moderators ask the employees how did they feel about performed activities and in this way they point out that opinion of every employee is important. The positive responses included “Finally we got time for that” or “We should do this more often”. The moderators show the participants how much they are able to change themselves. The day number two starts with the summary of objectives achieved on the first day and introduction of further potential of the group. Once again the employees are asked to consider what else could they remove from their premises and the discarded material is ready to be transported. Generally speaking, the workplace should look like the cockpit of a pilot, where everything is easily accessible and ready to be used. Since employees are the pilots in everyday situations, they know the best how to optimize their workplace. Finally, the moderators conclude the workshop with presentation of achieved success and savings, set the date when another workshop will be held and when does workshop of Level 2 starts. Ideally, the top officials should attend the final meeting to learn about what has been achieved and what are the next steps. Their presence has a great effect on motivation of the employees.

Level 2

After a couple of months, the workshop of Level 2 is held. The period of 2 months gives the employees enough time to get familiar with the new workspace organization and stabilize the new system. Level 2 concentrates on improvement in more details, namely standardization of information and material flow within a given department. Here it is important to note that the company is not looking for a uniform method of performing the work throughout the organization but rather for the best possible methods of performing the jobs. The company divided the standards into four main categories:

- Standards of the department, standards of the workplace and working environment
- Standards of the work and processes
- Standards of communication and information flow
- Standards of the services provided

Generally speaking, Alpha AG employees were working well. They used 90% of their work time for productive activities. The work they perform is also up to 90% free of any mistakes. But simple calculation reveals that if performance of every department is 90% (0.9) and performance of 4 departments is required to complete the output, the total performance in order to satisfy the customer’s need is only 66% ($0.9 \times 0.9 \times 0.9 \times 0.9 = 0.66$) and that is just not good enough. This means there was clearly enough room for improvement. For example, when the sales department received an order for the product, a sales person forwarded such order to a project manager. After revising the order, the project manager had to ask the sales representative additional questions, answers to which had to be provided by a client. The order was further forwarded to a purchaser in order to purchase components. However, the purchaser may ask additional questions to the project manager. The employee in the production department had to seek for information required by workers, or order additional missing parts, which were not ordered by the purchaser before. The entire process is rather tedious, though it can be solved by introducing a simple principle: do not accept any mistakes – make no mistakes – do not push any mistakes further. And that is exactly the goal of Level 2: continuous improvement through deployment of standards. However, not everything can be changed at once because problems tend to be more complex without any universal solution; solutions themselves are often complex and important solutions require support from top management as they consist of essential changes and may also be connected with certain spending. It is important to let the employees at certain department come up with their own standards for performed works as they are closely familiar with the character of the work.

Presentation and workshop material (board, pins, stickers etc.) have to be well prepared for the workshop at the 2nd level. The introduction phase led by the moderators also starts with introduction of the topic and requires 2 days. In this phase the participants are required to prepare standards for the entire department or division, which are then presented and proposed for further discussion. The question is how to find the topics for Level 2 workshops; it means how we identify areas for improvement. Alpha AG asks directly the participants before or at the beginning of the workshop. At the beginning the employees are asked to identify the areas that could benefit from improvement. These are written down and every participant has two votes he/she can give to the most urgent topics. The groups are formed depending on the number of topics, participants and moderators. Normally there are 2 or 3 groups, in special cases the number of groups grows to 5 or even 7. Thus, the employees are offered an opportunity to work on several topics that are the most important for them. One group normally consists of 3 to 6 participants; more is usually too much for productive discussion. Not all the employees from certain department have to be present at the workshop as normal operation of the department has to be secured. However, it is useful when the participants rotate in the workshop and share their knowledge; nevertheless, all the employees from a given department shall participate in final presentation and conclusion of the workshop. Another option how to find out topics for the workshop is to let the future participants find the topics themselves for example through brainstorming or own observations.

A challenge one has to face in this phase is to involve the experienced employees who are not interested in any change. The company should not give up their experience, yet it cannot make them to be creative in the process of change. The same situation occurred in Alpha AG. The older and well-experienced employee Mr. Smith at the accounting department was resisting any changes or even participation in the workshop declaring he knows “how the system works and what is needed”. In an attempt to offer him insight into the course of workshops, younger colleagues introduced him their suggestions also presented at the workshop. They started a constructive discussion and after a while Mr. Smith started noting why this or that would not work and other change would fix the problem. Not only did he admit that there are problems that need some attention, he also provided the discussion group with valuable input. He participated in the following workshop and later on became a moderator. This only proves that every employee requires individual approach and it is the task of the moderator to find it.

Level 3

Once we have removed all the waste from the workplaces at Level 1 and we have set standards for individual departments at Level 2, now it is time to make the employees cooperate together. Even if the departments perform their work in the right manner, there is still no guarantee that the right things are made as perceived by the customers (internal or external). The principle “with each other” presented in Level 2 has to be changed to “for each other” now so the information and material can flow continuously. Level 3 results in reorganization of all activities performed to satisfy internal and external customers. Alpha AG divided all activities within Level 3 into the three phases.

The company processes, which will become focus of further analysis, are selected in the *first phase*. Once the processes are identified, the workshop is held at which the participants are introduced by the moderators, problems are clearly defined and evaluated and then a one-year improvement plan is carried out. The participants, one for each affected department, should be well experienced. It is of key importance that the top managers avoid participating in the workshops at this phase as the participants are encouraged to speak freely about existing problems. Presence of officials makes the participants hide mistakes and therefore top management is welcome to join the workshop not before the concluding phase. This is not only important for success of 3rd level workshops, but rather for the success of the entire program. In order to explain what the content of Level 3 workshop is, let us describe a real process in Alpha AG. The sales department received an order and entered it into shared data processing system appropriately. Once the order was confirmed, its status was “Confirmed”. The system showed the purchasing department which items had to be ordered for the particular job. Unfortunately, the system did not contain specifications, which would make it possible for the purchaser to order the items. So he contacted the competent project manager, who had been assigned to this project by the sales department and hence, was also identified as a contact person in the system. However, even project manager did not have the right information because the sales department had not negotiated all the details of the contract yet and, as usually, the specifications were still to be required from the customer. Therefore, even deadlines could not be planned in advance. In this case we can identify a lot of useless communications steps with no positive results and this process is obviously ready for an improvement. Since the problems described above concern several departments, the first

phase of Level 3 deals mostly with the “complex problems”. It is important to define who will benefit from the workshop; in our case it would be the purchasing department. Normally 5 to 10 people from different departments participate in this workshop and the procedure is as follows:

1. At first, the “borders” of the process have to be defined; the team needs to decide which sections of the process they wish to analyze. In our case the starting point was entering the order into the system and ending point was order of components.
2. Then, the goals have to be set, it means what should be achieved. In our case we want to reduce the volume of regressive queries.
3. The processes (by process mapping) are displayed with the main question being “Who does what?” The departments are displayed vertically and tasks horizontally.
4. The problems are highlighted in the map (with post-it) and the participants are asked to discuss where the potential is and quite intuitively they are able to identify the bottlenecks. Here the participants only highlight the problems, they do not propose solutions.
5. Problems are divided into categories depending on volume of needed resources and benefit provided. At first, the problems with low resources and high benefits are solved; the problems with high resources and low benefits are solved as the last ones. Here the (internal, external) customer’s perception of benefit prevails.
6. The problems are solved then; usually solutions emerge spontaneously during the previous stages. Often moderators help the participants to find the solutions by asking the right questions. Therefore it is sometimes convenient when moderators do not have detailed knowledge of a given process, so they can play their neutral role.

The implementation plan is carried out with clearly defined responsibilities for individual measures to be taken. Experience of Alpha AG proves that the employees actively working on defining the problems are even willing to take responsibility for identified solutions. The participants have 2 months for making the changes. After additional 2 months the team meets again and discusses improvements achieved through measures taken. Leaders of departments and company officials are present at the final meeting to appreciate the achieved results and fruitful cooperation of teams. In Alpha AG it is often said at the end of the workshop: “Here people do not blame each other for problems anymore; we learnt how to analyze and solve these problems.”

Upon successful completion of the first phase and detailed analysis and improvement of the major processes, the company is ready for the *second phase*, which consists of the benchmarking of similar processes. The idea here is to let two teams working on similar processes to learn from strengths of each other. This may be especially beneficial for companies with several branches in a given country or located internationally. Of course, the workshops in this phase are not as detailed as workshops held in the first phase. Following the first phase, Alpha AG organizes a workshop for one representative at the sales division and one representative at the improved sales division. Thus, the representatives are given an opportunity to share their experience. The same is arranged for project managers, constructors, mechanics etc. Further improvements are also achieved in this phase.

Once the problems are analysed and solved in the first phase of Level 3 and revised and improved in the second phase, the internal customers and their internal suppliers get into centre of attention in the *third phase*, in order to further improve the information and material flow. This concerns not only the major processes but rather all the activities within organization. At first, the teams focus on the company-wide processes; then follow the processes at quality, HR, controlling, communication and other departments. The main question everyone should ask is “What can I, as an internal supplier, do better, so my customer can work better?” The idea of this concept is to achieve improvement of every process starting on the very end and moving backwards. When analyzing systematically all the partial steps even in a small organization, one can easily come up with as many as 30 partial workshops.

After the third phase is successfully completed, the entire process starts again with site improvements, identification of complex problems and analysis of processes, as the conditions in the environment keep changing and the implemented solutions may no longer be optimal. This is what we call continuous improvement.

Results, facts, figures and company culture

Based on the improvements, described in this paper, the company managed to increase its profit sevenfold compared to the results reported prior the concept implementation. In 2006 Alpha AG took in average 1.8 improving measures per one employee. Just for comparison the largest association, Alpha AG is the member of, reported on average 0.3 improving measures per one employee per year for all its member companies, which implemented improvement programs (lean management). To sum it up, Alpha AG is 6 times better than the average in its industry. Of course, it is positive for managers

to learn that the company is doing so great in comparison with other competitors. Though, it is still not important how better the company is doing. What is important is the fact that the company found its way to the employees. This is proved not only by the number of improving measures taken in a given period, but also by the fact that once the measures were identified, they were all without any exception implemented and the employees were convinced that the measures they had chosen were taken in order to make things better.

Still there is a question what are the actual results of improvement program. Let's look at the two examples from the non-manufacturing departments.

Level 2 workshop in purchasing department: 3 workshops were held at the purchasing department in headquarters of Alpha AG in 2005. In one of the workshops two changes were introduced:

1. Orders up to certain amount were only sent to Alpha AG headquarters via e-mail instead of fax. Thus, the waste of printing and signing the document, bringing it to the fax machine, dialling the fax number, waiting for sending and waiting for a confirmation and then going back to the desk could be removed, as this was done more than 12,000 times per year.
2. On the other hand one does not need confirmation from headquarters for every order up to certain value. "Dear colleague, we trust you. Please proceed and send us purchasing documents subsequently." This message was sent about 4,500 times per year.

This means that through these two measures 16,500 acts are done better and with higher efficiency and hence, only a small change can save a lot of time and effort.

Level 3 workshop in payment flow: One Level 3 workshop on payment flow topic was held in 2005. Until then the information flow about payments was unclear at many points. For example, the foreign sales partners were mostly aware on which date make the customers their payments. But the sales division of the company usually did not get this information in time and thus, after numerous phone calls and late notices for commission payments from their contracting partners, the employees often had to call to the central accounting or finance division to find out whether the payments had already been made. Almost every time the international partners were true about their claims and Alpha AG was often in delay with commission payments. This problem got combined with problem of inter-organizational accounting and even more questions between the branches followed. At the workshop 12 measures were identified and also taken later on. Each measure improved some app. 100 activities per year. Thus, the workshop resulted in app. 1,200 permanently improved activities per year.

No company can afford making a mistake of underestimating the importance and influence of the organizational culture. During the workshops the employees of Alpha AG acquired the feeling of real involvement. The large private broadcaster got interested in the improvement program at Alpha AG and they came to the factory to shoot a short success story. Even the management got surprised when a random employee at the shop floor (without any preparation or without being asked to do so) explained to the reporter: "Here I can take a lot of responsibility. I and my colleagues feel that our opinions matter and we are taken seriously for the first time. Nothing makes me as happy as working for this company." The fact that this speech was not prepared in any way and many other employees answered similarly proves that it is really worth of trusting the employees. They can really appreciate this trust and move the business forward – all with excitement and pride. It is hard to find a company where the mood is so positive. Another example can be found in a benchmarking project. During the tour around the factory there occurred a situation, when a visitor asked a random employee, working at the site, about the new system. He explained to the visitors that their improvement system is not any concept, but rather a philosophy and main mind setting on how to cooperate together. These two examples clearly show how the way the employees think changed.

In Alpha AG the employees are considered to be the key resource of the company and therefore the company treats them in this way. Any management, which treats its employees wrongly or misuses them, does not understand who is responsible for success of the company and its results.

Conclusion

This case study proves how any company can improve its performance through employee engagement. The employees are capable of behaving as responsible partners once they are given trust and responsibility. As already mentioned in the introduction, in 2006 the company was taken over by a

large supranational giant. The companies like that prefer the figures to anything else but, unfortunately, such focus drives their attention away from the customer. They ask the basic question: “What did you save with your improvement system?” This may be misunderstood as the company actually did not save any costs because the number of employees and technology stays the same. However, the company still managed to boost the output with the same number of employees and it is able to produce more effectively, faster with minimum waste. Today, instead of appreciating the work of the employees, the mother company tries to convince them that they and their results are not good enough and in return they expect increased productivity. As may be expected, the employees are not satisfied; they do not trust their new employers and the results go the opposite direction. Motivation with “not good enough” method does not bring the company to expected results. Today the company still reports profitability of over 10% though the overall results are worse compared to those of 2006; 3P concept is rather neglected now. Despite that we may conclude that the lean management in this company has had significantly positive effects on the company’s performance in the long run, though the future remains unclear.

A Study of Job Satisfaction in relation to Occupational Stress of Executives

*Dr. Shyam Lata Juyal, shyam.latajuyal@gmail.com
University of Haridwar, India.*

Abstract

In this study we examined the relationship between occupational stress and job satisfaction of private and public sector executives. The comparison of occupational stress and job-satisfaction of both sectors executives is also a part of study. A random sample of 100 executives (50 from each sector) was drawn from the study population. Data were gathered using reliable and valid tools. The findings indicated, private sector executives experienced more occupational stress on its sub-scales; role overload, unreasonable group and political pressures, intrinsic impoverishment, unprofitability and on total stress. Public sector executives experienced more job satisfaction and relationship on two variables were reported, significant by executives on the stress of role conflict, under participation, powerlessness, poor-peer relations, intrinsic impoverishment, low status and on overall occupational stress and with the level of job-satisfaction. However, a low and moderate positive statistically significant relationship was found to exist between occupational stress and job satisfaction.

Introduction

There is an enormous pressure on organizations to work in non-traditional environments. Globalization is at the center of this. It is one of the big reasons for the stress related to work. Working global means that executives and employees have to work in quite an uncertain environment; have a global mindset and be able with the unexpected. Globalization has also presented the executives and employees of organizations with many challenges. Moreover the concept of globalization has affected both the public and private sectors. Therefore, organizations treat this phenomenon very seriously as it directly affects their performance and ultimately their existence. Stress develops when there is a mix of demands and pressures on the person on one hand and knowledge and abilities on the other. A new age of technology, the advent of digital age has brought about geographical boundaries seemingly closer and which has become some of the main reasons for the increase in the work related stress. Apparently with lives moving as fast as a click of the mouse, work stress is increasing. Employees cannot afford to relax in such a business environment. Stress is therefore multi-dimensional and depends upon the organization whether they see it as a problem or as a solution. Therefore it is important for executives to know where to draw the line between work and stress. Growing globalization has increased the needs of executives and under immense pressure they find it difficult to draw the line between work and stress.

It has been identified that globalization has been the primary cause of concern for the work related stress. Globalization is broadly defined as the idea by which we understand the transition of human society into the third millennium (Waters, 2002, p.1). It is also defined as a strategic effort to treat the world or a significant part of it as a single market in which to do business in (Tallman and Fladmore-Lindquist, 2002). Stress in organizations has been deeply studied by many researchers (Robbins and Sanghi, 2006). There are various causes of stress that have been reasoned out by these researchers. Work stress is a major factor as it influences human functioning in emotional, mental and psychological ways (Arroba and James, 1987). Kinney (1985) stated that biological changes affect the way we think while Spielberger (1979) said that work stress is one of the most important factors affecting work productivity. Work stress has been taken so seriously in the United states that once it was named as the "disease of 20th century (Krohe, 1999). Wages is one factor which seriously affects job satisfaction. The problem is a bit too serious for a country like India. India being a predominantly rural country with a population of more than 1 billion people has access to cheap labor. Looking back at the Indian population and labor literature, India has grown at an annual rate of 2.27 percent in urban areas and 0.66 per cent in rural areas (Chaddha, 2002). The public and private sectors account for majority of the employment in India.

In a distress perspective, occupational stress presents when employees' knowledge, skills, abilities and attitudes cannot cope with or do not match to their work demands and pressures in organizations. Consequently, it may

decrease the ability of employees to control and manage physiological and psychological stresses, such as disturb their self-regulatory bodies, and cannot meet their duties and responsibilities as a member of an organization (Cox et al., 2000; Critchley et al., 2004; Fairbrother& Warn, 2003; Mansor et al., 2003).

Recent studies in this area show that the ability of employees to manage their physiological and psychological stresses may have a significant impact on job satisfaction (Fairbrother& Warn, 2003; Snelgrove, 1998; Swanson et al., 1998). According to an organizational behavior perspective, job satisfaction is broadly described as a result of employees' perception or appraisal of their jobs that may create a pleasurable or emotional state (Locke, 1976; Locke & Latham, 1990; Kreitner&Kinicki, 2007), In an occupational stress model, many scholars think that physiological stress, psychological stress, and job satisfaction are distinct, but highly interrelated constructs. For example, the ability of employees to properly control and manage their physiological and psychological stresses in performing job may lead to higher job satisfaction in organizations (Antoniou et al., 2003; Fairbrother& Warn, 2003; Stacciarini, 2004).

Findings from these studies reported that the ability of employees to cope with physiological stress (i.e., workloads, working conditions, physical health and working hours) and psychological stress (i.e., relationships at work, support, mental health and positive thinking) had increased job satisfaction in the workplace.

Theoretical evidence supporting the relationship between occupational stress and job satisfaction

Harrison's (1978) person environment (P-E) fit model, and Karasek and Theorell's (1990) job-demand-control model state that individuals who have experienced high work demands with low work-control will have difficulties to meet the job demands, this may lead to increased occupational strains. Spector and Goh's (2001) emotion-centered model of occupational stress posits that individuals who feel stressful when exposing with an event in particular environments may experience occupational strains. Then, the concept has been expanded by Mueller and Maluf (2002) to establish a physical stress theory, which posits that the level of one's physical stress will determine the person's predictable biological response. For instance, a person who can habitually reduce his/her level of physical stress will be more experience a positive biological response compared to a person who often has high level of physical stress. This situation may lead to higher job satisfaction (Swanson et al., 1998; Stacciarini et al., 2004).

A diverse literature is still lacking in some parts. The literature does not have the particular distinction between the public and private sectors of India. The work stress level in these sectors is undetermined. In this paper, we seek to find out the major differences between the stress level of public and private sectors of India. We shall first take a look at the Indian market and the employment ratio's and then look at two different sectors separately to make a distinction. We conclude by highlighting the key differences in both the sectors.

Many of the research efforts, so far have been directed towards problems related to policies and programmes, training and development of employees etc., for improving the productivity of an organization. In this paper, we shall assess the stress from occupational perspective and also look at the difference in the occupational stress and job-satisfaction of both public and private sector executives, and an effort to understand the two concepts jointly along with their relationship.

Objectives:

1. To assess the occupational stress of private and public sector executives.
2. To compare job satisfaction of private and public sectors executives.
3. To identify the relationship between occupational stress and job satisfaction of private and public sectors executives.

Research Methodology

Target Population

Data for the current study were taken from a more extensive investigation. The sample of this study consisted of 100 executives from two population; public sectors(50) and private sectors (50), drawn on the basis of random sampling from 6 large scale industries situated in uttarakhand state, India. Most of the public sectors participants were drawn from Haridwar and Dehradun cities and participants of private sectors from cities of Roorkee, Haridwar and towns

of these cities within 70 kilometers of Uttarakhand state. Biographical data indicated that the subjects who were selected in this study (as early middle age) their age ranged from 35 to 45 years, and the mean age 41.29. All the subjects were educationally well qualified, 80 (70%) had degree and remaining 20 (30%) had post graduate degree. Data collected on both sectors executives were at least working 8 to 12 years duration in the same sector and only male participants were included. All the subjects completed Occupational Stress Index (Srivastava and Singh, 1981) and Job-Satisfaction Scale (Srivastava, 1996).

Procedure and Administration:

The present study was performed on data from the deleted assessment of occupational stress as far as relationship between occupational stress and job-satisfaction of private and public sectors executives. Occupational Stress Index (Srivastava and Singh, 1981) and Job-Satisfaction Scale (Srivastava, 1996) administered individually by the researcher. A random sample was collected by the address register requesting for co-operation to administration of both sectors and stratified to match them on age, duration of Job accordance to sample and inclusion only male executives. Before administration clarified the purpose of the study to them and gave assurance for confidentiality of their answers, For this, did not write the name of participant on the self made performa and administered both scales at their own convenient places (not necessary to working place) and time.

Instruments :

Two scales were used for assessing occupational stress and Job-satisfaction of executives: The Occupational Stress Index and Job-Satisfaction Scale.

1. The Occupational Stress Index (OSI)

This Scale was developed by Srivastava and Singh (1981). It consists of 46 items with 5 alternative responses. Out of 46 items 28 are “true-keyed” and rest 18 are ‘false-keyed’. The items relate to almost all relevant components of the job life which cause stress in some way or the other, such as, role over-load, role ambiguity, role conflict, unreasonable group and political pressures, responsibility for persons, under participation, powerlessness, poor peer relations, intrinsic impoverishment, low status, strenuous working conditions and unprofitability. The reliability index ascertained by split half (odd-even) method and Chronbach’s alpha coefficients for the scale were found to be 0.935 and 0.90 respectively.

2. Job-Satisfaction Scale

This scale consisted of 38 items Likert type job-satisfaction scale developed by Srivastava(1996). Among 38 items, 28 indicate positive and 10 are negative responses for the measurement of job-satisfaction/dissatisfaction levels. Response categories for the job satisfaction scale ranged from ‘strongly agree’ to ‘strongly disagree’ with a 5 (strongly agree) to a 1 (strongly disagree) point value assigned for each positive items response and with a 5 (strongly disagree) to a 1 (strongly agree) point value assigned for each negative items. Each raw score converted into percentile values for assessing high, moderate and low levels of job-satisfaction/dissatisfaction.

Data Collection

The study is based on primary data. The data were collected from executives on two different questionnaire-cum-scales from different organizations in Uttarakhand state. The researcher visited so many places and personally requested the executives to fill the questionnaires as early as possible. Uttarakhand is a new developing state, due to that it was a difficult task to get the forms filled from women executives, as the number of women executives is very less in almost all the organizations whether in public or in private sector. So, we matched our sample on males only.

Data Analysis

The statistical analysis, we conducted descriptive statistic (Mean, SDs and 't' values) for assessing difference between occupational stress and comparing job-satisfaction of private and public sector executives. We then conducted χ^2 (non-parametric statistic) for knowing the relationship between occupational stress and job-satisfaction of executives. The data also presented in pictorial form with the help of bar graphs.

Results :

Hypothesis were analyzed in three phases. The first set of analyses examined the measurement of occupational stress in its 12 sub-scales; role over-load, role ambiguity, role conflict, unreasonable group and political pressures, responsibility for persons, under participation, powerlessness, poor peer relations, intrinsic impoverishment, low status, strenuous working conditions and unprofitability of private and public sector executives.

In the second phase of analysis examined whether any difference between job-satisfaction of executives working in private and public sectors' would exist.

The final phase of analysis identified the relationship in the 3 categories (high, moderate and low) of each sub-scales of occupational stress and the levels of job satisfaction (high, average and low) of private and public sectors executives.

The 't' test were conducted for continuous data and χ^2 (3x3) test were used for categorical data.

Table 1 shows significant decreases in the mean occupational stress scores of public sector executives. It could be seen from executives of private sector to public sector. The 't' values on the sub-scales of role overload ($t=4.54$; $p<0.01$), unreasonable group and political pressures ($t=3.10$; $p<0.01$), intrinsic impoverishment ($t=1.99$; $p<0.05$), unprofitability ($t=3.43$; $p<0.01$) and on total occupational stress ($t=2.74$; $p<0.01$) indicate significant difference between public and private sector executives. Mean scores on the above sub-scales confirmed that the executives of private sector found to have experienced more occupational stress than the executives of public sectors. Results clearly indicate that executives of private sectors were experiencing more stress due to role overload, unreasonable group and political pressures, intrinsic impoverishment and total stress as compared to executives of public sector. Stress of unprofitability only found more in public sector executives than the private.

The participants of both sectors represents significant difference on the variable of job satisfaction ($t=3.19$; $p<0.01$). Executives of public sector reported more job-satisfaction than the executives of private sector (see table 1).

In order to examine relationship between two variables (occupational stress and job satisfaction), χ^2 (3x3) was computed (see table 2). The χ^2 (4, $n=100$)=32.55, $P<0.01$ between the occupational stress and job satisfaction of executives was found to be significant. Frequencies of the subjects described high job-satisfaction is the result of low occupational stress and average job satisfaction correlated with moderate occupational stress of executives.

The similar analysis was carried out on the 12 sub-scales of occupational stress and job satisfaction (3x3) of private and public sector executives (Table 3). The results obtained in table 3 show the significant relationship between role conflict and job satisfaction of private (4, $n=50$, $\chi^2= 13.54$, $P<0.01$) and on the same sub-scale of public sector executives (4, $n=50$, $\chi^2= 10.87$, $P<0.05$).

Frequencies explain executives of both sectors were experiencing average level of job satisfaction because of moderate role conflict and high job satisfaction due to low role conflict.

On the under participation sub-scale of occupational stress, the executives of both sectors showed the significant relationship with job satisfaction. Regarding private sector, χ^2 (4, $n=50$) = 15.25, $p<0.01$ indicates high level of job satisfaction experiencing by executives with low, and average level of satisfaction with moderate level of under participation stress. Whereas, significant χ^2 value (4, $n=50$) =14.75, $p<0.01$ of public sector executives reported that high stress of under participation generates average level of job satisfaction (more than private) and low stress generates high job satisfaction (less than private). Moderate stress also shows average job satisfaction of both sectors executives. However, private sector executives possess frequency higher than the public sector.

The stress regarding powerlessness indicates significant relationship with job satisfaction on both sectors executives. χ^2 values (4, $n=50$) =10.77, $p<0.05$ of private and (4, $n=50$) =10.18, $p<0.05$ of public sector executives found significant in relation to stress of low powerlessness, low powerlessness stress possess high job satisfaction and moderate stress possess average satisfaction. It clarified that the executives of both sectors enjoy their job with

high level of satisfaction if their interest and opinion are duly considered in terms of power of position. In terms of poor peer relations ($\chi^2=12.09$; $p<0.05$), and intrinsic impoverishment stress ($\chi^2=11.32$; $p<0.05$), public sector executives showed significant relationship in the high and average level of job satisfaction with low and moderate stress. However, executives of private sector did not show any significant relationship in order to above, but frequencies showed the same trend as shown by public sector executives.

The job satisfaction regarding to low status, both sectors executives depicted significant χ^2 values (4, n=50)=16.61, $p<0.01$ and $\chi^2=20.57$, $p<0.01$ respectively. Frequencies indicated again the same trend, low stress concerning status of executives of both sectors experiencing high job satisfaction and moderate stress experiencing average satisfaction by them. It is noticeable that private sector executive possessed high frequency on average level of job satisfaction in relation to the same level of stress of low status than the executives of public sector and executives of public sectors showed higher frequency on high job satisfaction with low stress of low status as compare to executives of private sectors. It denoted that if higher authorities give due regard according to post of work of executives, they experience high satisfaction in their job. On the relationship between stress of strenuous working condition and job satisfaction, private sector executives showed significant χ^2 value (4, n=50)=9.54, $P<0.05$ and possess more frequency on average job satisfaction with moderate level of stress and high satisfaction with low stress.

Overall relationship denoted highly significant relation in the job satisfaction and occupational stress of both sectors executives. The value of χ^2 (4, n=50)= 20.07, $P<0.01$ (Private) and $\chi^2= 12.98$; $P<0.01$ (Public) indicated that total occupational stress on moderate level generates average level of job satisfaction and low stress gives high job satisfaction. It is noticeable that private sector executives possess high number of frequency on average job satisfaction and lesser on high satisfaction in relation to moderate and low occupational stress. Whereas, equal frequency on high and average level of job satisfaction with low and moderate stress showed by public sector executives. Distribution of frequencies indicated that job satisfaction of public sectors executives have less concern in relation to occupational stress as compare to executives of private sector.

Discussion

We assessed the occupational stress and job satisfaction of executives and identified the relationship between occupational stress and job satisfaction of private and public sector executives. There are three major findings of the current study was that; First, executives of private sector reported high occupational stress than the public sector. Second, public sector executives experience more job-satisfaction as compare to private. The third, executives of both sectors show significant relationship between occupational stress and job satisfaction.

Regarding first finding occupational stress found more in private sector on the sub-scales of role overload, unreasonable group and political pressures, intrinsic impoverishment, unprofitability and on total occupational stress as compare to public sector (table 1). This suggests that executives in private sector organization have a lot of work duties and responsibilities to perform and on the other hand there prevails departmental politics at the time of promotion. The jobs in private sector, although highly paid, are generally overloaded, and demand longer working hours as compare to public sector. A finding consisted with our study on the occupational stress of role overload. The stress of role overload in private sector may be defined separated into qualitative and quantitative role overload. If executives feel that they lack the necessary skill to complete an assigned work task, they are considered to experience qualitative role overload. Quantitative role overload occurs when an executive finds it difficult to complete an assigned task within an allotted period of time. (Kahn, 1978, Pines and Maslach, 1978; Maslach and Jackson, 1984). Manshor, Fontaine and Chong Siong Choy (2003) in their study examined the sources of occupational stress among Malaysian managers working in multi-national companies (MNCs). It was found that workloads, working conditions, and relationship at work were the main concern of the managers that lead to stress at work place.

Khoury and FarhadAnaloui (2010) also consistent of our result, they conducted a research to identify the primary and crucial stressors that Palestinian employees encounter. For this purpose a multi-stage disproportionate stratified random sampling method was employed. Results concluded that the employees in the private sector experience more stress than those in public or NGO sectors. Linda Lee Larson (2004) supported this study regarding job stress.

He found in his study that organizational job stressors in the work environment were more a source of stress than the so-called individual job factors.

Regarding job-satisfaction, as hypothesized, the results of this study revealed that the high mean score of executives of public sector on job satisfaction explain that the executives in public sector feel more comfortable with their jobs. The scores of private sectors are not appreciable on this variable. The difference that were found can be assumed for by the variable of occupational stress. It may be noted that executives of private sector's experiences more trouble with their boss, or when they are denoted, in that situation their job satisfaction is deteriorated. Whereas, executives working in public sector find that management has confidence in them, salary packages are satisfactory, job is secured and welfare facilities are sufficient in the organizations. Our findings is also consistent with Kohan and O' Connor (2002) they examined job satisfaction, job stress and thoughts of quitting in relation to positive affect (PA) and negative affect (NA). A high PA means a zest for life, excitement, and pleasurable engagement. Contrastly, a high NA is associated with feeling upset, nervous, and tense. They recommended a high positive affect (PA) is highly associated with job satisfaction of executives.

One such follow-up study showed that realization of expectation, company support, attitude, relation with fellow workers and pay were determinants of job satisfaction (De Vaney and Chen, 2003). Sloman (2007) found contradictive result from our study. He reported that private sector professionals to be more satisfied than their counterparts in the public sector.

In respect of relationship between occupational stress and job satisfaction of executives, finding shows low level of occupational stress increases job satisfaction level of the executives and moderate level of stress experiencing average job satisfaction (table 2).

The proper analysis of both variables on 12 sub-scales of occupational stress, and the job satisfaction experienced by private and public sector executives (table 3) clarifies that the stress of role conflict, under participation, powerlessness and low status have significant effect on job-satisfaction of both sectors executives. However stress of poor peer relations influence significantly only on job satisfaction of public sector executives and job-satisfaction of private sector executives affected significantly from the stress of strenuous working conditions. When executives experience low occupational stress of both the sectors on above significant results they show high level of job satisfaction and from moderate occupational stress they experience moderate satisfaction level. Moreover, results follow up the same trend, whereas, executives of public sector showed more job satisfaction and low stress than their counterparts executives of private sectors.

A study by North Western National Life Insurance Co. concluded that job stress is generally a consequence of two ingredients: A high level of job demands and little control over one's work. Many of today's workers are finding their jobs more stressful than were simply because their working too many hours.

Several studies have determined to support our results.

The study of Landsbergis (1988) and Terry et al. (1993) showed that high levels of work stress are associated with low levels of job satisfaction.

Ahsan et al. (2009) also conducted a research to evaluate the relationship between job stress and job satisfaction. He found a significant relationship between job stress and job satisfaction. A research was conducted by Tang and Chen-Hua Chang (2010) to examine how role stress and various performances of individuals are related. The study analyzed how role ambiguity and role conflict (via self-efficacy and job satisfaction) affect employee creativity directly and indirectly. The results showed that there is not only a direct and negative link between role ambiguity and creativity, but also a direct and positive link between role conflict and creativity. Yousef (2002) conducted a research to analyze the mediating role of job satisfaction between role stressors, namely role conflict and role ambiguity as sources of stress. Results showed that both role conflict and role ambiguity directly and negatively influence job satisfaction. It was also found that job satisfaction mediates the influence of role conflict and role ambiguity on various facets of organizational commitment.

Ahsan, N. et.al. (2009) investigated the relationship between job stress and job satisfaction among university staff in Malaysia. The determinants of job stress that had been examined under this study include, management role, relationship with others, workload pressure, homework interface, role ambiguity, and performance pressure. The results showed that there is negative relationship between job stress and job satisfaction.

Graphical representation of data further confirms the same results. The position can be clearly seen at a glance and a comparison can be quickly made with the help of following graphs.

Conclusion

Individuals under excessive stress tend to find their jobs less satisfying. Some of their intrinsic or extrinsic needs may be thwarted or not met sufficiently. Corroborating many studies in the literature (Hollingworth et. al. 1988; Keller, 1975), the findings of the present study also reveal the same. The subjects with lower job satisfaction were found to experience more stress in the form of role conflict, under participation, powerlessness, poor peer relations and low status compared to those with higher job satisfaction.

Sector (Private and Public) was found to be of importance in this study. The results of the study indicates executives of private sector are experiencing more stress and less job-satisfaction than the executives of public sector.

Further research has potential to provide relevant knowledge to guide administrators in the generation of robust frameworks that integrate the consequences and implications of the findings of the study.

Implications

In terms of practical contributions, the findings of this study can be used as a guideline by the management to overcome occupational stress problems in organizations. The objective may be achieved if management considers the following suggestions: firstly, update the content and training method. For example, the content of training programs need to emphasize more on soft skills, especially emotional intelligence. Secondly, promote work-life balance initiatives. For example, to reduce the executive occupational stress, such as organize company trips for them to relax their minds and bodies, as well as initiate physical fitness and sport games. Finally, encourage executives assistance program through professional consultants or internal counseling and guidance unit. For example, executives development programs should be well arranged in the interest of all levels of executives. Conducting one or two days seminars for creating awareness about the variables under study viz., organizational stress and job satisfaction, will also work favorably.

Scope for further research

The result of the present study indicate that there are so many related areas, open to further research. The study can be conducted with large sample again after some gap to find the positive or negative affect on job satisfaction of private and public sectors executives. The researchers have ample scope of research to study some psychological problems, that too by comparing public and private sector executives. Some separate studies can also be conducted for women executives because these days they are gaining more importance in cooperate sector. Now women in India have equal opportunity to get proper education and equal chances for getting good jobs. So, their problems should be analyzed and solved separately.

Strategic Management Using Evaluative Process Methods

Abstract

It is evident that little systematic research has been applied following new public sector governance theory and Resource Based Theory (RBT) in the strategic management context. This paper examines data using ‘the evaluative process method’ and uses both primary and secondary data sources. Environmental variables and governance issues of housing bodies in two countries, New Zealand and Australia are analysed. We use a mixed approach of analytical tools to explore the cause and effect relationships. To uncover causes and effects more effectively we have adopted both qualitative and quantitative methods of using ‘percentage of satisfaction’ from published data in the two organisations, HNZN and DH. This study provides a contingency plan for minimising risk of loss making during economic downturn. A better understanding of the new strategic management plan and development in the public sector context as a result of this paper will probably generate further research from both academic scholars and practitioners.

Introduction

With economic downturn and periodical earth quakes in Christchurch, there is uncertainty in New Zealand housing market. The current natural disasters such as earthquakes, floods, global uncertainties, rising unemployment and complexities, calls for the development of Social Sustainability Advantage (SSA) measure using Governance theory and resource based view (RBV) for government housing departments. SSA measure is needed during these times of rising unemployment and poor housing affordability. For this purpose the study integrates corporate governance stakeholder theory of Benn, Dunphy and Griffiths (2006), Freeman and McVea (2001), and Johnson, Scholes and Whittington (2008), along with strategy perspectives of the RBV of firm (Penrose,1959; Peteraf and Barney, 2003) for public organisation. Hansen’s (2007) research work on public organizations – ‘Strategic Management when Profit isn’t the End: Differences between Public Organizations’ used Porter’s strategic positioning (1985) and Barney’s (1991) RBV to examine corporate effectiveness.

This research examines Housing New Zealand Corporation (HNZN), and Department of Housing and Works (DHW) in Western Australia with regard to their planning and implementation methods used to minimise the risk of both customer discontentment (housing affordability issues) and Social Sustainability Advantage (SSA) of HNZN and DH.

The evaluative process method of the state housing market involves studying housing policy matters that are based on not only an understanding of the wants and needs of the community but also upon some idea of what those future wants and needs are likely to be. In this context housing policy evaluation is dependent upon good research methods used to evaluate past, current and forecast the future state of the housing market by examining the factors which determine housing demand and supply.

One of the purposes of the research is to present a balanced view of the existing housing governance and resource based systems in New Zealand and Western Australia. That is to examine the sustainability of housing stock in the short and long term. Our intention is to develop a Social Sustainability Advantage measure using data analysis of the housing market from 1980 through to 2010, a period of rapid change.

Development of the housing sector is a major driver for social and economic benefits. Housing New Zealand publishes short term and medium term forecasts of housing demand based on affordability, consumer

confidence and other variables. These projections are based on evaluative process method of leading indicators of the economy.

It is evident that little systematic research has been applied following new public sector governance theory and Resource Based Theory (RBT) in the strategic management context. This study provides an extensive examination of data using this method called 'the evaluative process method' and uses both primary and secondary data sources.

Environmental variables and governance issues of housing bodies in two countries, New Zealand and Australia are analysed. We use this evaluative process method, a mixed approach of analytical tools to explore the cause and effect relationships. To uncover causes and effects more effectively we have adopted both qualitative method, content analysis, and quantitative method of using 'percentage of satisfaction' from published data in the two organisations, HNZA and DH. Time series data from Australian Bureau of Statistics, ABS and Statistics New Zealand, SNZ are also employed.

Content analysis uncovers causes while secondary time series data, published outputs from HNZA, SNZ, ABS and DH are used to uncover effects. This study provides a contingency plan for minimising risk of loss making during economic downturn. A better understanding of the new strategic management plan and development in the public sector context as a result of this paper will probably generate further research from both academic scholars and practitioners.

The major expected outcome is the development of a model for the state housing market which provides policy makers with three key benefits:

1. A thorough investigation may reveal what factors are important in determining SSA outcomes and what the magnitude of their effects are.
2. The quantitative effects of such a study would necessarily carry over in the following areas:
 - The methodology used would provide a blueprint for research
 - The identification of key variables for sustainability measure would be of value to trans-Tasman researchers.
3. A-priori it is quite likely that our work would lead to the identification of two sets of influencing variables on SSA. Those factors driving long run trends in the market (obvious candidates are tax and benefit scheme trend, housing affordability trend, population, employment trends and income trends) and those which affect the market in the short run and are responsible for cyclical effects (interest rates, property prices, and HNZA, DH specific policy variable).

Theoretical frame work

The extant strategic management literature by Dean and Snell (1991), Ketokivi and Schroeder, (2004) in the strategic management field advocates the attainment of fit between the firm's strategy, structures and processes in order to attain competitive advantage. Old school of thought and conventional writers Penrose, 1959; Porter, 1985, 1991, 1996; Benn, Freeman and McVea, 2001; Peteraf and Barney, 2003; Phillipon, 2005; Dunphy and Griffiths, 2006; Hansen, 2007; Johnson, Scholes and Whittington, 2008 and others use the term 'Competitive Advantage'.

We will use the term Social Sustainability Advantage (SSA) for public sector instead of Competitive Advantage (CA) since there is no rivalry and competition similar to private sector. Policy makers in the field of public housing are interested in strategy, structures and processes in order to attain SSA. SSA here refers not only to maintaining efficiency but also long-term sustainability (that is creating efficiency using RBT framework) and meeting the needs of society through public organisations. The study integrates perspectives from governance issues – risk management and resource-based models by using both the internal and external factors in environmental analysis.

SSA is relatively a new field for public organisations since there is a lack of clear strategy for maximising public sector performance through optimal utilisation of state organisation's resources using environmental analysis and corporate governance literature. Traditional public organizations are highly regulated with fixed budget and not

working on market-like conditions and therefore a strategic management theory like Porter's strategic theory cannot be applied directly. Nevertheless for such organisations RBV is more suitable and can be directly applied. Hansen (2007) states that if the organization is more like a New Public Management organization with a high degree of autonomy, performance-based budgets and market-like conditions then both the strategic perspectives—Porter's and RBV—are applicable.

Though the main intention of New Zealand housing strategy aimed for the period 2006-2015 is to provide "access to quality, affordable homes for all New Zealanders" is relevant at all times, yet there are few adaptations that are necessary during economic downturn of 2009 and beyond. As the title indicates, the emphasis is on how public good is actually managed by the two government housing organisations. Strategic analysis is concerned with how these two housing organisations (and people within organisations) plan, manage and implement their strategic direction so that the risk of losses are minimised, Porter (1991), Hitt, et al. (2001) and Ketokivi and Schroeder (2004). The focus is on strategy and governance with regard to minimising risk of loss making during economic downturn.

The environmental model of resource management is dependent upon the strategically relevant resources they control and the strategies they pursue (Penrose,1959; Prahalad and Hamel,1990; Ray, Barney and Muhanna, 2004). The model assumes that resources in a firm are heterogeneous (Oliver, 1997) because the resources (for example, skilled staff) that organizations use to implement strategies are highly mobile in the market. The relevant resources they control are limited and therefore public organisations are urged to do a better job in minimising risks and better provision of public goods and services. Several strategic management writers posit that it is easier for the senior managers to convince their important external stakeholders that they deserve more resources to meet the growing public needs based on good partnerships with key stakeholders (Freeman and McVea, 2001; Benn, Dunphy and Griffiths, 2006).

Governance structure and SSA

Mabin, et al., 2001; Hitt, et al., 2001; Phillipon, 2005 discuss the importance of good stakeholder relationship for developing a sustainability management framework. This need for SSA is becoming increasingly important for public organisations. Government housing bodies are governed by the Housing Public Act of the country or the state.

Several experts in the field of strategy literature have focused on corporate governance as an important factor in the determinant of organisational performance outcome (Filatotchev, Toms and Wright, 2006; Nankervis, Compton and McCarthy, 1996). Conventional wisdom dictates that size and scope, managing agency conflict, and CEO strength are alone responsible for governance structures and performance. See Figure 1, which deals with resource selection including both internal and external environmental analysis leading to sustainable advantage. The following framework shows a feedback loop that connects strategic environmental analysis with risk management and managing change with the analysis of implementation. We have proposed a cumulative approach for corporate governance that shows how each stage feeds into the next during economic downturn. See figure 1: SSA framework.

Governance structures are also driven by the following factors:

- shareholders' desire to curtail management opportunism;
- the firms' efforts to appease major resource providers; and
- managers' attempts to manage environmental change.

Researchers such as Boone et al. (2007) point out that they have reached few definitive conclusions about the forces that drive board size and composition in governance process and outcome. This is termed as efficient board hypothesis. They state that their "results indicate that board size and composition vary across firms and change over time to accommodate the specific growth, monitoring, and managerial characteristics of the firm." According to efficient board hypothesis theory board compositions for specific categories of firms exist because

firms with specific categories have been observed to survive; which suggests that if the compositions were inefficient the firms would have failed.

Figure 1: Social Sustainability Advantage (SSA) Framework

Others such as Papania (2008) argue that ensuring the alignment between board members and the strategic roles they play in managing external relationships (Freeman and McVea, 2001) and developing internal capabilities (Pralalad and Hamel, 1990) are more important factors for the firm's sustainability than board size and composition. Their stakeholder model proposed that firm's survival is dependent upon proper strategic view of governance that is well executed through board composition and not just the standard board structures.

In the context of Business cycle, it is envisaged that greater the strategic resilience of the public sector's corporate level governance (Phillipon, 2005) during economic downturn higher is its sustainable advantage in servicing marginal households. This is found to be a function of social, human, natural and financial indicators of Sustainable social advantage (SSA) measure proposed.

The present study synthesizes corporate governance literature and theories such as RBT and others for public organizations. One of the main functions of the board and corporate governance processes is stewardship over resources at the same time promoting sustainability measure. SSA is consistent with resource based perspective of strategic management of gaining access to resources that will benefit the organisation through its ability to create sustainability. SSA approach synthesizes RBT (Barney, 1991, 2001; Barney and Arian, 2001; Oliver, 1997), with public governance literature (Carmeli and Cohen, 2001; Freeman and McVea, 2001), which stems from an understanding of social organisation and the resources the organisation controls.

3.0 Methodology: Evaluative Process Methods

Methodology is based on the Evaluative Process Method (EPM) used by researchers such as Patton (1980), Yin (1994), Denzin and Lincoln (2005), Malhotra (2008), Zikmund (2010). EPM combines both the qualitative and quantitative sources of programme evaluation. It integrates the theoretical with the practical evaluation of the programme. A combination of different methods is required to solve managerial issues in complex housing programmes. Further, the task of defining Social Sustainable Advantage for the programmes called for an EPM, a mixed methodology approach.

It was control tested using ABS Data, for Western Australia and SNZ Data for New Zealand. Although the model was quite flexible in its capacity to assimilate a diverse range of variables and data formats, the model's further development, the testing process and the results, is enhanced by the combination of the model's need for very high quality data (across a broad range of demographic, housing, and financial parameters) and the ability of existing data sources to meet this need. EPMs is used for generating valid, useful and credible data analysis using both qualitative and quantitative data. The primary aim is to develop an EPM model for assessing sustainability measure. The key variables and the interrelationships between the key variables were identified using semi-structured interviews with officials of DHW and HNZA. Secondary data, was drawn from the reports and published sources of these departments, the ABS and SNZ.

Qualitative research employing content analysis is used for identifying causes (e.g. resources) while final evaluation, secondary published sources is used to determine effect (e.g. satisfaction level). Annual report containing satisfaction surveys of employees, clients and management are used to compare two countries social housing bodies, New Zealand and Western Australia. Published research outputs, annual reports and statistical data from Australian Bureau of Statistics and Statistics New Zealand are used for this purpose.

We use causes and effects, both content analysis and published data in these case studies for the following reasons:

- content analysis uncovers causes
- published outputs from HNZA and DHW (secondary data) uncovers effects.

Evaluation process method used in this study has six main steps, which are listed below:

- Selecting published sources for analysis
- Determining the units of content
- Discussion with policy makers for preparing the content
- Coding the content based on resourced based theory
- Counting and weighting (percentage measure) which is discussed in the analysis section
- Drawing conclusions

A mixed methodology of both secondary data from published sources is used to check with primary sources for reliability purposes.

- A thorough content analysis along with few email discussion from policy officers of these two social bodies enhances the mixed methodology employed in this paper.
- Public and community-owned social bodies have usually several purposes, sometimes conflicting - but each individual program tends to have one main purpose, maximising societal satisfaction and minimising economic wastes.

The scale used to measure the resource capabilities for both these organisations is given below:

- moderate level measures a less than equal resource capability than its counterpart and between 50% to 65% of efficiency for that particular indicator.
- highly moderate level ranking measures a better resource capability than its counterpart (HNZA) and more than 65% of efficiency for that particular indicator.

As well as facilitating the modelling process, the exercise also served to demonstrate some of the flexibility and the pitfalls encountered in working with 'real' data. As noted by Straka (2000) most modellers have experienced a learning curve regarding data analysis of sustainability measure. For example, it became apparent that even with the relatively high quality ABS and SNZ data, there were a series of sampling and data attribute/quality issues that would need to be overcome before there could be any claims of accuracy or reliability. The model's capacity to identify the strength of relationship with SSA measure will be demonstrated to a point where it may limit further application. In other words, the model was developed to a point where it was registering the strength of the relationship between the variable and the dependant SSA measure, as reflected in each of the data sets analysed. Given the limitations with the data, however, these results should be understood to be indicative of in-progress development.

With better quality data the model would have the capacity to be calibrated to become much more sensitive to the relative impact of each sustainability factor. A series of interviews with program staff and family/financial counsellors sought reflections on the influence of the key variables as well as insights towards refining the programs and the associated SSA measure.

4.0 Environmental Analysis and Discussions

4.1 Creating a focus

When you set out to do resource based analysis, the first thing to acknowledge is that it is difficult to be comprehensive. One may understand that it is difficult to analyse all resources and its contents in all possible ways. What we have done here is to use the primary resources such as selected human, social and financial capital and analyse them for the two organisations, Department of Housing and Works (DHW) and Housing New Zealand Corporation (HNZC) separately. The authors argue that resource contingent perspective is paramount for senior managers responding to social housing pressure for improved housing during economic downturn. Housing policy makers seeking to understand the context where organisations are likely to be motivated to improve their SSA and social performance in the future is listed in the next sub-section for the two organisations.

The two selected organisations' major purpose includes engaging in public good by providing housing products and services. Their purpose incorporates not only services to social housing to low income individuals but also providing housing consent for private real estate businesses. The comparative study highlights the paradox that many public-sector organizations face in simultaneously pursuing public good and SSA. Here we incorporate resource dependency theory to address the paradox of maximising social gains with the limited supply of land.

Both the Department of Housing and Works (DHW) and the Housing New Zealand Corporation (HNZC) have organisational development (governance group) and communications group, which work with the Chief Executive and the leadership team, satisfactorily. The purpose of these groups is to build and maintain a culture to deliver the mission, demonstrate the values, and achieve the strategic objectives by aligning structure, systems, processes, staffing and people management, Boone et al. (2007). The governance group also provides communications support satisfactorily.

HNZC and DHW have increased their accountability to wider stakeholder interests. Managers are accountable not only to their CEO and ministers in the stakeholder chain but also to the wider community including lower income households by maintaining good partnerships (Benn, Dunphy and Griffiths, 2006; Freeman and McVea, 2001; Papania, 2008). There is decentralisation of resources including autonomy, some degree of performance-based long term planning in a business like behaviour (Hansen, 2007). The governance details of these two housing bodies are further discussed in the next sub-section, separately.

The three most important action areas that envisage the vision of HNZC strategy are supply of sustainable housing, improved housing assistance and affordability, and improved access to home ownership. According to HNZC (2008) "All New Zealanders should have access to affordable, sustainable, good quality housing appropriate to their needs". The outcome of state housing market both in Australia and New Zealand also depends upon the business cycle and the ability of individuals to pay their mortgage commitments or their rents. Nearly 50% of home

buyers are mortgagees. During economic downturn housing market faces difficulties since households frequently default on their mortgage payments during this period. Defaults may eventually lead to foreclosure, Peter and Peter, (2006). The governance issue here concerns itself with the interdependence between the public housing bodies (Kong, 2007) and their strategic thinking process (Cavana, Davies, Robson, and Wilson, 1999) and the final outcome of minimising losses.

Housing New Zealand Corporation: HNZN is expected to collaborate with related agencies that deal with public and their well being. This includes the Ministry of Social Development, Ministry for the Environment and the Department of Building and Housing. The Department of Housing, Government of Western Australia also collaborates with its related Departments. There could be improvement in collaboration by DHW and HNZN with other government departments by reducing red tape and bureaucracy involved through maintaining effective governance systems and stakeholder management (Jacoby, 2005; Papania, 2008).

Each year the Minister of Housing has outlined his expectations for the HNZN and DHW and placed the Statement of Intent in their respective Parliaments. Their annual reports have provided the deviation from the expected outcomes. There are a number of financial and non-financial ways that can be used to overcome these discrepancies. One of the discrepancies arise from public tenants complaints of poor quality public housing and overexploitation of existing depleted property resources.

A new CEO was appointed in 2006, whose focus was to build on the Corporation's capability to demonstrate excellence in its performance (managing change, Kanter, Stein, and Jick, 1992). Along with the recruitment of a new CEO was the development of an operating model to deliver on strategic priorities and provide a better service to customers. The Executive Team comprised of six general managers and the Chief Executive. The Operations group was led by the Chief Operating Officer, who has the overall responsibility for the delivery of services to Corporation customers, HNZN (2006). These changes are consistent with the views of Bartlett and Ghoshal (1994) where they examine changing the role of top management.

One of HNZNs corporate governance activities is the successful holding of board meetings, where the Board comprised of six non-executive members. The minutes are expected to be followed through in 2010 and beyond. During early 2008 all the Board charters were reviewed. The purpose of the review was to make the Maori Capability Committee more flexible and efficient. The amended Board charter provided the opportunity to appoint a new member, Bartlett and Ghoshal, (1994). This new member is appointed from outside with Maori capability expertise, not a Corporation Board member. This is a step in the right direction since capability expertise is expected to be improved, Papania (2008). It is not the size of the board that matters but the managerial capabilities as outlined by governance experts such as Hitt, et al. (2001), Benn, Dunphy and Griffiths, (2006) and Papania (2008).

The General Manager of Strategy, Policy and Research provide support to all the groups: policy and research; strategy development and implementation to the Minister, Board, Executive Team and the different organisational groups (HNZN,2009; Benn, Dunphy and Griffiths, 2006; Carmeli and Cohen, 2001; Freeman and McVea,2001). The governance issues of HNZN are stated as follows:

“(a) To give effect to the Crown's social recommendations by providing housing, and services related to housing, in a business-like manner, and to that end to be an organisation that exhibits a sense of social responsibility by having regard to the interests of the community in which it operates. Also exhibits a sense of environmental responsibility by having regard to the environmental implications of its operations and operates with good financial oversight and stewardship, and efficiently and effectively manages its assets and liabilities and the Crown's investment. (b) To ensure that the Minister of Housing receives appropriate policy advice and information on housing and services related to housing” HNZN (2006).

Similar systems and practices govern the Department of Housing and Works. Both HNZN and DHW exhibit a great deal of environmental responsibility and promote alternative source energy along with conventional source of energy to minimise social and ecological cost. This may increase the social benefit. Both organisations are aware of the Kyoto protocol and follow good environment friendly practices.

4.2 Development of Strategic Management in the New Public Sector Context^{iv}

The similarities and distinction between the strategic competencies of the Western Australian Department of Housing and Works and the Housing New Zealand Corporation housing programs are discussed in this section. In Table 1, performance with regard to selected competencies and how to improve HNZC (managing change) is discussed.

For the purpose of measuring the resource capabilities three kinds of capital: Social and human capital, Natural capital and Financial capital are considered. Annual reports of DHW from 2003 to 2008, Perth and Annual reports of HNZC from 2003 to 2008, Wellington are used for this purpose.

Recent program results indicate very low rates of mortgage possessions. Financial and Family counsellors also report relatively low incidence of mortgage possessions among Keystart recipients (Western Australia), which had been highly successful for more than 15 years. New Starter is NZ Welcome Home Loan programme — based on the mortgage insurance scheme piloted through Kiwibank — was introduced in 2005. Eligibility was widened and new home loan providers invited to take part in the programme in order to offer home ownership assistance to 5,000 first home buyers a year by 2010.

TABLE 1: ANALYSIS FOR HNZC

<p><i>Sustainable Advantage:</i> The public housing sustainable advantage depends on effectively managing public homes. The ways to overcome the overexploitation of government housing is to either renovate existing property or increase the supply of new building that is affordable, durable and easy to build. For example homes in Eastern Porirua, makeover programme, response to emergency housing needs in South Auckland and the development of a 90-day action plan can lead to more successful outcomes. An indication of the level of competency achieved is moderate with regard to environmentally friendly affordable homes supplied by HNZC.</p>
<p><i>Stakeholder Management:</i> As at 30 June 2008, the Corporation managed 68,644 properties that serve as homes for over 200,000 people. It is evident that a tenant satisfaction survey to gauge their service yielded the result of 71% level of satisfaction with regard to housing management of clients. This can be termed as slightly above moderate level of satisfaction. Besides partnership with local authorities, community providers and iwi to provide and finance social and affordable housing for New Zealanders can be termed as moderate.</p>
<p><i>Governance and Housing:</i> Policy advice should be translated into action through better servicing of clients. HNZC need to deliver on its commitments in future years. This would include periodical review of land development processes and structure for building affordable housing and managing risks of poor governance. An indication of the level of competency achieved is moderate with regard to governance and translating policy into action.</p>
<p><i>Strategic Asset Management:</i> Tangible asset management such as financial capital, natural capital, human and social capital are considered. At present HNZC can be ranked moderate in meeting the tangible asset criteria, while it can be ranked highly moderate in meeting the intangible asset criteria (human and social capital). Data from annual reports are used for this assessment.</p>

Following is the scale used to measure the resource capabilities of DHW:

- highly moderate level ranking measures a better resource capability than its counterpart (HNZC) and more than 65% of efficiency for that particular indicator.
- moderate level measures a less than equal resource capability than its counterpart and between 50% to 65% of efficiency for that particular indicator.

Table 2 is used to measure performance with regard to selected competencies and how to improve DHW (managing change). The four competencies are discussed below.

TABLE 2: ANALYSIS FOR DH(W)

<p><i>Sustainable Advantage:</i> DH(W) has highly moderate capabilities with regard to Renewal projects and the energy efficiency programme. DH(W) completed several renewal projects since 2001 and its competency in achieving long-term housing sustainability is above moderate.</p>
<p><i>Stakeholder Management:</i> DH(W) has demonstrated how policy advice is translated into action through the successful launch of Keystart Program, Aborigines shared equity scheme and others. It is necessary to improve the housing facilities of aborigines (ethnic minorities) in Western Australia because the percentage of homeless is higher compared to other ethnic groups. However, the overall level of housing need satisfaction of low-income household is higher in Western Australia compared with New Zealand and can be ranked as highly moderate outcome.</p>
<p><i>Governance and Housing:</i> A major focus of the policy work is stakeholder relationship with other agencies to provide housing options to its clients. DH(W) also has a tenant satisfaction survey to gauge their service yielded with regard to housing management of clients. This service can be termed as moderate since the level of satisfaction is above 50%. Besides partnership with local authorities, community providers and other government bodies to provide and finance social and affordable housing for West Australians can be termed as above moderate.</p>
<p><i>Strategic Asset Management:</i> An important achievement under is the completion of a review of financial governance. Tangible asset management such as financial capital, natural capital, human and social capital are considered here. At present DH(W) can be ranked as highly moderate in meeting the tangible asset criteria, while it can be ranked moderate in meeting the intangible asset criteria (human and social capital). Data from annual reports are used for this assessment.</p>

Figure 2 shows the strategic capabilities of DHW and HNZN separately. The above ranking (scaling) method is used to measure the resource capabilities of social, human, natural and financial capital.

Figure 2: Measuring the strategic capabilities, DHW and HNZN

- Social and Human Capital of *HNZN* (Highly moderate ranking)
- Social and Human Capital of *DHW* (Moderate ranking)

- Natural Capital of *HNZN* (Moderate ranking)
- Natural Capital of *DHW* (Highly moderate ranking)

- Financial Capital of *HNZN* - access to its own capital and access to others (for e.g. kiwisaver scheme for others) (Moderate ranking)
- Financial Capital of *DHW* (Highly moderate ranking)

4.3 Integration of Strategic Management into New Public Sector Management

The current and the above sections have explored the strategic resources and positioning of Housing New Zealand Corporation (HNZN) and Department of Housing and Works (DHW) for the purpose of providing an integrative model. The study has assessed the existing strategic management theories and suggests implementation strategy which may further lead to innovative changes in the value chain of these social organisations. The influences of environmental factors, financial factors, human resource capabilities and business cycle (macroeconomic) factors on the governance of public organisation calls for an implementation strategy based on contingency framework.

5.0 Implementing Strategy

For the purpose of implementing strategy, three strategies of DHW and HNZN using SSA is proposed for these public sector organisations. SSA develops the organizations resources with the goal of value creation and efficiency. Revenues earned and social objectives fulfilled by HNZN are highly dependent on the successful development and implementation of a cohesive corporate-level strategy.

Past experience could also create opportunities for the various generic organisation-level strategies, organizational resource management and strategic groups for DH. Some of the departments in these public sector organisations behave in a business-like condition while others do not do so and therefore the strategic management theories of RBT can be successfully employed compared with Porter's competitive advantage. Good corporate governance is dependent not only on the internal resource capabilities but also managing the external shocks by top leaders such as business cycle and property shocks and its impact on business for both these organisations. The arguments of the paper could be summed up in the following statements:

Strategy 1: Sound financial capital with regard to resource based evidence is DH's strength and this capability can be an effective tool for promoting SSA especially during economic downturn and in the future.

Strategy 2: Good social and human resource capabilities are HNZN's strength. HNZN can use and manage these resources effectively for its sustained social performance.

Strategy 3: The usefulness of managing change depends on the type of public organizations. For example, SSA inspired organizations such as DHW are more robust in managing change in a chaotic environment (external shocks) due to its additional natural capital (large land and built area) than its counterpart.

It has been shown in this paper that good resource management of product or service results in better corporate governance. This is true even during boom (and bust) for public sector. New public sector management is found to be a function of social, human, institutional, natural and financial capital, the construct of SSA. The usefulness of this study on corporate governance and stakeholder management promotes strategy for minimising risks and maximising performance (promoting SSA). Following the discussion on environment analysis, resource capabilities, Carmeli and Cohen (2001) Barney (1991, 2001), macroeconomic (external business cycle factors, Grimes 2004), and governance for public sector (Benn, Dunphy and Griffiths, 2006) a contingency framework is produced for the new public sector management.

6.0 Future Research

This study introduced framework by which scholars and practitioners may investigate a public corporation's profile of resources. The framework, labelled as SSA, is an endeavor to better understand the public housing corporation's core resources (i.e., most valuable, rare, inimitable and non-substitutable) that generate to superior performance. The resource profile of growing public housing department in Western Australia was examined and compared with slow-growing housing department in New Zealand. The results of this examination shed light on one of the most difficult challenges that resource-based strategists face — understanding the drivers of sustainability. By adapting the theoretical background and conducting the environmental analysis of housing bodies from the resource constraints perspective of social housing and by applying the corporate governance model of organisation during economic downturn, we have been able to identify the implementation strategy that is necessary.

It is evident that little systematic research has been applied following new public strategic management concepts and development of RBT in the public sector context. This paper examined the above concepts in the light of DHW and HNZN, the public sector organizations in the Trans-Tasman region. A better understanding of the new strategic management development in the public sector context as a result of this paper will probably generate further research from both academic scholars and practitioners.

7.0 Policy Implications

The research adds value to current policy discussions on housing affordability on the one hand, and the real possibility of the real estate ‘bubble’ from the bust behaviour. It highlights the tension between the need for property values to depreciate for New Zealanders so that they may not have an asset that accumulates wealth, contrasted with the need for home prices to be affordable for people with low-moderate incomes. This is also the case for Western Australian low-moderate income dwellers.

Both the countries income eligible homeownership assistance programs have had a successful track record over the past few years. Recent program results indicate very low rates of mortgage possessions. Financial and Family counsellors also report relatively low incidence of mortgage possessions among Keystart recipients (WA), while NZ Welcome Home Loan programme — based on the mortgage insurance scheme piloted recently through Kiwibank can learn from effective management of home loans (low incidence of mortgage possessions) through WA Keystart programme. Most directly these findings suggest both the need for, and the potential effectiveness of, homeownership assistance schemes that target low-to-moderate income earners in New Zealand.

There is a strong argument for expanding the Trans-Tasman coverage of such programmes. This need to expand government housing programmes is to be qualified by the recognition that the success is dependent upon the direction of property values and the ability of government and monetary system to stabilise the market. Moreover, the experience in the past suggests that it would be at this point that the sustainability model’s potential to identify enhanced resource provisions and other mechanisms would be most beneficial.

In this respect, the implications of land release mechanisms and other government decisions that impact upon property values need to be considered within a broader ‘whole of government’ and public good framework. Though the issues are complex there is a strong argument for promoting Social Sustainability Advantage in public housing management.

End notes

ⁱⁱ Satisfactory level is defined as a performance indicator with the measurement of not less than 50%.

ⁱⁱⁱ DHW has become DH, effective since December 2008.

- ^{iv} highly moderate level ranking (measures a better resource capability than its counterpart and more than 65% of effectiveness for that particular indicator)
- moderate level (measures a less than equal resource capability than its counterpart and value between 50% to 65% of effectiveness for that particular indicator)

Wage Determination and Discrimination According to Gender Using Different Preferences of Men and Women¹

*Lenka Filipova, lenka.filipova@vsb.cz

VSB-Technical University of Ostrava, Czech Republic*

Abstract

The paper has arisen as a part of the project dealing with the questions of measuring of wage determinants and wage discrimination on the basis of different subjective requirements of women and men on their wages. Using the ordered-response model (Ordered Probit), it analysed wage determination on the basis of Mincer's Wage Regression including dummies for role in a family. The analysis was carried out with the total sample of respondents and subsequently separately for men and women as well as for the respondents subjectively feeling and not feeling discriminated. The data were gained from questionnaire survey carried out in Ostrava city, Czech Republic. In general, the analysis did not prove previous conclusions of theories or empirical studies about prevailing influence of personal characteristics on the wage rate. The influence of family characteristics, especially family roles on the wage rate failed to be proved. Nevertheless, the analysis proved statistically significant differences in the wage determination between above mentioned groups of respondents.

Introduction

Wages are an important indicator in expressing human capital value. The standard Neo-classical theory of the labour market states that wages (the marginal costs of labour) should correspond with income from the marginal product of labour under the conditions of ideal competition. This principle is the basis for standard human capital theory which assumes that the amount of wages is influenced by the personality characteristics affecting labour productivity. Mincer (1974) expressed the relation of human capital to the amount of wages through a wage equation which has become the methodology basis for simulating wage determinants up to the present.

More sophisticated theories have been developed (such as those by Dickens and Katz, 1987 or Krueger and Summers, 1988), modifying Mincer's wage regression by adding a labour status description (the position in one's employment, working hours, type of employment contract, and qualification requirements), corporate factors (how large a company is, commercial and non-commercial sectors, and industries), institutional factors (legislation protection of employment and the minimum wage) and regional factors, which are now collectively referred to as wage determinants; any differences in wages are due to these determinants.

If the wage differentiation is not explained by objective wage determinant characteristics, it is referred to as wage discrimination. Nevertheless, no economic studies have worked with the sociological aspect of different requirements of men and women for the wage rate. According to sociological studies (Dudová, 2007; Hašková, 2003; Křížková, 2006; Moe, 2003 etc.¹¹) the unexplained differences in wages do not have to be caused by discrimination but different preferences of men and women, namely in relation to family existence. 'General' (gender) stereotype places an emphasis on the 'caring person type' and the 'family breadwinner type', with these types prevalently matching the 'simple' division by sex. A shift in this perception is seen in single-parent families. Men tend to put an emphasis on the caring type (part-time jobs and lower wages) while women on the income for the family (full-time jobs and higher wages). Where there are no children, the differences become blurred. The role of an individual in the family can then be seen as one of the wage determinants. This can be set in the preference theory which, as a part of the neoclassical economy, presents standard economic explanation of the decision-making process of individuals. Since Gary Becker (Theory of preferences, 1997) this theory has gained its relevance for all aspects of life decisions.

The aim of this paper is to connect a contemporary economic quantitative research of wage determinants with a sociological qualitative research of the impact of family roles and preferences on wage and to bring a new approach to the analysis of wage determinants and discrimination according to gender on the basis of modified Mincer wage regression where the vector of explanatory variables will include three types of factors: personal, firm and family characteristics.

Ordered probit model of wage determinants: data, methodology and variables

In the project called ‘Measuring Wage Determinants and Wage Discrimination’ questionnaire survey was carried out, the aim of which was to acquire data relating to wage determinants of individual respondents according to Mincer’s theory, their subjective requirements for wage rate and status in the family. The basic set researched was ‘prime-age’ working population of the city of Ostrava, Czech Republic. As the features of the basic set are known from Population and Housing Census carried out in 2001 the method chosen was quota selection which ensures consistent structure of the basic and the selective set. Quotasⁱⁱⁱ were provided for sex, age and field,^{iv} which individual respondents work in.

Survey was carried out in the city of Ostrava from 26 May 2010 to 1 July 2010. 399 questionnaires were distributed in total, out of which 391 were completed properly. Subsequently, the selection of 300 questionnaires was made in order to meet established quotas. For further validation of consistency between the basic and selective set structures with respect to defined quotas, a hypothesis of relative frequencies equality was tested for each quota. Results of statistic tests confirmed relative frequencies equality on the significant level of 5% and the selection can be considered as representative.

The wage determinant analysis was based on a standard model stemming from Mincer’s wage regression which was besides personal characteristics extended by traditional institutional and corporate characteristics. However, the aim of the research was especially following other influences on the wage rate which were based on sociological studies emphasising the influence of roles in the family on the wage rates. If the analysis confirmed the influence of family status and roles in the family on the wage rates, it would change the view of gender-based discrimination.

Questions related to the care of children and household were also a part of the questionnaire. Therefore, the distribution of selection set frequencies is shown in the following two charts with respect to the care of children and household (hereinafter “care”) according to the sex, education and wage rate before the econometric analysis. The question about prevailing care offered respondents three types of responses: I take care mostly; my partner takes care mostly and we both take care equally. Only respondents having children and with the marital status married or single living in common household were included in the charts.

The first chart shows that responses of common care prevail for both sexes and education, the second position is prevailing care of the particular respondent and least respondents granted prevailing care to the partner. The responses of university educated men are interesting, they grant prevailing care for themselves in 29%, only 7% of them responded the partner and the rest, i.e. 64% responded equal care. Whereas, in case of university educated women, 12% of respondents stated the partner as the prevailing caretaker, 24% granted the care for themselves and 65% stated equal care with the partner. The distribution of responses of skilled men is interesting as well, 22% of them granted the prevailing care to their partners, 19% to themselves and 59% equal care.

From this data distribution it is obvious that in case of subjective characteristics of role perception in the household it would be proper to specify and choose questions more precisely, so as not to be psychologically marked. Besides the question about the care of children, there could have been written the question about the risk losing the employment in the questionnaire. Here, an individual prefers job security with usually lower wage or prefers the employment with the higher prestige and higher wage but with a larger degree of responsibility and competition in the field or profession and thus higher risk. The question about the care of children and household could have been specified to average number of hours spent with children daily, not the vague formulated question about prevailing care. Moreover, there might have been written so called check questions which could have helped to eliminate too subjective views of the question. For instance the question about the number of hours spent with

children could be supported by the question about the average working hours a day, etc. This should be taken into consideration for the future research.

TABLE 1: CHILDREN CARE ACCORDING TO SEX AND EDUCATION

		Children care						
Sex	Education	Me	% of total	Partner	% of total	Equally	% of total	Total
Male	Primary	2	33			4	67	6
	Training	5	19	6	22	16	59	27
	High	1	7	1	7	12	86	14
	University	4	29	1	7	9	64	14
	Total of Male		12	20	8	13	41	67
Female	Primary		0	2	100		0	2
	Training	6	25		0	18	75	24
	High	12	30	2	5	26	65	40
	College		0		0	2	100	2
	University	4	24	2	12	11	65	17
Total of Female		22	26	6	7	57	67	85
Total		34	23	14	10	98	67	146

Note: figures in the table state absolute numbers of respondents. Only % of total columns represent the percentage of a particular category to the total number of respondents in the particular row.

The distribution of responses to the question about the care of children and household shows slightly rising proportion of responses granting prevailing care to the partner with the wage rise. Though, it is not possible to assume any more significant ties between wage and care of children and household from such data distribution.

TABLE 2: CHILDREN CARE ACCORDING TO NET WAGE^v

		Children care						
Net wage		Me	% of total	Partner	% of total	Equally	% of total	Total
To 10 000 CZK		4	27	2	13	9	60	15
10 001 - 16 000 CZK		11	20	5	9	38	70	54
16 001 - 22 000 CZK		9	20	2	4	34	76	45
22 001 - 28 000 CZK		6	30	3	15	11	55	20
28 001 - 34 000 CZK		1	17	2	33	3	50	6
34 001 - 40 000 CZK		1	33		0	2	67	3
40 001 - 46 000 CZK		1	100		0		0	1
52 001 CZK and more		1	50		0	1	50	2
Total		34	23	14	10	98	67	146

Note: figures in the table state absolute numbers of respondents. Only % of total columns represent the percentage of a particular category to the total number of respondents in the particular row.

Traditional model of wage determinants is simply expressed by the following equation:

$$\ln W_{it} = X_{it}\beta + \varepsilon_{it}, \quad (1)$$

where i represents an individual and t time period. Dependent variable (wage) is expressed in a logarithmic form and X represents independent variables vector, in this case wage determinants. Theoretical foundation of this specification is the theory of human capital and coefficients are interpreted as earnings from investments into the human capital. ε represents an error term.

However, in this analysis it was not possible to express wage in the logarithmic form and to use the method of least squares as the wage was created in categories. Ordinal logit or probit models are usually used for categorically explained variables. Eviews Software uses the ordered-response model (Ordered Probit) with analytic second derivative methods to obtain parameter and variance matrix of the estimated coefficient estimates (Quadratic hill climbing) for the particular variable type.

Hence, the model has the following form:

$$W_i = X_i\beta + \varepsilon_i, \quad (2)$$

where t index is missing as data only for one observation period are used. Explanatory variables have the character of dummy variables. In total, 10 variables were used for wage determinant definition, out of which 3 represented personal characteristics stemming out of Mincer's wage regression (sex, age, education), 4 characterized institutional and corporate factors (ISCO^{vi}, NACE^{vii}, ownership, company size). For our purposes of observation of the influence of family status on wage rate there were used 3 other variables in the analysis, 2 of which were objective (number of children, marital status) and one variable represented subjective view of the role in the family in the question who was involved more in care-taking of children and household.

The analysis was carried out with the total sample of respondents and subsequently separately for men and women. First, all above mentioned variables were included, then separately personal characteristics, institutional and corporate characteristics and family characteristics to verify economic significance including variables into the analysis.

Results of the total respondent sample (see Table 4 in the Appendix) showed that the model was statistically significant as a whole, as LR statistics came out statistically significant. There had to be made slight adjustments in explanatory variables as for the integration of some categories which were marked for great variability in observation and software could not process calculation of coefficients with such unbalanced data. This category adjustment was used for all following analysis. Category integration was made in the cases of education (1 primary + 2 vocational education; 3 secondary with "maturita" exam + 4 college), ISCO (ISCO 1 + 2; ISCO 6 + 7; ISCO 8 + 9), number of children (category 4+5+6, which equals 3 and more children) and also the explained variable (highest categories of real wage, i.e. cat. 5 – 9). The analysis was carried out for original and new categories separately but the results did not differentiate much, which was the reason why the original wage categorization was stated below and used for the result interpretation.

Analysis and results

Mincerian presumptions about wage determinants were confirmed from the point of view of variables, i.e. the influence of personal characteristics. Sex and age variables were statistically significant. From corporate statistics only company size variable proved to be slightly statistically significant, namely with categories 4 and 5 (250 to 5000 employees). From family statistics only the number of children variable was slightly statistically significant, namely in the category 3 and more children only.

However, coefficient interpretation is more complex in cases of models with qualitatively (categorically) explained variable given than in the case of the OLS method. Here coefficient shows the probability to change the category of the explained variable with the change of particular explanatory variable (result is calculated for extreme, or end categories), whereas it is not possible to determine which category of explained variable is referred to. The result only shows whether the category is going to increase in case of coefficient plus sign (in our case it will be higher wage), or in case of coefficient minus sign to decrease, i.e. the explained variable drops to lower wage. In our case it is essential to take into account the fact that other (explanatory) variables are expressed in the categories as dummy variables as well, i.e. result need to be interpreted in comparison to reference category which represents first dummy variable (category) to be clear. Thus, for instance the variable coefficient SEX_2 (women) shows that women have higher probability that their wage will be in the low-wage category than men; or for instance the variable coefficient EDU_5 (university education) says that university educated people have higher probability that their wage is in the high-wage category in comparison to people with primary education and vocational education. This analysis does not include variables related to the subjective view of the care of children as it would mean to exclude childless households from the analysis, thus the loss of the particular sample of individuals.

Furthermore, only analysis (see ask authors for full results) of personal characteristics on the basis of Mincerian wage equation was carried out. Here the statistical significance and the value of coefficients with particular variables did not differ from the previous equation which points to the fact that personal characteristics play a significant role for wage rate determination, as the theory of human capital suggests. The only exception in comparison to the previous equation was explicit, though very weak statistical significance of age, namely with the category AGE_2 (30 – 39 years). The coefficient showed that people in this age category had higher probability that their wage would range within the higher categories than in case of the reference age category, which was 20 – 29 years.

When following institutional and corporate characteristics all categories except for ISCO_3 - Technicians and associate professionals proved (ask authors for full results) to be statistically significant. According to the presumptions there was a coefficient minus sign with all followed ISCO categories pointing at the probability of lower wage in comparison to the reference category, which was ISCO 1 and 2 (Managers and Professionals). The property variable was also statistically significant when employees in the private sector had greater probability of higher wages compared to the public sector. The company size indicator did not influence wages significantly, only categories 4 and 5 (250 – 4999 employees) marked weak statistical significance with plus coefficient values which represented the probability of higher wage in comparison to reference category (up to 10 employees).

When only subjective and family characteristic were included into the equation, the model as a whole was statistically insignificant (ask authors for full results) for the reason that except for family status, no category out of those statistically significant variables had a significant impact on wage category. STATUS_2 category coefficient showed that married couples or people living in partnership had higher probability that their wage was in higher categories.

Analysis for men and women separately

The analysis carried out separately for men and women showed differences in statistical significance for wage determinants. When including all variables the model came out statistically relevant for both men and women (ask authors for full results). With men statistical relevance appeared in case of personal characteristics with the age category 4 (40 – 49 years), with minus, then with both educational categories with the presumed plus coefficient sign.

Furthermore it was necessary to aggregate ISCO categories into larger units (ISCO 1,2,3; ISCO 4,5,6; ISCO 7,8,9) for the calculation than in the case of analysis of the total sample. This aggregation was used for the rest of the component analysis. From corporate characteristics category ISCO 4,5,6 with plus sign was slightly statistically significant; company ownership (employments in private sector had higher probability of higher wage category than employments in public sector); company size categories 4 and 5 again with plus sign. From family characteristics the number of children variable proved to be statistically significant, namely in categories 3 and more children, they had also 1,5 times higher probability of higher wage category.

With women the situation was different. Only the age variable in the category 30 – 39 years with coefficient plus sign proved to be statistically significant from personal characteristics. The education variable did not prove to be statistically significant with women. Moreover, the university education category had to be excluded due to little number of observations. Corporate characteristics played a more significant role with women for wage rate determination. Basically, all observed variables and their categories were marked for statistic significance. The most impact proved to be in ISCO variable and in two other company size categories (4 and 5). Family characteristics did not play a significant role with women for wage rate determination; none of the variables was statistically significant.

When including personal characteristics stemming from Mincer's equation the model came out statistically significant, but only the education variable was statistically significant, namely in the university education category with the suggested plus sign showing the probability of higher wage categories. With women the model with personal characteristics came out only slightly statistically significant, whereas the age category 30 – 39 years with plus sign was slightly statistically significant only (ask authors for full results).

When analysing institutional and corporate characteristics separately (ask authors for full results) the model did not come out statistically significant for men as the only statistically significant variable from the observed characteristics was category ISCO 7, 8, 9 with the suggested minus sign. The other variables and their categories did not play a significant role with men for wage rate determination. With women the situation was opposite. When analysing corporate characteristics the model came out statistically significant as all observed variables in all their categories were statistically significant. High statistic relevance was especially in variable ISCO with coefficient minus sign. As though the ISCO variable compensated the importance of education. Company ownership and company size variables except for categories 3 and 6 were also significant. Nevertheless, the significance in other categories proved that categories according to company size were relevant for wage rate determination.

The analysis of family characteristics did not prove statistical significance with both men or women (ask authors for full results). With women none of the observed variable proved to be statistically significant, with men the family status variable and number of children variable in the category 3 and more children were slightly significant. Plus sign in the category STATUS_2 said that married men or men living in partnership had higher probability for higher wage category than single living men.

Analysis for respondents subjectively feeling and not feeling discriminated separately

Further analysis was carried out for individuals who feel discriminated against, ie according to their opinion they are payed less than they would expect, regardless of sex. From a total of 300 people questioned, 175 felt they were discriminated against in terms of salary (83 men, 92 women). In the table, the total number of men and women who consider themselves discriminated against in terms of wages is given divided according to education and marital status, as well as their share of the total number in the given category.

TABLE 3: SUBJECTIVELY DISCRIMINATED AGAINST ACCORDING TO SEX, EDUCATION AND MARITAL STATUS

Sex	Status	Education											
		Primary school		Training college		High school		College		University		All categories	
			% of total		% of total		% of total		% of total		% of total		% of total
Male	single			14	44	15	56			11	58	40	51
	m/p	3	50	21	70	11	69			8	50	43	63
Total male		3	50	35	56	26	60			19	54	83	57
Female	single			16	80	7	33	1	50	4	44	28	53
	m/p	2	67	23	85	23	51	2	100	14	58	64	63
Total female		2	50	39	83	30	45	3	75	18	55	92	60
Total		5		74		56		3		37		175	58

Note: m/p = married or partnership

In total, 57 % of men and 60 % of women considered themselves to be discriminated against in terms of wages. With both sexes there was a distinctly higher number of those considering themselves not paid according to their worth among spouses and common-law spouses (men and women 63 % of the total number in each category) than single people (men 51 %, women 53 %). The only exception was single men with a degree (58 %) compared to 50 % if they were married or living with someone. This might have something to do with age – young male graduates are often ambitious and expect high remuneration.

The highest proportion of people considering themselves discriminated against was women with apprenticeships (83 %), the lowest proportion was also found amongst women, this time with high school education (45 %). Among men the proportion of subjective discrimination across the respective categories was more even. The highest was among high school educated men (60 %), the lowest among those with a university education (54 %).

For the econometric analysis of people who consider themselves unfairly paid (see Table 5 in the Appendix) the model is statistically significant for all variables and men and women together. Gender and education, thus personal variables, belong again among important variables determining wages. Negative coefficient for the category SEX_2 expresses that women suffer from higher probability that their wages will be in lower wage

categories. Coefficients for educational categories showed that a higher level of education corresponds to higher wages. Regarding firm characteristics, the size of a company (with positive coefficients) was the only statistically significant variable. Family statistics did not prove to have statistical significance for wage determination.

Next step was the regression, according to the previous structure of analysis, for the personal, firm and family characteristics separately (ask authors for full results). Analysis of the Mincer equation, which only takes into account personal characteristics, was statistically significant as a whole, again with the statistically significant variables of gender and education, as in the previous analysis. Analysis of institutional and firm characteristics was statistically significant for subjectively feeling discriminated, too. Statistically significant variables were the firm size and ISCO. Family characteristics did not prove to be statistically significant, even though they were analyzed separately.

The model of wage determinants for subjectively not feeling discriminated (see Table 6 in the Appendix) was statistically significant as a whole, too. Gender played an important role again, in the sense that women have a higher probability that their wages will be in lower wage categories. From the personal characteristics of Mincer equation, tertiary education was the only statistically significant variable. Among firm statistics ownership and ISCO 7,8,9 were statistically significant. Among family characteristics, a variable of number of children in the category of 3 or more children was the only one statistically significant.

Further, personal, firm and family characteristics were analyzed separately (ask authors for full results). As far as personal characteristics are concerned, gender and university education played the most important roles. However, the variable of age also proved statistically significant in the category of 30-39 years with the positive coefficient showing the effect of working experience on wages in the sense that greater work experience correlates to a greater probability of higher wages in a given category. The model for the firm characteristics proved statistically significant in the variable of ISCO and ownership, firm size did not play any role here. The equation for the family characteristics was not statistically significant, the only statistically significant variable was the variable of family status.

Conclusions

The analysis was carried out with the total sample of respondents and subsequently separately for men and women and also separately for those who were subjectively feeling discriminated and those who were not. First, all variables mentioned above were included, then separately personal characteristics, institutional and corporate characteristics and family characteristics to verify economic significance of including variables into the analysis.

The results of the total respondent sample showed that the model was statistically significant as a whole. From the variables point of view, especially Mincerian presumptions about wage determinants proved to be right, i.e. the influence of personal characteristics. When analysing personal, corporate and family statistics separately, the models were statistically significant with statistically significant variables in case of personal and corporate characteristics. The model for family characteristics was not significant as the only statistically significant variable was the family status in this case. The other two family characteristics did not prove their significance.

The analysis carried out for men and women separately showed differences in statistical significance of wage determinants. When including all variables the model came out statistically significant for both men and women. With men, personal characteristics such as education and age played an important role. The analysis carried out separately for personal, corporate and family characteristics family status and the number of children, namely in the category 3 and more children, variables came out slightly statistically significant with men.

Statistical significance of education did not prove with women. Generally, the model with personal characteristics came out slightly statistically significant. On the contrary, corporate characteristics played an important role with women for wage rate determination, especially in ISCO variable (job classification). The model for family characteristics did not prove statistical significance; none of the variables was statistically significant.

Even in the case of analysis carried out separately for the respondents subjectively feeling and not feeling discriminated without the respect to gender the results showed differences in the statistical significance of wage determinants. In the case of subjectively feeling discriminated respondents more important were the variables of

education and firm size. Family characteristics were not statistically significant even though analyzed separately. On the contrary in the case of not feeling discriminated respondents variables ISCO, ownership and number of children in the category of 3 and more children played more important role. In both cases variable of gender was statistically significant with the negative sign. Because of the family characteristics not playing statistically significant role in this part of analysis, it is not possible to suppose that wage differences between men and women could be explained by these characteristics.

In general, the analysis did not prove previous conclusions of theories or empirical studies about prevailing influence of personal characteristics on the wage rate. The influence of family characteristics, especially family roles on the wage rate failed to be proved. The problem can be seen especially in asking questions about delicate topic of family roles which can bring rather psychologically marked and little objective responses. It should be advisable to take into account this aspect in the future research. Furthermore, check questions which could help to eliminate too subjective viewpoints of the question. For instance the question about number of hours spent with children could be supported by the question about the average working hours a day, etc.

Manufacturing Dissent: Domestic and International Ramifications of China's Summer of Labor Unrest

Abstract

The instances of labor unrest in the summer of 2010 are a clear indication that China has reached a critical developmental juncture. Rising social inequity and redistributive injustice reflect strains of economic growth that have proved as inevitable as they are consequential. Against the backdrop of an impending leadership transition and a global economy emerging from recessionary throes, China's changing labor market conditions will shape the future path of economic development and growth in substantive ways. In its effort to mitigate regional disparities, China is finding itself locked into a precarious socio-economic balancing act with far-reaching consequences for domestic stability and international competitiveness. What are the short- to medium-term implications for China's economy? Is China likely to experience its own version of a flying-geese pattern of economic development? What is the likely effect on China's global labor cost arbitrage and international competitiveness?

Keywords: China, labor unrest, social stability, economic development, competitiveness

Introduction

As it enters the second decade of the 21st century, China is displaying all the signs of transitioning into a new stage of economic development. The economic opening up of China in the early 1980s had sowed the seeds for "the most successful joint venture in world history" – the combination of Western capital and purchasing power and Chinese low-cost labor (Seigart, 2008). Throughout the initial reform period, policymakers focused most of their time and energy on crafting policies aimed at sustaining economic growth and development at all costs. On the surface, China's economic transformation is nothing short of an economic miracle. However, on closer analysis, the sustainability of its newfound status as a powerful engine for economic growth in Asia and the world critically depends on the government's ability to mitigate potentially destabilizing side-effects of rapid economic growth (Wolf, 2008). Moreover, the breadth and depth of the expanding fault lines in China's economic terrain serve as powerful reminders of the precarious nature of China's political economy and an economic development trajectory punctuated by social, institutional or political pressures and challenges (Shrink, 2007). As a newly-recognized lower-middle-income country (World Bank, 2009), the economic policies that suited China's take-off stage of development and helped to dispel the image of a low-income country need to be recalibrated to effectively ensure the realization of a well-off society (*xiaokangshehui*, 小康社会) and harmonious society (*hexieshehui*, 和谐社会). In recent years, the Chinese government has begun to openly acknowledge the urgency of charting a new economic course in order to address rising levels of social stratification and the emerging middle class dynamics (Li, 2010).

From a macro-economic perspective, the Chinese economy is also beginning to display noticeable strains. In an uncharacteristically blunt assessment indicative of Beijing's heightened sensitivity to economic conditions, Premier Wen Jiabao described the prevailing macro-economic conditions as "unstable, unbalanced, uncoordinated, and unsustainable." Amid rising concerns about the sustainability of an export-oriented development paradigm in light of the recent global economic downturn, ramping up

domestic consumption is rapidly emerging as a first-order priority of 21st century economic reform. Commenting on the country's contemporary "consumption conundrum" Michael Pettis, a professor at Peking University's Guanghua School of Management, states that "China has come to depend on exports, especially to the United States, to absorb that excess capacity -- something U.S. consumers were happy to do especially over the past decade. But the effect of jitters over the strength of that U.S. consumption shows that one of the most important reforms China needs now is to reduce its vulnerability to U.S. consumers by boosting consumption at home (Pettis, 2010)." Indeed, the need to rebalance economic growth is assuming a new level of urgency ahead of the 2012 leadership transition.

In 1986, Deng Xiaoping was quoted in an interview as saying that, "[T]o get rich is no sin. However, what we mean by getting rich is different from what you mean. Wealth in a socialist society belongs to the people. To get rich in a socialist society means prosperity for the entire people. The principles of socialism are: first, development of production and second, common prosperity. We permit some people and some regions to become prosperous first, for the purpose of achieving common prosperity faster..." The resulting capital and wealth accumulation not only created vibrant growth poles and agglomeration economies in China's coastal provinces but it also defied Deng Xiaoping's hope that "our policy will not lead to polarization, to a situation where the rich get richer while the poor get poorer. (Xiaoping, 1986)" Consequently, and in spite of the fact that China's economic reform efforts have transformed the lives of hundreds of millions of people, perceptions of relative deprivation continue to pervade China's contemporary socio-economic terrain.

By all accounts, the Chinese economy has reached a critical development juncture. A dramatic increase in labor disputes since the mid-1990s is a clear indication that the strains of economic growth are as inevitable as they are consequential. The wave of labor unrest in the summer of 2010 has renewed speculation about the eventual emergence of an 'independent' labor movement. And with society on track to growing old before becoming rich, expanding labor dissatisfaction remains a distinct possibility.

The central focus of this article is to evaluate the domestic political and social ramifications of an arguably 'newly-empowered' working class as well as the economic and competitive implications for China's position in global production networks. In other words, is the emergence of an 'organized' and 'independent' labor movement with the potential for large-scale socio-political transformation a possibility in the future? Does the fact that the Chinese economy has arrived at a critical juncture herald a "flying-geese" moment in terms of its developmental trajectory? In that context, we will also briefly discuss whether and how China might be able to address an already precarious socio-economic reality.

China's Economic Transformation: The Good, the Bad (and the Ugly?)

The adoption of an "Open Door" policy in 1978 put the Chinese economy on a path of fundamental transformation and vitality, eventually surpassing Japan as the world's second-largest economy in late 2010. Over the course of four decades of economic reform and restructuring, China's GDP has risen from Rmb362.4 billion in 1978 to Rmb33.5 trillion in 2009. The incidence of extreme poverty has also been in noticeable, albeit uneven, decline throughout the reform period. According to a study conducted by World Bank economist, the rural poverty rate declined from 76 percent in 1980 to less than 13% in 2001. Meanwhile, urban poverty rates dropped from 6 percent in 1981 to 0.5 percent in 2002 (Chen and Ravallion, 2007). Finally, the 'middle class' phenomenon is rapidly taking hold in China as well. McKinsey & Co. estimates that the share of urban households falling into the lower and upper middle class segments, at 22 percent in 2005, could reach 71 percent by 2015 and 79 percent by 2025 (Farrel, Gersch and Stephenson, 2006)

Overshadowing the obvious success of economic reform, however, is the fact that break-neck growth in the post-Mao era has also contributed to a widening of social inequalities (see figure 1). As Mancur Olson aptly noted, "...rapid economic growth means rapid economic change, and that economic change entails social dislocation". As a result it is conceivable that "*both the gainers and the losers from economic growth can be destabilizing forces*", which in due course may lead to political instability.¹ In short, China's post-Mao economic reform and restructuring efforts may well have sown the seeds for eventual social mobilization and pressurization of the political sphere.

China's gradual discrediting of the communist moral order in favor of a more market-conforming economic and social order was an early litmus test of Beijing's general commitment to economic reform and restructuring. Against the backdrop of the ideological *end-of-history* perspective, efforts towards deepening economic and social development – which Deng Xiaoping reaffirmed in his 1992 *Nanxun* (Southern Inspection) tour, urging renewed efforts at opening up (*kaifang*, 开放) assumed a heightened degree of urgency by the early 1990s (Wong and Zheng, 2001)

FIGURE 1: RAPID GROWTH & RISING INEQUALITY (1979-2009)

Source: National Bureau of Statistics, China Statistical Yearbooks; Jiandong Chen and Wenxuan Hou, “New Approach to Estimate the Chinese GINI Coefficients from 1978 to 2003” (paper presented at the 2008 conference of the Chinese Economic Association (UK).

Seen from the perspective of the Chinese leadership, it was seen as instrumental in helping to address institutional uncertainties and weaknesses as well as build a new foundation of political legitimacy (Zheng, 2004). Committing to sustaining economic growth, deepening economic development and improving people's overall livelihood came to be seen as the only remaining option for consolidating political legitimacy, while at the same time minimizing pressurization of the political sphere. From a societal perspective, meanwhile, the emergence of a “post communist personality”, defined by its “ethos” of consumerism and unprecedented opportunities for individual wealth and pleasure” provided an additional imperative for deep reform (*shenhuagaige*, 深化改革) (Wang, 2002).

The socio-political and socio-economic ideologies adopted by Beijing since 2000, including Jiang Zemin's ‘Three Represents’ (*san gedaibiao*, 三个代表) and Hu Jintao's ‘Scientific Development Concept’ (*kexuefazhan guan*, 科学发展观) underline the government's keen appreciation of the latent dangers of rising income inequality. In light of the very real possibility of “growing old before growing rich”, popular support for deepening marketization is progressively coming under strain (Fang and Wang, 2009). Seen in conjunction with obvious growth and income disparities between coastal and rural regions, it is hardly surprising that perceptions of distributive injustice are on the rise.

Sweeping state-owned enterprise (SOE) reform efforts, begun in earnest under Premier Zhu Rongji in 1998 accentuated feelings of relative deprivation in Chinese society. The resulting privatization drive largely coincided with the gradual phasing out of the ‘iron rice bowl’ (*tie fan wan*, 铁饭碗) – essentially a cradle-to-grave social contract that amplified the declining profitability woes of many SOEs (Yusuf, 2002). Apart from this economic policy shift, other contributing factors behind China’s strains of economic growth include changing social attitudes as reflected by an emerging middle class, rising expectations of a new generation of (migrant) workers, structural challenges of China’s pension system, mounting employment pressures and the specter of rising inflation (Gold, 2006).

In recent years, the social challenges related to SOE layoffs have been exacerbated by placement problems for college graduates. Beginning in 1999, the government embarked committed to an expansion of higher education, partly to offset temporary employment pressures for high school graduates competing with laid-off SOE workers (Cao, 2006). As a result of aggressive commercialization, the number of college graduates increased from 850,000 in 1999 to just over 6 million in 2009. The Ministry of Education estimates that roughly 25 percent, or 1.5 million of the 6.3 million students who graduated in 2010 have failed to secure a job (Roberts, 2010).

From a short-term perspective, the socio-economic pressures of graduate unemployment will present the Chinese government with a serious challenge as it aims to create a ‘harmonious’ and ‘well-off’ society by 2020. Without immediate prospects of a job, many college graduates of rural families decide to remain in China’s larger cities – where they have become known as the ‘ant tribe’ (*yizu*, 蚁族) – in the hope of eventually landing a job. Against the backdrop of thirty years of reform and economic development, people in the lower social strata are no longer content with resigning themselves to ‘let some people get rich first’ (*rang yibu fen ren xianfu qi lai*, 让一部分人先富起来). Rather, in the contemporary setting, Deng Xiaoping’s ‘to get rich is glorious’ (*zhifuguangrong*, 致富光荣) dictum appears to instill a sense of entitlement in China’s working class. Not content with delaying gratification in the face of perceptions of relative deprivation, and considering changes in social attitudes, demands and expectations among China’s new generation of migrant workers and masses of unemployed graduates, a scenario whereby these (and other) ‘social underdogs’, driven by a sense of entitlement to at least partake in a comfortable lower-middle class lifestyle, are channeling their general social discontent into an “angry youth” (*fenqing*, 愤青) consciousness, thus posing a clear and present danger to social stability and challenging the political legitimacy of the Chinese Communist Party, is becoming an increasingly distinct possibility. “Once this consciousness takes root,” notes Yu Jianrong, director of the Social Problem Research Center, Rural Development Institute of the Chinese Academy of Social Sciences, “it will cause more social unrest at the grass-roots level. We can see this budding mentality at Internet forums where views opposing mainstream values are expressed with regard to political proposals or controversial social issues. These defiant opinions reflect the social underdogs’ dissatisfaction and protest, and if not checked, will aggravate hatred against the bureaucracy (Jianrong, 2010).”

Rather than gradually ushering in political liberalization and higher levels of accountability, if not strengthening the prospects for democratization, China’s sustained economic reform has reinforced a perception of socio-economic entrapment among China’s less-fortunate social groups. A perception that is further aggravated by the government’s failure “to create employment conditions and expand employment through promotion of economic and social development,” as stated in Article 10 of the 1994 Labor Law (Labor, 1994). Viewed against the backdrop of a “decentralized predatory state (Pei, 2008)” and endemic institutionalization of corruption (Wederman, 2004), the intensifying assertiveness of China’s working classes is as much an indication of civil society stirrings and democratization ambitions as it is a manifestation of frustration over unfulfilled or delayed economic gratification.

Deliberate yet cautious pragmatism – famously captured by Deng Xiaoping’s observation that “it doesn’t matter if the cat is black or white; as long as it catches mice, it’s a good cat” (*baimao, heimao, nengdaihaozijiushihaomao*, 白猫, 黑猫, 能逮耗子就是好猫) and “Crossing the river by feeling for stones (*mozheshitouguohe*, 摸着石头过河) – has become a hallmark of the Chinese Communist Party (CCP) over the course of three decades of economic reform and restructuring.

In light of a rising incidence of labor unrest, public order disturbances (扰乱公共秩序犯罪) and other so-called ‘mass incidents’ (群体性事件), reliance on such pragmatism alone, while necessary, may

not be sufficient to deal with the broader consequences of China's remarkable economic transformation, global economic integration, and disruptive changes in social attitudes (Guthrie, 2007). Labor unrest, disputes and strikes are no longer just limited to regions that experienced widespread economic and social dislocation as a result of SOE reform efforts, nor are the grievances limited to layoffs or social welfare and insurance concerns. A significant number of mass incidents, which have risen roughly ten-fold since 1993 to reach 87,000 in 2005, meanwhile, are fueled by frustration and anger against corrupt and heavy-handed practices of local and/or regional government officials (Fewsmith, 2008)

The accumulating challenges and pressures in China's social sphere carry highly consequential levels of cumulative and systemic risk. Failure to embrace and implement more sweeping, pro-active and broad-based policy initiatives would inevitably increase the pressure on the political sphere to a level not seen since the events that led up to the Tiananmen Square Incident in 1989. At present, the documented incidents of social unrest have been geographically dispersed, without any real evidence of broader coordination between or feelings of unity among the people involved. This does not, however, detract from the possibility of such incidents triggering large-scale mobilization and potentially coalescing into a broad-based and coordinated movement (Murray Scott, 2004). In short, on the eve of a leadership transition in 2012, China has arrived at a critical juncture in its developmental path, with far-reaching consequences for political, economic and social stability.

China's New Labor Regime: Good Intention, Bad Timing?

Aware of simmering tensions among the working class over the cumbersome and time-consuming labor arbitration and redress process, and wanting to pre-empt disruptive waves of labor activism, China's National People's Congress promulgated the Labor Dispute Mediation and Arbitration Law (*Zhonghuarenmingongheguolaodongzhengyitiaojiezhongcaifa*, 中华人民共和国劳动争议调解仲裁法) on 29 December 2007 (effective 1 May 2008). This followed the earlier adoption of a new Labor Contract Law (*Zhonghuarenmingongheguolaodonghetongfa*, 中华人民共和国劳动合同法) on 29 June 2007 (and effective 1 January 2008), designed to "improve the labor contract system, specify the rights and obligations of both parties to the labor contracts, protect the legitimate rights and interests of the workers and construct and develop a harmonious and steady employment relationship."² Finally, the government published its first-ever white paper on human resources development on 10 September 2010, outlining policy measures to deal with employment pressures, appeared intended to convey the institutional commitment to creating an effective and efficient human resources development legal system (China Daily, 2010).

In what would appear to be an ironic turn of events, these new laws – adopted in the hopes of reducing rapidly expanding fissures in China's socio-economic firmament and streamlining labor mediation and arbitration processes – have also proved instrumental in lifting the lid of a cauldron of long-simmering discontent, amid renewed concerns about the *real* redistributive capacity of the country's developmental model (Ravallion, 2010).

China's labor regime has entered a new phase. Although the new regime is not without lingering flaws and while concerns over "effective protection of workers' rights" in light of much-needed improvements with regard to "respect for the rule of law and commitment to fundamental rights in general" will persist, it nevertheless presents a marked improvement over the previous regime (Lu, 2008). For their part, and judging by dramatic uptake of labor disputes in 2008 ("Fig 2") – possibly influenced to some degree by the onset of the 2008 global economic crisis and its fallout in China's manufacturing sector – workers have signaled a new sense of empowerment to put demands on a system that for far too long had been overly dismissive of their concerns.

Labor strife in the mid- to late 1990s was primarily a response to the government’s gradual privatization efforts as well as a reflection of concerns of economic and social dislocation experiences by laid-off SOE workers. This ‘first wave’ of unrest was largely centered on the Northeastern (*Dongbei*, 東北) region – Loaning, Jilin, and Heilongjiang provinces, also commonly identified as China’s rustbelt. The dramatic jump in labor disputes in 2008, culminating in the dramatic labor mobilization in the summer of 2010, however, reflects the ever-increasing scope of social dissatisfaction. No longer geographically limited to the rust belt, labor discontent has been manifesting itself throughout the country, including most notably in the summer of 2010 in China’s ‘sunbelt’ (i.e. Guangdong province) (Lee, 2007). By 2008, ‘accepted’ labor disputes in Guangdong province accounted for 22% of the national total, up from 13% in 2001. Over that same time period, Guangdong registered a staggering 650% increase in the number of disputes, compared to a national average growth of 348% (Table 1). Concerns over the implementation of labor contracts, meanwhile, have consistently taken primacy of place among the various causes of labor disputes (“Fig. 3”).

TABLE 1: LABOR REMUNERATION AS A CASUAL FACOTOR 2001-2008

	National Level		Guangdong Province	
	Number of LaborDisputes	Labor Remuneration	Number of LaborDisputes	Labor Remuneration
2001	154,621	45,172 (29%)	20,348	8,102 (40%)
2002	184,116	59,144 (32%)	24,061	9,811 (41%)
2003	226,391	76,774 (34%)	42,228	20,335 (48%)
2004	260,471	85,132 (33%)	41,732	20,167 (48%)

2006	317,162	103,887 (33%)	54,855	24,628 (45%)
2007	350,182	108,953 (31%)	55,473	22,185 (40%)
2008	693,465	225,061 (32%)	150,023	65,027 (43%)

Source: China Labour Statistical Yearbook, various years.

From the national level perspective, wage remuneration has only marginally increased as a causal factor in relative terms. However, the unusually sharp uptake in remuneration-related disputes Guangdong province in 2007-2008, resembles a heretofore unprecedented rejection of the *compliant labor* myth. Nowhere would this be more disconcerting than in Guangdong province, which has long been described as the world's factory floor. Moreover, the very notion of *cheap labor*, and by extension China's primacy of place for global low-cost manufacturing is likely to be affected by the trends emanating from the summer of labor unrest. As such, the ripple effects of China's summer of labor unrest extend beyond the domestic sphere and could conceivably constitute a credible challenge to the sustainability of China's rising primacy of place and ambitions in the global economy.

From Domestic Concerns to International Ramifications

From a policy perspective, China is facing a consequential 'two-level game' political economy dilemma (Putnam, 1988). The most immediately viable options to defuse the rapidly accumulating domestic pressures invariably limit Chinese policy flexibility on important trade and currency issues on the international stage. After years of unquestionably reaping the benefits of global economic integration, the "globalization straightjacket" has caught up with China. The solution to the policy conundrum is anything but clear-cut: how to mitigate labor unrest and wage pressures without weakening China's global labor arbitrage? How to simultaneously address domestic concerns while also deflecting the growing chorus of international criticism and policy pressures directed against a rising China? Judging from contemporary reality, the Chinese government, keenly aware of its precarious political legitimacy, is trying to balance developmental/foreign investment pragmatism with economic mercantilism.

Whither Chinese Labor Arbitrage?

True convergence of wages will be a long time in coming, and yet the rising assertiveness of Chinese workers is beginning to prompt fears of an impending cheap labor shortage, with consequential implications for foreign businesses. In a recent 2010 report, the U.S.-China Business Council identified cost increases – including wage hikes and tax increases – as major operating concerns (USCBC, 2011). With the growth in number of labor disputes fueled by demands for wage hikes between 2011 and 2008

exceeding the national average growth by nearly 180%, China's global labor arbitrage is likely to be strained. The very notions of an abundance of cheap labor and the 'China price' will be in need of reappraisal (Harney, 2010). In recent years, a gradual but consistent hollowing-out has befallen China's low-end manufacturing activity, with neighboring economies, including Vietnam, India and Thailand being lower-cost competitive beneficiaries.(Yang, 2010)

In the near- to medium-term, China will still be in a position to defend its global labor arbitrage position through an internal "flying geese" developmental approach (Fang, Wang and Yue, 2009)The Chinese government's 10 April 2010 publication of "Opinions of the State Council Concerning Further Improving the Work of Utilizing Foreign Investment" is an attempt to moving up the value-adding chain – partly by encouraging investment flows into "high-end manufacturing, high-tech, modern services, renewable energy, energy conservation and environmental protection industries" – while also retaining a

competitive low-cost manufacturing advantage by encouraging foreign companies to locate labor-intensive, low-end manufacturing activities to its second- and third-tier cities that still enjoy a comparative labor-cost advantage (Table 2) (Ding and Neuman, 2010).The ability to sustain that advantage, however, is intricately linked to a highly controversial issue at the international level – China’s position on currency revaluation.

The Labor-Yuan Nexus

The leadership in Beijing is fully cognizant that key to mitigating labor unrest is constant job creation and keep incomes rising. And, at the heart of this strategy is ratcheting up exports. The oft-mentioned phrase that China is the “world’s factory” is both a blessing and a curse. China is not only the world’s largest exporter of manufactured products, but also a major exporter of agricultural commodities and other raw materials. This means that the Chinese economy is structurally dependent on exports. China’s share of merchandise exports increased from about \$10 billion in the late 1970s to \$326 billion in 2002. More precisely, China’s total share in world trade expanded from 1 percent in 1980 to about 6 percent in 2004 (Sharma, 2009) In 2004, China’s merchandise trade with the world totaled around \$1.3 trillion – the result of annual growth rates above 30 percent in some years. By end-2004, China had become the third-largest trading nation in dollar terms, behind the United States and Germany and just ahead of Japan (OECD, 2011). By 2008, net exports (or the trade-balance surplus) were about 12 percent of GDP (up from 2 percent earlier in the decade), and exports represent about 40 percent of China’s GDP. Overall, with the

sum of exports and investment representing about 80 percent of GDP, China's aggregate demand depends on its ability to sustain an export-based economic growth.

Thus, Beijing not only has an enormous stake in its export-led strategy, it is willing to engage in mercantilist economic policies – much to the chagrin of the United States and other countries -- to further advance it. As is well known, to the United States, the origins and persistence of its massive trade deficit with China is due to Beijing's mercantilist economic policies (Tables 3 and 4). The U.S. contention regarding China's mercantile behavior is rather straightforward: Beijing engages in gratuitously unfair trade practices via outright protectionism, and most perniciously, by deliberately manipulating its currency. Specifically, in maintaining an undervalued exchange rate, Beijing has been able to dramatically increase its export growth and pile-up large current account surpluses – the latter by aggressively intervening in foreign exchange markets to keep its currency from appreciating. This in turn has resulted in a massive build-up of foreign exchange reserves (Goldstein and Lardy, 2005). On the other hand, if Beijing allowed market-forces to determine the value of its currency, its current account surpluses would be much lower and American trade balances much healthier (Morrison and Labonte, 2009)

TABLE 3: U.S. MERCHANDISE TRADE WITH CHINA 1980-2007

Year	U.S. Exports	U.S. Imports	U.S. Trade Balance

Not surprisingly, American manufacturers with the backing of lawmakers in Congress have long argued that the artificially low yuan has placed American companies at a huge competitive disadvantage *inter alia* contributing to the bankruptcy of U.S. companies and the loss of tens of thousands of American jobs (Hufbauer and Wong, 2004). The contention is that the yuan is so undervalued (by some accounts as much as 40 percent) that it amounts to an unfair trade subsidy. This unfair advantage permits a flood of cheap Chinese-made goods into the United States, but makes American products expensive in China (Lardy, 2005). Thus, it is claimed that if the yuan was traded at its true market worth the bilateral imbalance between the two countries would be substantially reduced, if not altogether eliminated. This is because China's exports to the United States would become more expensive in dollars and would therefore decrease, while China's imports from the U.S. would become less expensive in yuan and therefore increase.

To make matters worse, China's unwillingness to allow the yuan to appreciate has, in turn, made other Asian Pacific Rim countries reluctant to allow their currencies to appreciate because of their fear of losing further export sales to China. As the U.S. trade deficit with China soared to record levels, the Bush administration and now the Obama administration, have come under intense pressure to take unilateral action to address the problems associated with the artificial undervaluation of the yuan. If earlier, U.S. lawmakers called for an immediate Chinese exchange rate adjustment, now many are increasingly calling

for punitive tariffs on cheaply priced Chinese imports unless China sharply revalues its currency. Yet, we claim that the imperatives of creating jobs and mitigating potentially destabilizing labor unrest is so strong that Beijing is not going to abandon its mercantilist economic policies anytime soon.

Conclusion

Current disagreements as to whether or not its developmental model has reached the Lewisian turning point (Fang, 2009).notwithstanding, China has reached a critical juncture, with obvious and far-reaching implications for the country's labor market equilibrium and sustained global economic competitiveness. The Chinese government may delay but cannot prevent further emancipation of a labor force harboring rising expectations and an unwillingness to accept social dislocation and relative economic deprivation in the name of national economic growth (Chang, 2008). In the long-term, the expectations of this new generation of workers and the changing labor regime will prove a highly complicating combination for the competitive sustainability of China's global low-cost labor arbitrage, and consequently, low-value added manufacturing. Thus China's political elite is facing a truly consequential policy conundrum, given that resorting to mere symptomatic treatment of social dissatisfaction cannot and will not negate the need for carefully recalibrated economic and social policies.

It would be equally ill-advised to eschew broader contextualization of the implications of current socio-economic dynamics for global economic competitiveness in the medium- to long-term. While it may be a near-term comfort that the rate of labor productivity growth – estimated at 13 percent per annum over the 2003-2010 period in apparel manufacturing – “comfortably outstrips that of Brazil, Vietnam, Indonesia, and Turkey (Jacob and Waldmeir, 2011),” the government can ill-afford policy complacency at this stage. And while it may be contextually unwarranted to draw comparisons between the recent developments in Egypt and the broader Arab world and the potential for stepped-up democratization pressures in China (Pei, 2011), it is nonetheless pertinent to reflect on the distinct possibility of recent socio-economic stirrings in China potentially reshaping the country's political economy space in fundamental ways. The path ahead is irreversibly and intricately linked to the policy choices and abilities of the Chinese leadership to come to terms with the demands and expectations of a new generation of workers in a changing China. Anything short of that carries the distinct possibility of jeopardizing the twin goals of achieving a well-off society (*xiaokangshehui*, 小康社会) and harmonious society (*hexieshehui*, 和谐社会).The challenge for China's incoming fifth generation of leaders will lie in their willingness to embrace a whole new degree of pragmatism, as the country embarks on a new chapter in its developmental path in the aftermath of the summer of discontent of 2010.

Ethical Leadership and Effective Leadership: An Analysis Based on the Results of the GLOBE Student Research in Slovakia

Anna Remišová, anna.remisova@fm.uniba.sk
Anna Lašáková, anna.lasakova@fm.uniba.sk
Comenius University in Bratislava, Slovak Republic

Abstract

In the first part of the paper, selected influential theoretical considerations of the issue of ethical leadership are being discussed. Next, authors describe briefly the methods used in the empirical research based on the GLOBE Student research project (Global Leadership and Organizational Behavior Effectiveness) which was conducted among Slovak university students of managerial and engineering study programs. Paper deals with the analysis of ethical leadership from Slovak students' point of view. Using the factor analysis method, implicit variables are identified and dimensions of ethical leadership in regard to Slovak cultural environment are characterized. Level of effectiveness of ethical leadership styles are examined, too. Finally, statistically significant differences between various groups of students in regard to ethical leadership attributes are analyzed. The results indicate that what is ethical is also effective in leadership.

Key words: GLOBE Student research project, Slovak leadership styles, ethical leadership, managerial ethics.

Introduction

Ethical leadership is still relatively new concept in managerial and leadership studies. Although in the framework of the western leadership theory it was researched by some scientists (Trevino, L. K., Brown, M., & Hartman, L. P., 2003; Resick, Ch., J., Hanges, P. J., Dickson, M. W., & Mitchelson, J. K. A, 2006; De Hoogh & Den Hartog, 2008; Bellingham, R., 2003), gaining knowledge about leadership in CEE countries is still stagnant. There is just limited understanding of what exactly the ethical leadership is and the body of empirical research on ethical leadership is only slowly beginning to build up. Ethical leadership is important for successful implementation of corporate social responsibility (CSR) principles and is vital for overall employees' ethical conduct because of the impact of leaders, and especially of senior executives (Trevino, L. K., Brown, M., & Hartman, L. P., 2003, p. 7), which they have on the behavior of their employees. As Schein noted (Schein, E. H., 2009), through decision-making on how to solve problems of internal integration and external adaptation of organization leaders apply their own assumptions, values and traits of own character. If leader's solutions work, followers of the leader have tendency to accept values and assumptions which lie behind the solutions.

Bellingham in his work *Ethical Leadership. Rebuilding Trust in Organizations* (Bellingham, R., 2003) identified some of the best practices ethical leaders are proficient in, which are striving for consistency and congruence, long-term thinking, holistic outlook, power sharing, ensuring diversity of voices, developing employees' commitment and capacity to learn, create a human workplace, build relationships, foster community, accept ownership and accountability, resist self-interests, put people and creativity in the centre, be authentic, be collaborative and constructive, develop stories of integrity and create a culture of trust (Bellingham, 2003, p. 6).

In one of the most influential work in regard to ethical leadership, Trevino and colleagues assume that ethical leadership is a construct of five basic dimensions of leader's behavior and personal traits: people-oriented behavior, visible ethical actions and traits, standard setting and accountability, broad ethical awareness and decision-making processes (Trevino, L. K., Brown, M., & Hartman, L. P., 2003, p. 15 - 17). Although this research was based only on perceptions of ethical leadership and dealt with no more than 40 US participants, some important conclusions were drawn. The study identified differences among two groups studied in the research and hence drew attention on the importance of social context from which respondents in ethical-based research come from.

Another important study on the ethical leadership was done by Resick and colleagues in 2006. In this article (Resick, Ch., J., Hanges, P. J., Dickson, M. W., & Mitchelson, J. K. A, 2006) ethical leadership scales were developed from the GLOBE project quantitative questionnaire which assessed effective leadership based on Likert-

type seven-point scale, where 1 meant that this behavior or characteristics greatly inhibits a person from being an outstanding leader and 7 meant that this behavior or characteristics contributes greatly to a person being an outstanding leader. The GLOBE leadership model is based on the assumption, that “leadership is a social label given to individuals if either a) their personality, attributes, and behaviors sufficiently match the observer’s beliefs about leader or b) the observer attributes group success or failure to the activities of perceived leaders” (Lord&Mahler, 1991 according to Dorfman, P. W., Hanges, P. J., Brodbeck. F. C., 2004, p. 670). This assumption derives from in leadership theory known as the *Implicit Leadership Theory*, which the GLOBE conceptual model extended to so-called *Culturally Endorsed Leadership Theory*. The GLOBE conceptual model works on the assumption, that culture plays an important role in influencing perceptions of the members of a given culture about what leadership attributes and behaviors are desirable and effective (Dorfman, P. W., Hanges, P. J., Brodbeck. F. C., 2004, p. 671). The GLOBE project questionnaire does not originally measure ethical leadership; the authors executed q-sort analysis, exploratory factor analysis and confirmatory factor analysis to develop dimensions of ethical leadership behavior and personal traits. Their research supported four-factor model of ethical leadership, namely Character and Integrity dimension, Altruism dimension, Collective Motivation dimension and Collective Encouragement dimension (Resick, Ch., J., Hanges, P. J., Dickson, M. W., & Mitchelson, J. K. A, p. 350).

In contrast to the Trevino et al research (Trevino, L. K., Brown. M., & Hartman, L. P., 2003), Resick and his team did not work with perceptions of ethical leadership but with the value level of how should a leader be and behave like; leadership scales assessed in the GLOBE questionnaire represent preferred, or better to say, desired end-states (Javidan, M., House, R. J., Dorfman, P. W., 2004, p. 45). That is perhaps why two dimension, Ethical Awareness and Ethical Accountability, which were identified in the Trevino et al research were not supported in the Resick’s empirical research. To summarize it, Resick and his team assume that four ethical leadership dimensions, Character and Integrity, Altruism, Collective Motivation and Collective Encouragement, proofed to be universally endorsed as important for effective leadership, but 62 cultures involved in this research differed according to the level of endorsement for each of ethical leadership dimensions (Resick, Ch., J., Hanges, P. J., Dickson, M. W., & Mitchelson, J. K. A, p. 354).

Another influential study of ethical leadership by De Hoogh and Den Hartog (2008) was a multi-method study where authors examined relationships of leader’s social responsibility with three different aspect of ethical leadership and with the despotic leadership style. Their results showed that ethical leadership was positively related to perceived top management effectiveness as well as to optimism of subordinates regarding the future, both the future of organization and their own future within it (De Hoogh, A. H. B. & Den Hartog, D. N., 2008, p. 297). The three ethical leadership dimensions, namely Morality and Fairness, Role Clarification, and Power Sharing were measured using three scales adapted from the *Multi-Culture Leader Behavior Questionnaire* (MCLQ; by Hanges and Dickson, 2004 according to De Hoogh, A. H. B. & Den Hartog, D. N., 2008, p. 303) and measured respondents’ perceptions of behavior of leaders respondents were familiar with.

In our introduction to the topic of the ethical leadership we referred to four influential concepts of ethical leadership, all of them verified in empirical research. Although authors used various approaches as well as methods for their research, and results are not fully comparable due to various methodologies, some common characteristics of ethical leaders could be outlined. However, all four concepts of ethical leadership presented here are linked to western conception of leadership. CEE countries are just seldom an object for leadership research in international context. Empirical research dealing with the ethical leadership style and its building elements from Slovaks’ point of view was, to one exception, out of researchers’ interests. The only one research dealing with this issue compactly is a survey, which was conducted among students of the University of Economics in Bratislava in the end of the 20th century (see Remišová, A., 2011). The main research outcome was a model of the leader’s profile of moral virtues. Three dimensions of that model were drawn: 1. relationship of leader towards him/herself (items like self-knowledge, self-esteem, self-confidence, self-control, etc.), 2. leader’s interpersonal relationships (items like tolerance, zero of others, honesty, fairness, justice, empathy, tactfulness, etc.), and 3. ethical characteristics regarding leader’s professional performance (items like responsibility, flexibility, creativity, maintain high morale,

punctionality, objectiveness, strong-mindedness, steadiness, consistency, etc.). This model included moral virtues that outlined the ideal (preferred) portrayal of an ethical leader from the point of view Slovak students studying economic study programs.

Our paper aims at delineating traits and behaviors of ethical leaders in regard to their effectiveness from the viewpoint of Slovak respondents. From the methodological point of view, the Resick et al study (Resick, Ch., J., Hanges, P. J., Dickson, M. W., & Mitchelson, J. K. A., 2006) stays closest to our approach. We derived our empirical study from the GLOBE Student project which started consecutively with the GLOBE project itself. The international comparative research GLOBE Student project is being conducted in cooperation of international team of researchers. Members of this team are: Rainhart Lang (Germany), Doina Catana a Gheorghe Alexandru Catana (Romania), Renata Krzykala-Schaefer (Poland), Danijel Pučko a Tomaž Čater (Slovenia), Kurt Rudolph (Tatarstan), Petra Skálová a Zdeňka Konečná (Czech republic), Danijela Bogdanic (Bosnia and Herzegovina) and Anna Remišová a Anna Lašáková (Slovak republic). In the GLOBE Student project the former GLOBE project methodology, only with slight differences, is being applied. Whereas in GLOBE project societal culture, organizational culture and leadership attributes are studied, the GLOBE Student project is focused on the research of societal culture, leadership attributes, and preferences of students in the field of managerial decision-making. Factors influencing value preferences of students are also a part of the GLOBE Student questionnaire. Questions dealing with societal culture and leadership attributes are the same in both research projects. In this paper our research questions are:

- 1) What are the characteristics of ethical leadership from Slovak students' point of view?
- 2) Is there any latent structure caused by implicit variables within the identified ethical leadership behaviors and traits? If yes, of what character are these hidden variables?
- 3) What is the level of effectiveness of ethical leadership styles from Slovak students' point of view?
- 4) How different groups of students differ in their assessment of effectiveness level in regard to ethical leadership behaviors and traits – in other words, are there any statistically significant differences between various groups of students in regard to this issue?

Method

Overview of sample demographical data from the one-way frequencies analysis. The GLOBE Student research was conducted on the pool of 339 respondents. Our respondents were students from Slovak University of Technology and Comenius University in Bratislava. Almost 97,1 % of respondents belong to the age category 18 – 25 years. From demographical evidence following data were selected: women: 48,1 % of respondents; only Slovak language spoken at home during childhood: 87,9 % of respondents; interested in a manager career after graduation: 79,6 %; interested in founding a business venture: 66,4 % of respondents. Furthermore, students studying at the Comenius University in Bratislava: 45, 4%, and at the Slovak university of Technology: 54, 6%. Graduate students in our sample: 55, 2%, and the undergraduate students were represented in 44, 8%.

Questionnaire method. In the GLOBE Student project the effectiveness of leadership styles was assessed within 21 leadership dimensions which were consecutively grouped to six second-ordered leadership dimensions. These dimensions were composed by 112 single leadership items representing concrete behaviors and trait of a leader. Respondents had to assess their level of effectiveness on the seven-point Likert-type scale, where one stands for very low level of effectiveness and seven represents very high level of effectiveness of a leader (for methodology of the GLOBE project see House, R. J., Hanges, P. J., Javidan, M., Dorfman, & P. W., Gupta, V. (eds.), 2004). We

assumed that the GLOBE Student leadership questionnaire contains moral virtues of a leader within the 112 leadership items. However, it has to be underlined that the GLOBE Student questionnaire focused on the effectiveness of leaders primarily. Hence, results presented in this paper consider the effective ethical leadership behavior, which means ethical behaviors and leadership traits which are assessed by Slovak respondents in regard to effectiveness of a leader.

Further methods used in this study. Our next step was asking 60 students of Management and International Management at the Faculty of Management, Comenius University to perform a q-sort data analysis aimed at identifying all ethical leadership items in the GLOBE Student questionnaire. Students were to consider the written descriptions of single 112 items and to decide which of these items belong under the category of ethical leadership. For further analysis, only those items were ranked as ethical, which at least fifty times were indicated by students. The q-sort data analysis ended at 33 items of ethical leadership.

In the next phase we performed exploratory factor analysis using the maximum like-hood analysis as a factoring method. For rotation the Orthogonal Varimax with Kaiser's normalization was used. The eigenvalue was set up to the value of 1. After conducting the Scree test, a four factor solution was selected to be the best fitting the data (for methodology in regard to factor analysis see Costello, A. B. & Osborne, J. W., 2005). Next, to be able to assess differences between various groups of people in our sample, we conducted independent samples t-test analysis.

Results

1. Factor analysis. After exploratory factor analysis four-factor solution was chosen. Our four factors consisted of 26 items out of former 33 leadership behaviors and traits. The average communalities for four factors were between 0,45 lowest to 0,55 highest. These communalities are not considered high, however, according to Costello and Osborne "common magnitudes in the social sciences are low to moderate communalities of .40 to .70" (Costello, A. B. & Osborne, J. W., 2005, p. 4). Four factors – four dimensions of ethical leadership regarding the leadership effectiveness within the Slovak culture were identified as follows: 1. The Integrative Harmonizer, 2. The Decisive Persistent Influencer, 3. The Supportive Cooperator, and 4. The Helping Friend. First two dimensions consist of nine items and second two dimensions consist of four items. The Integrative Harmonizer dimension encompasses leadership behaviors like being diplomatic, inspirational to others, trustworthy and just. Also calmness, communicativeness, justice, intra-group face-saving activities and positive attitude are important part of this dimension of ethical leadership behavior. The second dimension, Decisive Persistent Influencer, is composed by attributes like being mediator of conflicts, substantially decisive and motivational activating others in the group, building confidence in the group, as well as showing patience, honest thoughts together with being a dynamic and team-building person from the viewpoint of followers. The third dimension is called the Supportive Cooperator and consists of attributes like collaborativeness, encouragement, dependableness and increasing the morale of followers by offering encouragement and praise. And finally, the fourth dimension is labeled as Helping Friend. It covers items loyalty, being empathetic for others, generous and fraternal toward followers.

2. The level of effectiveness of ethical leadership. One of our research goals was to investigate the levels of effectiveness of ethical leadership behaviors from the viewpoint of our respondents. To be able to rate the overall effectiveness of ethical leadership dimensions, mean values were calculated for all four dimensions. Two most effective dimensions are the Integrative Harmonizer and the Supportive Cooperator, both with mean value of effectiveness 5,82. The style of the Decisive Persistent Influencer follows with the mean value 5,66. The least effective is the style labeled as the Helping Friend with mean values of effectiveness of 4,63. However, also this ethical leadership style is considered as effective. According to our research no identified ethical leadership style was found ineffective.

Table 1 shows results of descriptive statistical analysis for the single 26 ethical leadership items.

TABLE 1: DESCRIPTIVE STATISTICS FOR ETHICAL LEADERSHIP ITEMS WITH MEAN VALUES OF THEIR EFFECTIVENESS FROM THE VIEWPOINT OF SLOVAK STUDENTS (ON THE SCALE WHERE 1 = LEAST EFFECTIVE AND 7 = MOST EFFECTIVE).

Questionnaire item	Mean value of effectiveness	Std. Deviation	Ethical leadership dimension concerned
Inspirational	6,24	1,26	Integrative Harmonizer
Trustworthy	6,13	1,34	Integrative Harmonizer
Diplomatic	6,10	1,33	Integrative Harmonizer
Communicative	6,07	1,27	Integrative Harmonizer
Encouraging	5,96	1,26	Supportive Cooperator
Motive arouser	5,94	1,29	Decisive Persistent Influencer
Dependable	5,90	1,40	Supportive Cooperator
Team-builder	5,90	1,34	Decisive Persistent Influencer
Just	5,88	1,32	Integrative Harmonizer
Dynamic	5,86	1,29	Decisive Persistent Influencer
Collaborative	5,83	1,23	Supportive Cooperator
Decisive	5,77	1,42	Decisive Persistent Influencer
Positive	5,61	1,35	Integrative Harmonizer
Confidence builder	5,59	1,28	Decisive Persistent Influencer
Morale booster	5,59	1,29	Supportive Cooperator
Mediator	5,59	1,34	Decisive Persistent Influencer
Honest	5,53	1,42	Decisive Persistent Influencer
Calm	5,51	1,45	Integrative Harmonizer
Patient	5,45	1,28	Decisive Persistent Influencer
Integrator	5,45	1,54	Integrative Harmonizer
Intra-group face-saver	5,34	1,25	Integrative Harmonizer
Group-oriented	5,34	1,27	Decisive Persistent Influencer
Loyal	5,22	1,42	Helping Friend
Generous	4,82	1,38	Helping Friend
Fraternal	4,74	1,51	Helping Friend
Compassionate	3,71	1,43	Helping Friend

According to the values of mean effectiveness of assessed behaviors or personal traits, as the most effective behaviors are being rated the inspirational, trustworthy, diplomatic and communicative behavior of a leader. On the other hand, items which are just moderately effective are being fraternal and generous. These three attributes are rated by Slovak students as just somewhat effective in leadership behavior. And at last, being compassionate is by young Slovaks assessed as not so effective as other ethical behaviors.

3. Sample differences in regard to the ethical leadership styles. Our next research question was how different groups of students differ in their opinion on effectiveness of ethical leadership. Tables 2, 3, and 4 show only statistically significant differences. We used independent samples t-tests for measuring ($p < 0,05$). We

compared students according to their gender (table 2), level of study (table 3), the university they attend and their interests in founding a business venture and developing own management career after graduation (table 4).

TABLE 2: DIFFERENCES BETWEEN FEMALE AND MALE RESPONDENTS IN THE SLOVAK SAMPLE.

Questionnaire item	Gender	N	Mean value of effectiveness	Std. Deviation	t-test	Sig. (2-tailed)
Diplomatic	Female	163	6,27	1,18	2,23	0,03
	Male	176	5,95	1,45		
Mediator	Female	163	5,77	1,34	2,39	0,02
	Male	176	5,42	1,33		
Inspirational	Female	163	6,47	1,14	3,24	0,00
	Male	176	6,03	1,33		
Trustworthy	Female	163	6,31	1,30	2,39	0,02
	Male	176	5,96	1,36		
Just	Female	163	6,04	1,30	2,21	0,03
	Male	176	5,73	1,32		
Collaborative	Female	163	6,17	1,14	3,06	0,00
	Male	176	5,77	1,33		
Encouraging	Female	163	6,17	1,14	2,95	0,00
	Male	176	5,77	1,33		
Morale booster	Female	163	5,75	1,20	2,28	0,02
	Male	176	5,44	1,36		
Motive arouser	Female	163	6,19	1,20	3,44	0,00
	Male	176	5,72	1,33		
Communicative	Female	163	6,28	1,15	2,86	0,00
	Male	176	5,89	1,34		
Confidence builder	Female	163	5,78	1,24	2,64	0,01
	Male	176	5,41	1,30		
Team-builder	Female	163	6,07	1,20	2,28	0,02
	Male	176	5,74	1,45		

According to results shown in the table 2, female respondents rate effectiveness of ethical behavior of leaders significantly higher than men in our sample in 12 out of 26 ethical leadership items. Apparently, activities like, for example, team-building, confidence building, communicativeness, encouragement, justice, mediating conflicts, being diplomatic and trustworthy are assessed by women as more effective than by men in our sample.

TABLE 3: DIFFERENCES BETWEEN UNDERGRADUATE AND GRADUATE RESPONDENTS IN THE SLOVAK SAMPLE.

Questionnaire item	Level of study	N	Mean value of effectiveness	Std. Deviation	t-test	Sig. (2-tailed)
Diplomatic	Undergrad	152	5,87	1,66	-2,80	0,01
	Grad	187	6,29	0,95		
Mediator	Undergrad	152	5,40	1,49	-2,26	0,02
	Grad	187	5,74	1,19		
Inspirational	Undergrad	152	6,07	1,50	-2,20	0,03
	Grad	187	6,39	1,01		
Integrator	Undergrad	152	5,25	1,74	-2,10	0,04
	Grad	187	5,61	1,33		
Decisive	Undergrad	152	5,51	1,66	-2,97	0,00
	Grad	187	5,98	1,14		
Motive arouser	Undergrad	152	5,72	1,52	-2,76	0,01
	Grad	187	6,12	1,04		
Communicative	Undergrad	152	5,86	1,53	-2,69	0,01
	Grad	187	6,25	0,97		
Confidence builder	Undergrad	152	5,27	1,52	-4,07	0,00
	Grad	187	5,85	0,97		
Group-oriented	Undergrad	152	5,14	1,42	-2,61	0,01
	Grad	187	5,50	1,12		
Dynamic	Undergrad	152	5,65	1,55	-2,65	0,01
	Grad	187	6,04	1,01		

In line with the results included in the table 3, there are 10 significant differences out of 26 measured ethical leadership items between undergraduate and graduate students in our sample. In all 10 cases undergraduate students rated ethical leadership items as being less effective than graduate students did. Although our sample is not representative of all Slovak student population, this result seems to be interesting. Graduate students, compared to undergraduate students, prefer significantly more leader's behavior which is diplomatic, conflict solving, inspirational, integrating others, decisive, motivational, communicative, confidence-building, group-oriented and dynamic.

As already mentioned, we compared students in our sample also in regard to the university which they attended. Results showed that in only 4 out of 26 items there were not found any statistically significant differences. This result clearly indicates that there are substantial differences between students at Comenius University (CU) and students at the Slovak University of Technology (SUT) regarding their assessment of effectiveness of ethical leadership traits and behaviors. Students at Slovak University of Technology scored considerably lower than students from the Comenius University.

Finally, differences between students in the Slovak sample according to their interests in management career after graduation and in founding a business venture were investigated. In the questionnaire, students were asked, if they would like to develop their own management career after graduation as well as if they were interested

in founding a business venture after graduation from university. Table 4 illustrates statistically significant differences between groups which stated “yes” and “no” to these two separate questions.

TABLE 4: DIFFERENCES BETWEEN RESPONDENTS IN THE SLOVAK SAMPLE ACCORDING TO THEIR INTERESTS IN MANAGEMENT CAREER AFTER GRADUATION AND IN FOUNDING A BUSINESS VENTURE.

Questionnaire item	MNG Career	N	Mean value of effectiveness	Std. Deviation	t-test	Sig. (2-tailed)
Morale booster	Yes	270	5,67	1,27	2,38	0,02
	No	69	5,26	1,34		
Generous	Yes	270	4,73	1,39	-2,38	0,02
	No	69	5,17	1,28		
Dynamic	Yes	270	5,96	1,19	2,19	0,03
	No	69	5,51	1,59		
Items	Business venture	N	Mean	Std. Deviation	t-test	Sig. (2-tailed)
Loyal	Yes	225	5,36	1,38	2,55	0,01
	No	114	4,95	1,47		

In relation to our findings illustrated in the table 4, students who tend to build their own management career after graduation rated as being effective significantly more the moral booster and dynamic traits of a leader than students, who answered “no” to the question, did. Traits like being energetic, highly involved and motivational as well as confident and encouraging are preferred more by those, who think of career advancement in management. On the other hand, being generous, this means being helpful to other, willing to give resources to others, etc. is considerably less preferred by students who want to build a management career for themselves. And as for the second question regarding founding a business venture after graduation, students who stated “yes” to this question regard loyalty as effective significantly more than students, who do not want to found a venture.

Discussion

The ethical leadership dimensions within Slovak cultural environment according to Slovak students of managerial and technical study programs at two of the most influential Slovak universities were examined in this paper. In this perspective our results show preferences of future managers, because students who participated in our study are supposed to be on managerial positions in the future after graduation from university. We derived our study from the theory of culturally endorsed leadership theory, methodologically based on the GLOBE Student research project. We assume that leadership preferences are determined by the cultural background. Hence, results presented in this paper relate to Slovak cultural environment. The relevancy of our study is determined by number of participants, and although our paper does not map ethical leadership in its complexity, it could be considered as an useful starting point for further examination of the concept of ethical leadership in CEE countries. Additionally, as noted already, this study points to preferences of future managers, thus indicating a trend for the future regarding patterns of effective ethical leadership behaviors and personal traits.

Methodological approach used in this paper was inspired by the study of Resick, Ch., J., Hanges, P. J., Dickson, M. W., & Mitchelson, J. K. A (2006). However, we arrived at different outcomes and used more in-depth analysis of the Slovak results. Our results are indicative of four distinct effective ethical leadership dimensions, which were identified on the sample of Slovak university students. First, 33 ethical leadership items from the GLOBE Student questionnaire were identified using the q-sort data analysis. Next, the exploratory factor analysis

was conducted, revealing four dimensions of ethical as well as effective behavior of a leader, using 26 out of former 33 items. Four underlying variables, namely the Integrative Harmonizer, Decisive Persistent Influencer, Supportive Cooperator and Helping Friend were identified. Next, mean values of effectiveness of 26 ethical items as well as four dimensions of ethical leadership were calculated. To have more detailed results, statistically significant differences in our sample were examined, too.

According to our results, it is assumed in general that what is ethical is also effective in leadership from the viewpoint of our respondents. All ethical items assessed in the questionnaire, except one, were rated as effective. The only one exemption was the “compassionate” attribute, scoring 3,71 on the seven-point scale (1 stands for the least effective and 7 is the most effective leadership behavior). Being helpful, empathetic and showing mercy is in the Slovak cultural context not straightforwardly preferred as an effective behavior. However, all four detected ethical leadership dimensions, the Integrative Harmonizer, the Decisive Persistent Influencer, the Supportive Cooperator and the Helping Friend, were proofed to be effective from the students’ point of view. The most effective ethical leadership styles are the Integrative Harmonizer and Supportive Cooperator.

After conducting the independent samples t-test procedure regarding selected demographic data in our sample, some interesting conclusions were attained. First, women in our sample tend to put greater emphasis on the ethical leadership, rating effectiveness of ethical behavior of leaders significantly higher than men in our sample in 12 out of 26 ethical leadership items. Second, graduate students in our sample are more humane-oriented than undergraduate students. In 10 cases there were statistically significant differences between these two groups. Undergraduate students rated ethical leadership items as being less effective than graduate students did. Third, we found enormous differences between students at Comenius University and students at Slovak University of Technology and their assessment of ethical leadership behavior. In 22 out of 26 ethical leadership behaviors examined, students at CU rated these behaviors as being more effective than students at SUT. Technically oriented students in our sample assessed ethical leadership items as with considerably lower effectiveness than students of management at the CU. We assume that the difference lies primarily in the composition of study programs. Students at SUT are oriented toward more technical subjects, whereas students at CU attend more humane-oriented studies with focus on HRM, organizational behavior as well as business ethics. Finally, there were found also some significant differences between students who want to have a management career after graduation from university and students who do not. Students, who tend to build their own management career after graduation, rated as being effective significantly more the moral booster and dynamic traits of a leader than students, who answered “no” to the question, did. Students, who would like to found a business on their own after graduation, regard loyalty as effective significantly more than students, who do not want to found a venture. Being loyal in this research context means to be willing to help others and stay with them if they have hard times to overcome. Respondents in our research, who want to build something on their own, a business organization, tend to put greater value and emphasis on being able to help others, if they need support.

To summarize it, Slovak ethical leadership styles include leader’s behavior and personal traits like being inspirational, trustworthy, diplomatic, communicative, encouraging, motive arouser, dependable, team-builder, just, dynamic, collaborative, decisive, positive, confidence builder, morale booster, mediator, honest, calm, patient, integrator, intra-group face-saver, group-oriented, loyal, generous, and fraternal. Under the “label” ethical leader young Slovaks comprise four distinct styles, which are the Integrative Harmonizer, Decisive Persistent Influencer, Supportive Cooperator and Helping Friend. All four ethical styles are assessed as being effective.

As for the practical usability of this study, it should be noted, that our results point primarily toward preferences in regard to ethical leadership styles within the Slovak culture. First, selection as well as training and development on the managerial level should be taken into account in regard to the results of this study. If the implicit leadership theory is considered (see for instance Den Hartog, D. N., House, R. J., Hanges, P. J., Ruiz-Quintanilla, S. A. & Dorfman, P. W., 1999), the level of acceptance of a leader by his or her followers is higher, if

the leader behaves according to followers' beliefs and preferences of how should the leader be and behave like. Selection of leaders in Slovak business organizations, and subsequently training and development of leaders should take into account preferred ethical personal traits and behaviors. Second, expatriate managers on international assignments should take information delivered by this study into consideration when working with Slovak employees, too. Furthermore, to be perceived by followers as a trustworthy leader, leader's behavior should be in concordance with certain moral obligations defined within the ethical leadership styles. Finally, we believe that this research could be a basis for intercultural comparisons at the level of ethical leadership. It may possibly serve also as a new insight to ethical leadership styles, which are culturally endorsed and rooted in the Slovak culture.

Handling Cultural Diversity - Cultural Intelligence and its Importance

*Rozalia Sulikova, rozalia.sulikova@fm.uniba.sk
Comenius University in Bratislava, Slovak Republic*

Abstract:

Globalization process has opened new possibilities for numerous managers to become active in multinational organizations at their domestic as well as foreign work environments. Typical feature of these organizations is the multicultural work environment. Therein, interpersonal interaction differs from the interaction in the monoculture organization by different attitudes, perception, values or communication styles of employees. These variances stems from different nationalities with the different cultural background within the organization. Managers in order to be more effective leaders thus have to possess specific competences. In this connection attention should be paid to enhancement of cultural intelligence of managers. To be cultural intelligent it includes not only ability to recognize and understand cultural differences but also to interact in an appropriate manner. Cultural intelligent manager is able to modify properly his own behavior not only according to his knowledge and experiences about foreign culture, but he/she is able to utilize knowledge and experiences of others as well.

Understanding the meaning what cultural intelligence is helps managers in the process of becoming successful global managers. It eliminates many problems expatriates are facing and moderates the intensity of the cultural shock.

Preparation of effective global managers can already begin in the education process. Useful in this field are specific oriented training programs such as sensitive training or self-development training.

Introduction

Globalization of the business is closely related to increasing frequency of international interaction of managers and employees, closer teamwork and need of new form of international collaboration. It increases demand for international management, for managers with international competences and effective leadership abilities in multicultural work condition.

Intercultural interaction of managers and teams is not always satisfying. Advantage of jointed organization and multicultural teams, possible synergy effect of the wide spectrum of people's knowledge, experiences and views is not exploited by the managers enough. The reason why managers are not able to take advantage of those synergies is due to their unreadiness to interact and to lead people from cultural diverse work environment. The appropriate leadings skills and personality traits are missing.

A solution for getting through this obstacles effectively and achieving that employees in multicultural work environment will perform above the standards lies in understanding how cultural specifics - believes, attitudes, way of perceptions, habits, thinking, preferences etc. influence interpersonal interactions. In order to achieve it, managers have to be willing to change own mental processes often characterized by high degree of rigidity and stereotyping. Managers have to be willing to self-development, to development of their high level cultural and emotional intelligence. So in the forefront is human factor – intensive preparation of managers for cross-cultural interaction, for effective leading in diverse work environment.

Preconditions for acquiring necessary cultural intelligence

Developing of cultural intelligence require some necessary preconditions. To the most important preconditions belong:

- Self development
- Ability to understand one's behavioral determinants
- Ability to understand behavior of others
- Ability to understand cultural influence on the behavior

- Ability to understand cultural influence on the interpersonal interaction process

Without objective self-understanding it is not possible to comprehend others. Without understanding of how our behaviors determine behavior of others it is not possible to understand why others behave in that particular way. It is necessary also to realize that the same situation or problem is possible to perceive differently without any perception being wrong - it might be, it is only different. It is crucial to realize that people may have different values and attitudes that determine their way of interacting. Such way of thinking requires open mind, openness to the new ideas, openness to the changes and differences as well as becoming more flexible. Development of mentioned characteristics opens opportunity for new ways of cross cultural interaction and collaboration.

Above mentioned new approaches to the multinational collaboration highlight the reason why it is necessary to enable mainly for young managers in the global organizations to gain not only theoretical knowledge in this area but also practical experiences from cultural diverse environment through rotating work programs. Mainly young people can obtain in this way such experiences that can later be better converged into their work. Added value of staying in foreign country, in a close relation with people with culturally different background, lies in higher level of self-knowledge, self-confidence and stronger self-belief these young managers will gain.

It is possible to hear many times: who is an effective global manager? What are the main characteristics of the global manager, how should he behave? How should his profile look like – what are his main traits, skills and abilities?

According to the many researches that are focused on the determinants of the effective interpersonal interaction of managers in the multicultural work environment, it is possible to say that there are some personal characteristics which allow some people to better adapt and which also help them to get through the difficulties in cross cultural interaction. Among such characteristics, worth to further development by managers, belong (S. Schneider, J. L. Barsoux, 2003):

- Interpersonal skills - ability to create positive relationships and working atmosphere
- Languages abilities
- Motivation
- Tolerance toward ambiguity
- Flexibility
- Patience and respect
- Cultural empathy
- Sense of humor

P. Caligiuri's (in CH. M. Solomon, M. S. Schell, 2009, p.291) research results suggest that foundation for effective global manager in global environment lies in these personal attributes:

- Goal oriented tenacity – to be able to achieve the goals also in the high stressed intercultural environment when difficulties occur.
- Managing complexity - effective global manager need the specific knowledge, skills, abilities to achieve their goals in global environment where responsibility is more complex, decision making is more challenging.
- Cultural sensitivity – open-minded approach is needed toward the attitudes and behavior of people from different culture. Such approach enables to form better social alliances and to manage cross-cultural conflicts. It is the most critical personality attribute related to the successful global manager.
- Emotional resilience - emotional stability is a universal adaptive mechanism that allows better adjustment and coping with stress.
- Ability to form relationship – high level of sociability has a positive correlation with success as a global manager. Leaders with high level of sociability are in global environment more satisfied, they create easier relationship with others, they learn better from social interaction and are much better positioned in comparison to their colleagues missing this crucial ability.

As we can see in presented overviews, above mentioned attributes are the components not only of emotional intelligence (EQ) but also components of a cultural intelligence (CQ). Level of EQ and CQ is not unchangeable. It is possible influence them and increase them through learning process, receiving feedback from

social environment, through social interactions and experiences from visited foreign countries or through gaining new knowledge in passive or active form (e.g. teaching by means of seminars, workshops).

Requirements for EQ

High level of EQ is nowadays a common criterion in selection process for managerial position in many, mainly international organizations. It includes such characteristics (D. Golleman, 1998) as:

- Knowledge about own emotion – it determines adequacy of self-understanding, self-evaluation, recognition of own strong and weak sides. Tools that might be helpful in achieving it are 360° feedback, self-reflection or self- observation.
- Emotion handling – self-control, self-regulation. This characteristic enables us to deal with aggression, stress, fear that hinder internal balance of individuals, mental activity and overcome obstacles.
- Self-motivation – an ability to integrate emotions into effort, an ability to take the initiative, to increase demands toward one-self.
- Sensitivity toward others/empathy - it is directly proportionally influenced by the level of self-perception. Empathy allows us to become comfortable with feelings of others, it allows us to see thing through others' point of view. Interpersonal sensitivity and empathy is necessary for interaction in diverse cultural environment.
- Savoir-faire

High level of EQ does not guarantee effective intercultural interaction and effective cross culture leadership. It is only one precondition. Another one is cultural intelligence - CQ. Its relevance might be shown on numerous examples when the best experts were sent to foreign countries but did not succeed there due to their low ability to adapt themselves in line with a new culture.

Various studies were conducted in order to find reasons, and later also the methods, how to overcome these difficulties. Among proclaimed explanations was unpreparedness of managers for intercultural interactions, the cultural shock or managers' inability to adapt in effective way on diverse cultural conditions.

Solution for changing it lies in increasing CQ of managers, mostly of those who work in multicultural work environments.

What to do to be culturally intelligent

CQ includes the capability to interact effectively across cultures. Cultural intelligence is ability to create effectively interactions with people with different cultural backgrounds. It enables us to understand cultural differences and to act appropriately across cultures.

Cultural intelligence is created by (D. C. Thomas, K. Inkson, 2003, p. 23):

1. Knowledge - culturally intelligent manager requires knowledge about culture and basic principles of cross - cultural interaction – what culture is, how culture varies and how it affects behavior.
2. Mindfulness - culturally intelligent manager practices mindfulness, ability to pay attention in a reflective and creative way to the stimulus that appears in intercultural situations.
3. Ability to choose appropriate behavior form that is correct for different intercultural situation.

Cognitive aspect (head) of CQ creates the ability to pick up factual elements about relevant behavior for particular situation. Physical aspect (body) of CQ shows ability to adopt behavior to the foreign habits. Emotional-motivational aspect (heart) of CQ includes motivation to make refinements (A. J. DuBrin, 2010).

All these components are in the relationship to each other and the process of becoming culturally intelligent is based on the knowledge and on the emotional intelligence. It is not sufficient only to know dimensions of cultural differences (for example created by Hofstede, 2006). It is necessary to understand in which way they influence the behavior, communication, negotiation, problems and conflicts solving, decision making etc.

Most well known examples of dimensions of cultural differences are:

- Power distance – people with high level of power distance accept autocratic approaches.
- Uncertainty avoidance - people with high level of uncertainty avoidance prefer strong, clear structure of task, situation, and certainty.
- Individualism vs. collectivism – the goal of people with high level of individualism is their self-development, they try to be the best, they prefer individual decision and follow their own interest. On the other hand, for collectivism it is typical a teamwork, team decision, discussions and collective interest.
- Accent to the present time vs. future – this orientation influences choice of the strategy, decision-making processes, preference of immediate profit versus long-term one.

Development stages of CQ

Culturally intelligent people see and understand connection between culture, they are aware that knowledge about cultural differences must be understood in context. There are certain personal characteristics that individuals possess, or should be developing in order to increase the level of CQ. These are (D. C. Thomas and K. Inkson, 2008, p.103):

- Integrity – well-developed sense of oneself, understanding how own belief system, attitudes and values influence own behavior and the well-developed sense how we interact with others.
- Openness, humility – important is to exhibit respect and willingness to learn from others, to admit that there is also other point of views. Active openness includes interest in other people, in other cultures. Without this inquisitiveness and interest, opportunity to develop CQ is declined.
- Hardiness – it is courage, resolution, and capability to cope with unfavorable conditions, to deal with stress and be able to learn from such situations. Interpersonal interaction with people from different culture involves also some tensions, emotions, ambiguity. It requires hardiness to go through these difficulties.

Awareness of oneself, of own characteristics is crucial for developing CQ. High level of CQ corresponds with the high level of the objectivity of self-understanding. Often our self-perception does not correspond with perception of others about our personality. People are not familiar with own characteristics or do not want to be familiar with them. People see themselves in more positive way than others do it, or than the reality is. Most important therefore is to have a correct picture of ourselves and to listen to the feedback from our surrounding.

We all know that basic feature of the *perception* is selectivity. Also this perception is culturally determined. Influenced is what we pay attention to, what we perceive as important and what not. Differences are in the frame of reference, in which way we interpret perceived stimulus. It might occur that the same situation is interpreted differently. One example might be when people from collectivistic culture prefer, or are more focused on, information connected to team/group rather than to individuals. Basic knowledge about culture can prevent or minimize misunderstandings caused by the diversity.

Another process that determines our behavior and that influences interpersonal interaction, is process of *categorization*. This process makes easier to put information together. Categorizing help us to mentally file people into various groups base on mutual specific features. Problem occurs when information are minimal or not objective. Then, categorization gives a place to stereotype. Negative aspect of stereotype is that all people are assessed in the same way, differences among them are not recognized and influence of cultural diversity on the behavior of categorized people is not taken into account. Many times space for the preconceived opinion is created.

Effective interpersonal interaction across culture are also disturbed by such personal characteristics as ethnocentrism, unsociability, egocentrism, lack of interest in other people, self-conceit, timidity, low equableness, disparagement etc. These features hinder acceptance of cultural differences and effective adaptation to given cultural conditions.

It is possible to state that necessary requirement for effective cross-cultural interaction is to change the way of the thinking and behaving towards the higher cultural sensitivity.

To be cultural intelligent does not occur instantly, it is relatively long process during which people only step by step develop their cultural sensitivity. According to D. C. Thomas and K. Inkson (2003, p.105) it occurs in several steps:

- Reactivity to external stimuli – in this stage people mostly do not see cultural difference, they show tendencies to parochialism. Attended is a mindless adherence to one's own cultural rules and norms.
- Recognition of others cultural rules and norms and motivation to learn more about them.
- Accommodation of different cultural rules and norms into own mind, into own way of thinking. It includes deeper understanding of differences, ability to recognize appropriate form of behavior in different cultural situations. Although people in this stage know what to say and in which way to interact in different cultural situations, it still requires their effort.
- Assimilation of diverse cultural norms into alternative behaviors. People in this stage are able to use appropriate form of behavior for specific cultural situations. They are no more stressed in culturally different conditions; they feel comfortable, other people accept them easily.
- Proactivity – in this stage people are able to perceive and recognize such changing signals in cultural context that others do not. They automatically adjust their behavior.

Developing of CQ requires basic knowledge about culture, about the role of different believes, values, attitudes for interpersonal interaction. It requires also motivation to learn from social experience and ability to transfer knowledge into the practice.

Activity that support the development of CQ:

- studying abroad
- working abroad
- tourism
- working in the multinational organization
- being a member of multicultural working team
- daily interaction with people of different cultural background (attendance of foreigner students during the studies etc.)
- passive way of receiving information – discussion clubs, films, books etc.

Closer cooperation of business, new communication technologies enable better connection among people. Since their interactions are more frequent and easier, it increases also probability of more conflicts and misunderstandings. Ground for it lies in differences among cultures. On the other hand, closer interaction of people creates also a possibility for learning and for changes in attitudes.

Cultural differences and training programs

Most effective way for improving our CQ is trough own experiences. Own experiences efficiently enable us to learn and to understand foreigner culture.

Many people already realize that communication style in different culture is different. They realize necessity to respect another style of communication, necessity to adapt the behavior for specific cultural context in everyday life. The situation is eminent in business area, particularly in management - in teambuilding, problem and conflict solving, leading, motivating, engaging employees etc. Therefore, it is crucial to address these problems already in the pedagogical process, in education of the future managers through development program.

When we try to enhance CQ through development program we should be aware that selection of the content and also of the methods is culturally determined - in some culture/nations are preferred active, participative style of learning with non-directive methods of work, in other cultures may prefer passive and directive style.

International teams and CQ

Nowadays, teamwork is typical setup in many organizations. Teamwork in monocultural organizations is usually not problematic. Collaboration is effective, group and teams are highly productive. However, more problems may occur when the organization is multicultural with members of the team coming from different nations with different cultural background. To create effective international team and to be able to utilize their knowledge and various

frames of references, managers have to be also at least partially psychologists. Managers should have deeper information not only about human nature, personality and specifics of groups/teams processes (their way of interactions, group functions, stages of development, sources of possible conflicts, possible negative expression of behavior) but also about influence of the culture on teamwork, on interaction and cooperation of team members.

Findings from many studies focused on the problem (Hofstede, G. 1996, Early, P.C., Gibson, C.B. 1998, Triandis, H.C. 1994, Susic, J.J., Jung, D.I. 2002 and others) of understanding the personalities of individual team members. Increasing mutual understanding of the team members is a fundamental task of the team manager in a global environment. But achieving so requires having competent managers. They should act as facilitators and also as the team members. They should be familiar with needs, preferences and other specific attributes of every team member. They should be familiar with cultural specifics and their impact on the behavior. They should know what behavior is appropriate under various conditions; they should recognize possible sources of conflicts.

In order to select the most appropriate managers able to lead the international teams/group, more attention should be given to their personal features and interpersonal skills as well as to their level of EQ and CQ. High level of EQ and CQ creates preconditions to better act in multicultural environment, to better adjust to the situation, respect another approaches and to lead people in global organization.

Cultural diversity is manageable if managers and team members choose the right strategy and their model of thinking avoid stereotypes, ethnocentrism and parochialism. Then, the creative and positive atmosphere full of trust and acceptance, with the openness to the innovative, creative and flexible way of thinking is created.

According to the various studies - for example J. Brett, K. Behfar, M. C. Kern (2006), most problems arise from:

- different style of communication - indirect vs. direct communication style – that may create problem in relationship or misunderstanding of problem
- accent and fluency – which may influence way of perception of status or competence or motivation
- different attitudes toward hierarchy and authority – culture influences the need for different design of the teams – some people prefer flat structure, other hierarchical one
- different norms for decision making - culture determinates the way how quickly decisions should be made, to which degree should they be supported by analysis, who should make those decisions, etc.

So, how to deal with problematic situations in the team? It is not possible to advice one generic best way for dealing with problems. It is obvious that the correct assessment of problem together with context of situation is crucial. Then, next step is to choose the appropriate strategy. As an advised approach from above mentioned study, authors counsel following most used strategies:

- Adaptation – the team members alone find the way how to interact, how to solve the problems. It presumes willingness to know the cultural differences, cultural gaps as well as willingness to participate on problems solving.
- Structural interventions – changing the shape of the team (for example when conflict stems from status differences).
- Managerial intervention – (manager behaves as an arbitrator) – early setting of team norms.
- Exit – leaving the team – as a last choice.

One of many examples in which cultural habits can influence behavior of group/team member may be shown on the orientation towards individualism/collectivism dimension:

Individualistic nations – nation where people have high level of self-interest and autonomy, focus is given on short perspective and highlighted are differences among group members. Preference is given to the individual evaluation and reward and on the individual responsibility. More attention is given to identifying differences and diverse skills among the members in comparison to collectivistic nations.

Collectivistic nations – people more emphasize shared values, collective work, collective decision and responsibility. More preferred is also evaluation of a group/team as a whole and collective reward. Group/team members are more cooperative and spend more time together. Initially they require more time to fulfill the task, as they are firstly focused on building social relation and on the establishment of mutual trust. Only after that managers

have a room for increasing their productivity. (Solomon, CH. M., Schell, M. S., 2009, Sosik, J. J., Jung, D. I. 2002 and others).

The group work or teamwork might be highly productive in every organization no matter the culture. But in intercultural environment it is necessary to know not only how each culture influences the human behavior but also how culture affects the behavior of the group as a whole. These circumstances require a high level of managers' CQ.

Leadership style and CQ

Effective leadership may be defined as an ability to influence people in a way they use maximum of their own potential to achieve goals of the organization. These goals should be at the same time at least partially reflected in their own goals.

There is no single most effective leadership style. Leadership styles have to reflect specifics of the culture and what might be appropriate in one society might not be necessary appropriate for other culture. Thus, leadership styles have to reflect the specifics of the context at certain situation – e.g. personalities of subordinates (their traits, beliefs, values, attitudes skills, needs etc.).

The notion about how should effective leader or leadership style look like is determined not only by the factors stemming from the national and organizational culture but is based on the individual idea of each subordinate as well. However, there exist some assumptions helping global leaders to become “masters” in their domain. These are:

- Having sense of the needs and expectancies of others
- Understanding and openness towards other way of perception and thinking
- Openness to the another system of values and attitudes
- Ability to communicate affectively and listen actively
- Applying individual approach
- Possessing developed observational skills
- Having ability to modify behavior with regard to the situation
- Being adaptable
- Being flexible
- Being open towards diversity
- Being open to the feedback

Global leaders have to be adaptable, flexible, willing to listen and to learn, be tolerant toward differences. They should have high level of cultural sensitivity (cultural sensitivity is a part of CQ and might be enhanced by listening, perceiving, observing and asking).

Leaders should be aware of problems of cultural misunderstanding in 5 main areas (A. J. DuBrin 2010):

- Language differences
- Differences in religion
- Work habits
- Women's role
- Personal appearance and behavior

Examples of different view about effective leaders:

In different cultures subordinates might perceive managers in very different way. While one subordinate may find manager effective when manager seek and support positive interpersonal relation and collegiality, subordinate from other culture might find it not convenient. Subordinate might regard manager as an effective when he/she pays attention to productivity and level of achievement of organizational goals is high. Interpersonal relation might not be so much significant.

Also required level of loyalty to the supervisor and organization is not in all culture same. Differences are also in acceptance of power, level of participation, style of communication etc.

Many organizations often use 360° feedback for performance evaluation. This method, in which each person interacting with evaluated person provides feedback on his/her performance, is quite favorably accepted. However, in hierarchically oriented culture it might be misunderstood. Evaluation of managers by subordinates in hierarchically oriented culture is not always possible, as it might be perceived as a sign of lack of respect and regarded irreverent.

Another well-known example in western-European-style cultures is expected participation of all employees. Expected is clear, open expression of own opinions and ideas, expression of satisfaction and dissatisfaction. Involvement in decision-making process is welcomed and constructive critique is positively received. Formal position does not necessary bring guarantee of respect.

On the other hand, in another culture direct expression of disagreement, expression of critique may be perceived as impolite. Formal position correlates with high level of formal respect among subordinates. Misunderstanding of the cultural habits many times results in a failure of managerial interaction. Managers with a high level of CQ understand particularities of the culture and are able to appropriately adjust their behavior to the situation.

Conclusion

The goal of this article is to show the importance of emotional and cultural intelligence for effective intercultural interaction, for effective leadership in multicultural work environment and to show necessity of develop young managers to be more able act effectively in global business environment – validity of this requirement is supported already by many researches. One possibility for achieving the goal of raising effective global managers lies in modification of educational processes at universities. Focus should be given at the development of emotional and cultural intelligence.

New ways of international collaboration bring new requirements on the profile of managers. Needed are such personal characteristics that were not until now considered to be important – cultural sensibility, adaptability, flexibility, creativity and ability to work in international teams. These are only few characteristics out of many to which attention should be paid.

Is It the Same Old Story? It Is the Modern Business Management!

*Cezar Scarlat, cezarscarlat@yahoo.com

Elisabetta Pavan

Abstract

This study refers to a set of Romanian, Italian and Venetian proverbs, in line with precedent research work related to proverbs on business principles, management and entrepreneurship, which is a research premiere in this respect. Relatively new principles of the modern business management are met in generations-old proverbs. The research methodology involved three major steps: selecting the set of Romanian proverbs on business management and entrepreneurship; finding the appropriate corresponding Italian and Venetian proverbs; making comments on their similarities. The survey focused on Venetian proverbs as the Northeast of Italy has an interesting business story: Veneto had been rural for ages in the mainland and more than advanced in trading in the Serenissima Republic of Venice, and today the Region is highly developed in small businesses. The research results emphasize that many business principles are common in the proverbs and languages surveyed. The conclusions are further discussed by authors in more details. The implications are notable for both researchers and practitioners in the area of business management and entrepreneurship.

Introduction

The business and trade, while developing arts and crafts, have always offered wonderful opportunities for interaction – between different people, customs, and cultures. Doing business and trading, the people needed effective communication means in order to manage their businesses and administer the related institutions. The folk wisdom has treasured – from popular prospective – this language of business, over all natural, cultural, and language obstacles – in its extreme concentrated but self-explanatory form: proverbs or, as Lauhakangas (2007) has called it “proverb speech” – “a kind of speech where a proverb or a proverb-like saying is used (inner speech included)”. Surprisingly, the relatively new principles of business management and entrepreneurship have quite interesting correspondents in peoples’ proverbs. Certain proverbs distillate the people’s experience, from diverse business situations, management positions, and entrepreneurial standpoints – regardless their country of origin. Hence, their universal and global value.

Universal and global value of proverbs

Today, any serious discussion on business – either theoretical or practical – cannot avoid the global context. The original assumption that “global” means as well the “universal” applicability of the advanced (North-American) principles of business management has proved to be wrong (Adler 1991): “far from ignoring the common body of knowledge, international dimensions expand our understanding of people’s behaviour at work to include the diversity and complexity of today’s global economic environment”.

The global economy is the theatre for spectacular or discrete strategic alliances, mergers and acquisitions. Unfortunately – but healthy for business and just normal from statistic point of view – some of them fail. The blame for failures of international alliances is on cultural clash, on conflicting national and organisational cultures

(Cacciaguidi-Fahy and Cunningham 2007). On the other hand, successful alliances are based on cross-cultural mutual understanding. The typical intercultural conflicts are described between foreign managers and local staff. The origin of conflicts is not so much on account of the intercultural business communication process or linguistic issues but it arises mostly due to different cultural attitudes (Hofstede 2001). The five cultural dimensions¹ as identified and defined by Hofstede, were subject for a more recent research in Romania; they demonstrate – surprisingly or mostly not – similarities as far as high PDI, low IDV, high UAI, and short term orientation (low LTO). The country cultural profiles are significantly similar to other Balkan countries as well (Luca 2005, 134).

Gibson (2001) shows that the higher the PDI, the more likely teamwork metaphors will be used. Metaphors are means of communication as their purpose is “to convey a series of messages through a process of association and images” ... and they convey “the essence of the organisation’s strategic intent and its core values” (Cacciaguidi-Fahy and Cunningham 2007, 137) – which are essential messages to be communicated in multi-cultural working environments and global economic context. The proverbs are just another type of metaphors (Ruxandoiu 1966) and “can interfere the normal ways of thought or decision. They can be useful tools to strengthen the opinion of a risk taker in the decision-making process when there is no single “right” solution.” (Lauhakangas 2007).

Many proverbs appear in several cultures – as sign of universality. This is why the simple presence of a certain proverb in a certain language does not necessarily mean that it originates in that culture (Gheorghe 1986). Because the proverbs have a relatively large area of circulation – as demonstrated previously – deeper comparative studies are required in order to develop a sentence in this respect.

Regardless their geographic location, all proverbs deal with the following three major aspects: people’s ability to make right judgments (decisions); people’s exceptional sense of justice; special sense of humour – which make them “universal spiritual values” (Rudica and Costea 2004). Actually, the first two aspects are basic management values as well. Therefore, this paper focuses mostly on the business management and entrepreneurship meaning of the selected Romanian, Italian and Venetian proverbs. Romania and Italy were selected as countries with similar cultural background – in terms of Latinity.

A linguistic and (inter)cultural point of view

According to Mollica and Neussel (2007) proverbial language is an important component in knowing a language and its culture, since proverbs are an important indicator of a person’s overall linguistic competence. In foreign language teaching proverbs are used both to focus on language, on its metaphorical usage, and to take notice of culture. There are a lot of proverbs in different languages that are both semantically and formally the same and, as suggested in this study, similarities may be considered a sign of universality (see above: Universal and global value of proverbs).

Anthropologists have found that, in non-literate societies, study of the proverbs used by a native tribe offers clues to the world view of its members regarding education, law, business and marriage. There is no aspect of life that proverbs do not comment on and, in non-literate societies, they serve as rules of conduct and basic wisdom to be adhered to by subsequent generations (Mieder 1986).

A linguistic point of view

The American Heritage Dictionary of the English Language (Morris 1979) defines a proverb as a short, pithy saying in frequent and widespread use, expressing a well known truth or fact. In the Macmillan English Dictionary (2002) a proverb is defined “a short well-known statement that gives practical advice about life”, while in the Oxford Advanced Learner’s Dictionary (Hornby 2010) it is: “a well known phrase or sentence that gives advice or says something that is generally true”. Mieder (1986) defines proverbs as small pieces of human wisdom that have been handed down from generation to generation and that continue to be valid even in our modern technological age.

According to Mollica (2010), Norrick, whose linguistic analysis of the proverb is considered a basic reference, proposes two definitions of the proverb. The first is ethnographic, and states that a proverb is a traditional, conversational didactic genre with general meaning, a potential free conversational turn, preferably with figurative

meaning (Norrick 1985). The second is a supra-cultural definition which holds that a proverb is a typically spoken conversational form with didactic function and not associated with a particular source (Norrick 1985).

Mollica (2010) affirms that proverbial language, an important component in knowing a language and its culture, is replete with metaphors. The ability to exploit this form of popular speech necessitates at least some knowledge of metaphor in order to decode its significance and appropriateness to the context of a given discourse.

Communication depends on speakers' and listeners' shared knowledge and the communicative process is facilitated by the extent to which they have similar meanings for the terms used and the behavioural norms shared. The process relies equally on knowledge of language and knowledge of culture, or better still, on cultural awareness.

Interculturally speaking

People belong to and are moulded by a series of interlocking cultures which influence the way they view the world, make decisions and interact with others. Proverbs may help to reflect both on our own and on others' cultures and on the relationships between them; that is, through understanding proverbs we are able to improve both our cultural and intercultural awareness. National cultures have a massive influence on people's values, attitudes and behaviours and today people from different cultures have daily opportunities to negotiate, interact with people from other cultures. Therefore it is very important to develop awareness of cultural differences as multicultural groupings are becoming more common both in professional settings and elsewhere.

The list proposed in this study not only encourages us to think about cultural differences in preparation for intercultural encounters but also helps us to identify and understand similarities. Each of these encounters will be quite different and whether someone adapts to the cultural norms of the person he/she is negotiating with, or to the norms of a third culture, or whether he/she comes to a compromise, will depend both on his/her personality and experience and on those of the negotiating partner.

The purpose of this study is to raise awareness of cultural differences and help prepare them to deal with such differences in a non-judgmental way. Fantini (2000) states that intercultural communication competence means transcending the limitations of one's world view. Since it is likely to feel more comfortable with one's own culture, realizing that other people might also feel the same, knowing and using proverbs that share the same principles helps not dismiss the cultures of others. Through proverbs we can fulfill what Willems (2002) says can be reached through an education for intercultural communication competence: open up to other ways of thinking and other logic; find a tongue in which we can communicate our humanity to each other; learn to see that our own view of the world is just one among many.

The schema theory

According to Greene (1986) schema theory refers to the way knowledge is represented and organized in the mind, a perspective that provides an expectation-driven conception of the role of knowledge. The schema theory states that pre-existing knowledge provides the main criterion and context through which information is processed and interpreted. What people experience, and are told, enters their memories: the schema is a hypothetical mental structure for representing non specific concepts stored in memory and it guides information encoding, organization and retrieval. It originates from recurring contacts with similar experiences and is used to make sense of analogous experiences or of new situations.

Schemas are like drawers that may be filled with information and contain the default values for actions that people expect to happen in a certain situation (see also 'expectancy grammar': Oller 1979). They are what makes people think that something should be done in a certain way: when facing a new situation things may appear 'strange' and this implies a new schema must be acquired.

Proverbs can supply missing schemas, they are small pieces of human wisdom and can provide common underlying assumptions of the social group / culture concerned and give a sense of security and reliability, thus may foster intercultural communication among people.

Romanian, Italian, and Venetian proverbs

The proverbs are considerably older than the modern management science. A remarkable book demonstrates that there are proverbs in Bible (see the Book of Proverbs, attributed to Salomon and long considered the “Gospel” of the people), which have an older origin – Egyptian, Sumerian or Babylonian (Gheorghe 1986, 41-43). Many Greek and Latin authors appreciated proverbs: Hesiod, Euripides, Aristotle, Cato, Virgil, Cicero, Seneca, and Phaedrus.

It is worth remembering Erasmus von Rotterdam *Collectanea Adagiorum* (1500); by the time he died Erasmus had added 4,658 adages to his collection, many are accompanied by explanatory notes that are often like brief essays on political and moral topics, categorised by subject.

Still today proverbs could be considered as part of our historic and collective memory, though most of the time they have been and are replaced by superficial slogans that cannot be referred to the complex existential world. They come out in subjects referring to our cultural identity and to our life experiences (Lopez 2001). Bernardi (2009) affirms that for a long time the North-Eastern part of Italy was governed by local authorities (there were alliances with other Italian empires like the Holy Empire or powerful Signorie (Lords), but mostly it was run by the Serenissima Republic) and only for a few decades by the French or by the Austrian empire. This is reflected in the Venetian attitude and ability for self-government and produced related proverbs and mind-sets: *Magari col culo a la piova, ma parón ti!* (to be your own boss makes you even accept having your back [wetted] by the rain); *Mègio parón de sèssola che servidor de barca* (it’s better to own a small shovel than to work on a ship: it’s better to run a small business yourself than to work in a big company) and its variation on the Dolomites: *Mejo parón d’on panèr che servidor d’on forno* (better to own a small oven than be just one worker in a bakery). For people from the Tre Venezie region it has always been better to be independent, to run their own business.

The first considerable systematic collections of Romanian proverbs started early in the 19th century: Iordache Golescu (about 1827-1845) collected 18,366 proverbs in 854 handwritten pages; Anton Pann (1847) has collected 1,144 proverbs and presented them categorized by topics in 25 groups; he has enlarged the collection (to 3,015 proverbs) in 1852-1853. The Pann’s collection is important as he initiated one of the two important developments in the proverbs literature: *organizing the proverbs material by topics*. Most of the Golescu’s proverbs were taken by Iuliu A. Zanne and made accessible to the public in the 8th Volume (1900) of his monumental work in ten volumes (Zanne 1895-1903/1912). This gigantic scientific work of 8,000 pages, produced a century ago, is larger than all collections of proverbs which were published in Italy, Spain and Portugal all together, over the last hundred years; and unique in the world, considering the quality of the printing (Gheorghe 1986, 56).

The second development – starting from collections of proverbs – is to produce *comparative studies*. In 1863, the Romanian poet George Cosbuc has written the foreword to Ida von Düringsfeld’s comparative study about proverbs from 83 languages and dialects – among them there were 19 Romanian proverbs (von Düringsfeld 1863). There are more examples in this respect: analogous proverbs in Latin and nine modern European languages (Mawer 1885).

This empirical research started in Romania (Scarlat 2007, 2008b) and it is aiming at becoming broader, towards other countries or regions – like Balkans (Afendras and Scarlat 2007) or Arabian world (Scarlat and Afendras 2008). This paper aims at analyzing the equivalence between basic principles of business management and entrepreneurship – on the one hand – and the meaning of a sample of Romanian, Italian, and Venetian proverbs – on the other.

Business, management, and entrepreneurship by proverbs

The idea to use proverbs as examples or small cases appeared as extremely useful when teaching management to undergraduate students, which have none management experience and even no practical experience at all. At master level, the students have not only practical experience but significant management practice (Scarlat 2007, 2008a). There is a large spectrum of ways to use the proverbs as teaching aids in management and entrepreneurship classes²: as simple examples to strengthen or underline a new situation or abstract definition; as subject and

icebreaker for debates and group discussions; as homework to write essays; as research subject; or even as relaxing moment when the students seem to be less connected.

Amid the commonality, different people have their own way to express history-long life experience. In spite of similar life experience and conclusions, there are numerous proverbs expressing local and national peculiarities. This is why proverbs can be successfully used as a teaching aid when working with international undergraduate students either. The proverbs offer a valid pretext for cross-cultural communication, knowledge exchange, and teamwork, since “proverbs are multifunctional and flexible instruments of everyday reasoning, although they may maintain solidified attitudes or traditional modes of thought of a certain culture” (Lauhakangas 2007).

Through proverbs learners become aware not only of new elements of language, culture and management principles, but also of those aspects of behaviour and thinking patterns that may differ from their own.

Illustrative samples of Romanian, Italian, and Venetian proverbs are presented below, according to 21 different key-issues of business, management, and entrepreneurship (7 for each). It is significant to notice that:

- i. All the 21 principles are covered by proverbs in both languages.
- ii. There is an astonishing *high degree of correlation between Romanian – on one hand – and Italian or Venetian proverbs – on the other*: out of a sample of 33 Romanian proverbs on business, management and entrepreneurship issues (12, 11 and 10 respectively), 27 have Italian or Venetian correspondents (10, 9, and 8 respectively). Note that many of them are literally similar.

Business principles

“Romanian original version” & its loose English translation	Italian and Venetian proverbs & loose English translations	Comments on business principles
“Când sunt doi, puterea crește” Two means more power	“Due teste sono meglio di una” (It.) Two heads are better than one	<i>Business partnership</i> The importance of reliable partnership. Partnership (“two”) means more business potential (“more power”). When partnership is not reliable, based on mutual trust, and partners disagree (they “argue”), then both partners will loose and the competition wins (“the third party wins”).
“Când doi se ceartă, al treilea câștigă” When two argue, the third party wins	“Un legno solo no arde” (Ven.) A piece of wood doesn’t burn by itself “Tra i due litiganti, il terzo gode” (It.) When two argue, the third will benefit (literally: will enjoy)	The importance of coalitions – based on <i>win-win principle</i> . These proverbs apply for <i>teamwork</i> and team members as well.
“O mână spală pe alta și amândouă fața” One hand washes the other and both wash the face	“Una mano lava l’altra” (It.) One hand washes the other	In Italy it is mainly used in its literally meaning, to underline that there is always a third party ready to take advantage from a quarrel.
“Nu poți mânca miezul dacă nu spargi nuca” Crack the walnut to eat its kernel	“Col nulla non si fa nulla” (It.) With nothing you can do nothing “A chi no vol făr fadighe, el teren ghe produse ortighe” (Ven.) The soil will only produce nettles for whoever doesn’t want to make an effort.	<i>Business means effort</i> In order to enjoy the results of the business (“eat the kernel”) one has to put some efforts and work on it first (“crack the walnut”). The opposite it is not necessarily true.
“Paraua para câștigă” The coin earns other coin “Ban la ban trage” Money goes to money	“I soldi fanno soldi” (It.) “Schèi fa schèi” (Ven.) Money makes money “Chi più spende meno spende” (It.) He who spends more will spend less. “Chi ha buon vento naviga, chi ha denaro costruisce” (It.) Whoever has good wind will sail, whoever has money will build.	<i>Business needs (financial) resources</i> Basic rule of business is that it’s not possible to get profits with no expenses; in order to have profits, one has to spend first. Higher the expenditure, higher the expected profit (although not proportionally) and vice versa (although not reversibly). Financial resources (capital) are important to develop a business.
“Câștigul și paguba sunt frați de cruce”	“Non si fanno frittate senza rompere le uova” (It.)	<i>Duality gain-loss (profit-loss)</i> The loss is part of the business game as the gain (profit)

Gain and loss are sworn brothers “Nu e câștig fără pagubă” There is no gain without loss	You can't make an omelette without breaking the eggs. “Chi non semina non raccoglie” (It., Ven.) He who doesn't sow won't reap. “Avaro agricoltor non fu mai ricco” (It.) A greedy farmer was never rich “Buto ‘na sgârdoea par ciapâr un lusso!” (Ven.) Throw a minnow to catch a pike	is (“are sworn brothers”). Both gain and loss are associated to the business risk. More than that, the business risk and probability to gain are complementary: Business risk = 1 – Probability (gain) Higher risk business could lead to higher profit but higher loss too; and vice versa; When the risk is low, the profits are small as they share to all. Sometimes it is necessary to risk in order to get a good gain. It is important to be enterprising. This is the case of many Venetian workers that lost their works and started they own-run business.
“Cine nu riscă nu câștigă” Who does not assume the risk does not win (No pain, no gain) “Cine se teme de brumă nu pune viță de vie” Who is afraid of hoarfrost shouldn't cultivate grapevines	“Chi non risica non rosica” (It.) If you don't risk you won't gain.	<i>Assuming the business risk</i> Entering in business (“cultivate grapevines”) – hoping and planning an income (the grapes, wine and so on ...) means assuming the associated risks as well (like “hoarfrost”) – which do not depend on decision maker as they are external factors (here, the meteor-environment). The second proverb is more explicit and definitely clear
“Nu trece gârla dacă nu-i vezi fundul” Do not cross the river if you do not see its bottom	“Chi non può rendere fa male a prendere” (It.) If you can't pay back, don't borrow	<i>Assessing the risk</i> The businessman has to assume the risk but ... assesses the risk! Business is not gambling. The risk has to be correctly assessed – in order to better appreciate its consequences and plan the necessary resources accordingly (even to think at backup measures). A talented businessperson does not assume unnecessary risks or risks generated by total lack of information (no information on the depth of the river waters) in her/his business. S/he will gather the related information to this issue and then will plan the business (how/when/where to cross the river) and implement it (cross the river, finally) successfully.
“Frate-frate, dar brânza-i pe bani” The cheese is for money, even for brothers	“Conti chiari, amicizia lunga” (It.) Honest accounts, long friendships	<i>Business vs. family or friendship</i> Business principles are very strict: the business should not mix with family or friendship. When they meet, then the business relationships have priority over the friendship or family relationships (business comes first: “cheese is for money, even for brothers”).

Management principles

“Romanian original version” & its loose English translation	Italian and Venetian proverbs & loose English translations	Comments on management
“Așa-i lumea, din bucăți, vede unul face toți” The world is made out of distinct parts: one sees and all others do	“Se a mezzogiorno il re ti dice che è mezzanotte, contempla le stelle” (It.) If at noon the king says it is midnight, just contemplate the stars. “El tempo e la rason xe sempre del paròn” (Ven.) The boss always rules both time and reason (i.e. the boss is always right).	<i>Hierarchy principle</i> Organisations are hierarchically structured in managers (at different levels) and staff. The organization (“world”) is structured (“made out of distinct parts”): the role of the top manager (the “one”) is to supervise (“see”) and make the right decisions. The execution people just “do” in order to implement the manager's decisions.

<p>“Turma fără câine o mănâncă lupul” The flock which has no dog is eaten by the wolf “Vai de târla fără câini și de casa fără stăpâni” The sheepfold with no dogs and house with no masters are to weep for</p>	<p>“L’asino che aveva tanti padroni è morto di fame” (It., Ven.) A donkey with many owners will starve to death.</p>	<p><i>The supervising role of the manager</i> Any organisation (“flock”, “sheepfold”, “house”) must have a manager (“dog”, “master”). Lack of professional managers leads to business failure under the pressure of external factors (it is “eaten by the wolf”).</p>
<p>“Când pisica nu-i acasă, șoarecii joacă pe masă” When the cat is not at home, the mice play on the table</p>	<p>“Quando manca il gatto, i topi ballano” (It.) When the cat’s away the mice will (dance) i.e. play <i>This proverb have equivalents in French and other languages too</i></p>	<p><i>Controlling function</i> The manager (“cat”) has to permanently control its organisation (“home”); otherwise, the adverse factors (“the mice”) will provoke damages in key areas of the organisation (not only “at home” but even “on the table”).</p>
<p>“Croitorul bun măsoară de trei ori și taie o dată” The good tailor measures three times and cuts once “Judecă și apoi vorbește” Think and then talk</p>	<p>“Chi laora senza disegno laora senza inzegno” (Ven.) Anyone who works without a plan works without getting results</p>	<p><i>Documenting the decisions</i> The good decisions (“cuts”) have to be well prepared and documented (measured “three times”) by good managers (“good tailors”). Decision-making is a complex process: the decision cycle starts with gathering and processing the information; then developing decision options and selecting the right decision (“think”), <i>and only then</i> the decision is transmitted (“talk”).</p>
<p>“Înghite cât poți mesteca” Bite as much as you can chew “Întinde-te cât ți-e plapuma” Stretch as much as your cover allows</p>	<p>“Non fare il passo più lungo della gamba” (It., Ven.) Don’t take a step longer than your leg.</p>	<p><i>Setting the right objectives</i> The objectives should be set in SMART manner (Specific, Measurable, Achievable, Relevant, and Time-related). The objectives (“bites”) have to be correlated to the management and operational capacity (“as much as you can chew”) and available resources (“as much as your cover allows”).</p>
<p>“A veni la spartul târgului” To come when the fair is over “Bate fierul cât e cald” Hammer while the iron is hot</p>	<p>“Chiudere la stalla quando sono scappati i buoi” (It., Ven.) (It’s no use) shutting the stable door after the cattle have bolted. “Inutile piangere sul latte versato” (It.) It’s no use crying over spilt milk “Battere il ferro finchè è caldo” (It., Ven.) Strike while the iron is hot</p>	<p><i>Decision opportunity</i> When decision is made too late (“when the fair is over”), the opportunity is gone and the decision (“to come to the fair”) is useless. Or, one can get the expected result (the iron’s desired shape) as long as the iron is heated only; when cooled, it’s too late to hammer it!</p>
<p>“Capul face, capul trage” The head does, the head is responsible for</p>	<p>“Non riposa colui che ha carico d’altrui” (It.) The person in charge does not rest.</p>	<p><i>Assuming the responsibility</i> The head of the organisation is responsible for the consequences of the decisions s/he is making (“does”).</p>

Entrepreneurship principles

“Romanian original version” & its loose English translation	Italian and Venetian proverbs & English approximate translation	Comments on entrepreneurship
<p>“Nu tot ce zboară se mănâncă” Not everything that flies is eatable “Nu tot ce strălucește e aur” All that glitters is not gold.</p>	<p>Non è oro tutto ciò che luccica (It.) All that glitters is not gold.</p>	<p><i>Assessing the business ideas</i> The skilled entrepreneur has the talent to assess correctly the business ideas (“everything that flies”): only a few of them are good, workable and profitable (are “eatable”) while others are not.</p>
<p>“Norocu-i după cum și-l face omul”</p>	<p>“Aiutati che il ciel/Dio t’aiuta” (It.)</p>	<p><i>The entrepreneur and opportunity</i></p>

The good luck is made by the man himself	God helps those who help themselves <i>In the Italian (and English) version the presence of God (not luck) is that who will help the active man.</i>	The entrepreneurial spirit and skills are more important than chance. The business success (“good luck”) depends mostly on the entrepreneur’s potential (“man” – wonderful synthetic word for entrepreneur!) to see and use the opportunities. The entrepreneur is neither dependent nor waiting for hazard.
“Nu averea face pe om, ci omul averea” The man makes its wealth, not vice versa	“Tute le tere se bone par chi che sa coltivarle” (Ven.) All land is good land for those who know how to cultivate it.	<i>The entrepreneur-resources relationship</i> The entrepreneurial spirit and skills are more important than money (the capital). The business success (“wealth”) depends mostly on the entrepreneur’s potential (“man”, again!).
“Peștele de la cap se împute” The fish starts to rot at head “Copacul putrezește de la rădăcină” The tree starts to rot at the roots	“Il pesce è marcio dalla testa” (It.) A fish rots from the head down.	<i>Leadership</i> The role of leaders: the performant entrepreneurs are good examples to follow for their people. The opposite is true as well: the poor managers (rotten “fish head” or “tree roots”) provoke the failure of entire organisation (“fish” body or “tree”).
“Ce poti face azi nu lăsa pe mâine” Do not put off what you can do today till tomorrow “Leneșul mai mult aleargă și scumpul mai mult păgubește” The lazy man runs more and the tight-fisted man pays more	“Non fare domani quello che potresti fare oggi” (It.) Do not put off what you can do today till tomorrow “Chi prima va al molin, prima masèna!” (Ven) Whoever gets to the mill first grinds first.	<i>Active attitude</i> Avoiding the risk and prudence in excess lead to passivity (“lazy” and “tight-fisted” attitude), which is very costly in business (“man runs more” and “pays more” finally). Entrepreneurial spirit is to accept the risk, assess the risk, and have an active attitude: <i>act!</i> <i>Carpe diem: do not postpone, act!</i>
“Cine caută găsește” The man who is seeking, finds	“Chi cerca, trova” (It., Ven.) Anyone who seeks, finds “Con un colpo solo no se taglia un albore” (Ven.) You don’t fell a tree with just one chop.	<i>Perseverance</i> Perseverance, determination and diligence are strengths of successful entrepreneurs; they believe in their vision and persistently follow their way towards the goals set (they are “seeking” the goals). Finally, they achieve (“find”) their goals. <i>However, perseverance is not stubbornness.</i>
“Trestia care se pleacă în bătaia vântului nu se frânge” The flexible cane is not fractured when the wind blows	“Megio perder un dedo che tuta la man” (Ven.) It’s better to lose a finger than to lose a whole hand	<i>Flexibility</i> Flexibility doesn’t mean lack of verticality or character. To be flexible “when the wind blows” is to understand the unfriendly environment, adapt, and resist. When the environment is friendly again, the entrepreneur comes back and his business (“cane”) is vertical again by itself, with no effort.

It was not the purpose of this paper to present all the possible examples to illustrate all the aspects of business, management, or entrepreneurship. The above examples were not selected randomly either. As part of a more comprehensive work in progress (Scarlat, forthcoming), they were just a sample used to emphasize and document the idea that modern management science has strong roots in proverbs.

Conclusions

This paper is one in a series of first attempt to publicly present managerial aspects – as *principles of business, management, and entrepreneurship* – reflected in Romanian, Italian, and Venetian proverbs’ popular wisdom. The empirical research started in Romania and then it is aiming at becoming broader, towards other countries – as Italy.

The proverbs are one of the most significant means to synthesize, concentrate, distillate and treasure this generations-long life practical experience. Long before the management science to be born, the ancient businesspeople were successful – based on “only” their common sense, experience and best practice, continually transmitted along the generations.

Based on a sample of Romanian, Italian and Venetian proverbs, a set of 21 different key-issues of business, management, and entrepreneurship (7 for each) were analyzed. The major conclusions are these:

- (i) All the 21 principles are covered by proverbs in both languages.
- (ii) There is an astonishing *high degree of correlation between Romanian and Italian or Venetian proverbs*: out of a sample of 33 Romanian proverbs on business, management and entrepreneurship issues (12, 11 and 10 respectively), 27 have Italian or Venetian correspondents (10, 9, and 8 respectively).
- (iii) The proverbs have an unexplored and challenging potential to be used as teaching aids, while working with undergraduate students mainly but with international students as well.
- (iv) The proverbs used in our demonstration were considered as Romanian and Italian or Venetian, considering the respective territories as their origin. From popular perspectives, they emphasize the people's managerial talents in business and entrepreneurship. Although, this does not mean that only Romanian, Italian or Venetian proverbs enjoy this extraordinary property. Many proverbs are common in cultures of several peoples, regardless the country of origin, surpassing the country borders; hence, their *universal value* and potential to be used *globally as metaphors* in cross-cultural working environment.

To note that the results of this research are in line with previous cross-cultural comparative studies – following similar research matrix: Romanian vs. Malaysian proverbs (Scarlat and Kasim 2008); Romanian vs. Finnish (Scarlat and Tatila 2009); Romanian vs. Portuguese (Scarlat and Albuquerque 2009).³

One proverb says: Proverbs are people's coins.

Australian management perceptions of the performance management - firm effectiveness conundrum

*Alan R Nankervis, alan.nankervis@rmit.edu.au
RMIT University, Australia*

Abstract

Most contemporary human resource management (HRM) theorists agree that performance management systems underpin strategic human resource management theory, and that their processes and outcomes should be measured and reflected in relation to firm effectiveness. Firm effectiveness is evidenced in such quantitative outputs as productivity, profitability, return on investment, employee turnover, and in qualitative aspects such as employee morale, employee voice, and organisational climate, amongst many others. Whilst some authors (notably, Guest 1995; Storey 1999; Boudreau and Ramstadt 2009) suggest that the time is overdue for HRM researchers and professionals to prove empirically that HRM practices fulfill their promise to contribute significantly to the 'bottom line' of the firms which they serve, there has been only a limited response by HRM researchers to this call. In addition, most of these studies have evaluated the overall contributions of HRM strategies and systems to firm effectiveness rather than the specific outcomes of performance management systems.

This paper reports on a focused study of the links between performance management systems and firm effectiveness in a selection of Australian public and private sector firms. In a departure from earlier studies which primarily explored the perceptions of specialist human resource managers, this study canvassed the opinions of senior managers in a wide variety of firms. The findings both reflect and challenge the assumptions of strategic human resource management theory, and provide both conceptual and practical insights of value to general managers, human resource management professionals, and subsequent researchers, in Australia, Asia, and globally.

Introduction

One of the key contemporary issues of strategic human resource management (SHRM) theory, not yet fully supported by empirical evidence, is the link between HRM functions and firm effectiveness (Legge 1995). A number of studies (Delaney and Huselid 1996; Ulrich 1998, 2007; Wood 1999; Guest et al 2000; Elias et al 2004; Kaplan and Norton 2004; Green et al 2006) have attempted to analyse these links and to assess the contributions of human resource management strategies and processes to business goals and outcomes. This paper aims to add to these research findings, and thence to contribute to this gap in the HRM literature.

There is an incipient body of literature that suggests that SHRM theory is gradually becoming incorporated and reflected in firm practice, with some encouraging results. Wood (1999), for example, emphasises the significance of 'synergy, fit and integration as key concepts in modern human resource management' (p. 367), but cautions that the contingency theory of HRM implies that 'internally-fitted (HRM) practices that match the strategy of the firm will perform best' (p. 368).

This paper uses SHRM theory to explore the links between an arguably core HRM activity (namely performance management systems) and firm effectiveness, in an attempt to contribute to ongoing research in the area. The following sections of the paper examine the various meanings of firm effectiveness, together with the theoretical linkages between performance management systems (PMS) and firm objectives and outcomes, before reporting on the findings of a recent survey exploring the perspectives of senior Australian managers on such issues.

Firm effectiveness – Some definitions and associated issues

Common 'bottom line' firm measures such as profitability, productivity, return on investment, efficiency and competitiveness are often used to assess firm effectiveness, but broader definitions blend these quantitative characteristics with more qualitative features such as the level of employee involvement and satisfaction, organisational flexibility and staff retention rates. As examples, Yeo (2003: 199) defines effectiveness as '...financial performance, where the consideration of budgets, assets, operations, products and services, and human resources are crucial in determining the overall bottom line of an organisation'; the Aberdeen Group (2007: 4) considers that the two key performance indicators are increased firm profit and 'an increase in the employee retention rate during the last twelve months'; and Roy et al (2005: 252) believe that 'the most appropriate definition of (firm) effectiveness is...the net satisfaction of all constituents in the process of gathering and transforming inputs into output in an efficient manner' (see also Connally, Conlon & Deutsch 1980).

There is general agreement, however, amongst writers on the subject of firm effectiveness (for example, Ahmad 1999; Parhizzani & Gilbert 2004; Leslie & Tilley 2004; Roy et al 2005; Sung et al 2005; Greiling 2006) that firm effectiveness measures are grounded in a plethora of sometimes conflicting theory – including 'the goal model, the system model, the internal process, the human relations approach, and the political approach' (Ahmed 1999: 543) – which has led to 'little consensus on the meaning of (firm) effectiveness' (Roy et al: 251). The research undertaken for this paper was based on the premise that, whilst quantitative measures of firm effectiveness remain significant indicators of financial performance, there are additional qualitative features such as customer service, shareholder and employee satisfaction, which can complement such narrow perspectives. This premise is supported by SHRM theory and parallels the research undertaken by the U.K Chartered Institute of Personnel Development on associated issues (CIPD 2005).

The following section of the paper summarises the theoretical and research evidence on the links between performance management systems (PMS) and firm effectiveness as a precursor to the presentation and discussion of the research findings gleaned from the recent Australian study.

The performance management - firm effectiveness conundrum

Research studies conducted by Vandenberg et al (1999), Sung et al (2005) and Watson Wyatt (Anon 2006) evidenced strong links between high performance work systems (HPWS) and HR programs respectively with firm performance, measured in narrow financial terms such as productivity and profitability. Vandenberg et al (1999: 301) emphasised the importance of employee participation systems (for example, information about HR processes, customer feedback, knowledge of the business and the power to make work decisions) on firm performance; Sung et al suggested that HR 'reward and commitment practices' (p. 15), including broad performance management systems, are the key aspects, driven by business strategies; whilst the Watson Wyatt study concluded that 'eight years of research...has consistently found a strong correlation between HR program design and (firm) financial performance' (Anon 2006: 1). All of these aspects can be considered as inputs to or outcomes of a comprehensive and integrative performance management system, but the central research question is whether in fact there is a demonstrable link between performance management systems and overall firm effectiveness – this is the performance management-firm effectiveness conundrum.

Research by Huselid (1995), Delaney and Huselid (1996), Youndt et al (1996), Becker & Gerhart (1996), Patterson et al (1998), Guthrie (2001), CIPD (2001, 2005), Lawler (2005), Cheng et al (2006), the Aberdeen Group (2007), and Chang (2007) all reported that the alignment of performance management systems and business strategies resulted in improved firm effectiveness. The 2001 CIPD (p. 7) study concluded that 'more than thirty studies carried out in the UK and US since the early 1990s leave no room for doubt that there is a correlation between people management and (firm) performance, that the relationship is positive, and that it is cumulative – the more and the more effective the practices, the better the result'. This latter finding is supported to a degree by several recent Australian studies (for example, Nankervis and Penrose 1991; Nankervis and Leece 1995; Nankervis and Compton 2006).

Thus, whilst strategic HRM theory and several empirical studies concur that the linking of PMS with organisational objectives and outcomes can contribute significantly to enhancing firm effectiveness, there is also contrary evidence. The following study was conducted to ascertain the perspectives of (primarily) generalist managers (line, middle and senior) on these issues, in order to contribute to their ongoing discussion.

Methodology

The study was conducted by survey and explored a sample of Australian line, middle and senior managers obtained from existing databases. The survey included six sections with 130 questions, and was partially based upon the 2005 CIPD survey conducted in the UK to allow subsequent comparison, although significant variations and additions were also included. The sections included organisation and participant details; organisational strategies, values & culture; views on performance management; your organisation's current performance management system; performance management systems (general); and outcomes of performance management. All questions were either multiple choice or Likert Scales to allow quantitative data recording, and were analysed using SPSS and ANOVA analysis techniques.

Research findings

In total there were 304 usable responses from a predominance of executives/senior managers (53.8%), middle managers (22.4%), and HR professionals (14%), with a smaller proportion of line (8.9%) managers. This paper reports on participants' general perceptions of the overall links between their PMS and firm effectiveness, in particular relation to vision, values and performance alignment; high performance cultures; general views of performance management; performance management systems; performance management systems and practices; and performance management system effectiveness. These quantitative findings are complemented by some of the qualitative comments made by respondents on each of the constructs, and regarding their overall satisfaction with their current PMS.

Quantitative findings

ANOVA analysis of the data revealed a significant mean score difference between executives/senior managers, line managers, and human resource professionals on the incorporation of *firm visions and values*, with the former being more positive than the latter. This difference and in the same direction was also illustrated with respect to the statement that 'the mission/vision statement is an important component of performance management', that is that HR professionals were less positive about the connection than their executive counterparts. Specifically, the means for executive/senior management (3.67) and line management (3.85) differed from that of HR professionals (3.24). Similarly, with respect to the statement that 'strategy and directions are important in performance management in this organisation', executive/senior management scores (mean 3.96) were significantly more positive than those of their HR counterparts (mean 3.55).

With respect to the existence of a *high performance work* culture, which was refined from the literature and in alignment with the former CIPD study, to include the characteristics of customer care, quality, flexibility, competence, skills/learning targets, business awareness, working relationships, contribution to team, financial awareness, productivity, aligning personal objectives with organisational goals, and achievement of objectives, only four of these components elicited significantly different responses from executive/senior managers and HR professionals.

Thus, in response to the statement, 'our high performance culture is characterised by customer care', executive/senior management were significantly more supportive (mean score of 4.14) than either HR professionals (mean 3.80) or line managers (mean 3.60).

Similarly, with respect to the relationship between quality and HPC, executives/senior managers (4.17) were more positive than their HR counterparts (3.86). With respect to the statement 'Our high performance culture is characterised by competence', once again executives/senior managers (4.14) and HR professionals (3.77) expressed different levels of support, as they did in relation to HPC and working relationships (executives/senior managers – a mean of 4.15, compared to a mean of 3.74 for HR professionals). There were no significant differences recorded on the other characteristics – namely, flexibility, skills/learning targets, business awareness, contribution to team, financial awareness, productivity, aligning personal objectives with organisational goals, and achievement of objectives. With average mean scores for these characteristics it may be assumed that they are considered equally important aspects of performance management systems by both participant groups, if only moderately so, but that more operational outcomes such as customer care, competence, quality and working relationships are perceived as more important by executives/senior managers, but less so by HR professionals.

Managers' *views of performance management* encompassed (inter alia) links to stretch goals, integrated approaches, line management ownership, developmental versus evaluative foci, motivational aspects, links to firm culture, qualitative versus quantitative techniques, training, communication issues, and links to rewards systems. In only five of these aspects were there significant differences in the means between executive/senior managers and HR professionals – namely, performance management as part of an integrated approach to people management, as 'a continuous and integrated part of the employee-line manager relationship', line manager ownership of the system, training, and the role of PMS in firm culture. In these aspects, executives/senior managers (mean 4.51) were supportive of PMS as an integrated approach to people management, but less positive than HR professionals (mean 4.68). Similarly, HR professionals (mean 4.73) are more positive than executives/senior managers (4.38), middle-management (4.61) and line-management (4.33) regarding the view that PMS should be 'a continuous and integrated part of the employee-line manager relationship'. Finally, HR professionals were more likely to agree (mean 4.64) that line-managers should own the performance management system, compared with both executives/senior managers (4.31) and the line-managers themselves (4.04). With respect to training for performance management, HR professionals (mean 4.23) were significantly more positive than their executive/senior management counterparts (3.77).

Finally, there were significant differences between all levels of management regarding the role of PMS in strengthening firm culture – middle-managers (4.45), HR professionals (4.35), executives/senior managers (4.13) and line-managers (3.92).

A broad variety of possible *links between PMS and other HR functions or processes* were included in this section of the questionnaire, notably job design, staffing strategies, learning and development, rewards and remuneration, succession planning, employee discipline and counselling, HR information systems, and HR planning. Only four of these links elicited significant responses, namely staffing strategies, learning and development, succession planning, and employee counselling. Thus, whilst their levels of support for all of these links were considerably less positive than on the former issues, executives/senior managers (mean 2.45) were more supportive than either line-management (2.26) or HR professionals (2.09) with respect to the link between PMS and staffing strategies. Similarly, executives/senior managers (mean 3.02) were more supportive of a link to learning and development outcomes than are their line-manager counterparts (2.56). With respect to links to succession planning, middle-managers (2.22), executives/senior managers (mean 2.57) and HR professionals, (2.43) were more positive than line-managers (1.84). Finally, employee counselling links were supported more strongly by executives/senior managers (2.8), HR professionals (2.37), and middle-managers (2.34) than by line-managers (1.88).

With respect to the *integrative aspects of PMS*, the survey addressed HR horizontal alignment issues ('performance management is integrated with other people-management processes'); development-focused PMS; employee-firm integration; and 'performance management is an integral part of the people management strategy'. It also explored perceptions such as 'performance management is bureaucratic and time-consuming' and 'the aims and objectives of performance management are well communicated and fully understood'. The views of middle-management (mean 3.30), executives/senior managers (3.21) and line-managers (2.77) were significantly different regarding the integration of PMS and other HR processes, and in relation to a primarily developmental focus of performance management – executives/senior managers (mean 3.15), compared with line-managers (2.81). They also differed concerning the integration of employee and firm goals through performance management systems –

executives/senior managers (mean 3.31) versus line-managers (2.92). Similarly, middle-managers (mean 3.53), executives/senior managers (3.52) were more likely to agree that PMS is ‘an integral part of the people management strategy’ than line-managers (3.08).

On the more perceptual questions, line-managers (mean 2.42) and middle-managers (2.34) were more likely to agree that ‘performance management is bureaucratic and time-consuming’ than their executive/senior manager (2.02) and HR professional (1.77) counterparts. Similarly, executives/senior managers (mean 2.86) were more supportive than line-managers (2.46) that ‘the aims and objectives of performance management are well communicated and fully understood’.

Not surprisingly then, the perceptions of *the effectiveness of the PMS* varied slightly between the respondents, with executives/senior managers (mean 2.69), line-managers (2.54), HR professionals (2.49) and middle-managers (2.41) considering it effective. The following qualitative responses provide some interesting reflections on the above quantitative findings, and enlarge upon earlier data.

Qualitative Findings

A single qualitative question in the survey requested respondents to identify the *three key issues* in performance management systems. Whilst it necessarily elicited multiple different responses, the main themes which emerged were different for executives/senior managers, middle-managers, line-managers and HR professionals, although there were some shared views. Thus for executives/senior managers, the issues most frequently mentioned included can be summarised as a common or shared understanding of the PMS; adequate training in the need for and use of the system, and an associated culture of accountability. ‘Common or shared understanding’ encompassed such aspects as specific communication of the purposes and value of the PMS; ‘buy in’ and commitment at all firm levels, especially by management; adequate feedback mechanisms; user-friendly systems; linkages between employee KPIs and firm goals; and clarity of purpose. Some examples of such comments follow: ‘open and transparent communication’, ‘acceptance by employees of the system’, ‘recognition that performance management is not a punitive process, but a process of continuous improvement’, and ‘integration into the organisational culture...it needs to become part of the organisational narrative’. More cynical comments included ‘culture eats performance management every day for breakfast’, ‘scrap them, dismiss the HR department, scrap the bonus system’, ‘should be abolished’, and ‘it is not a tick box, nor an opportunity to have a go’.

PMS training was perceived to include not only functional or process details, but also identification of the mutual benefits of performance management, and shared recognition that performance management should be a ‘normal everyday event’ or a ‘positive process’; and which might be conducted as a several stage process – for example, ‘one-on-one, class and then follow-up instruction’. Measurement and accountability aspects mentioned encompassed clear links to firm objectives, ‘needs to be able to extract trends across the business, objectives must be cascading and linked to the business strategy’, realistic goals (‘SMART principles’), individual employee accountability, and ‘selecting the right KPIs/metrics, to measure them and assign appropriate weighting to make it clear which are the most important’. One respondent suggested holding HR managers accountable as they have ‘the primary responsibility for the conduct of performance management programs (unit cost- relationship with achieving outcomes – identify professional development’.

Middle manager responses can be summarised as commitment, ownership and alignment. With respect to commitment, comments such as ‘everyone in the organisation has to take the process seriously’, ‘support from senior management’, and ‘a cohesive and understanding management team’ are reflective. The importance of stakeholder ownership of the PMS was expressed in such suggestions as ‘consultation (buy-in), user-friendly system’, ‘ownership from executive management, ownership and input by staff recognition and developmental plan for staff’, and ‘stakeholder involvement in the development of the system’. Alignment was explained through feedback ‘in both directions’, ‘alignment from top to bottom of goals’, and ‘integration with the vision, values, business plans and HR activities’.

Line managers focused more clearly on operational issues such as user-friendliness, effective communication about the PMS purposes and processes, and employee benefits. The need for simple, transparent, and consultative systems was frequently raised, from the perspectives of both employees and their supervisors – as examples, ‘it should be a system that is easy to use and is not time demanding’, and ‘effectively and timely reporting systems which matches the culture and maturity of the organisation...simple to use’. Communication and employee benefits issues raised included an emphasis on employee motivation, ‘direct feedback to employees on how they are performing’, and regular HR surveys – ‘PMS should encourage employee development by encouraging skill and competency enhancement’.

Many of these themes were also echoed by the HR professionals who responded to the survey, but they placed more emphasis on strategic aspects such as linking employee and firm goals; multiple stakeholder ‘buy-in’, especially executives, middle and line managers; and clear alignment between PMS and all other HR systems. The flavour of such comments includes the following:

- . ‘link performance to behaviours, relationships, and the individual to the organisation’
- . ‘managers and employees as ambassadors of the process...’
- . ‘aligning individual and organisational goals...’
- . ‘easy to use system that is appropriate to the organisation and that is linked to the organisation’s strategic and operational goals’

With respect to respondents’ *satisfaction with their current PMS*, there was a variety of comments on their effectiveness from all management levels. Those who were ‘mildly’ or ‘very’ satisfied cited such issues as in-house system development; close links to firm culture change and/or other HRM processes; senior management support; positive staff feedback and a ‘positive’ supervisor-employee review process; the ability to retain staff through KPI-linked performance bonuses; well-structured and integrated systems; regular revision of the PMS; reviewer skills; user-friendly procedures; and consistent applications across the firm, for their satisfaction. Illustrative comments included:

- . ‘...directly designed to foster change in culture – 70% behaviour and values, 30% outcomes’
- . ‘...executive management always receives positive feedback from staff’
- . ‘it is an accepted system that provides the opportunity for staff and management to have face to face discussions about their performance. It is generally an overwhelmingly experience’
- . ‘the tool/system we use does require work to line up competencies with our values’
- . ‘we are able to retain staff in a tight labour market (skills shortage) by paying above average salaries, linking some KPIs to performance bonuses, providing candid feedback on individual and group performance, and by maintaining a harmonious work environment’
- . ‘the system is well understood and reviewed regularly to keep up to date with trends and feedback...simple not time-consuming, motivates employees’
- . ‘it’s an integral part of our culture and an essential tool in the balanced scorecard methodology we employ’
- . ‘I am satisfied because it’s consistently applied across the whole organisation, which drives outcomes...’.

For those respondents who were most dissatisfied with the efficacy of their PMS, the main themes included their difficulty of usage; a compliance rather than a developmental focus; lack of alignment with firm values and goals; inadequate reviewer training; lack of senior/middle/line management commitment and support; insufficient communication about the PMS; inconsistency of application across the firm; or simply, the absence of a formal system. Particular comments included the following:

- . '...it is non-existent...'
- . '...not enough people know how it works and utilise it effectively...it is not taken seriously...implemented in a patchy fashion'
- . 'the system is not yet established enough...still in transition and under ongoing review'
- . 'too cumbersome and compliance-based'
- . 'organisational vision, values and strategies are not well defined, therefore individual goals and objectives cannot be related back to organisational objectives'
- . 'lack of commitment by senior management and the board, no link to succession planning or pay scales...the process is just to tick a box at audit time'
- . 'the systems are in place and well-documented and communicated. However, the nature of the industry being what it is, everyone is hard pressed for time, and the senior management has failed to communicate the need and the relevance of a proper and properly implemented system'
- . 'no matter how hard we try, (PMS) have the opposite effect'
- . 'the current system does not express the employee value proposition'.

Discussion

Whilst the findings reported in this paper include a blend of factual and perceptual data on the nature, characteristics, linkages and overall effectiveness of the performance management systems employed by the respondents' firms, they also provide valuable information on the different views of executive, middle and line managers, and HR professionals. Both executives/senior managers and HR professionals reported that their firms' performance management systems (PMS) enshrine their vision and cardinal values, but the former were in stronger agreement than the latter. Line managers were even less supportive. As this would seem to be a factual matter rather than a mere perception, the responses suggest that HR professionals and line managers are less convinced than their senior managers of the actual alignment between PMS and firm visions and mission statements. These findings might also imply that the rhetoric of such a strategic alignment (as asserted by authors such as Becker & Gerhart 1996; Delaney & Huselid 1996; Guest et al 2000) is not so well achieved in practice, and reflects Aberdeen's (2007) findings.

With respect to the links between high performance cultures, PMS, and desired firm outcomes such as customer care, quality, competence and working relationships, it appears that executives/senior managers differ from HR professionals, and line managers on all such criteria. All of these can be considered to be more operational than strategic issues. There were no significant differences between the responses of different levels of management on desirable PMS outcomes such as flexibility, business awareness, financial awareness, and the alignment of employee and firm goals, but the majority of responses were less than effusive, implying collusion on a 'lowest common denominator' approach to the more strategic implications of PMS.

In contrast, there were considerable differences in the opinions of HR professionals versus other firm managers with regard to the integrative approach of their PM systems; their role as a 'continuing and integrated part of the employee-line manager relationship'; line manager 'ownership' of performance management; the need for specific performance management training; and the importance of PMS in strengthening firm culture. HR professionals were considerably more supportive of all of these elements than executives/senior managers and line managers, and middle managers only agreed with them with respect to the last element. It may be inferred here that HR professionals are more focused on the strategic aspects of PMS, especially in relation to their broader firm outcomes (culture, cascading responsibilities, upgraded skills through specific training, and embedded systems), and is consistent with some previous research (for example, Guest et al 2000; Jas & Skelcher 2005; CIPD 2005; Lawler 2005; Green et al 2006; Greiling 2006; Nankervis & Compton 2006). However, even if this were true, the less supportive views of their executive/senior, middle and line management counterparts are likely to interfere with even the best plans. Of particular concern is the apparent reluctance of line managers to accept their natural 'ownership' of the performance management system.

With respect to the horizontal alignment of performance management with all other HRM systems – one of the two key pillars of SHRM theory (Cascio 1999; Ulrich 1998, 2007; Green et al 2006) – fewer of the respondents were actively supportive of the links to staffing strategies, learning and development, succession planning and employee counselling. Surprisingly, executives/senior managers valued the link between performance management and overall staffing strategies more highly than either HR professionals or line managers, and the latter were consistently less supportive with respect to links with learning and development, succession plans and employee counselling. This is of considerable concern, as line managers represent the crucial operational conduit between the performance of their employees and the potential achievement of desired firm goals and objectives (Connally et al 1980; Patterson et al 1997; Sung & Ashton 2005), and as HR professionals could be expected to be mainly responsible for the firms' overall staffing strategies (Jas & Skelcher 2005; Green 2006).

Consistent with their responses in other parts of the survey, line managers were significantly less enthusiastic than either executives/senior managers or HR professionals about the more strategic elements of PMS, including the integration of PMS and other HR processes (horizontal alignment); the affiliation of employees' performance objectives with firms' financial goals; the perception that PM systems should be an integral part of HRM strategies (vertical alignment). Whilst not surprising (see Nankervis & Leece 1997; CIPD 2005; Nankervis & Compton 2006), this finding suggests that many of the performance management systems reported on do not appear to have involved line management sufficiently in their design and implementation stages and/or that communication strategies have been less than adequate. In partial confirmation of this, as the key players in the implementation of PMS, both middle and line managers (as opposed to other managers) more commonly agreed that communication about performance management was inadequate, and that PMS were often 'bureaucratic and time-consuming'. Similar findings have been reported in other such studies (Parhizzani & Gilbert 2004; CIPD 2005; Brown 2005; Sung & Ashton 2005).

Finally, the findings of this study demonstrate many similarities with earlier research in respect of the features which contribute to the perceived effectiveness of PM systems – namely, the importance of a common understanding of their goals and processes between all stakeholders; comprehensive and ongoing communication strategies; ownership of the chosen system by all users; user-friendliness; and clear links between PMS, all other HRM processes, and with firm culture and desired outcomes (Nankervis & Leece 1997; Stanton et al 2005; Greiling 2006; Nankervis & Compton 2006). Not surprisingly perhaps, executives/senior managers and HR professionals (in that order) were generally more impressed with the effectiveness of their systems than either middle or line managers, and focused on arguably more strategic elements (for example, cultural outcomes, horizontal and vertical alignment) compared with a more operational focus for middle and line managers (for example, commitment, ownership, user-friendliness, employee benefits).

Conclusion

This paper reports on some of the quantitative and qualitative findings from an Australian research study which focused on the perceptions of a wide range of managers (executives/senior managers, middle and line managers, HR professionals) on the links between performance management and firm effectiveness. Whilst the data confirm the findings of many similar studies – in particular, that the rhetoric of performance management system designers is not always shared by all firm stakeholders or reflected in operational realities; and that linking PMS to firm effectiveness is often problematic - the paper contributes to the associated literature by demonstrating the sometimes conflicting imperatives of different management levels. Thus, executives/senior managers in this study were the most supportive of a strategic approach to the PMS-firm effectiveness relationship, followed by HR professionals, whilst middle and line managers were clearly more focused on operational and implementation perspectives.

More detailed data collected in this survey will drill further down into the specific contributions of PMS to such firm performance indicators as productivity, return on investment, profitability, and competitiveness, and will be reported in subsequent publications. However, it is evident that further research should focus on determining the actual links between PMS and firm performance, as reflected in such crucial measures as cost-effectiveness, return on investment, enhanced productivity and increased profitability.

THE RELATIONSHIP OF BUSINESS STRATEGY AND HUMAN RESOURCE MANAGEMENT PRACTICES ON PRIVATE AND PUBLIC LIMITED COMPANIES IN MALAYSIA

Juhary Ali, juhary@aeu.edu.my
Koon Vui Yee
Asia e University, Malaysia

Abstract

This study investigated the relationship between two business strategies (differentiation and low-cost) and six human resource management (HRM) practices (recruitment & selection, training & development, compensation, performance management, employment security and work-life balance) and the extent to which such relationship bring differences to Public and Private Limited companies in Malaysia. Therefore, the main objective of this study was to develop the conceptual model to measure the interaction effects of business strategy and HRM practices. Structural equation modeling (SEM) used to examine the effect of business strategy to HRM practices and to examine the invariance effect of the two businesses ownership in the model. This study found that differentiation strategy was one of the business strategies that tend to emphasize on all six HRM practices while low-cost strategy found to emphasize on four HRM practices only. The results also indicated that the effects of business strategy and HRM practices implemented in Public Limited companies were only slightly different from the ones implemented in Private Limited companies.

Introduction

The influence of human resource management (HRM) practices on the overall performance of organizations has been in major research in the past decade in the developed countries. The results of these research indicating significant association between HRM practices and organization performance (e.g., Dyer & Reeves, 1995; Huselid, 1995; Becker & Gerhart, 1996; Guest, 1997; Cully, 1999; Harel & Tzafrir, 1999; Appelbaum, Bailey & Kalleberg, 2000). However, changes or trends that emerging today such as globalization, changes in the nature of work, and technology that requiring HRM practices to be more business oriented and strategically focused when managing organization. Firm size found to be an important predictor of HRM practices (Ng & Maki, 1993; Wagar, 1998; Kotey & Slade, 2005). Large firm were detailed, formal and much likely to adopt most of the HRM practices. It would be practical to investigate the relationship of business strategy and HRM practices in various different settings to examine the differences of effect due to firm size.

In this study, significant effect derived between different types of business strategy among HRM practices were determined as well as the comparison of the two variables between Public and Private Limited companies. This research study addressed the following questions concerning the relationship among business strategy and human resource management (HRM) practices.

- Research Question 1: Is there a relationship between HRM practices and the business strategy?
Research Question 2: Are there identifiable combinations of HRM practices that align and fit into related business strategy?
Research Question 3: Is Public Limited and Private Limited companies have the same identifiable combinations of business strategy and HRM practices?

Significance of this study was as follows:

For conceptual perspective, the study examines the relationship between HRM practices at the business strategy level. Business strategies was defined using Porter (1980)'s generic strategies. HRM practices in this study measured using the existing practices that seldom used in other empirical research. By examining variations of HRM practices such as employment security and work-life balance to business level strategies, the alignment between this relationship could discover in relation with Porter (1980)'s generic strategies. This methodology can further provide understanding of any systematic variations of HRM practices to different strategies of business level.

From the practical perspective, the findings of this study were useful to firm executives as they could adopt the pattern of human resource management practices within specific strategic conditions of organization and firm size. Furthermore, these findings will be useful to all management level as well as HR practitioners to

design their HRM practices at the hard or soft approach in order to improve firm performance as well as strengthening their firms competitive advantage.

Theoretical background and hypotheses development

According to Ferris, Hochwarter, Buckley, Harrel-Cook and Frink (1999), strategic HRM divided into three perspectives that are universalistic, contingency and configurational perspectives. Universalistic perspective claimed that availability of a set of HRM practices that are combined effectively are perform better than others that do not, hence, suggested to all organization to adopt these practices (e.g. Geringer, Frayne & Milliman, 2002; Truss, 2001). The contingency approach is attempted to link variations of HRM practices to specific organizational strategies (e.g. Hoque, 2000; Khatri, 2000). The configurational perspective is referring with how patterns of multiple, planned human resource deployment and activities achieve the organization's goal and argued that HRM practices should look as a system than individually (Doty, Glick & Huber, 1993, Meyer, Tsui & Hinings, 1993). In this study, concept of strategic fit was adopted as according to various researchers, the right adoption of HRM practices is vital because it assists business firms to enhance their competitiveness and support managerial efficiency (Wright & Snell, 1998).

The Relationship between Business Strategy and Human Resource Management Practices

The concept of business competitive strategy derived primarily from Porter's (1980, 1985) classifications of generic strategies: Cost leadership, Differentiation, and Focus strategies. Miles and Snow (1984) on the other hand, classified business strategies into defender, prospector, and analyzer. They also proposed each business strategies with correspondences human resource management practices. In reference to Porter's generic strategy, Schuler and Jackson (1987a) have used the terms slightly different from those of Porter to classify business competitive strategies. The terms are cost reduction, innovation, and quality enhancement. Besides, they have designated different types of employee behavior and HRM methods that would be best suited to each business strategy.

An organization could achieve its competitive strategy by implements an effective HRM practices. Effectives HRM needs to be systematically coordinated all individual HRM measures and it could directly influence employee attitude and behavior. Dowling and Schuler (1990) combined the respective HRM practices into strategies of utilization, facilitation, and accumulation, which were the three types of business strategy suggested by Schuler and Jackson (1987a). Dyer and Holder (1988) reclassified the combination of HRM practices and business strategies as inducement, investment, and involvement, respectively.

According to contingency theory, HRM strategies must be associated with specific business competitive strategies to enhance organizational performance (e.g., Miles & Snow, 1984; Porter, 1985; Schuler & Jackson, 1987a). The concept of "fit" is referring to the interaction of HRM strategies and business strategies in ways that will help to retain and motivate employees. Huselid (1995), however, concluded that adoption of high performance work practices alone is more important than the alignment of HRM practices with firm competitive strategy. Similarly, MacDuffie (1995) also found there was no evidence to support the linkages between appropriate HRM practices and mass production to compete with flexible production methods.

Although some of the previous research showed no consensus on the relationship between business strategy and human resource management practices, but in this study concept of strategic fit adopted and formulate the hypothesis below. In other words, it hypothesized that the strategic linkage between business strategy (i.e. differentiation and low-cost strategy) and human resource management practices (i.e. recruitment & selection, training & development, compensation, performance management, employment security and work-life balance) showed significant relationship.

H1. There is positive relationship between business strategy and HRM practices

Differences of Large Firms and Small Firms in Business Strategy and Human Resource Management Practices

Most research conducted using large-scale organizations and found different HRM systems or bundles of practices do contribute to the performance of these organizations, by employee retention, increasing

productivity, or even by improving profitability (Arthur, 1994; Delery & Doty, 1996; Huselid 1995; MacDuffie 1995). However, there were few studies that identified HRM practices in small medium enterprises (SMEs) and even fewer that focus on the relationship between HRM practices and performance (Heneman, Tansky, and Camp 2000). Most of the studies have reported the relationship between HRM practices and performance in large organizations rather than SMEs. Though there was debate as to the extent to which HRM practices results from large could applicable to small firm, these findings are of interest and provide the basis for theoretical examinations of the smaller firm (Chandler & McEvoy 2000; Deshpande & Golhar 1994).

In comparison with HRM practices of small medium enterprises (SMEs) or small firm were not as developed and were less structured than in the large enterprises (Hornsby & Kuratko, 1990, 2003; Kerr & McDougall, 1999; Marlow & Patton, 1993). Overall, this caused SMEs lacking of expertise on HRM methods and techniques. Therefore, relationships between HRM practices and performance in SMEs are not clear as compared to the ones observed by many researchers in large businesses. Again, this explained the need to increase research in this field (Cardon & Stevens, 2004; Hornsby & Kuratko, 2003; Katz, Aldrich, Welbourne & William, 2000; Tansky & Heneman, 2003).

Thus far, majority of the theoretical arguments proceeding from various viewpoints of different scholars have found that in large-size organizations are more likely to involve in human resource management and therefore would implement more extensive, advanced and complex HRM practices. Heneman and Berkley (1999) found that a greater percentage of large firms (50-99 employees vs. 20-49 employees) used more formalized and systematic recruitment and selection practices, more formalized compensation practices, and more special hiring inducements and hiring bonuses. Similarly, In De Kok and Uhlaner (2001) study on 16 small Dutch firms (10-41 employees), they found company size to be associated with more formal HRM practices, including greater performance appraisal and employer-based training is conducted.

However, there was some analysis of HRM systems in the empirical literature of different firm size to be inconclusive with the previous findings. Cardon and Stevens (2004), who reviewed existing research on managing people in small firms, provide a useful summary of what is known about HRM practices related to staffing, compensation, training and development, performance appraisal, organization change and labour relations. These authors noted that although recruitment and selection in SMEs is very important, but also problematic; SMEs focuses greatly on a total rewards perspective than do large firms; that training employees is important in SMEs; and that SMEs usually uses formal appraisals. Besides, Cassel, Nadin, Gray and Clegg (2002), on the other hand, found in the study that recruitment and selection procedures used in a medium-to-great extent by 61% of SMEs, following by performance appraisal systems, which were used to an average or large degree by 58% of SMEs. The least used HRM practices in their sample were those related to employee rewards, such as incentive schemes, which were used to an average-to-large extent by only 40% of SMEs. Decision-making and employee development appeared to use by mostly of the majority of small firms.

H2. There is significant difference on types of business ownership in the relationship between business strategy and HRM practices.

Methodology and Data Analysis

In conducting this study, 200 companies consist of profit making Public Limited and Private Limited selected randomly as population set. The sample includes 100 Public Limited and 100 Private Limited companies. Equal number of firms selected to ensure a representative sample. There were two respondents to the questionnaire. The first respondents, was the employees from non-human resource (HR) departments. They were required to providing information on business strategy, HRM practices in their company and employee outcomes. The second respondent was the person identified as the human resource manager. The respondent expected to have knowledge and able to answer questions pertaining business strategy as well as HRM practices within the organization. Huber and Power (1985) suggested several approaches to reduce potential measurement error when there was only informant per organization. They claimed that “if only one informant per organization is to be questioned, attempt to identify the person most knowledgeable about the issue of interest”. A usable survey of 61.5% from HR manager and 64.2% from non-HR employees was collected back corresponding to 123 and 642 responses respectively.

The independent variables for this study were drawn from business strategy and human resource management practices. Measures of business strategy (10 items) and human resource management practices (46

items) were utilized based on past studies of Dess & Davis (1984) and Guest, Conway & Dewe (2004) respectively. Both of instruments used a 7- point, Likert-type format. Therefore, the scale measurement of the dependent variables for this study was ordinal-type data. Figure 1 proposes the hypothesized structural model for the study. It consists of two exogenous variables (differentiation strategy and low-cost strategy) and six endogenous variables (recruitment & selection, compensation, performance management, training & development, work-life balance and employment security).

The 642 dataset were coded and saved into SPSS Version 14 and analysed using AMOS Version 16.0. During the process of data cleaning and screening for accuracy for data input, outliers, normality and multicollinearity, 22 dataset were deleted due to incomplete cases while another 49 data set were deleted due to Mahalanobis distance values more than χ^2 value ($\chi^2 = 137.208$; $n=90$, $p<0.001$) leaving a final 571 dataset to be analysed. Several statistical tests and analysis were then conducted such as reliability test, validity tests using confirmatory factor analysis (CFA) for construct validity, discriminant validity for multicollinearity treatment, descriptive analysis, correlation and structural equation modeling analysis using AMOS 16.0 (SEM). To summarize, SEM uses graphs to describe causal relation among business strategy, human resource management practices and employee outcomes.

Findings

On the sample, 52.7% of the subjects were female and 46.2% were male. The age groups was as follows: 61.5% were 21-30 years old, 25.2% were 31-40 years old, 6.0% were 41-50 years old, 2.6% were 51-60 years old and 4.7% were found incomplete. Most of the non-HR department employees held the SPM/Diploma/STPM (55.3%), Adv. Diploma/Bachelor/Prof. Degree (40.6%), Master Degree (2.6%), PhD/DBA (0.2%) and 1.2% found incomplete. Majority of the sample surveyed held first-line management (63.7%), follows by non-managerial (22.9%), middle-level management (9.6%), top-level management (3.5%) and 0.2% found incomplete. The distribution of monthly income was as follows: 40.8% were RM2001-3000, 34.5% were RM1001-2000, 12.1% were RM3001-RM4000, 6.7% were more than RM5000, 2.8% were RM4001-RM5000, 2.1% were not more than RM1000 and 1.1% were found incomplete. Most of the sample surveyed were from Private Limited Company (65%) while Public Limited Company (35%).

Descriptive Analysis of Variables

The research framework examined the relationship of two types of business strategy and six dimensions of HRM practices. Nunally (1978) suggested that reliabilities in the range of 0.50 to 0.60 were acceptable in the early stages of research. Overall most construct shows Cronbach's alpha readings above 0.60 (Table 1) and this items were within the acceptable range of coefficient suggested by Nunnally (1978).

Table 1 *Descriptive Statistics of Variables*

Variable Name	No. of Items	Mean (Std. Dev)	Cronbach's Alpha
Business Strategy			
Differentiation	5	4.17 (1.09)	0.815
Low Cost	5	4.26 (1.03)	0.808
HRM Practices			
Recruitment & Selection	5	3.75 (1.17)	0.553
Compensation	8	3.80 (1.11)	0.742
Performance Management	9	4.00 (1.08)	0.719
Training & Development	5	4.02 (1.18)	0.770
Work-Life Balance	5	3.96 (1.09)	0.625
Employment Security	5	4.06 (1.14)	0.651

Confirmatory Factor Analysis (CFA) Results

From the confirmatory factor analysis result in Table 2, we observed that the factor loadings of all observed variables or items are adequate from 0.518 to 0.915 except RS1 (0.491). The factor loadings or regression estimates of latent to observed variable should be above 0.50 (Hair et al, 2006; Bryne, 2001). This indicates that all the constructs conform to the construct validity test. The remaining number of items for each construct is as follows: business strategy (8 items), HRM practices (16 items) and employee outcomes (16 items). Confirmatory factor analysis conducted on every construct and measurement models (see Table 3). All CFAs of constructs produced a relatively good fit as indicated by the goodness of fit indices such as CMIN/df ratio (2 to 5); Goodness of Fit Index (GFI) of $>.90$; and root mean square error of approximation (RMSEA) of values less than $.08$ ($<.08$), comparative fit index (CFI) of $>.90$ and Tucker-Lewis index (TLI) of $>.90$.

The modified measurement model has a good fit with the data based on assessment criteria such as GFI, CFI, TLI and RMSEA (Bryne, 2001; Anderson and Gerbing, 1998). Table 3 shows that the goodness of fit of generated or modified model is better compared to the hypothesized model.

Table 2 *Confirmatory Factor Analysis Results of Construct Variables of Hypothesized Model*

Variable	Code	Attributes	Factor Loadings
Business Strategy: (8 items)	D1	Products (services) in this organisation are innovative and continually	0.799
	D2	This organisation aggressively entering new markets with new types of products (services).	0.739
	D3	This organisation consistently develop new product and new markets.	0.824
	D4	This organisation often changing the characteristics of products (or services) to satisfy customers' various tastes.	0.687
	LC1	Products (services) in this organisation are stable and consistently defined throughout the market.	0.728
	LC2	This organisation analyze costs and revenues carefully by keeping costs under control and selectively produce new products and enter new markets	0.714
	LC3	This organisation carefully analyze emerging trends and adopt those which have proven potential only.	0.738
	LC4	This organisation maintains a secure financial position through cost and quality control.	0.734
HRM Practices: (16 items)	RS1	Employee selection process for a given job is extensive in this organisation (for example, Use of tests, work sample, aptitude test)	0.491

Hypotheses Results

Since the hypothesized of full model in this study (Figure 1) did not achieve model fit as RMSEA, GFI, CFI and TLI was less than 0.90, hence the explanation of hypotheses result is based on modified full model (Table 4 and Figure 2). Table 4 demonstrates that hypothesis H1 which stated there is positive relationship between business strategy and HRM practices was partially supported as in this study except low cost strategy did not have significant relationship with compensation (C.R.= -0.706 <1.96; p=0.480 >0.05) and work-life balance (C.R.=1.928<1.96; p=0.054>0.05).

Testing for Invariant Results

For this study, comparison was made between two groups, Public Limited and Private Limited companies. First, equal factor structures across two groups were examined. Results indicated that there was only marginality better fit to both dataset with TLI=0.870, GFI=0.904 and CFI=0.892. After modification were made, the goodness-of-fit indices for revised model, GFI, TLI and CFI were 0.920, 0.925 and 0.905. All the indexes were above the threshold of 0.90, and are indicative that the hypothesized model of business strategy and HRM practices structure fit well across the two-business ownership. After having established the good fit of the model, testing for the invariance of factorial measurement and structure across groups was measured. The results of the model comparison are reported in Table 5.

Table 5 Goodness-of-Fit Statistics for Tests of Invariance

Model Description	Comparative Model	χ^2	df	$\Delta \chi^2$	Δ df	Statistical Significance
1. Revised Hypothesized Model (Model 1)		530.653	332	-	-	-
2. Factor loadings, regression paths variances & covariances constrained equal	Model 1	578.918	360	48.265	28	p<0.01

11. Model 1 (a) with LC→RS, LC→TD, LC→CR, LC→PM and LC→ES constrained equal	Model 1	569.147	356	38.494	24	p<0.05
12. Model 1 (a) with LC→RS, LC→TD, LC→CR, LC→PM and LC→WLB constrained equal	Model 1	560.426	356	29.773	24	NS

Table 5 reveal differentiation strategy paths to HRM practices are non-significant while the low cost strategy paths to HRM practices was significant (p<0.05). Thus, the invariance hypothesis testing was rejected.

However, although there was an observed measure of low-cost strategy to HRM practices were found to be operating not equivalently for both Public Limited and Private Limited companies, the majority of the HRM practices, which have invariant to low-cost structural regression paths: recruitment & selection, training & development, compensation, performance management, and work-life balance. Only one of the HRM practices which employment security found to variant between two groups. As a result, those statistics of chi-squares lead to rejection of hypotheses of invariance across two groups in assessment of measurement weight and structural regression paths. This showed hypothesis 2 “There is significant difference in types of business ownership in the relationship between business strategy and HRM practices” showed mixed results.

Discussion

This study attempts to examine the goodness of fit of the hypothesized structural model by integrating business strategy and HRM practices. As expected, the hypothesized model do not achieve model fit: CFI, GFI, and TLI were less than threshold of 0.90. This implies that hypothesized model was not supported. However, the modified model accomplished model fit and supports some direct effects between dimension of business strategy and HRM practices. Firstly, the results indicated that differentiation strategy had a direct positive relationship with all the six HRM practices. This findings is somewhat consistent with the results of Chang and Chen (2002) as they claimed differentiation strategy tends to focus on new product and process, development and improvement, therefore, training & development, team and performance management were the likely the appropriate requirement. Second, low-cost strategy had significant positive relationship with performance management and employment security but significant negative relationship with recruitment & selection, and training & development. However, low-cost strategy found to have no significant relationship with compensation and work-life balance. These findings are somewhat consistent with the results of Schuler and Jackson (1995) studies where they suggested the appropriate HRM practices for organization employing cost-defender strategy include relatively fixed and stable job descriptions, career paths that encourage specialization and result oriented performance appraisal system, compensation at par with market levels and minimum levels of employee training and development. This showed that organization that emphasizes on low-cost strategy will focus lesser on employee training and development.

According to the results of invariance tests using multiple group analysis, the model was verified to have measured the same factor loadings across two groups of companies (Public Limited vs. Private Limited). The results in this study showed non-significant results which mean there was invariance or no difference of factor loadings between the two-business ownership. However, the results from path analysis revealed differences in the regression coefficients and error variances between the two groups. Prior to testing for invariance, this study found differentiation path to be invariant but low cost path was found to be different across the two groups ($p < 0.05$). This study revealed that regression path of low-cost to employment security ($p < 0.05$) to be significantly variant across groups. Large organization in this case that is Public Limited companies are more likely to develop HRM practices that approved and favourably assessed by society (Shaw, Tang, Fisher & Kirkbride, 1993; Cohen & Pfeffer, 1986). This is consistent with the result as large organization will likely to focus on employment security than small organization as Private Limited companies less likely to expose to community view and bring lesser influence to environment.

Suggestion for Further Research

Future research should be replicated with financial measurement as well as other significant variables, such as differences of industry sector such as primary agricultural, manufacturing and services sector be added into the hypothesized causal structural model. The conceptualization and measurement of HRM practices needs to be redefined. Although all six HRM practices represented well in the present study, these indicators may need to change in different settings and countries. In addition, testing the model within an experimental design would enable researchers to use the model to explain causal structures. Therefore, a more systematic analysis is called for, because the data used in this thesis are cross-sectional in nature and time-series data would allow a better test of causal order.

Conclusion

In conclusion, this study has conceptual and methodological implications. For example, a reliable and valid measurement model for business strategy covering two domains (differentiation and low-cost) and HRM practices covering six domains (recruitment & selection, training & development, compensation, work-life balance, employment security, performance management) was developed and tested by a CFA. Although this measurement model is not included with every HRM practices adopted and implemented by companies, but it has covered majority representative domains of HRM practices suggested by HRM researchers (e.g. “Best practices”, Guest, 1997). Besides, the use of Structural Equation Modeling (SEM) enabled the specification and estimation of a complex model of relationship between business strategies and HRM practices. This method also facilitated the comparison of these complex relationships for Public Limited and Private Limited companies. The finding of this study is important as previous empirical studies have proven that the combinations of model between HRM strategies with organizational strategy represent the best way to achieve companies’ business objectives (Pan, 2007) and obtain better economic results in terms of productivity and return over equity (ROE) than their main competitors (Portales Echeverria, 2001).

Employee Gender Characteristics Among Retail Sectors

Joshua Chang, j.chang@curtin.edu.au

Antonio Travaglione

Curtin Business School

Abstract

Employee gender characteristics vary among different retail sectors. For example, male dominated retail sectors such as hardware employ more male staff, while female dominated retail sectors such as cosmetics employ more female staff. The purpose of this paper is to explain such gender differences in retail employment. The data used for this study is a subset of the 'Australia at Work' survey, which is a longitudinal survey tracking the experiences of the Australian labour force via telephone interviews. In answering the research questions, a subset of telephone interview data from the 'Australia at Work' survey consisting of 702 respondents employed in the retail industry will be analysed. The results indicate that retail employment in Australia is dominated by females, and that certain retail sectors were found to have different employee gender characteristics. Managerial positions in retail were found to have only a slightly larger proportion of males, implying that there is little gender discrimination in retail managerial positions in Australia as compared to findings from the United Kingdom and the United States. Customers are likely to have preferences as to who they are being served by when shopping for specific products, affecting their purchase decisions and consequently the business performance of stores. Hence, managers can use such information in employment decision making to create a competitive advantage and increase profitability.

Key words: Management, Employment, Demographics, Gender, Retail.

1. Introduction

The retail industry is the largest employer in Australia (Wanrooy et. al. 2009). Due to changes within the retail industry such as changing retail structures, improving technological developments, and evolving customer characteristics, there is a need for current research in this area. In particular, research on retail employment will provide businesses with information that can improve hiring decisions and business strategy. As customers of different categories of products have varying expectations of retail staff, businesses need to make informed hiring decisions to improve customer service and consequent profitability. Hence, research on demographic stereotypes in retail employment is important. Research points out that gender stereotypes exist in retail employment (for example, Sparks, 1991; Fischer, Gainer, and Bristor, 1997; Taylor and Tyler, 2000; Korczynski, 2002; Lynch, 2002; Foster, 2004; Pettinger, 2005). Most of the existing research on gender stereotypes in retail employment has been carried out in the United Kingdom and to a lesser extent the United States, with no significant study undertaken in Australia, despite retail being its largest employer. Based on the foregoing, research is necessary to address these issues in the Australian retail context. Therefore, the purpose of this paper is to identify gender characteristics in retail employment within Australia.

2. Stereotypes In Retail

A substantial body of literature points out occupational differences between males and females. Occupational segregation occurs when workers are excluded from certain jobs, and over represented in others, for reasons such as race, gender, or national origin (Gabriel and Schmitz, 2007). Tikka (1999) points out that there are more male dominated occupations than female dominated occupations, in consideration that the female occupations tend to be lower paying, lower status, with fewer advancement opportunities. Gabriel and Schmitz (2007) highlights that recent analyses of gender employment patterns suggest that occupational differences between men and women are a

persistent presence in the U.S. labour market. For example, traditional blue-collar occupations continue to be male dominated, while women remain concentrated in service and clerical occupations. Likewise, Finch and Groves (1983) suggest that employers consider women to be better at service roles due to their natural ability to care for others. McGauran (2000) explains that gender segregation in the labour market depends on the supply of workers of each gender, and the interplay between the cost of workers and the skills sought of them. McGauran's findings suggest that a less regulated labour market, in conjunction with few male peripheral workers, contributes to stronger gender segregation in the labour force. According to Brockbank and Airey (1994), occupational segregation is the tendency for women to work in particular sectors of the labour market which are exclusively, or almost exclusively, staffed by females, giving the example of the retail industry.

Gender specific characteristics can explain the occupational differences. Generally, men are perceived to be more suited to more physically demanding roles (Lynch, 2002), such as work that involves heavy lifting like construction, and women are perceived to be more suited to social interaction roles such as customer service. Pettinger (2005) found that men dominated where goods were heavy, valuable or when the clientele was largely male and 'male' jobs were more likely to be associated with craft and training than female jobs. Sparks (1992) highlights that the expansion of the female component in retail employment has in the past been associated with increasing part-time employment. While there is a fundamental shift from full-time to part-time employment irrespective of gender, female part-time employment remains as a massive component of modern retail employment and operations. Brockbank and Airey (1994) postulates that the traditional pattern of part-time employment for married women has provided retail employers with a readily available pool of labour, and that they accept inferior terms and conditions to accommodate their traditional child-care and domestic obligations.

Retail employment has been found to be dominated by women (Brockbank and Airey, 1994; Sparks, 1992; Office for National Statistics, 2006; Pilcher, 2007). Sparks (1992) found that retailing in the United Kingdom has for a long period been a primarily female occupation, and there is evidence of a continued feminisation of the workforce, with one in seven of all women work in retailing. This is supported by Brockbank and Airey's (1994) finding that retailing in the United Kingdom is dominated by women. Pettinger (2005) explains that the gendering of retail employment lies with the feminisation of customer-service work due to the emotion management content. This is reiterated by Pilcher (2007), who points out that women are disproportionately represented in the service sector's five 'C's'; 'Catering; Cashier or Checkout, Clerical, Cleaning and Caring' occupations, most of which require a degree of emotional labouring. Similarly, Lynch (2002) found that departments such as checkouts and administration tended to be dominated by part time females.

Substantial research concludes that gender stereotypes exist in retail employment (Sparks, 1991; Fischer, Gainer, and Bristol, 1997; Taylor and Tyler, 2000; Korczynski, 2002; Lynch, 2002; Foster, 2004; Pettinger, 2005). Fischer et al (1997) state that gender stereotype or in-group bias/homophily may exist and influence evaluations of service quality depending on whether the service provider is a male or a female. Foster (2004) argues that certain retail sectors are "gendered", that is the products they sell have stereotypical male connotations, such as car sales or men's fashion, or stereotypical female associations like cosmetic sales and ladies' fashion and very often the gender of customer-facing staff reflect this association. Research by Brockbank and Airey (1994) shows that in one company which retails maternity and child-care products exclusively, 93 percent of employees were female.

In the example for DIY (Do-It-Yourself) stores, Sparks (1991) points out that male customers perceived male staff to have better technical knowledge and are more physically competent to handle products than female staff and often preferred to seek advice from male staff rather than female staff, with a particular preference toward older male staff. This is due to the assumption that males were more likely to have carried out home improvements or worked as a trade person than women. This finding is supported by Foster (2004), who found that DIY is an activity predominately undertaken by men and many items sold in this sector have stereotypical masculine connotations, such as power tools and electrical, plumbing and building products. Where female staff were employed in DIY stores, they tended to be located on the checkouts, returns desk and in "non expert" roles on more feminine product

areas like decorative, gardening and showrooms (Sparks, 1991). This finding is consistent with Korczynski's (2002) research, which found that trade experts were male and most checkout operators were female in DIY stores. This appeared to be a result of gender assumptions built into the roles. Men were generally perceived to be more adept at retail skills. For example, Bradley (1989: 232) wrote "...the sale of a carpet is considered to involve certain socially defined skills, whereas the sale of hosiery is not. Men predominate in carpet departments; women in hosiery. Of course, selling hosiery requires a variety of skills; they simply go unrecognised".

Fischer, Gainer, and Bristor (1997) state that in some service settings, women expect to receive better service from women and men from men. Pettinger (2005) states that gender is embedded in the work and employment relations in retail in a unique way: female sales assistants tend to serve female customers with products that are culturally 'feminine'. Notwithstanding, women were more likely to work in men's departments than men in women's departments, because of the way the occupation of sales assistant is feminised. The concept of female staff serving men can imply a degree of sexualization in their roles. For example, Hochschild (1983) suggests that the role of female flight attendants are sexualised by advertising using slogans such as 'Fly me, you'll like it', which could imply that they not only had to be 'unfailingly helpful and open to requests' but also should 'respond to the sexual fantasies of passengers' by acting in a 'sexy' manner, flirting with customers as though their behaviour is not 'intrusive or demeaning'. Hochschild also highlights the contrast between genders by stating that females 'enhance the customer's status' while males 'deflates the customer's status', giving the example that debt collectors are typically male.

McGauran (2000) found that women are considered better than men at cleaning and stocking goods and at selling to other women, and that women are more likely to be employed for their appearance, in less-skilled posts, and as part-timers. Kerfoot and Knights (1994) wrote that 'a nice mumsy face at the desk' would both increase sales and smooth the flow of production. Accordingly, Taylor and Tyler (2000) found that male managers recruiting telesales staff made stereotypical gendered assumptions about women possessing a 'natural' ability to 'chat' and build up a 'rapport' with others. Kerfoot and Korczynski (2005) state that gender stereotypes about women's 'proper' place in relation to paid work and their presumed attachment to so-called 'softer' skills in service work act to reinforce and reproduce gender division in the workplace.

Research shows that gender differences exist in retail management positions (Brockbank and Airey, 1994; Lynch, 2002; Schmidt and Parker, 2003; Broadbridge, Maxwell, and Ogden, 2006; Gabriel and Schmitz, 2007; Harris, Foster, and Whysall, 2007). While women dominate the retail sector, their dominance is in the non-managerial positions. Brockbank and Airey (1994) and Harris et al. (2007) found that retailing is dominated by women but managed by men. Where women were employed in management, they are more likely to be represented in the junior and middle management positions (Broadbridge et al, 2006). Schmidt and Parker (2003) found that senior management and director level positions in retailing are largely male. Where women are in managerial positions, Brockbank and Airey (1994) wrote that they are believed to be more likely to have a better understanding of their predominantly female staff and customers, and possess a greater ability for developing relationships with them.

The traditional view postulates that men are more capable than women at work, hence occupying the more important positions with women occupying subordinate roles. Bradley (1989) wrote that women and men's participation in retailing has its roots in the onset of capitalism and the existence of male trade union bargaining power which was used to define certain jobs/areas as skilled and kept as male preserves. According to Broadbridge (1997), where skill and knowledge were perceived to be required men prevailed; while if women were found in traditionally male sectors of retailing they were employed as counter assistants or cash clerks. Similarly, Lynch (2002) points out the retail jobs defined as 'peripheral' and 'low skill' were predominately filled by women, whereas men filled occupations considered to be 'skilled', such as management positions.

The reported paucity of women in retail management positions (for example, Lynch, 2002; Schmidt and Parker, 2003; Gabriel and Schmitz, 2007; and Harris et al. 2007) may be due to the unwillingness of female employees

taking up management positions. Harris et al. (2007) found that half of female part-time retail employees were not seeking promotion. Gabriel and Schmitz (2007) suggest that the male dominance of males in senior management is likely to be voluntary, as opposed to gender discrimination as a cause. In their study of gender differences among workers, it was found that while gender differences in occupational attainment persist, they apparently result from voluntary choices of men and women and from long-term changes in labour markets, such as the simultaneous growth of white-collar occupations and women's labour force participation rates. However, research by Kerfoot and Knights (1994) points out that some employment practices deliberately target 'mature' women returners to the workplace who were subsequently employed in low-paid, low-status work outside the main organisational career structure.

3. Research Questions And Methodology

The purpose of this paper is to identify gender characteristics in retail employment within Australia. The data used for this study is a subset of the 'Australia at Work' survey, which is a longitudinal survey tracking the experiences of the Australian labour force. In 2009, the survey documented the findings of a total of 6,801 respondents via telephone interviews. The relevant subset of the data used for this study consists of 702 respondents who are employed in the retail industry. Only data from selected questions in the survey will be relevant for use in this study. Chi square tabular analysis will be employed to confirm the statistical significance among the relevant data based on significance at the $p < 0.05$ level.

4. RESULTS

In answering the foregoing research questions in this study, the results (see Table 1) indicate that retail employment in Australia is dominated by females employees in general. Certain retail sectors were found to have different employee gender characteristics. Managerial positions in retail were found to be dominated by a slightly larger proportion of males while women dominated in non management positions such as supervisory and other positions. The findings are largely similar to previous research in this area, suggesting that such relevant aspects of retail employment in Australia have similar characteristics compared to the United Kingdom and the United States.

Table 1: Respondents classified by Retail Sector and Gender

Retail Sector		Gender		Total
		Male	Female

Total	Count	300	402	702
	% within Industry	42.7%	57.3%	100.0%

A chi square test carried out on this table produced a value of 106.95 ($p < 0.001$), indicating statistical significance at the $p < 0.05$ level.

Among the retail sectors, the grocery and supermarkets sector is largest employer, employing 18.2% of the total of 702 respondents sampled. This is followed by cafes and restaurants at 9.3%, accommodation at 8.0%, takeaway food at 7.0% and department stores at 5.6%. Female employees dominated retail employment in general, with 57.2% of all employees being female. This can be attributed to the likelihood that females are more inclined to homemaker or childcare duties and hence suit the part-time / casual nature of retail employment more than males.

Certain retail sectors were found to be dominated by male employees. The most male dominated category is electric and electronic goods with 81.0% being male employees, followed by motor vehicle and parts at 80.4%, garden supplies at 80.0%, and hardware at 63.0%. This finding suggests that retail sectors that involve technical knowledge and involve physical work are largely staffed by males, which corresponds with the findings of Broadbridge (1997), Sparks (1991), Korczynski (2002), and Foster (2004).

Where female employees dominated, the retail category of clothing employed 85.7% females, followed by pharmaceutical, cosmetics, and toiletries at 82.1%, department stores at 69.2%, newspaper and books at 68.2%, takeaway food at 65.3%, supermarkets at 64.1%, and cafes and restaurants at 63.1%. These findings are consistent with a wide range of research. For example, the finding that female employees dominate in areas where customers are more likely to be female such as clothing, cosmetics, and toiletries, have been documented by Fischer, Gainer, and Bristor (1997), and Pettinger (2005). The identified sectors of takeaway food, supermarkets, and cafes and restaurants where female employees dominate tend to be less skilled, check-out related, and part-time posts, a finding consistent with Broadbridge (1997), McGauran (2000), Lynch (2002), Korczynski (2002), and Pilcher (2007).

In relation to managerial positions in retail employment, 15.7% of the respondents were in managerial roles, with 17.7% in supervisory roles and 66.6% in other roles. It was found that the gender division in managerial roles was not substantial, with 53.0% of males in managerial roles (see Table 2). However, there is a higher percentage of females in supervisory roles at 61.9% (see Table 3) and other roles at 66.6% (see Table 4). This finding does not substantially correspond with the non-Australian context findings of Lynch (2002), Schmidt and Parker (2003), Broadbridge et al. (2006), and Gabriel and Schmitz (2007) that found managerial positions in retailing to be male dominated.

Table 2: Respondents classified by Managerial position and Gender

5. IMPLICATIONS AND CONCLUSIONS

The results suggest that gender stereotypes exist in retail employment in Australia. Such stereotypes can relate to perceptions and expectations of customers, management decision making, and discrimination. The demographic characteristics of retail staff can affect service quality. As suggested in the literature review, customers are likely to have preferences as to who they are being served by when shopping for specific products, affecting their purchase decisions and consequently the business performance of stores. Hence, managers can use such information in employment decision making to create a competitive advantage and increase profitability. For example, males shopping for DIY goods perceive male staff to be more knowledgeable (Sparks, 1991). This is reflected in the findings that products requiring technical expertise are male dominated.

It was also found that products for females such as cosmetics and clothing were more likely to be staffed by females. This implies that female employees are more suitable for female related products, as similarly pointed out by Fischer, Gainer, and Bristor (1997), who pointed out that women expect to receive better service from women and men from men. Notwithstanding, it was found that females dominate retail employment in general and from an employer's perspective, this can be explained by research stereotyping women with a 'natural ability' to build rapport (Taylor and Tyler, 2000), possessing 'softer skills' (Kerfoot and Korczynski, 2005), and sexualisation (Hochschild, 1983). This implies that female employees are more adept in retailing to both genders as compared to males, which can explain the finding that females dominate in retail employment and that female employees are stereotypical of retail positions.

As reported in the results, the slightly larger percentage of males in managerial positions does not substantially correspond with the non-Australian context findings of Lynch (2002), Schmidt and Parker (2003), Broadbridge et al. (2006), and Gabriel and Schmitz (2007) that managerial positions in retailing are male dominated. However, it is unclear if demographic differences in retail employment are the result of employer preferences or if certain demographic profiles, such as females as reported, generally prefer to work in certain retail positions. Therefore, further research in this area is recommended.

MINDFULNESS-BASED STRESS REDUCTION (MBSR)

V. Naredran, rajeshwari18@yahoo.com

Raveendra Babu

Mohan Lal Sukhadia University, India

Abstract

Aim

The aim of this paper is to create awareness on the concept of Mindfulness-Based Stress Reduction (MBSR) and how it works as a stress reduction technique.

Brief description

The world today has become a boxing ring; each one is competing to knock down others by hook or crook. Survival of the fittest is the buzz word going around. The cut throat competition and fight for existence has spawn stress that is unbearable. Uncontrolled stress will cause life threatening diseases or uncomfortable life to speak the least.

Mindfulness Based Stress Reduction is a technique that uses the thoughts, mind, nature and ancient yoga to control, reduce and eliminate stress. It does not require any special equipment or elaborate arrangements for practising the technique. The technique could also be practiced 24x7, and requires a few hours of guidance from the experts.

Retuning to nature is one way to reduce stress. Mindfulness Based Stress Reduction uses a combination of many art forms also along with Yoga and it has been found to be very effective in treating patients with terminal illness like cancer

Interpretation of stress is a highly individualistic perception. Effects of stress, coping ability also varies from person to person. *Stress is experienced when one perceives that the demands of work are greater than the ability to cope.* This threshold will be determined by various factors, such as cultural background , personality traits, health, gender, age and circumstances to name a few.

The important aspect is that the stress is an internal reaction to an external stimulus. There are conflicting situations which confronts us that lay strain on our resources, time, and ability to cope with demands of life. If we conclude that the required resources needed to effectively deal with a situation are beyond what we have available, we say that that situation is stressful - and we react with a classical stress response

Stress a Predestined Response

Contribution made by eminent neurologist Walter Cannon and scientist Selye is worthy in the area of study regarding stress. Walter Cannon coined the term homeostasis to further define the dynamic equilibrium of human body. He also was the first credited with recognizing that stressors could be emotional as well as physical. Through his experiments, he demonstrated the "fight or flight" response that man and other animals share when threatened. Further, Cannon traced these reactions to the release of powerful neurotransmitters from a part of the adrenal gland, the medulla. (Neurotransmitters are the body's chemicals that carry messages to and from the nerves.) The adrenal medulla secretes two neurotransmitters, epinephrine (also called adrenaline) and norepinephrine (noradrenaline), in the response to stress. The release of these neurotransmitters leads to the physiologic effects seen in the fight or flight response, for example, a rapid heart rate, increased alertness, etc.

The external stimuli will create an internal response no matter who you are as Neurotransmitters start working inside your body. Hence stress is an inevitable condition which need to be controlled and coping strategies have to be thought of.

Why We Respond Differently To A Given Situation

1. Perception and interception of situation differently.

2. Resource utilisation is not similar.
3. Availability of resources and skills are different.

Some situations which are not negative ones may still be perceived as stressful. This is because we think we are not completely prepared to cope with them effectively. It is common to experience stress before moving to a nice house or when a prize is won which are not a negative situation. Hence it is not the external stimuli only responsible for the stressful situation; it is the way one assigns or attaches thoughts to it. Your interpretation of events and challenges in life may decide whether they are invigorating or harmful for you.

A persistently negative response to challenges will eventually have a negative effect on your health and happiness. Experts say people who tend to perceive things negatively need to understand themselves and their reactions to stress-provoking situations better. Then they can learn to manage stress more successfully.

Mindfulness-Based Stress Reduction

By end of the day do you remember what breakfast you had in the morning or lunch? If you don't, you are not mindfulness. Human brain can travel faster than light. Thoughts could take you to moon or any inaccessible place it is impossible physically for you to reach.

- **Thoughts And You**

Most people identify so strongly with their minds and thoughts they think they are their minds and thoughts. This strong belief does *not* correspond with reality. Just because many people believe something does not make it true. For thousands of years people thought the earth was flat and that belief did not correspond with reality either.

Our thoughts and feelings are changing constantly. They seem to go on, automatically, by themselves, whether we want them to, or not. In other words we are subservient to our thoughts.

We think of next event before one finishes and end up in neither place. This is what happened while you were having breakfast or lunch. You were obsessed with the events in the office, a task unaccomplished, a scheduled business meeting and such hosts of routine events.

- **Origin Of Mindfulness-Based Stress Reduction**

Dr. Jon Kabat-Zinn developed the Mindfulness Based Stress Reduction (MBSR) program at the University Of Massachusetts Medical Centre. MBSR has evolved into a common form of complementary medicine addressing a variety of health problems since its inception. The National Institutes of Health's National Centre for Complementary and Alternative Medicine has provided a number of grants to research the efficacy of the MBSR program in promoting healing. Completed studies have found that pain-related drug utilization was decreased, and activity levels and feelings of self esteem increased, for a majority of participants.

Mindfulness-based stress reduction (MBSR), a form of stress relief rooted in the practice of mindfulness and cognitive therapy. It has gained popularity in recent years and has been found to be a rather effective means of stress relief. Used therapeutically, mindfulness-based therapies have been shown effective as a treatment or complementary treatment for more serious conditions such as borderline personality disorder, generalized anxiety disorder, and depression. Mindfulness-based stress reduction has been effectively used to help treat everyday stress, as well as the more significant stresses experienced by people with HIV, heart disease, and other serious chronic health conditions. It is possible to learn Mindfulness-based stress reduction through classes or by a trained therapist

- **How It Works**

MBSR can help you to either remove or change the source of stress, alter the way you view a stressful event, lower the impact that stress might have on your body, and teach you a way of coping. MBSR as a stress management therapy will have the objective of pursuing one or more of these approaches. *Mindfulness based stress reduction is simple, portable and effective* based in your relationship with your own mind or breath, there are no gadgets required to be used. It could be literally practiced all time regardless where you are.

Mindfulness Based Stress Reduction brings together mindfulness meditation and yoga. Although MBSR is training with potential benefits for all types of participants, historically, students have suffered from a wide range of chronic disorders and diseases. MBSR is an 8-week intensive training in mindfulness meditation, based on ancient healing practices, which meets on a weekly basis. Mindfulness practice is ideal for cultivating greater awareness of the unity of mind and body, as well as of the ways the unconscious thoughts, feelings, and behaviors can undermine emotional, physical, and spiritual health. The mind is known to be a factor in stress and stress-related disorders, and meditation has been shown to positively affect a range of autonomic physiological processes, such as lowering blood pressure and reducing overall arousal and emotional reactivity. In addition to mindfulness practices, MBSR uses martial arts to help reverse the prevalence of disuse atrophy from our culture's largely sedentary lifestyle. This had been found useful especially for those with pain and chronic illnesses. The program brings meditation and yoga together so that the virtues of both can be experienced simultaneously.

- **Increases Focus**

Ever imagined what will happen to a batsman facing a pace bowler, if he loses concentration for a split second? He could be out and spell disaster for his team. Some eminent sports personalities use this technique of MBSR knowingly or unknowingly. **Philip Douglas "Phil" Jackson** former American professional basketball player and widely considered one of the greatest coaches in the history of the National Basketball Association (NBA), had known to using this technique.

- **Removes Clutter**

Avoiding other thought and remaining in the present reduces clutter and gives clarity to mind. MBSR allows the job in hand to be done well and further motivates on the next task when its turn comes.

- **Allows Relaxation**

The technique is based on yoga the ancient Indian relaxation and rejuvenation programme, only difference being it includes and combines other art forms, martial arts etc. Concentrating on the breath cycle itself allows one to calm down and relax.

Some people prefer to practice mindfulness based stress reduction by innocently watching their breath. By watching the breath we become more aware of that which is going on and come back to the present. Simply allow the attention to gently notice the inhale.....and exhale...and inhaleand exhale...and inhaleand exhale..... This quiets the mind. One would feel secure in the wonderful gift of life.

- **Watch The Mind**

Mindfulness based stress reduction allows watching the mind to learn the truth about who we really are.

And thus, we become less involved with the mind's pain.

- Watch the mind
- without judgments,
- without "shoulds,"
- with no effort to control.

Watch the mind as it changes, as it plays its games and runs its conditioned patterns.

The thoughts and patterns go on, almost by themselves. They go on without any help from you. The thoughts and its association to the inner self is what create the stress, pain and anguish in us.

As per the MBSR the thoughts keep changing opinions and decisions taken once may not hold any relevance at all on a later date. Hence no point in brooding in the irrelevant things that is what MBSR teaches us.

Enjoy the Nature

Next time when you are in the nature's lap, don't forget to listen to the birds chirping; the rhythmic sound of a cascade, the caresses of the breeze that pass by least you will be breaching a golden rule of MBSR. When God created us, he endowed enough entertainment around us to recreate, only we have to tune back to the original frequency. Drifting back into nature will rejuvenate you; it will fill your inner self with colours and fragrances that a human being can imitate. The nature path is the destined path for human development.

The Influence of Work Motivation, Job Resources, and Work Engagement on Proactive Behavior

Lintang Ayuninggar, lintang_ayuninggar@yahoo.com

Abstract

An important issue in today's human resource management is to have employees who perform proactive behavior. Unlike a business environment a decade ago, a recent crisis and though competition demand company to perform not only better but also quicker in responding customers demand. To do that having employees who actively seeking a more responsibility is a must. This study is based on previous research developed a comprehensive model to examine the antecedents of proactive behavior. We include three forms of work motivation (job self efficacy, role breadth self efficacy, and role orientation), job resources, and work engagement in the model to figure out their effects on proactive behavior. Adding absorption as another dimension of work engagement, this study examined the relationship between job self efficacy, role breadth self efficacy, role orientation job resources, work engagement, and proactive behavior using structural equation modeling.

Keywords: job self efficacy, role breadth self efficacy, job resources, work engagement, and proactive behavior.

As the world changes, business is changing. These changes need response. Response needed by these changes can emerge as new demands on how work has been done before. These changes, (1) emerged against the background of worldwide economic recession and the pressure of this recession placed on companies to enhance their competitiveness, and (2) embody the strategic view that such competitiveness is best achieved through increased responsiveness to customer demand, by controlling cost whilst simultaneously improving quality and tailoring output more specifically to customer requirements (Parker, Wall, and Jackson, 1997). It is answering why modern companies need employee with proactive behavior. Proactive behavior refers to anticipatory action that employees take to impact themselves and/or their environments (Grant and Ashford, 2008). That behavior includes taking initiative in pursuing personal and organizational goals (Frese & Fay, 2001), actively adapting to new environments (Ashford & Black, 1996), taking charge (Morrison & Phelps, 1999), expanding roles (Parker, Wall, & Jackson, 1997), and implementing ideas and solving problems (Parker, Williams, & Turner, 2006). Modern organization need their employee to be more proactive, initiative, responsible in professional development and more committed to high quality of working standard (Bakker and Leiter, 2010).

Writers have suggested that proactive behavior at work improves job performance (Bateman and Crant, 1999). Proactive people see opportunities and act on them, take initiative, persist until goals are reached or change is brought about (Burke and Koyuncu, 2010). Crant (2000) refers to proactive behavior as "taking initiative in improving current circumstances; it involves challenging the status quo rather than passively adapting present conditions". As Crant (2000) suggested, because of its wide-ranging impact, proactive behavior has the potential to be a "high-leverage concept rather than just another management fad".

Global crisis influence more than anybody could predict. Indonesia is one of many countries affected by the crisis. One of Indonesian sectors influenced by crisis is the bank industry. Based on a quick survey (2008) by Bank of Indonesia, with a topic of "The Impact of Financial Global Crisis on Bank Industry and Other Economic Sectors in Central Java", it is said that the crisis is a barrier for Indonesia economic growth. Moreover, bank industry will be suffering for the low economic growth because there will be a decrease number of loans distribution which as a matter of fact, loan department is an important department underpinning bank industry. Recent crisis and though competition would be very strong reasons for companies to consider about proactive behavior.

Previous research by Ohly and Fritz (2007) included job self efficacy, role breadth self efficacy, intrinsic motivation, and role orientation as the antecedents of proactive behavior. Result revealed that only role breadth self efficacy is significantly related to proactive behavior when examining all motivational variables simultaneously while job self efficacy, role breadth self efficacy, and role orientation had no significant relation with proactive behavior. Different with research by Ohly and Fritz (2007), a research by Parker, William, and Turner (2006) suggests that role breadth self efficacy and flexible role orientation had positive links with proactive work behavior. Another research by Salanova and Schaufeli (2008) found the mediating role of work engagement (i.e. vigor and dedication) among job resources (i.e. job control, feedback and variety) and proactive behavior at work. Schaufeli, Salanova, Gonzalez-Roma, and Bakker (2002) defined work engagement as a positive, fulfilling, work-related state of mind characterized by vigor, dedication and absorption.

This article follows the latter view and considers proactive behaviour in terms of personal initiative (Frese, Fay, Hilburger, Leng and Tag 1997; Salanova and Schaufeli, 2008), which is a behavioral pattern whereby the individual takes an active self-starting approach to work, thereby going beyond formal job requirements. Proactive employees show personal initiative and are action-directed, goal-directed, seek new challenges, and are persistent in the face of obstacles. The aim of this current study is to understand more about antecedents of proactive behavior. Based on previous research developed a comprehensive model to examine the antecedents of proactive behavior (Salanova and Schaufeli, 2008; Ohly and Fritz, 2007), we combine previous models and adding one dimension on a variable for capturing the whole dimensions of this construct (see figure 1). Many research revealing about proactive behavior held on western setting. We examine the relationship between job self efficacy, role breadth self efficacy, role orientation job resources, work engagement, and proactive behavior to see whether this new model has a good fit in explaining the factors influencing proactive behavior and to see whether it works in Indonesia setting.

Job Self Efficacy and Proactive Behavior

Self-efficacy refers to an individual's self-beliefs, related to their own ability to perform specific tasks successfully (Bandura, 1998 in Ayupp and Kong, 2010). Job self-efficacy has been found to be related to proactive behavior (Morrison & Phelps, 1999). Self-efficacy beliefs determine how people feel, think, motivate themselves and behave. People with high assurance in their capabilities approach difficult tasks as challenges to be mastered rather than as threats to be avoided. They set themselves challenging goals and maintain strong commitment to them. They heighten and sustain their efforts in the face of failure. They quickly recover their sense of efficacy after failures or setbacks. They approach threatening situations with assurance that they can exercise control over them (Bandura 1994).

Hypotheses 1: Job self efficacy will be positively related with proactive behavior

Role Breadth Self Efficacy and Proactive Behavior

Role breadth self efficacy concerns the extent to which people feel confident that they are able to carry out a broader and more proactive role, beyond traditional prescribed technical requirements. Its focus is not on what people do (i.e., their behavior), but rather on what they feel they can do (Parker, 1998). It has been said that one key requirement for this is that employees have to be proactive and use their initiative (Frese et al., 1996). Role breadth self efficacy, and other form of self efficacy, is an important determinant of proactive behavior (Axtell and Parker, 2003). Employee with role breadth self efficacy will feel capable for taking initiative to actively change their working condition and more related to proactive behavior (Parker et al., 2006)

Hypotheses 2: Role breadth self efficacy will be positively related to proactive behavior

Role Orientation and Proactive Behavior

Role orientation targets the degree to which individuals incorporate certain responsibilities into their work-role (Parker, Wall, & Jackson, 1997). Aligning with Parker (2000), this can mean a move away from narrow "that's

not my job” mentality to an orientation in which employees see broader problems as their responsibility and recognize the importance of being proactive. Role orientation is related to proactive behavior (Unsworth, Wall, & Carter, 2005).

Hypotheses 3: Role orientation will be positively related to proactive behavior

Job Resources, Work Engagement, and Proactive Behavior

Job resources refer to those physical, psychological, social, or organizational aspects of the job that either/or (1) reduce job demands and the associated physiological and psychological costs; (2) are functional in achieving work goals; (3) stimulating personal growth, learning and development (Demerouti et al., 2001). The JD-R model posits that job demands (i.e. physical demands, time pressure, shift work) are associated with exhaustion, whereas lacking job resources (i.e. performance feedback, job control, participation in decision making, social support) are associated with disengagement (Demerouti et al., 2001). Work engagement refers to a positive affective-motivational state of fulfillment that is characterized by vigor, dedication, and absorption (Schaufeli, Salanova, Gonzales-Roma, & Bakker, 2002). Favorable job characteristics foster high levels of energy and persistence in the face of obstacles (i.e. vigor), as well as the fulfillment of personal needs and identification with the job (i.e. dedication) (Salanova & Schaufeli, 2008). It requires additional effort to start proactive behavior and to persist in it (Frese, Fay, Hilburger, Leng, & Tag, 1997). For individuals to engage in proactive behavior, it is necessary for them to care about their work and to regard it as worthwhile to invest the extra effort. When dedicated to their work and enthusiastic about it, individuals will be more likely engage in proactive actions to keep the work situation a positive one and to further improve it. To perceive opportunities for proactive behavior and to persist in it, it is important for individuals to become absorbed in their work and to concentrate on it. It is crucial for them to resist the temptation to detach from work in the case of emerging difficulties (Sonnentag, 2003).

Hypotheses 4: Job resource will be positively related to work engagement and in turn, work engagement will be positively related to proactive behavior

Method

Sample and Procedures

We used 267 (105 men and 162 women) bank employees from 40 bank offices in Surakarta, Indonesia with organic employee and 2 years minimal working on the bank as the characteristics of purposive sampling technique applied. Survey method used on data collection with 90% response rate (300 were sent and 271 were back). From 271 data sets, 267 were used on the calculation.

Instruments

Proactive behavior. To measure proactive behavior, we used 3 items developed by Salanova & Schaufeli (2008) and 2 items developed by Frese et al., (1997) on a 5-point scale which ranged from 1 (*never*) to 5 (*always*). The internal consistence (Cronbach α) was 0.900.

Job self efficacy. To measure job self efficacy, we used 3 items developed by Wang & Netemeyer (2002) on a 5-point scale which ranged from 1 (*not sure at all*) to 5 (*totally sure*). The internal consistence (Cronbach α) was 0.716.

Role breadth self efficacy. To measure role breadth self efficacy, we used 7 items developed by Parker et al., (1998) on a 5-point scale which ranged from 1 (*not sure at all*) to 5 (*totally sure*). The internal consistence (Cronbach α) was 0.896.

Role orientation. To measure role orientation, we used 3 items developed by Ohly & Fritz (2007) on a 5-point scale which ranged from 1 (*not true at all*) to 5 (*totally true*). The internal consistence (Cronbach α) was 0.848.

Job resources. There are three types of job resources in this study. Autonomy/job control measured with 3 items developed by Hackman and Oldham (1974) on a 5-point scale which ranged from 1 (*totally disagree*) to 5 (*totally agree*). The internal consistence (Cronbach α) was 0.894. Feedback measured with 4 items developed by Sims, Szylagyi, & Keller (1976) on a 5-point scale which ranged from 1 (*not true at all*) to 5 (*totally true*). The

internal consistence (Cronbach α) was 0.878. Task variety measured with 3 items developed by Sims, Szylagyi, & Keller (1976) on a 5-point scale which ranged from 1 (*not true at all*) to 5 (*totally true*). The internal consistence (Cronbach α) was 0.895.

Work engagement. To measure work engagement, we used 9 items Utrecht Work Engagement Scale (Schaufeli et al. 2002). The internal consistence (Cronbach α) was 0.824 for vigor, 0.813 for dedication, and 0.884 for absorption.

Data Analysis

Structural Equation Modelling (SEM) methods as implemented by the AMOS 4.01 program (Arbuckle and Wothke, 1997) with maximum likelihood estimation were used to test the models. The goodness-of-fit of the models was evaluated using (Hair et al., 2006) : (1) the χ^2 goodness-of-fit statistic; (2) the Root Mean Square Error of Approximation (RMSEA); (3) the Goodness of Fit Index (GFI) with rule of thumb ≥ 0.90 ; (4) the Adjusted Goodness of Fit Index (AGFI) with rule of thumb ≥ 0.90 ; (5) Normed Fit Index (NFI) with rule of thumb ≥ 0.90 ; (6) Tucker Lewis Index (TLI) with rule of thumb ≥ 0.90 ; and (7) Comparative Fit Index (CFI) with rule of thumb ≥ 0.90 . However, χ^2 is sensitive to sample size, so that the probability of rejecting a hypothesized model increases when sample size increases. To overcome this problem, the computation of relative goodness-of-fit indices is strongly recommended. Values of RMSEA smaller than .08 indicate an acceptable fit.

Results

Validity test using SPSS 15.0 resulted in dropping 2 items. Running data on measurement model excluded the two items dropped on the previous step resulted in dropping 3 more items. The measurement model achieved goodness of fit indices except for AGFI; (1)The χ^2 goodness-of-fit statistic was 492,454; (2) RMSEA was 0.013; (3) GFI was 0.901; (4) AGFI was 0,882; (5) NFI was 0.910; (6) TLI was 0.995; and CFI was 0.995. However, this model can be accepted (see table 1).

Structural model also achieved goodness of fit indices except AGFI; 1)The χ^2 goodness-of-fit statistic was 507,915; (2) RMSEA was 0.016; (3) GFI was 0.889; (4) AGFI was 0,880; (5) NFI was 0.907; (6) TLI was 0.992; and CFI was 0.993. Although AGFI did not reach the cut value (≥ 0.90), the delta between cut value and reached value is relatively small (0.02). So, this structural model can be accepted.

By using 0.01 as level of significance, the value 2.58 should be reached by critical ratio for accepting paths hypothesized in this study. Critical ratio for relationship between job self efficacy and proactive behavior showed the value of 2.915 and 3.990 for relationship between role breadth self efficacy and proactive behavior. These findings support hypotheses 1 and 2. Critical ratio for relationship between role orientation and proactive behavior showed the value of 0.740. It means hypotheses 3 was not supported. Critical ratio for relationship between job resources and work engagement showed the value of 7.706 and 3.033 for the relationship between work engagement and proactive behavior. Thus, hypotheses 4 was supported. However, these results achieved without including direct effect of job resources to proactive behavior. Different result obtained by including the direct effect of job resources to proactive behavior. Result showed critical ratio value of 7.698 on the relationship between job resources and work engagement, and 1.021 (not significance) for the relationship of job resources and proactive behavior.

Discussion

Results showed support for hypotheses 1. It indicates that the increase of job self efficacy on employee will also increase employee proactive behavior. This result consistent with prior study (Speier & Frese, 1997) showed that self efficacy enhances employee personal initiative. People with high assurance in their capabilities approach difficult tasks as challenges to be mastered rather than as threats to be avoided. They heighten and sustain their efforts in the face of failure. They attribute failure to insufficient effort or deficient knowledge and skills which are acquirable. They approach threatening situations with assurance that they can exercise control over them (Bandura, 1994). Support also achieved by hypotheses 2. This result support the study of Ohly & Fritz (2007); Morrison & Phelps (1999); Parker (1998). People with high role breadth self efficacy have more confidence in performing a

broad range of activities (Parker, 1998), they will feel capable of taking initiative to actively change their current job situation compared to people with low role breadth self efficacy.

This study was not supporting hypotheses 3 saying role orientation will be positively related to proactive behavior. This study consistent with prior study (Ohly & Fritz, 2007). This study used measurement instrument developed by Ohly and Fritz (2007) for role orientation. Different result can be obtained by using other measurement instrument. Result showed that measurement instrument developed by Ohly & Fritz is not fit in some setting. Moreover, bank employee on this research restricted by control activities and segregation of duties as mentioned in standard of bank internal control system of Indonesian bank by Bank of Indonesia. So, we see no chance for this people to apply flexible role orientation on their work.

Full support for hypotheses 4 was achieved. As predicted, job resources positively related to work engagement which in turn positively related to proactive behavior. Job resources play a vital role in the development of work engagement, and refer to physical, social, or organizational aspects of the job that are functional in obtaining work goals, reducing job demands, and providing opportunities for personal growth and learning (De Lange et al, 2008). Job resources like social support or support provided at the departmental level play an important role in reinforcing positive images of oneself, and in fostering positive work outcomes like work engagement (Demerouti et al., 2001). The insignificant direct effect of job resources on proactive behavior might be better explained by including job demand variable on the calculation.

Implication

Results suggest that job self efficacy and role breadth self efficacy enhance employee proactive behavior. Further, job resources enhance work engagement which in turn enhances proactive behavior. Based on these results, bank/organizations may increase the level of employee job self efficacy, the level of role breadth self efficacy, and provide job resources (autonomy, feedback, and task variety) for enhancing proactive behavior. According to Bandura 1977 in Jackson 2002, there are few things should be considered to enhance self efficacy; performance accomplishment, vicarious experience, verbal persuasion, and emotional arousal. To enhance role breadth self efficacy, bank/organizations need to provide a good work design, training, and good communication quality in the workplace.

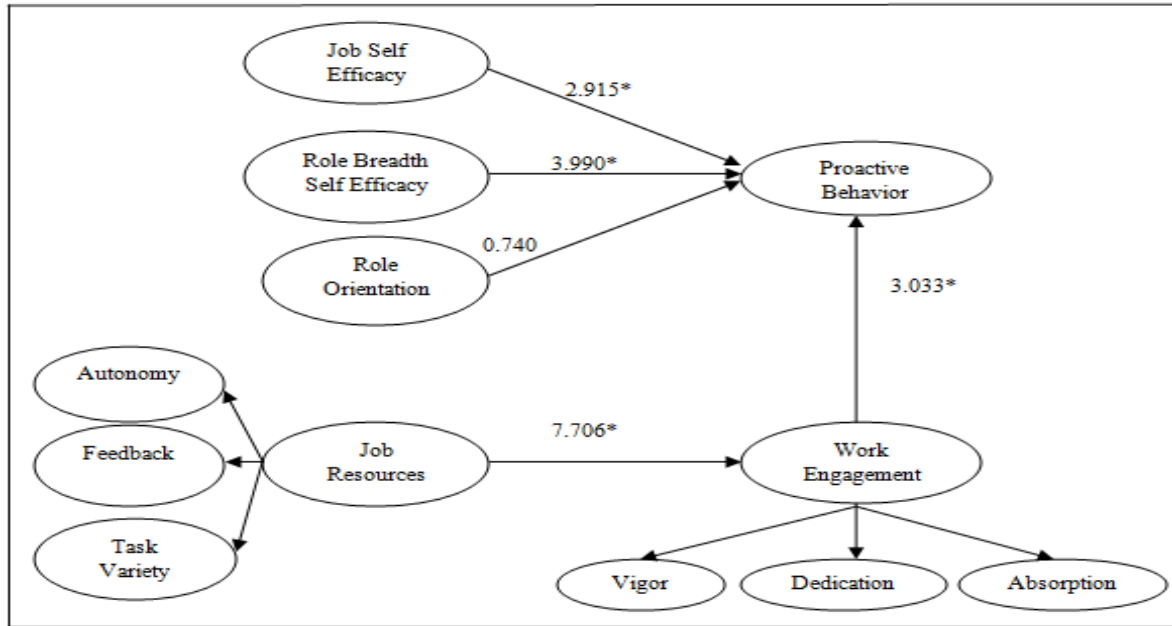

Limitations and Future Research

This research supports three of four hypotheses. However, this study has some limitations. First, sample used in this research come from bank employee only. It affects the generalization of this study. There is an obvious need to conduct this study within other organizations to ascertain the generalization of the findings. Second, data used for this study is self-reported data. It might be influencing the bias and accuracy. Future study might achieve better accuracy using multi-rater method in collecting data. Third, measurement instrument used for role orientation is different with what has been used in many prior studies which has a better generalization level. It is suggested to use measurement instrument which contextually fit or the one having good level of generalization. Fourth, job demand variable which might explain the direct effect of job resources to proactive behavior better, was not included in this study. Including job demand variable on explaining relationship of variables involving job resources is essential.

The Killer Stress

V. Naredran, *rajeshwari18@yahoo.com*
Raveendra Babu
Mohan Lal Sukhadia University, India

Abstract

Aim

The aim of this paper is to discuss stress, its manifestations on human beings and ways to reduce the stress affecting the quality of life.

Brief description

Stress is an inevitable part of modern life and its going to stay this way, whether you like it or not. Stress need to be understood in its entirety to develop personal coping techniques. Stressors are highly distinctive in nature and what are stressors for one individual may not be cause of concern for others.

Two live case studies have been included in the paper to elucidate the importance of stress related problems. The need to reduce stress may be disputable; so is whether the stress givers can become victims to stress themselves. Stress is alarmingly contagious. There are many a cause for stress and stressors could be identified and blocked if a stress diary is maintained.

The article has given insight into organisational intervention in coping with stress at work place and spelt out how as an individual one can reduce stress. Importance of emotional intelligence is also mentioned in the article.

Case One

Amith, (name changed) a dashing twenty five year young Indian software engineer, was extremely happy getting a high paid salaried job in a South African diamond mining company. A room next to his office for living, snacks beside him to munch while he is continuously working on the computer was more than what he could ask for besides the large pay packet. He was fit as fiddle when he joined the company. However, hours of working on the computer without moving from his seat, and heavy snacking made him obese and he looked like a pumpkin in two years.

Parents of Amith fixed his marriage as he was expected to come home in the winter break after a long two years stay in the foreign land. The date of his arrival came and gone, but there was no news from Amith. The old parents got worried and contacted the company's office in Johanna's burg. To their utter dismay, they were told their only son is no more. When the parents were making plans for his marriage, Amit was fighting for his life after a massive heart attack; the company did not even bother to inform them! *Amith was a victim of inappropriate work culture, stress, an utterly unethical management and an unruly life style.*

Case Two

Nothing could stop me from becoming a General one day, thought the young officer, when he passed out from Indian Military Academy sixteen years back. Presently, a Lieutenant Colonel in the Indian Army, Lieutenant Colonel Yogesh Sharma (name changed) is suffering from stress related ulcer. Loosing over ten kilos in a span of two years and his expected promotion, he was a nervous wreck when he met me in lawns of an officer mess somewhere in the western sector.

Posted at a coveted appointment that controls the logistics, man power and coordination in large sector, the Lieutenant colonel was under tremendous amount of work pressure. Is it the work pressure that landed him in this dire predicament? "NO. Not the work stress alone" the officer confided to me. It was the humiliation that meted out by his boss day in and day out that was responsible for the situation, he later told me. The officer had under gone a torturous tenure under a boss who never accepted any mistakes and instead of correcting or guiding the junior officer, the senior officer used to call him at unearthly time to admonish and ridicule him.

The officer's career has been doomed beyond repairs, his dreams shattered and his health has been ruined due to mismanagement of his boss. What do we learn from such cases? Yes, there is distressing amount of stress present in the organisations and pathetically disproportionate reduction measures in place. There are no balanced work life policies which can assure a stress free quality life.

Stress Coping Techniques

Stress management encompasses techniques intended to equip a person with effective coping mechanisms for dealing with psychological stress, with stress defined as a person's physiological response to an internal or external stimulus that triggers the fight-or-flight response. Controlling the source of stress or learning to set limits and to say "No" to some demands that bosses or family members may make are some ways of coping with stress. However you run into a problem of spoiling the relationship in such cases and a tradeoff need to be done. One must know how tactfully to decline the needs in such situations.

The term *stress* had none of its contemporary connotations before the 1950s. It is a form of the Middle English *destresse*, and from the Latin *stringere*, means to draw tight the word was derived. The word had long been in use in physics to refer to the internal distribution of a force exerted on a material body, resulting in strain. **Walter Cannon** used it in 1934 to refer to external factors that disrupted what he called *homeostasis*.

The recent usage came in to being out of **Selye's** experiments during 1930s. He coined the term "**eustress**" for positive stress, and "**distress**" to the bad stress.

He argued that all people have a natural urge and need to work for their own benefit, a message that found favor with industrialists and governments. He also coined the term "**stressor**" to refer to the causative event or stimulus, as opposed to the resulting state of stress.

Factors in Stress

Stress affects people in different ways and what one person finds stressful can be normal to another. How they appraise the situation will depend on various factors, including:

- their background and culture;
- their skills and experience;
- their personality;
- their personal circumstances;
- their individual characteristics;
- their health status;
- their ethnicity, gender, age or disability; and
- other demands both in and outside work.

Signs of Stress

The first signs that indicate that employees might be suffering from excessive pressure or stress are changes in behaviour or performance. The kinds of change that may occur are shown in the table below.

❖ Work performance	➤ Regression
❖ declining/inconsistent performance	➤ crying
❖ uncharacteristic errors	➤ arguments
❖ loss of control over work	➤ undue sensitivity
❖ loss of motivation/commitment	➤ irritability/moodiness
❖ indecision	➤ over-reaction to problems
❖ lapses in memory	➤ personality clashes

❖ increased time at work ❖ lack of holiday planning/usage	➤ sulking ➤ immature behaviour
➤ Withdrawal ➤ arriving late to work ➤ leaving early ➤ extended lunches ➤ absenteeism ➤ resigned attitude ➤ reduced social contact ➤ elusiveness/evasiveness	❖ Aggressive behaviour ❖ malicious gossip ❖ criticism of others ❖ vandalism ❖ shouting ❖ bullying or harassment ❖ poor employee relations ❖ temper outbursts
❖ Other behaviours ❖ out of character behaviour ❖ difficulty in relaxing ❖ increased consumption of alcohol ❖ increased smoking ❖ lack of interest in appearance/hygiene ❖ accidents at home or work ❖ reckless driving ❖ unnecessary risk taking	🚩 Physical signs 🚩 nervous stumbling speech 🚩 sweating 🚩 tiredness/lethargy 🚩 upset stomach/flatulence 🚩 tension headaches 🚩 hand tremor 🚩 rapid weight gain or loss 🚩 constantly feeling cold

Most Common Causes of Stress

Human being is a psychological paradox. There is no predictable behaviour pattern and each personality complex and unique in itself. People react and behave differently to stressful situations. What is stressful situation to one person may not be a stressful situation to other at all. The threshold level varies due to the common causes are:-

- Bereavement
- Family problems
- Financial matters
- Illness
- Job issues
- Lack of time
- Moving home
- Relationships (including divorce)

Mental Health at Work Place

People with mental health problems are not a uniform or homogenous group. Individuals will face challenges specific to themselves and many may need little or no support at work.

Employers who wish to create a healthy work environment will recognise the need to establish policies and procedures in the area of mental health that set out a tangible programme with measurable targets and an effective auditing process. Mental health policy should be an integral part of any organisation's health and safety at work policy.

❖ Self help for treating stress

Exercise - exercise has been proven to have a beneficial effect on a person's mental and physical state. For many people exercise is an extremely effective stress buster.

Division of labour - try to delegate your responsibilities at work, or share them. If you make yourself indispensable the likelihood of your feeling highly stressed is significantly greater.

Assertiveness - don't say yes to everything. If you can't do something well, or if something is not your responsibility, try to seek ways of not agreeing to do them.

Alcohol and drugs - alcohol and drugs **will not help you** manage your stress better. Either stop consuming them completely, or cut down.

Caffeine - if your consumption of coffee and other drinks which contain caffeine is high, cut down.

Nutrition - eat plenty of fruit and vegetables. Make sure you have a healthy and balanced diet.

Time - make sure you set aside some time each day just for yourself. Use that time to organize your life, relax, and pursue your own interests.

Breathing - there are some effective breathing techniques which will slow down your system and help you relax.

Talk - talk to you family, friends, work colleagues and your boss. Express your thoughts and worries.

Seek professional help - if the stress is affecting the way you function; go and see your doctor. Heightened stress for prolonged periods can be bad for your physical and mental health.

Relaxation techniques - mediation, massage, or yoga have been known to greatly help people with stress.

Measures To Reduce Stress At Work Place

To reduce workplace stress actions could be taken including:

- Undertaking a stress audit and subsequently directing resources to reduce or eliminate the sources of stress
- People management skills development for managers at all levels
- The development of a supportive work ethos to encourage staff to discuss stress and seek support when experiencing stress.

Sources of stress being not identical and highly individualistic in nature, cannot be eliminated, other interventions may be considered, such as:

- stress management and training in relaxation techniques
- promoting healthy behaviour and exercise
- personal counselling schemes.
- Practice of Yoga and other stress busters.

❖ **Keep a stress diary**

If you're not sure what causes your stress, keep a stress diary at work for two to four weeks, and then review it to spot the triggers. Each day, make a note of:

- the tasks you did and meetings you had at work that day
- how you felt at the start of the day: whether you're cheerful and optimistic, or dread going to work
- specific times when your mood changed
- whether you avoided certain tasks or people
- any situations that led to difficult scenes or unpleasant feelings
- whether too much is being asked of you
- whether you're worried that you might lose your job
- whether you enjoy what you're doing, or not. Quite simply, are you in the wrong job?

❖ **Reducing job stress by taking care of yourself**

Start by paying attention to your physical and emotional health. When your own needs are taken care of, you're stronger and more resilient to stress. The better you feel, the better equipped you'll be to manage work stress without becoming overwhelmed.

❖ **Get moving**

Aerobic exercise –perspiring -is an effective anti-anxiety treatment lifting mood, increasing energy, sharpening focus and relaxing mind and body.

❖ **Make food choices that keep you going and make you feel good**

Eating small but frequent meals throughout the day maintains an even level of blood sugar in your body. Low blood sugar makes you feel anxious and irritable. On the other hand, eating too much can make you lethargic.

Avoid alcohol and nicotine

Alcohol temporarily reduces anxiety and worry, but too much can cause anxiety as it wears off. Drinking to relieve job stress can also start you on a path to alcohol abuse and dependence. Similarly, smoking, nicotine is a powerful stimulant – leading to higher, not lower, levels of anxiety.

Get enough sleep

Stress and worry can cause insomnia. But lack of sleep also leaves you vulnerable to stress. When you're sleep deprived, your ability to handle stress is compromised. When you're well-rested, it's much easier to keep your emotional balance, a key factor in coping with job and workplace stress.

❖ **Reducing job stress by prioritizing and organizing**

When job and workplace stress surrounds you, you can't ignore it, but there are simple steps you can take to regain control over yourself and the situation. Here are some suggestions for reducing job stress by prioritizing and organizing your responsibilities.

❖ **Time management tips for reducing job stress**

- **Create a balanced schedule.** Analyze your schedule, responsibilities, and daily tasks. All work and no play is a recipe for burnout. Try to find a balance between work and family life, social activities and solitary pursuits, daily responsibilities and downtime.
- **Don't over-commit yourself.** Avoid scheduling things back-to-back or trying to fit too much into one day. All too often, we underestimate how long things will take. If you've got too much on your plate, distinguish between the "shoulds" and the "musts." Drop tasks that aren't truly necessary to the bottom of the list or eliminate them entirely.
- **Try to leave earlier in the morning.** Even 10-15 minutes can make the difference between frantically rushing to your desk and having time to ease into your day. Don't add to your stress levels by running late.
- **Plan regular breaks.** Make sure to take short breaks throughout the day to sit back and clear your mind. Also try to get away from your desk for lunch. Stepping away from work to briefly relax and recharge will help you be more, not less, productive.

❖ **Task management tips for reducing job stress**

- **Prioritize tasks.** Make a list of tasks you have to do, and tackle them in order of importance. Do the high-priority items first. If you have something particularly unpleasant to do, get it over with early. The rest of your day will be more pleasant as a result.
- **Break projects into small steps.** If a large project seems overwhelming, make a step-by-step plan. Focus on one manageable step at a time, rather than taking on everything at once.

- **Delegate responsibility.** You don't have to do it all yourself, whether at home, school, or on the job. If other people can take care of the task, why not let them? Let go of the desire to control or oversee every little step. You'll be letting go of unnecessary stress in the process.

Reducing Workplace Stress by Improving Emotional Intelligence

Even if you're in a job where the environment has grown increasingly stressful, you can retain a large measure of self-control and self-confidence by understanding and practicing emotional intelligence. Emotional intelligence is the ability to manage and use your emotions in positive and constructive ways. Emotional intelligence in the workplace has four major components:

- **Self-awareness** – The ability to recognize your emotions and their impact while using gut feelings to guide your decisions.
- **Self-management** – The ability to control your emotions and behaviour and adapt to changing circumstances.
- **Social awareness** – The ability to sense, understand, and react to other's emotions and feel comfortable socially.
- **Relationship management** – The ability to inspire, influence, and connect to others and manage conflict.

❖ **Reducing stress in the workplace with emotional intelligence**

The more emotional intelligence you have, the more stress you can avoid in the workplace. Fortunately, emotional intelligence is not something we're born with; it's something we can learn and develop.

The skill set that enables you to acquire these capabilities can be learned but requires the development of emotional and nonverbal ways of communicating that include:

- Learning to recognize your particular stress response and become familiar with sensual cues that can rapidly calm and energize you.
- Staying connected to your internal emotional experience so you can appropriately manage your own emotions.
- Learning to recognize and effectively use the nonverbal cues that make up 95-98% of your communication process. It's not what you say but how you say it that impacts others –for better or worse.
- Developing the capacity to meet challenges with humour.
- Learning to navigate conflict by becoming a good listener.

❖ **Reducing workplace stress by breaking bad habits**

As you learn to manage your job stress and improve your work relationships, you'll have more control over your ability to think clearly and act appropriately. You will be able to break habits that add to your stress at work – and you'll even be able to change negative ways of thinking about things that only add to your stress.

❖ **Eliminate self-defeating behaviours**

Many of us make job stress worse with patterns of thought or behaviour that keep us from relieving pressure on ourselves. If you can turn around these self-defeating habits, you'll find employer-imposed stress easier to handle.

- **Resist perfectionism.** No project, situation, or decision is ever perfect, and you put undue stress on yourself by trying to do everything perfectly. When you set unrealistic goals for yourself or try to do too much, you're setting yourself up to fall short. Do your best and you'll do fine.
- **Clean up your act.** If you're always running late, set your clocks and watches fast and give yourself extra time. If your desk is a mess, file and throw away the clutter; just knowing where everything is saves time and cuts stress. Make to-do lists and cross off items as you accomplish them. Plan your day and stick to the schedule — you'll feel less overwhelmed.
- **Flip your negative thinking.** If you see the downside of every situation and interaction, you'll find yourself drained of energy and motivation. Try to think positively about your work, avoid negative-thinking co-workers, and pat yourself on the back about small accomplishments, even if no one else does.

❖ **Find Ways to Dispel Stress**

- **Get time away.** If you feel stress building, take a break. Walk away from the situation. Take a stroll around the block, sit on a park bench, or spend a few minutes meditating. Exercise does wonders for the psyche. But even just finding a quiet place and listening to your iPod can reduce stress.
- **Talk it out.** Sometimes the best stress-reducer is simply sharing your stress with someone close to you. The act of talking it out – and getting support and empathy from someone else – is often an excellent way of blowing off steam and reducing stress.
- **Cultivate allies at work.** Just knowing you have one or more co-workers who are willing to assist you in times of stress will reduce your stress level. Just remember to reciprocate and help them when they are in need.
- **Find humour in the situation.** When you – or the people around you – start taking things too seriously, find a way to break through with laughter. Share a joke or funny story.

❖ **What managers or employers can do to reduce stress at work**

It's in a manager's best interest to keep stress levels in the workplace to a minimum. Managers must act as positive role models, especially in times of high stress. All of the tips mentioned in this article are twice as important for managers to follow. If someone that we admire remains calm, it is much easier to remain calm ourselves – and vice versa! There are also organizational changes that managers and employers can make to reduce workplace stress.

❖ **Improve communication**

- Share information with employees to reduce uncertainty about their jobs and futures.
- Clearly define employees' roles and responsibilities.
- Make communication friendly and efficient, not mean-spirited or petty.

❖ **Consult your employees**

- Give workers opportunities to participate in decisions that affect their jobs.
- Consult employees about scheduling and work rules.
- Be sure the workload is suitable to employees' abilities and resources; avoid unrealistic deadlines.
- Show that individual workers are valued.

❖ **Offer rewards and incentives**

- Praise good work performance verbally and institutionally.
- Provide opportunities for career development.
- Promote an "entrepreneurial" work climate that gives employees more control over their work.

❖ **Cultivate a friendly social climate**

- Provide opportunities for social interaction among employees.
- Establish a zero-tolerance policy for harassment.
- Make management actions consistent with organizational values.

Conclusion

Stress has become an inevitable part of modern life, like it or not it is going to stay. Coping with stress is the only way to survive. The stress creators and the stress takers need to understand this in a more realistic perspective.

Employees can be more productive when they are satisfied and their stress level could also be reduced. Considering the return on investment and the social cost of the adverse effects of the stress, managerial intervention in the stress reduction programmes will be good trade off.

Relationships between culture and values: A comparative study between Finland and India

*Vesa Routamaa, vmr@uwasa.fi
University of Vaasa, Finland
Nivedita Debnath, ndleekha@gmail.com
Avery Dennison (India) Private Ltd.*

Abstract

Globalization and opening economy have increased the number of professionals working across cultural boundaries. In the light of these changing socioeconomic configurations, it is becoming increasingly important to understand the cultural values of these professionals for effective cross-cultural management. Values of professionals differ across cultures and knowing the relationship between values and cultures can assist the professionals with better understanding of the behavior in the workplace and consequently help in the cross-cultural management. This paper compares the relationships between values in the Indian and Finnish contexts, and will provide insights to those professionals who are attempting to adjust to a new culture and seeks success at working across cultural boundaries. The cultures of the countries concerned will be conceptualized based on Hofstede's dimensions. For comparative reasons, especially Schwartz's definitions of values are used to measure values. Power, Achievement, Hedonism, Stimulation, Self-direction, Universalism, Benevolence, Tradition, Conformity, and Security in Finnish and Indian cultural context will be compared. Also work goal values will be compared to illustrate possible differences in attitudes and motivation to work. In addition to cultural differences, there are certain diverse values and their influence. A manager coming from different culture requires coaching in the relevant cultural differences in terms of values to be able to adapt to the country and apply appropriate leadership style.

Introduction

International business, foreign direct investments, expatriate work and any international cooperation require an understanding of the differences between cultures. For example, business negotiations, expatriate managers and professionals, management of foreign personnel, and cross-cultural teams presuppose a good knowledge of cultural differences. As Hofstede (1984) defines it, culture is "the collective programming of the mind that distinguishes the members of one human group from another". Hofstede's cultural dimensions (masculinity-feminism, collectivism-individualism, power distance and uncertainty avoidance) serve well to explain the differences of values of different countries. (Cf. Routamaa, Hautala & Mohsin 2007). For example, India, Indonesia, Japan, Malaysia Pakistan and the Philippines, represent more masculine and collectivist countries than the feminine and individualist European Nordic countries, and, presumably, there are also some systematic differences in values.

However, research on expatriates indicates that failed expatriate assignments are still costly and numerous. Kale and Barnes (1995, p.271-280) recommend a combination of Hofstede's national cultural dimensions, Reynold's typology for organizational culture and the MBTI as a method of understanding personality for international sales training. Studies abound with recommendations on how to increase expatriate success mostly by contributing lists of "suitable" personality characteristics and behaviors required to succeed in a new culture. Black, Mendenhall and Oddou (1991) introduce three main skill areas that expatriates need to focus on to survive in a new culture: skills related to maintenance of self, skills relating to fostering relationships with host nationals and skills that promote a correct perception of the host environment and its social systems. Berry, Kim and Boski (1988, p.63) introduce three strategies for coping with this adjustment process. Expatriates can adjust psychologically by adjusting their behavior to the environment, or they can adjust by changing the environment, or they can move to a more congenial environment. Recently more emphasis has been placed on cross-cultural training, but research shows this to be sporadic and culture-based. Some personal characteristics needed for a successful assignment are technical ability, stress tolerance, flexibility, communication skills, and cultural empathy (Hiltrop & Jassens 1995, p.358-365). For example, Routamaa & Rautiainen (2002) found that the psychological type has an association with the expatriate adjustment in a new culture.

Along with globalization, value types and values from a cross-cultural perspective have awakened great interest in recent years (e.g. Abramson & Inglehart, 1995; Hofstede, 1980, 1991; Markus & Kitayama, 1991; Schwartz, 1992, 1994; Schwartz & Bardi, 1997; Schwartz & Ros, 1995; Smith & Schwartz, 1997; Inglehart, 1997; Triandis, 1990).

Taylor (1871) defined culture as “that complex whole that includes knowledge, beliefs, art, laws, custom, and any other capabilities and habits acquired by man as a member of society”. Fundamental webs of culture constitute patterned ways of thinking, acting, feeling, and interpreting (see e.g. Kluckhohn 1951, p.86; Ting-Toomey, 1985, p.75). Ronen (1986, p.18) sees culture as “the frame of reference” of individuals, and Harris and Moran (1987, p.102) discuss the “mental frameworks” which groups, organizations and nations develop. The more individuals conform to each other in terms of background variables such as nationality, education and sex, the more likely it is that they perceive their social environment similarly, and in that way share the same subjective culture (Hofstede 1984). Dealing with values here, the subjective culture is of special interest over the objective culture, which is composed of a more concrete infrastructure (cf. Routamaa & Pollari 1998).

Hofstede’s definition referring to *the collective programming* is a good frame of reference in which to analyze values in a cultural context. Studying work-related values at the societal level, Hofstede (1984) identified four dimensions.

Power distance can be defined as the extent to which the less powerful members of institutions and organizations within a country expect and accept that power is distributed unequally. **Individualism** pertains to societies in which the ties between individuals are loose: everyone is expected to look after himself or herself and his or her immediate family. **Collectivism** as its opposite, pertains to societies in which people are integrated into strong, cohesive groups from birth, which throughout their lifetimes continue to protect them in exchange for unquestioning loyalty. **Uncertainty avoidance** is defined as the extent to which the members of a culture feel threatened by uncertain or unknown situations. This feeling can be expressed through nervous stress and a need for predictability for example, by a need for written and unwritten rules. **Masculinity** pertains to societies in which social gender roles are clearly distinct, and femininity pertains to societies in which social gender roles overlap. (Hofstede, 1991, p.23-158) Also a fifth dimension, **long-term versus short-term orientation**, has been identified in a survey with the Chinese Value Survey instrument carried out by M. H. Bond (Hofstede, 1993), which could be of great use if some comparative data across countries were employed. In high uncertainty avoidance cultures, in organizations the concern is with long term rather than short-run results.

In spite of the criticism (see e.g. Spector, Cooper & Sparks, 2001; Hofstede, 2002; Spector & Cooper, 2002), Hofstede’s studies and cultural dimensions serve the understanding of cultural differences well. Different cultural contexts may also explain the differences of values of different countries. Culture, “software of the mind” or “collective programming”, as Hofstede puts it, may affect our values. However, as Routamaa and Pollari (1998) found, the mutual relationships between values and personality types may be fairly similar in each culture. They also found that cultural background affects leadership style. In the masculine culture, the average manager may favor more dedicated, benevolent autocratic behavior. Correspondingly, the feminine culture with its negotiating and compromising practices refers to integrated, even related styles. However, the leadership style differences between personality types were similar in both cultures except that they were more task oriented in the masculine culture. Accordingly, a similar relationship between culture, values and personality types may be assumed.

“Software of the mind” functions as a filter when people interpret what kind of values they emphasize. Do the values differ significantly because of the cultural differences when the personality type is controlled? Controlling of the type may provide an answer to the question of the effect of the culture. This paper will compare the relationships between personality types and values in Indian and Finnish contexts, but actually, the countries are not as important as the cultures they represent.

Next, the study compares Finland and India which represent the cultures concerned here, in relation to Hofstede’s cultural dimensions and based on Hofstede’s (1984) results, and the differences will be characterized to the extent they are relevant to potential value and work goal value differences.

Cultural differences between Finland and India

Comparison of power distance and masculinity dimensions between Finland and India reveals that both are higher in India. Finland is characterized by a small-power distance, and femininity. In the individualism-collectivism dimension, Finland is in the individualism cluster whereas individualism is near to the world average in India. Uncertainty avoidance is higher in Finland (See Table 1).

In feminine cultures, the preference for resolving conflicts is compromise and negotiation. In masculine cultures, there is a feeling that conflicts should be resolved by a good fight: Let the best man win (Hofstede, 1991, p.92). In feminine cultures a humanized job gives more opportunities for mutual help and social contacts. The masculine leadership culture is assertive, decisive, 'aggressive', and a decision-maker is looking for facts rather more than a group-discussion leader. The management in a feminine culture is less visible, more intuitive than decisive and more consensus-seeking than the counterpart in a masculine culture (Hofstede 1991, p.94). In weak uncertainty avoidance, masculine cluster, *achievement* and *esteem* are typical whereas *security* and *belongingness* are typical of strong uncertainty avoidance, feminine cluster (Hofstede 1991, p.125).

On the power distance and uncertainty avoidance dimensions, Finland is in the cluster of small-power distance and strong uncertainty-avoidance, whereas India is in the cluster of large-power distance and weak uncertainty avoidance. The old caste system and nearly 200 years under British rule has affected power distance. Countries with strong uncertainty avoidance but small power distance have organizations like the *well-oiled machine model*; the activities are structured without concentrating on the authority. In the large-power distance, weak-uncertainty-avoidance countries, a *family* organization with an omnipotent owner-manager is characteristic; so a concentration of authority without structuring of activities may be observed (Hofstede 1991, p. 142-143).

TABLE 1: COMPARISON OF HOFSTEDE'S CULTURAL DIMENSIONS IN THE CASE OF JAPAN AND FINLAND

Cultural dimensions	Finland	India
Power distance	Small	High
Masculinity	Low	Somewhat masculine
Individualism	Individualistic	A bit over average
Uncertainty avoidance	Over average	Under average
Long term orientation	Very long (Estimated)	Short

It may noted, however, that India is a country of various cultures, religions and over three hundred languages. That is, the weights of cultural dimensions may vary a lot in different regions. For this reason, maybe, the dimensions in Table 1 have got quite moderate, in a way average grade. It may be noted, however, that in-group collectivism is high even though institutional collectivism is in the midrange (see House, Hanges, Mansour, Dorfman and Gupta 2004). Family with more than two generations form the basic unit of Indian society. Concerning uncertainty avoidance, one difference between Finland and India is religion. Presumably, many religions in India may give better trust to the future than Lutheranism, national church in Finland, mostly based on quasi-membership without genuine faith.

Values

In accordance with Hofstede's "social programming", values are also seen as "abstract social cognitions" that help people's adaptation to the environment (Claxton & McIntyre, 1996). According to Comte, value consensus is usually defined as concurrence among members of a society concerning their values (Comte, cited by Partridge, 1971; see Schwartz & Sagie, 2000).

Theoretically, the values, that is the types of values used here, are based on Schwartz's (1992) and Schwartz and Boehnke's (2004) definitions. (Table 2). Spirituality is not included in the questionnaire used here.

TABLE 2: TYPES OF VALUES AND SUB-VALUES OF THE STUDY

<p>Achievement - Implies personal success through demonstrating capabilities while respecting the social standards that the individual has to respect. The associated values include ambition, influence, capability, success, intelligence and self-respect.</p> <p>Benevolence - Is associated with the values of being helpful, responsible, forgiving, honest, loyal, and capable of mature love and true friendship.</p> <p>Conformity - The restraints on action, inclination and impulses that are likely to upset or harm other individuals or groups and violate social norms or expectations are the relevant goals here. The associated values include obedience, self-discipline, politeness and honoring of parents and elders.</p> <p>Hedonism - Pleasure and the sensuous gratification of oneself are the defining goals here, leading to pursuit of pleasure and enjoyment of life.</p> <p>Power - The attainment of social status and prestige and control or dominance over others and resources define this motivational type. Values associated with this include social power, wealth, authority, preserving a public image and social recognition.</p> <p>Security - Safety, harmony and the stability of society, of relationships and of self-preservation are the defining goals of this value type. The relevant values include national security, reciprocation of favors, family security, a sense of belonging, social order, health and clean living.</p> <p>Self-direction - Independent thought and action in choosing, creating, exploring (creativity, freedom, choosing one's own goals, curiosity and independence).</p> <p>Spirituality - Implies meaning and inner peace through the transcendence of everyday life. The associated values include a spiritual life, meaning in life, inner harmony and detachment.</p> <p>Stimulation - Values derive from the assumed need of individuals and groups for variety and stimulation in order to maintain an ideal level of activity, motivating an exciting life, a varied life, and a daring outlook.</p> <p>Tradition - Springs from commitment to, and acceptance of, the customs and ideals that are imposed by an individual's culture or religion. The associated values are tradition, devotion, and acceptance of one's lot in life, humility and moderation.</p> <p>Universalism - This motivational type is defined by understanding, appreciation, tolerance and protection for the welfare of all other people and of nature. The associated values include equality, unity with nature, wisdom, a world of beauty, social justice, broad-mindedness, protecting the environment and a world at peace.</p>

The work goal values indicate what goals are important in an ideal job. The goals concern, for example, using of skills, challenges and contribution, work content, working relations, recognition, career opportunities, security, earnings, work conditions, company prestige, benefits, serving one's country, etc. Actually, the work goals presented by Vunderink & Hofstede (1998) are a lot in line with Maslow's need hierarchy.

Sample and Method

The research aimed at comparing values and work goal values in two different cultures in terms of Hofstede's cultural dimensions. Of course, the use of Hofstede's cultural dimensions could be criticized for example in terms of the aging of Hofstede's research. The world has changed and cultures may have converged a little since that time. However, Hofstede's research serves as useful, common frame of reference in this comparison. The sample consisted of 794 Finnish people and 93 Indian people who completed the questionnaires. In case of the value questionnaire (Schwartz), a 7-point scale was provided for respondents to indicate how important the values presented are. The 56 value items loaded logically in the samples producing ten factors. Further, the possible effects of the sample size and composition could be asked. Both samples are heterogeneous in terms of gender and age. Samples were obtained from several organizations and adult students. According to earlier studies (e.g. Routamaa, Hautala & Mohsin 2007; Routamaa & Heinäsuo 2006), possible minor in-culture discrepancies do not obscure cross-cultural comparisons. The effect of sample size to consistency was tested comparing a random 93 observations sub-sample of the Finnish data to the whole data of 794

observations. The means of the values as well as the ranking order had no noteworthy changes. Keeping this in mind it may be concluded that the Indian sample is representative enough for a comparative study. The means and significances of the value differences between the cultures and value rankings will be reported.

In order to measure work goal values, a 5-point scale questionnaire (Vunderink & Hofstede 1998) was administered. 22 items indicate how important it would be to a respondent to have the goals presented in an ideal job. To conceptualize the work goal values into easier comparable form, using factor analysis, sum variables representing Maslow's need hierarchy was obtained.

Results

Values

Table 3 presents the value rankings in terms of means. In Table 4, the relative ranking orders are listed and compared. Benevolence in terms of being helpful, responsible, forgiving, honest, loyal, capable of mature love and true friendship is among the two top values of both cultures. Self-direction is also among top three in both countries. Instead, hedonism is third in Finland whereas ninth in India. Pleasure and enjoyment are more important in feminine, individualistic culture. Respectively, universalism is the top value in India. Unity with nature, wisdom, a world of beauty, protecting the environment and a world at peace, among others, are typical for hedonism and also imaginable in Indian culture of various religions better than in western oriented, individualistic Finland. Universalism is more typical of collectivist cultures; in fact, averagely, India is not very collectivistic. Interestingly, two of the three final values, stimulation and power are the same, and occur in the same order in the two cultures. Tradition is valued a bit higher in India. Further, achievement is usually a more typical value for masculine cultures than feminine ones (cf. Routamaa, Hautala & Mohsin 2007). That is, orientation towards work is also different in masculine cultures compared to feminine cultures, which should be recognized by those coming to work from a different culture. The ranking of achievement is higher and averagely much more valued in India. Conformity is also much more important in India. Security is higher ranked in Finland but it must be noted that the mean value of it is also much higher in India. That is, the ranking orders in Table 2 cover the fact that the only value ranked higher in terms of mean value in Finland is hedonism. Otherwise, all other values are higher valued in India. In table 3 the first number is the mean value, number in parenthesis is the ranking and the third number is standard deviation.

TABLE 3: RANKINGS OF MEANS OF THE VALUES IN THE TOTAL SAMPLES IN FINLAND (N= 782) AND INDIA (N=92)

	Power	Achievement	Hedonism	Stimulation	Self-Direction	Universalism	Benevolence	Tradition	Conformity	Security
Fin n=782 Mean Std. Dev.	2.92 (10) 1.24	4.39 (7) 1.17	5,08 (2) 1.18	4.12 (8) 1.32	4.88 (3) 0,92	4.49 (6) 1.05	5.28 (1) 0.92	3.21 (9) 1.18	4.46 (5) 1.13	4.83 (4) 1.02
India n=90 Mean Std. Dev.	4.61 (8) 1.42	5.73 (1) 1.02	4.66 (6) 1.64	5,10 (9) 1.52	5.80 (3) 0.92	5.85 (5) 1.06	5.84 (2) 0.87	5.20(10)) 0.95	5.79 (7) 0.95	5.67 (4) 0.92

TABLE 4: VALUE RANKINGS OF FINLAND AND INDIA

Finnish values:	Indian values
1. Benevolence	1. Universalism
2. Self-Direction	2. Benevolence
3. Hedonism	3. Self-Direction
4. Security	4. Conformity
5. Universalism	5. Achievement
6. Conformity	6. Security
7. Achievement	7. Tradition
8. Stimulation	8. Stimulation
9. Tradition	9. Hedonism
10. Power	10. Power

Work Goal Values

Table 5 presents the work goal values in both countries. 22 values were grouped using factor analysis. Five items were omitted because the factor loadings spread to many factors. Four factors were found. Self Actualization (Cronbach's Alpha 0,657), Social Needs (Cronbach's Alpha 0,560), Safety Needs (Cronbach's Alpha 0,629) and Psysiological Needs (Cronbach's Alpha 0,715). Standardized sum variables will be used in order to compare the countries concerned. Additionally, as single item recognition of good job illustrates Esteem needs. Cronbach's Alpha of Social Needs is low because it includes two items that are the opportunity to help other people and serve your country. Patriotism, the latter item is quite high valued in India (mean 4.03***) whereas not so much (2.07***) in feminine, individualistic Finland. That is, to measure the social needs, the work goal values do not constitute very good variables but acceptable enough to compare the cultures. It may be noted, however, that in this case the measure of social needs illustrates more affection and not so much belongingness. Regardless, the work goal values can be conceptualized using Maslow's need hierachy. In spite of all criticism, Maslow's need hierarchy is a good method to measure individual motivation and society level of needs fulfillment. Against most sources, it must be noted that the upper needs can be satisfied even though the lower needs are not satisfied very well. But on the society level, the need hierarchy roughly illustrates also the importance order of the needs. It may be noted that both the more numerous Finnish data and Indian data produced the same factor structure.

Self-actualization is as important in both cultures. In Finland it got the highest mean value but in India shared third rank. The order in Finland is (1) Self Actualization, (2) Esteem Needs, (3) Safety Needs, (4) Physiological Needs, and (5) Social Needs. Correspondingly, in India the order is (1) Safety Needs, (2) Esteem Needs, (3, 4) Physiological Needs and Self Actualization and (5) Social Needs. As can be seen in Table 4, statistically there are not significant differences in self actualization and esteem needs between the countries. That is, these work goals are highly valued in both countries. Instead, social needs, safety needs and physiological needs are significantly higher valued in India.

In high power distance and masculine cultures safety needs and physiological needs are significantly more important than in feminine, individual culture. In more collective culture of India, also social need in terms of affection to fellows and country are much more important than in individual, feminine culture. Accordingly, it may be concluded that the individualism is more dominant than feminism.

The differences in work goal values in terms of need hierarchy means remarkable differences in motivation that must be taken into account in management and leadership.

TABLE 5. WORK GOALS VALUES IN FINLAND AND INDIA.

COUNTRY		N	Mean	Std. Deviation	Asymp. Sig. (2-tailed)
SelfActualization	Finland	790	4,12	,469	
	– India	91	4,07	,580	,561
EsteemNeeds	Finland	791	4,10	,695	
	– India	92	4,23	,665	,112
SocialNeeds	Finland	786	3,05	,801	
	– India	93	4,04	,855	,000***
SafetyNeeds	Finland	800	4,08	,820	
	– India	92	4,97	1,048	,000***
PhysiologicalNeeds	Finland	790	3,54	,630	
	– India	91	4,07	,592	,000***

Conclusions

What are the lessons to be learned based on the analyses above? Firstly, the study confirmed the results of earlier studies that posit that there are culture-based weights in the values that must be taken into consideration in international business. The study revealed that there is a certain amount of conformity among members of a society concerning their values. That is, there may be some shared values over the individual values. These different relationships between culture, values and work goal values make expatriate work and cross-cultural management very demanding.

The most typical values for the higher power distance, low uncertainty avoidance and masculine culture were universalism, benevolence and self-direction. Hedonism was very low ranked compared to feminine, individualistic culture (cf. Routamaa, Hautala & Mohsin 2007) and also many masculine and collectivist cultures (cf. Routamaa, Hautala & Tsuzuki 2010). The means in India were significantly higher with the exception of hedonism.

The most typical values for the low power distance, somewhat average uncertainty avoidance, individual and feminine culture were benevolence, self-direction and hedonism. The latter revealed the biggest difference from the opposing culture. A challenge for managerial work especially in feminine culture is that power is valued very low but somebody always takes the power if not the manager. This may be one reason for so usual bullying in Finnish organizations.

In global business, leadership and expatriate work is challenging. The business person or traveler should recognize the value differences within countries in order to succeed in business or leisure relationships. As was noted, for example, hedonism and universalism were very differently valued in cultures concerned. Personal relationships are a sensitive area where insulting values may cause confusion. The great number of unsuccessful expatriate recruitments is a serious example of the scarce understanding of cultural and value differences.

Concerning especially leadership behavior, the results of work goal values in terms of Maslow's needs hierarchy revealed important differences between the cultures. Based on situational leadership approach (see Figure 1) (e.g. Hersey & Blanchard 1969), human oriented (supportive behavior) and task oriented (directive behavior) leadership should be applied according to subordinates need structure. Subordinates whose physiological needs are high posit especially directing leadership. Safety needs require secure circumstances in terms of norms, rules and advices, that is directing and coaching leadership. The more social needs are weighted, the more coaching and supporting leadership is appropriate. Esteem needs are most related to supporting style, and finally, self-actualization requires mostly delegating style.

Given these relationships between leadership styles and needs, on the average in Finnish culture, supporting and delegating leadership styles are more often required whereas in India, there is more use of directing and coaching styles. That is, leaders must adjust their leadership behavior quite a bit when moving from organization to another in intercultural context.

FIGURE 1: SITUATIONAL LEADERSHIP DIMENSIONS AND APPROPRIATE STYLES (HERSEY & BLANCHARD 1969).

To succeed as a manager in a foreign culture requires training and coaching in cultural aspects and values. For example, a manager in a masculine, collective, high-power distance culture has to take into account physiological needs and security values, which demands more task-oriented leadership behavior, while for example hedonism and higher needs in an individualistic, feminine culture require more delegating and people-oriented leadership. A manager coming from an individualistic and feminine culture may also experience difficulties in applying a task oriented and collective leadership style when used to functioning in work communities colored by individually oriented hedonism and benevolence. Correspondingly an expatriate coming from a high-power distance, collectivist and masculine culture to the opposite culture may feel insecure and inactive in an uncollective milieu of hedonism. That is why knowledge of cultural dimensions and values, and knowledge of the relationships between them is a big challenge for expatriates. In future studies, also the role of personality should be considered.

Employee control and choice in Workplace grievance resolution processes

*Penny Webster, Penelope.webster@rmit.edu.au
RMIT University, Australia*

Abstract

There is increased evidence of the cost of grievances in the workplace, to individuals and to the organisation. Contemporary grievance resolution system research indicates that the provision of complementary ADR processes may be associated with a range of positive outcomes. However, these outcomes would necessarily be contingent on the employee selecting the 'right' ADR process. Additionally, control over ones environment has been linked to health and well-being outcomes. This paper explores the individual's experience of grievance resolution in three Australian organisations. Data from in-depth semi-structured interviews conducted with 25 employees was analysed using thematic narrative techniques. The findings reveal an association between the organisations actions that covertly dis-empowered the individual and the individual's reports of significant psychological harm and damage to career prospects. These dis-empowering tactics may actually increase the overall risk to the organisation and as well as placing an unacceptable burden on the individual.

Introduction

Workplace grievances are a difficult topic. They are inevitably troubling and frequently distressing, not only for the aggrieved and the alleged perpetrator but also for third parties. These same reasons also make them difficult to research. While there is now a substantial body of research into bullying and harassment, the subject of most workplace grievances, there is little academic work focussed on the internal grievance resolution process (Saam, 2009). The emerging interest in this field includes the work of Bendersky's (2003, 2007) on complementarities in grievance resolution systems, Van Gramberg's (2006) multi-level study of alternative dispute resolution processes and Mahoney and Klaas' (2008) study of dispute resolution in the workplace. This current study aims to contribute to our understanding of how grievance resolution processes operate in the workplace by exploring the experiences of grievants; the individual who lodges a grievance with the hope of satisfaction.

Unionised workplaces were the focus of research on dispute resolution and grievance filing in the USA (Lewin & Peterson, 1988), which explored the operational mechanics of the system, with limited attempts to reveal the theoretical basis. This set a basic framework of information about a range of objective measures such as settlement rates, level of process at which settlement occurs, and the time taken to reach settlement (Lewin, 1988). However, the participant's subjective evaluation will also give a valid assessment of the effectiveness of a grievance resolution system. Assuming that the purpose of the grievance system is to resolve the matter to the participants' satisfaction, the participant's perceptions of fairness and dignity of the process are also valid (Bemmels & Foley, 1996; Clark & Gallagher, 1988). In their review of the literature, Bemmels and Foley (1996) argued that it was timely to utilise a subjective approach to exploring the operations of a grievance resolution process.

In a departure from the traditional measures of effectiveness discussed, Bendersky (2003) reviews and analyses a multi-component system that catches and handles all grievances, industrial disputes and interpersonal conflict. She theorises that access to, and employee choice of, complementary processes, will activate a range of positive indirect outcomes. There are several basic underlying assumptions of her model. The anticipated positive outcomes are all contingent on the organisation allowing the parties in conflict to choose a combination of dispute resolution processes. The impact of choice, and the degree of control and empowerment that necessarily accompanies the freedom to choose, may independently contribute to the effectiveness of the resolution process independently from the effects of the intervention chosen.

A second assumption is that the parties will somehow make an appropriate choice in matching the type of conflict and type of dispute resolution process, thereby achieving the best possible outcome. As previously discussed, an employee complaining of being targeted by another's bad behaviour is generally in a highly stressed state. In such a state of distress, their decision-making is likely to be impaired, thus reducing the likelihood of them making an efficacious choice.

Diametrically opposed to a framework of complementary alternate dispute resolution processes are the rigid, conveyor belt type processes that are often quasi legal processes (Giacobbe-Miller, 1995). They rely on assessing claims, collecting information and evidence, substantiating claims, controlling risks, meeting procedural timelines, witnesses, investigation of fact and outcomes that can include disciplinary measures. This model is broadly based on society's expectations of retributive justice, that is, punishment of the offender.

Conceptual background

The principles or values on which justice judgements may rest are many and varied; they include *equality, equity, need, duty, retribution, restoration, rectification, reciprocity, entitlement, impartiality* and *participation* (Selznick, 1992). Although nowhere can it be said that any of these arise from the pure or original state as described by Rawls's *veil of ignorance*, rather they have become embedded or accepted over time within the reality of complex historical contexts. Further, concepts of justice, or the principles on which justice judgments and expectations are made, change over time and between contexts. *Justice* is not a static state but a fluid dynamic concept that is subject to a range of competing influences. Nor is a particular form of justice a uniform cultural norm within this or that society, group or individual. Within any given organisational context a number of justice principles may be operating, and at times these may be in contradiction or opposition with each other (Pfeffer & Langton, 1988).

Rawls develops a strong argument for adoption of the principle of equality as the fundamental basis of justice. He argues that if you operate behind the *veil of ignorance* then you would agree on two principles. The first principle is maximising basic liberties compatible with a similar system of liberty for all. Within an institutional setting this would imply the *impartial application and consistent interpretation of rules* (Rawls, 1972 p. 504) over time and circumstance; thereby providing certainty and reducing uncertainty (Lind & van den Bos, 2002). This principle is similar in application to the first two of Leventhal's six elements of procedural fairness; consistency and bias suppression (Leventhal, 1980). The application of these principles would provide the employee with a degree of control over the grievance resolution process. Additionally, The belief in one's ability, and hence capacity to exert some control over their circumstances, has a great influence over levels of motivation and emotions (Bandura, 1995).

Uncertainty heightens the need for fairness, sensitises the individual's justice judgments and may increase the impact of stress (Lind & van den Bos, 2002). The opposite is found in the identification of successful coping strategies, as these rely on clarity and acceptance of definitions of bullying behaviours, acceptance of the damage to the target and also clear objective remedies that will elicit a return to normal working relationships (Zapf, 2001).

Methods

The workplace grievance resolution process is a contemporary phenomenon that is contextualised within a time and place (Schwandt, 2001) where the boundaries between the phenomena and its context can be blurred (Yin, 2003). A case study approach is recommended when the research question calls for *an empirical inquiry that investigates a contemporary phenomena within its real life context* (Yin, 2003 p 13). The research strategy is that of exploring the exception, seeking to understand those phenomena that current theory does not adequately explain. In order to do this, an inductive approach to data collection is engaged and an interpretative analytical strategy applied to the data. This approach aims to enable a fresh view of experiences of employees who lodge a grievance and to allow the underlying theories to emerge.

Scholars have called for a fresh exploration of workplace grievance resolution systems using qualitative methods (Greenberg, 2001; Leung, 2005; Lewin & Peterson, 1988), particularly to include the subjective perspective of the individual. This study has used a social constructionist approach and interpretative analysis techniques to produce knowledge that will deepen our understanding of the employee who appeals for assistance and protection from workplace bullying and harassment.

Research setting

Many organisations express sensitivity when approached about research into workplace grievances (Renzetti & Lee, 1993). In order to overcome this sensitivity, credibility and trust between the researcher and the organisation needs to be established and maintained throughout the study (Renzetti & Lee, 1993). Drawing from the author’s professional networks, senior managers in eight organisations based in two major Australian cities were directly approached, via personal contact and then a written request in the form of a briefing paper. As an inducement to participate, organisations were offered a de-identified report and recommendations to improve their grievance resolution processes.

The key considerations in selecting the organisations were theoretical relevance and a size. Cases that varied in the dimensions of ownership type, industry, size and demographic composition were selected. Additionally, prediction of contrasting results, would lead to theoretical replication. Initial contact suggested that two cases were confident that their grievance resolution system met high of standards of justice and fairness, while the third was not sure.

The size criteria of the organisation was calculated by estimating the minimum number of employees needed to yield at least six to ten grievances over the past five years. Accepted prevalence rates of bullying behaviour are estimated at between 1 and 4 per cent of employees (Zapf, Einarsen, Hoel, & Vartia, 2003), and the limited evidence suggests that reporting rates are fairly low. Hence, it was estimated to ensure a reasonable number of potential participants, the minimum number of employees would be approximately one thousand.

These sampling tactics led to three organisations being selected as research sites. One organisation was a large tertiary institution, the second was a medium size semi autonomous government instrumentality and the third was an alliance of three organisations, two private and one public sector, that came together to construct a freeway. This final case was included, despite its small size, on the basis the General Manager indicated there were a very high rate of grievances. Details of the characteristics of these organisations are set out in Figure 1.

Figure 1 Characteristics of the cases

	Size	% Non-Ongoing employees	% Female	% Professional	Diversity – indigenous	Turnover	Interviewees
Case 1: Edu – Org	7,100	17%	52%	42%	0.006%	16%	9
Case 2: Asset – Org	1,000	13%	38%	43%	5%	1%	6
Case 3: Alliance – Org	285	8%	18%	16%	1%	7%	10

Source: Documents collected by Author 2006 and 2008

The research strategy is to use in depth semi-structured interviews consistently across multiple case studies to find rich data that will allow for consideration of the employees perspective of the grievance resolution system.

The sampling criterion was that the interviewees had been involved in a grievance resolution process, and were willing and able to engage in an in-depth interview about their experiences. Sampling tactics were designed to protect the volunteers' privacy, employees responded directly to the researcher from a general invitation sent by the organisation. Interviews were conducted off site, in a mutually convenient location. These tactics resulted in 25 employee volunteering to undertake an in depth interview with the researcher about their experiences.

Data collection

Information about each organisation was collected to contextualise the data from the participants. This included publically available material such as Annual Reports as well internal documents such as relevant policies and procedures. This enabled an analysis of the organisations values and a description of its characteristics and culture to be portrayed. A simple description of each organisations grievance resolution systems was obtained.

This study adopted an constructionist approach, hence the research interview revealed data that is *locally and collaboratively produced* (Rapley, 2004 p. 16). This acknowledges that people construct their sense of self in the present while providing individuals with an opportunity to present themselves to another as adequate, or better, within their own terms of reference. The research interview creates a space where there is less risk that the impressions made will later influence opportunities in the workplace. The researcher created a safe environment by establishing rapport, and by demonstrating empathy through acknowledging emotions and concerns as legitimate. Interviews were conducted in a mutually agreed location, most were off site.

Prior to embarking on the interviews an interview protocol was drafted. Each interview commenced with a short introduction about the study followed by questions that re-orientated the person back to their pre-event condition and perspectives. Next the interviewee was asked to reconstruct the events surrounding the grievance and attempts at resolution. Four simple open-ended research questions guided the interviewee and issues of interest were followed as they arose. The interviewee was re-orientated back to the present situation at the end of the interview.

Interviews were between forty minutes and one and a half hours of duration and were taped, with the interviewees consent, primarily to assist in the data analysis stage. It was important to be able to listen and re-listen, to the whole way of describing the experience. It is not just words that are relevant to communication, but the tone, inflections, hesitations, speed of delivery and non-verbal noises that create and communicate meaning. Additionally, a taped interview reduces the reliance on summaries and paraphrasing and reduces the role that perspective has on the interpretation of meaning.

Data analysis and reduction

The interviews were transcribed by professional transcribers, which created more distance and a letting go of early impressions about what was said. The stages include data reduction to eliminate noise and sorting based on issues, data categorisation that revolves around themes and then a final stage of data interpretation.

The interview content was fractured and then tabulated under general headings. After all comments from each interviewee were grouped under headings, an initial coding process was undertaken (Charmaz, 2006; Webb & Mallon, 2007). This process of analytical interpretation selects and names concepts in the narrative without any attempt to summarise, order or group them. The codes stick closely to the actual words of the interviewee. Codes ranged from simple concepts such as *Misrepresentation* and *On the outside of the group* to more detailed descriptions such as *Considered his treatment although unjust, to be just a small hiccup in the overall scheme of the organisation*. Phrases, words and sentences were coded, where possible *in vivo* codes where used to preserve the integrity of the interviewees meanings, for example the term *cut and burn* was retained, which means to use up and then discard (Charmaz, 2006).

The codes were then transferred onto a table which enables a simultaneous view of initial codes to be examined. Then the main conceptual themes were identified. During the process of data interpretation a review of the literature was undertaken. As patterns, in the form of similar behaviours and feelings emerged, then interpretation of their meaning occurred.

The Organisation, its Grievance Resolution Process and the revelations of the Interviewees

EDU – ORG

Edu – Org’s texts state that individual excellence and the advancement of its personnel is the primary organisational aim, it’s structure is simultaneously rigidly hierarchical and highly flexible with chaotic and obscured decision-making delegations. Additionally, the texts place high importance on garnering external awards, and present a strong imperative to enhance and protect Edu – Org’s organisational reputation. The senior executives applied a number of different strategies and techniques aimed at containing the risk of damage to the organisation’s reputation. This was identified clearly by this informant when she noted:

I think it’s just that organisations have become so risk-averse that you just have to say the word ‘risk’ to a senior executive and they just say ‘what do we do to stop that’ EDU - GP1 (45:35)

The dominant characteristic of Edu-Org’s written grievance resolution system is its lack of detail; especially its lack of reference to procedural justice criteria, indeed there is an absence of process or steps to be undertaken. This lack of information creates uncertainty for both the grievants and the grievance handlers, and may be linked to organisation level trust judgments (Lind & van den Bos, 2002).

It was a most unpleasant process for the person who was dismissed and I have to say I felt the whole process, whilst it was handled appropriately within the framework, didn’t really address the sorts of issues that should have been addressed by the process. EDU - GH1 (29:10)

The interviewee considered that the decision-making criteria established by the grievance resolution system actively hindered the collection of relevant information and therefore acted to protect people accused of improper decisions. He described in some length how the evidence submitted was incomplete and inadequate, which led to considerable frustration. However, the requirement to disprove the motivations of the alleged perpetrator was primary, and led to a focus away from the grievant. In this matter, the interviewee went on to say he considered that the limitations of process forced an unsafe outcome. Unsafe because it did not sufficiently address the grievant’s concerns, thereby increasing the likelihood of an appeal to an external agency.

Interviewees were asked if they believed that justice was achieved, the terms *substantive* and *procedural justice* were not used. In his response he said:

Justice would have been probably a way of finding the truth of the matter, rather than working within a particular framework that to a certain extent obscured some of the truth of the matter. EDU - GH 1 (48:25)

This interviewee expressed considerable inner turmoil, on one hand he believed he has operated ethically and appropriately because he had adhered to the requirements of the written grievance resolution process. On the other hand, he steadfastly believed that the grievant did not get justice, that the truth of the matter was not revealed and that therefore the grievance resolution process acted to re-affirm an incorrect action.

In addition to the lack of detail or clear steps within a grievance resolution procedures, individual investigators lacked knowledge of justice processes. The investigators had limited knowledge of the elements of procedural justice, and the distinction between procedural justice, distributive or substantive justice and interactional justice. This legally qualified investigator described justice as:

I was thinking about fairness really. I think there’s two types of fairness there and one is in implementing the procedure fairly and one is in being fair in your dealings with aggrieved parties, and the other side for that matter. Well, I think fairness in terms of procedures is actually following and applying the procedure as it’s written. EDU - GH2

This interviewee was not wrong, just incomplete in his understanding of justice processes. Consistency with the procedure does not necessarily lead to justice if the procedures do not meet the rules of procedural justice. The written procedures were narrow and restrictive. The limited steps and lack of procedural justice

criteria obscured the process from external review, creating uncertainty for employee who may wish to lodge a grievance.

Additionally, the minimal documentation that does exist, beyond some basic posters, is difficult to locate. The HR department is not delegated to respond to a grievance and can only refer the grievant back to their supervisor. The only other course of action is to appeal directly to the CEO; not a course of action immediately attractive to many personnel. Clearly, the ramifications of these difficulties were understood by this interviewee, a senior manager with over 30 years of service at Edu – Org.

One of the problems with our policies and procedures as I see it is that there isn't always an alternative to if the person who's harassing you or bullying you is your head of department who you can go to – other than going to the (CEO) – but that's not what everybody wants to do. EDU - GP1 (10:35)

Some grievants made direct approaches to the HR department, only to receive words of sympathy but a clear directive that no action would be taken. This interviewee was not advised of the existence of a grievance resolution process or of external avenues open to her. She was given to understand that her account of bullying was accepted but that the alleged perpetrator was beyond the control and direction of central administration.

What sort of reactions did you get from HR?

'Oh, isn't that sad. Yes, we'll try, but we really can't...there's a culture in the... Department, well we'll try and do something, but you know we really can't do much'. EDU - G1 (44:35)

Informants' uniformly recognised that Edu – Org would be protected by the grievance resolution process; indirectly they acknowledged the primacy of Edu – Org's needs over individual needs. In particular, grievants and grievance handlers referred to inadequate protection from retaliation and, indeed, a reluctance to put in place protective measures for the grievant. The grievance resolution system was focussed on obtaining objective evidence and presenting a case that would withstand legal scrutiny. Informants provided clear and unequivocal descriptions of bullying behaviour; hence their expectations that an exemplary resolution process would address the issues and protect the grievant were not unreasonable.

Although Edu – Org implied that its internal process would meet the highest ethical standards, the lack of prescribed procedural justice left grievants without a guarantee of procedural fairness. Grievants described their uncertainty as a sense of floundering, indeed two informants displayed extreme distress during the interviews. These attributes all have the effect of discouraging the employee from making a grievance and blocking the progress of a grievance for those who do.

ASSET - ORG

A desk top analysis revealed a comprehensive and detailed Grievance Resolution Policy and Procedure, as well as a Code of Conduct and Disciplinary Procedures. According to these documents, targets of bullying or harassing behaviours are recommended to confront the perpetrator or to seek assistance from their supervisor in the first instance. If the target is not satisfied with the outcome they are advised to make a written complaint. Then the HR department appoints an investigator to seek verifiable facts and then to determine if the grievance is substantiated. Senior managers make the decisions about outcomes.

During the interviews, investigation officers expressed concerns about the limitations that the process placed on them. This was expressed as:

(T)here was a lot more going on than what I was investigating. Something was going on. I certainly didn't come to the conclusion that nothing was going on, but I was not able to substantiate those particular claims as (it) was written. Asset-org GH3 18:10

Interviewees reported that the HR department had refused to act unless they put their complaint in writing. Several interviewees noted that they were required to have a diary of events before the HR department would

accept their grievance. In reality, this meant that the grievant had to withstand a further extended period of bullying and harassment before the organisation would intervene.

Interviewees expressed their disappointment that the HR department did not provide the level of expert support and assistance that they expected. For instance, interviewees reported that they were not advised of their rights and entitlements during the grievance resolution process. This included not advising that they could take sick leave if they experienced distressing psychological or physical symptoms because of the alleged bullying. Neither did the HR department put in place any strategies to protect the grievant from ongoing bullying during the resolution process.

When I was going through the process [Asset – Org] never said to me, 'Take time off.' VECCI did. VECCI said, 'Are you still there working with those two people?' I said, 'Yes I am.' She goes...they were horrified. They said, 'Has [Asset – Org] told you are entitled to be...' I said, 'No.' She said, 'I'm ringing [Asset – Org] this minute.' She went and rang them and said, 'What the hell are you doing having her still working under that circumstance.' [Asset – Org] never mentioned to me that I could have time off. Just things like that. That they just – they just didn't want to know about it – and still don't want to know about it. Asset – Org G1 (38:35)

This lack of support from the HR department had serious consequences for some interviewees. The incidents described included significant threats of violence for one person and, in a different matter, a potential job loss for another person. The following quote comes from a grievance handler who was trying to intervene and de-escalate an upward bullying matter.

I feel like we were let down by lack of support from the organisation, not my immediate supervisor. I had words to my supervisor and said 'look I have to get out for a while.' I was going home and just abusing the kids and bloody yelling and screaming because I'd had a gutful. I was just angry and tense I reckon. He organized the shrink and I took time off. Asset - Org GH1 (42:35)

This grievance handler experienced a new workplace injury that he attributed to a seriously deficiency in the level of support he received during his attempts to resolve a grievance. He describes the consequences for his health and well-being, and refers to the deleterious effect on his family. Additionally, the workplace was also negatively affected; his workplace commitment was lowered, leading to changes in his performance the workplace.

There were also suggestions that the different elements of the grievance resolution system were confusing:

Sitting from where I am, most of [the verbal support] came from my Regional Manager. Yes, but we should have ... I was just a bit bemused, I suppose, from all the misinformation and different processes that were available to us. GH1 (30:35)

Alliance – Org

Alliance – Org did not have written grievance resolution policies and procedures, rather, parts of each parent organisation's grievance resolution policies were drawn from and applied informally, with some reference to industry custom and practice, to create an informal flexible approach. If the initial approaches to alleged perpetrators failed to achieve a resolution, then the verbal grievance led to informal interventions strategies by the immediate supervisor. If these failed, or the matter was serious, then the problem was elevated to the senior management team where a group decision was made. This means in many instances the matter will be considered and decided by a group who will *promptly resolve any dispute elevated to it...on a best for project basis.*

Grievance handlers described their experiences as sometimes out of their control; they were uncertain about what steps to take and received little guidance in response to requests for assistance. Specific concerns were raised about the investigation process, particularly around aspects of evidence gathering and testing, and allowing parties to be informed and to be heard. This disquiet about the process was not alleviated by the group decision-making, particularly as some interviewees believed that gossip, or group pressure, had influenced the

decision-makers. Grievants expressed a general feeling that the organisation attempted to avoid the grievance, noting difficulty in accessing decision-makers, a tendency to shift blame or use delaying tactics to avoid dealing directly with the issues presented. Whether the organisation responded to the grievance or avoided it, all the described experiences were characterised by procedural injustice.

The interviewees, both grievance handlers and grievants, gave numerous examples of senior managers avoiding a direct response to requests for information or action. In its mildest form the response was sympathetic but non-committal, for example when this grievant explained the details of his complaint he was seeking an active response, instead he got murmurings of sympathy:

I have in the time since brought it up to sort of specific people. Nobody has ever said, ever explained it all. They just say, 'That's terrible, they shouldn't have done that. G1 (36:35)

This grievant never got a clear response to his complaint of serious defamation occasioned by the making of a film which portrayed him as grossly negligent.

The confusion and vagueness about the resolution process was particularly evident when the interviewees turned to the actual investigation process used. Bearing in mind that grievance handlers in this situation were also members of the management teams who made final decisions, concerns about evidence not being tested lead to concerns about the reliability of the outcome. This was expressed in the following quote where the interviewee was not confident that the evidence available was sufficient to make a judgment:

But these allegations came out of it which of course – it never got followed though to actually document that evidence as such – to demonstrate that that was happening. It never came out in the open. GH1 (1:06:16)

Other procedural issues were also raised. This grievance handler noted that one party to the grievance did not ever have an opportunity to be heard or to defend himself from the allegations:

I don't think he ever got given an opportunity to plead his case. ...I think if I had my way again, I think he should have been given an opportunity to speak directly to those people, and never got given that, which is I think...so all they got fed was stuff that was coming in from the [other parties] side of things. GH1 (1:13:03)

Group belonging emerged as a key theme for the grievant via the perceived impact on their professional reputation and their relationships with their colleagues. Reputation was considered a critical professional identifier in an industry environment of short term projects and few major organisations undertaking those contracts. The importance of reputation was as an entrée to the next job, and to enable the quick development of team based work groups. One supervisor spoke extensively about his belief that his professional reputation had been badly damaged by his informal grievance.

After, six months later, when I went to other jobs, I had a few other supervisors and they talked to me about it after I got to know them. And a few of them actually said, 'When I heard you were coming to my job I wasn't all that happy because I thought you were a bit of a scammer and a bit of a trouble maker.' So like they told me that after they got to know me and they were comfortable with me. G1 (46:35)

It was also clear that grievants were reluctant to come forward in the first place, as they were concerned about losing their job:

They knew better, but there's this thing about 'will I lose my job?' GH3 (45:35)

Chaotic and quick decision-making left grievants bewildered but not significantly damaged, in terms of their health and well-being and their prospects for future work. The clear hierarchy and the overriding decision-making criteria of 'best for project' appeared to act as a protector against harm. Employees knew what to expect if their conflicts got out of control.

Discussion: control and choice in grievance resolution processes. Empowering or Dis-empowering the grievant?

Grievance resolution systems in Australian workplaces inevitably require the target to attempt to resolve their complaint with the alleged perpetrator in the first instance. This requirement makes several assumptions. First, it assumes that the bullying, harassing or bad behaviour is a form of conflict in which both parties are equally able to defend themselves. Second, it assumes that the grievant is not experiencing psychological trauma to the extent that their ability to negotiate with the alleged perpetrator is impaired. Third, it assumes that the grievant has not already made any attempt to protect or defend themselves or that these attempts may also have exacerbated to the problems. Additionally, it ignores the evidence that targets of bullying are frequently too ashamed or too frightened to seek early intervention and so the problem is entrenched by the time assistance and guidance from the organisation is sought (Hubert, 2003). Grievance resolution systems that make provision for a support person to accompany the grievants may not be sufficient to allay all these concerns.

This inevitable first step, often referred to as the principle of resolving the conflict as close to the source as possible, assumes the grievant has the capability to exercise choice and control over both problem and the intervention. A number of organisational tactics emerged from the data that appeared to be aimed at dis-empowering the grievant. These included obscured or difficult to find policies and procedures, restricting or thwarting access to external qualified support, and chaotic decision-making processes. A quick escalation to the CEO, with attended concerns about exposure to unknown persons within the organisation and loss of control over process, was cited as a grievance resolution system that was construed as being used to silence the grievant. As well as these deliberate actions, the data also revealed as widespread the general act of omission, namely a general lack of focus on the grievant, their concerns and well-being.

In a situation of a grievance there is a clear asymmetry of resources between the organisation and the individual making the grievance (Aksoy & Weesie, 2009). The grievant is significantly less powerful than the organisation. However, there is considerable potential for harm to the organisation to occur if the substance of the grievance is not adequately attended to. A strategy of dis-empowering the grievant is not consistent with (1) the organisation's responsibilities under OH&S regulations, (2) with research that shows increased levels of satisfaction within an organisation when complaints are appropriately rectified in a timely manner, (3) with theoretical reasoning that links guaranteed fairness with increased trust.

Additionally, a dis-empowered grievant's capacity to assist a search for systemic causes of the grievance problem is thereby diminished. A dis-empowered grievant will become self-absorbed, confused and over reactive, thereby reducing their ability to provide consistent and reliable information.

The organisation's motivation for engaging in these dis-empowering tactics could vary from (1) an assertive risk management strategy, (2) an over inflated belief in the power of the grievant, (3) a belief that the grievant will go away if the process is made difficult, or (4) a belief that only serious grievances will overcome the barriers and proceed. The potential danger is that a grievant may have a prolonged association with feelings of helplessness, powerlessness and distress which may induce a significant psychological disability such as a learned helplessness or chronic depression and anxiety. The substantially increased risk of damage to the health and well-being of the grievant increases the likelihood of legal action and overt retaliatory action, either self-directed such as terminating employment or suicide, or even organisation directed aggression such as physical attacks on property or associated persons. An organisational audit may conclude that these dis-empowering tactics actually increase the overall risk to the organisation, as well as placing an unacceptable burden on the grievant.

Limitations and further study

Inductive case study research has natural boundaries and limitations relating to the conventional paradigms of validity, reliability and objectivity that are well known (Lincoln & Guba, 1985). This interpretive inquiry creates credibility, dependability, transferability and confirmability via qualitative research traditions of thick data, multiple sources of data and transparent research protocols and analytical techniques (Anafara, Brown, & Mangione, 2002). In addition, this study has a number of specific boundaries relating to the subject matter. It is skewed towards the negative experiences of grievants and grievance handlers as they volunteered to participate in this research in higher numbers. This is taken into account by refraining from claims that exclude the

possibility of the grievance resolution system being a positive experience. However, research that tests the analysis and conclusions of this study would need to gather data more broadly within a greater range of organisations.

Alleged perpetrators were not sought as participants because of the interpretative and analytical difficulties associated with social desirability effects. However, there is a paucity of research undertaken from the perspective of the abrasive manager. Research which specifically focuses on this cohort, including their experience of being named as a bullying, and their experience of the grievance resolution process would start to address this gap.

A significant limitation of social constructionist research is the distinct possibility that individuals are not fully cognisant of the social structures and attitudes in which they are embedded. The available data in this study does not have the power to investigate this notion. However, an emerging area of research is interested in how procedural justice may obscure perceptions of, and hostile feelings about, distributive injustice (MacCoun, 2005).

This study suggests that the individual's degree of control over the selection of resolution process may have a direct impact on their perceptions of the outcomes. Future research that separates the effect of control and choice, and the effect of the intervention strategy would clarify this.

Conclusion

Two organisations carried out a number of actions that disempowered the grievant significantly. These acts ranged from locating the grievance resolution policies and procedures in obscure and difficult places, refusal to accept or act on verbal grievances, not advising grievants of entitlements, and not publishing process criteria. Participants who had experienced these types of acts reported significant negative impact on their health and well-being and on their career prospects.

Employee motivation as a part of human resources activities

*Nadežda Fuksová, nadezda.fuksova@stuba.sk
Slovak University of Technology in Bratislava (STU), Institute of management*

Abstract

The article provides a synthesis of employee motivation theories and offers an explanation of how employee motivation influences human resources activities in industry. In addition to explaining why it is important to analyse employee motivation the author described the relevant employee motivation theories and also analysed the results from survey companies in industry.

The data were collected from employees of diverse type of organisations to gain wide representation of sector composition. In all, 200 self-administered questionnaires were distributed among the employee of different sectors and they returned 175 completed useable questionnaire for response rate 87, 5 %. The participation in survey was voluntary and confidentiality of responses was ensured.

The final segment of the paper provides an illustration with explanation the differences in theme of employee motivation in industry. There is thus a reason to attach the main differences in employee motivation and consider the potential application of new approaches in employee motivation as a part of human resources activities. Results of literature review and empirical research indicate that the employee motivation has an impact on the human resources activities. The present study is an attempt to find out the major factors that motivate employees.

Results of study show that employee motivation can be influenced by many motivation factors. For evaluating the research the study use the statistical method especially the factor analyses. There are several motivation factors which are necessary for right setting of employee motivation in companies.

Implications of the study for managers in the context of employee motivation as a part of human resources activities have been discussed. Guidelines and limitations for future research are also in the results of this article provided.

Background of Study

Work motivation is usually described as the set of psychological processes that cause the initiation, intensity and persistence of behaviour. (Pinder, 1984) Motivation is considered the most important and the most difficult function in the management process. Work motivation influences also the other part of the human resources management in companies. Motivation is a desire to achieve a goal. Combined with the energy to work towards that goal. The topic of motivation employees is extremely important to managers and supervisors.

Most organizations do not give it much thought until something starts to go wrong. Pain gets people's attention.

Four reasons explain this fact:

1. Motivation is intangible
2. Motivation drives all human action.
3. We can intuit our own motivation and see shifting nature and intensity. We can measure the motivation of workers indirectly.
4. Motivation is lost in a twilight zone.

Human motivation at work is the core of the field of organizational behavior. In work and other parts, motivation is often described as being „intrinsic“ or „extrinsic“ in nature. (Sansone and Harackiewicz, 2000)

Kovach (1987) says that if company knows why its employees come to work on time, stay with the company for their full working lives and are productive, then the company may be able to ensure that all of their employees behave in that way. The other scientists as Wiley (1997) says that the success of the company depends on understanding what motivates their employees and the relation of this conclusion with the improving of the productivity. To understand the concept of motivation can be helped the managers to identify what motivates their employees.

Literature review

Helliegele, Slocum and Woodman (1992) conclude that motivation as the force acting on our within a person that causes the person to behave in a specific, goal directed manner. (p. 204) Motivation encourage employee motivation for their own survival. (Smith, 1994) There are several definitions of motivation for example: motivation is the psychological process that gives behavior purpose and direction (Kreitner, 1995), the motivation is a predisposition to behave in a purposive manner to achieve specific, unmet needs (Bedeian and Lindner, 1995) and the motivation is also the will to achieve (Bedeian, 1993)

The purpose of this article, 14 motivation factors have been examined. This section focuses on discussing the most motivating employees and try to define basic sources for motivation factors design. The basis of the investigated motivation factors are the motivation theories such as Maslow's need-hierarchy theory, Herzberg's two factor theory, Vroom's expectancy theory, Adam's equity theory, Skinner's reinforcement theory. According to Maslow theory, employees have five levels of needs. (Maslow, 1943) The five levels of needs are physiological, safety, social, ego and self actualizing. The sequence of satisfying human needs is: the lower level needs had to be satisfied before the next higher level need would motivate employees. Herzberg's two factor theory consists of two factors: motivators and hygienes. Vroom's expectancy theory is about relation effort and performance. It means that employee effort will lead to performance and performance will lead to performance (Vroom, 1964). Adam's theory states that employees seek to maintain equity between the inputs that they bring to a job and the outcomes that they receive from it against the perceived inputs and outcomes of others (Adams, 1965). Skinner's theory states about positive and negative aspects of relation between behavior and outcomes. (Skinner, 1953)

Purpose

The purpose of this study is to describe the basic differences between motivation factors of employees in industry. To manage change, companies must have employees committed to the demand of significant change and as such committed employees are the potential source of competitive advantage (Dessler, 1993). Well known is the fact about the personal costs, for example Fitz-enz (1997) states that in USA the average company loses about one million dollar with every 10 managerial and Professional employees who leave the company. This study also discusses the motivational factors. The range of examined motivational factors was based in context of work motivation theories. A survey was distributed among different levels of managers in the industry. Moreover, the basis of this study covers data analysis the relationships between socioeconomic data, organizational data and the motivational factors.

Methodology

The data were collected from employees of diverse type of organisations to gain wide representation of sector composition. In all, 200 self-administered questionnaires were distributed among the employee of different sectors and they returned 175 completed useable questionnaire for response rate 87, 5 %. The participation in survey was voluntary and confidentiality of responses was ensured. The questionnaire was structured after a survey of motivation literature as a background for the study. The number of motivational factors was designed after the study of famous motivational theories which gave the basis to this study.

Measured motivation factors which were designed as a result of literature about motivation theories and also chosen from former research are: company policy, interpersonal relationships, work conditions, salary, information about activities of the company, non-monetary rewards, corporate culture, justice of the employer, recognition and appreciation, work criteria and methods used at work, relationships with colleagues, job security, opportunity to work through team work, possibility of education which is not provided by the employer.

Results and Discussion

A total of 200 copies of questionnaire were distributed to the chosen managers in the industry of Slovak republic. The managers were chosen in basis of strict survey sampling. The method of factor analysis was used to analyse the relations between the motivation factors. In fact, the similar name for motivation factor is motivation tool because employer uses this variable as a potential device for influencing the work motivation in company. The results of factor analysis are four factors. Each group contains the dependence of motivation factors. This dependence can be direct or indirect. The step before factor analysis was correlation matrix of motivation factors and then was used factor analysis for specifying the correlations between the motivation factors in context of factors (factor analysis). The four groups of factors separated from factor analysis give the opportunity to see the additions between the motivation factors and also give chance to specify similarities of each group of characterized factors. The value of KMO was 0,853. It means a high value of coefficient KMO. (according to standard table – theory)

The main two motivation factors (tools) which has significant coefficient high than 0,6 but less than 1 in every factor of the factor analysis are:

In Factor 1 – job security, possibility of further education which is not provided by the employer

In Factor 2 – corporate policy, work criteria and methods used at work

In Factor 3 – salary, non-monetary rewards

In Factor 4 – work conditions, corporate culture

Note: results of factor analysis, 14 motivation factors, N=175

Source: Own research

The results of the survey can be used by organizations to develop policies, practices, and strategies that would enable higher levels of work motivation.

Empirical evidence

The survey presents a new empirical evidence in support of a relational signalling approach to analyse of motivational factors. In the results is an evidence that future research is needed to systematically study the impact of applying the results of motivational factors in decision making (in the field of HR management). The part of the research results which are presented in this article has a big potential to develop the new ideas in the work motivation. In addition, more practice surveys may be conducted to demonstrate causality in a more survey results.

Guidance and limitations

There are many different types of motivation factors including potential for increasing work motivation like geographical position of company, or communication between employer and employees, etc. All these have good and bad points, and better and worse ways of deploying them.

Conclusion

One of the conclusions from this study is that the some of the factors above can contributed to a work motivation and are also significant for HR management. The analysis showed relation between some of the motivation factors and this relation can be the base for futher research.

This paper shows the new possibilities in research of motivation factors. Due to the results of statistical methods which were used for this study there are a lot of new questions which can be considered in study of work motivation. Based on analysis of motivation factors, according to which affective settings of work motivation is the chance that can company get the possitive results in productivity, this study showed that work motivation has several difficulties and thus must be specify for every company through chosen motivation factors.

A central message of the present study is that work motivation should be accompanied by the set of „right“ motivation factors in order to make both the required performance and productivity and hence to reach a goal of company in strong compatatave industry area. In this line, the study discussed a possible relationship between motivation factors which were described through statistical data.

The factor 1 can be named security and possibility prefered by employees. The factor 2 can be named as character of the job. The factor 3 can be named as rewards. The factor 4 can be named as a work environment. The limititations are the groups of factors which were used for research. For furher research it will be helpful to extend the group of analysing factor of work motivation.

However once analyzed work motivation and its motivation factors, this study concludes that this survey knowledge should be only the one from the group of many steps aiming at developing the work motivation as the succesful instrument of company in recent compatatave area of business units (companies). In particular, the companies should concetrare their efforts on setting the package of chosen motivation factors compatible with the knowledge from motivation theories by stimulating improvements on company productivity.

Impact of international remittances on schooling in the Philippines: does the relationship to the household head matter?

Tomoki Fujii

Abstract

We study the impact of international remittances on schooling in the Philippines. Unlike previous studies, we allow for the potential heterogeneity in the impact across households due to the school-age child's relationship to the head of household. This is potentially important, because the employment opportunities abroad are usually taken at the expense of the time with children. We find that there are negative guardian effects when children with overseas parents are looked after by someone other than their parents. However, these negative effects tend to be outweighed by the positive impacts of remittance flows from overseas.

Introduction

International remittances have become one of the most important sources of global financial flows in developing countries. Reported remittances to developing countries have soared from around \$30 billion dollars in 1990 to over \$160 billion dollars in 2005 (World Bank, 2006). This amount is approximately double the amount of official development assistance, and comparable to the magnitudes of foreign direct investment and foreign portfolio investment. Since reported remittances do not include unofficial remittances, which may be as large as formal flows (Brown, 2006) international remittances may well be larger than any other types of financial flows once unofficial remittances are taken into consideration.

International remittances have also been remarkably stable. They are not subject to the conditionalities imposed by donors or the herd behavior of private investors (Kapur and McHale, 2003). Further, remittances flow from households to households. Thus, they are less likely to be influenced by official corruption or haphazard institutional changes than other types of international flows.

Chami et al. (2005) find that, unlike other types of financial flows, there is a negative correlation between remittances growth and per capita GDP growth. Thus, remittances are countercyclical, so that the economic slowdown can be mitigated by increased flow of remittances. At the individual level, remittances could serve as a form of insurance. Yang (2007) find that roughly 60 percent of declines in household income are replaced by remittance inflows from overseas.

Insurance motives are not the only reason why migrants send remittances. Remittances may also be due to altruistic considerations. For example, Osili (2007) find that poorer origin families tend to receive higher transfers, other things being equal. Agarwal and Horowitz (2002) find that per-migrant remittances tend to decline with the number of migrants in the household, indicating that altruistic motives to remit may be more important than insurance motives. Therefore, if altruistic motives are indeed important, poor countries can potentially receive a disproportionately large amount of remittances.

It is, therefore, no surprise that researchers and policy-makers have become increasingly interested in the role of remittances in development. Using cross-country regressions, Adam and Page (2005) find that remittances tend to reduce poverty in the developing world. Similar findings are made using household surveys in ten Latin American countries (Acosta et al., 2008) and in the Philippines (Sawada and Estudillo, 2007).

One channel through which remittances may promote development is investment in human capital. In El Salvador, Edwards and Ureta (2003) find that incomes from remittances help children remain in school. Other sources of incomes have a similar effect, but their effects are much smaller. Calero et al. (2009) find that remittances tend to increase school enrollment for the poor but not for the non-poor in Ecuador, suggesting that the remittances may help the poor overcome binding resource constraints. Yang (2008) find that favourable exchange-rate shocks are associated with more child schooling and less child labor in the Philippines.

This study also aims to shed light on the impacts of remittances on human capital investment using household survey data in the Philippines. The Philippines is an interesting and important country to study, because the size of remittances is large in the Philippines. In 2003, the size of remittances were about 10 percent of the Gross Domestic Product (Goldin and Reinert, 2007). This is more than seventy times larger than the foreign direct investment and official development assistance combined.

There have been a number of studies on the impact of remittances on development in the Philippines (Ang, 2009; Lauby and Stark, 1988; Sawada and Estudillo, 2007; Yang, 2007, 2008). Unlike previous studies, however, we explicitly consider the relationship between the children of the emigrant worker and the characteristics of the households that the children belong to. This is important, because the money remitted from the emigrant worker may not necessarily benefit the children of the emigrant worker, if the remittance is "intercepted" by the household head in the receiving country. Therefore, the impact of remittances on human capital investment may well depend on the relationship between the household head and the child.

We explore the potential importance of the relationship between the child and the household head with two different regression models. The first model uses the schooling outcome directly. We test whether the characteristics of the households receiving the remittances affect the education outcome. We also estimate a model of education expenditure share. This allows us to see whether the transfer money go to education.

This paper is organized as follows: In Section 2, we describe the data used in this study and present key summary statistics. Section 3 presents the regression results followed by conclusions in Section 4.

Data and Summary Statistics

We use the Family Income and Expenditure Survey (FIES), the Labor Force Survey (LFS) and the Survey on Overseas Filipinos (SOF), the Consumer Price Index (CPI) for various years. These data are collected by the National Statistics Office of the Philippines and available for purchase. The FIES data contain detailed household expenditure and income data, and the LFS data contain employment, demographic, and education variables for each individual in the household. The SOF data contain information on remittances and the characteristics of the emigrant workers. The FIES and LFS can be merged at the unit-record level for 1997, 2000, and 2003.

For the analysis of the education expenditure share, we further merge the annual CPI data into the merged FIES-LFS data by a combination of year and province. The prices are normalized so that the national average price for year 2000 for each good is equal to 100. Since the definitions of goods in the CPI and FIES data are not the same, we have aggregated goods in both data sets to match the definitions. As a result, we have the following ten categories: (i) cereal (CR), (ii) meat, fish and dairy products (MF), (iii) fruits and vegetables (FV), (iv) other food (OF), (v) housing related expenditure (HS), (vi) utilities, communication and transportation (UT), (vii) personal care and household maintenance (PH), (viii) other good (OG), (ix) education (ED), and (x) other services (OS).

Table 1 shows the changes in the amount of remittances and other modes of transfers over time. As we can see in Column (1), a majority of overseas Filipino workers send remittances to home, and the amount of remittances has more than doubled over a decade. The cash brought home has also grown substantially (Column (4)). Though the proportion of households receiving a cash transfer brought back by overseas Filipino workers is relatively small (Column (3)), the average amount is larger than the other two modes of transfers. The amount of in-kind transfers has not changed as much as other modes of transfers (Column (6)). This table clearly indicates the increasing importance of remittances in the Philippines over time.

Table 2 compares the characteristics of contract overseas Filipino workers against average Filipino workers. The proportion of the overseas contract workers have not changed much between 1993 and 2002 (Column (9)), but their characteristics have changed. The overseas workers are slightly younger than average workers (Columns (1) and (2)). The proportion of female workers has generally increased over time, and this proportion is larger for overseas Filipino workers than other workers (Columns (3) and (4)). One major difference between the contract overseas Filipino workers and average Filipino workers is the level of education. The former is much better educated. Overwhelming majority of the overseas workers have at least high-school diploma, but the corresponding proportion for the average Filipino worker is 50% or less. The difference is even more striking for college graduates. More than one in three overseas workers are a college graduate, but the corresponding proportion is less than one in seven for other workers (Columns (7) and (8)).

Table 3 reports various household characteristics by the relationship of the individuals aged between 10 and 14 with the head of household. We categorize the relationship of those aged between 10 and 14 to the household head into the following four main categories: child, grandchild, other relative and non-relative. For example, child means that the person is either son or daughter of the head of household, and this group accounts for 86.9 percent of the children aged between 10 and 14 in 2003. Those children whose household heads are grand parents account for 8.2 percent, and other relatives—including brother, sister, niece, and nephew— account for 4.3 percent. The group of children under the non-relative category includes boarders and domestic helpers, and they account for 0.6 percent. These proportions are similar in 1997 and 2000.

The reason we restrict the sample to those aged between 10 and 14 is as follows: First, the LFS data do not contain direct observations of school attendance. Thus, we use being a student as defined by the usual occupation over the last twelve months for the schooling outcome variable. Second, the usual occupation is not recorded for individuals under age 10. Thus, we exclude individuals under age 10. Finally, we also exclude observations for individuals above age 14, because older individuals may have completed compulsory education.

The exact definition of being a student is slightly different from year to year due to the design of the LFS survey. For year 1997, student is one of the possible usual occupations, and we use this as the school attendance variable. For years 2000 and 2003, we defined as students those who are not engaging in a gainful activity due to their studies. As a result, some of those who are studying and working simultaneously are included in 1997, but excluded in 2000 and 2003, though the proportion of such people is likely to be small.

It should be noted that the drop of the proportion of students between 1997 and 2000 is not driven by the slight discrepancy in the definition described above. Education statistics also suggest similar drop. According to the World Development Indicators published by the World Bank, the net enrollment ratio for primary education, which measures the proportion of primary-school-age children enrolled in a primary school, has dropped from 92.9% in 1998 to 90.2% in 2001 and the number of out-of-school children has increased by 42% during the same period.ⁱ

As we can see from Table 3, there is a clear pattern between the child's relationship to the household head and the proportion of girls. The proportion of girls is much higher than the national average for "other relative" and "non-relative" groups. This is because many of the girls in these groups work as a domestic helper. This also

explains why the average household expenditure per capita is high for these groups, because only wealthier households can afford to hire domestic helpers.

Table 3 also shows that the share of income transferred from abroad varies with the child's relationship with the head of household. The share is higher for "grandchildren" and "other relative" groups. This is because many of the children in these groups have parents working abroad. Thus, while the remittances parents send for the children may increase the schooling, the fact that they are not taken care of their parents may offset the positive effects for children in these groups.

The bottom part of Table 3 indicates that such negative effect may exist. The proportion of students is on average highest for the "child" and "grandchild" groups. They are followed by the "other relative" and "non-relative" groups. Given that the parents and grandparents are likely to care about (and potentially benefit most from) the education of their children or grandchildren more than other relatives and non-relatives, this observation is not surprising. In what follows, we control for various confounding factors in regression analyses and try to separate the effect of increased remittances from the "guardian" effect, so that we can see whether higher incomes due to remittances outweigh the negative effects of being taken care of by someone other than parents.

Regression Results

We first look at the effects of remittances and guardian on the schooling outcome variable directly. Let S_i be the indicator variable that takes one if individual i (aged between 10 and 14) is a student and zero otherwise. We assume that there is a latent variable S_i^* such that $S_i = \text{Ind}(S_i^* \geq 0)$, where $\text{Ind}(\cdot)$ is the indicator function which takes one if the argument is true and zero otherwise. Further, we assume that S_i^* can be written as $S_i^* = X_i^T \beta + \varepsilon_i$, where X_i a column vector of covariates for individual i , and β is a vector parameters to estimate. With an additional assumption that ε_i has a standard normal distribution, we have the probit model as follows:

$$P(S_i = 1 | X_i) = P(\varepsilon_i \geq -X_i^T \beta | X_i) = E[\varepsilon_i \geq -X_i^T \beta | X_i] = \Phi(-X_i^T \beta),$$

where $\Phi(\cdot)$ is the cumulative distribution function for a standard normal distribution. We estimate β by the maximum likelihood estimation.

The basic regression results are reported in Table 4. These results are based on the merged LFS-FIES data pooled for years 1997, 2000, and 2003. Because of the slight discrepancy in the definitions of being a student across years, we have also run regressions separately year by year (not reported). Since the sample size becomes smaller, some of the coefficients become insignificant. However, most of the results we discuss here are consistent with the year-by-year regression results. We shall highlight the cases where the pooled regression and year-by-year regressions yield noticeable discrepancy.

Column (S1) in Table 4 reports the results for the simplest model with a minimum set of regressors. $LPCOTOT$ is the logarithmic total expenditure per capita in the household. As expected, richer households are more likely to send their children to school, and the marginal impact of the per capita expenditure is decreasing since the coefficient on $LPCOTOT^2$ is negative (and significant). $ABSHARE$ is the share of household income received from abroad. This coefficient is positive and significant, suggesting that the income from abroad (mostly remittances) has a positive impact on schooling of children in the household over and above the impact due to increased income. These findings are consistent with the existing literature and robust with respect to the choice of regressors.

Column (S2) provides the estimation results with household and individual variables and their interaction terms with $ABSHARE$. Columns (S3) to (S5) are the estimation results for the same model except that they include various fixed-effect terms. Column (S3) includes age fixed effects. The age fixed effects are potentially important as children tend to quit school when they get older. Column (S4) includes all the variables in (S3) and region fixed effects. Because the Philippines are heterogeneous across regions, the region fixed effects are also potentially important. Column (S5) includes all the variables in (S4) plus year fixed effects, as various factors may have changed over time.

The coefficient on $ABSHARE$ is positive and significant in all cases in Table 4. Therefore, the remittances do seem to help increase schooling, even after controlling for a number of factors. Notice that there is a potential endogeneity problem here. Those households that receive income from abroad may be the type of households that care about schooling more than other households. Hence, positive coefficient on $ABSHARE$ may reflect, to some degree, the preferences of households, rather than the foreign income effect. As a result, the impacts of the foreign remittance may be exaggerated in these estimations.

The coefficient on $HHFEM$, an indicator variable that the household head is female, is negative and significant. The coefficient on $HHHIGH$, an indicator variable that the household head has graduated from high school, is positive and significant. Thus, other things being equal, the children living in a household headed by a female is less likely to be a student than those in a household with a male head. Also, the children whose household heads have graduated from high school are more likely to be in school than others after controlling for various factors.

The relationship of the individual (child) to the household head also matter. $GRAND$, $OTHREL$ and $NONREL$ are indicator variables that the relationship of the individual to the household head is grandchild, relative other than children or grand children, and non-relative, respectively. Thus, if the individual is a grandchild of the household head, the individual is more likely to be a student, other things being equal. In Column (S2), the coefficient on $GRAND$ is positive and significant at a 10 percent level. However, the results are not robust as the coefficients are not significant in Columns (S3) to (S5).

The coefficients on *OTHEL* and *NONREL* are both negative and significant. This indicates that, other things being equal, the children whose household heads are not a parent or grandparent are less likely to go to school. Further, the absolute value of the estimated coefficient is particularly large for *NONREL*, suggesting that the non-relatives are very unlikely to be sent to school after controlling for other factors.

In Columns (S2) to (S5), the coefficients on *ABSHARE* × *HHFEM* is positive and significant, though only at a 10 percent level. Therefore, women may be more likely to spend the remittance incomes to education. We shall get back to this point later when we discuss the expenditure share equation. On the other hand, the coefficients on *ABSHARE* × *HHHIGH* is not significant except for Column (S4). Hence, the fact that the household is headed by a high school graduate does not appear to change the impact of remittances on child schooling.

The interaction terms between the relationship to the head of household and *ABSHARE* also exhibit interesting patterns. First, *ABSHARE* × *NONREL* is negative and significant as expected. Further, in all cases, the absolute value of the coefficient is higher on the interaction term than the coefficient on *ABSHARE*. This indicates that those children who fall under the non-relative category are unlikely to go to school if their households rely more on remittances. This makes sense as many of them are working as a domestic helper, among others.

Second, *ABSHARE* × *GRAND* is also negative and significant, though only at a 10% level. Therefore, among the households where the guardian of the school-age children is a grandparent, the children are less likely to be a student if the share of income from abroad is larger. However, we are unable to draw strong conclusions as the corresponding coefficients in the year-by-year regressions are not significant. Finally, *ABSHARE* × *OTHREL* is not significant. This indicates that the impacts of remittances may be similar between those children whose household heads are parents and those children whose household heads are other relatives.

The regressions results discussed so far tell us how remittances are related to the student status of children. However, they don't tell us whether the income received from abroad is indeed used for education. Therefore, we also estimate some models of educational spending.

Let w_h be the education expenditure share, or the education expenditure over the total expenditure expressed in percentage. Theoretically, this function depends on prices and total expenditure. In addition, we include additional covariates ξ_h including a constant term. Assuming a linear relationship, we have the following model:

$$w_h = \alpha_0^T p_h + \alpha_1 LPCTOT_h + \alpha_2^T \xi_h,$$

where p_h is a column vector of logarithmic prices, $LPCTOT$ is the logarithm of the total expenditure per capita in the household as before. Since w_h is homogeneous in degree zero in prices and total expenditure, we may drop the price for any single good to (implicitly) impose this constraint. Thus, we drop the price of the other services from the regression.

Table 5 reports the regression results for expenditure shares expressed in percentage. The *LP* variables are the logarithmic prices. For example, LP_{CR} is the logarithmic price for the cereal. *NSCLCHILD* is the number of school-age individuals in the household aged between 6 and 15. *GRAT*, *ORAT* and *NRAT* are the ratio of school-age individuals who are grandchildren, other relatives and non-relatives of the household head to *NSCLCHILD*, respectively. We use these household-level variables because the expenditure shares are measured at that level.

Column (E1) in Table 5 reports the estimation results for a smallest model based on the ordinary least squares (OLS) estimation. The results indicate that richer households tend to spend a larger share of income. For example, a 1 percentage point increase in total expenditure is associated with an approximately 0.02 percentage point increase in the expenditure share. Also, the coefficient on *ABSHARE* is positive and significant. The households with larger share of income coming from abroad tend to spend a larger share of income on education. These observations are consistent with the schooling regressions discussed earlier.

As with the schooling regression model, the interpretation of the coefficient on *ABSHARE* requires some caution. The kind of households that receive a larger share of income from abroad—which may be the kind of households that would take pains to send a household member abroad to finance education—may coincide with the kind of households that spend more share on education due to the preferences of the household. Therefore, our results in part may reflect the preference of households, rather than the causal effect of incomes from abroad.

The coefficient on *NSCLCHILD* is significant and positive, as expected. Households with a larger number of school-age children tend to have a larger education expenditure share. One additional child is associated with about 0.3 percentage point increase in education expenditure share.

In Column (E2), we report the estimation results for a model with additional controls at the household level. While the coefficient on *HHFEM* is very close to zero, suggesting that the gender of the head does not affect the education expenditure share. However, the coefficient on *HHHIGH* is positive and significant. Therefore, when the head of household is a high school graduate, a larger share of expenditure tends to go to education.

The coefficient on *GRAT* is negative and significant. This is unexpected from the schooling regression results. This may reflect the fact that the households in which the school-age members are guarded by their grand parents may have additional needs that do not appear in other households.

Also, the coefficients on *ORAT* and *NRAT* are negative and statistically significant. Therefore, other things being equal, the share of expenditure that goes to the spending on education tends to be smaller when the proportion of school children who are not children or grandchildren of the head of the household is larger. This result is expected from the schooling regression results, because the school-age children who are an other relative or non-relative are less likely to be a student than others.

Column (E3) reports the estimation results for a model that includes all the regressors in Column (E2) and some interaction terms between *ABSHARE* and various household-level variables. This regression tells us whether the way income from abroad is used may be different across different households.

The coefficients on $ABSHARE \times HHFEM$ and $ABSHARE \times HHHIGHT$ are not significant both statistically and economically. Hence, whether the head is a female and whether the head has graduated from high school do not seem to change the way remittances are used.

The coefficients on $ABSHARE \times GRAT$, $ABSHARE \times ORAT$ and $ABSHARE \times NRAT$ are also not statistically significant. However, the point estimates are not small. According to the estimates in Column (E3), one percentage point increase in the share of income from abroad is associated with 0.023 percentage point increase in the share of education spending when the household head is a parent of all the school-age children in the household, whereas the corresponding figures for 0.020, 0.029 and 0.011, when relationship of all the school-age children to the head of household in the households is grandchildren, other relatives, and non-relatives.

Column (E4) reports the regression results for a model that includes both year and region fixed effects. The inclusion of these fixed effects is potentially important, but it does not change the main results that have been discussed so far. One notable difference is that the coefficient on LP_{ED} becomes positive and significant. One explanation for this difference is that prices may have captured in Column (E3) a number of confounding factors that vary across regions or years. Thus, once we control for the region and year as well as other observable characteristics, higher education price is associated with higher expenditure share for education, suggesting that education expenditure may be inelastic.

Columns (E1) to (E4) are based on the OLS estimation. The results are good if the measurement of *LPCTOT* is not subject to errors. However, if it is, the measurement error will also end up in the left-hand-side of the equation, causing the OLS estimate to be biased. Therefore, as a robustness check, it is important to address this potential source of bias.

The standard procedure to deal with this issue is to use the instrument variable (IV) approach. Therefore, we instrument *LPCTOT* by the logarithm of total income per capita in the household. The estimation results due to the IV estimation are reported in Column (E5). As the comparison between Column (E4) and Column (E5) makes clear, the potential bias due to *LPCTOT* is small, if any and it does not change the qualitative nature of the results we have discussed so far. Note that the

Conclusions

Remittances have increasingly become an important driver of development in many developing countries. The Philippines is one notable example of such countries. This study has shed light on how income from abroad is used using schooling and education expenditure share regressions.

We have found that the income from abroad tends to increase both schooling and education expenditure share. This indicates that international remittances tend to help households finance human capital investment, which in turn is likely to help improve the long-term prospect of the country's development, provided that the human capital formed due to the income from abroad stay in the Philippines.

Whether or not international remittances help the development of the Philippines in the long run, our finding does indicate that they are likely to improve the education of school-age children in the Philippines. One qualification that has to be made is that our results may be in part driven by the heterogeneous preferences across households. Previous studies, however, have also found that international remittances are indeed used to finance human capital investment.

One important difference of this study from previous studies is that we explicitly take into account the relationship of the school-age children to the head of household. This is potentially important because it is not uncommon for the Filipino parents to ask other people, including relatives, to look after their school-age children while they are working abroad.

We find that the incomes from abroad do not benefit a small fraction of those school-age individuals who are not related to the head of the household. Otherwise, international remittances do appear to affect the education of school-age children positively. However, the way they affect are different between those individuals who are grandchildren of the head and those who are relatives but not children or grandchildren of the head.

In the absence of incomes from abroad, it is also the case that those school-age individuals who are a relative of but not a child or a grandchild of the head are less likely to be a student than those individuals whose household head is a parent or grandparent. However, when the parents ask their relatives to look after their children to work abroad, remittances could compensate for being an "other relative." This can be seen by the fact that, after controlling for various factors, a larger proportion of the income from abroad goes to the education spending in households with higher shares of other relatives among school-age children (though the coefficient on $ABSHARE \times ORAT$ is not statistically significant).

The question is how large the compensation by international remittances is. To answer this question, let us do a simple calculation with a realistic parameter values. Consider a typical school-age individuals who is a relative of, but not a child or a grandchild of, the head of household. Then, for such a child, $LPCTOT = 10 (\approx \ln 22,0026)$ and $ABSHARE = 0.1$ would be a reasonable choice given the summary statistics reported in Table 3.

Now, consider a counterfactual where the child stayed with his parent. Assume this parent is the same in all aspects as the actual head of household for the child, except that the parent has no income from abroad, so that

$LPCTOT = 9 (= 10 \times (1 - 0.1))$ and $ABSHARE = 0$. While this is obviously a strong assumption, this is not an unreasonable assumption.

By comparing between the actual outcome with this counterfactual, we can measure the impact of emigration and remittances combined on schooling. Taking the estimates from Column (S5) in Table 4, the combined impact on the systematic component ($X\beta$) in the schooling regression is $\Delta X_i^T \beta = 1.774 \cdot (10 - 9) - 0.074 \cdot (100 - 81) + 0.358 \cdot 0.1 - 0.179 \cdot (1 - 0) - 0.001 \cdot (0.1 - 0) = 0.225 > 0$. Thus, the net impact is still positive around the observed averages.

Using similar calculations, we can also see that the negative effect of being an “other relative” on schooling outweighs the positive effect of foreign incomes when $ABSHARE$ is less than 0.049 (assuming $LPCTOT = 10$). Thus, our results indicates that remittances from abroad tends to compensate for the fact that the child is an “other relative,” if a reasonably large amount of income comes from abroad.

The calculations above are essentially based on the assumption that the (potential) senders of remittances have the same characteristics as the receivers. What if we drop this assumption? If the senders are wealthier in the first place, then our results would exaggerate the possibility of compensation. That is, by letting the child be taken care of by a poorer relative, the child may be less likely to go to school, even if remittances may partially compensate for being an “other relative.”

Despite this caveat, it is still the case that international remittances are indeed used for education. Further, if the opportunities abroad are attractive enough, they help improve schooling in the Philippines, even after the potential negative effects of being guarded by non-parent relatives are taken into consideration.

Religion in the United States: Focusing on Islamic Interest Free Financing idea for The American Market?

*Nadeem M. Firoz, firozn@mail.montclair.edu
Montclair State University, United States of America*

Abstract

Interest free is not a new idea in the Islamic world. There are many laws in most countries that implement interest free banking. The areas of the world that follow this law are the believers of Islamic background. This trend has migrated out of the native area and the idea has traveled into the global markets of many nations. The principles and real world examples as the author proposed: are that interest-free financing constitutes a feasible alternative for the American market. The discipline that it imposes on the individual can be attractive to Americans, whose poor saving habits and paycheck-to-paycheck spending mentality, coupled with an economy whose cycles follow the interest rate, have left many deep in debt. Interest-free banking may be a welcome alternative for individuals seeking a more conservative approach. On a larger scale, it can also help bring more stability to an economy so heavily based on the interest rate. This idea is already infiltrated in the north American market.

Introduction

A Nation in Debt

This has been the view that the age-old American dream begins when through hard work, anyone can succeed in life. This is based on the freedom given by the United States government. Nevertheless, this dream is nothing more than a nightmare as people become victim of poor work ethics and become part of the generation that focuses on buying with credit (Aggarwal and Yousef, 2010; 28).

This change in households' behavior was examined in a paper by Dynan and Kohn of the Federal Reserve Board. Putting aside constraints on borrowing, some of the factors that can contribute to households' decisions to take on more debt include less patience among consumers, less uncertainty in the economy making the need for reserves less urgent, lower cost of debt, increasing house prices, and changes in demographics. Looking at the real world where constraints do exist, in addition to the factors mentioned above, changes in the economy that reduce these constraints can increase the occurrence of borrowing. Presumably as a result of the emergence of a number of the aforementioned factors, American households began to demand more debt to finance their purchases, as will be evidenced by statistics later (Dynan and Kohn, 2007; 376).

Plague of borrowing on Debt

Lenders saw consumers' increasing willingness to borrow as an opportunity to improve their business by focusing less on their traditional role as creditors collecting on debts, and instead on increasing profits by using different tactics to earn as much as possible from each customer. This new behavior of creditor companies, in tandem with consumers' (Morgensen, 2006; 1-3). tendency to think in short-run and borrow as much as possible, has left a large number of American households deep in overwhelming debt. Whether from consumption or mortgages, Americans

over the years accumulated a large amount of debt, and a significant portion of their hard-earned money that goes straight to their creditors (Sukkuk, 2010). As a matter of fact, the ratio of all household debt to disposable personal income, a common measure of indebtedness among groups of people, has grown tremendously since 1952 (see Figure 1), with a value of 108 percent in 2004 (Weinberg, 2006; 178-179). This means that Americans are aggregately spending more than they earn in which many of them indefinitely are stuck paying for things they cannot afford and should never have bought.

Comparing debt service (estimated required payments on outstanding mortgage and consumer debt) to disposable personal income (gross income less income tax) produces the debt service ratio, an estimate by the Federal Reserve Board of the portion of earnings spent on debt relief ("Disposable/Discretionary Income", 2008). As shown in Figure 2, neither the debt service ratio nor the financial obligations ratio, which additionally takes car lease payments, rental payments, etc. into account, has changed significantly since 1980 ("Household Debt Rising Fast in the US", 2007). Figure 3 further illustrates the extent of debt held by American consumers, showing the growth of the ratio of household debt to the value of household assets from 1961 to 2002 (Campbell and Hercowitz, 2006; 20-21). Taking both graphs' statistics together, this indicates that while Americans have been accumulating more debt over the years relative to property and income, they are not paying more out of income to relieve these debts, and so they continue to grow.

Turmoil in the Domestic Economy

In turn, one major side effect of the situation described above is that customers, and thus the economy as a whole, have become highly sensitive to shocks in the economy, since holding more in debt and less in assets puts households in a financially precarious position ("Growing Interest", 2010). Households holding a large amount of debt are less able to adapt to changes in real income or in the real interest rate, while those with less debt have more cash on hand and are as a result less affected by these shocks. The results of this sensitivity to change are not as bad as they may sound. However, since shocks in the interest rate and income level can offset each other (Dyan and Kohn, 2007; 21). But the fact remains that holding a significant amount of debt makes a household's financial position almost as risky as the market itself, which is not a good place for a household. A household is supposed to be a safe haven for its occupants and this includes financial safety. If a household's finances ebb and flow with the state of the economy, it is not properly functioning in this particular area. Under the system in place in the United States, creditor companies are implicitly encouraging consumers to spend their money impulsively and irresponsibly, leaving many households naked in this situation.

Identically, while the current state of the American household may be something of a sob story, it may not quite touch the hearts of those without such troubles. However, the story does not stop at the individual household. The economy as a whole is also beginning to suffer, since more people are defaulting, causing more banks to report losses, which in turn affects shareholders (Morgensen, 2008; 1). Eventually, the financial troubles that the credit system has placed on consumers comes back full-circle, and the economy suffers for it. This phenomenon is also illustrated by the IS/LM model of Keynesian economic theory, an example of which can be found in Figure 4 ("IS/LM Model", 2008). In this model, IS represents all equilibria at which total spending equals total GDP, while LM represents all equilibria between demand and supply for money. The LM curve can be controlled by monetary policy (i.e., the Federal Reserve Board), while the IS curve is influenced by exogenous variables such as government deficits. A shock in the economy that shifts the IS to the right raises both the cost of money (interest rate) and the GDP, affecting one household at a time. Under the traditional interest-charging banking system, credit is a good

thing (Weinberg, 2006;177). and people are encouraged to use as much credit as they can, until they get trapped into an inescapable hole of debt that first hinders their own financial health, and then goes on to affect the economy at large(Shahinpoor, 2009).

Moreover, a more immediate and direct problem inherent in the traditional banking system is that the practices go against some of the principles of certain religions, including Islam, which is currently the second-largest religion in the world, after Christianity, and is growing quite fast (“Islam”, 2008). With a growing market both internationally and within the United States, as immigration and conversion figures have been significant in recent years, it would be prudent to offer services for this group of people domestically rather than letting them take their business outside the country (“Islam in the US”, 2008).This will be discussed further in a later section.

Potential Cure

Above all, the American banking system as it is inadequate, not only because it fails to serve a growing population, but also because of the effects it has on many of its captive customers, and ultimately on the economy at large. Given these problems, Author proposes that American banks add to their service lines the option of interest-free financing, in which loans are more realistically estimated. Author recognizes that there will be difficulty in making a switch, given the habits of American consumers and the scarcity of profit potential by creditors in interest-free financing, but author believes that its potential benefits outweigh the “negative” aspects. By making loans more realistic as to the consumer’s ability to pay, the consumer will be able to live with less debt relative to income or assets owned, and will be more able to satisfy outstanding debt. This, in effect, will benefit the banks by securing more return on debt, which will transfer to the shareholders. Of course profits to creditors may not be quite as high as they are under the current system, but there will be more stability in performance, and much less volatility. As the effect transfers from one party to the next, the implementation of interest-free banking can help to bring more stability to the economy and reduce its cyclical nature due to uncertainty in debt.

Analysis of Comparable Writing

In short, the modern concept of Islamic banking is not particularly old, coming out of a return to the rules by many Muslims (Taylor,2003; 4).There are many aspects of Islamic banking that have been developed to comply with the religious beliefs of Islam(Naser, 1997), but the part that concerns us most at this time is the concept of interest-free financing – what it is, how it works, the pros and cons, and how to implement it if it does indeed suit the American market.

At first it would be useful to know what interest-free financing is and what it entails. Islamic banking focuses on sharing of profits and losses, and the prohibition of charging or paying interest (“Islamic Banking”, 2008).As will be expanded upon later, interest is avoided by use of the main concepts in Islamic banking – profit sharing, safekeeping, joint venture, cost plus, and leasing – each with its own way of lending without charging interest. A study by A.F. Darrat shows empirically that an interest-free banking system is the only one that “offers a reliable short-run link between the monetary aggregate and the policymakers’ goal of price stability” (Darrat, 2000; 806-807).

There are other examples of interest-free financing, in which others have taken the model set forth by Islamic bankers and applied it elsewhere in the world. The best example of this is JAK bank in Sweden, which will

be discussed further below. Of course, with every decision that can be made, there are pros and cons, reasons to go ahead and reasons to pull back. Some of these will be discussed briefly.

To finish, there will be a more detailed strategy on how to successfully bring interest-free financing into the American market as a supplement to the current banking system, followed by a conclusion about what has been outlined here.

The Scope of Today's Market

Banking as usual

Marketing mix. Today, the conventional banking and financial institutions are based entirely on the concept of interest-bearing instruments (Thomas, 2006; 82). Under the Four P's, the *product* traditional banking offers is any kind of financing plan (Perreault, Cannon, and McCarthy, 2008; 35-38). This includes credit cards, mortgages, and car financing, whether for purchasing or leasing. It gives people the ability to purchase items without having all or any of the money at the time of the purchase. However, there is a *price* for borrowing, namely an interest rate charged on all financing plans. Other prices include monetary consequences for late payments, being financially responsible as a co-signer, and the other fees charged for services. A few examples of *places* where these financing plans are offered are campuses, commercial banks, car dealerships, real estate agencies, and even retail locations, whether on-line or in store (Thanasegaran, 2010). These financing plans are *promoted* through television and internet ads, magazines and newspapers, as well as on college campuses through sales promotions. When a person experiences a low interest rate or obtains many perks, word of mouth is the main method of promotion.

Demographics. Traditional banking can best be exemplified in the United States. According to Ebonya Washington, author of "The Impact of Banking and Fringe Banking Regulation on the Number of Unbanked Americans," 10 to 20 percent of Americans do not possess either a savings or a checking account (Washington, 2006; 106). This statistic indicates that many Americans rely on financing plans for consumer spending. Although the United States is in a rough time, consumer spending has grown at an annual rate of about 2.7 percent during the first three quarters in 2007 (Cooper, 2007; 27). Easy access to credit has been the main fuel for this increased spending. Banks and other financial institutions contributed to this easy access to credit because they were willing to lend households ever increasing amounts of money. To these financial institutions, loans to consumers, in the aggregate, were viewed as low-risk and profitable (Mandel, 2007; 57). However, the risk has increased to consumers. The Economic Survey of the United States 2007 reports that household debt has risen "particularly fast over the past decade in the United States". The outstanding amount of household financial liabilities increased from 89 percent of personal disposable income in 1993 to 139 percent in 2006. This is an unusually large rise by historical standards (Business and Finance, 2007). Although household debt in all income ranges has grown, this growth has been the most prevalent among households with medium and low levels of income. In addition, disparities in borrowing behavior continue to exist between minority and nonminority households. However, these disparities have begun to decline (Weinberg, 2006; 179-180).

Banking without interest

Marketing mix. In interest-free banking, the *product* is the same as that of traditional banking, which is any kind of financing plan. However, a person's purchasing power is more limited under interest-free banking because the *price* of borrowing is based on how much one has saved or will save in order to repay the debt. Without the interest as

part of the price, consumers have a better outlook on how to spend their money, giving them more financial security and reliability in their own cognizance. Unfortunately, right now the only places that offer interest-free banking are Islamic countries or other areas where interest is prohibited. However, this concept can also be appealing to people who want to be more responsible in their spending, which leads to *promotion*. Right now, not much promotion is done because interest-free banking is in effect because of religious laws or government regulation. But what authoris advocating in this paper is to promote to those people who want to be more responsible with their money (Aggarwai and Yousef, 2010). This type of banking system is ideal for those people who have been burned by debt before and want more discipline in their spending.

Demographics. In the last two decades, there has been remarkable growth of interest-free banks in many parts of the world. According to Ali F. Darrat, author of “Monetary Stability and Interest-free Banking Revisited,” this is partly due to the recent revival of Islamic values in most Muslim countries and the extensive research in support of the relative efficiency of these interest-free banks (Darrat, 2000; 803). Not only have Muslim countries been taken participation in interest-free banking, certain accommodations have been made for Muslims here in the United States. For example, University Islamic Financial Corporation, a bank based in Ann Arbor, Michigan, has accommodated special concerns of Muslims offers rent-to-own agreements for home buyers, along with savings accounts that offer profit sharing rather than interest (Galst, 2008; 6).

Comparatively, the concept of interest-free banking is also prevalent among Jews and Hindus. The Torah, which contains the first five books of the Old Testament, has two specific verses that forbid the collection of interest. Rabbis of the Talmud have extended these laws, prohibiting the borrower as well as to the lender from using interest (Jacobs, 1995; 3). These rabbis are known as “Talmudic rabbis” because they have contributed to the series of commentator books known as Talmud (Telushkin, 2008). For Hindus, the Vedic texts of Ancient India (2,000-1,400 BC) mention the “usurer” several times. This term has been interpreted as any lender at interest. However, the Sutra texts (700-100 BC) make more frequent and detailed references to interest payment. During the time of the Sutra text, the first sentiments of contempt for usury were expressed (Sukkuk, 2010). For example, Vasishtha, a well known Hindu law-maker of during that time, made a special law which prohibited higher castes of Brahmanas (priests) and Kshatriyas (warriors) from being usurers or lenders at interest (Visser and McIntosh, 1998).

Different Methods to Routine Commerce

Islamic Style of Banking

This alternative method of banking is commonly known as Islamic banking because of its deep roots in the Islamic religion (Thomas, 2006; 82). Islamic banking is not only about prohibiting the receipt and payment of interest, it is also supported by other principles of Islamic doctrine which advocate risk sharing, individuals' rights and duties, property rights, and the sanctity of contracts (Kader, 2010). With this in mind, Islamic banking investments should provide a stimulus to the economy and encourage entrepreneurs to maximize their efforts while maintaining the morals of the communities (Maniam, Bexley, and James, 2000; 22).

For instance, instead of a basis on the payment of interest, the Islamic financial system is based upon the sharing of profit and loss (Darrat, 2000; 803). Risk in business sharing may be allowed but risk in the form of gambling or mere speculation is prohibited by Islamic law. Under Islamic banking, investors should be focused on searching for projects that adhere to the Shari'a. With this in focus, investors should also be willing to share in the

success or failure of the project because all profits or losses are shared by all parties involved and earnings may not be guaranteed or predetermined (DiVanna, 2006).

Furthermore, in all Islamic financial services, compliance with Shari'a law is overseen and assessed by a board of independent Islamic scholars. The Islamic financial system restricts investments in certain business sectors whose products are forbidden by the Shari'a, such as alcohol, pornography, gambling, non-halaal food, and interest-bearing financial activity. This limitation can be extended to those with questionable moral values that may not have been directly stated in the Islamic laws such as tobacco industries, anything harmful to the environment, or genetic experiments such as cloning. These limitations, not directly stated in the Islamic laws, are based on an individual or community's opinion (Maniam, Bexley, and James, 2000; 22). The filtering process also includes acceptable limits on a company's debt level, interest income, accounts receivable and corporate governance levels (Thomas, 2006; 82).

United States Style of Banking

In contrast to Islamic banking, the United States banking has largely become focused on card rather than cash or check payment (Naser, 1997). This includes both credit and debit cards. There has been a steady increase in credit card users over the last two decades (Sappideen, 2007; 124). According to The Country Commerce, the most widely used form of short-term financing in the US is lines of credit at commercial banks (Country Commerce, 2008; 63). The shift from cash to credit cards as the medium of payment has also increased the availability of credit facilities, giving almost anybody who wishes to accept a credit card that option. Because of the growing burden of consumer debt, new challenges must be met. Now, retailers must update their systems for electronic payment. Coupled with, commercial law systems, which were originally designed for paper-based transaction systems, must also be updated (Sappideen, 2007; 120). However, the greater the usage and acceptance of payment cards, the more valuable they are to the consumer, retailer, and the company issuing the card (Sappideen, 2007; 122). With a credit card, the consumer now has the ability to purchase big-ticket items or buy in more quantity. This benefits the retailer because now he or she can generate more profits with the increase in sales (Al-Shams CEO Eyes Promoting, 2010). The company issuing the card also benefits from the interest and late payment fees because the consumer often falls into the trap of buying things he or she cannot afford and paying for it later.

With this in mind, for mid- to large-sized US corporations, commercial paper is a popular tool to use for short-term financing, since it is often cheaper than bank credit. Commercial paper can be described as "essentially an unsecured promissory note that a company issues and sells to investors, generally through investment banks". These corporations benefit because foreign companies pay higher interest than US firms with the same credit ratings, and commercial paper interest rates are usually below the bank prime rate. After all, commercial paper is exempt from the registration requirements of the Securities and Exchange Commission under certain stipulations (County Commerce, 2008; 64).

MARKETING INTEREST-FREE BANKING

In order for Islamic Banking or Interest-Free to become successful within the western world or, more specifically, within the United States, one must prepare a marketing strategy that identifies the target market and the specific marketing mix to be implemented (Perreault, Cannon, and McCarthy, 2008; 33).¹ The target market—a homogenous group of customers—is fairly easy to identify: it consists of the Islamic population in the U.S., which ranges anywhere from 1.1 million to 6.7 million, (these statistics are highly disputed) and other people who have been in debt and want to control their spending and would like some help in doing so (“Islam in the United States”, 2008).² The marketing mix are the controllable variables that financial institutions can put together to satisfy the target group. This mix consists of a product, pricing, place, promotion. Combining the correct strategies together can yield positive results for financial institutions who try to implement an Islamic Banking strategy.

Product

The first element of a proper marketing mix is the product. According to Sudin Haron of Northern University of Malaysia, “financial institution such as commercial banks, investment banks, merchant banks, finance companies, discount houses and insurance (Thanasegaran, 2010) companies that choose to offer products or services without an interest element can be considered as performing business using Islamic banking products” (Haron, 2008; 26). Therefore, any financial product that is interest free may be marketed as in accordance with Islamic principles. Using this as a working definition, author can now identify what products can be offered by analyzing other Shari’-compliant banks. Basically, there are four broad categories that these banks use to classify their products: profit-loss sharing, principles based on fixed charges, principles based on free charges and principles that apply directly or indirectly to the operation of Islamic banks. Author will consider the first three broad categories to understand what they entail (Haron, 2008; 30).

Profit-Loss Sharing

In the Islamic world, two governing principles encapsulate the concept of profit-loss sharing. These are *mudarabah* and *musyarakah*, which mean profit sharing and partnership respectively. In a *mudarabah* or profit sharing arrangement, there is an agreement between at least two parties. One acts as the investor and the other as an entrepreneur. The investor entrusts the money to the entrepreneur who then uses it to derive a profit (Kiva, 2010). The principal and a pre-agreed amount of profit are returned to the investor and the entrepreneur retains the rest (Haron, 2008; 30). The investor bears all the risk if there is no profit.

Alternatively, *musyarakah* or partnership establishes a relationship between the investor and the borrower. However, in this arrangement, both parties put up money for the business and they agree on profit sharing ratio that will be used to distribute earnings (Haron, 2008; 30). In both these principles, the investor acts more like an equity owner receiving dividend distributions based on the performance of the borrower’s operations.

Fixed Charges

In the Islamic principle of *murabaha*, or cost plus financing or financing resale, “the lender buys goods wanted by the borrower for resale to the borrower at a higher price agreed upon by both parties” (Haron, 2008; 31). The borrower is given a period of time to pay off this debt just like any other loan. Some critics have argued that this is just interest by another name such as a finance charge. One banker is quoted as saying, “The whole is, I want to

lend but I don't want to call interest 'interest'" ("Are Finance Charges in Islam's Interest"). Proponents of Murabha claim that the way something is done, although having the same outcome, can make the act good or bad, ethical or unethical. Therefore, even though cost plus financing in essence acts just like interest (Hasan, 1985), it is not considered to be interest because of the way in which these financial instruments are treated.

Free Charges

Finally, there is the *Qard Hassan*, otherwise known as a benevolent loan. This type of loan requires that the borrower return the principal back to the lender. Additionally, the borrower has "the discretion to reward the lender for his loan by paying any sum over the above amount of the principal" (Haron, 2008; 31). Depending on the borrower, the lender can receive little to no additional compensation for the use of his funds.

Having considered these various approaches to financial instruments, it seems that the most viable approach to use in the United States would be that of fixed charges for individuals or businesses and profit-loss sharing for businesses only. Fixed charges for individuals is most like an interest bearing note. Financial institutions have little to do when it comes to converting their products for these religiously inclined individuals. One economist noted, "Un-Islamic elements could be removed from current banking practices to create a system that is both viable and acceptable to Islam." (Gafoor, 1996; 1-86). This clearly is the case with fixed charges that do not bear an interest element. As for profit-loss sharing, this may become a viable business arrangement between lending institutions and the businesses because it creates a closer relationship than conventional loans. In profit-loss sharing you have a partner- partner relationship rather than lender-borrower relationship (Al-Thani, 2010).

Pricing

The second element of a proper marketing mix is the price. At what price should the finance charges be set? Pricing has always been an important factor to consider. If the price is too high, demand will not follow, but if set just right, the quantity demanded will reach an ideal equilibrium. However, pricing is especially sensitive within the context of Islamic banking because if the price is perceived as excessive, then it may not be in harmony with Islamic teachings (Visser and McIntosh, 2008).

Wane A. M. Visser helps us understand this delicate issue by describing usury as unearned income. He wrote:

"In Islam God 'permits trade yet forbids usury': The difference is that profits are the result of initiative, enterprise, and efficiency. They result after a definite value-creating process. Not so with interest ... interest is fixed, profit fluctuates" (Visser and McIntosh, 2008).

Therefore, when making price considerations, one must be careful not to set finance charges too high, and that the return to the investor is not viewed as interest but rather as profit from a "value-creating process."

Place

The third element of the product mix is the place or channels of distribution. This should be a relatively easy variable to control because financial institutions already have the infrastructure in place—networked banks—in which to offer these interest-free products (Rammel, 2007). However, these institutions must determine whether to

market to consumers, businesses or both. This all depends on the location or region of the country the bank plans to sell its product. A careful marketing study of the environment will help with this endeavor.

Promotion

The final element of the product mix is the promotion of the product. This too takes no more special effort than traditional financial product promotions. Just like other products, banks can promote interest-free products by various forms such as: broadcast media and print media. Promotion mix and placement work in tandem with each other; one must find the right mix and know where the best to place these promotions for maximum response. One possible promotion method would be to advertise in popular Islamic focused magazines, or in mass transit areas where there is a high volume of traffic. This will ensure that (1) the right audience is targeted, and (2) the message reaches as many people as possible. This is one of a countless number of possibilities; only through a thorough market study can the ideal promotion mix be achieved.

In any event, having reviewed the four elements of the marketing mix, it seems very possible that financial institutions can transplant interest-free banking within the U.S. The most significant of these endogenous variables is the product itself. One must carefully consider what form of interest-free banking to offer within the confines of the U.S. borders that will be both economical and financially viable.

Findings & Suggestive Discoveries

All things considered above, writer feels that implanting interest-free banking in the U.S. is not only feasible but also attractive to Americans and good for the economy. With this in mind, the following section will help magnify these points.

Feasibility in U.S. markets

Several studies have shown that interest-free financing can be implemented in countries other than Islamic territories (Yousefi, 1997; 869). One such study pointed out “the empirical evidence in support of the efficiency of interest-free banking system may not be country-specific...and perhaps more robust than author thought.” (Darrat, 2000; 806), (“Interest Free Banking”, 2001). Several other sources have shown the level of growth potential in this niche (Shahinpoor, 2009). One report stated that the Islamic finance market has grown 15 percent annually in the last three years, and is approximately a \$700 billion industry. So profitable is this niche that banks such as Citigroup, HSBC and Deutsche Bank have already devoted divisions to Islamic finance (Timewell and DiVanna, 2007), (Wiseman, 2008; B.6).

Furthermore, writer can look at the success that other countries have enjoyed to get an idea of how we in the U.S. might fare. Reports from Turkey, where implementation of Islamic financing was politically motivated, show that special finance houses—banks established to offer interest-free financing—have enjoyed on average two to four percent growth in market share per year (Okumus, 2005; 51). In Malaysia, Islamic banking commands 9.5 percent market share and is expected to reach 20 percent by 2010; with an annual growth rate of 37 percent, this seems very reasonable (Saifuddin, 2004; 1). Looking at the demographics within Malaysia reveals an interesting fact, “seven out of 10 Malaysians who opt for Islamic banking are non-Muslims” (Saifuddin, 2004; 2).

Based on these facts, it seems very feasible to implement an interest-free banking system within the U.S. Writer has seen that this “niche” market is not country specific, has exponential growth, and is not solely dependent on

religious affiliation. Before jumping to any conclusions, we must first consider the pros and cons of implementing riba-free financing.

Implementing in U.S. Markets

Writer has already hinted at, interest free banking has many positive aspects to it that can benefit the U.S. It imposes a discipline on individuals that can be attractive to the American market where poor savings and many other financial burdens have put Americans deep in debt. Nationally, it can help bring a higher level of stability to the economy. Ali F. Darrat, a noted economist on the subject, has said:

“in contrast to the interest-based banking system, the interest-free system displayed a well-behaving velocity of money, had a structurally stable money-demand relationship, exhibited monetary aggregates that are policy-controllable, and finally the interest-free monetary aggregate have a reliable link with the ultimate policy objective (price stability)”(Darrat, 2000; 803).

Clearly, there are many financial and social benefits to implementing a riba-free banking system in the U.S. However, opponents have argued against interest free financing stating that “ it would probably be technically and politically impossible to manipulate rate of spending, taxing, etc., so as to maintain an acceptable degree of economic stability” (Poindexter, 2008; 163)(Rammel, 2007).However, we must interject and cite all the countries that have enjoyed success with interest-free financing for years now. This argument does not hold water in the face of the many affirmative examples of interest-free financing, some of which were described earlier.

CONCLUSIONS

All-in-all, interest-free financing is not a new concept or unique to Islam. What is new is the growth of the global market, which has caused the practice to migrate outside of its native area. Interest-free financing is not only profitable but also socially beneficial. Therefore, it is apparent that interest-free financing is a feasible alternative not only for those with religious convictions that conflict with traditional banking, but also for the U.S. market at large. As long as due care is taken in selecting the proper marketing mix, author has high confidence that the American market can reap the benefits of providing financing interest-free for all.

Abstract

During the Meiji Era and again in the aftermath of the Pacific War, Japan rapidly established itself on the world stage as a major participant in global business from very adverse and inauspicious beginnings. In the case of the Meiji Era expansion, the dramatic advances have commonly been interpreted as resulting from the herculean efforts of ex-samurai leaders acting as agents of the administration, and in the post war reconstruction period, a larger societal sub-group, Japanese ‘salary men’. With this background in mind, and coming after a period of some two decades of economic decline, the current empirical research study was undertaken for the purpose of establishing an appropriate mindset ‘profile’ for the contemporary global business era. After establishing the constructs by which ‘global mindset intensity’ could be assessed, a questionnaire survey was undertaken with Japanese international managers in western Japan. Based on their findings, the researchers have tentatively suggested that the ideal corporate role model of Japan’s post war reconstruction and growth period, the ‘salary man’, was now effectively redundant, and that the currently accepted ideal profile was more worldly and individualistic, with expertise and ‘global mindset intensity’ drawn from personalized international business experience, reminiscent of established Western business ideals.

Introduction

Japanese industry is renowned for the speed and scale of the recovery made in the decades after the end of the Pacific War, and the way in which it was pivotal to the reconstruction, even the rehabilitation, of the Japanese economy and as a by-product, Japanese civil society. Another way of interpreting this is to acknowledge that Japanese national pride was slowly but surely reinstated by the cumulative international successes of its flagship companies. A long list of particular examples come to mind, such as Sony Corporation, National Panasonic, Seiko, Canon, Mitsubishi Motors, Nissan and Toyota, to cite but a few.

In many cases, very large Japanese companies such as these, as part of vertically or horizontally integrated industrial conglomerations, imported raw materials from around the world and manufactured a wide range of consumer products for domestic and global markets. With their unique approaches to the conduct of government relations, industry structure, corporate management and inventory and production processes, they were highly successful, to the point that they excited protectionist sentiment around the world, and sometimes opposition in foreign markets, although their approaches were also the subject of widespread admiration and emulation by Western managers, and their management techniques were often taught in universities and executive level training courses by Western academics.

Indeed, the analysis of the Japanese approach to business, often broadly characterized as the 'Japanese Management System', was at the heart of a quite polarized debate in academic literature, especially as Japan seemed poised to take over world economic leadership from the United States in the late 1980s. McCormick (2004) has done an excellent job, not so much in taking up the argument from one perspective or another, but in setting out a detailed discussion which showed that the Japanese 'model' had been constructed and debated at factory, company and national levels depending upon the perspectives of the creators of these models. And as with other fairly recent commentators, such as Pudelko and Mendenhall (2007), in the light of the failure of the Japanese economy in the 1990s, and slow economic growth beyond that, McCormick also turned his attention to the evolution of the Japanese management system and the influence upon it of apparently more successful Western approaches. In McCormick's case, he forecast that there might be less homogeneity in the future management systems of Japanese organizations, while Pudelko and Mendenhall suggested that the well established Japanese tradition of adapting foreign ideas and technologies might in the future once again come to the fore, likely resulting in unforeseen and effective innovations.

The Japanese struggle to adapt and shape their formerly ascendant management approaches to new global realities was cast into particular relief by a quite recent article about world management systems in *The Economist* magazine, where comparison was made between the emergence of emerging economy multinationals, primarily based in China and India that were utilizing so-called 'disruptive' innovative technologies and approaches to management, and the dramatic ascension to world leadership of the Japanese motor vehicle industry some three decades earlier that had been based on revolutionary, innovative, contingency driven processes associated with what became known as "lean manufacturing" or lean production (The new masters of management, 2010: 2). As is now well known, Toyota Motor Corporation achieved iconic status in this respect.

Ironically, in this emerging global context, the current trials and tribulations of Toyota Motor Corporation with respect to quality control issues and mass vehicle recalls represent a spectacular fall from grace that must have been a heavy blow to Japanese national self-confidence. Recent media discussion (for example, *The machine that ran too hot*, 2010) suggested that Toyota's difficulties were related to a competitive thrust to become the world's largest automaker (achieved in 2008), in which the legendary focus on quality was compromised, resulting in the recall of hundreds of thousands of motor vehicles around the world and financial losses running into billions of dollars. It has also been recently asserted (*Accelerating into trouble*, 2010) that compounding this situation were management and governance failures that restricted the detection and correction of such problems at an earlier stage, creating obstacles in dealing with authorities in countries outside Japan in relation to the legal and regulatory consequences of the alleged omissions. These particular issues, in combination with the relative stagnation of the Japanese economy since the economic collapse of the late 1980s, inevitably lead to the following questions:

- 1 Did the so-called Japanese Management System cease to adapt to contemporary circumstances after the end of the 1980s?
- 2 Are Japanese multinational corporations in a position to effectively cope with contemporary global challenges?

Essentially, the current study addresses the second of these questions, in terms of the mental preparedness of Japanese international managers based in the Kobe region to effectively engage with the contemporary dynamic global business environment, with all its demands in terms attitudes and values, skills and competencies. In short, the current study focuses on the 'global mindset' of Japanese international managers. The general concept of 'global mindset' is briefly introduced and examined, before the current empirical study is explained.

The Concept of Global Mindset

Globalisation is the process whereby the political, economic, socio-cultural and technological structures and systems of nations around the globe are integrated into the world economy. National and industry level initiatives such as the deregulation of industries, development of foreign direct investment policies and applications to join trading blocs, provide organisations with the necessary impetus and institutional architecture to embrace globalisation (Jeanett, 2000). These initiatives at the national and industry level in turn create a globalised business environment which makes it imperative for organisations with global ambitions to reshape their structures, systems, policies and processes in order to leverage the opportunities associated with

globalisation. In this context, Gupta and Govindarajan (2002) contend that the heightened business intensity facilitated by initiatives linked to globalization necessitates continuous organisational level reform, and a number of researchers have reported that as organisations have been required to deal with a rapidly changing and dynamic complex global economic landscape, a new breed and calibre of multinational manager is required (Beechler, Taylor, Boyacigiller, and Levy, 1999; Gupta and Govindarajan, 2002; Rhinesmith, 1995). It is clearly important for this new breed of managers to develop skills, values and competencies that foster smooth functioning in the dynamic marketplace and contribute to the creation of efficient and effective global organisations. Within this context, a growing body of international management literature has emphasised the importance of the cultivation and development of a ‘global mindset’ (see Table 1.1 below) as one of the critical elements in providing the human resource platform required to develop and nurture an intelligent global organisation (Gupta and Govindarajan, 2002; Murtha, et al. 1998; Rhinesmith, 1992; 1993; 1995).

Table 1.1. Different Conceptualisations of a Global Mindset

Research	Conceptualisation of a Global Mindset
Perlmutter (1969); Heenan and Perlmutter (1979)	Geocentrism is a global systems approach to decision making or state of mind where “...HQ and subsidiaries see themselves as part of an organic worldwide entity...good ideas come from any country and go to any country within the firm” (1979: 21)
Fayerweather (1969); Prahalad and Doz (1987); Bartlett and Ghoshal (1998)	A transnational mentality is the capacity to deliver global integration, national responsiveness, and worldwide learning simultaneously (“a matrix in the minds of managers”).
Calof and Beamish (1994)	Centricity is defined as a person’s attitude towards foreign cultures. Geocentrism can be characterised by the following factors: “...all major decisions are made centrally...substantial co-ordination exists between offices..., and focus is on global systems.”
Kobrin (1994)	Geocentrism defined using Heenan and Perlmutter (1979) above.
Caori, Johnson and Sarnin (1994)	Global mindset is viewed as a cognitive structure or mental map that allows a CEO to comprehend the complexity of a firm’s worldwide environment.
Sambharya (1996)	Study taps into the ‘cognitive state’ or ‘belief and values’ of a top team
Murtha, Lenway and Bagozzi (1998)	Global mindset defined using Fayerweather (1969), Prahalad and Doz (1981; 1987), and Bartlett and Ghoshal (1989).
Rhinesmith (1993); Jeanett (2000)	Global mindset is a state of mind able to understand a business, an industry, or a particular market on a global basis.
Govindarajan and Gupta (2001)	Global mindset is defined as a “...knowledge structure...that combines an openness to an awareness of diversity across cultures and markets with a propensity and ability to synthesise across this diversity.”.
Bouquet (2005)	A behavioural approach to measure global mindset focussing on the actual (and more readily observable) time and effort that top team members devote to making sense of international issues, both for themselves and for the benefit of the multinational enterprise (MNE) overall.

Source: Ananthram (2008); Bouquet (2005)

While many scholars agree that a global mindset is essentially a cognitive structure, and that human beings are highly dependent on cognitive filters to sort otherwise overwhelming complexity in the information environment, there is still considerable argument about the essential constituents of a global mindset and how it might be cultivated and nurtured (Bouquet, 2005; Calof and Beamish, 1994; Dowling and Nagel, 1986; England, Dhingra and Agarwal, 1974; Gupta and Govindarajan, 2002; Jeannet 2000; Murtha, Lenway, and Bagozzi, 1998; Perlmutter, 1969; Rhinesmith, 1992; 1993; 1995; Rokeach, 1973; Sambharya, 1996; Westwood and Posner, 1997). Building on the existing theory in the international management literature, global mindset intensity is defined by the current study as:

The ability and willingness of managers to think, act and transcend boundaries of goals, values and competencies on a global scale.

The primary aim of this study is to identify and test some of the skill sets that are believed to be associated with the development and cultivation of a global mindset in a Japanese setting. The next section identifies these skill sets from the international management literature and develops hypotheses for empirical testing.

Literature Review and Hypotheses Development

Global managers need attitudes and skill sets that facilitate their efficient and effective functioning in the complex and dynamic global business environment. In this context, a number of studies (Beechler, et al. 1999; Gupta and Govinarajan, 2002; Jeanett, 2000; Rhinesmith, 1995) have recommended *managerial* level reform, with particular reference to the cultivation of a global mindset. Murtha, et al. (1998) and Harveston (2000) contend that a critical success factor for any organisation is the level of global mindset orientation amongst its managers.

A number of studies have linked managerial global mindset with certain *individual level* and *organisational level* characteristics (Beechler, et al. 1999; Bouquet, 2005; Murtha, et al. 1998; Harveston, 2000). *Individual level* characteristics are certain innate traits and competencies, which to a certain extent are inherently developed by the managers and contribute towards the cultivation of a global mindset (Beechler, et al. 1999; Kedia and Mukherji, 1999). Managers are expected to possess these *individual level* characteristics, which they bring to the organisation, and are later nurtured within the organisation. These attributes develop as a by-product of upbringing, social interaction, psychological state, economic environment and technological interest and prowess. In addition, the internal and external environment to which an individual is exposed tends to have a strong correlation with the expansion and nurturing of these attributes (Bouquet, 2005).

Research has identified a number of individual level characteristics, three of which include: *knowledge and information* about different cultures and contexts (Kedia and Mukherji, 1999; Rhinesmith, 1992; 1993; 1995), *personal, cultural and professional skills and abilities* to work in multicultural environments (Ali and Horne, 1986; Kedia and Mukherji, 1999; Rhinesmith, 1992; 1993; 1995), and level of *risk tolerance* which is defined as the extent to which managers are willing to make risky decisions about international activities (Covin and Slevin, 1989; Roth, 1992). These traits enable managers to think, act and transcend global boundaries and foster global thought.

These *individual level* characteristics, when supplemented by certain *organisational level* characteristics, enable the reshaping of managerial outlook such that globalisation is embraced. *Organisational level* attributes are skill sets that are instilled in managers with the help of certain actions and plans developed by organisations (Beechler, et al., 1999) often resulting in formal and informal training programs and mechanisms for managers. This training, in turn, enables managers to develop skill sets that are essential for operating successfully in the global marketplace. These *organisational level* skill sets are categorized as *global identity*, *boundary spanning activities* and *level of international experience*. By being privy to numerous global activities, managers derive a psychological advantage, and essentially adopt a global identity (Beechler, et al. 1999). *Boundary spanning activities* can be classified as internal activities (global responsibility designations, global team participation, ad hoc project groups, networks, and shared tasks or jobs across national boundaries) and external activities (international strategic alliances, joint ventures, international mergers, and international supplier agreements and joint marketing plans) (Adler and Bartholomew, 1992; Bartlett and Ghoshal, 1989; 1998; Beechler, et al. 1999) which provide managers the necessary connections and channels to expand the business globally. Lastly, the *level of international experience* is defined as the amount of experience that a manager has accumulated in an international context which includes foreign assignments, education and vacations (Christensen, Da Rocha, and Gertner, 1987; Harveston, 2000; Tung and Miller, 1990). These *organisational level* traits also enable reshaping of global thought. An in-depth understanding of these *individual* and *organisational level* managerial enablers and their relationships with managerial global mindset intensity is presented next.

Individual Level Characteristics of Global Mindset Knowledge and Information

Knowledge as an asset, and knowledge management as a process, has gained tremendous importance especially in a globally competitive environment (Naik and Iyengar, 2003). Managers and subordinates possess a certain level of *knowledge and have access to information* which needs to be utilised appropriately to gain maximum advantage for the organisation. Indeed, organisations realise the importance of knowledge as a valuable resource (Grainger and Miyamoto, 2003; Miller and Wurzburg, 1995; Ortenblad, 2004). The ability of organisations to store and share knowledge through structured processes, often involving technological intervention, is vital to ensure the smooth functioning of operations (Baines, 1998; Gunasekaran, Khalil and Rahman, 2003). In this

context, Chatterjee, (2003: 44) explains that, "...knowledge as an asset has emerged as a paradigm of utmost importance at all levels and in all types of organisations across the world..." The growing importance of knowledge and its management as a strategic tool has been appreciated by multinational organisations across the globe (Milton-Smith, 2003; Stevens, 1996). At the managerial level, knowledge comprises of a number of components that provide better managing outcomes in the global context. Kedia and Mukherji (1999) have identified three dimensions of *knowledge and information*, namely, the appreciation of the existence of socio-political differences, cultural differences and the mastery over technology.

Knowledge of socio-political differences across countries and regions is vital in order to communicate with managers across different international contexts. Indeed, "...multinational companies are particularly vulnerable to multiple political, cultural and economic systems within which they operate..." (Fatehi, 1996: 237). Managers therefore, must have adequate knowledge of counterpart national level economics. In other words, knowledge about the dynamics of the various economies in which the organisation operates or is planning to operate is crucial to the dealings with managers of the host organisations and the ultimate viability and sustainability of organisations engaged in cross-border business activity. In addition, knowledge of political frameworks of the various host governments including government policies and knowledge of societal priorities of the various host economies in which the organisation operates or is planning to operate are also vital for global economic success.

Another vital facet of knowledge as identified by Kedia and Mukherji (1999), is the knowledge of *organisational and societal culture and cross-cultural issues that impact upon organizational management*. Bartlett and Ghoshal (1989) and Hofstede (1990) support the view that a thorough understanding of the host country organisational and societal culture is of paramount importance in order to engage in successful cross border dealings. Hence, a thorough understanding of the cultural protocols underpinning the various divergent national contexts of the environment in which the host organisation operates is also important for managers.

Kedia and Mukherji (1999) highlight the importance of international managers acquainting themselves with *information systems networks facilitated by the information and technological revolution*. Managers operating in a borderless context must understand and be capable of working critical communication channels and networks, as well as with information systems for data storage and retrieval (Baines, 1998; Gunasekaran, et al. 2003). As organisations become more and more dependent on technology for their day to day operations, it has become essential for managers to possess computer and information literacy skills, not only in order to access and disseminate knowledge and information to different areas of the organisation, but also to expedite communication with managers across the globe (Helpman and Rangel, 1999).

Possession of a deeper level of *knowledge and information* at the managerial level enables managers to be able to comprehend the complexity in the economic, socio-cultural, political and technologically dynamic global environment. Furthermore, *knowledge and information* literacy engenders a global perspective and a global outlook (Jeanett, 2000) and has been identified as being related to the *global mindset intensity* of managers (Kedia and Mukherji, 1999; Rhinesmith, 1993). These arguments provide underpinning for the three hypotheses of H1a, H1b and H1c.

H1a. Knowledge of socio-political differences across countries and regions will positively influence global mindset intensity.

H1b. Knowledge of organisational and societal culture and cross cultural issues that impact management will positively influence global mindset intensity.

H1c. Knowledge of information systems networks facilitated by the information and technological revolution will positively influence global mindset intensity.

Skills and Abilities

Skills enable us to put knowledge into practice. Prahalad and Cowin (1983) and Cheney, Hale and Kasper (1990) contend that the effective application of knowledge to periodically reorganise structures, rethink strategies, revamp systems and revise policies at the organisational level is vital to ensure long term survival of organisations engaged in global business. In fact, how managers apply knowledge within organisations has been the subject of considerable discussion in the literature. In has been suggested that along with the possession of knowledge and information, managers need appropriate skillsets to use and apply the acquired knowledge and

information effectively and efficiently (Ali and Horne, 1986; Athanasaw, 2003; Dvorak, 1983; Kedia and Mukherji, 1999; Rhinesmith, 1992; 1993; 1995). These skillsets are engendered as a result of continuous communication and interaction with the internal and external environment in which the individual operates. In this context, Adler (1983) has identified some of the essential *skills and abilities* managers need to possess to work successfully in cross cultural global environments.

The current study explores three categories of *skills and abilities* identified by Adler (1983). These are *professional and managerial skills* which include skills managers need to possess while working in both a domestic and multinational environment, *personal and social skills* which allow managers the ability to manage their relationships with people from different contexts successfully, and *cross cultural and international skills* that are particularly important for managers working in geographically dispersed multicultural environments. Kedia and Mukherji (1999) have developed a theoretical model linking *skills and abilities* of managers with their *global mindset orientations*. These scholars argue that dynamic and competitive environments require diversified managerial skills and abilities, which give managers the necessary competencies to function effectively in the international environment. Stumpf (1989) and Rhinesmith (1993) have argued that managers who are exposed to the multinational environment are able to continually upgrade their skillsets which in turn tends to enhance their global mindset intensity. These arguments support the postulation of the following three hypotheses, H2a, H2b, and H2c.

H2a. Professional and managerial skills will positively influence global mindset intensity.

H2b. Personal and social skills will positively influence global mindset intensity.

H2c. Cross cultural and international skills will positively influence global mindset intensity.

Risk Tolerance

Cross border business dealings are risky given the uncertainty in the political, economic, socio-cultural and technological environments in which internationally oriented organisations operate (Clark and Knowles, 2003; Ricks, 2003; Stiglitz, 2002). While the economic notion of 'higher risk higher return' applies to the context of globalisation, organisations and managers operating in this dynamic marketplace have to understand the potential benefits and costs associated with global business (Bird and Stevens, 2003; Johnson, 2002; Sitkin and Pablo, 1992; Williams and Voon, 1999). Several studies have explored the relationship of *risk tolerance* and globalisation (Ali and Swiercz, 1991; Kedia and Chhokar, 1986; Sullivan and Bauerschmidt, 1990) and found that managers working in multinational companies operating across national borders perceive risk taking as an entrepreneurial opportunity, since a level of risk (business risk, political risk, economic risk, exchange risk, interest rate risk, credit risk) must be taken into account when managers are making the associated decisions.

Diversifying into international markets is more often a strategic decision by organisations depending, amongst other factors, on the availability of resources (Robbins, et al. 2003) and the managerial perception of risk (Roth, 1992). This cognitive involvement in terms of managerial perception relates to *global mindset intensity*. That is, the ability and willingness of international managers to perceive global expansion as an opportunity rather than a threat (Harveston, et al. 1999; Williams and Voon, 1999). Roth (1992) contends that interpreting risk in international business as an opportunity requires a mindset orientation that appreciates globality. Building on existing theory in the international management area, the following hypothesis, H3, is presented.

H3. Risk tolerance will positively influence global mindset intensity.

Organisational Level Characteristics of Global Mindset

Global Identity

Managers working in multinational organisations are perceived as possessing a *global identity* giving them a psychological advantage over managers working in local organisations (Beechler, et al. 1999). *Global identity*, in turn "...encourages managers to think about the firm as a whole and to ignore cultural and other boundaries as appropriate..." (Beechler, et al. 1999: 13). A number of theories have linked *global identity* with *global*

mindset intensity (Beechler, et al. 1999; Cox, 1994; Ziller, 1973). Beecher, et al. (1999: 14) explain that "...the cognitive complexity and learning orientation of global mindset make it possible for managers to grasp the difficult, diverse, high intangled dispersed operations of the firm, and to understand the highly differentiated cultural, political, economic and market conditions in which both affiliates and individuals of the firm operate." In addition, leading researchers contend that the ability and willingness of managers to think, act and transcend boundaries of values and goals on a global scale requires global identity and thinking (Bartlett and Ghosal, 1989; Bouquet, 2005; Kanter, 1994). These contentions provide underpinning for Hypotheses H4.

H4. Global identity will positively influence global mindset intensity.

Boundary Spanning Activities

Boundary spanning activities have been defined as interactions exposing individuals and organisations to external information and social environments, thereby affecting managerial views and strategic behaviour of organisations (Beechler, et al. 1999). The significance of individual *boundary spanning activities* has been recognised in diverse theoretical and empirical literature addressing new institutionalism (Powell and DiMaggio, 1991), managerial elites (Pettigrew, 1992), and inter-organisational relationships and strategic alliances (Oliver, 1990). These latter initiatives, which include international strategic alliances, joint ventures, international mergers and acquisitions, international supplier agreements, global responsibility designations, global team participation, ad hoc project groups, networks, and shared tasks or jobs across national boundaries, are reportedly enabled by increased managerial participation in *boundary spanning activities*. (Adler and Bartholomew, 1992; Bartlett and Ghosal, 1989; 1998; Pucik, 1992).

Beechler, et al. (1999) have reported the relationship between *boundary spanning activities* and *global mindset intensity*, and conceptualize *boundary spanning activities* as structured opportunities to foster global mindset development. Empirical studies by Calori, Johnson and Sarnin (1994) and Kobrin (1994) provide evidence that *boundary spanning activities* help shape the cognitive structures and processes of individuals, that is the *global mindset orientations* of managers, by providing access to diverse sources of cultural, economic and socio-political information. Murtha, et al. (1998), and Kanter (1991) also provide empirical evidence on the linkage between *boundary spanning activities* and the shaping of *global mindset orientations*. The current study tests the relationship between *boundary spanning activities* and managerial *global mindset intensity*. Based on the foregoing, hypotheses H5a and H5b are formulated.

H 5a. Boundary spanning activities (importance) will positively influence global mindset intensity.

H 5b. Boundary spanning activities (involvement) will positively influence global mindset intensity.

Level of International Experience

A number of studies have reported the relationship between managerial *international experience* and globalisation of business activities (Bilkey, 1978; Cavusgil, 1982; Tung and Miller, 1990). These studies contend that managers are likely to develop a deeper level understanding of the context in which their organisation operates when they have first hand experience of living, working and liaising with their business counterparts overseas. In addition, it is expected that managers with international degrees and qualifications would have superior knowledge of foreign market conditions than managers with a local education (Harveston, et al. 1999).

The *level of international experience* also influences the level of *global mindset intensity* (Bloodgood, Sapienza and Almeida, 1997). Researchers contend that knowledge of and exposure to different work practices, policies and procedures in foreign locations provides managers with superior ability to work in a global context by providing a cognitive mind frame that is more receptive to globality (Bouquet, 2005; Jeanett, 2000). Further, senior managers with greater exposure to international activities and a higher *level of international experience* are generally more adept at thinking and acting globally, and hence are in possession of a mindset orientation attuned to the dynamic international environment (Bantel and Jackson, 1989; Hambrick and Phyllis, 1984). With this background in mind, hypothesis H6 is formulated as follows:

H 6. Level of international experience will positively influence global mindset intensity.

Empirical Research Methodology

Research Design

The study was conducted in two major phases. In the first phase a survey questionnaire developed by Ananthram (2008) was translated into Japanese and back translated into English with the collaboration of a professional bi-lingual translator. Meanwhile, professors at a prominent prefectural university in western Japan had accepted an invitation to collaborate in the research project, and part of their role was to mobilize industry networks for the purposes of survey data collection.

In the second phase, two hundred hard copy questionnaires were mailed by the Japanese research collaborators to potential respondent managers employed in globally oriented Japanese organisations in the Hyogo area of western Japan. By the end of a three month period, eighty two questionnaires had been returned (the identity of the managers and organizations were kept anonymous), of which eleven were incomplete and assessed as invalid. The final usable sample was therefore seventy one, which provided a valid response rate of 35.5 percent. A brief description of the demographic characteristics of the respondents is presented in Table 1 below. The data was analysed with various statistical tests utilizing SPSS software.

Demographic Profile of Questionnaire Survey Respondents

Table 1: Demographics (N = 71)

	%		%
Managerial Level		Gender	
Executive	36.6	Female	2.8
Senior	26.8	Male	97.2
Middle	23.9		
Supervisory	12.7		
Age (in years)		Industrial Sector	
Less than 30	2.8	Manufacturing	59.2
30 – 39	8.5	Services	40.8
40 – 49	32.4		
50 and above	56.3	Educational Background	
		Senior High School	7.0
Tenure (in years)		University	93.0
Less than 10	16.9		
10 – 19	19.7	International Dimension in Education	63.4
20 and above	63.4		

The demographic information above indicates that the great majority of survey respondents (and therefore focus group participants) were males above forty years of age who held managerial level posts, evenly divided between manufacturing or service sector industries. Most respondents held university degrees, and the great majority had more than ten years experience in their respective organizations, and therefore in that industry sector.

Measures, Factor and Reliability Analyses

Knowledge and Information

A scale developed by Ananthram (2008) was utilized in the survey as a means of assessing the three dimensions of 'Knowledge and Information'; namely, *knowledge of information systems networks facilitated by the information and technological revolution* ('Knowledge 1'), *knowledge of socio-political differences across countries and regions* ('Knowledge 2'), and *organisational and societal culture and cross cultural issues that impact management* ('Knowledge 3'). Three items were developed for each of the three constructs. Responses were given on a seven point Likert scale (1 = extremely unimportant to 7 = extremely important) to indicate the level of importance each item had in working in the global marketplace. Factor analysis using varimax rotation revealed three constructs, however the three items measuring Knowledge 2 and one item measuring Knowledge 1 were skewed. Subsequently these items were deleted. Knowledge 1 was subsequently using two items with a Cronbach alpha of 0.83 and Knowledge 3 was measured using three items with a Cronbach alpha of 0.81.

Skills and Abilities, and Risk Tolerance

'Skills and Abilities' was measured using an adapted version of a scale initially developed by Adler (1983) and shortened from 27 to 16 statements by Ali and Horne (1986) and later adapted by Ananthram (2008) as a 14 item scale. The scale is linked to three sub-dimensions of the necessary attributes, namely, *professional and managerial skills*, *personal and social skills*, and *cross cultural and international skills*. The three dimensions were assessed by asking four, seven and three questions respectively. Respondents reported their perceptions on the level of importance of the skills and abilities for global business on a seven point Likert scale (1 = extremely unimportant to 7 = extremely important).

'Risk Tolerance' was measured using a scale developed by Covin and Slevin (1989) and later adapted by Roth (1992) and then by Harveston, Kedia and Davis (1999) in their seminal work on the internationalisation of born global and gradual globalising firms. This measure was then adapted by Ananthram (2008). Managerial risk tolerance was assessed through five questions dealing with global activities. Respondents were asked to respond on a seven point Likert scale (1 = extremely unimportant to 7 = extremely important).

The items for skills and abilities and risk tolerance were factor analysed using varimax rotation. Four factors were expected and four obtained. One item measuring skills and abilities and one item measuring risk tolerance were deleted owing to the items leaking over different constructs. Some of the items comprising the three constructs for skills and abilities loaded onto different constructs. This was attributed to the change in context given that the instrument was developed in the West and the current study was being conducted with Japanese managers in the East. After careful review of the items and given that exploratory factor analyses were conducted, the construct *personal and social skills* was renamed as *personal soft skills*. The Cronbach Alpha scores for the three constructs, *cross cultural and international skills*, *personal soft skills* and *professional and managerial skills* were 0.86, 0.74 and 0.71 respectively. The reliability measure for risk tolerance was 0.82.

Global Identity, Level of International Experience and Global Mindset Intensity

An eight item scale developed by Ananthram (2008) was employed to measure 'Global Identity'. Respondents were asked to report on a seven point Likert scale (1 = extremely unimportant to 7 = extremely important) to indicate the level of importance each action had in working in the global marketplace.

'Level of International Experience' was measured using an instrument developed by Harveston (2000) that had been adapted from Harveston, et al. (1999). The adapted instrument was later employed by Ananthram (2008). Level of international experience was assessed through four questions. Respondents were asked to respond on a seven point Likert scale (1 = very rarely to 7 = very extensively) to indicate their level of involvement with each activity.

Following the work of Barham (1987), Cateora (1996), Gray (1997) and Kedia and Chhokar (1986), 'Global Mindset Intensity' was assessed by asking managers a series of questions about their attitude towards globalisation. Questions were adapted from Burpitt and Rondinelli (1998) that was later employed by Ananthram (2008). Respondents were asked to report on a seven point Likert scale (1 = strongly disagree to 7 = strongly agree) to indicate their level of agreement/disagreement with each statement.

The 16 items were subject to factor analysis using varimax option. Three factors were expected and three obtained. One item measuring global identity was deleted owing to its leaking across constructs and hence measured using a seven item scale. The cronbach alpha scores were 0.84, 0.84 and 0.85 respectively for *global identity*, *level of international experience* and *global mindset intensity*.

Boundary Spanning Activities

The study employed a ten item scale developed by Ananthram (2008) and asked respondents to indicate the importance of, and, their frequency of involvement with, the 'Boundary Spanning Activities' identified from the literature. Respondents were asked to respond on a seven point Likert scale (1 = extremely unimportant to 7 = extremely important) to indicate the level of importance each activity had, in working in the global marketplace. Respondents were also asked to report on a seven point Likert scale (1 = very rarely to 7 = very extensively) separately, to indicate their level of involvement with each activity. Factor analysis was not conducted for this variable owing to the fact that boundary spanning activities are reported in the literature to be comprised of independent, mutually exclusive activities enabling convergence of cross border informational boundaries (Murtha, et al. 1997). The reliability assessment reported Cronbach Alpha scores of 0.81 for the *importance of boundary spanning activities* and 0.91 for the *involvement with boundary spanning activities*.

Results

Multiple Regression Analysis

Table 3 presents the multiple regression analysis for the assessed skillsets with *global mindset intensity*. Multiple regression analysis was performed separately for the *individual level* and the *organisational level* skillsets. The results indicated that four of the assessed ten constructs were positively related to *global mindset intensity*; namely, *personal soft skills*, *risk tolerance*, *global identity* and *level of international experience*. Therefore, hypotheses H2b, H3, H4 and H6 were supported.

Table 3. Results of Multiple Regression Analysis

Constructs	Global Mindset Intensity	
	b	T
Individual Level		
H1a - Knowledge of Information Systems Networks Facilitated by the Information and Technological Revolution	.031	.360
H1c - Knowledge of Organisational and Societal Culture and Cross Cultural Issues that Impact Management	.049	.525
H2a – Cross Cultural and International Skills	.018	.171
H2b – Personal Soft Skills	.328	3.208**
H2c – Professional and Managerial Skills	-.011	-.127
H3 – Risk Tolerance	.670	8.024***
R ²	.606	
Adjusted R ²	.569	
F	16.415***	
Organisational Level		
H4 – Global Identity	.296	2.739**
H5a – Boundary Spanning Activities (Importance)	.124	1.007
H5b – Boundary Spanning Activities (Involvement)	.009	.084
H6 – Level of International Experience	.340	2.802**
R ²	.258	
Adjusted R ²	.213	
F	5.738**	

Notes: a. H1b – ‘Knowledge of organisational and societal culture and cross cultural issues that impact management will positively influence global mindset intensity’ was not included in the multiple regression model as the items were deleted during the factor analysis stage.

b. b = beta, t = t value, F = F statistic.

c. *p < 0.05, **p < 0.01, and ***p < 0.001.

Concluding Discussion

This paper began by briefly reflecting on the human efforts that made possible the historic transformation that began in Japan after the middle of the nineteenth century when a domestically focused, essentially agrarian nation became a world industrial power within some fifty years, and again in the second half of the twentieth century when Japan emerged from the chaos and trauma of defeat in the Pacific War to challenge for world economic leadership by the late 1980s. The champions of these herculean efforts were the ex-samurai chosen by the Meiji Administration to lead the initial economic transformation, and the more prosaic Japanese ‘salary men’, whose collective commitment and relentless energy dragged a dispirited Japan into the economic sunlight in the postwar period.

The current research study surveyed Japanese international managers in the contemporary age of globalism, and comes, of course, some two decades after the start of Japan's relative economic decline. After establishing the constructs by which 'global mindset intensity' could be measured, a questionnaire survey was conducted for the purpose of establishing how Japanese international managers conceptualized an appropriate mindset for the global business era. Of eleven constructs offered to them, only four were supported, and these were 'personal soft skills', 'risk tolerance', a 'global identity', and 'international experience'.

By placing this response in its temporal context, the researchers are tentatively suggesting that the most recent ideal business role model, the collectivist 'salary man', is now more or less redundant, and that the ideal is now a more worldly, individualistic, global business man, whose expertise and 'global mindset intensity', is very much based on personalized international business experience, reminiscent of Western business ideals. For Japan, this is a radically different model, and one that might be quite confronting to many middle aged and older Japanese. In making these tentative observations, the authors are very mindful of major limitations of the study, for example the exploratory nature of the research, the fact that the data is really a perceptual 'snapshot', its regional focus, and the very limited size of the sample. Clearly repeated, larger scale and more broadly cast data collection would provide a stronger basis for asserting fundamental change in the nature of perceptions of global mindset intensity in Japanese international managers, but the current study at least provides some signposts for future research efforts.

GO GLOBAL TO JAPAN: ANALYSIS OF INWARD FDI DISTRIBUTION

Victoria KRAVTSOVA, vk2010@ier.hit-u.ac.jp
Hitotsubashi University, Japan

Abstract

For many years, Japan has attracted exceptionally low levels of Foreign Direct Investment. This study sets out to provide a better understanding of the activity of foreign affiliates in Japan, and suggests strategies Japanese policy makers may undertake to optimize the potential for positive spillover effects from Foreign Direct Investment in the future. Using firm-level data, the pattern of distribution of capital and labor of foreign affiliates operating in Japan is presented and analysed. From 1999 to 2008, foreign affiliates have grown rapidly in numbers, paid capital and number of employees. Nevertheless, dynamics differ between foreign affiliates depending on their origin, position in relation with international trade flows, the nature of the activity they undertake and their place within the organizational structure of their parent multinational company.

Key words: inward foreign direct investment, multinational company affiliate, Japan.

JEL codes: F23, O32, O33

1. Introduction

As this is written, *The Economist*¹ magazine trumpets China's achievement in overtaking Japan as the world's second largest economy. Considering the underlying economics behind this fact, it seems safe to predict that, in the very near future, Japan will be overtaken by the other strong and dynamic neighbors. In fact, Japan is already behind countries like Taiwan or Singapore by the level of GDP per capita adjusted by PPP.

How could this happen to Japan, the nation of highly motivated workers and the birthplace of most innovative giants in car making and electronics? The simple answer is that Japan has lost its pace with globalization. As *The Economist* notes, the main signs of Japan's backwardness today are clear: the rate of replacement of old firms with new ones is exceptionally low; entrepreneurial spirit has been shunted aside in favor of an all-out squabble to secure lifetime employment as a salaryman or kaishain. Seniority endorsement is a part of corporate culture in Japan, with promotions going to the older rather than the the most able employees. Such a system fails to provide adequate incentives to the talented, and so the quality of human capital is dropping.

All these facts might have been safely quarantined as 'cultural' peculiarities and shielded from further scrutiny, were it not for the fact that they've come to knock on Japan's economic doors so loudly. One of the indicators of economic interconnectedness with the rest of the world is the flow of Foreign Direct Investment (FDI). As our analysis will show, there is evidence that some of the trends that have sapped Japanese firms of dynamism are at work among MNC affiliates operating in Japan, as well.

The focal feature of FDI inflows into Japan has long been its extraordinarily low level, long near the very bottom in the league table of developed nations. Graph 1 shows this pattern from 1997 to 2008. The positive shift observed from 2006-2008 is outcome of an aggressive policy to attract FDI introduced by prime-minister Koizumi in 2004. While governments efforts and 'pushes' come and go, the level of FDI continues to fluctuates around zero.

Could it be that Japan is so distinctive because of its geographical position, so remote from the rest of G8 countries? Is it because it is the only Asian country in Graph 1?

Graph 1. Share of FDI inflows in GDP (%) in high-income G8 countries, 1997-2008

Source: World development indicators, 2010

To shed some light on this, we can look at Graph 2, where the level of FDI in the top ten Asian countries is presented.

Graph 2. FDI inflows in GDP level top 10 Asian countries in 2008.

Source: World development indicators, 2010

At first glance, Japan's performance does not look so bad. Among these ten economies Japan comes in third place, behind two much more populous nations, China and India. It bears noting that these FDI inflows are purposefully expressed in absolute terms, not relative to GDP (where Japan would look much worse), or to population.

The marketplace for FDI is a competitive one, where nations fight to attract more advanced technologies, better qualified labor, and enhanced potential for job creation and knowledge transfer. Japan is clearly losing the fight

to attract FDI to more aggressively developing nations, which have a comparative advantage in hosting labor-cost-saving foreign technologies. In this picture, Japan *is* in a league of its own, enjoying the distinctive advantages that accrue to developed economies, such as abundant domestic investment, high levels of social security and strong intellectual property rights protections (Belderbos et al, 2006). These are positive features that help to attract the technology-intensive investment that Japan needs. On the one hand, this type of investments in R&D laboratories and core technology development takes place in the headquarters of the multinational company that it is not “easy to move”. On the other hand, it cannot be a good reason for Japan to be ‘satisfied’ with its low level of FDI, especially if we get back to the graph 1, which shows that developed nations, with similar economic conditions, were far ahead of Japan.

One way to look for an explanation of the relatively low level of FDI in Japan is to analyze the pattern of FDI flows that Japan already hosts. The aggregate data analysis presented above obfuscates key dynamics at the level of the firm, which are left unobserved. Using firm-level data this paper seeks to shed light on questions such as “what kind of FDI does Japan facilitate and what are its main features?” and, “what has changed during the last decade and what are the pattern of FDI behavior that might be observed in the future?” This analysis aims to be useful not only to international economist studying cross-border capital movement, but also to policy-makers.

The rest of the paper is structured as follows: first, the main theoretical concepts are discussed to provide a basis for the main empirical question in section 2; the paper will describe data and methodology in section 3; the results will be discussed in section 4 before concluding in section 5.

2. Literature overview

Although foreign direct investment (FDI) has been widely recognized as a catalyst of economic development, different economies have long adopted dissimilar FDI policies. From a historical perspective, there is no ‘paved road’ in the direction of FDI. It is easy to find parallels to the relative *resistance* and recent *reluctant* attitude towards FDI in *Japan* in the development history of other economies. Examples can range from closed economies, such as USSR and Cuba, to relatively open economies like South Korea in 1980s and India, with its ongoing restriction on FDI in the retail sector today (Sridhar and Prashad, 2007). Where does Japan stand in this picture? Can the history shed light on the currently, exceptionally low level of inward FDI in Japan? And what does recent literature suggest about the ground for structuring future policy with regard to FDI?

When considering the relative restrictiveness towards FDI in Japan today, it is important to keep in mind that not so long ago, during Tokugawa Era (1603-1867), Japan experienced economic isolation at the scale comparable with former USSR or today’s North Korea. Throughout that period, only Chinese and Dutch settlements in Nagasaki Harbor and the outlying islands of Ryukyu (current-day Okinawa) and Hokkaido (the Northern part of Japan) were allowed to trade with China, Korea and Russia and, sporadically, with the Netherlands. During so-called “closed country” (sakoku) policy, it was forbidden to trade and be engaged in trade with foreigners until 1858 (and the launch of the “unequal treaties”ⁱⁱⁱ), when a number of additional ports were opened for international trade (Auslin, 2004). This negative and restrictive attitude towards foreign business in Japan, and therefore FDI, remained the dominant policy framework until 1899.

It is at that time that the Japanese government sought policy guidance from another powerful Empire at that time – Great Britain – and subsequently received the following advice from British Socialist Herbert Spenser (in 1892): “...Apparently you are proposing...to open the whole Empire to foreigners and foreign capital.’ I regret this is a fatal policy....There should be, not only a prohibition of foreign persons to hold property in land, but also a refusal to give them leases, and a permission only to reside as annual tenants....The distribution of commodities brought to Japan from other places may be properly left to the Japanese themselves, and should be denied to foreigners.” (borrowed from Endymion Wilkinson’s book *Japan Versus the West, 1991*). As the history books tell it, Japan pressed on with its reforms regardless and, following the revision of its foreign policy in 1899, allowed many of the “giants” of Japanese economy to be established using foreign capital (Paprzycki and Fukao, 2008). However, in the wake of the rising wave of nationalism of the 1930s and into post-war period, FDI and foreign trade came to experience renewed hostility in Japan.

In more contemporary times, the end of 20th century is characterized by various efforts by the Japanese government to attract FDI. These efforts were temporarily successful during the bubble period, but never led to a sustainably higher level of recurrent inflows. Among the most recent FDI policy undertakings are changes in 2003ⁱⁱⁱ leading to deregulation and opening up several sectors of the Japanese economy to investment by foreign

capital, while also setting up the necessary legal framework to facilitate mergers and acquisitions (M&As). However, inside Japan, this wave of FDI was sometimes considered as a misfortune or even a new generation 'unequal treaty', one forced on the country due to its financial weakness, rather than its military shortcomings as in the 19th century. In effect, FDI inflows were followed by an amplified occurrence of corporate bankruptcies. An increasing number of shares was available in the market due to a fall in cross-shareholding as a result of industrial reorganization. At the same time, the appreciating Yen rendered Japanese assets ever more valuable and attractive to foreign investors.

However difficult it is to change the mindset and attitude of the nation towards FDI, especially when the country encompasses a long history of 'closedness' and economic success built on inward-oriented policy, there is no parallel that can be drawn from the past that could adequately capture the importance of FDI in today's highly globalised world. The transfer and exchange of ideas, knowledge and technologies at unprecedented speed are the central characteristics the modern economy. Often, FDI facilitates this process, which is part of what makes it so vital for any economy. Japan is no exception. With that in mind, some considerations developed in the academic literature on FDI should prove useful to Japanese foreign investment policy:

The role of FDI in the diffusion of technology in a host economy can be seen either through its *direct* or its *indirect* impact. For Japan, with its profusion of domestic investments, the *direct* effect of FDI (transfer of new technology (capital) and organizational skills (labour) to the affiliates) is not necessarily the most relevant aspect. In some cases, when FDI is needed to fill a given technological gap, then it becomes a priority to look at the kind of FDI is attracted. It is especially in these types of cases that the quality, or type, of knowledge that foreign firms transfer to their affiliates becomes an important determinant of the effect of FDI on the host country.

Looking into the *indirect* impact of FDI, that is, at the impact of technology spillovers from more advanced foreign investment enterprises (FIEs) to local or domestically owned enterprises, four main avenues can be identified (Aitken and Harrison, 1994, Blomström and Kokko, 1998). First, there is the pressure of having to compete with the foreign affiliate: this channel operates by stimulating local firms to introduce new products to defend their market share and to adopt new management methods to increase productivity. The level of competitiveness of domestic firms is crucial here (Wang and Blomström, 1992, Glass and Saggi, 1998). Second, spillover effects can take place through *cooperation* between FIEs and upstream suppliers (backward linkages) and downstream customers (forward linkages) by introducing, for example, higher quality standards for both vertically and horizontally linked firms. Since, in many cases, foreign affiliates are export-oriented, local firms might gain via improved *market access*, also known as *export spillovers*, by becoming integrated into new distribution networks, etc. Some studies suggest that the level of embeddedness of foreign affiliates into the domestic market is positively correlated with spillover effect of FDI (Rodríguez-Clare, 1996, Smarzhinska, 2004). Third, *human capital* can spill over from FIEs to other enterprises as skilled labor moves between employers (Haaker, 1999; Fosfuri et al. 2001). And, fourth, geographical proximity of local firms to FIEs can sometimes lead to *demonstration* or *imitation* effect (Das, 1987; Wang and Blomström, 1992). For a firm the benefits of exporting include faster growth of shipments and productivity, risk diversification, increased innovation, better investment opportunities leading to improved survival prospects and gains for workers in terms of higher pay and improved future employment opportunities (Bernard and Jensen, 1999). As a consequence of increasing exposure to trade, the most productive firms are induced to participate in export markets while less productive firms continue to serve the domestic market only. The least productive firms drop out of the market. It follows that trade-induced reallocations towards more efficient firms will eventually lead to aggregate productivity gains^{iv}.

Firms that internationalize have to overcome barriers to exporting, and therefore invest in resources and capabilities (i.e. absorptive capacity) that provide them with the ability to compete effectively in overseas markets. These investments allow them to achieve higher productivity levels as a prelude to exporting (or engaging in outward FDI). In addition to the predominant roles of productivity, general empirical findings show that the determinants of a firm's export decision include trade liberalisation (Baldwin and Gu, 2004), sunk entry costs (Bernard & Jensen 2004b; Girma *et al.*, 2004; Das *et al.*, 2007) and some firm-level characteristics such as size (Aw and Hwang, 1995; Roberts and Tybout, 1997; Bleaney and Wakelin, 2002; Gourley and Seaton, 2004); experience including *ex ante* success (Bernard and Jensen, 1999; Greenaway and Kneller, 2004; Kneller and Pisu, 2007); export spillovers (Aitken *et al.*, 1997; Greenaway *et al.*, 2004); and foreign networks (Sjoholm, 2003).

The FDI literature suggests that firms locate in close proximity to reduce the costs of purchasing from suppliers, or shipping to downstream customers. Co-location is also likely if there is a large, common pool of labour; and/or to obtain knowledge spillovers that occur when similar firms engage in, say, R&D to solve similar or related problems. The need for close physical proximity (and density) is mainly predicated on the notion that a significant part of knowledge that affects economic growth is tacit and therefore difficult to codify. Such knowledge does not move readily from place to place as it is embedded in individuals and firms and the organizational systems of different places (Cooke and Morgan, 1998; Gertler, 2003).^v That is, geographic boundaries are important since spillover affects are limited by distance.

A greater range of activities (e.g. R&D, business services, cultural and lifestyle amenities, and the overall quality of the public infrastructure – cf Florida, 2002; Glaeser *et. al.*, 2001) leads to inter-industry spillovers. Multinational firms tend to locate their head office management and R&D functions in urban agglomerations. Thus these agglomerations not only tend to generate more product innovations, but there is more likelihood of yielding spin-offs and/or start-ups, which creates a thicker entrepreneurial culture. This is an important consideration for Japan as most foreign affiliates are located within the Tokyo area. Potentially, these firms can benefit from urbanisation externalities due to the size and heterogeneity (or diversity) of an urban agglomeration. In the FDI literature, this effect is labelled Jacobian spillovers (Jacobs, 1970, 1986), which emphasises the importance of benefits from economies of scope rather than scale.

A second theme in the literature investigates the effects of subsidiary-headquarter relationships in the creation of motives for entry. The role of multinational company (MNC) strategy and subsidiary-headquarter relations has mainly been discussed in the international business literature, often around the idea of “autonomy”. Starting with White and Poynter (1984), it is possible to distinguish between different types of affiliates depending on their role in the MNCs’ international production network. The simplest type of affiliate is the *marketing satellite*, which sells the parent’s products in the host country, perhaps providing customer services as well, but without engaging in local production. The *miniature replica* affiliate manufactures a range of the parent MNC’s products in the host country mainly for sale in the host country’s market. In the economics literature, this type is referred to as a horizontal affiliate and is typically motivated by potential savings related to transport and trade costs (e.g. tariffs).

Horizontal affiliates are distinct from vertical investments, which are based on the geographical separation of the different links in the production chain, where cost considerations and cross-country differences in factor prices determine the location of affiliates. In the categorization presented by White and Poynter (1984), there are three vertical affiliate types. One is the *rationalized manufacturer*, which produces in the host country but sells to the world market. Another is the *product specialist*, which has comprehensive responsibility for developing and manufacturing products for the MNC’s worldwide network as well as for the world market. Finally, the most advanced affiliates are the *strategic independent unit*, which has the freedom to establish new product lines and to develop new markets. While the strategic independent unit is often part of a vertical production chain, it is also possible that some may be entirely disconnected from the other activities of MNC. One motive for such investments could be diversification.

The opportunity for a subsidiary to move from the simplest type to more advanced forms typically takes the subsidiary through a creative transition (Papanastassiou and Pearce, 1994) and involves higher affiliate autonomy as well as higher innovative capability. The emergence of “technological-creativity-based independence” at the subsidiary level provides enormous potential for MNC localized competences (technological, managerial and marketing), but at the same time this should not be “disruptive and undermine the synergistic value of existing attributes” of the current collective scope of the MNC (Pearce, 1999). In his study Pearce (1999) pointed out that the attempt on the part of creative subsidiaries to enrich their knowledge scope should be balanced within the MNC collective technological trajectory through logical product evolution. One example of creative transition is the shift from ‘miniature replicas’ to ‘rationalized manufacturers’. On the one hand, it is reasonable to assume that rationalized manufacturers require different technical skills from those of the parent, since they are vertically differentiated from it. This suggests a relatively high level of capability on the part of rationalized manufacturers. However, the technologies used by affiliates are often older and more standardized than those employed in the parent company’s own operations, as described in product life-cycle models. This tends to reduce the need for independent capability (Vernon 1966). Moreover, vertical affiliates are strategically important in the production networks of MNCs and it is likely that rationalized manufacturers are tightly controlled by their parent to avoid delays, quality problems and other complications that might affect the entire production chain. Similarly, it is unclear exactly what innovative capability is required by horizontal

affiliates. They produce goods similar to the parent company, which implies relatively high capability, but their technologies are not necessarily of the latest vintage and they are rarely involved in product and technology development. Hence it is hard to predict which of these two affiliate types has the higher innovative capability. The multinational faces costs of transferring its know-how that are increasing with technological complexity. The role of the cost of technology transfer has been included in the theoretical model of multinational behavior and empirically tested by Keller and Yeaple (2008). They find that technology transfer gives rise to increasing marginal costs of serving foreign markets, which explains why multinational firms are often relatively more successful in their home market than in foreign markets. The model predicts that as the costs of technology transfer between multinational parent and affiliate increase, firms with complex production technologies find it relatively more difficult to substitute local production for imports from the parent. The empirical evidence also confirms that as the costs of technology transfer from the home market increase, affiliates concentrate their imports from the parent on technologically more complex intermediates.

It should also be pointed out that not all types of FDI lead to 'positive' spillovers. In some cases, FDI can limit domestic producers to low value-added activities or eliminate them altogether by relying on foreign suppliers (Dunning, 1994). FDI can also lead to a decline in the overall growth rate of the host economy by reducing competition or 'crowding out' local producers.

For a developed and advanced economy, like Japan, given the relative ease with which foreign technology can be bought transferred to Japan, FDI policy should rather aim at maximizing the *indirect* or spillover effect of FDI. To summarize the existing literature on FDI, the following characteristics of foreign affiliates are considered to be important for FDI spillovers: the position of the affiliate within MNC organizational structure, because it influences the level of autonomy of the affiliate to enhance its technological capability; the level of technological advance of the MNC in the domestic market (nationality or the origin of the MNC), the level of integration/embeddings into host economy, the prospect for the affiliate itself to benefit from externalities such as geographical location and the level of industrial concentration.

In this paper, we examine and systemize the depicted characteristics of foreign affiliates operating in Japan in 1999 and 2008. Data availability and methodology is presented in the next section.

3. Data Description and Methodology

The dataset used in the present research contains information on foreign affiliates operating in Japan in 1999 and 2008. It comes from the *Toyo Keizai's micro-data*. Toyo Keizai conducts its own surveys for this database and obtained some of the best coverage available of Japanese affiliates of foreign firms –*Kaigai Shinshutsu Kigyo Database* (see Ito and Fukao, 2005 for the description of the earlier version of the dataset). For comparability purposes all monetary variables have been denominated using purchasing power parity (PPP) from World Development Indicators (WDI) database.

The data contains information on the date of establishment of the affiliate, number of employees, paid in capital, foreign share in capital, industry at 2-digit level for manufacturing and services, export and import share, listed and non-listed status as well as full address and contact details of the affiliate.

The information on the mother company includes the nationality, number of shareholders and their participation in the company. Based on the nationality of the mother company six geo-economic groups have been formed to control for the origin of the capital: Europe and USA are the two largest and most distinctive groups. FDI from such emerging markets as Brazil, Chile, China, Egypt, Hungary India, Indonesia, Malaysia, Pakistan, Philippines, Russia, Thailand and United Arab Emirates (UAE) have been present in Japan and form the third group. The East Asian Tigers (South Korea, Hong Kong, Singapore and Taiwan) make up the fourth group, while the rest of Asia and the rest of the Americas are respectively the fifth and sixth groups.

The data on the nationality of the mother company is mostly missing in 1999. Accounting for non-missing observations, the distribution of the foreign affiliates operating in Japan by the country of origin is presented in Graph 3.

Table 3. Determinants of the Capital and Labour distribution in foreign affiliates operating in Japan, 1999 and 2008

The base line in geo-economic grouping is USA.								
The rest of countries grouped as follows: Europe: {Sweden; Belgium; Czech Republic; Denmark; Finland; France; Germany; Greece; Iceland; Ireland; Italia; Lichtenstein; Luxemburg; Netherlands; Norway; Spain; Switzerland; UK; Israel}								
Americas: {Canada; Cayman Islands (UK); Virgin Islands (UK); Bermuda; Brazil; Ecuador; Jamaica; Papua New Guinea}								
Australia, New Zealand and the rest of Asia: {Fiji; Australia; New Zealand; Iran; Kuwait; Saudi Arabia; Sri Lanka}								
Emerging markets: {Brazil, Chile, China, Egypt, Hungary India, Indonesia, Malaysia, Pakistan, Philippines, Russia, Thailand and United Arab Emirates (UAE)}								
Asian Tigers {South Korea; Hong Kong; Singapore; Taiwan}								

As it can clearly be seen from the Graph that the number of affiliates has increased between 1999 and 2008, especially due to the increase in the population of affiliates from the USA and Europe, which has doubled during the period. At the same time, the number of affiliates from the neighboring Asian Tigers' countries has increased five-fold from 58 in 1999 to 292 in 2008. During this period, the population of foreign affiliates from emerging markets has increased from 23 to 131. Observing this pattern of dynamics during 1999-2008 it will be interesting to see if this increase in population leads to a similar developments in terms of the capital and the number of jobs these affiliates bring to Japan.

To test the hypothesis of the determinant factors influencing the size of foreign affiliate, a number of independent variables have been created. To capture the importance of the Jacobian spillover effect, a city-dummy has been created as binary variable equal to “unity” for affiliates that are in Tokyo and “zero” elsewhere. The majority of affiliates are based in Tokyo (more than 75% in the whole sample), while the number of affiliates increased in both Tokyo and non-Tokyo area from 1999 to 2008. In graph 4 geographical distribution of foreign affiliates operating in 2008 in Japan is mapped. As the graph shows, foreign affiliates tend to choose location in big cities. Nevertheless, almost every prefecture in Japan has a foreign affiliate. How significant the role of location on the amount of capital and labor attracted by different foreign affiliates in Japan will be revealed later using regression analysis.

Involvement in trade is based on the information on the extent of affiliates involvements in export and import activities. Four size groups have been assigned in accordance with international classification, as follows: micro – fewer than 10 employees, small – fewer than 50 employees, medium – fewer than 100 and big defined as 100 employees or over.

Table 1 presents the distribution of foreign affiliates in manufacturing and service sectors among different size-groups. As more affiliates are created in service sectors (5037 out of 6632) the majority of *manufacturing* foreign affiliates are big non-SME plants (48.28), while the largest share of *service* affiliates are small (36.17%).

Table 1. Descriptive statistics on the distribution of foreign affiliates operating in Japan in year 1999 and 2008

Groups/Industry type	Services		Manufacture		Total
	Number of affiliates	Share in total number	Number of affiliates	Share in total number	
non-SME	1,522	30.22%	770	48.28%	2,292
micro	1,118	22.20%	176	11.03%	1,294
small	1,822	36.17%	404	25.33%	2,226
medium	575	11.42%	245	15.36%	820
Total	5,037	100%	1,595	100%	6,632

To explore the structure of this relatively large dataset and characterize the variability among observed variables in terms of a potentially lower number of unobserved variables (called factors) *factor analysis* is used. Each component's *eigenvector* or *characteristic vector* is defined. Based on the Keizer rule, the number of factors with an eigenvalue greater than unity will be left to perform the principal component analysis and rotation of the matrix. The identified underlying groups of factors are grouped into an empirical model, which can be presented as follows:

$$\begin{Bmatrix} \text{Number of employees} \\ \text{Paid in capital} \end{Bmatrix}_{i,c,t} = f(\text{Affiliates Characteristics}, \text{Headquarter Characteristics}) \cdot \epsilon_{i,c,t}$$

where subscript i, c, t refer to respectively industry, country and year. The dependent and independent variables are entered in logarithmic terms.

To estimate the empirical model, a seemingly unrelated regression (SURE or SUR) has been used. SURE regression is characterized by joint estimation of several regression models, each related because the error term of each regression may be correlated. Estimating a SURE regression for the three dependent variables together - productivity, number of affiliates and returns on patents and license –allows the error term ϵ_1, ϵ_2 and ϵ_3 to be correlated and the full variance-covariance matrix of the coefficients is estimated using the asymptotically efficient, feasible, generalized least-squares algorithm described in Green (2003, pp. 340-362) and in the STATA Manual (2007, pp.337-344).

The Breusch-Pagan test of independence suggests that we can reject the hypothesis that the correlation of the residuals in the three regressions is zero^{vi}. This result motivates the choice of the SURE model over the main alternative: independent panel regressions.

4. Results discussion

To study the patterns of relationship among variables, with the goal of exploring the nature of the variables, we first turn to factor analysis. The results of principal-component factor analysis are presented in table 2.

Table 2. Results of Factor analysis/correlation: Eigen value and Rotated factor loadings (pattern matrix) and unique variances

Variables	Eigenvalue	Factor1	Factor2	Factor3	Factor4	Factor5	Uniqueness
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)

Note: model is estimated using principal-component factors

The first column of Table 2 presents the results of the first step of the factor analysis, which estimates the eigenvalue of each variable. Based on this information, the number of factors chosen for further analysis is based on the Keizer rule, which specifies that those factors with an eigenvalue greater than unity should be preferred. In our case, five factors have been chosen and the results of the rotated matrix are presented in Columns 3-8.

The first group of factors is formed by such variables as paid-in capital, number of employees and SME category indicator and relates to the size of foreign affiliates. Since there is no other indication of the value of FDI in terms of R&D or patterns in the analysed dataset, this group of factors will be used as a proxy for the activity of foreign affiliates operating in Japan. These variables form the core of FDI policy, in terms of government's orientation towards maximizing the capital, technology and skills embedded in employees. In the next step, these variables will form a dependent variable and the model described earlier will be estimated, using the simultaneously unrelated regression analysis discussed previously.

The level of foreign share and status of the firm (whether it is listed or not listed) form the second, financial, group of factors. In column 5, the third group of factors underlying the organizational structure of the foreign affiliates was significant – vertical affiliation (whether affiliate operating in Japan is in the same industry as the mother company abroad) and the geographical location. The fourth group of factors were those related to trade: the share of exports and imports in total sales. This group of factors scored high. And the final, fifth, group is somewhat vaguer, related as it is to geography. It focuses on the country of origin of the parent company, (whether the FDI comes from the developed or the developing world,) and the location of the affiliate (whether the foreign affiliate is based inside or outside of Tokyo).

In the first step, the determinants of the capital/labour ratio are examined. The results are presented in Column 2 of Table 3. The results suggest that the capital/labour ratio in foreign affiliates operating in Japan is higher in the smaller establishments as dummies for all three types of SMEs (micro, small and medium) are positive (relative to the non-SMEs, which are used as a base line here) and highly significant. Affiliate age has a negative impact on capital intensity. At the same time dummy variable for the year 2008 is positive and significant, implying that in 2008 foreign affiliates had a higher capital labour ratio than in 1999. This controversy is partially explained by the next set of regressions, where the effects on capital and labour have been separated into two regressions. These results imply that foreign affiliates operating in Japan tend to become less capital intensive with age and, as they grow in terms of number of employees, they attract less capital relative to the labour force. In other words, the number of employees relative to the capital is higher. These results may be a reflection of the policy of lifetime employment so widespread in Japan. As long as a foreign affiliate is new and employs an efficient amount of workers, capital/labour ratios remains relatively

high. But over time, the establishment finds it difficult to react adequately to changes in market conditions by reshuffling the skills of its workers: e.g. by dismissing obsolete labour and taking on employees with the relevant skills needed. Instead, the foreign affiliate is forced to keep the old employees and hire new ones at the expense of a more efficient balance of capital and labour. The policy of a lifetime employment has been discussed by many other researchers before (see Ito and Fukao, 2004) and the results of our research suggests that foreign affiliates operating in Japan are not immune to the economic consequences of this policy, either.

Interestingly, the capital/labour ratio is significantly higher for affiliates originated from Europe and the East Asian Tigers (South Korea, Hong Kong, Singapore and Taiwan). This is especially important, as the number of affiliates from these two groups plus the USA have been growing significantly from 1999 to 2008, as has been shown in Graph 3. At the same time, it is not clear from the first model whether the determinants (independent variables) are specific to the capital/labor ratio distribution (dependent variable) or differ for capital and labor distribution. Keeping this point in mind, regression analysis has been applied for the amount of capital and labor as dependent variables, using the seemingly unrelated regression equations (SURE) model. The results in Columns 3 and 4 of Table 3 support the previous findings that older establishments tend to hire significantly more employees. The amount of capital attracted by foreign affiliates in 2008 is statistically significantly higher than it had been in 1999.

Interestingly, foreign affiliates from Europe, emerging economies and the East Asian Tigers are smaller in terms of number of employees than American affiliates. It is striking that, as noted before, the affiliates from Europe and South Korea, Hong Kong, Singapore and Taiwan tend to be smaller in size but have statistically higher capital/labor ratios than their American counterparts. These results suggest that the neighboring Asian countries, which have experienced very rapid and dynamic development, have expended the bulk of their capital recently. For Japan, this can be viewed as a reliable source of high-quality investment and the prospects for further cooperation at the regional level should become a policy objective in the near future. Among the trade indicators, the coefficient for imports suggests that the more foreign affiliates rely on imports, the lower the capital intensity is and, since this result holds strongly through the rest of the regressions where capital and labor have been used separately as dependant variables, the lower amount of capital and labor is attracted by foreign affiliate. One of the reasons for this outcome is that the import intensity of the foreign affiliate might indicate strong ties with the traditional suppliers instead of installing vertical and horizontal linkages with local producers. This feature of foreign affiliates activity in Japan is not surprising, as widespread *keiretsu* style relationships with suppliers and customers can be hard for foreign firms to break into. On the other hand, the barriers to foreign affiliates seeking to integrate themselves with the Japanese economy, whether those barriers be cultural or economic, have a negative impact on the Japanese economy, reducing the potential spillover effect of FDI. The positive role of linkages with local firms has been widely discussed in the FDI literature (see Rodríguez-Clare, 1996, Smarzhinska, 2004). The necessity of tightly embedding foreign affiliates within the host economy stems from the role linkages play as channels for knowledge exchange via the introduction of new standards and the learning involved in the process of technology adjustment to the needs of production.

The trade behavior of foreign affiliate is an aspect of the organizational structure of the MNC. As was pointed out in the literature review (White and Poynter 1984), it is possible to distinguish between different types of affiliates depending on their role in the MNCs' international production networks. In the case of foreign affiliates operating in Japan, it was possible to distinguish between vertical and horizontal foreign affiliates. For Japan as a host country seeking to maximize spillover effects from FDI, the ideal scenario would be for foreign affiliates to go through a creative transition - shifting from 'miniature replicas' to 'rationalized manufacturers'. Rationalized manufacturers require different technical skills from those of the parent MNC, since they are vertically differentiated from it, which implies a relatively high level of capabilities on the part of the rationalized manufacturers (see the literature review above).

However, testing the hypothesis that vertically integrated foreign affiliates have higher technological capabilities leads to negative results. Contrary to expectations, regression analysis suggest that vertically integrated affiliates in both service and manufacturing firms tend to have significantly less capital and fewer employees than their horizontally integrated counterparts.

These results have to be treated with extra caution, as the value of capital and the sheer number of employees is far from been an optimal proxy for the technological capabilities of affiliates. Further analysis on innovative activity and productivity performance of foreign affiliates is needed before definitive conclusions can be drawn.

Moreover, the currently available data on foreign affiliates in Japan does not allow us to distinguish between different types of affiliates within the broad categorization into those with vertical and horizontal organizational structures. Additional data would shed more light on the nature of the relationship between headquarters and the extent of autonomy that foreign affiliates operating in Japan have. Given the presently available data, we can go no further in interpreting these results than to point out that, compared with horizontal affiliates, their vertical counterparts do not possess more capital and employees, likely due to some as yet unobserved difference between different types of horizontal and vertical foreign affiliates. Even though foreign share does not play a significantly positive role in the capital/labor ratio of affiliates (column 2) it is significant for the amount of capital the parent MNC brings into Japan and for the number of employees at work in the foreign affiliates (Columns 3 and 4). This result is mainly driven by manufacturing affiliates (Columns 5 and 6). The number of shareholders also plays a significant positive role for both services and manufacturing foreign affiliates, but whether or not a company is listed is not significant in most of the models, apart from column 5, where it plays a significant positive role in the amount of capital of manufacturing foreign affiliates have. These results suggest that foreign affiliates operating in Japan tend to be bigger in terms of capital and number of employees with the higher number of shareholders and greater foreign share, especially so in the manufacturing sector, where firms with higher amounts of paid-in capital tend to be listed in the stock exchange as well.

Furthermore, in this first set of regressions the Manufacturing dummy, an indicator that the foreign affiliate belongs to the manufacturing industry (leaving services as a base for comparison), scores positively and significantly, indicating that the establishments in manufacturing industries have higher capital intensity as well as employing more capital and labor. This result motivated the further division of the sample into subsamples of manufacturing foreign affiliates and their counterparts operating in service sectors as comparison of the pattern of two distinctive groups can shed light on otherwise unobserved relationships.

The difference can be observed by comparing Columns 5 and 6 (subsample of manufacturing firms) with Columns 7 and 8 (subsample of firms service sectors). The age of the foreign affiliate is positively related to the size of the foreign affiliate both in service and manufacturing sectors. Nevertheless, age is not significant for capital formation in the service sectors (Column 7) and the dummy for 2008 in the subsample of foreign affiliates operating in the service sectors is significantly high. This indicates that significantly (statistically) more capital has been attracted by the service sector foreign affiliates in 2008 than in 1999, while no significant difference is observed among manufacturing affiliates.

An interesting distinction can be observed in the role of exports, with manufacturing exporters tending to have higher capital, while foreign affiliates involved in export activity in the service sector are relatively smaller both in terms of capital and number of employees.

For Japan, FDI in both the manufacturing and service sectors are important due to the boost in competition they bring, and due to other sources of the potential spillover effects (see Aitken and Harrison, 1994, Blomström and Kokko, 1998). The government has historically supported export activity of firms operating in Japan and the positive role of export activity has been recognized on many levels. At the same time, our findings suggest that different mechanism are involved in the export activity of foreign affiliates in the service and manufacturing sectors. While younger and more dynamic small firms tend to be more competitive than their larger counterparts within the service sector, older and more capital-intensive firms in the manufacturing sectors tend to break export barriers more easily in Japan. Some of the foreign affiliates are established in Japan specifically for the purpose of exporting - so called "born to be global" affiliates - and therefore often carry the legacy of strong technological and organizational back-up from the experienced mother company. Exports have been recognized as one channel for the spillover of organizational and technological knowledge (Bernard et al., 2005, Aitken *et al.*, 1997; Greenaway *et al.*, 2004, Aw et al., 2007, 2008, 2009) to the domestic firms. Therefore, the international activity of foreign affiliate in connection with productivity of domestic firms needs to be studied further.

5. Conclusions

While government efforts and 'pushes' come and go, the level of FDI inflows into Japan fluctuates around zero and has remained at the very bottom of international comparisons among developed nations for many years. Among many others, one way to look for an explanation for the low level of FDI is to analyze the pattern of FDI that Japan has already been hosting.

As our data suggests, the number of foreign affiliates in Japan has increased from 1999 to 2008, especially due to the increase in the population of affiliates from the USA and Europe, which has doubled during these years. At the same time, the number of affiliates from the neighboring East Asian Tigers has increased five-fold, alongside the population of foreign affiliates from emerging markets, which has likewise grown rapidly. In order to identify the pattern of FDI behavior that might be observed in the future, firm-level data has been used to test whether the pattern of increasing population of foreign affiliates is similar the pattern of developments in terms of the capital and the number of jobs these affiliates bring to Japan.

In the first step, we examined the determinants of the capital/labour ratio, with the results suggesting that the capital/labour ratio of foreign affiliates operating in Japan is higher in smaller establishments relative to non-SMEs. The age of the establishment has a negative effect on capital intensity, implying that foreign affiliates operating in Japan tend to become less capital intensive over time and that, as they grow in terms of number of employees, they attract less capital relative to the size of the labour force. These results may be a reflection of the policy of lifetime employment so widespread in Japan. With time, the establishment finds it ever more difficult to adapt to the changes in the market by changing the mix of skills among its employees. Instead, the foreign affiliate is forced to keep its legacy employees as it hires new, leaving it with an inefficient capital/labour ratio. Lifetime employment has long been a controversial topic in Japan (see Ito and Fukao, 2004). Our results suggest signs that foreign affiliates operating in Japan are not immune to the economic consequences of this policy.

While the age of foreign affiliates is positively related to the size of the foreign affiliate, both in service and manufacturing sectors, age is not significantly related to capital formation in the service sectors. Our results also indicate that statistically more capital has been attracted to the foreign affiliates in 2008 than in 1999 in the service sectors, while no significant difference is observed in manufacturing affiliates.

An interesting distinction can be made with regard to the role of international trade in the distribution of foreign capital. Manufacturing exporters tend to have more capital, while foreign affiliates in the service sectors involved in export activities are relatively smaller both in terms of capital and of number of employees. The results suggest that the more foreign affiliates rely on imports, the lower their capital intensity is and the less capital and labor they attract. One of the reasons for this outcome may be that the import intensity of the foreign affiliate indicates strong ties with the traditional suppliers in place of vertical and horizontal linkages with local producers within Japan.

While the existing data on the activity of foreign affiliates in Japan does not allow us to distinguishing between different types within vertical and horizontal organizational structure, our analysis is limited to the interpretation of the vertical vs. horizontal status of the affiliate. One of our findings suggests that, compared with horizontal affiliates, their vertical counterparts do not possess more capital or employees. Due to the inability to observe key differences within affiliates' organizations and in terms of the level of autonomy they enjoy within their respective MNCs, further studies on the importance of organizational structure on the performance of foreign affiliates are needed.

It is interesting to note that the capital/labour ratio is significantly higher for affiliates originating from Europe and the East Asian Tigers (South Korea, Hong Kong, Singapore and Taiwan). This is especially important, as the number of affiliates from these two groups, plus the USA, grew sharply between 1999 and 2008 (see Graph 3).

For Japan, the recent expansion of Asian capital abroad can be viewed as a reliable source of high-quality investment. The search for prospects for further cooperation on the regional level should become a key objective for Japan in the near future.

End Notes

i "Japan as number three. Watching China whizz by" *The Economist*, Aug 19th 2010

ii When the Commodore of the United States Matthew Perry forced open Japan in 1854, the country was soon prompted to sign the "Ansei Treaties" (1858). The series of treaties between East Asian countries and the West was called 'unequal' largely due to the fact that they were signed in the wake of various military failures and effectively forced their rulers to abandon the monopoly on trade. For example, the most important points of these "Ansei Treaties" (which was a series of treaties between Japan and five nations – Holland, England, France, Russia and US) are: opening such cities as Edo, Kobe, Nagasaki, Niigata, and Yokohama's as ports to foreign trade; fixed low import-export duties, subject to international control that deprived the Japanese government control of foreign trade and protection of national industries; ability of foreign citizens to live and trade at will in those ports (with the exception of the opium trade, which was successfully resisted); it also forced Japan to exchange diplomatic agents and accept a system of providing protection and responsibility over foreign residents to the laws of their own consular courts, rather than the Japanese court system (Auslin, 2004).

iii In January 2003, for example, Prime Minister Koizumi announced a goal to double the stock of FDI in Japan by 2008.

iv Other more recent international trade models incorporating firm-level heterogeneity also include Bernard *et al.* (2003) based on Ricardian differences in technological efficiency; Helpman *et al.* (2004) explicitly comparing exporting and outward FDI as alternative modes of entry; Yeaple (2005) focusing on heterogeneous competing technologies, trade costs and labour skills; Bernard *et al.* (2007) drawing on heterogeneous productivity; and Aw *et al.* (2007, 2008, 2009) adding a new dimension of R&D to the export-productivity debate.

v For evidence and more discussion on spillovers being spatially bounded, see Thornton and Flynne (2003); Bottazzi and Peri (2003); and Baldwin *et al.* (2008). Recently, Peri (2005) used patent data for a panel of 113 European and North American regions over 22 years, finding that the externally accessible stock of R&D had a positive impact on firm innovation but that only about 20 percent of average knowledge is learned outside the region of origin and only 10 percent outside the country of origin. In contrast, Lehto (2007) used R&D data for Finnish firms and found that only when other firms' R&D is located in the same sub-region is there any positive spillover effect. On this evidence, R&D spillovers appear to be localised. However, there are also studies that find stronger support for international knowledge spillovers, rather than localised spillovers. These emphasise transmission through international trade, FDI, international technology transfer, and other forms of internationalisation (e.g. Gong and Keller, 2003; Niosi and Zhegu, 2005)

vi It was also confirmed that the correlation of the residuals of the regression on the returns on patents has lowest correlation with the residuals from the other two models. Nevertheless, running this regression independently reduces the overall r-squared and therefore the joint SURE model has been preferred.

Stock volatility and pension funds' holdings in an individual capitalization-based system

Viviana Fernandez, vfernandez@ing.puc.cl

Universidad Católica, Chile

Abstract

The aim of this article is to discuss the empirical relation between volatility and pension fund holdings in Chile, a pioneer of an individual capitalization-based pension system. Specifically, we test for the feed-back effect between pension funds and stock return volatility by means of Granger causality and Arellano-Bond regressions for a dynamic panel. Discussion of this topic has been provided for the United States and other economies from the mid 1990's onwards (e.g., Sias 1996; Del Guercio 1996; Eakins, Stansell, and Wertheim 1997; Faugère and Shawky 2003; Binay 2005; Nagel 2005).

To this end, we gathered data on pension fund holdings for 42 firms which actively traded on the Santiago Stock Exchange between December 2002 and July 2008. Such holdings were computed based on information gathered by the Superintendencia of Pension Funds on multi-funds A, B, C, and D, established in Chile in September 2002.

Our estimation shows that there are feed-back effects in both directions. Specifically, our results show that an increase in pension funds' stock holdings translates into more stock return volatility. This finding is congruent with Sias (1996)'s. The feedback sign from volatility to pension funds' holdings found in the data is less clear-cut, as it may be either positive or negative. Our evidence, however, suggests that it is more likely that an increase in volatility leads to a decrease in pension funds' holdings. This would be indicative of pension funds' preference for safer stocks, as previously reported by Faugère and Shawky (2003) for a market decline.

Keywords: pension funds, stock return volatility

Introduction

Over the past twenty years, pension funds have played an increasingly important role in Chile's financial market. Indeed, in November 1980 the pension system in force in Chile at that time was reformed by Decree-law (D.L.) No. 3,500, establishing a new pension system for elderly retirement, invalidity and survival based on individual capitalization. The Chilean Pension System was essentially designed to ensure retirees a stable income, which is related to the immediately past salary they earned during their working lives. The Pension System is managed by private entities, known as Pension Fund Administrators (AFP). These institutions are limited companies, whose sole purpose is the administration of a pension fund and other activities strictly related to pension management, in addition to granting and administering provisions and benefits established by law.

Nowadays, pension funds are authorized to invest their funds on securities issued by the Central Bank of Chile, Retirement-adequacy Bonds (*Bonos de Reconocimiento*) issued by Chile's Treasury; instruments issued by domestic financial institutions, such as deposits, mortgage notes, bonds and equity securities; bonds of public and private companies; shares of listed companies, shares of listed real-estate companies, shares of investment and mutual funds; short-term debt instruments; and, foreign financial assets. The later include foreign debt obligations issued or guaranteed by foreign states, foreign central banks, foreign banks or banking institutions; bonds of foreign companies; shares of foreign companies and banks; shares issued by mutual funds and foreign investment funds; short-term debt obligations issued by urban districts, regional states or local governments; bonds convertible into shares issued by foreign companies; structured notes issued by foreign entities, among others.

Law No. 19,795, dated February 28, 2002, introduced a system of five multi-funds (A-E), which differ primarily in the proportion of their financial resources invested on fixed-income securities. Fund type A has the smallest share of resources allocated to such securities, which gradually increases in Funds B, C, D and E. To

illustrate, as of December, 31, 2009, the share of domestic and foreign fixed-income securities in funds A, B, C, D, and E was 19.8, 39.0, 59.1, 79.4, and 98.4 percent respectively.

In general, funds A and B involve a higher risk-return relationship, relative to funds C, D, and E, given that more resources are allocated to equity. However, both funds aim at maintaining adequate diversification to mitigate the borne risk. In particular, the share of domestic and foreign equity in fund A ranges between 60 and 80 percent, whereas in fund B, it ranges between 40 and 60 percent. By contrast, the upper bound for equity in fund E is merely 5 percent. Multi funds also differ in their share of foreign assets. As of December, 31, 2009, the share of foreign securities in funds A, B, C, D, and E was 70.8, 52.5, 35.0, 25.0, and 3.6 percent, respectively.

One issue analyzed by the extant literature on portfolio asset allocation of institutional investors is whether they are attracted to less-risky assets. In particular, some articles have focused on testing the prudent man hypothesis in the U.S. market. The prudent man rule is drawn from the standard of reasonable care of the traditional trust law, which requires that a fiduciaryⁱ behaves faithfully and discreetly, based on his/her observation of how men of prudence, discretion and intelligence handle their own affairs involving the permanent disposition of their funds (e.g., Droms 1992). Some examples of this line of research are Del Guercio (1996), Sias (1996), Eakins, Stansell, and Wertheim (1998), Gompers and Metrick (2001), and Faugère and Shawy (2003).

The aim of this article is to study the feed-back effect between stock return volatility and pension funds' stock holdings in Chile, which pioneered private capitalization of retirement funds in the early 1980's. To this end, we gathered data on pension funds' holdings of 42 firms which actively traded on the Santiago Stock Exchange during the December 2002-July 2008 period. Such holdings were computed based on information of multi-funds A, B, C, and D, established in Chile in September 2002, and supplied by the Superintendence of Pension Funds. In addition, and in order to provide some background information on the multi.-fund system, we processed and present some figures on the portfolio composition of multi-funds by instrument type, financial sector, and economic sector for the May 2001-June 2008 period.

Our work contributes to the extant literature in two ways. Firstly, to our knowledge, this is the first study of its kind for an emerging country, which, in addition, was the first one to introduce an individual capitalization-based system, as opposed to a pay-as-you-go one, two decades ago. Secondly, our empirical work is based on Arellano-Bond's panel data technique, which allows us modeling properly the feed-back effects between stock volatility and pension funds' holdings in a dynamic setting.

This article is organized as follows. Section 2 presents a literature review of the main articles devoted to study the relation between stock market volatility and pension funds' holdings. Section 3 in turn reports some statistics of the Chilean multi-fund system in what regards to average portfolio composition of multi-funds by financial instruments and economic sector. Section 4 presents an empirical analysis of the relation between pension funds' stock holdings and stock volatility in Chile based on our sample of 42 firms. Finally, Section 5 summarizes our main findings.

Literature review

As previously mentioned, one strand of the literature has focused on testing the prudent man hypothesis in the U.S. market (e.g., Del Guercio 1996, Sias 1996, Eakins, Stansell, and Wertheim 1998, Gompers and Metrick 2001, and Faugere and Shawy 2003).

In particular, Sias (1996) conjectured three reasons why institutional investors might be attracted to less-risky assets. First, many of them are subject to the prudent man's rule. Second, institutional investors' information gathering may be less costly and less subject to processing errors. Third, institutional investors may be more rational and, hence, less susceptible to fads or noise trading. To his surprise, Sias found that institutional investors are associated with riskier securities. Sias interpreted his finding of a contemporaneous and positive co-movement between volatility and institutional holdings as congruent with two hypotheses. One of them is that institutional investors may be attracted to riskier assets because they think such assets may outperform market benchmarks in the future. The other hypothesis is that institutional investors may play a destabilizing role in that an increase in institutional holdings may result in an increase in market volatility. Sias found support for the latter.

Sias gathered weekly returns, annual institutional holdings, and annual market capitalization for all securities listed on the NYSE from 1977 to 1991. In order to test whether more volatility attracts institutional investors, Sias regressed the fraction of shares held by institutional investors in year t on the fraction of shares held in $(t-1)$, the return over $(t-1)$, and the change in the natural logarithm of volatility from $(t-2)$ to $(t-1)$:

$$\text{Inst. Own}_t = \beta_1 + \beta_2 \times \ln(\text{volatility}_{t-1}) + \beta_3 \times (\text{Inst. Own}_{t-1}) + \beta_4 \times \text{return}_{t-1} + \varepsilon_t \quad (1)$$

Sias concluded that, in eight out of the fifteen sampled years, β_3 was negative and statistically significant, which gave little support to the first hypothesis.

In order to test the second hypothesis, Sias estimated the following regression model:

$$\ln(\text{volatility}_t) = \beta_1 + \beta_2 \times \ln(\text{volatility}_{t-1}) + \beta_3 \times (\Delta \text{Inst. Own}_{t-1}) + \beta_4 \times \text{return}_{t-1} + \varepsilon_t \quad (2)$$

He found that the coefficient on the lagged change in institutional holdings, β_3 , was positive and statistically significant in every sampled year. Therefore, the evidence favored the hypothesis that an increase in institutional holdings induces an increase in volatility.

Eakins, Stansell, and Wertheim (1998) in turn investigated the relation between the level of institutional ownership and some firm specific factors: beta, the current ratio (CRNT), debt to asset ratio (DTOA), a dummy variable that takes on the value of 1 if the firm pays dividends (DIVDUMMY), the market value of outstanding shares (MRKVL), the price/earnings ratio (PE), a dummy variable that takes on the value of 1 if the firm is ranked by S&P (RANKED), the return on assets (ROA), the total asset turnover (TAT), and the turnover ratio (TRNOVR)—i.e., common shares traded annually/shares outstanding.ⁱⁱ

Eakins et al. speculated on the corresponding sign each coefficient should have. Regarding beta, they claim that it is unclear whether institutional investors should prefer low or high betas. Indeed, some empirical evidence shows that institutional investors are attracted to higher risk firms. However, such finding would be inconsistent with institutional investors' prudence. Therefore, in their view, the sign on beta is ambiguous. Regarding CRNT, if institutional investors act according to the prudent man hypothesis, there should be a positive relation between this firm factor and institutional ownership. DTOA in turn represents another risk measure and, similarly to beta, its sign can be either positive or negative. If institutional investors are concerned with return, more leverage will be appealing; otherwise, if institutional investors are guided by prudence, they should prefer firms with low debt ratios. Regarding DIVDUMMY, the literature suggests that dividends may be a vehicle to mitigate agency problems. In addition, dividend-paying firms are usually more mature and older, attributes that institutional investors would find desirable. Therefore, DIVDUMMY should be positively correlated with institutional ownership.

In turn, larger firms are usually perceived as less risky, as they have more analysts' coverage and better access to capital markets. Therefore, institutional investors should prefer larger firms. The price/earnings ratio in turn is determined in part by the stock riskiness and the firm's growth opportunities. Specifically, the P/E ratio is greater for less-risky stocks and/or firms with more growth prospects. Eakins and et al. conjecture that institutional investors will prefer firms with average P/E. As to RANKED, ROA, TAT, and TRNOVER, Eakins et al. argue that they should be positively associated with institutional ownership. In particular, ranked firms are subject to periodic assessment by outside analysts; a high ROA is indicative of greater operating efficiency and more effective management; a high TAT suggests that a firm assets are utilized efficiently; finally, a high TRNOVER will attract institutional investors because it will be generally associated with larger firms. And, the latter are usually acceptable to most investors. In addition, as institutional investors try to avoid exerting price pressure when trading, they will prefer firms with high turnover ratios.

Based on a sample of firms listed on the NYSE, the AMEX, and the NASDAQ, Eakins et al. conducted quintile regression analysis to determine the degree of co-movement of institutional ownership and the above-mentioned financial indicators. Their empirical results suggest that institutional investors prefer mid-range values of betas, CRNT, DTOA, MRKVL, ROA, TAT, and TRNOVR. Econometric estimation for the full sample

indicated that institutional ownership was positively associated with DIVDUMMY and RANKED, although rather weakly with the former. PE by contrast did not exhibit any explanatory power.

In a more recent study, Gompers and Metrick (2001) examined institutional investors' demand for firm characteristics in a sample covering the 1980-1996 period. Specifically, in the vein of Eakins et al. (1996) and Del Guercio (1996), they regressed institutional ownership on size (i.e., market capitalization), book-to-market, dividend yield, price per share, a dummy variable indicating whether the firm is included in the S&P 500, volatility of monthly returns, firm age, momentum, and turnover. The authors found that institutional investors prefer stocks with high liquidity and greater market capitalization. In particular, institutional investors' tilting towards large companies would explain the partial disappearance of the small-firm stock premium over time. Gompers and Metrick, however, did not find empirical support for the prudent-man rule as to the existence of an inverse and statistically significant relation between institutional ownership and return volatility.ⁱⁱⁱ

A study on the association between institutional ownership under market stress was conducted by Faugère and Shawky (2003). They found that, during the NASDAQ decline occurred between March and November of 2000, institutional investors preferred holding less-volatile stocks. Such finding would be indicative of institutional investors' greater sensitivity to downside risk relative to individual investors. In Faugère and Shawky's viewpoint, a more conservative attitude towards risk from institutional investors' side may be attributed to their fiduciary responsibilities.

Faugère and Shawky's empirical findings were based on two cross-sectional regressions for individual securities (i) in the NASDAQ and securities in the NYSE, which were used as a control group:

$$\text{Mean return}_i = \alpha_0 + \alpha_1 \times \text{Inst. Own.}_i + \alpha_2 \times \text{turnover ratio}_i + \varepsilon_i \quad (3)$$

$$\text{Std. dev.}_i = \beta_0 + \beta_1 \times \text{Inst. Own.}_i + \beta_2 \times \text{turnover ratio}_i + u_i \quad (4)$$

The reason for using the NYSE securities as a control group is as follows. During the 2000 sizeable market decline on NASDAQ, those stocks largely owned by institutional investors exhibited higher mean returns with lower standard deviations. Such regularity was not observed for the stocks listed on the NYSE. Therefore, Faugère and Shawky conjectured that institutional investors may be more able to handle downside risk than individual investors. Based on that observation, they fitted equations (3) and (4) to the NASDAQ and NYSE stocks for two sub-periods: March 29-July 31, 2000 and August 1-November 30, 2000. For the NASDAQ securities and for both sub-periods, Faugère and Shawky found a positive and statistically significant association between mean returns and institutional ownership and a negative and statistically significant association between standard deviation and institutional ownership. For the control group, by contrast, Faugère and Shawky did not observe a consistent and highly significant relation between institutional ownership and mean returns or standard deviation.

More recent literature on institutional investor holdings is provided, among others, by Binay (2005), who assessed the risk-adjusted equity investment of all institutional investors in the United States during 1981-2002; Nagel (2005), who analyzed short-sale constraints on institutional ownership; and, Chen and Hong (2006), who studied the association between institutional ownership changes and security returns around analysts' earnings forecast.

An overview of the Chilean multi-fund system in figures

Tables 1 and 2, and Figures 1 and 2 shed some light on the portfolio composition of the previously described funds A through E for the period May 2001-June 2008. The sample excludes the most recent global economic crisis, due to its impact on worldwide financial markets.

In particular, Table 1 shows that, on average, during May 2001-June 2008, fund C, the largest fund in terms of monetary holdings, held the greatest shares of financial instruments issued by domestic state-owned (i.e., The Central Bank of Chile, the Treasury, and *Instituto de Normalización Previsional* (INP)^{iv}, financial, and corporate financial institutions (64.71, 56.8, and 53.9 percent, respectively), and foreign institutions (41 percent) among all funds. The second fund in size, B, with USD 16,147 million administered, concentrated 21.1 percent of the

resources allocated to the domestic corporate sector (i.e., stocks and bonds), and 26.7 percent of the funds allocated to foreign assets.

Table 2 exhibits the share of domestic stocks and bonds in the multi-funds by economic sector. On average, 9 percent of fund A was allocated to stocks of the electric power sector during September 2002-June 2008. In turn, nearly 15 percent of fund E was invested on the service sector bonds during May 2001-June 2002. Overall, the fund invested primarily on domestic shares, and to the least extent on domestic bonds, was A (i.e., 35.5 and 3.29 percent, respectively, of the whole fund), while E exhibited exactly the opposite pattern (0 and 25.5 percent of the fund allocated to domestic stocks and bonds, respectively).

In contrast to Table 1, which shows the share of each fund by issuer type with respect to all funds, Figure 1 depicts the average portfolio composition of each individual fund for the sample period. For instance, funds A and E held, respectively, the greatest and smallest share of foreign assets (nearly 53 and 3.5 percent, respectively). In turn, funds A, B, and C maintained shares of over 20 percent in the corporate sector's stock and bonds, while fund E held about 44 percent of its overall investment in safe fixed-income securities issued by state-owned institutions.

Figure 2, Panels (a)-(e), provides more disaggregate information on the financial instruments that made up the alternative portfolio funds over the sample period. For instance, about 15 percent of fund E was invested on mortgage-backed securities, while such percentage only reached to 1.42 for fund A (Panel (a)). On the other hand, corporate stocks and mutual shares issued by foreign institution had more weight in fund A, followed by fund B. The investment allocated to commercial bank deposits, however, tended to be more even across funds, as Panel (e) shows.

Pension funds' holding and stock volatility: An empirical analysis

The data

In this section, we first concentrate on some statistics of the pension funds' holding of domestic stocks over the period December 2002-July 2008. Stock pension funds' ownership of a given stock, in a given month, is computed as the ratio of the amount of money invested by pension funds on such a stock to its market capitalization. The sampled firms are reported in Table 3. The first column shows the firm mnemonic, the second one provides the economic sector each firm belongs to, according to Economatica database^v classification, and the third column gives the Superintendence of Pension Fund Administrator (SAPF)'s sector classification. The latter is quite broad, so the second column is also included in order to rely on more information about the economic sector of each firm. For instance, AntarChile S.A is classified within the natural resources area by the SAPF, but it is indeed a holding company which invests on forestry and industrial companies.

The 42 firms were chosen so that their stocks were traded, at least, 50 percent of the business days within a month. Such a choice allowed us to rely on at least 10 observations to compute the monthly return volatility for each stock. Table 4 presents the mean, minimum, maximum, and standard deviation of the overall pension funds' ownership of the sampled firms.

As we can see, in terms of average ownership over December 2002-July 2008, the firms CTC-A and Entel (Telecommunications), Endesa (Electric power), Cristales, Concha & Toro and San Pedro (Industrial) stood out as the ones with shares of over 20 percent. By contrast, pension funds' ownership of Almendral and AntartChile (holding companies with investments on telecommunications and Natural resources, respectively), Santander Bank and LAN airline (services), and Gener (electric power) averaged figures of less than 2 percent.

For further illustration, Figure 3 depicts the evolution of pension funds' ownership of three firms over the sample period: Concha & Toro, LAN, and Vapores. As we see from Panel (a), pension funds' ownership of the former remained relatively stable, around its sample average of 22 percent. Panel (b) shows in turn that pension funds' holding of LAN exhibited an increasing trend from August 2006 approximately, to reach 6 percent by the end of the sample period. A very small percentage of pension funds' holding, prior to August 2006, explains the small sample average ownership of 1.5 percent. Finally, Panel (c) shows that pension funds' ownership of Vapores increased noticeably over the sample period, from 2 to 12 percent approximately.

Granger causality test

We next focus on the relation between stock return volatility and pension funds' holdings. As mentioned in the Literature review section, Sias (1996) examined the relation between institutional holdings and volatility, and found that institutional investors are associated with riskier securities.

As a preliminary approach, we plotted the contemporaneous stock return volatility against the one-month lagged pension funds' holdings for the panel of 42 firms previously described. As Figure 4 shows, there is some evidence of a positive correlation between the two variables. (The pair-wise Pearson correlation coefficient for the whole sample is 0.12). However, such a positive association may be somehow driven by the presence of some outlying observations.

In order to examine the causality between the two above-mentioned variables, we utilized the Granger-causality tool for a panel data set devised by following Hoffmann, Lee, Ramasamy, and Yeung (2005)'s approach. In particular, we considered four different estimators: pooled ordinary least squares (OLS), fixed effects (FE), pooled least absolute deviations (LAD)^{vi}, and Kim-Maddala (1992)'s random-effect (RE) model, discussed by Fernandez (2006). Fixed effects have the advantage of accommodating for omitted variables, but they are biased under a dynamic specification. Therefore, the Granger causality tests based on FE should be taken cautiously. Pooled OLS, pooled LAD, and Kim-Maddala's FE are consistent, provided that the equation error term is uncorrelated over time.

Table 5 reports pair-wise Granger causality tests. As we see, we reject the null hypothesis that pension fund holdings do not affect stock return volatility, but we cannot reject the null hypothesis conversely. In other words, based on Granger causality, we do not find support for the hypothesis of pension funds' preference for riskier stocks. That is to say, our evidence goes in line with Sias' findings.

Arellano-Bond regressions

In this section, we take a closer look at the relation between volatility and pension funds' holding by using Arellano-Bond (1991)'s dynamic approach to panel data modeling. In doing so, we also control for market capitalization (e. g., Faugère and Shawky 2003). We fit various regressions aimed at gauging the feed-back effect between market volatility and pension funds' holdings. Specifically, we concentrate on the whole sample and two economic sectors which gather a relative large number of sampled firms: Industrial and Services. We divide the whole sample and the two economic sectors into deciles when analyzing the feed-back between holdings and volatility. The decile segmentation allows us to calibrate the feed-back extent across firms of different sizes, as measured by market capitalization. Our results are reported in Tables 6 through 9. The figures in the tables are the p-value associated to each explanatory variable. The entries highlighted in grey indicate p-value less than or equal to 10 percent.

As can be seen, when using Arellano-Bond's technique and controlling for market capitalization, it becomes apparent the effect of volatility on pension funds' holdings. This is disagreement with our findings from Granger causality, which failed to detect a feed-back effect from volatility to pension funds' holdings. For instance, when focusing on the whole sample (Table 6 a)-b)), we find a contemporaneous or instantaneous effect of return volatility on pension funds' holdings in deciles 1 through 3 and deciles 8 and 10. There is also a lagged effect of volatility in deciles 2, 6, and 8 through 10. Conversely, when looking at the feed-back from holdings to volatility in the whole sample, we find a contemporaneous effect only in deciles 1, 6, and 10. Lagged effects are observed at deciles 1, 3, 4, 6, 9, and 10.

For the two economic sectors under consideration, we observe that the feed-back effect between volatility and pension funds' holdings is rather weak for the Industrial sector, whereas for Services, the statistical significance pattern resembles more closely that of the whole sample (Tables 7 and 8, respectively).

When looking at the sign of the estimated regression coefficients, our results show that for the whole sample an increase in pension funds' holdings translates into more stock return volatility, as documented by Sias (1996). The feedback sign from volatility to pension funds' holdings found in the data is less clear-cut, given that it may be positive or negative. The evidence, however, suggests that it is more likely that an increase in lagged volatility leads to a decrease in pension funds' current stock holdings. This pattern would be indicative of pension funds' preference for safer stocks, which is in agreement with Faugère and Shawky's evidence.

In other words, our results highlight that, in spite of their preference for low-risk stocks, pension funds may play a destabilizing role as being the source of more stock return volatility.

Conclusions

The aim of this article was to discuss the empirical relation between volatility and pension funds' holdings in Chile, a pioneer of an individual capitalization-based pension system. To this end, we gathered data on pension fund holdings for 42 firms, which actively traded on the Santiago Stock Exchange during December 2002 and July 2008. Such holdings were computed based on information of multi-funds A, B, C, and D, established in Chile in September 2002, and supplied by the Superintendence of Pension Funds.

Specifically, we tested for the feed-back effect between pension funds and stock return volatility by means of Granger causality and Arellano-Bond regressions for dynamic panels. Our results showed that there are feed-back effects in both directions. Specifically, we conclude that an increase in pension funds' holdings translates into more stock return volatility. The feedback sign from volatility to pension funds' holdings found in the data is less clear-cut. The evidence, however, suggests an inverse relation between the two variables, which would be indicative of pension funds' preference for safer stocks.

Table 1 Average portfolio composition of multi-funds: May 2001-June 2008

(a) Figures in millions of December 2008 USD

Fund	State-owned institutions	Financial institutions	Corporate sector	Foreign assets	Current assets	Total fund
A	371.8	2,028.0	2,503.1	5,979.6	16.4	10,898.8
B	1,659.1	4,325.3	4,101.3	6,033.6	27.4	16,146.7
C	9,847.3	13,777.2	10,467.0	9,262.7	89.6	43,443.7
D	2,636.1	3,462.0	2,073.1	1,236.4	24.8	9,432.3
E	702.5	664.6	260.2	87.9	6.0	1,721.2

(b) Percentage shares

Fund	State-owned institutions	Financial institutions	Corporate sector	Foreign assets	Current assets	Total fund
A	2.44%	8.36%	12.90%	26.46%	10.00%	13.35%
B	10.90%	17.83%	21.14%	26.70%	16.67%	19.78%
C	64.71%	56.80%	53.94%	40.99%	54.58%	53.21%
D	17.32%	14.27%	10.68%	5.47%	15.08%	11.55%
E	4.62%	2.74%	1.34%	0.39%	3.66%	2.11%
Total	100%	100%	100%	100%	100%	100%

Notes: (1) The figures were originally deflated by the Chilean CPI taking as a basis December 2008. Then they were transformed into US dollars by means of the average monthly exchange rate (CLP/USD) of December 2008. (2) Statistics for funds A, B, and D are available only from September 2002 onwards.

Table 2 Average percentage share of domestic stocks and bonds in total assets: May 2001-June 2008

Fund	Economic sector											
	Electric power		Telecommunications		Services		Industrial		Natural resources		All sectors	
	Stocks	Bonds	Stocks	Bonds	Stocks	Bonds	Stocks	Bonds	Stocks	Bonds	Stocks	Bonds
A	9.04%	0.60%	4.74%	0.08%	7.82%	2.07%	5.21%	0.13%	8.66%	0.41%	35.46%	3.29%
B	7.91%	1.49%	4.19%	0.18%	7.03%	4.91%	4.34%	0.38%	8.46%	1.15%	31.93%	8.11%
C	6.38%	2.98%	3.38%	0.49%	5.00%	7.73%	3.05%	0.79%	6.85%	1.97%	24.66%	13.96%
D	5.33%	3.44%	2.26%	0.54%	3.14%	10.29%	2.21%	0.96%	5.04%	2.51%	17.97%	17.73%
E	0.00%	5.15%	0.00%	0.82%	0.00%	14.95%	0.00%	1.57%	0.00%	3.03%	0.00%	25.52%

Note (1) Statistics for funds A, B, and D are available only from September 2002 onwards.

Table 3 Sampled firms

	Firm	Economic sector ⁽¹⁾	SAPF classification
1	AGUAS-A	Water, Sewage and Other Systems	Services
2	ALMENDRAL	Finance and Insurance	Telecommunications
3	ANDINA-A	Beverage Manufacturing	Industrial
4	ANDINA-B	Beverage Manufacturing	Industrial
5	ANTARCHILE	Other Financial Investment Activities	Natural resources
6	BANMEDICA	Offices of Physicians	Services
7	BANVIDA	Other Investment Pools and Funds	Services
8	BCI	Banks	Services
9	BSANTANDER	Banks	Services
10	CAP	Iron and Steel Mills and Ferroalloy Manufacturing	Natural resources
11	CCT	Tobacco Manufacturing	Industrial
12	CCU	Beverage Manufacturing	Industrial
13	CEMENTOS	Cement and Concrete Product Manufacturing	Industrial
14	CGE	Electric Power Generation, Transmission and Distribution	Electric power
15	CHILE	Banks	Services
16	CINTAC	Forging and Stamping	Industrial
17	CMPC	Pulp, Paper, and Paperboard Mills	Natural resources
18	COLBUN	Electric Power Generation, Transmission and Distribution	Electric power
19	CONCHATORO	Beverage Manufacturing	Industrial
20	COPEC	Gasoline Stations	Natural resources
21	CORPBANCA	Banks	Services
22	CRISTALES	Glass and Glass Product Manufacturing	Industrial
23	CTC-A	Telecommunications	Telecommunications
24	CTC-B	Telecommunications	Telecommunications
25	D&S	Other General Merchandise Stores	Services
26	ENDESA	Electric Power Generation, Transmission and Distribution	Electric power
27	ENERSIS	Electric Power Generation, Transmission and Distribution	Electric power
28	ENTEL	Telecommunications	Telecommunications
29	FALABELLA	Department Stores	Services
30	FASA	Health and Personal Care Stores	Services
31	GASCO	Natural Gas Distribution	Services
32	GENER	Electric Power Generation, Transmission and Distribution	Electric power
33	IANSA	Sugar and Confectionery Product Manufacturing	Industrial
34	INFORSA	Converted Paper Product Manufacturing	Natural resources
35	LAN	Scheduled Air Transportation	Services
36	MADECO	Steel Product Manufacturing from Purchased Steel	Industrial
37	PARAUCO	Real estate lessors	Services
38	QUINENCO	Other Investment Pools and Funds	Industrial
39	SAN PEDRO	Beverage Manufacturing	Industrial
40	SECURITY	Management of Companies and Enterprises	Services
41	SQM-B	Nonmetallic Mineral Mining and Quarrying	Natural resources
42	VAPORES	Deep Sea, Coastal, and Great Lakes Water Transportation	Services

Note: (1) Classification taken from *Economica*.

Table 4 Percentage of firm ownership by domestic pension funds: December 2002-July 2008

Firm	Mean	Std. Dev.	Min	Max
AGUAS-A	5.51%	0.66%	4.03%	6.35%

Endnotes

ⁱ A fiduciary is defined as a person who holds assets in trust for a beneficiary (www.wordreference.com)

ⁱⁱ Some of these explanatory variables were used in a previous study by Del Guercio (1996), who investigated the effect on prudent-man laws on the behavior of institutional investors. She concluded that banks managers choose the composition of their portfolio in such a way that stocks which are viewed as prudent and high-quality by courts received a much greater weight. The opposite was empirically observed for mutual funds. Del Guercio points out that this finding could explain why banks and mutual funds portfolios have performed differently over time. In addition, she found that banks' tilting toward S&P highly-ranked stocks translated into a higher demand for large-capitalization and low book-to-market ratio stocks. Such finding could be a driving force behind the role of firm size and the book-to-market ratio as risk factors, in addition to beta.

ⁱⁱⁱ Some weak evidence in favor of an inverse association between the two variables is reported in Table 5 of their article.

Credit quality and economic development in China

Abstract

China's economy has had significant growth rates in recent years: the banking system has been the main source of financing this process.

From a space viewpoint, the economic organization of China is described as a de facto federalism, in which each region can be considered as an autonomous economic entity: in China 59.7% of gross domestic product (GDP) is produced in the Eastern region, 23.2% is due to the Central region and 17.1% in the Western region.

There are significant differences also in the contribution of different sectors to national economic growth (tertiary sector accounts for 40% of GDP).

The aim of this research is to investigate the relationship between Chinese economic growth and bank loans, by regions and sectors, from 2003 to 2009.

The assumption is that the distribution and the quality of loans by banking system reflect the differences in development by regions and sectors in China.

In literature, the main contributions about the link between enterprises and banking system pay particular attention to the transformation of China since the '70s and the gradual systematic and institutional change from planned economy to market economy.

The methodology adopted is a linear regression analysis. Following the voluminous literature on economic growth, we make use of: as dependent variable, per capita gross domestic product; as independent variables, the ratio between loans and population, the ratio between the number of graduates in Regular Senior Secondary Schools and population. Besides, with the aim to consider the impact of credit quality on economic growth, we include in the set of independent variables even the ratio between non performing loans on total loans. Finally, to evaluate the phenomenon over time, we also introduced some dummy variables. All variables are on a provincial basis.

Data will be from National Supervisors and Bureau of Statistics publications.

Introduction

During a shutdown period for economic development and a global financial crisis, which was considered more serious than the crisis of 1929, China has continued to grow at rates of 9.5%, despite many internal contradictions and a financial system that, only recently, has undergone structural and regulatory changes.

The aim of this research is to investigate the relationship between Chinese economic growth and bank loans, by regions and sectors, during the period 2006-2008ⁱ. The economic growth experienced by China in recent years has affected all the three regions of the country, although the eastern one has grown at a rate much above the others. There are significant differences also in the contribution of the three economic sectors to national economic growth: the most productive economic sector is the secondary one, even if, all sectors contribute in supporting economic growth with an increasing level of productivity. The contextual assessment of the amount of loans granted by banking intermediaries shows, however, a greater weight of credit to the tertiary sector and to the eastern region. The quality of credit granted is improved in the last three years: the percentage of non-performing loans on total loans shows a significant reduction, in accordance with the policies of the Chinese Government. The assumption is that the distribution and the quality of loans by banking system reflect the differences in development by regions and sectors in China. So, we analyze the influence of bank loans on the formation of gross national product in the thirty-one Chinese provinces. In particular, we focused on credit quality, in terms of non-performing loans, assuming that,

in normal conditions of economic growth, if the level of non-performing loans is higher, than banks will be less willing to make new loans and this could impact on economic growth. However, in the case of China, which has a very high growth rate, it is reasonable to expect that the support to the country's economic growth by the banking system takes place through the granting of more loans that will be physiologically associated with even higher levels of risk. We also introduce a second variable: the level of education, because we believe that, in presence of higher levels of education, the degree of entrepreneurship and, therefore, the demand for credit and the local gross product increase.

The work is organized as follows: the next paragraph gives a brief account of the literature; then, the following paragraph is devoted to empirical verification. The last paragraph contains, finally, some reflections based on evidences obtained from research.

Literature review

It's possible to ideally divide into two periods the history of the economic development in China: a first phase, until the early '70s, marked by a so-called "*forced growth*"ⁱⁱ, in line with the dictates of Maoist economic conception (Kornai 1972), and a second phase, called "*export and investment – led*" (Charles & Karouni 2008), which began at the end of the '70s and still in progress.

In literature, the main contributions analyze the link between enterprises and banking system, with particular attention to the transformation of China since the '70s and the gradual systematic and institutional change (Charles & Karouni 2008) from planned economy to market economy (Chiarlone & Amighini 2007).

As an alternative to the interpretative key of the economic development strategy of China represented by the "*export and investment – led*", it was identified an approach of financial growth.

The role of financial institutions in China has proven difficult to assess. Checks on China were conducted using two main approaches: through the analysis of the causal relationship between finance and developmentⁱ and through cross-section surveys (Sanacuore 2008). Studies related to the first approach were on the basis of financial deepening indicators or using so-called "unconventional" approach, which pay attention to political and cultural factors (Iannini 2008). The cross-sectional surveys have, instead, based on the assumption that the economic organization of China, from a space viewpoint, is described as a *de facto* federalism, in which each region can be considered as an autonomous economic entity (Boyreau-Debray 2003). The finance-development nexus testing has led, in most cases, to conclude that China is a "counterexample" to evidences of substantial literature on the topic: despite the inadequate financial system and regulatory framework, in fact, China economic growth size is surprising (Allen 2005)ⁱⁱⁱ. Xiaoqiang Cheng & Degryse (2007), employing data for 27 Chinese provinces over the period 1995–2003, argue that banks have had a larger impact than non-banks on local economic growth as they benefited earlier and more profoundly from China's financial reforms than their non-bank counterparts. Some observers contend the Chinese legal system and formal financial sector are too weak to enforce sound governance, so the nexus of law, finance, and growth cannot hold (e.g. Allen, Qian & Qian 2005; Boyreau-Debray 2003). Others propose that banks in China, despite their relative weakness, contribute to growth (e.g. Hasan, Wachtel & Zhou 2006; Ayyagari, Demirgüç-Kunt & Maksimovic 2007): Liu & Li (2001) find that growth of provincial aggregate output is positively related to the growth in lending of the largest banks and self-raised funds; Baizhu Chen & Phillips (2004) find that provinces with more bank deposit to gross domestic product (hereinafter GDP) ratios tend to experience higher economic growth. The ownership structure of the banking system is one of the central elements in the relationship between banks and economic development in China. Through a soft control on state banks, China has been successful in financing public owned company, avoiding the collapse of many industries, with implications, however, adverse to the quality of loans (Boyreau-Debray 2003; Iannini 2008). The empirical results suggest that the credit disbursed by banking sector to the public one had a negative impact on economic growth, attributable to the obligation to support state-matrix enterprises, characterized by low profile of efficiency and

productivity (e.g. Firth, Lin Chen & Wong 2008; Phillips & Kunrong 2005). About the critical factors that affect the quality of financial intermediation, Démurger, Sachs, Woo, Bao, Chang & Mellinger (2003) and Iannini (2008) analyze the state of banking and financial regulatory systems, still far from the standards of advanced countries and the destination of flows from banking sector, markedly influenced by government authorities.

Although some authors question about the applicability of the concept of allocative efficiency in a transition country (Maswana 2005), there is no doubt that the privileged destination of bank credit to finance public companies has influenced the role of banking sector in supporting Chinese economic growth, as to bringing it closer to a political function (Iannini 2008). The braking effect of granting credit to public enterprises is also confirmed by cross-section investigations (Boyreau-Debray 2003).

At present, the banking system is the main source of financing in China (Ferri & Chiarlone 2007; Tong Li 2008), partly due to the limited development of alternative solutions (Hansakul 2006): the liquidity of the system and, therefore, the availability of resources to be allocated to credit, however, are assured by high levels of domestic savings, not pursued through an efficient management of intermediaries. The size of bank credit could become an endogenous source of weakness for the country (Moreno 2002): a structure of companies' accounts affected by the weight of financial costs and, on the other hand, banks' exposure to them could, in fact, trigger dangerous phenomena of "credit crunch" (Iannini 2008).

Following the studies focusing on the relationship between economic growth and banking sector in China, this paper is to address the topic on a regional and sectoral level.

Empirical analysis

The empirical analysis is divided into two parts: the first one, using a multivariate linear regression, looks at the influence on GDP exerted by the quantity and quality of bank loans and by the educational level of the population for the thirty-one Chinese provinces, during the three years from 2006 to 2008; the second one presents a descriptive analysis of the contribution of the three economic sectors to GDP formation.

Data and description of variables

The main purpose of our empirical research is to investigate whether the level of financial sector development and education influence the economic growth in China's regions.

Following the voluminous literature on economic growth, we make use of: as indicator of economic growth, per capita GDP in every province (gdp); as indicator of financial sector development, the ratio between loans and population per province (loans); as measure of the influence of human capital on growth we use the ratio between the number of graduates in Regular Senior Secondary Schools and population by province (scol). Besides, with the aim to consider the impact of credit quality on economic growth, we include even the ratio between non performing loans on total loans by province (npls).

The analysis refers to 31 China's administrative provinces for the period 2006-2008. The data is compiled from the China Statistical Year Book (2007-2009) and China Banking Regulatory Commission Annual Report (2007-2009). All monetary values are considered at current prices.

Model specification

This section presents the specification of our empirical model.

The equation of linear multiple regression is as follows:

$$\mathbf{y} = \alpha + \beta_i \mathbf{X}_i + \varepsilon \quad (1)$$

Where \mathbf{y} represents per capita gdp for each province, and \mathbf{X} is the vector of independent variables, in which we introduced two dummy variables (d2007; d2006), with the aim to analyze the phenomenon in three years:

- $x_1 = loans = \text{total loans/population}$;
- $x_2 = scol = \text{graduated in regular senior secondary school/population}$;
- $x_3 = npls = \text{non performing loans/total loans}$;
- $x_4 = d2007 = \text{dummy variable} = 1 \text{ if year} = 2007, \text{ else} = 0$;
- $x_5 = d2006 = \text{dummy variable} = 1 \text{ if year} = 2006, \text{ else} = 0$.

Table 1 presents summary statistics of the variables used in this paper. N refers to province-year observations, 31 administrative provinces (3 regions) during the period 2006-2008. gdp is expressed in thousands Rmb^{iv} per capita gdp per province; loans are in thousands Rmb per capita loans per province; scol is in thousands persons per province; finally, npls are in percentages of loans. The explanatory variables show a great deal of variation; the range indicates that there are some outliers (Beijing, Shanghai). However, in our opinion, these provinces are so important to the Chinese economy that cannot be excluded from the analysis. Table 1 shows a consistent difference among provinces, in terms of contribution of different provinces to national economic growth, and also in terms of education and dynamics of bank loans.

TABLE 1: SIMPLE STATISTICS

Variable	N	Mean	Std Dev	Sum	Minimum	Maximum
gdp	93	22.13876	13.91061	2059	6.07370	72.53609
loans	93	16.27639	19.52517	1514	0.05516	93.14954
scol	93	597.45987	154.55867	55564	284.80036	1600
npls	93	0.16397	0.83587	15.24930	0.01070	8.12000

Table 2 indicates a strong correlation between gdp and loans, while the correlation between gdp and scol is modest; npls is negatively correlated with gdp but, also in this case, the value is low. This fact means that, when non-performing loans increase, then GDP decreased (albeit modestly). This behaviour is contrary to our expectations for a country with a growth as high as China. However, it should be noted that the country has undergone a major redevelopment of credit due to the high level of non-performing loans in banks' balance sheets. Therefore, this correlation is probably more the result of government policy than the actual degree of risk aversion/attitude by banking system. The independent variables are poorly correlated among themselves.

TABLE 2: CORRELATION MATRIX

Pearson Correlation Coefficients, N = 93; Prob > r under H0: Rho=0							
	gdp	loans	scol	npls	year	d2007	d2006
gdp	1.00000						
loans	0.90764	1.00000					
	<.0001						
scol	0.09186	-0.09593	1.00000				
	0.3812	0.3603					
npls	-0.12156	-0.11392	-0.12769	1.00000			
	0.2457	0.2769	0.2225				
year	0.22481	0.02540	0.26647	-0.16295	1.00000		
	0.0303	0.8091	0.0098	0.1186			

Our model presents an R-square of 0.8823 and an Adjusted R-square of 0.8756 (Table 3); the F-test is significant. Overall, the model results are in line with our expectations. Parameter estimates present positive values for all variables, excluding for the two dummies which, in line with expectations, have negative values: this means that going forward over the years the GDP grows (Table 4). Even the coefficient for npls is positive, according with our

expectations, but the t-value is not significant. For this reason, we built the model also without the variable npls: the results show a slight decrease of R-square (0.8815) and a simultaneous slight increase of R-adjusted (0.8761), so we can conclude that the variable in question does not help to explain the model (Table 5 and 6).

The second part of this work takes into account data on the contribution of primary, secondary and tertiary sectors of economy to the formation of gross domestic product, in every province of China. The analysis is conducted using descriptive assessments, because the number of observations does not permit application of regression analysis, as in the previous case.

Graph 1 shows the percentages of gross regional product for each province (hereinafter: grp) on Chinese gross domestic product during the period 2006-2008. The Eastern region has the greatest impact on GDP in all the

three years. The most productive provinces are Guangdong, Shandong and Jiangsu. Provinces such as Beijing and Shanghai have a lower impact than expected: such data may be justified by the local presence of legal and administrative headquarters of many companies, whose manufacturing plant are located in other provinces. Less productive provinces are located in Western China: Tibet, Qinghai, Ningxia. These provinces are characterized by socio-political tensions or they are prevalently mountainous provinces inhabited by ethnic minorities and with an economy mainly based on agriculture.

Graph 2 points out that the distribution of gross regional product among the three strata of industries^v remains essentially stable for the three years in every region; this fact applies, in particular, to the secondary and tertiary sectors, while the primary sector follows a more different pattern across the regions: in the Eastern region, it increased in 2008, while it recorded a decrease in the Western region in the same year.

Table 7 presents summary statistics on grp by sectors during the period 2006-2008. The first column, for any year, shows that, on average, each province is eligible for the production of GDP to 3.23%, but with significant differences in every province, as shown by the minimum and maximum values (0.12 % and 10.91% in 2008); the standard deviation, in fact, has a value ranging between 2.71% and 2.78% in three years. This trend is confirmed in all the three years. The analysis by sector shows the contribution of each economic sector to the production of GDP by province: the greatest contribution, on average, is provided by the secondary sector, which is increased in the three years, while the primary and tertiary sectors reduced their contribution in three years (in average, by province).

Graph 3 shows the level of loans by economic sector in relation to total loans and the proportion of non performing loans to total loans by economic sector. It is clear that, in this case, although in all economic sectors non-performing loans have declined over the three years, the primary sector has the highest level of non-performing loans and it is also the sector that, in all three geographic regions, contributes less to the production of grp.

The tertiary sector has a higher level of loans and a lower rate of non-performing loans compared to the secondary one, but contributes less to the formation of grp. This could be explained by the ability of Chinese companies to finance themselves, mainly through exports.

GRAPH 3: LOANS AND NON-PERFORMING LOANS BY SECTOR, 2006-2008

Source: Our elaborations on data by China Banking Regulatory Commission.

Conclusion

In this paper we analyze the influence of bank loans and educational level on the formation of gross national product, distinguishing the analysis among the different administrative provinces of China. In particular, for bank loans we focused on credit quality, in terms of npls, assuming that, in the case of China, which has a very high growth rate, it is reasonable to expect that the support to the country's economic growth by the banking system takes place through the granting of more loans that will be physiologically associated with even higher levels of risk. The idea behind the introduction of a variable on the level of education, instead, is that in presence of higher levels of education also the degree of entrepreneurship increases. The statistical model shows good overall results and the analysis of individual parameters meets our expectations, with the exception of the variable npls, that doesn't help to explain the phenomenon. Regression analysis performed on provincial data confirm our expectations with regard to credit quality, but it demonstrates that the quality of bank credit is not a significant variable in explaining the

evolution of GDP, while the amount of credit and the educational level are statistically significant. A possible explanation could be found in the long-established presence of non-performing loans in Chinese economy, mainly because of the widespread practice among banks to extend credit to public enterprises without adequate analysis of creditworthiness. Recently, in addition, government policies have facilitated the reduction of non-performing loans. These two factors may have influenced banks' behaviour and, accordingly, the results of the survey. Possible further research could, therefore, consider the years to come: it is plausible that the weight of bad loans will be and the consideration, that intermediaries will have of them, will increase. Besides, the relationship between the variables could also be tested in other countries.

The second part of this work takes into account data on the contribution of primary, secondary and tertiary sectors of economy to the formation of gross domestic product, in every province of China. The distribution of gross regional product among the three strata of industries remains essentially stable for the three years in every region; this fact applies, in particular, to the secondary and tertiary sectors, while the primary sector follows a more different pattern across the regions. The primary sector has the highest level of non-performing loans and it is also the sector that, in all three geographic regions, contributes less to the production of grp. The tertiary sector has a higher level of loans and a lower rate of non-performing loans compared to the secondary one, but it contributes a little bit less to the formation of grp. This could be explained by the ability of Chinese companies to finance themselves, mainly through exports.

ⁱ In the first phase of this research, we decided to analyze a longer time period 2003-2009; however, due to the lack of some data, (particularly data of loans per provinces), we have fallen back on a shorter period, 2006-2008; besides, data for 2009 gross national product will be available by local authorities only since the spring of 2011: for that reason, this analysis will be subsequently updated. Finally, the statistical model chosen, in which two dummy variables were introduced to take into account the years, it would be overly complex without great advantages in terms of statistical significance.

ⁱⁱ The concept of "forced growth" is linked to that one of sacrifice, as a conscious renouncing a certain level of consumption in order to reap benefits for the future. Sacrificing consumption, in fact, it would be possible to increase profitable investments and thus support growth in the future.

ⁱⁱⁱ There were, however, appropriate specifications of this general result: Allen (2005) distinguishes players of Chinese economy among state-owned enterprises, listed companies and private sector, noting that while the finance-growth nexus would be checked for state-owned enterprises and listed companies, it doesn't remain valid for the private sector.

^{iv} It is the national currency of China.

We have a passion - make the law
Too false to guide us or control!
And for the law itself we fight
In bitterness of soul.

“And puzzled, blinded thus, we lose
Distinctions that are plain and few:
These find I graven on my heart:
That tells me what to do.

Rob Roy's Grave by William Wordsworth

Abstract

Using Eastern metaphysical concepts as a guide, this study presents a theory for an interpretation of the role of human disposition in fraudulent financial reporting (FFR). The theory proposed has two major components, the TRS framework and the LAG cycle. The TRS framework incorporates constituent qualities of a person which drive behavioral tendencies of the person. The Lust-Anger-Greed (LAG) cycle shows how these tendencies operate, in consonance with an attachment, in an act of fraud. The theory has the potential to provide a holistic understanding FFR as a human act. In a predictive manner, it demonstrates how to differentiate actors (of fraud) from non-actors. The theory presents a systemic understanding of the root drivers of fraud and allows for a re-interpretation of the fraud triangle. To promote further research based on the theory, the study provides a series of propositions and certain potentially relevant measurements.

Introduction

Whereas considerable time and efforts have been devoted to study the two pre-conditions – pressure and opportunities – that could lead to fraudulent financial reporting (FFR), the magnitude of investigation about rationalizations, the third side of the fraud triangle, thus far has been very limited. While the amount of past research efforts have been limited in this area, there is even greater paucity of insightful research outcomes that could lead to further enhancements in both research and practice to mitigate fraud risks. In part, this may be due to not just the paucity of research attempts, but also the locus of research questions, data, and methodology. Compounding the difficulty in breaking new grounds is the absence of an overriding framework of behavioral disposition that could potentially provide a holistic understanding of underlying variables leading to fraudulent acts.

This paper presents a comprehensive attempt to articulate a framework of behavioral disposition, which is then applied to the human act of fraud. We address the ever intriguing question – why ordinary decent human beings commit fraud? – as we propose a theory of human predisposition and its relationship to fraud. This foundational work potentially offers three other benefits. First, a series of testable propositions have been outlined for further work in this area. Because such work will stem from the proposed theory, the collective insights from such efforts will likely lead to a sort of convergence in the comprehension of disposition of actors (of fraud). Second, we attempt to frame selected known findings within the proposed theory, which permits a degree of assimilation and validation of what we already know. Finally, while almost all efforts in the past have focused on the actors and the anatomy of their acts, for a complete understanding of pertinent issues, we need to know the non-actors as well. The efforts to separate past (and potential prospective) actors from the non-actors will allow us to also learn about the characteristics of non-actors. Such knowledge can be helpful in proactive solutions to the ever rising crime of FFR. After all, despite many years of conscious efforts to detect pressure points and plug opportunities, cases of FFR continue. There is every reason to hope that a well-defined framework of behavioral

disposition will lead to new energies and more productive results in our pursuits to find natural and reliable antidotes.

There are reasons to believe that a reconsideration of behavioral disposition at a fundamental level is important. First, while Cressey's (1953) study to find the drivers of financial fraud ultimately led to the development of the fraud triangle, the rationalization dimension of the triangle still remains ambiguous in terms of definition, interpretation, and application. We argue that even the name, rationalization, may be non-descriptive, or at least not helpful, in grasping the total scope of human predisposition. Second, any insights on disposition will likely lead us to interpret more effectively the other two dimensions, pressures and opportunities, for they are impacted by human disposition as well. Third, we postulate that there is an overcrowding of red flags that need to be pruned in order to improve audit efficiency while at the same time improving the odds of detecting fraudulent acts. The theory articulated here could play a significant role in this regard. Finally, only a better comprehension of behavioral predisposition will allow us to improve our understanding of ways in which actors are different from non-actors, or when a non-actor could turn into an actor of fraud. Pressures and opportunities appear inadequate in finding reliable answers to questions concerning FFR.

In this research, we focus on human disposition, its characteristics, and its sources. Using key lessons from Eastern metaphysics, we build a model that sets the foundation for new thinking on FFR, especially in the context of human disposition. Our attempt here is to develop a theory and set out several propositions for consideration for investigation. Toward this aim, we rely mainly on two major threads rooted in Eastern metaphysics, further develop each, and link the two. First, we present in the following section the TRS framework as the basis for classifying human predispositions. We then use the framework to describe how dispositions of actors play a role in FFR. Second, we introduce a model, called the LAG cycle; this model explains why people commit fraudulent acts. Third, the theory is completed by linking evaluative judgments dependent upon human predisposition (drawn from the TRS framework) with the behavior triggered by the LAG cycle.

The TRS Framework

According to Eastern metaphysics, the quality of being drives the psychological action in a human. Broadly interpreted, this is the *shraddha* (faith) that drives a human being to pursuits of his or her choice. In Aurobindo's words (1996, 492), "The soul's faith, not mere intellectual belief, but its concordant will to know, to see, to believe and to do and be according to its vision and knowledge, is that which determines by its knowledge and power the measure of our possibilities of becoming . . ." Once determined by the quality of being, these actions are visible as outer quantitative dispositions of the person. A comprehension of the quality of a being permits an informed interpretation of the person's outer quantitative dispositions, which are based on his *inner* state. As Aurobindo aptly puts it, "It is the inner state, motive or direction which gives their value to our works, and not merely the apparent outer direction, . . . or even the sincere intellectual belief which seems to justify us in the performance" (1996, 486-87). Three dominant inner states are: nescient, or people who suffer from ignorance (inertia) of action and knowledge; subscent, or people who suffer from ignorance (inertia) of knowledge, but not action; and coscient, people free from either type of inertia. Nescients are indolent, subscent are suffering from attachment to yet unprocessed objects of desire, and coscient are active, but non-attached.

Corresponding to the inner states, three dominant types of disposition have been articulated in Eastern metaphysics. These are extensively narrated in the *Bhagavad Gita*¹ and interpreted by many, including Aurobindo (1996), Radhakrishnan (1979), and Tilak (2004). Comparable types also exist in various Eastern religions, including

¹ See chapters and stanzas, 2(45), 3(27-29), 7(12,13), 14(5-25), 16(1-17), 17(2-22), and 18(7-9).

Buddhism, Jainism, and Sikhism.² Identified here in a notational form, T, R, and S represent three dominant psyches of humans.³ Figure 1 presents an overview of the TRS framework.

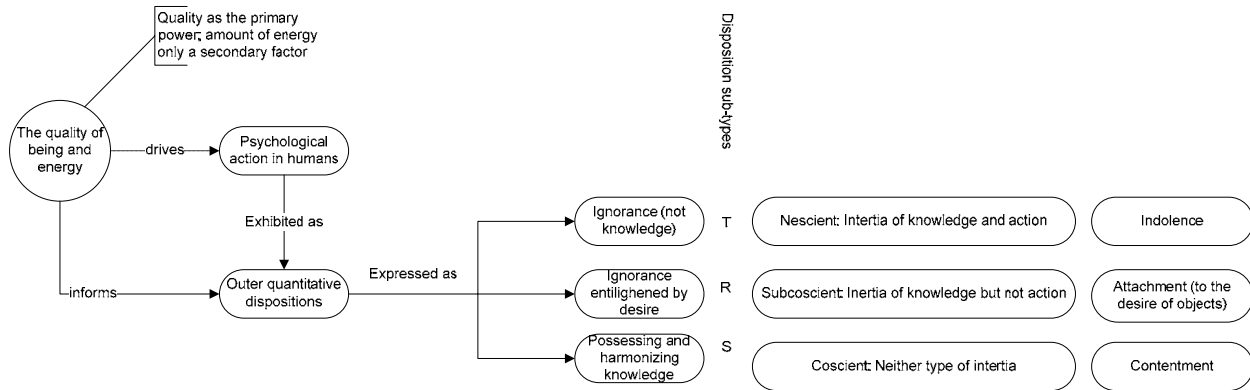

FIGURE 1: AN OVERVIEW OF THE TRS FRAMEWORK

Type T exhibits indolence or inertia. People expressing T tendencies are incapacitated or negligent, and when they work, they are prone to error, inattention, and misunderstanding. Because they have unsteady Reason, they have a tendency to lie or cheat and deprive others of their rights and resources. They can be harmful. Lack of any direction or goal, ignorance, dullness, inactivity, too much sleep – these are some of the signs of T tendencies. A compulsive gambler, an obsessive drinker, and a person who threatens his family – they all exhibit an overwhelming presence of T qualities. Ts are self-destructive. Within the context of the agency theory, in a principal-agent relationship, they undoubtedly are not qualified to serve as an agent. Investors in a company are likely to lose when their CEO’s disposition is of Type T, for the Ts don’t know right from wrong, nor can they act with energy and passion.

Type R exhibits liking and longing, constantly exhibiting desire for unprocessed satisfaction. Action in pursuit of unprocessed satisfaction is a very visible trait of Rs. Passion to seek whatever appeals to them indicates the dominant presence of the constituent quality R. Unrest, fever, excitement – these are all behavioral descriptors of Type R. People expressing R tendencies exhibit a kind of passion that drives them to announce their worldly hopes and dreams and to passionately work toward them. In Jeffery Skilling’s words, “I’ve never been not successful in business or work – ever.”

The type S tendencies bring out the goodness in us. The goal of a Type S person is to search for lasting happiness; they believe in action and equally, they are seekers of knowledge. They exhibit not only contentment resulting from an inner quality of satisfied Will, but also delight and content produced by harmony between the Soul and the surrounding *Matrix*. Being a Big Brother to someone, mentoring a youngster, working in the soup kitchen of a center for the homeless, helping build a home for the Habitat for Humanity – these are all likely expressions of S quality. Other-centered in their focus, Ss seek altruistic motives. They constantly think of their duty toward others. They can be trusted agents of others. Because they are other-centric and outward looking, of the three disposition types, they are the least likely to be the victims of ego attachment. Intuitively, Ss belong to the universe of non-actors.

² Eastern religions focus on defining and guiding a way of living. Toward this purpose, an understanding of one’s predisposition plays a key role.

³ In Sanskrit, the three subtypes are: *Tamsik*, *Rajsik*, and *Sattvik*. Notational symbols T, R, and S represent these subtypes, respectively.

Figure 2 presents the behavior concordant with the disposition of a person. The disposition driven by constituent elements should be recognized as a sphere; each sphere drives the human choice; a complete repertoire of choices one would make in each sphere is not possible to articulate, nor absolutely necessary. Tendencies are more important to recognize; the particular nature of behavior emerging from these tendencies would vary and may at times appear outwardly different depending on the circumstances.

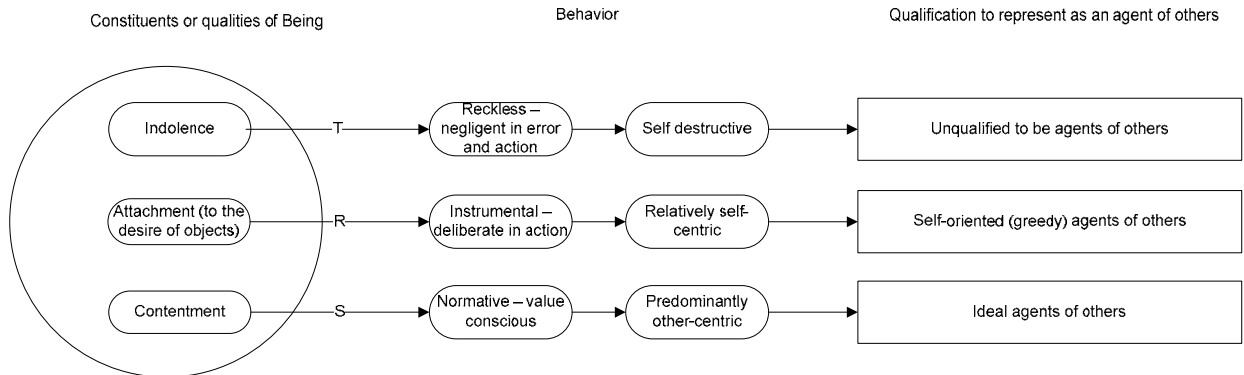

FIGURE 2: DISPOSITION AND BEHAVIOR

Some evidence of the TRS framework surfaces in various other sources as well, although the symbols assigned to the dispositions vary. Rumi, the Thirteenth century Sufi saint and poet, describes three kinds of creatures: the descendants of Adam, beasts, and angels (Baldock, 2006). A combination of intelligence and lust, descendants of Adam are those who struggle between their animal and angelic nature. Attachment to objects of their desire is natural for descendants of Adam. In our classification, they are more like Rs, somewhere between Ts (animal like) and Ss (angelic). Beasts express predominantly Type T tendencies; they are pure lust and lacking in intelligence, like an animal which sees nothing but its stable and fodder. Comparable to Ss are Rumi’s angels, they are pure light and free from lust, so they do not have to struggle with sensual passions.

All humans possess each of the three qualities, although a particular quality is likely to dominate over the others. The three qualities are collectively exhaustive but they coexist in different degrees. The dominant quality governs the person’s behavior or disposition. For example, a nutritious drink (fresh milk) is the likely preference of Ss, while Ts may tend to choose curded or stale milk; in the middle are Rs who prefer a tasty variation of a nutritional ingredient (say, ice cream or hot chocolate instead of pure milk) to factor in the passion for food. It is quite possible that S tendencies may make you want to help at a center for the homeless, while Rs go to a theme park, and Ts become the couch-potatoes watching MTV in the dark basement of their home. Bumper stickers on cars provide good material to understand people’s tendencies. A Type S will stick up “Donate blood,” while Rs would announce that their son or daughter is an honor student at a local school, and Type T would simply say, “_ _ _ happens” (expletives deleted). Although the examples offered here are at the material level, the dominating constituent quality determines not just the physical, but also mental, intellectual, and moral development of the person. Our constituent qualities expressed in terms of our disposition have a lot to do with the quality of life – both private and work-life -- we weave.

In sum, intrinsic to a person’s choices is the person’s disposition. There is an evaluative dimension implicit in the human disposition, leading to the quality of choices we make. Table 1 presents a summary of the three dispositions

TABLE 1: A SUMMARY OF TYPES OF DISPOSITION

Disposition sub-type	Broad parameters	Specific behaviors (flags)
Type T	Inertia of knowledge and action; ignorance; recklessness	Careless, perfunctory, wholly self-regarding
Type R	Inertia of knowledge, but not of action; ostentation; ego; pride; passion; desire for outcomes and rewards	A strong lust after the fruit of action. A vehement demand for the reward of one's work. Violent or egoistic personal desire.
Type S	No inertia of knowledge or action; principled-behavior	Best efforts without counting on the desired outcome. Transparent. Equable under all conditions.

The dispositions described here are not totally disconnected from each other, but rather form a continuum of three spheres, each representing its own dominant tendencies. At one end is the Type T, in the middle is the Type R, and Type S takes the other end. Put differently, the continuum suggests indolent or slothful (Ts), self-centric (Rs), and non-attached(Ss) behavior, respectively. This can be seen as stages of development of a being, first improving on the inertia of action, followed by the rise to neither type of inertia (action or knowledge).

Business Executive's Disposition

The CEO is probably the most influential leader in the life of an organization. The organization mirrors in many ways the disposition of the chief executive, for example, in the culture of the company. Thus, it seems reasonable to postulate that the constituent qualities of the CEO and the resulting behaviors transcend the company she leads. Presumably, most business executives are Type R; if so, it is likely that the leader's behavior and in accordance with it, the behavior of the organization he leads can be expected to be passionate, goal directed, and results focused. It is highly unlikely, although possible, that the chief executive of a successful company is Type T, indolent suffering from inertia of action and knowledge, or Type S, an other-centric person.

P 1:*Disposition of business executives is dominated by the constituent quality R.*

The COSO (1999) Fraud Study found that in 83 percent of frauds examined, the CEO and the CFO had colluded. In a follow up study (2010), COSO found that during the period 1998-2007, The SEC named CEO and/or CFO for some level of involvement in 89 percent of fraud cases. Although most observations in this paper can be extended to other C-level executives, we focus on the CEO, whose disposition pervades the entire organization, establishing a culture in which the CEO is comfortable in leading the organization.⁴The organizational culture that sets the tone at the top is thus a derivative of the CEO's disposition and not something independently determined. Additionally, the upper echelons perspective (Hambrick and Mason, 1984) suggests that organizational outcomes viewed as reflections of the values and cognitive bases of powerful actors in the organization could potentially shed more light on strategic choices top executives make. The chief executive undoubtedly assembles a team in which the executive can place high level of comfort in orientation similar to his or her own. Consequently, studying the CEO – who

⁴ Jennings (2006) argues that ethical culture, or lack thereof, controls all the other quantitative factors; ethical collapse occurs when any organization has drifted from the basic principles of right and wrong. This is consistent with the argument advanced here. The builder of the culture is the chief executive who will transform the company culture to his or her own disposition. Jennings' seven signs are largely the artifacts of a CEO and apparent, but not the only, outcomes of the culture that the CEO nurtures.

matters - within the context of the TRS framework can provide most insights on the executive's behavior leading to indiscretions.⁵

Undoubtedly, the CEOs are driven. Arguably, they are Type R, more like the descendants of Adam. They want to show the world that they can achieve. Performance at all levels is important to them; they often are extremely uncompromising in accepting poor performance. They are driven, goal focused, and constantly exerting toward that end. The achievement of desired outcomes is the center of their world. If business leaders were not made of this stuff, results would be difficult to come by, and businesses would look myopic and slothful. The energy produced by the Rs is unique in creating the worldly wealth, if not lasting happiness. Having a CEO who is a strong R as the agent of a corporation produces leverage for the investors (the principal). However, this advantage comes at a risk: the agent could be a "beastly descendant of Adam" or "an angelic descendent of Adam." The former could cause harm at some point, while the latter is a safe bet.

The presence of disposition cannot be turned on or off. The dominant predisposition does not suddenly change, nor can it be suppressed when one comes home from work; it can only be transformed slowly over a long period of time and with conscious awareness and action. Consequently, the private life of a Type R CEO is as ostentatious as is his public life. Marrying an attractive executive assistant while divorcing a spouse in a long married life (as in Bernie Ebbers' case) is driven by the same disposition to seek aggressively whatever attaches to the CEO's mind. Passionate "angels" at work are also angels at home and in other aspects of private life, and passionate beasts are beasts even in their private lives. Thus, the consistency in expression of one's disposition cannot be masked; it pervades one's life, including private life. So, it is not surprising that Albrecht and Albrecht (2003) identified "extravagant lifestyles" as a category of the symptoms of fraud. If extravagant lifestyle belongs to the actor, modest living despite all the affordability is the lifestyle of non-actors like Warren Buffet (Berkshire Hathaway), Narayana Murthy (Infosys), and Bharat Desai (Syntel).

Financial Fraud Cases and the Executive's Disposition

To illustrate the TRS framework, we discuss examples of predispositions of executives, the actors, from known fraud cases and present related details in Appendix A. Here, we attempt to match the disposition types to an actor based only on an informal review of what is public knowledge.

Type T is reckless. Their disposition suggests that they are not worthy agents of investors. Generally, the cases of type T executives are extreme and relatively rare. The actor is almost invariably negligent and indifferent. In total disregard for the law, this person is not only unethical, but is also recognized for his flagrant violation of the laws of the land.

The Rs are capable of becoming the sinners. Getting results at any cost can be their passion. Aurobindo predicted with deep insights in human behavior the state of things to come in the corporate world:

Although it is apt to put on these things the construction which will most flatter and justify its desires and to uphold as right and legitimate the means which will best help it to get the coveted fruits of its work and endeavor. That is the cause of the three-fourths of our falsehood and misconduct of the human reason and will. *Rajas* [Type R] with its vehement hold on the vital ego is the great sinner and positive misleader (Aurobindo, 1996, 504).

And yet, it would be incorrect to say that in their overdrive mode, every Type R executive exercises indiscretion. Even in Type R disposition, where potential for "sin" is high, some may prevail as non-actors. We discuss this point further in the following paragraphs.

⁵ There is no intention here to preclude studies of dispositions of other executives, or even directors. Such studies are feasible and could potentially be helpful in providing insights on FFR.

Type R – A Closer Look

While the dominant predisposition drives one’s behavior at all levels, all three qualities exist in a human at any given time. In essence, the dominant types form a spectrum, beginning with pure self-centricity in the likes of Thrasymachus of Plato’s *Republic*, to pure altruism, reflected in Mother Teresa of Kolkata. Thus, there is a chance that, along the spectrum, some of the Rs are leaning toward T tendencies (beastly descendants of Adam), and while other Rs are leaning toward S tendencies (angelic descendants of Adam). Put differently, goal-seeking, hard driving leaders belong to the disposition R (Rumi’s descendants of Adam), but they could be seen as binary in nature, as in beastly descendants of Adam (we call them R(t)), or angelic descendants of Adam (R(s)).

Clearly, evidence from the past shows that while some executives have committed fraud, many others have clean records. We refer Rs that might potentially indulge in indiscretion as subtype R(t) suggesting some leaning toward T tendencies, expecting that they will “manage” every obstruction they face to achieve results they are attached to. And we denote subtype R(s) – Type R leaning toward S tendencies – as those who have not and will not in all likelihood commit fraud. We refer them as R(s) because their disposition is moderated by the significant presence of S tendencies. R(s)s are difficult to characterize from historical facts because of lack of documented studies of non-actors (The SEC does not seem to collect data on them). Such executives are likely to surface rarely, if at all, in the list of reported cases of FFR. The examples below appear to be those of Type R(s).

Case	Person	Descriptors of the person
Berkshire Hathaway	Warren Buffet	Transparent. Exudes enlightened unselfishness. Unconditionally emphasizes reputation and integrity in all aspects.
Infosys	Narayana Murthy	Empowering. Other-centered. Exudes enlightened unselfishness. Follows pure reason.
Syntel	Bharat Desai	Uncompromising integrity. No mercy toward ethical lapses. Clear lines followed on what is personal and what is business.

Because R(t)s are leaning toward the lower quality of disposition, they are more likely to commit indiscretion, while the R(s) at the higher stages of development would be able to resist the temptation to commit acts of indiscretion. What could be the fundamental differences between the actors that belong to the R(t) subtype and the non-actors (R(s))? Why could one group be potentially much more vulnerable than the other? As shown in Figure 3, a possible answer lies in Kohlberg’s work on moral development. Kohlberg’s (1984) levels of moral reasoning are: pre-conventional (obedience and punishment orientation and self-interest orientation), conventional (interpersonal accord and conformity – social norms; law and order morality), and post-conventional (social contract orientation; universal ethical principles). These are somewhat comparable to Rest’s (1973) moral development schemas: personal interest, maintaining norms, and post-conventional. R(t)s seem to align with those who maintain norms ordinarily, but they are capable of putting personal interest above everything else, even at the cost of violating norms they are used to comply with in ordinary course. In contrast, R(s)s not only follow law and order scrupulously, but also are uncompromising in their commitment to the universal ethical principles. Thus, R(s)s lean on pure reason when they face a crisis that tests their true character.

P 2: More likely actor is an R(t), and the more likely non-actor, an R(s).

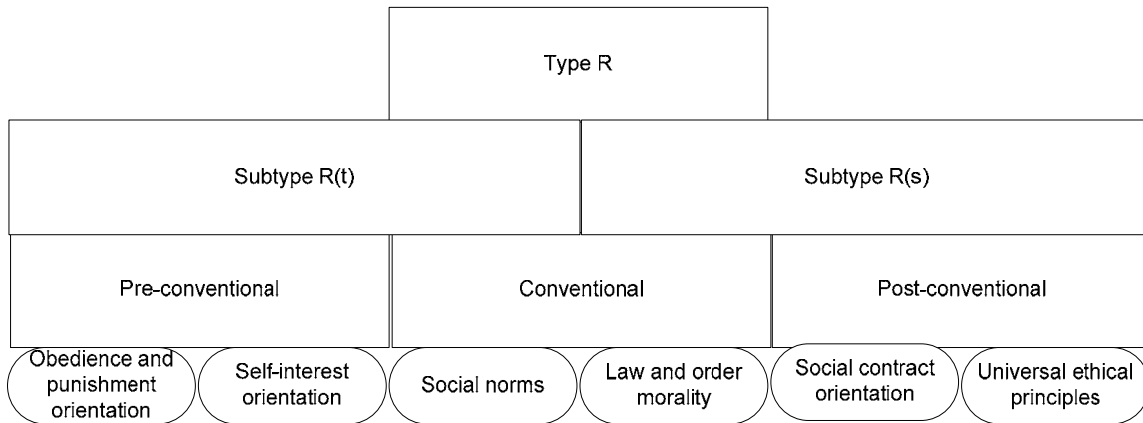

FIGURE 3: A CONCEPTUAL DISTINCTION BETWEEN R(T) AND R(S)

T.H.Green (1884, p. 355) describes two profiles, comparable to R(t) and R(s), in terms of a kind of devotion to great objects or to public service, suggesting that “there is a sense in which to be always fingering one’s motives is a sign rather of an unwholesome preoccupation with self than of the eagerness in disinterested service which helps forward mankind.” Green clearly draws the line between those serving self-interests and those serving others.

Using the disposition of a person, one can contrast the behavior of those who commit fraud (an actor) with those who don’t (non-actors). Actors are more likely to be self-centric in their pursuits. In their self-serving mode, they are vulnerable to disengagement from exercising discretion, instead rationalizing their act with practical reason. They are capable of defying the restraint from external sources, such as the society and the regulatory agencies. In such cases, the regulatory and social power fails to mitigate *ex-ante* their disengagement with moral agency. Non-actors, because of their other-centric disposition, are leaning toward behavior that is beyond some practical reason to commit indiscretion. Taking care of the stakeholders, including investors, is their aim and in this sense, they are ideal agents of the stockholders within the context of the agency theory. They understand that the results of their efforts will be impacted by forces beyond their control; what matters is that they give their best in achieving them. Toward this goal, they work hard; however, they report unadulterated performance. To them, tweaking the results is simply not acceptable. In sum, this is where a non-actor triumphs over compelling situational forces, or temptations, exercising pure reason as a guide. The non-actors believe that their duties stem from their stakeholders’ rights. To quote Green (1884, p.379):

A true Moral Philosophy does not recognize any value in conformity to a universal rule, simply as such, but only in that which *ordinarily* issues in such conformity, *viz.* the readiness to sacrifice every lower inclination in the desire to do the right for the sake of doing it.

As an example of a non-actor, take Azim Premji, Chairman of Wipro. Among the tips for success that he shares, two are very prominent: Never compromise on fundamental values, no matter what the situation, and play to win, and yet, leave the rest to the force beyond (Reliance Energy Management Institute, 2008). Unattached to expectations of outcomes and keeping the motive focused on service to his stakeholders, Premji has demonstrated fundamental traits of a non-actor.

Is it possible to distinctly identify R(s)s from R(t)s? Perhaps, but the task will be challenging. According to Ramamoorti (2008, p. 527), Thomas Golden of PriceWaterhouseCoopers, an experienced forensic accountant, believes that FFR perpetrators fit one of two profiles: “greater good oriented” (likely R(s) in our typology) or

“scheming, self-centered” types (likely R(t)). If this is true, both types - R(t) and R(s) - commit fraud; consequently, distinction between R(s) and R(t) would not help differentiate between actors and non-actors. While we revisit this point later, the task of differentiating is formidable. T.H. Green (1884, p. 359) asserts: “Among the respectable classes of a well-regulated society there is little in outward walk and conduct to distinguish the merely respectable from the most anxiously conscientious.” We believe *the merely respectable* are the R(t)s and *the most anxiously conscientious*, R(s)s. Green (1884, p. 360) continues, “If we could watch him closely enough, indeed, even in outward conduct there would appear to be a difference.” We believe he is describing R(s)s as he further asserts, “Into the duties which he is expected to fulfill he will put much more meaning than is put by those who claim their fulfillment, and will always be on the look-out for duties which no one would think worse of him for not recognizing; . . . he feels the necessity of rules of conduct which . . . are not yet a recognized part of that morality, and thus have no authority with those whose highest motive is a sense of what is expected of them.” We believe that R(t)-R(s) typology is mutually exclusive and collectively exhaustive, and is potentially helpful in identifying distinguishing behavioral traits of actors and non-actors.

Finally, innate human leanings are quite possibly biased toward selfishness from birth.⁶ It’s a natural state that is hard to deemphasize, let alone evict altogether. Self-centric behavior is magnified by attachment to desired objects of possession, be it profits, share price, bonus, or dealing with pride or shame, illness or well-being. A rather vague term used to describe self-centric people is “ego,” which suggests attachment to objects, tangible or intangible. Attachment is rooted in wanting something, and thus the attached person is constantly striving for it in the material world. So, the challenge is in the development of the self – through increased awareness and change of attitude – from being self-centered to becoming other-centered (Raval and Raval, 2010, 195-222).

P 3: *Those who exhibit uninterested desire, R(s), (that is, non-attachment⁷ and orientation to serve others) are likely to be free from indiscretion. And those who are attached will be tempted to commit indiscretion; their capacity to withstand temptations is limited.*

This proposition infers that not all R(t)s may be found to indulge in indiscretion (more about this in the next section), but there is a strong likelihood that those who are found to have exercised indiscretion belong to this group, that is, they form a subset within the universe of R(t)s. With respect to R(s)s, it is highly unlikely they would exercise indiscretion. Thus, the proposition is conditional for R(t)s and unconditional for R(s)s.

Among the R(t)s, the constituent elements to prompt indiscretion always exist. But what would trigger an act of indiscretion? An intense desire (temptation) to possess the yet unprocessed is prerequisite to such an act. Temptation is independent of disposition; R(t)s with no temptation to lure them into an act would be less likely to commit the indiscretion, for the “honey that attracts the bee” does not exist. One’s disposition is a necessary but not sufficient to commit an act of indiscretion; the presence of temptation to which one gets attached is a prerequisite condition for indiscretion to occur. The TRS framework establishes grounds to explore the potential of someone to exercise indiscretion. The triggering mechanism that makes a person to indulge in the act of indiscretion is the LAG cycle, discussed in the following section.

The LAG (Lust, Anger, Greed) Cycle

Based on the *Bhagwad Gita* (see Chapter 2, 2.62-63) and its interpretations, Raval and Raval (2010, 39-53) named the phenomenon as the LAG cycle and further elaborated on it in the current context. The name, LAG, does not imply any sequence, but simply exemplifies the key elements: lust as a form of attachment (temptation to possess

⁶ Thomas Hobbes in *Leviathan* (1668) advances this claim, however, sources in Eastern metaphysics convincingly argue why a person can be unselfish.

⁷ The term non-attachment as used here is not synonymous with detachment. Non-attached individuals can be actively engaged in purposeful activities.

the unprocessed object of desire), anger (affective responses) and greed (the intensity of wanting the unprocessed object at any cost).

We begin with an actual case unrelated to FFR. A 28-year old sixth-grade teacher, Rachel, was accused of having sex with a 13-year old student. Many intense weeklong affairs followed. To counter any obstructions from the boy, Rachel offered him incentives, such as alcohol and the use of her car. Indiscretion ensued. Upon conviction, Rachel was sentenced to ten years in prison. Put differently, Rachel thought of an *intentional* act. The immediate environment (the classroom filled with adolescent boys) provided the stimuli that triggered the temptation of sensory experience (sexual contact). The stimuli generated contemplation on the object of senses (young boy and his male attractiveness). Further contemplation enhanced the intensity of the thought of possessing the object (the male student and sensory experience). Rachel's desire to have sex was affirmed by her belief that this was within her influence. This generated further affective emotions in her. Rachel became intimate with the male student. Her mind got confused, and Reason could not prevail over her. She reacted to the stimuli. In the end, she was convicted of having sex with a minor and was sentenced to serve a term in prison.

Although Rachel's example focuses on lust as such, the term lust is used here in a broad sense: an overwhelming desire to possess, achieve, or experience something. Lust results in increased intimacy with the object of desire. In a business, lust may be driving the executive to achieve goals in revenues, profits, or stock prices. By nature, a material goal has the power to create strong attachment and the consequent desire to achieve it at any cost. Intimacy in many ways permits the person to study the drivers of whatever it is that the person is seeking. This confirms one's belief that this is in the realm of possibilities, and intensifies the attachment to what is desired. The bond between belief and desire makes the person now feel capable of maneuvering the possession of the object of desire, fueling the obsession further.

A key premise of the LAG cycle is that there exists an attachment at the time of the act of indiscretion. Indiscretion follows the attachment to the object of desire. For example, Mark Hurd, former CEO of Hewlett-Packard (HP), sought an intimate relationship with a female contractor at the company. An investigation found no violations of the sexual harassment policy of the company. However, some of the expenses of personal meetings with her were recognized as company expenses. The HP board's vote (6 vs. 4) to accept his resignation signals how strong an achiever Mark Hurd was, but he presumably was an R(t) who got trapped into the LAG cycle.

In a journey through the LAG cycle, not much may be noticed by others, for until an intervening crisis emerges, the true disposition of the executive will not be visible. For example, without some sort of obstacle to her act, Rachel would never have been charged. And few would have known about Mark Hurd's affair if some of the expenses related to it failed to receive notice from others.

An act of indiscretion can happen in prosperous times also; for example, in light of exceptional superior profits, the CEO may initiate income-smoothing maneuvers, but these may not be noticed as indiscretions. The inflection point is where some form of adversity hits the scene, making the intended maneuvers impossible.

The combination of attachment and obstacles makes the executive angry. The thought, "How could it be that what I want is escaping me?" is constantly bothering the executive. "Something is unachievable" is not in the executive's frame of reference. The disconnect between wanting and valuing, however temporary it may be, triggers an intentional action. Disillusionment rules and moral judgment to distinguish between right and wrong becomes clouded. Indiscretion happens. Following the first misstep, the cycle of wrongdoings may continue – and all this could be within controlled orchestration by the chief. The ongoing maneuvers may be necessary for continued acceleration (or maintenance) of the wrong doing, or for hiding the act until, hopefully, normalcy returns and the act is forgotten, ignored, or it simply remains undisclosed outside the close quarters. The more likely scenario, however, is that the obstructions will force the crime out in the open. The LAG cycle is like a trap; if at the time of initiation of the act, the person's disposition did not stop him from the entry, there is no going back. In his open letter to the Board of Satyam Computers, when Mr. Raju (the actor who was Chairman of the company at the time) said, "It was like riding a tiger, not knowing how to get off without being eaten," we believe he was referring to his LAG cycle.⁸⁸ Figure 4 presents our view of the LAG cycle.

⁸⁸ www.expressindia.com/latest-news/Satyam-fraud-full-text-of-Rajus-letter-to-Board/407799.

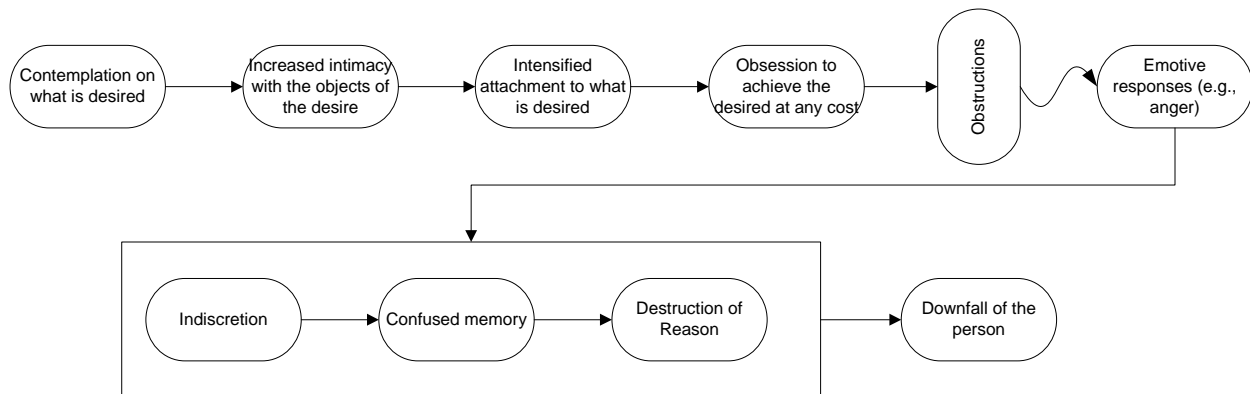

FIGURE 4: THE LAG CYCLE

In sum, stimuli to possess or experience something trigger desire. Desire to perform an intentional act is supported by the believability that this can be accomplished. The disposition of the actor makes an act that is generally unthinkable as acceptable. To illustrate key elements of the LAG cycle, Appendix B presents examples from past cases of FFR.

When adversity strikes in some form, obstructions to achieving the committed goals can be insurmountable. Meanwhile, the dominant disposition, $R(t)$ or $R(s)$, drives the behavior. Exogenous factors are not supporting the obsessive goal, but the attachment to it is so strong that it triggers emotive responses, typically anger and frustration. This in turn causes the executive to indulge in indiscretion. Indiscretion causes confused memory; pure reason is defeated, and some sort of practical reason is advanced to legitimize the act. Eventually, the unmasking of the veil over indiscretion arises from the insurmountable obstructions to any intense desire to achieve the desired at any cost.

An attachment begins with the thought of achieving or possessing some result and may be transient or durable. Consequently, it is difficult to predict the tenure of attachment; it could be a matter of hours, days or weeks, or even months or years. Additionally, any indiscretion in response to stimuli is only local to the situation; that is, a person who acts indiscreetly in one situation does not necessarily always exhibit indiscretion in every situation. Moreover, there is nothing inherent in the stimulus itself to make it an attachment; what attracts one person may not attract another and what attracts one person at one time may not attract the same person some other time.⁹

P 4: Attachment combined with disposition $R(t)$ leads to an entry into the LAG cycle. Non-attachment in $R(s)$ prevents the executive from entering the LAG cycle.

The culture appropriate to the executive behavior is likely to be in place well before the obstructions arise and the act of indiscretion occurs. One can surmise this as an aggregate outcome of the executive's predisposition and not of any particular act, for no such act is planned in advance. On the other hand temptations which may cause attachment are not staged, anticipated, or programmed. They emerge as external stimuli that attract the person to seek the unprocessed.

⁹ This addresses Cressey's dilemma (1953, p.12), "the central problem is to account for the differential in behavior indicated by the fact that some persons in positions of financial trust violate that trust, whereas other persons, or even the same person at a different time, in identical or very similar positions do not violate it."

An obstruction that forces disclosure of the act may not arise for a long period of time, or ever. If in the life of the executive with R(t) tendencies, the triggering event never surfaces, everything may seem uneventful, although the potential for fraudulent behavior exists because of the possibility of attachment. In such cases, the success is celebrated; investors revere the R(t), and no one notices any impropriety. Could it be that the published cases of FFR represent only a tip of the “iceberg?”

P 5: *Some proportion of FFR cases is likely to never have been identified outside of the “close quarters.”*

Bandura (2002) discusses the dual nature of moral agency. He argues that there are two interacting and complementary sides to moral behavior, the inhibitive and the proactive. The inhibitive nature supports the power to refrain from behaving inhumanely. Social influence is the dominant force here, and sanctions are the common means of regulating the behavior. In some respect, this nature of moral agency is implicit in the SEC’s desire to plug the opportunities. The sad news is, already identified and (perhaps even) legislated requirements to disclose opportunities do not stop the actor from creating new ones and committing indiscretion. To reiterate, an attachment is not a constant; its significance lies in the only critical way the actor bonds with it, and only if the actor bonds with it. A standard list of opportunities that might present themselves as attachments is unlikely to be effective.

Bandura asserts that the inhibitive nature of moral agency is the one from which a person can disengage slowly over time, giving practical reasons that rationalize his or her approach. A CEO, for example, can over time build a team that is thus disengaged and insulated from perceiving their behavior as harmful to stakeholders. Although a slow process, the business leader realizes that it is effective in controlling the key people in the organization.

Such tolerance in threshold to distinguish – even temporarily – right from wrong reinforces one’s disposition more toward R(t) subtype, which permits indulgence in utterly ostentatious behavior. The situation gets worse as the executive reinforces such behavior through his or her own culture and leadership team. Over time, the organization moves into the operational mode seen by most everyone as a completely legitimate machine to make money.

P 6: *Over time, the leadership team builds a culture that supports its own reflection of moral agency.*

In the end, when a fraud is noticed by the outside world, there is nothing that is overcoming the CEO or her team. The obstructions cause this type of illusion. The seeds of wrongful acts have already grown by the time such a fraud is noticed. The only thing different is that without obstructions to the achievement of objects desired, there would be no need for the elements of fraudulent behavior to heighten to a visible level. In the eyes of media and the regulators, it could have been a non-event.

Bandura’s second side of moral behavior – the proactive side – has to do with the power to behave humanely. There are no absolute external norms for those who have the inner stamina to behave humanely. They consciously determine in each situation the right thing to do, and follow their consciousness without putting first their self-interest. These are the subtype R(s) in our description of human disposition. Their attitude is pure and uncontaminated by self-interests. They do not care for opportunities to commit fraud, or for incentives that might materialize in an undeserved gain for themselves. They prove that the two sides of the fraud triangle, opportunities and incentives, are necessary but not sufficient explanation of the act, and even so, certainly less significant. The real source of the positive power to behave humanely is the inner moral strength; nothing else works as an effective surrogate for it. Passionate but other-centric, non-attached at the core, they are driven by truth, contentment, compassion, humility, and love. We believe the R(t)s like the prohibitive side, inviting catch-me-if-you-can arrogance in them. The R(s)s find the proactive side most natural to them. They exist for their stakeholders, no temptations can bring them on the side of R(t)s.

P 7: *Having more of R(s)s – the non-actors - as CEOs is desirable for the economy, financial markets, and the investors, because their presence will minimize, if not eliminate, the fraud problem.*

Cressey's Work on Financial Fraud and the Fraud Triangle

The initial formulation of Cressey's (1953, p. 27) second hypothesis, for which he credits Riemer's (1941) observation, was that *opportunities* inherent in trust positions form *temptations* if the incumbents develop anti-social attitudes which make possible an abandonment of the folkways of business behavior. The positions of trust are violated when the incumbent defines a need . . . as an *emergency* which cannot be met by legal means (emphasis added). Moreover, Cressey (1953, p. 28) argued, if such an emergency does not take place trust violation will not occur.¹⁰ The next revision of the second hypothesis avoided the use of the term emergency and instead emphasized the actor's psychological isolation, resulting from having committed a non-socially sanctionable financial obligation which, consequently, must be satisfied by a private or secret means. The final version of Cressey's (1953, P.30) hypothesis reads as follows:

Trusted persons become trust violators
When they conceive of themselves as having
 A financial problem which is non-shareable,
 are aware that this problem can be secretly resolved by violation of the position
 of financial trust,
And
 are able to apply to their own conduct in that situation verbalizations which
 enable them to adjust their conceptions of themselves as trusted persons with
 their conceptions of themselves as users of the entrusted funds or property.

Cressey's (1953) comprehensive study of sources and motivation for financial fraud is a noteworthy milestone in this research area. Further analysis and development based on the foundational work of Cressey led to the fraud triangle and its use as a primary framework to look into financial frauds. Taking a comparative view of what we propose here and Cressey's work, we find that the two are not identical, but notable parallels exist. First, the term emergency, although dropped from the final version of the hypothesis, has a close relationship to "obstructions" in the LAG cycle. Without obstructions, one may never have to reach the heights of indiscretion. Cressey dropped the term "emergency" after considering some of the participants' feedback, that while an emergency had been present at the time they violated the trust, other, perhaps even more extreme emergencies, had been present when they did not violate it (p. 28). We believe that emergency is in some way a perception of the obstacle, for it is described as emergency "which cannot be met by legal means," that is, obstructions exist in achieving them. Moreover, not all emergencies result in trust violations; only those where the attachment to yet unprocessed object of desire exists. We contend that emergency is not the differentiator between actors and non-actors, but the vulnerability to temptations is. R(t)s are more susceptible to collapse as victims of temptations, not R(s)s, and even among R(t)s, the obstructions would trigger indiscretion if and only if the actor experiences an intense desire for the unprocessed object. Second, in comparing Cressey's work with the LAG cycle, it appears that a problem becomes non-shareable immediately upon the exercise of indiscretion by the actor. There is nothing inherent in the problem itself to become non-shareable. In a principal-agent relationship, the agent should have significant hesitation in being transparent about the temptation that caused the agent to commit fraud. For example, Raju Ramalingam of Satyam Computers did not disclose his act to the company's board of directors until he reached a stage where the act could not be perpetuated any more. In our earlier example, Rachel, a married woman, would probably keep her affair with the student undisclosed to her husband. Thus, the temptation (intense desire to achieve the goal to which the agent is deeply attached) causes the indiscretion, which in turn results in the problem becoming non-shareable. Any behaviors that emerge from non-shareability of the problem could potentially be

¹⁰ We believe trust violation is likely to occur but will not be disclosed.

explained by Nathanson’s compass of shame (1992), which suggests various emotive responses of the actor, including withdrawal/avoidance and attack other or attack self.

The non-shareability of the problem appears to reach an end under two conditions. First, if the fraud becomes public knowledge and enforcement actions begin, the internal conflict of the actor intrinsic to the idea of non-shareability is no more relevant. Second, if the act remains within the “close quarters” there may never arise a need to disclose publicly why one indulged in the act; the non-shareability may persist, albeit in a muted form, perhaps even weakening over time. Some actors (e.g., Patrick Kuhse) even choose to tell their stories once many years have passed since the act of indiscretion, and such disclosure is not likely to cause any personal harm.

The disclosure of an indiscretion would most likely be followed by public disclosure of rationalizations of the individual. In our understanding, the apparently practical reasons (as distinguished from pure reason) put forth by the actor are called rationalizations. The initial thought process that establishes a reason for acting is for one’s own justification; we call it an internalization, or rationalization *ex ante*. Interestingly, when the person determines that an act will be committed, she internalizes *ex ante*; and when it becomes known to others, it must be externalized for the consumption of others. An integrated view of Cressy’s hypothesis and the LAG cycle is presented in Figure 5.

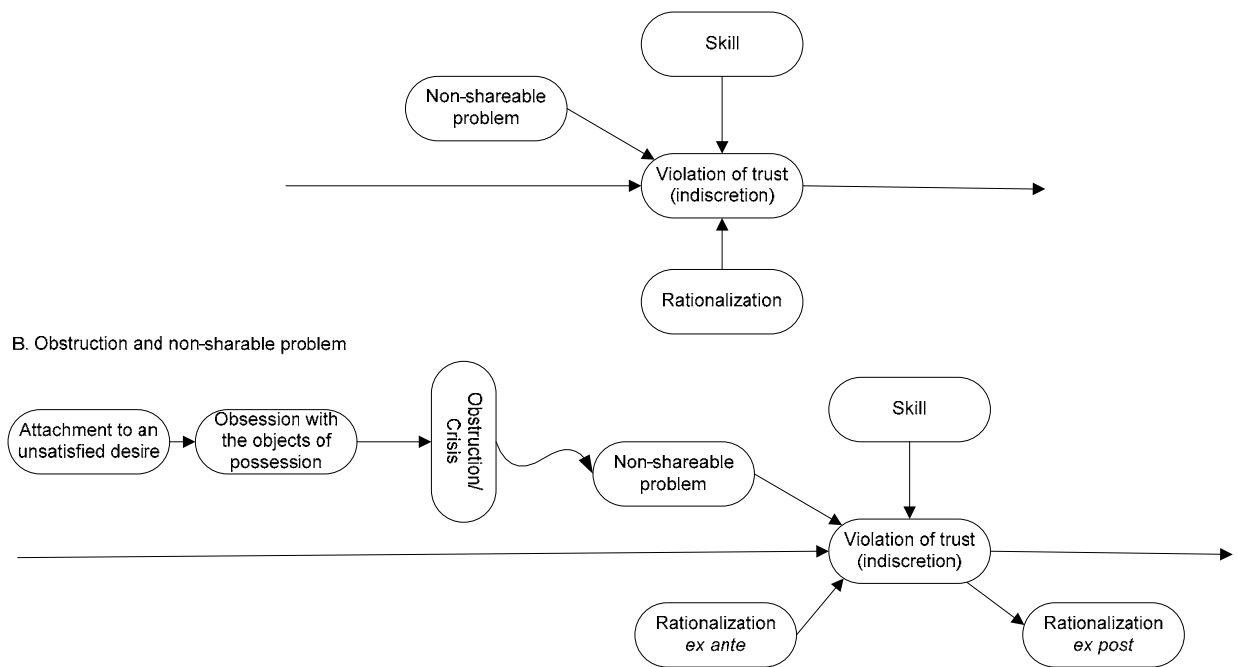

FIGURE 5: AN INTEGRATED VIEW OF CRESSEY’S HYPOTHESIS AND THE LAG CYCLE

Further research following Cressy’s work resulted in the fraud triangle which has been a valuable model for learning about FFR. Numerous studies have explored the fraud triangle from various perspectives, and the overall conclusion is that this fraud model is effective in explaining financial reporting frauds (Hogan, 2009). The triangle has been used to identify red flags, based on the three conditions of which the triangle is comprised. In turn, knowledge of red flags has been used in the consideration of audit process improvements and/or drafting regulatory requirements. And yet, the problem of fraud is not fully addressed, the most inadequately addressed factor being the possible role of human quality in such acts.

Of particular significance to this research is the Rationalization side of the fraud triangle. Although all three sides of the triangle imply human psychology, rationalization differs from the other two sides (opportunities, pressures) in that rationalization (particularly, *ex ante* rationalization) is a process internal to the human, whereas opportunities and pressure are externally visible phenomena. We borrow from Bogart's work (1980) to explain the concept of feed intelligence and discuss the differences between opportunity and pressures on one hand, and rationalizations on the other.

Feed Mechanisms and the Fraud Triangle

According to Bogart (1980), information intelligence can be of three types: feedback, feedforward, and feed within. Feedback is information about system outputs that is fed back into the system. Feedforward is information about system environment or inputs that is fed forward into the system. Feedwithin is information about the system's *internal* flows, operations, resources, and information which is fed back into the system. The structure that supports the emergence and use of information intelligence is often called a feed mechanism.

Among the three forms of information intelligence, perhaps the one that is widely known is the feedback. The next most known is the feedforward, and the least known is feed within. Feedwithin information intelligence is not directly related to either input or output. Instead, it relates to the transformation process between inputs and the environment at one end, and outputs at the other. According to Bogart (1980, 241), it is information about the throughput of a system or disposition of parts of a system relative to such throughput. Sensors throughout the system's processes capture signals of the system's states and transmit via (feed within) loop the information to the receiver *within* the system. The receiver then interprets the information and takes appropriate action.

Thus, feed within information intelligence is primarily internal to the system, and concerns the internal processes and their relationships that collectively produce the throughput of the system. It communicates and orchestrates events internally. An introspective intelligence, it is in the nature of feeding the "soul" of the system. It has little to do with immediate inputs or outputs, or near-term goals of the entity.

In terms of feed mechanisms, we believe the opportunities trigger feedforward intelligence and pressure, feedback intelligence. On the other hand, an *ex ante* rationalization emerges from feed within, a strictly internal process not visible to the outside world. We contend that feed within information intelligence available to the actors is limited and perhaps not as advanced; in contrast, non-actors are likely to have cultivated feed within processes in them to an advanced level.¹¹ *Ex ante* rationalizations emerge from within, and have a great deal to do with whether the person will enter the LAG cycle; the entry is concurrent with an *ex ante* rationalization as he enters the LAG cycle. In contrast, *ex post* rationalization may emerge from others' views rather than from within the actor himself.

P 8: *Ex ante* rationalizations of the actor are pertinent in the explanation of the act; *ex post* rationalizations are not.

The Theory: Connecting the Framework to the Cycle

Why do we need both the TRS framework and the LAG cycle to explain indiscretion? The answer lies in the fact that a person's disposition plays a key role in the act, but by itself, it is not enough; the attachment to the object of desire is equally necessary for the act to occur. Without attachment, even a person of subtype R(t) disposition may not indulge in the act. And attachment most likely would take hold (materialize as an entry into the LAG cycle) for persons of certain dispositions. Consequently, both disposition and the process of engaging in the LAG cycle are necessary to develop a behavioral explanation of the act. Figure 6 summarizes the role of the framework and the cycle.

¹¹<http://video.forbes.com/fvn/forbes400-10/bharat-desai-billionaire-yogi>. This video from *Forbes Magazine* shows the lifestyle of Syntel, Inc., Chairman, Bharat Desai and how he practices feed within.

		The LAG Cycle	
		Actor	Non-actor
The TRS Framework	Potential actor	R(t)s with attachment	R(s)
	Potential non-actor		R(t)s without attachment;R(s)

FIGURE 6: ROLE OF TRS FRAMEWORK AND THE LAG CYCLE

Nescients and subscentists are likely to fall prey to temptations, for they suffer from a disposition that represents inertia of knowledge, which in turn makes them prone to commit a wrong act. Their value judgments can be, and are often likely to be self-centric, causing an alliance with the temptation. Temptation suggests a potential wrong-doing. It is not value-neutral.

What comes first, opportunity or temptation? We reiterate Reimer's assertion: the *opportunities* inherent in trust positions form *temptations* if the incumbents develop anti-social attitudes which make possible an abandonment of the folkways of behavior [emphasis added]. We believe this to be not entirely true; temptation, surfacing on its own, makes the person seek out – put in focus – a fitting opportunity if the person wishes to yield to the temptation. An opportunity implies an advantage, a favorable condition to do something, but its origin does not have to be the temptation. Moreover, once temptation takes hold, it is possible that the prospective actor will find in focus a particular opportunity helpful in fulfilling the temptation. If a fitting opportunity does not support the planned act, the actor may create a new opportunity that serves the temptation on hand. All other opportunities, however promising they might be, seem irrelevant to the prospective actor. Finally, whereas temptation suggests what one so badly wants (desire), opportunities relevant to this intense desire improve or confirm the belief that the object of temptation is within reach.

Interestingly, the theory articulated here does not give much significance to the presence or absence of incentives.¹² Ramamoorti *et al* (2008) effectively noted that greed is not the final answer. If this is true, then the existing beliefs on the role of incentives in FFR would require a reexamination.

Insights From Academic Research

Ramamoorti *et al*(2008) discuss Tomkins' work on the theory of emotions, which was further developed by Nathanson (1992). Tomkins argued that people experience nine core emotions (or affect). These emotions are triggered by stimuli in the environment. The emotions play a dual role: communicating unmet needs and providing motivation for action. Nathanson extended Tomkins' work to develop a framework, S-A-R; in essence, it conveys that stimuli trigger affect (emotions), and affect in turn generates reaction. With some exceptions, SAR is comparable to the LAG cycle, for example, the LAG cycle considers the role of attachment to an object of desire and also the role of disposition of a person in the happening of the act. And it also suggests the role of obstructions in pacing the emotions and the reaction that follows in the form of an indiscretion.

Another leading development outside of the FFR focuses on the nature of intentional action. Davidson's (1980)belief-desire model that attempted to explain intentional action was further addressed by Velleman (2000). Taking this as an initial formulation, Setiya (2007) extended the model to a more robust form. We are leaning mainly on Setiya's work in the following discussion.

First, it is necessary to recognize that there are involuntary and basic actions, and there are voluntary and intentional actions. Fraud is discretionary; it is an intentional action. Hence, the discussion of nature of intentional

¹² In their study on CFO Intentions of Fraudulent Financial Reporting (2005), Gillett and Udin found that compensation structure is not a good indicator of CFO intentions to report fraudulently.

action and its relationship to the theory proposed here is crucial. Second, it is important to recognize that in acting intentionally, our reasons are up to us – we decide why we do something as well as what we do – and we seem to recognize our reasons, as such (Setiya, 2007, 39). Third, the belief-desire model, which is independent of reasons, can be described as follows:

We want something to happen, and we believe that some behavior of ours would constitute or produce or at least promote its happening. These two attitudes [a desire and a belief] jointly cause the relevant behavior (Adapted from Velleman, 2000, 5).

The desire is involved in the proximate motivation of intentional action (Setiya, 2007, 32) but its existence is in tandem with the belief. The two co-exist in the desire-belief model to explain intentional action. Setiya (2007, 39-40) argues that we choose the reasons on which we act and we know without observation not only *what* we are doing, but *why*. Taking something as one's reason is both desiderative or motivational (expressing desire) and cognitive (expressing related belief). Taking-as-one's-reason is not simply belief, or desire, but a state that has features of both.

An intentional act is a result of both motivation of action and the motivation of desire. The motivation of action is value-neutral and is driven by means-end efficiency; it drives the intentional action. The motivation of desire is a function of disposition, “a state whose presence entails that there is something I want (Setiya, 2007, 104).” The motivation of desire is evaluative while the motivation of action is explanatory.

Relating the nature of intentional act to the LAG cycle and TRS framework, we find that the LAG cycle is explanatory; it does not hypothesize the reasons for someone entering the cycle. The TRS framework is evaluative in that it presupposes a state whose presence entails, or induces, the thought that there is something a person wants.

The Measurement Challenges

Human Disposition: T-R-S

Researchers have been working on the development and validation of instruments to measure human disposition according to the T-R-S framework. First documented attempt to develop an inventory to measure T-S-R came from Peremeswaran (1969) who named the inventory as the “Guna” inventory¹³. It consists of 80 items with three factors, one measuring Type T (29 items), the other Type R (27 items), and the third, Type S (24 items). The Likert-type attitudinal scale used in this inventory has three scales (agree, disagree, and doubtful), and the total score on each disposition is simply the aggregate of scores on items on the corresponding factor. In a manner similar to the Eysenckian dimensions of personality, the factors on the inventory are treated as independent. Mohan and Sandhu (1986) developed Triguna inventory to measure the three dispositions. They found that Type S was distinct from Type R and Type T. Separately, Das (1987, 1991) developed a similar inventory. He found that T, R, and S are negatively correlated with each other and that R is closer to S than T in the sequence T, R, and S. Pathak *et al* (1992) developed categorized norms and percentiles to measure a person's disposition in the sequence TRS. The three dimensions in their psychometric measure showed low correlations with each other, suggesting that the dispositions are truly independent of each other. Subsequently, Matthew (2010) developed an IAS (Inertia, Activation, and Stability) rating scale which essentially measures TRS dispositions. The IAS rating scale has shown high reliability and construct validity. Maruthamet *al* (1998) constructed a similar inventory, and found that correlations between T, R, and S were low, but significant.

While the studies as such attempted to construct a potentially valuable psychometric inventory, attempts to validate the constructs were limited. A first systematic approach toward this is reported by Dasa (1999) who named the refined inventory as VPI (Vedic Personality Inventory). The original 90-item instrument was shortened to 56

¹³ The term *Guna* in Sanskrit means constitution or disposition. Triguna in Sanskrit represents the three dispositions, T, R, and S.

items, using the results of reliability and validity tests. For the shortened inventory, Cronbach's alpha for the three subscales (T, R, and S) exceeded .93, and the corrected item-total correlation of every item on the shortened VPI with three subscales was greater than 0.50. Three measures of convergent validity and four measures of discriminant validity provided evidence supporting the construct validity of the instrument. Finally, the loading of each item on the scale was stronger for the intended subscale than the other two subscales. The factors are non-orthogonal, suggesting that the three dispositions, T, R, and S are not entirely independent.

Moral Development: DIT-2 scale

Previously, we referred to Rest's work on moral stages (schemas) based on Kohlberg's work. Influenced by Kohlberg's six-stage theory of moral reasoning, Rest developed the DIT (Defining Issues Test) as an assessment of how adolescents and adults come to understand and interpret moral issues. Rest viewed moral judgment development as a social and cognitive construct, and identified three schemas within the construct, suggesting progressively higher level of moral judgment development: a narrow self-focused interpretation of moral issues (Personal Interest Schema), an understanding of the broader social world and associated group-based claims on moral decisions (Maintaining Norms Schema), and a reliance on post conventional moral principles (Post conventional Schema).

Human disposition is a pervasive influence at all levels (physical, aesthetic, intellectual, moral, and spiritual), including the moral stage. Consequently, the TRS framework is likely consistent with Rest's work. Measures of TRS would probably correlate with the DIT measures. And thus, insights gained from studies on moral judgment using DIT would further our understanding of differences between actors and non-actors in the FFR realm.

Separately, DIT research has potential to contribute insights on moral development. To quote Thoma (2006, p. 88): "Taken together, these efforts support the view that DIT research is a progressive force in the field and has been efficient in suggesting new directions for study, particularly in the more applied areas such as . . . professional ethics . . ." There are no known studies in FFR as yet that have used DIT-2¹⁴ construct.

Implications

This paper delineates a new line of thought on a fundamental premise that an act of fraud of any kind is a human act, and ultimately, it has to do with human psyche. A fresh thinking on the anatomy of fraud leads us to resort to two related views: the TRS framework and the LAG cycle. The theory advanced here has the potential to not only clarify but also extend our understanding of fraudulent behavior.

If the intention is to help prevent or detect fraudulent behavior, we will have to learn much more about dispositions. What are the sources of disposition? How does one inherit the initial disposition? How do you effect change in disposition? In the following paragraphs, we note briefly some of the areas where we believe the theory advanced here is likely to shed more light and may even clear up some of the noise, confusion, or misgivings. The discussion below is not exhaustive, but rather illustrative of how the foundations of this study could contribute to the field of FFR.

College Education

College education can play a significant role in improving one's moral development. Contrary to the belief that education does not help differentiate actors from non-actors, we propose that higher education offers the potential to transform self-centric young adults (possibly, actors) into other-centric grownups (likely, non-actors). If there was one thing that could facilitate disengagement from selfishness and attraction to serving others, it is the higher education. Traditionally, universities have been regarded as the institutions for raising awareness of one's larger

¹⁴ DIT-2 is an improved, more current, version of DIT. Besides improving the context for some of the cases, the new construct represents refined process and online administration.

purpose in life. As Lewis (2006, p. xii) asserts, “the fundamental job of undergraduate education is to turn eighteen- and nineteen-year-olds into twenty-one- and twenty-two-year olds, to help them grow up, to learn who they are, to search for a larger purpose for their lives, and to leave college as better human beings.” Indeed, the true role of universities has been much broader than finding a paycheck at the end; they are meant to produce not the careerists, but the characterologists. In T.H. Green’s words, the former is a kind of devotion to great objects and the latter, a devotion to public service. Finally, a large body of research shows that college years are a time of significant development in the realm of moral judgment (for a review, see King and Mayhew, 2002).

Red, Yellow, and Green Flags

Research in the area of fraud risk factors is extensive and ranges from the investigation of how the auditors make the fraud risk assessment to surveys to determine the relevant risk factors. Additionally, studies have focused on determining the relative importance of risk factors. Apostolou *et al* (2001) used the analytical hierarchy process methodology to construct auditors’ decision models rather than having auditors provide a simple ranking of the importance of risk factors. Their sample consisted of 140 practicing auditors (43 Big 5 auditors, 50 auditors from regional/local firms, and 47 internal auditors). They found that 58.2 percent of the total possible 100.0 percent decision weight is associated with management characteristics and influence over the control environment, compared to 27.4 percent assigned to operating and financial stability characteristics and 14.4 percent to industry conditions. The three single most important red flags (compensation tied to accounting practices, attitude about internal control, and securities law violations) accounted for almost 40 percent of the total decision weight.

While it is important to not ignore operating and financial characteristics and industry conditions in assessing fraud risk, the evidence in the Apostolou *et al* study (2001) clearly points to the top management team, led by the chief executive. The risk at this level borders on inherent risk, as distinguished from control risk. The disposition of the chief cannot be controlled, nor can the culture cultivated by the executive.

Another important consideration here is this. As the number of flags grows, the assessment of fraud risk becomes much more diffused. If some of the flags are marginally relevant, or relevant only under special circumstances, the efficiency of the process may suffer and the risk of Type II errors (accepting the false) may increase. Additional research to study flags that are misleading, or not as red as originally thought, might prove helpful. Finally, research to determine if there are any green flags that would obviate the fraud risk would help. “Extravagant lifestyle,” suggested by Albrecht and Albrecht (2003) as a category of the symptoms of fraud, warrants further investigation. And if this would be a red flag to look for, the lifestyle of potential non-actors –modest living despite all the affordability has the potential to operate as a green flag.

Corporate Social Responsibility

Jennings (2007) argues that one of the signs of ethical collapse in FFR is that good in some areas atones evil in others. For most part, her discussion on “goodness” focuses on personal and corporate philanthropy. Her indictment (p. 237): As long as they were good to the environment, strong on diversity, involved in the community, and generous with charitable donations, their schemes and fraud at work were not a problem.”

We disagree. A person’s disposition (and if she is a CEO, the company’s culture reflecting her disposition) prompts the type of philanthropy: Ts will focus on serving with a strong urge for self-interest, Rs will resort to cause marketing through philanthropy, and Ss will do it for the sake of community’s well-being with a complete disconnect with self-interest. In Jennings’ (247) words, “. . . the same type ego that fuels a fraud also craves the spotlight;” this, of course, applies to R(t)s – the pool of executives who might commit indiscretion, not R(s)s.

People with disposition R(t) are deep in self-interest. It is no surprise that Dennis Kozlowski’s donations Boca Raton charities at the behest of a public relations executive in all likelihood were prompted by the desire to improve self-image. And his motive behind a hefty donation to Nantucket Conservation Foundation could very well have a hidden agenda of keeping the land next to his property undeveloped, an intent that the Foundation had implicitly endorsed. Self-interest and ostentations are clearly the red flags for noticing R(t)s.

One needs to be cautious, however, in blending every philanthropic behavior into one intention. There are R(s)s out there that have done very well in serving the community (e.g., Warren Buffet, Narayana Murthy, Bill

Gates). We believe that one's disposition is revealed by the character and intent of philanthropy. In turn, this would allow us to identify an executive as a subtype R(t) or R(s). However, not all R(t)s identified through self-interested philanthropy may be found to have committed fraud, but the potential exists, only to be activated by attachment.

Related Party Transactions

From their literature review of related party transactions, Gordon et al (2007) drew certain conclusions including the following (p. 82):

- Related party transaction disclosures are present in the Securities and Exchange Commission filings of most public companies.
- While listed as a fraud risk factor in authoritative literature, related party transactions do not appear to be more common in companies committing fraud than in companies in which no fraud had been detected. . . . the presence of related party transactions alone does not appear to significantly increase external auditors' client risk assessment.

The related party transactions present yet another opportunity for fraud and yet, the evidence is mixed at best. For example, Bell and Carcello (2000) compared samples of companies that commit fraud to samples of companies that did not commit fraud. They found no differences in the existence of related party transactions between the two groups. If the related party transactions are to be considered a key risk area, given the pervasive presence of such transactions (including other transactions or relationships structured with similar intent), the task of assessing fraud risk becomes more like finding needles in a haystack. The probability of Type II error increases and audit efficiency decreases. The idea of evaluating every opportunity, structured as a related party transaction, in the fraud risk assessment process seems infeasible, for the requisite variety in structuring these transactions is limitless. The only effective way to plug the opportunities would be to prohibit such transactions altogether, but this would be an extreme regulatory step, infringing upon the right to conduct business in the manner the management sees fit.

The case of related party transactions offers strong arguments for looking at other cost-effective and preferably preventive, means of governance and assurance. We surmise that a person's disposition has little to do with such transactions, except where they represent potential self-interest of the executive, or a trigger for temptation to seek the unprocessed at any cost. The latter, however, is difficult to claim, for attachments can be transient; related party transactions are not a prerequisite to fall prey to temptations. An analysis of related party transactions – which are ultimately just another set of windows for opportunities – from this perspective could prove valuable in determining the level of emphasis the professions and regulators should place on this area.

Non-actors

Throughout this paper, we have emphasized the need to identify non-actors as a source of learning. If we understand non-actors, there would be hope to transform potential actors. The argument we advance is that almost all, if not all, R(s)s are likely to be found non-actors. In addition, not all R(t)s may commit fraud. This is because they are likely to fall prey to temptation only when they are attached, not otherwise. Consequently, related to R(t)s, we need to determine the role of attachment that pulls them into an act of indiscretion. For such studies, the SEC's database is unlikely to provide potentially relevant data, for the SEC enforcement actions are limited to suspected actors only, and even in this critical but limited universe, such data do not involve consideration of dispositions or attachments of the actors at the time of the act. Moreover, such data certainly leave out non-actors, both R(s)s and those R(t)s who did not commit an act (or who did not get caught).

Limitations

Several limitations of this study are significant and need to be addressed in future studies along these lines. First, the approach is new and would undoubtedly raise more questions. While metaphysically sound, its effectiveness in the FFR arena will require further analysis and reflection. Major pieces of the puzzle need to be discovered through further research. For example, what forms of attachment are likely in financial reporting? What is the relationship, if any, between opportunity and attachment? Is it likely that following an attachment, the actor creates fitting

opportunities? What role does desire-belief model play in the act of indiscretion? What factors influence or confirm belief to a degree where desire is acted upon? Second, there are significant measurement issues in this new thread of research. For example, are DIT-2 measures relevant to determine dispositions of people? How valid are the inventories of TRS? How do we measure windows of attachment and if successful in this attempt, what possibilities exist to consider them as red flags? Finally, if we are successful in producing evidence to support the theory, how could this new knowledge be put to use? Would it be possible to assess the disposition of the chief executive? Can we recruit or qualify candidates on the basis of their dispositions? How would corporate governance be affected by the theory?

Despite these unknowns of the new grounds broken here, there is significant upside to the theory. It takes us to the root cause of acts of indiscretion. Chasing the opportunity and incentive dimensions has not helped us much in improving the financial reporting and governance climate. Opportunities and incentives will remain as exogenous variables which can be manipulated any time; they provide an endless exercise in creativity and manipulation. The core of the problem lies in the conduct of the person(s) who become possessed for a time with an object of desire; in their minds, it is a must; they must achieve that because their desire-belief model supports it.

If proven, will the theory help eliminate all financial fraud? Definitely not, but it will help ameliorate the crippling problem profoundly. Underlying the theory is a proactive solution implicit in the transformation of disposition of actors, to help executives grow the traits of a non-actor. This can be accomplished through increased awareness and commitment to moral duty, using feed within exercises such as meditation (Raval and Raval, 2010, 207-222). Even if modest progress is made along the line of research proposed here, the auditing profession and the regulators can become more proactive in stopping the bleeding of financial markets. The red flags identified so far have mixed evidence of working as real red flags. And we have not explored green flags as yet; they are important in leading us to better solutions. In the proposed theory, a strong and perhaps quite valid presumption is that the answer lies outside of the substantive domain of financial reporting and perhaps even beyond what we know from the fraud triangle.

Albert Einstein once remarked, "If at first, the idea is not absurd, there is no hope for it." As farfetched as these propositions may appear, there is hope. The downside risk is minimal; upside potential is significant. Knowing why fraud occurs in the first place can result in saving corporations and their market caps, improved audit effectiveness, putting trust back in the world of investing, and putting lesser emphasis on regulations and the law, which provide only incomplete remedies and onerous side effects. The loss of a corporation due to fraudulent acts means that communities of which they are a part suffer losses, including unemployment, lost support to the local economy, and reduced social responsibility initiatives.

APPENDIX A
EXAMPLES OF PREDISPOSITION OF EXECUTIVES

Year	Case	Person involved	Descriptors of the person
TYPE S:			
1932	International Match Company	Iver Kreuger	Indifferent as a student; some suspected cheating during his student days; his agents used threats and bribery to buy match factories.
1938	McKesson & Robbins	Philip Musica (a.k.a. F. Donald Coster, M.D., Ph.D.)	Little education. Imposter. Devious. Convicted of fraud twice (avoided import tariffs, forged documents) and went to prison before age 30.
TYPE R:			
1996	Sunbeam	Albert J. Dunlap	Tenacious. Intensely focused on worldly success. Layoffs and plant closings a common occurrence in his turnaround management.
2000	Enron	Jeffrey Skilling	Drive. Passion for success. Young, eager to be rich; conscious about personal status.
2000	WorldCom	Bernie Ebbers	Charismatic. People pleaser. Distributing favors to buy loyalty.

APPENDIX B
EXAMPLES OF THE LAG CYCLE

Actor	Temptation feeding lust	Obstruction causing affect	Reaction
Charles Ponzi	The thought of international arbitrage (neither illegal nor fraudulent) of postal reply coupons, later translated into a <i>ponzi</i> scheme.	Inability to meet the gap between interest paid to investors and income earned on the funds invested. Continuing to pay high returns was impossible. The rapid growth of his company attracted attention of regulators and the media.	Tried to pacify the investors, employed his former cellmate to hide his past. Ultimately, the <i>Boston Post</i> exposed the fraud.
Patrick Kuhse	To earn superior levels of commissions from the State of Oklahoma on bond investments of the State.	Upon suggestion from the Oklahoma State employee friend in charge of bond investments, agreed to pay kickback to her, for she approved excessive commissions for him. Later, his friend fired a disgruntled employee who blew the whistle on the scam.	Departed for Costa Rica.
Tommy Ingram	To earn kickbacks from a contractor.	Large contracts required competitive bidding.	Break the jobs down below \$25,000 limit, where the low unit-price contractor could be given the job without further bidding.
Barry Minkow	To make his business grow and look prosperous, despite financing difficulties and lack of revenues.	When he attempted to raise funds through his stock of ZZZZ Best, the accountants wanted to inspect the company's operations.	Minkow borrowed fake offices for a tour of "Interstate Appraisal Services" and used an incomplete building to present a fake restoration job.
Raju Ramlingam	Merger of a real estate enterprises with an outsourcing company, Satyam Computers.	Shareholders strongly rejected the proposal.	To support leveraged debt, built fictitious, but believable prosperity in Satyam's financials.

This research was supported by a grant from the Graduate School, Creighton University. The paper has benefited from comments on a prior version of the paper from W. Bruce Johnson (University of Iowa), Beverly Kracher (Creighton University) and research workshop participants at Creighton University.

Changing Facets of FDI and Conceptual Issues in Internationalization

Debdeep De, debdeep.de@jiit.ac.in

Pinaki Dasgupta, pinaki@iift.ac.in

Deemed University, India

Abstract

One of the most important phenomena in the process of globalization is the continued significance of regions as focus of economic activity. Systemic processes of rapid technological change enhanced capital mobility and inspired inter-regional competition for investment triggers the dynamics and notions of regional development. Aspects of trade relationship with several countries have undergone changes which opened up new opportunities with the multinational companies. This paper is an attempt to explore how Foreign Direct Investment (FDI) has been able to transform the value chain approach specifically in the manufacturing sector thereby reinforcing aspects of internationalization process. The options of efficient manufacturing by exploiting the economies of scale came into consideration and India became the most favored destination of FDI. The paper emphasizes the importance of FDI from a theoretical perspective and tries to develop an understanding on the different implementational issues which may be vulnerable to an economy's development.

I. Introduction

The historical experience of advanced economies shows that establishing a broad and robust domestic industrial base holds the key to successful development because of its potential for strong productivity and income growth. The process is associated with a strong investment drive in industry, rapidly rising productivity and a growing share of the sector in total output and employment. A rapid increase is observed in the share of fragmentation-based trade in world trade. The production process in certain industries has become standard fragments which can be effectively used in a number of products. Examples include long-lasting cellular batteries originally developed by computer producers and now widely used in cellular phones and electronic organisers; transmitters which are used not only in radios (as originally designed) but also in personal computers and missiles; and electronic chips, the use of which has spread beyond the computer industry into consumer electronics, motor vehicle production and many other product sectors. As international networks of parts and components supply have become firmly established, producers in advanced countries have begun to move the final assembly of an increasing range of consumer durables (for example, computers, cameras, TV sets and motor cars) to overseas locations in order to be physically closer to their final users and/or to take advantage of cheap labour. At the early stages of international fragmentation of production, the processes normally involved a multinational enterprise (MNE) building a subsidiary abroad to perform some of the functions that it once did at home. Over the years, fragmentation practices have begun to spread beyond the domain of MNEs. As production operations in host countries became firmly established, MNE subsidiaries have begun to subcontract some activities to local (host-country) firms to which they provide detailed specifications and even fragments of their own technology. Moreover, many MNEs in electronics and related industries have begun to rely increasingly on independent contract manufacturers for the operation of their global-scale production networks – a process that has been facilitated by the standardisation of some components and by advances in modular technology. Through this process assemblers push investment and price risk to the independent suppliers and increase their own efficiency. These new developments suggest that an increase in fragmentation-based trade may or may not be accompanied by an increase in the host-country stock of FDI.

Theories concerning internationalization of the firm have been mainly dealing with the questions about what are the underlying reasons for firms deciding to enter international markets. Another core question has been dealing with which types of operation forms firms are choosing when making the entry and when further developing their foreign operations. The third issue has been the geographical spread and development of international business activities. The present paper focuses on the basic theories of the process of internationalisation and the role of FDI enhancing the process. The paper is divided into different sections. Section I is the introduction followed by Section

II which theorizes the process of internationalization. Section IV gives an idea about the international production network and value chain which is followed by Section V which gives an overview of the global FDI flow. Section VI discusses specific FDI flows between EU and India as illustrative of the economies involved in the process of investment. It also points out the findings of the select Italian companies investment scenario in India. The next part is Section VII which illustrates the Sectoral flow of FDI in the context of a parts and component sectors. Finally Section VIII concludes highlighting the nexus between FDI and value chain mentioning the concerns existing in the process.

II. Internationalization

Internationalization is the process of increasing of involvement in international operations across borders (Welch and Lucstarinen, 1988). According to Cunningham and Homse (1982), internationalization is continuous process of choice between policies which differ may be only marginally from the status quo. This view was also endorsed by Bilkey (1978), Rothchild (1983), and Cavusgil (1984). It is an ongoing strategy process of most business firms and their strategy process determines the ongoing development and change in international firm in terms of scope, business idea, action orientation, organizing principles, nature of managerial work, domination values and converging norms.

Significant models and theories in the field of international business describe the internationalization process as a gradual development taking place in distinct stages and over a relatively long period of time. Various theories in international business, such as Product cycle theory of Vernon (1966), Oligopolistic theory of Knickerbrocker (1973), Monopolistic Advantage theory of Hymer (1976), International Theory (Buckley and Casson, 1976), Uppsala school's Stage theory (Johnson and Vahlne, 1977), Eclectic paradigm (Dunning, 1988) and the Network Theory of Axelsson and Easton (1992) proposed in different times, explain the process of internationalization differently. The existing theories are largely based on the assumption that firms become international long after they have been formed. Explained below are some of the theories of Internationalization.

The traditional classical macroeconomic theory of FDI hypothesises that the rate of profit has a tendency to drop in industrialised countries, often due to domestic competition, which creates the propensity for firms to engage in FDI in underdeveloped countries (Cantwell, 2000). In 1960, Hymer introduced a microeconomic theory of the firm, focusing on international production considering the key requirements for an individual firm in a given industry to invest overseas and thus becomes an MNE (Cantwell, 2000), including tradable ownership advantages and the removal of competition. The micro-level theory of the MNE replaced the seemingly redundant macro-level theory of FDI, due to its flaws. Hymer noted four discrepancies: (1) the older theory suggested that flow of capital was one directional, from developed to underdeveloped countries, whereas in reality, in the post-war years, FDI was two-way between developed countries; (2) a country was supposed to either engage in outward FDI or receive inward FDI only. Hymer observed that MNEs, in fact moved in both directions across national boundaries in industrialised countries, meaning countries simultaneously received inward and engaged in outward FDI; (3) the level of outward FDI was found to vary between industries, meaning that if capital availability was the driver of FDI, then there should be no variation, as all industries would be equally able and motivated to invest abroad; (4) as foreign subsidiaries were financed locally, it did not fit that capital moved from one country to another.

Thus the classical macro-level theory was based on the concept of a perfectly competitive market, where the increase in demand and subsequent super-normal profits gained in an industry in one country would cause profits to eventually drop with the flooding of the market with new entrants. If a foreign firm entered the market, the extra costs of being foreign would drive them out of business when prices decreased, meaning that they would have to have something which offset the disadvantages of being foreign.

Hymer argued that MNEs can only exist in an imperfect market, where firms have non-financial ownership advantages *vis a vis* other firms in the same industry, meaning that the driver for the MNE lies with the individual firms, rather than the country's capital availability. Another result of structural market failure is the removal of conflict between firms within a given industry (Yamin, 2000). Hymer discusses the nature of the "market power" (Cantwell, 2000) approach of firms and their oligopolistic (Yamin, 2000) interdependence, as they focus on the

domination of the market, the raising of entry barriers and the removal of conflict, all by collusive agreements. Firms, in theory then invest abroad in order to dominate more markets, raise profits and create more conflict-removing oligopolies. Hymer also states that only the largest of firms, such as those in an oligopoly, could sufficiently offset the costs of being foreign with their strong ownership advantages.

The OLI – approach by Dunning (1979, 1981) is an ‘eclectic’ approach stating that ownership, location and internalization variables collectively forms reasons for international trade and investments of firms. The stage approach to internationalization is related closely to the growth and economic reasoning, but taking also the managerial behavior like learning and commitment into account. The spatial perspective is also incorporated. This approach is also the other classical models which usually look at the nation state as a geographical – statistical unity. The Transaction Cost Analysis (TCA) assumes that markets are competitive and that low control modes exist. Because of opportunism, suppliers are forced to perform efficiently. This theory is useful in order to explain the vertical integration decision of organizations. Companies integrate in case of high asset specificity and to retain control over specific advantages. Furthermore it shows how firms especially MNCs evaluate whether or not to establish a manufacturing subsidiary in a market abroad.

The Retail Internationalization Process Model (RIP) assumes that companies internationalize when they can not grow adequate in their domestic market. The RIP model postulates an interplay of the firm’s and the decision maker’s characteristics, along with the external environment, serve as promoter or inhibitors for whether a firm will initiate international retail activities, maintain a constant level, increase or decrease its level of international retail involvement, or completely withdraw from its international market. With the help of this theory strategic decisions, like where to allocate the firms resources and how to enter the market, can be made. The model is dynamic and reiterative.

Another Internationalization Process model is the Innovation – Related Internationalization Model (IM). This model concentrates on the internationalization as innovation. The models focus on the learning sequence in connection with adopting an innovation. The authors assume that there exist push and pull mechanisms in initiatives to export and for movements to next stages. The IM sees the internationalization process as evolutionary and learning process like the Uppsala Model.

The Strategic Choices Model with its Multidomestic Strategy, International Strategy, Global Strategy, and finally Transnational Strategy describe different strategies how to enter the host country during an internationalization process of a company. These strategies are used according to the extent of pressure for cost reductions and local responsiveness.

Another model, which can be used in addition, is the Adaptive Choice Model. The ACM is an outcome of a case study and should complement the recent stage models. It handles the dilemmas in which managers can find themselves during the internationalization process according to Strategic, Structural and Human Resource Choices, which are left out in the stage models on the basis of their limitation.

Classical theories “Growth”, (Penrose 1959), The Hymer model (1960) concerns more with the economic reasons for firms entering into foreign markets, especially internalization gains and profit opportunities. Company growth opportunities and economic logic’s are according to these views are the guiding lines, also explaining why firms internationalize their operations. The “Uppsala internationalization theory” takes a stepwise approach, which postulates that the firm enters foreign markets gradually through learning commitment processes (Johanson & Vahlne 1977).

The modern theories of FDI for example the Dynamic Capability perspective argue that ownership specific resources or knowledge are necessary but not sufficient for international investment or production success. It is necessary to effectively use and build dynamic capabilities for quantity and/or quality based deployment that is transferable to the multinational environment. The Integration-Responsiveness Perspective states that FDI is a complex process requiring coordinating subsidiary activities across national boundaries which includes the coordination of activities across countries to build efficient operations networks and response to specific host country needs.

III. International Production Network and Value Chain

There is a drastic shift of trade pattern from one way trade to intra industry trade in the region especially in East and South East Asia. Globalization has given rise to new and more complex trade patterns particularly trade associated within international production networks (IPN). While a large part of international trade still involves products made more or less entirely within countries, the proliferation of production networks is gradually internationalizing many commodities and services. The international value chains and associated production networks in the region are emerging as the organizing framework for production, investment and trade in an expanding range of product groups such as garments, agro industry, furniture, automobiles/ automotive parts, consumer electronics, telecommunications and ICT, as well as various services.

Several experts relate the rising trade in Asia with the literature of 'flying geese' pattern of development led by Japanese investment. According to this idea, as production costs in the first tier countries (Korea Rep., Taiwan etc) are increasing, investment was flowing to other developing countries for production of parts and components. Ahearne et.al, (2006) argue that this pattern finally gives rise to a country like China which moves into the product space vacated by the first and second tier economies with greater integration of trade across the region in production networks. However, Bernard and Ravenhill (1995) argues whether the phenomena is due to 'flying geese' pattern or not more focus is required to understand the changing production relation between local and transnational firms to demystify the dynamics of production network and thereby the forces behind this rising trade in components. According to this idea, production patterns are becoming more standardized. Parent MNCs can now outsource several fragments of the final product without fear of losing the knowledge of patented components. Components producers are also competing neck to neck and ready to share risk along with the parent MNCs. In this context, Bernard and Ravenhill (1995) mentioned about the production network of microelectronics. Ernst and Kim (2002) consider that production relations between MNCs and suppliers got influenced by rapid trade liberalisation and ICT revolution which in turn help these firms to get integrated. Kojima (2000) mentions that shortening of product life cycle is one more reason to force firms to fragment their production process locating them in different countries which not only reduces the production cost but at the same time help firms launch new products simultaneously in different countries to have a quicker access to the consumer base. Tung (2003) also pointed out that flying geese pattern may not hold good while we analyse pattern of development in different industries. The fragmentation of production and corresponding firm specialization in tasks is leading towards the development of a new paradigm for international trade (Grossman and Rossi-Hansberg, 2006). As a result, SMEs involvement in international trade is increasing and efficiency level of these firms while delivering the goods and services are also improving significantly. According to Ernst and Kim (2002), two types of flagship model influence the trade in components: 'brand leaders' and 'contract manufacturers'. Flagship company remains in a position to control other smaller firms in different locations and thereby the extent of trade. Under the 'brand leadership' companies such as Cisco, GE, IBM, etc. connect themselves to number of firms globally. The suppliers here have to go a lengthy process of certification to ensure that they meet leader Companies' requirement. Unlike brand leaders, contract manufacturers, such as Flextronics or Solectron, establish their own (international) production networks that serve the global brand leaders. So, components trade can occur within the large network of the same companies or among various independent but interconnected suppliers. Kimura and Ando (2005) claim that the international product fragmentation depends on firms' capability to control the production process. Firms will outsource more from different smaller firms if they have relatively less control on the production process. Otherwise, they will develop vertically integrated branches internationally.

Policies and incentives towards SMEs in many countries help them to be more efficient which in turn assist firms to become effective players in international supply chain. Though Japanese investment in early years have initiated the process but high technology absorption skill of many SMEs pushed themselves up in the value chain which is one of the targets of these highly integrated players. In this context, many companies,

particularly smaller enterprises, are finding that success and value creation may be achieved through specialization in a limited set of activities, outputs and market niches.

IV. Global Trends in FDI

FDI shows a steady rise which took the peak in 2000. Although there was a slight down fall was happen in between 1990 to mid-1991, but from mid-1991 it was recovered very quickly and between 1992 to 2000 world saw an enormous amount of rise FDI.

FIGURE 1: TRENDS IN GLOBAL FDI FLOW

Source: Calculations based on UNCTAD Database

In 1991-92 world aggregate FDI inflows was less than 200 billion US dollars which rose to 1400 billion US dollars in 2000. But this boom in FDI didn't continue even a year in between 2000 and 2001 FDI fall sharply and this fall prevailed upto mid-2003. Global FDI inflows rose modestly in 2004 following large declines in their value in 2001 (41%), 2002 (13%) and 2003 (12%) and rose consistently till 2007 as depicted in Figure 1.

V. Trends of FDI in India

Country-wise details of FDI flows reveal the continued predominance of Mauritius, the US and the UK, as major investors in India. Sector-wise, FDI flows into India were attracted by the increasing competitiveness of select manufacturing industries and services, particularly business and computer services.

FIGURE 2 TRENDS IN FDI FLOW IN INDIA

Source: SIA Newsletter, Government of India (Figures for 2009 are till October)

At the global level, services have been the key attraction for foreign direct investors, a structural shift indicative of off-shoring. Among the major sectors apart from services sectors such as computer software and ITES, other sectors such as telecommunication, electrical equipments, chemicals, cement industry, transportation, pharmaceuticals, metallurgical industry are the major attractors of FDI.

TABLE 1: INDIA'S INFLOWS OF FDI: MAJOR SOURCES

Country	2000-2005 (Jan-Dec)	2006 Jan-Dec	2007 Jan-Dec	2008 Jan-Dec	2009 Jan-May
Mauritius	349,666.91	222,207.52	319,437.05	598,586.46	255,168.51

VI. I. FDI in India: The Case of EU

India-EU relations have grown up substantially in both quality and depth in the last few years. In the economic sphere, ties have expanded and the parties have worked closely together to strengthen the multilateral trading system and to pursue a constructive dialogue on trade and investment and economic cooperation. EU is an important source of FDI for India. EU accounts for about 19.5% of total India's FDI inflows. In terms of Cumulative FDI inflows to India since April 2000, EU ranks 2nd. In 2007, EU's investment in India rose by 266.66% from 2006. EU invested \$ 13.9 billion in 2007. Whereas, EU's total investment in China was only \$2.56 billion in 2007.

The top 5 sectors attracting FDI inflows in India from EU are Services sector, Computer software & hardware, automobile industry, chemicals (other than fertilizers) and electronics.

TABLE 2: TOP 5 SECTORS ATTRACTING FDI INFLOWS FROM EU (FROM JAN 2000 TO JUNE 2007)

Ranks	Sector	Amount of FDI inflows	Sector's share in total FDI inflows From E.U
		In US\$	
1	Services Sector (Including Financial & Non-Financial)	2,417.32	35.92
2	Computer Software & Hardware	366.89	5.49
3	Automobile Industry (Including Passenger Cars Etc.)	359.19	5.33
4	Chemicals (Other Than Fertilizers)	322.68	4.93
5	Electronics	241.33	3.83
Total of above		3,707.41	55.50

Source: DIPP

Some of the leading EU companies of the world that have invested in India are Cairn, Castrol, Fiat, etc.

TABLE 3: TOP 10 FDI INFLOWS FROM EU COUNTRIES THROUGH INDIAN COMPANIES (Jan 2000-June07)

Nos.	Name of the Indian Company	Name of Collaborator/ Country/ Routes	Sector	Amount of FDI inflows Rupees/ (US\$)
1.	Cairn (I) Ltd	Cairn UK Holdings, U.K.	Business Services	Rs.66,632.4 (US\$1,462.8)
2.	Digital Global Soft Ltd.	Hewlett Packard Leiden B.V. Country: Netherlands Route: Acquisition of shares	Electrical Equipments (including computer software & electronics)	Rs. 9,505.2 (US\$206.6)
3.	Castrol India Ltd.	Castrol Ltd. Route: Acquisition of shares	Fuels (power & oils refinery)	Rs. 8,645.7 (US\$192.1)
4.	Micro Inks Ltd.	MHM Holdings GMBH. Route: Acquisition of shares	Chemicals	Rs.8,478.2 (US\$191.0)
5.	Himachal Futuristic Communication Ltd	Ecom Communication Ltd.	Electrical Equipments (including computer software & electronics)	Rs. 8,103.8 (US\$168.8)
6.	Emaar MGF Land P. Ltd	Horizon (I) BV Netherlands	Developing and subdividing real estate into lots	Rs.6,820.5 (US\$150.0)
7.	SAB Miller India Ltd.	-	Chemicals (other than fertilizers)	Rs. 5,973.7 (US\$129.9)
8.	Fiat India automobiles Pvt Ltd.	- Italy	Transportation Industry	Rs. 4,318.4 (US\$100.4)
9.	Mysore Cements Ltd	Cementrum I.B.V. Netherlands	Cement & Gypsum Products	Rs. 3,591.0 (US\$79.0)
10.	Hazira LNG Pvt. Ltd.	-	Fuels (Gas Transmission)	Rs. 3,368.8 (US\$73.2)

VI. II. FDI from EU to India: Summary Findings of Select Italian Companies

Survey findings of most of the companies located in India revealed that they are subsidiaries/branch offices of the Italian firms. They are able to setup their offices long back, however, the expansion of the companies in their Indian counterpart is not observed. Infact some companies have actually opened offices about a decade but the profit growth in the Indian counterpart is not quite contributory vis-à-vis their Italian counterpart. As far as the operations are concerned, very few companies have operational set up in India. Those who have their operational setup have very strong quality checks, and most of the equipments are imported from Italy. As a result of which, the price line of the product ranges manufactured in India are quite high since the quality is comparable of international standards. Thus the penetration of the products in the Indian market is quite low. Same is the case for the products directly imported from Italy. They cater only to a very small scale premium segment of the society. Thus most of the people who were interviewed were of the opinion that the standards really don't fit for all segment of the society. In some cases, its only the component which when ordered by the original equipment manufacturer gets imported and the Indian counterpart does only the liasioning for that particular product. Thus most of the products which are being sold are demand driven that too for only a premium segment. India was destined as one of the major markets in Asia. But since most of the operational units are not here they are still able to reap the economies of scale. The value chain

in most of the cases is quite simple and really does not add value as in many cases it's like a placing an order and supplying the same relationship. Infact most of the industries are yet to identify themselves in the value chain. As far as the operational issues are concerned a lot of problems arise in terms of taxes, apart from legal queries. The strategic location in Mumbai helps them in the sense of proximity of sea, and airports which takes care to some extent the smooth logistical functionality. Almost all the companies have well developed integrated IT systems and advanced mode of communication for interacting with their Italian counterparts. Though most of the companies plan to increase in the coming years however, the basic issue which was observed is the positioning and marketing of the products to penetrate the huge Indian market.

VII. Sectoral Overview of FDI

The Top 5 sectors attracting FDI in India from all the countries are services sector, electrical equipments, telecommunications, transportation industry and fuels (power & oil refinery).

TABLE 4: SECTORAL FDI FLOW IN INDIA

<i>Sector</i>	<i>2000-2005 (Jan-Dec)</i>	<i>2006 Jan-Dec</i>	<i>2007 Jan-Dec</i>	<i>2008 Jan-Dec</i>	<i>2009 Jan-May</i>
Services Sector	77,389.43	175,032.22	145,099.52	339,475.12	161,526.06
Computer Software & Hardware	122,234.01	87,492.90	102,148.54	78,102.50	13,360.47
Telecommunications	72,564.74	41,699.46	43,541.50	115,954.81	40,563.20
Housing & Real Estate	2,085.82	21,166.32	60,621.07	113,451.38	68,509.19
Construction Activities	17,554.24	36,613.91	51,924.40	103,623.52	38,989.45
Miscellaneous Industries	93,368.09	12,051.93	17,295.30	68,839.35	13,029.55

Source: SIA Newsletter, Government of India

In India, FDI is freely allowed in majority of sectors which include services sector. In few sectors, existing and notified sectoral policy does not permit FDI beyond a ceiling. FDI for virtually all items/activities can be brought in through the Automatic route under the supervision of the Reserve Bank of India (RBI), and for the remaining items/activities through Government approval considering the recommendation of the Foreign Investment Promotion Board (FIPB).

VII.I. Sectoral Flow of FDI: A Case of Investment in Parts and Components

FDI inflows to emerging East Asia grew at a remarkably high rate from the mid-1980s to 1998 as a result of which the share of emerging East Asia in world total FDI inflows increased from 8 percent in 1985 to 22 percent in the mid-1990s. Within the economies in East Asia, China and India are the major recipients of FDI among emerging market economies. Two developments are important concerning recent FDI in emerging East Asia. One is its resilience even during the period of economic crisis. Compared with other forms of international capital flows such as bank lending, which declined precipitously before and after the crisis, FDI inflows remained relatively stable in emerging East Asia, even in those economies that were seriously affected by the crisis—except for Indonesia. Another important development is the increase in mergers and acquisitions (M&As) as a mode of entry, particularly after the economic crisis. Historically, green-field operations used to be a preferred mode of entry for multinationals in East Asia, mainly because of restrictions on equity participation. The economic crisis changed this environment. Emerging East Asia with a keen interest in attracting FDI relaxed the restrictions. In addition, the huge decline in the values of East Asian currencies and assets encouraged foreign investors to undertake M&A.

In India the FDI flows as a percentage of GDP is more or less consistent over time. India receives large FDI from EU and USA apart from Japan. For parts and components also there is a consistent flow of FDI over the years. FDI in COMPONENTS is around 4-5% of Total FDI in India. The percentage share of FDI in parts and components over a period of time (as shown in the Figure below) reveals that the percentage share has been consistent except for the year 2006.

FIGURE 3: FDI IN PARTS AND COMPONENTS IN INDIA (% SHARE)

Source: Calculated from SIA Statistics

On the other hand the FDI figures for East Asian economies like Thailand has experienced a lots of ups and downs. The major source of FDI in Thailand is Japan and other East Asian countries, though Western countries are also important. In case of Thailand it is around 60% in 2005. Asian FDI in COMPONENTS sector of Thailand experienced a fall in 2006 both in metal, machinery and electronic sector. It s see from the figure below that among the South East Asian economies excepting Malaysia is on the top in 2005 for the electronic products in Thailand followed by Taiwan.

FIGURE 4: FDI IN ELECTRONIC PRODUCTS IN THAILAND FROM ASIAN ECONOMIES

Source: Calculations based on data from BOI, Thailand

In metal products and machinery sector also the FDI in Thailand experiences ups and downs. Here also the major investment comes from Thailand followed by Taiwan. Over the last few years it has been observed that FDI in both the electronic products and the metal and machinery products have decreased substantially.

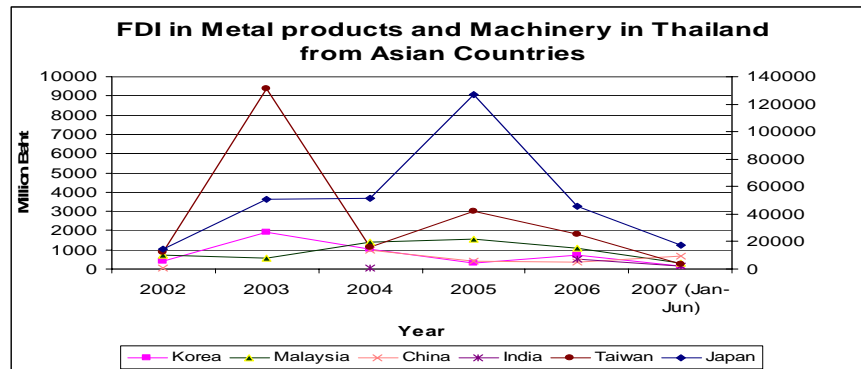

FIGURE 5: FDI IN METAL PRODUCTS AND MACHINERY IN THAILAND FROM ASIAN ECONOMIES
Source: Calculations based on data from BOI, Thailand

VIII. FDI and Value Chain: A Nexus

Thailand, Malaysia and Indonesia are already having large component sector and now new countries like Vietnam is getting investments in the component sector. But, India and South Asia are still outside the regional groupings of East and South East Asian countries and hence are not in a position to get the benefit of trade integration. As business in component sector is based on low margin and high volume, further liberalization will help South Asian countries to get networked more with East and South East Asian economies.

Firms are now part of a value chain which is placed across the countries. In the process, firms especially SMEs initially begin production with existing level of capabilities and upgrade capabilities of manufacturing and make attempt to learn process and product innovation skills, access technological knowledge. Through this, they independently start producing related goods (differentiated products, upgradation of models, etc.) and try to access to large export markets and finally exploit economies of scale. Some fragments of the production process in certain industries have become standard fragments which can be effectively used in a number of products (eg cellular batteries, electronic chips). Companies take these opportunities to exploit the economies of scale. The experiences they gain in the process eventually help firms to move to new and more profitable product segments which in turn pushing them to catch up with the advanced firms. The process started with East Asian firms (Japanese, Korean and Taiwanese) and later influenced South East Asian Players.

A dramatic shift is observed in export composition away from the standard light manufactured goods (clothing, footwear and sport etc) and towards other more sophisticated product lines, in particular various products classified under the category of machinery and transport equipments. In East Asia pivotal role was played by big players who have been more and more inclined towards assembly operations expanding value chain to other countries. The share of parts and components in 'total trade' is much larger compared to 10 years back and growing rapidly over time increasing the importance of the region as an assembly centre in the global economy. Some countries have improved the efficiency level and moved up the value chain and rests are still at the lower end of the value chain.

However, foreign companies often form monopolies in the domestic market. Due to their sheer size, good quality and low cost products, they might drive out small-scale firms. While in host countries long-drawn procedures, lack of infrastructure, etc., sometimes results in withdrawal of investments. Again developing countries might not have the capacity to absorb the technology. For example, poor infrastructure, low level of education, rigidities in labour legislation and other regulations are obstacles in the Indian economy. Some technologies may not be even suitable for conditions of the host country.

Job creation, which is one of most prominent benefit in host economy, may remain confined to in existing well-developed urban sectors where levels of education, training and infrastructure are high. As far as the development of SMEs is concerned, Small scale and rural businesses have a low capacity to attract FDI and could be left out or even forced out of business due to lack of financial resources or be compelled to use informal sources of financing.

Investors could take advantage of weak environmental legislation in developing countries, by using technologies that are cheap but harmful to the environment. Given the capacities and constraints of developing countries, free capital movements make them more vulnerable to both external and internal shocks. While developing countries' dependence on foreign finance to cover their current account deficits also makes them financially vulnerable.

Hybrid methodology for Evolving Strategies to Improve the Relative Efficiencies in Banking Sector

*Vishnu prasad Nagadevara, nagadev@iimb.ernet.in
Indian Institute of Management Bangalore, India*

Abstract

Financial development creates enabling conditions for growth through either supply-led or demand-pull factors. Development of an efficient financial system is important for the economic development. There are 80 different banks operating in India. While all of them face similar constraints as mandated by the government and the Reserve Bank of India, each bank, evolved its own set of strategies to maximize its efficiency. Consequently, the relative efficiencies of these banks vary. This paper investigates into the relative efficiencies of the three categories of banks and identifies the possible factors which lead to the efficient functioning of banks. A hybrid methodology is used to identify the factors leading to these inefficiencies. Initially, DEA was applied to identify the banks that are relatively inefficient. Subsequently, causal analysis was carried out using techniques such as ANNs and classification trees. Based on this analysis, factors leading to relative inefficiencies are identified.

Introduction

Financial development creates enabling conditions for growth through either supply-led or demand-pull factors. A large body of empirical research supports the view that development of an efficient financial system contributes to economic growth (Rajan and Zingales, 2003). Documented evidence indicates that various measures of financial development such as stocks, bonds, access to credit, liquidity, assets and liabilities of financial institutions are positively related to economic growth (King and Levine, 1993; Levine and Zervos, 1998). Historically, the Government of India (GOI) has been evolving various strategies for enhancing financial inclusion through increase in banking penetration starting with the creation of State Bank of India in 1955. The nationalization of commercial banks in 1969 and 1980 were major policy initiatives in this direction. In order to bring more rural population into the ambit of financial services, special policy initiatives were introduced. Some of these are the Lead Bank Scheme in 1970, setting-up of Regional Rural Banks (RRBs) in 1975, introducing a Self-Help Group (SHG)-Bank Linkage Programme in 1992 and formulating the Kisan Credit Card scheme in 2001 (Mohan, 2006 and Thorat, 2007).

Indian banking sector was well developed even prior to its political independence in 1947. There was significant presence of both foreign and domestic banks and well developed stock market (Bery, 1996). The system expanded rapidly after nationalization of major commercial banks in late 1969 and now ranks in the top quarter among developing countries (Khanna, 1995). There were two successive nationalizations of banks in India, one in 1969 and the other in 1980 and as a result public sector banks occupy a predominant role in Indian financial system. Besides the above banks, as of June 2009, there were 86 Regional Rural Banks with 15,384 branches, 736 State Cooperative bank branches (2008) 11,921 District Central Cooperative Bank branches (2008), 95,633 Primary Agricultural Cooperative Credit Societies (<http://RBI.org.in>). Despite a phenomenal expansion of number of branches, the population served per branch stood at 13,000 (RTPB, 1997). Indian banking is particularly interesting because of the diversity of bank ownership forms. Indian banks can be classified into three ownership groups; publicly owned, privately owned and foreign owned. It is expected that there will be performance variation across groups of banks.

Though, Tyagarajan (1975), Rangarajan and Mampilly (1972) and Subrahmanyam (1993) have examined various issues relating to the performance of Indian banks, none of these studies have examined the efficiency of bank service provision in India. Some recent studies did measure the efficiency in service provision of Indian banks but they suffer from certain limitations as shown by Sathye (2009).

It is expected that there will be performance variation across groups of banks. This obviously requires that the relative efficiency of Indian banks is measured and compared with banking efficiency in other countries. There is

little reliable empirical research on bank efficiency in India although Bhattacharya, Lovell and Sahay (1997), Chatterjee (1997) and Saha and Ravishankar (2000) have examined various issues relating to the performance of Indian banks.

Not surprisingly, extensive research has been conducted on bank efficiency using data for the United States of America. However, there is also a growing body of literature for developing countries with an increasing number of studies conducted using data for transition economies in Europe, for Pakistan, India and China (Berger, Hasan and Zhou, 2009). From an accounting perspective, bank efficiency has been traditionally evaluated by a cost-to-income ratio.

“The alternative approach is neoclassical production theory, which has become increasingly common in empirical analyses. In this case, a bank is assessed as an economic unit and managers have the option of evaluating efficiency by considering multiple inputs and outputs and also of decomposing cost efficiency into allocative and technical efficiency. Perhaps it is as a result of the heterogeneity of the outputs and inputs related to banks why there is a lack of consensus in the literature as to their precise classifications. Consequently, the intermediation and production approaches are often utilised as classification guides. The intermediation approach assesses deposit-taking entities as financial intermediaries that utilise labour and capital to transform deposits into loans and other earning assets; the production approach is predicated on the entity as a producer of loan and deposit services from labour and capital. The choice of approach may alter the efficiency scores obtained but not the qualitative conclusions” (Daley and Mathews, 2009, p7)

“The most common findings for developing nations are that on average, foreign banks are more efficient than or approximately equally efficient to private domestic banks. Both groups are typically found to be significantly more efficient on average than state-owned banks, but there are variations on all of these findings. To illustrate, some research using data from the transition nations of Eastern Europe finds foreign banks to be the most efficient on average, followed by private domestic banks, and then state owned banks. However, another study of transition nations finds the mixed result that foreign banks are more cost efficient, but less profit efficient than both private domestic and state-owned banks. A study using 28 developing nations from various regions finds foreign banks to have the highest profit efficiency, followed by private domestic. For cost efficiency, the private domestic banks rank higher than the foreign banks, but both are still much more efficient than state-owned banks. Two studies using Argentine data (prior to the crisis in 2002) find roughly equal efficiency for foreign and private domestic banks, and that both are more efficient on average than state-owned banks). A study of Pakistani data finds foreign banks are more profit efficient than private domestic banks and state-owned banks, but all of these groups have similar average cost efficiency” (Berger, Hasan and Zhou, 2009). Finally, a study of Indian banks finds that foreign banks are more efficient on average than private domestic banks.

The above approaches are now associated with conducting empirical research on banking efficiency utilizing frontier parametric and non-parametric techniques. The parametric approaches impose a structural form on the data and are subject to criticism. Despite certain drawbacks, non-parametric approaches are commonly used since they avoid the restrictions of a defined functional form and infer the results from the banks’ output directly (Daley and Mathews, 2009).

Data Envelopment Analysis (DEA) is a mathematical programming technique grounded in the principle of benchmarking and seeks to identify the most efficient entity based on a ‘frontier’ of efficiency constructed over the data using only the data within the sample (Nagadevara and Ramanayya. 2009). Because DEA provides an objectively determined numerical efficiency value, it may be particularly valuable in assessing and strategizing on the efficiency of different banks. The standard DEA model outcome for efficiency is a value between 0 and 1 indicating the level of efficiency from least to fully efficient. Thus DEA is a tool to measure relative efficiency. The Data Envelopment Analysis uses linear programming approach to identify the banks which are efficient and those which are inefficient. The operations at the bank level are considered as the units for the study. The mathematical model for the analysis is given below:

Min θ_k

Subject to

$$\sum_j A_{ij} \lambda_j \leq a_k \theta_k \quad (\text{for inputs})$$

$$\sum_j A_{ij} \lambda_j \geq a_k \quad (\text{For outputs})$$

$$\sum_j \lambda_j = 1$$

Where θ_k = efficiency score of the bank k which is under consideration
 A_{ij} are the coefficients corresponding to ith bank and jth input/output
 λ_j = are the weightages associated with jth bank

The above problem is a linear programming problem. The optimal solution of this problem will result in a value of 1 for θ_k , if kth bank is efficient. If the kth bank is not efficient, then the optimal solution will result in a value of less than 1 and the values of λ_j will be the corresponding weights associated with the “peer banks” (which are most efficient) of the kth subunit. Appropriate policy directions in terms of the desirable levels of inputs and outputs can be given to the inefficient banks by using these weights. It is important to emphasize here that the above linear programming problem needs to be solved for each of the banks separately. A relatively efficient bank is one that cannot produce more outputs with the given set of inputs or the same set of outputs with fewer inputs. The advantage of unconstrained functional parameters allows the DEA flexibility to construct a linear frontier of relative efficiency by ‘enveloping’ the banks within the sample, with the ‘best practice’ banks forming the frontier.

While there have been many studies devoted to the measurement of efficiency of various banks in India as well as other developing countries, these have not emphasized on the factors that lead to different levels of efficiency. This paper attempts to bridge this gap by identifying various factors that impact the efficiency levels of the banks in India. In addition, it also builds a predictive model in order to predict the probability of a bank that is likely to become relatively less efficient.

Objectives

The objectives of this study are

1. To identify the banks (in India) that are relatively efficient and those that are relatively inefficient
2. To identify various factors that influence the efficiency levels of banks
3. To build and evaluate predictive models in order to predict which of the banks are likely to become inefficient.

Methodology

India had a total of 82 banks operating in 2007. Two of these banks have merged with other banks in 2008. Thus, this study is for the 80 banks that operated in India during the years 2007 to 2009. Data with respect to various characteristics of these banks was collected for the three years, namely 2007, 2008 and 2009 (for the financial year ending on 31 March in the corresponding year). The data was collected from the Reserve bank of India website (<http://rbi.org.in>). There were 28 Nationalized banks, 29 Foreign banks and 23 Private (Indian Banks in 2007. By 2009, there were 27 Nationalized banks, 31 Foreign banks and 22 Private banks. The efficiency levels of these

banks in each of the three years are estimated using Data Envelopment Analysis. The datasets for the three years is combined into one single dataset. The variables in the dataset included all those which were used for the DEA as well as the efficiency levels of individual banks in each year. These 240 observations have been classified into two categories – those which are efficient in the particular year and those which are relatively in efficient. This dataset is used to build classification trees (CART) for predicting the inefficient banks. In addition, the output of the classification trees is used to identify the factors that lead to inefficiencies of the banks in India.

Results and discussion

Data envelopment Analysis is used to identify the banks that were inefficient in each of the three years under study. The DEA model involves multiple outputs and inputs. The variables that are used as outputs and inputs are presented in Table 1.

TABLE 1. VARIABLES USED IN DEA (OUTPUTS AND INPUTS)

Outputs	Inputs
<i>Gross NPAs</i>	Cash-Deposit ratio
NET NPAs	Ratio of intermediation cost to total assets
Return on assets	Ratio of wage bills to intermediation cost
Return on equity	Ratio of wage bills to total expense
Return on advances	Ratio of wage bills to total income
Return on investments	Cost of deposits
Return on advances adjusted to cost of funds	Cost of borrowings
Return on investments adjusted to cost of funds	Cost of funds
Business per employee (in Rs.lakh)	
Profit per employee (in Rs.lakh)	

The first two outputs, Gross and Net NPAs are taken as negative outputs. There are 10 outputs and 8 inputs. Based on the DEA, there were 26 banks which were inefficient in 2007. This number has gone up to 35 in 2008 and 36 in 2009. Majority of the inefficient banks were nationalized banks. Table 2 presents the summary data with respect to the inefficient banks for the three years. Only two foreign banks were inefficient in 2007 and 2009. Of the 80 banks studied, there were 17 which were inefficient in all the three years. Of these 17, ten belonged to the Nationalized category, one was a foreign bank and the remaining 6 were private banks.

TABLE 2. NUMBER OF INEFFICIENT BANKS BY CATEGORY

	Actual Numbers			Percentages		
	2007	2008	2009	2007	2008	2009
Nationalized	16	14	20	61.54	40.00	55.56
Foreign	2	7	2	7.69	20.00	5.56
Private	8	14	14	30.77	40.00	38.89
Total	26	35	36	100	100	100

Table 3 presents the average values of the variables used in carrying out the DEA. These averages are presented year-wise and separately for the efficient and inefficient banks. In addition to the averages, the ratios of averages

between the inefficient and efficient banks for each of the variables, year-wise are also presented. In each of the three years, the Gross NPAs and Net NPAs have been consistently higher for the inefficient banks. The net NPAs of the inefficient banks have been more than double of that of the efficient banks. Similarly, the cost of deposits and cost of borrowings have been consistently higher with the inefficient banks, as compared to the efficient ones, in each of the three years. Similar is the case with wage bill (as measured by the ratio of wage bill to total expenses as well as the ratio of wage bill to total income).

TABLE 3. AVERAGE VALUES OF THE VARIABLES USED IN DEA

Variable	Year								Percentage
	2007			2008			2009		
	Efficient	Inefficient	Percentage	Efficient	Inefficient	Percentage	Efficient	Inefficient	
Gross NPA	39321.63	110008.85	279.77	53116.09	92951.97	175.00	56808.74	125187.71	220.37
Net NPA	14265.74	47234.77	331.11	20166.02	44739.49	221.86	25436.85	56199.86	220.94
Cash Deposit ratio	8.26	7.26	87.86	10.16	10.71	105.44	8.79	7.08	80.53
Cost of borrowings	4.94	9.10	184.02	4.80	6.70	139.54	8.10	9.93	122.61
Cost of deposits	4.38	5.05	115.32	5.11	5.69	111.35	5.10	6.23	122.34
Cost of funds	4.69	5.02	106.92	5.18	5.74	110.80	5.28	6.24	118.07
Ratio of intermediation cost to total assets	2.60	2.32	89.15	2.12	2.58	121.64	3.13	2.07	66.29
Ratio of wage bill to intermediation cost	47.82	58.94	123.24	46.82	52.61	112.38	43.46	57.80	133.00
Ratio of wage bill to total expense	17.92	19.47	108.70	14.70	16.41	111.59	16.29	15.09	92.65
Ratio of wage bill to total income	12.21	15.29	125.19	9.54	12.77	133.88	10.49	15.84	151.00
Business per employee in Rs. lakh	818.74	454.04	55.46	951.75	714.53	75.08	1184.41	680.13	57.42
Profit per employee in Rs. lakh	16.03	2.30	14.37	27.90	7.83	28.08	30.32	2.32	7.65
Return on advances	10.08	9.24	91.70	9.81	10.30	104.93	10.67	10.61	99.41
Return on advances adjusted to cost of funds	5.39	4.22	78.43	4.63	4.56	98.40	1.62	0.49	30.48
Return on assets	1.66	0.72	43.22	2.18	1.02	46.73	1.80	0.80	44.35
Return on equity	13.22	12.54	94.83	15.02	13.41	89.29	11.93	15.17	127.22
Return on investments	7.45	7.01	94.03	7.65	7.31	95.56	7.09	6.75	95.29
Return on investments adjusted to cost of funds	2.76	1.99	72.11	2.47	1.58	63.73	5.39	4.37	81.11
Efficiency	1.00	0.88	88.47	1.00	0.86	86.03	1.00	0.82	82.07

The business per employee of the inefficient banks has been hovering around 55 percent of that of the efficient banks, with the exception of 2008 where it moved up to 75 percent. The profit per employee of the inefficient ones also has been very low over the three years touching the lowest at 7.65 percent of the efficient banks in 2009. On the other hand, the return on equity was better among the inefficient banks in the year 2009. But, the return on assets has been less than 50 percent of the efficient banks, even though return on advances is comparable to that of the efficient ones.

While DEA helps to identify the inefficient banks as compared to the other efficient ones, it does not isolate the factors that lead to the inefficiency. Of course, it helps to prescribe strategic corrections in improving the efficiency by identifying the peer banks that are efficient and comparable to the specific inefficient ones. The identification of the peer banks will also help in target setting for these inefficient banks. Nonetheless, it is important to identify the factors that lead to inefficiency because it helps in setting the policy within as well as across banks.

In order to identify the factors that influence the efficiency levels among the banks and to prioritize them, the data with respect to the three years under study are combined into one single dataset. The banks are categorized into efficient and inefficient ones based on the DEA. Using this as the dependent variable, classification trees were built using CART as well as C5.0 methodology. In addition, the same dataset was used to build Artificial Neural Networks (ANNs) for predicting the inefficient banks. Table 4 presents the prediction accuracies of these three prediction models.

TABLE 4. PREDICTION ACCURACIES OF THE THREE TECHNIQUES USED

EFFICIENCY	Predicted			Overall Prediction (%)	
	Efficient	Inefficient	Total		
Neural Nets					
Actual	Efficient	108	35	143	84.44
	Inefficient	15	82	97	
CART					
Actual	Efficient	125	18	143	91.82
	Inefficient	20	77	97	
C5.0					
Actual	Efficient	131	12	143	94.76
	Inefficient	11	86	97	

Among the three prediction techniques used, Classification trees, C 5.0 turned out to be the best from the point of view of overall prediction accuracies with an accuracy level of 94.76 percent. Artificial Neural Networks had given the lowest prediction accuracies with 84.44 percent. The CART (Classification and Regression Trees) had a prediction accuracy of 91.82 percent.

Since C5.0 had given the best prediction with respect to the efficiencies, the importance of different variables for prediction is extracted from the classification tree. These variables with the corresponding importance are presented in Table 5. The most important variable for predicting the relative efficiencies of banks is the Gross NPAs. The wage bill (in relation to intermediation cost as well as to total expenses) is also very important. In addition, the cost of borrowings and cost of deposits are also important in predicting relative efficiencies. The two

variables namely Profit per employee and return on investments are of very low importance. In other words, it is necessary for the banks to concentrate on these variables, especially Gross NPAs and wage bill to maintain the efficiency levels year after year. If these variables are not watched carefully, the banks are likely to become relatively inefficient.

TABLE 5. IMPORTANCE OF DIFFERENT VARIABLES IN PREDICTING THE EFFICIENCY

Variable	Importance
Gross NPA	0.35
Ratio of Wage bill to Intermediation cost	0.22
Cost of borrowings	0.14
Ratio of Wage bill to total expenses	0.11
Cost of Deposits	0.08
Year	0.07
Profit per employee	0.05
Return on investments	0.01

Summary and Conclusions

Financial development creates enabling conditions for growth through either supply-led or demand-pull factors. Development of an efficient financial system is important for the economic development of the country. There are 80 different banks which operate in India. These can be categorized into Nationalized Banks, Foreign Banks and Private Banks. Data was collected for three years for each of these 80 banks. The banks that are relatively inefficient are identified in each of the three years, 2007, 2008 and 2009 using the concept of Data Envelopment Analysis (DEA). Out of a total of 240 data points, consisting of 80 banks for 3 years each, 97 are found to be inefficient. After classifying the banks into two categories, namely, efficient and inefficient ones, the data is used to build three different prediction models. These are Classification Trees (C5.0), Classification and Regression Trees and Artificial Neural Networks. The prediction accuracies of each of these techniques are estimated. It was found that C5.0 provides the best prediction accuracies. Variables that are important in the prediction of efficient banks vs. inefficient banks are identified based on the C5.0 classification tree model. It was found that Gross NPAs, wage bill, cost of borrowings and deposits have to be watched carefully in order to maintain the efficient nature of the banks. Those banks which can monitor and control these variables closely will turn out to be more efficient ones.

The Effects of Tax Policy on SMEs In Thailand

Papaporn Chunchatrachai, p.chunchatrachai@postgrad.curtin.edu.au

Jeff Pope, jeff.pope@cbs.curtin.edu.au

Curtin University, Australia

Abstract

While tax compliance costs are often neglected in many developing countries such as Thailand, these costs are important for policy-making. This paper discusses the effect of tax policy on Small and Medium Enterprises (SMEs) by highlighting tax compliance costs as a burden for Thai SMEs, especially in terms of Thailand corporate income tax (CIT). This study lays the foundation for the first attempt to measure CIT compliance costs of SMEs in this country. It is probably timely for policy-makers and politicians, in Thailand to consider the role of tax compliance costs in future policy. It is hoped that this paper helps contribute to such a debate.

Introduction

Small and Medium Enterprises (SMEs) are acknowledged as a key component of the Thai economy. This has led the government sector to provide support in the form of SME tax policy implementation. One significant instrument in supporting SMEs has been a tax policy change. Most tax policy changes have been issued without much attention to the cost of tax compliance. In general, it seems a routine requirement to comply with the tax authority's policies for SME taxpayers. This is also regardless of the cost involved and SME taxpayers are still responsible to comply with the tax laws.

Furthermore, it is widely accepted as being a problem for various countries. It is clear then that the effects of tax policy can be a tax burden to SMEs by increasing the tax compliance costs. This paper will discuss SME tax policy and how this tax policy can increase tax compliance costs of SMEs in Thailand. It is time for policy-makers in Thailand to consider tax compliance costs before issuing a new policy. The discussion of this paper is organized as follows: firstly, it discusses the importance of SMEs in Thailand and their vital role in the Thailand economy; secondly, the paper looks into corporate income taxation dealing with SMEs in Thailand and what the requirements are for SMEs; finally, the paper identifies the effects of tax policy by highlighting tax compliance costs as a burden for SMEs in Thailand and the situation of the current tax compliance costs study.

SMEs in Thailand

SMEs definition

SMEs are made up of different types of business organizations in Thailand, such as sole proprietorships, partnerships and limited companies. This paper will focus only on partnerships and limited companies because they will be taxed under corporate income tax. SMEs possess many desirable characteristics, including a high usage of labour and an economic usage of capital assets. The Ministry of Industry's definition of SMEs is the main definition used by the business sector. This SME definition is characterised by the number of salaried workers, and fixed assets and it is classified into three sections: production, service and trading (wholesale and retail). In general, enterprises having a total number of employees less than 200 and fixed assets less than 200 million baht are categorised as SMEs (Office of Small and Medium Enterprises Promotion, 2002)(see

Table 1).

TABLE 1: SMALL AND MEDIUM ENTERPRISES DEFINITION BY MINISTRY OF INDUSTRY THAILAND

Type	Small		Medium	
	Employees	Fixed Assets (million baht)	Employees	Fixed Assets (million baht)
Production	Not more than 50	Not more than 50	51-200	51-200
Service	Not more than 50	Not more than 50	51-200	51-200
Wholesale	Not more than 25	Not more than 50	26-50	51-100
Retail	Not more than 15	Not more than 30	16-30	31-60

Source: Office of Small and Medium Enterprises Promotion (2002)

In the Thai tax system, SMEs are defined in a more rigorous manner. In order to receive benefits, the companies must possess the following:

(1) Reduced corporate income tax rate for Thai companies with paid-up capital of 5 million Baht and below. These companies are subjected to a corporate income tax rate of 20% on one profit up to 1 million Baht and 25% on net profit over 1 million Baht up to 3 million Baht. Profit exceeding 3 million Baht is subject to corporate income tax ordinary rate of 30%. (Effective for accounting period starting on or after 1st January B.E. 2545)ⁱ

(2) Thai company with durable assets (excluding land) less than 200 million Baht and hiring employee less than 200 people grant an initial allowance on assets as follows:

(a) Computer hardware and peripheral can depreciate on the acquisition date at 40% of its total cost. The remaining will be depreciated at a regular rate for at least 3 accounting periods;

(b) Durable building and plant can depreciate on the acquisition date at 25% of its cost. The remaining will be depreciated at a regular rate not exceeding 5% of the total cost per annum;

(c) Machinery and equipment can depreciate on the acquisition date at 40% of its total cost. The remaining will be depreciated at a regular rate not exceeding 25% of the total cost per annum. (Effective for assets which are acquired on or after 31st January B.E. 2545)ⁱⁱ

(3) Full corporate income tax exemption for qualified venture capital (VC) company on dividend income and capital gain from sale of stock receiving from investing in Thai company with the durable assets (excluding land) less than 200 million Baht and hiring employee less than 200 people. A qualified VC company must be as the following:

(a) A company incorporate in Thailand which doing venture capital business as prescribed in Ministerial Notification with capital not less than 200 million Baht and paid-up capital at least of 50% in the first year. The remaining capital will be paid up within 3 years starting from the date of registration;

(b) VC company must be registered with the office of Securities and Exchange Commission within 3 years from 31st January B.E. 2545;

(c) VC company must have share of paid up capital in SMEs not less than 20% for the first year, 40% for the second year, 60% for the third year and 80% for the fourth year;

(d) VC company must hold SMEs stock for at least 7 consecutive years or at least 5 years if that SMEs can register in Stock Exchange of Thailand;

(e) A manager of VC company must hold a securities business license in a type of joint investment management which is approved by the offices of the securities and exchange commission. (Effective on or after 31st January B.E. 2545)ⁱⁱⁱ

(4) Income tax exemption on dividend or income from sales of securities receiving from the VC's exempt income. (Effective on or after 31st January B.E. 2545)^{iv} (The Revenue Department, 2006)

The SME definition provided by the Ministry of Industry Thailand is a general term widely acknowledged. In order to qualify for tax benefits, SMEs must meet strict requirements as set by the Revenue Department. Thus, SMEs can receive considerable tax benefits if they comply with each rigorous requirement. SMEs have to be aware of many factors to enjoy the benefits of policy implementation. For example to receive tax benefits, SMEs have to understand the classification system for tax deduction purposes. Sometimes, the definition of SMEs is also difficult because the nature of its criteria and purposes are variable (Cameron & Massey, 2003). It seems that SMEs have to meet many conditions to run their businesses. Otherwise, they will lose the benefits that they have gained. They have to provide enough information about their own circumstances to enjoy tax benefits, so they may have to spend money to employ tax professional to help them.

The Number of SMEs

The number and ratio of SMEs has increased since 2007. In the year 2009, there was a total number of 2,896,106 SMEs, making up 99.8% of the overall number of enterprises in Thailand, significantly greater than the number of large enterprises (4,653 or 0.2% of the overall number of enterprises) (Office of Small and Medium Enterprises Promotion, 2009) (see Table 2). Due to the large number of SMEs in Thailand, they have the potential to make a significant contribution to the Thai economy.

TABLE 2: THE NUMBER AND RATIO OF ENTERPRISES

Size	Number of Enterprises			Percentage/Enterprises		
	2007	2008	2009	2007	2008	2009
SMEs	2,366,277	2,827,633	2,896,106	99.6	99.7	99.8
Large Enterprises	9,091	4,586	4,653	0.4	0.2	0.2
N/A		4,158	-		0.1	-
Total	2,375,368	2,836,377	2,900,759	100.0	100.0	100.0

Source: Office of Small and Medium Enterprises Promotion (2007-9)

The percentage contribution of SMEs to Thailand's GDP for the years 2007, 2008 and 2009 was 38.7%, 38.1% and 37.8% respectively (See Table 3). The number of SMEs has increased recently but the value of GDP has fallen. Although the number of SMEs is larger than the number of large enterprises, the large enterprises contribute more to Thailand's GDP. This shows that there is still a mismatch, so tax policy needs to enhance robust SME productivity. If constructive policy is formulated to support SMEs, the GDP of SMEs to Thai economy may increase.

TABLE 3: THE GDP OF ENTERPRISES

Size	GDP (%)		
	2007	2008	2009
SMEs	38.7	38.1	37.8
Large Enterprises	46.3	45.8	45.9

SMEs Taxation in Thailand

Taxation in Thailand is under the authority of the Revenue Department (RD) as personal income tax (PIT), corporate income tax (CIT), petroleum income tax, value added tax (VAT), specific business tax, and stamp duties. CIT and VAT are the main taxes faced by the business sector. This paper will focus only on CIT. Taxpayers (individual and business organisations) have a legal duty to declare their income and pay tax to the RD elaborated in the self-assessment system. As a result, income declaration and tax payments are assumed to be correct. In some cases, assessments may be conducted by the RD in certain circumstances, such as failure to file tax returns or filing of false or inadequate tax returns.

Corporate Income Tax

Basically, SMEs are registered under business organization law, are subject to taxation as stipulated in the Tax Code and are subject to income tax on income earned from sources within and outside of Thailand. This is known as 'Corporate Income Tax' or 'CIT'. In general, CIT ("Revenue Code," 1938) is a direct tax levied on net profit by subtracting all allowed deductible expenses from total sales. The allowed deductible expenses are subjected to conditions commonly found in the Thai tax code. CIT rate in Thailand is 30% on net profit. Reduced rates are applied depending on the type of tax payers. More specifically, the Thai government provides CIT rate for SMEs with paid-up capital less than 5 million baht as follows: for net profit less than 150,000 baht - tax rate is exempt; for net profit between 150,000 to 1 million baht - tax rate is 15%; for net profit between 1-3 million baht - tax rate is 25%; and for net profit more than 3 million baht - tax rate is 30% (Fiscal Policy Office, 2008)(See Table 4).

Moreover, net losses of CIT can be carried forward for up to five consecutive years. Taxes are due on a semi-annual basis within 150 days of the close of a six-month accounting period. Except for newly incorporated companies, an accounting period is defined as a 12 month period. Returns must be accompanied by audited financial statements. SMEs must file a half-year return and pay 50% of the estimated annual income tax by the end of the eighth month of the accounting period.

TABLE 4: CORPORATE INCOME RATES OF SMES

Taxpayer	Tax Base	Rate
Small company which refers to a company with paid up capital less than 5 million Baht at the end of each accounting period.	Net profit not exceeding 150,000 baht	Exempt
	Net profit over 150,000 baht up to 1 million baht.	15 %
	Net profit over 1 million baht up to 3 million baht.	25 %
	Net profit exceeding 3 million baht.	30 %
Company listed in Market for Alternative Investment (MAI)	Net profit for first 20 million baht. Remark: for 3 accounting periods beginning on or after January 1 st , 2008.	20 %
	Net profit for the amount exceeding 20 million baht	30 %

Source: The Fiscal Policy Office (2008)

In the 2009 fiscal year (October-September), the CIT collected was 392,172 million baht (14,487.4 million AUD dollars)^v. The CIT collection ranked second in the list of total tax collection in Thailand. The highest revenue is VAT (see Table 5).

TABLE 5: TAX COLLECTION IN FISCAL YEAR

Tax Type	Fiscal Year 2009	
	Tax Collection (Million Baht)	Percentage
Personal Income Tax	198,095.44	17.40
Corporate Income Tax	392,171.86	34.44
Petroleum Tax	90,712.40	7.97
Value Added Tax	431,775.38	37.92
Specific Business Tax	18,099.04	1.59
Stamp Duty	7,487.83	0.66
Other Income	222.95	0.02
Total	1,138,564.90	100.00

Source: The Revenue Department of Thailand (2009)

The RD is the main department among three main agencies (i.e. the Revenue Department, the Excise Department and the Customs Department) under the Ministry of Finance that collects more than half of the total tax collection in Thailand. Each year, Thailand's tax collection is expected to exceed Government targets. Enhancements to the tax system's efficiency and profitability are sought, and tax base expansions are expected to increase. Presently, the RD increases tax collection by improving the audit system. However, the level of tax

compliance costs should be considered by promulgating a Taxpayer's charter. The reducing of tax compliance costs can also show the RD's concern for the Thai taxpayers because it reduces the taxpayer burden. This might enhance voluntary taxpaying, especially from the SME taxpayers. The large number of SMEs can play a vital role in contributing to tax revenue for the Thai economy. Changing taxpayers' perceptions is a constructive strategy that the RD should implement.

The Effects of Tax Policy on SMEs

Tax compliance costs are the costs taxpayers incur when dealing with the tax authority to comply with their legal requirements (Sandford, Godwin, & Hardwick, 1989), and in this case it is a private sector cost. Besides private sector costs, public sector costs are incurred by the revenue authority. To understand 'public sector costs' it is clearer to use the term 'administrative costs' to identify the cost of salaries and wages, including national insurance contributions and superannuation costs; accommodation costs (including rents, rates, heating, lighting and cleaning); postage, telephone, printing, stationery; travel; and computing and other equipment costs of all staff in the revenue department (Sandford, et al., 1989).

In order to reduce administrative costs, the RD might have to shift the burden to taxpayers by transferring administrative costs to compliance costs. Thus, the differences between public costs and private costs identify an area of high compliance costs, indicating the importance of administrative costs and especially compliance costs to policy makers (Sandford, et al., 1989); both these costs are by no means independent (Oliver & Bartley, 2005).

The level of compliance costs are a major concern to small business because most politicians like to provide tax incentives without concerns about tax compliance costs (Pope, 2008). Tax compliance costs become a tax burden for SMEs when they have to deal with complicated compliance rules. As identified by Ariff and Pope (2002), what is needed for such small and medium businesses is for tax compliance costs to be minimal. Adding to the compliance costs in the United States is the impact coming from the complexity of taxing income by lawmakers attempting to achieve political goals using tax policy, such as assigning tax burdens based on income level, and encouraging various socially beneficial activities (Moody, Warcholik, & Hodge, 2005). Factors contributing to tax system complexity include the economic environment faced by taxpayers, taxpayer behaviour, and the administration of tax policy such as compliance and administrative costs. These concerns demonstrate that the effects of tax policy can be to increase both the number and complexity of the rules and regulations leading to higher reporting requirements and hence higher compliance costs. The following will discuss the effects of tax policy on Thai SMEs which can be a tax burden to SMEs.

The content of tax policy tends to become complex and confusing

When the tax policy is passed in Parliament and becomes legal, the tax policy tends to become complex and confusing. Most Thai SMEs lack of tax knowledge, so they have to use tax professional staff to help them with filing tax, record keeping and dealing with the RD. This is the obstacle of the SMEs that cannot keep tax compliance costs low.

The self- assessment system

The self-assessment system is a way of transferring the public cost to tax payers. The self-assessment system in Thailand is a responsibility the government places on taxpayers to administer themselves. SMEs are required to register as taxpayers, file taxes, keep records and prepare for audit by tax auditors or the CPA (Certified Public accountant). SME taxpayers are legally responsible for the accuracy of the information they provide in their tax declarations. If the RD check the accuracy of the information and find information missing or incorrect, SMEs will be subject to penalties. It is the legal duty of the SME taxpayer to pay the correct tax amount, so it is hard for them to have a low compliance costs in the self-assessment system.

According to the Thai tax code, SMEs are the same as large enterprises in the self-assessment system. There is no exemption for SMEs in reducing declaration of filling tax process. Although they are different sized enterprises, they have to comply with the same process of declaration of filling tax. SMEs have to prepare the documents for audit by auditors just like the large enterprises. It is not surprising that the estimation of a large share

of small business activity is carried out underground rather than in the official economy (Schneider, 2005). A reduce in formalities for SMEs might significantly ease compliance costs and might thereby help SMEs keep compliance costs low, thus increasing the number of SME voluntary taxpayers.

Awareness of tax compliance costs in policy making process

Studies related to tax compliance costs research have been conducted in many countries throughout the world (for example: see Table 6) and it is widely recognised that there is a problem with the regressive nature of tax and other burdens on small businesses (Evans & Walpole, 1997; Pope, 2005; Sandford, et al., 1989).

	Slemrod & Blumenthal	1996

Several studies and reports imply that compliance costs are very important and have an impact on the tax system. Unfortunately, the Thai government sector has undertaken policy implementation to support SMEs without consideration of tax compliance costs.

Six phases or periods for developing compliance costs of taxation in a policy area have been identified by Pope (1992; 1993): Phase one is the period where the issue of compliance costs is denied; phase two is the recognisable period of compliance costs by experts; phase three is the signal period to estimate the tax compliance costs to experts; phase four is a period where there is compliance costs recognition by policy makers; phase five is the formulating period of policy actions in compliance costs; and phase six is the monitoring period to estimate the compliance costs. Thailand's development of compliance costs is in phase two or three; therefore, more can be done to close the gap in the development of compliance costs in the Thai tax system. It is probably time, then, to attempt to measure income tax compliance costs for SMEs in Thailand.

The conflict between tax benefit policy and tax collection growth policy

Tax revenue is the main source of income for Thailand to finance government spending on goods and services. The main duty of the three major revenue agencies (i.e. the Revenue Department, the Excise Department and the Custom Department) is tax collection; their duty is to increase tax collection annually. The RD in particular is the primary tax collection agency. Providing tax benefits is likely to decrease the level of tax revenue. This appears to be a confused policy, but it is a common approach for the Thailand tax system.

Too many rules and regulations for SMEs

It is common now to hear about integration among government departments from government spokesmen. To start the integration process among government departments, the Ministry of Industry, Ministry of Commerce and Ministry of Finance should work with all sectors for such integration, and address. The example of the problem is: There are too many variable definitions of SMEs which currently prevent companies from receiving the benefits. This will be a joint initiative among all government departments. Moreover, the reduction of rules and regulations for SMEs should be considered by government departments. It will help SMEs to keep tax compliance costs low to receive tax benefits by reducing the complicated system.

The paper presents the effect of tax policy on SMEs in Thailand and it increases SME tax compliance costs. The measure of compliance costs will be helpful for Thai SMEs. First, the study of SME tax compliance costs will identify the impact of SME compliance costs when they comply with tax requirements, showing the hidden costs in the Thai tax system and the Thai economy; second, the study will develop recommendations to support SMEs in reducing their compliance costs and will assist in increasing efficiency to help SMEs operate in a competitive global economy. Third, the study will develop a model to increase theoretical and practical awareness of the importance of SME compliance costs to the general economy; it will help both the public and private sectors to be more alert and responsive to tax compliance costs in the Thailand tax system. Fourth, the study will identify constructive policy recommendations to inform Thailand policy makers, and alert them to the importance of tax compliance costs in the policy making process. Finally, this study will lay the foundation for further study in the field of compliance costs in Thailand.

Conclusions

Currently, there is no tax compliance cost study in Thailand, and it is the first attempt to measure the compliance costs in Thailand. The effect of tax policy is tax burden for SMEs in Thailand at this time. The measure of tax compliance costs is needed to prove the effect to Thai SMEs tax policy and to reduce the burden on the SME sector. Most SMEs would probably prefer a simple system and lower levels of tax compliance costs. This is something that policymakers and politicians should reconsider, because current tax policy tends to increase tax compliance costs.

Factors that Influence Sukuk Retail in Indonesia

Nevi Danila, nevida@stie-mce.ac.id

STIE Malangkucecwara (Malangkucecwara School of Business), Indonesia

Abstract

Retail Sukuk is developed by ministry for domestic investors in bond market to strengthen the government's bond against volatility due to foreign investors movement. It helped to finance the budget deficit. The question is that what variables affect the price of retail Sukuk. This paper will examine what factors that affect individual investors to buy retail Sukuk 01(SR01). Investigating factors that affect SR01 price is crucial because Indonesia, as the world's most muslim populous country, is supposed to have muslim investors who are more concerned to Islamic finance products to invest. Thus, the government has a potential new market segment (diversification of investor base) to finance the budget through domestic market. The result suggests that only interest rate (conventional) affects the price. It implies that the investors are only concern on the return; the religious factor apparently does not come in the picture.

Introduction

The Sukuk market has emerged in 2002 with Malaysian government's US\$600mn. Sukuk issuance has been dominated in parts of Asia and GCC countries. The development of the Sukuk market has been facilitated by sovereign benchmark issues. In value of terms, about 36% of Sukuk issues originated in Asia (Malaysia, Pakistan, and Brunei), and 62.1% in the GCC during period 2001-2007. Corporate issuance has grown rapidly around 2,380.7% from year 2003 to year 2006. Sukuk al Ijara (43.6%) was the most popular amongst corporate and governments wanting to raise funds in the Islamic debt markets. It is followed by Sukuk al Musharakah (27.5%), and Sukuk al Mudaraba (18.4%) (El-Quqa, et.al., 2008).

Indonesia government issued sovereign Sukuk legislation in May 2008. It is a bit late because a private sector already issued Sukuk since 2003. A recent report from Ernst and Young (2009) also shows that between 2007 and 2009 Sukuk are still largely originated from Malaysia and the GCC. Issuance from other jurisdictions such as Indonesia is increasing, but it is still negligible. Thus, private sector is an initiator of Sukuk development in Indonesia. With the legislation, it is expected that the Sukuk market will be more developed, and finally it will be able to attract foreign investors, especially from Middle East, even though the retail Sukuk is now focused for domestic market/investors.

According to Sunarsip (2008), Indonesia's Sukuk market faces few challenges: first, shari'a financial market is not liquid, the reasons are: first, a small market that is less than 5% out of the whole financial market, and regulation of Bank Indonesia; the liquidity is also a concern in global market, as suggested by Zaidi (2007) - CEO Islamic International Rating Agency, Bahrain - "at present, the size of the secondary market is relatively small although secondary trading of Sukuk is on the rise". Second, there is uncertainty about a tax; third, most of shari'a financial products are debt-based or debt-likely products.

Throughout 2009, Indonesia capital market showed an uplifting growth. It was shown from sharia product growth in Indonesia capital market: 14 Sukuks of 8 (eight) Issuers got effective statement from Bapepam-LK. Accumulatively, up until December 2009, there were 43 Sukuks was issued or an increase by 48.28% compared to 2008 which was only 29 Sukuks (Bapepam-LK, 2009).

The first Indonesia global Sukuk – dollar denominated Sukuk- was sold oversubscribed seven times. The investors were from Asian (32%), Middle East (30%), US (19%), European (11%), and Indonesia (8%)(Suharmoko, 2009). However, around September 2010, Indonesia was reviving sales of Islamic bonds two months after consecutive auctions fell short of target because of insufficient trading volume. To overcome this problem, Waluyanto – director general of the Debt Management Office – said that the government would continue to add to the number of Sukuk issuances to further boost the liquidity in the secondary market (Permatasari and Manurung, 2010). Regarding to retail Sukuk (SR), the Sukuk is designated to individual investors and only for Indonesian (domestic) investors. As Arab News reported that "in January 2009, the Indonesian Ministry of Finance issued the country's debut sovereign retail local currency rupiah Sukuk – an offering which raised 5 trillion rupiah (\$540 million) from domestic market as part of its public borrowing requirement".

Retail Sukuk is developed by ministry for domestic investors in bond market to strengthen the government's bond against volatility due to foreign investors movement. There are 14,295 investors purchasing the Sukuk (Suharmoko, 2010). The first and second retail Sukuk (SR 01 and 02) were sold like hot cakes. It helped to finance the budget deficit. The question is that what variables affect the price of SR. Due to the absence of appropriate Sukuk pricing model, then model of conventional bonds price as proxy for Sukuk pricing is employed here. Moreover, to study whether the investors consider the religious factor, I use sharing profit and loss rate as well as conventional interest rate in the model.

This paper will examine what factors that influence individual investors to buy retail Sukuk 01(SR01). Investigating factors that affect SR01 price is crucial because Indonesia, as the world's most muslim populous country, is supposed to have muslim investors who are more concerned to Islamic finance products to invest. Thus, the government has

a potential new market segment (diversification of investor base) to finance the budget through domestic market. Moreover, the government does not need to have exchange rate exposure relates to non domestic currency denominated Sukuk.

Literature Review

Sukuk

Sukuk are “certificates of equal value representing undivided shares in ownership of tangible assets, usufruct, and services or (in the ownership of) the assets of particular projects or special investment activity” (AAOIFI, 2008). The difference bond from Sukuk is that “bond is a contractual debt obligation whereby the issuer is contractually obliged to pay to bond holders on certain specified dates, interest and principal; while Sukuk holders are entitled to share in the revenues generated by the Sukuk assets as well as being entitled to share in the proceeds of the realisation of the Sukuk assets” (Thomas, Cox, and Kraty, 2005).

According to Jobst (2007), two stage verification process are required to implement Islamic securitization: (1) the type of underlying assets and generation of returns, and (2) the transaction structure. Furthermore, several conditions must be met in adapting conventional securitization for Islamic securitisation. Those are as follows: (1) “there should be a real purpose behind raising fund, and the type of collateral assets realizing the securitised revenues must be clearly identified and cannot be consumed; (2) there should be fair share of risk and return among participants; (3) collateral assets should be free from debt, and prohibited (haram) activity; (4) “the structure should provide investor compensation for business risk from direct participation in securitized assets and should not imply an exchange of debt for interest-generating investment return; (5) investor should hold an unconditional and unsecured payment obligation and not a guaranteed promissory note”; (6) investors must possess the assets; (7) the investment proceeds of investors must not be reinvested in short-term cash instruments or interest bearing debt; (8) the underlying assets and securitised obligations must be not used for speculative purposes, and turn over should be kept low; (9) takaful should be employed for replacing conventional insurance; (10) “any form of credit enhancement and/or liquidity support and limitations of prepayment risk must be in a permissible form” (Jobst, 2007).

There are two ways to create Islamic financial securities: direct structuring of securities and process of asset securitisation. In direct structuring process, securities are issued first, then the proceeds/funds are used to finance the certain assets/projects with the client company. The profits from the project/assets will be distributed among security holders. While in asset securitisation process, the existing assets of the client company are identified, pooled, and then are securitised (El-Quqa, et.al., 2008)

Regarding to Sukuk structure, there is a debate whether the structure is asset-backed or asset-based. In asset-backed Sukuk, the originator sells the asset to special purpose vehicle (SPV) that issues the Sukuk. SPV owns the asset, and uses the asset to obtain return. Most of Sukuk structure are not asset backed. Furthermore, the Sukuk holders do not have recourse to the originator. Asset-backed Sukuk are closer to an equity position, while asset-based Sukuk are closer to debt because Sukuk holders have recourse to the originator if there is a shortfall in payments (Hayat, 2010). According to Nassif et. al. (2009), to increase Sukuk share in financial market, the flexibility of the Sukuk instrument is required. As they mentioned that most Sukuk issues have been debt-like, the structure might be designed as an equity instrument through convertibility. It could access a much wider investor base.

In addition, El-Quqa, et.al. suggest that the issuance of Sukuk with asset-based structure will have an impact on their ratings. In asset-based Sukuk, the holders rely for payments on the company in the same way as in corporate bond issue. “More importantly, in an asset-based Sukuk, the market value of the underlying assets has no bearing on the redemption amount as this is fixed at the outset when the relevant undertakings are agreed. More recently, the market has seen issuance with a mix of cash and assets, and in several cases, Sukuk have been issued for a new business with no tangible assets. The issuance of convertible and exchangeable Sukuk are more recent developments”.

The use of Sukuk in the world of Islamic finance has become increasingly popular in the last few years, both because they provide the means to raise government finance through sovereign issues, and as a way of companies obtaining funding through the offer of corporate Sukuk Benjamin (2007, as cited in Mohamad, et.al., 2010).

Reasons why Sukuk is attractive to investors could be identified as follows (Benjamin, 2007 cited in Mohamad, et. al., 2010):

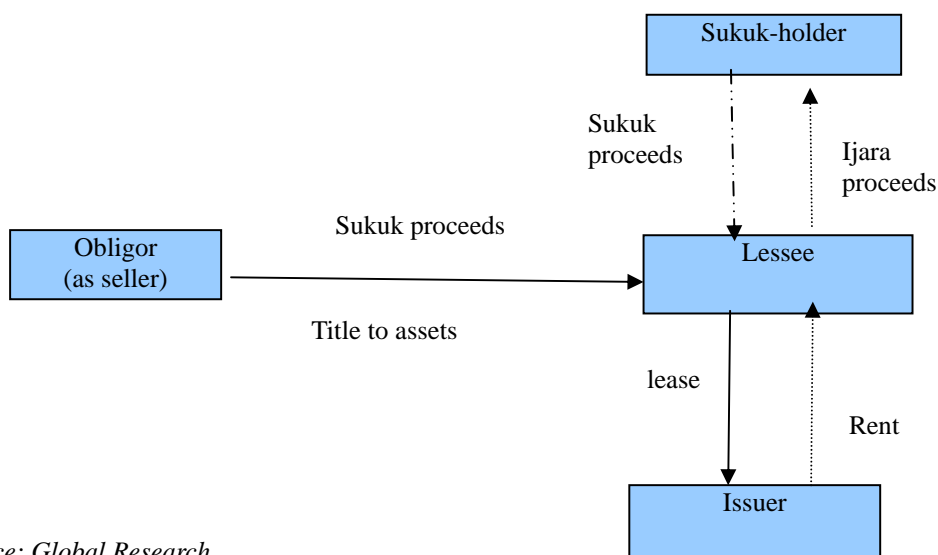

- It is asset-back securitization that is, there must be an underline asset or Special Purpose Vehicle (SPV).
- It pools investors’ resources together to satisfy their yearning for profit while satisfying the financial needs of the issue.
- Sukuks bring a new source of funds, generally at attractive rates
- They are vital to developing deeper and more liquid Islamic capital markets
- Sukuk are based on an investment process which involves investors mixing their funds with other investors’ funds in order to make profits.

- They are a tradable Shariah-compliant capital market product providing medium to long-term fixed or variable rates of return.
 - They are assessed and rated by international rating agencies. They provide regular periodic income streams during the investment period with easy and efficient settlement and a possibility of capital appreciation .
- In Indonesia case, retail Sukuk is attractive due to some reasons below:
- it is risk-free instrument since it is guaranteed by the government.
 - The return is higher than conventional interest rate
 - The return is fixed and paid monthly
 - it is tradable, since there is secondary market for this instrument
 - it has positive expected return
 - it can be utilized as a collateral
 - it is shariah compliance

Sukuk Structure

There are different kinds of Sukuk. They are as follows (Usmani, 2006):

1. Ijarah (leasing) Sukuk: the company sells certain assets to the Sukuk issuer who pays the assets using the proceeds of the Sukuk issuance, and holds title of the assets on trust for the Sukuk holders. Then, the issuer leases the assets back to the originator for a fixed period of time. At the maturity date, the originator/obligor may have the right to purchase the assets back from the issuer at a price which would represent the redemption value for the Sukuk holders at maturity (El-Quqa, et.al., 2008). Figure 1 below describes Sukuk al ijara structure.

Source: Global Research

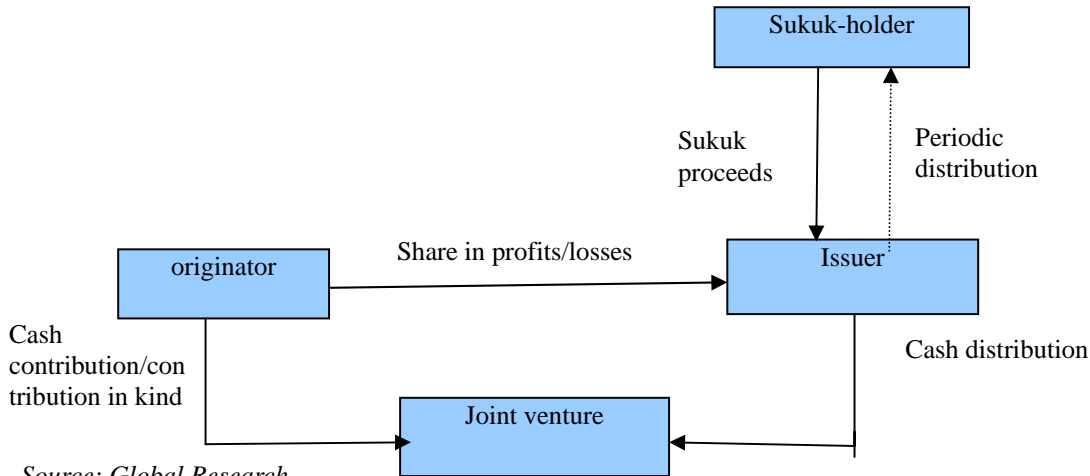

Figure 1: Sukuk Ijara structure

There are three forms of ijarah Sukuk (Usmani, 2006):

- a) Sukuk of ownership in leased assets: the Sukuk are issued by the owner of leased asset or by a financial intermediary represent the owner of the asset with the goal of selling the asset and recovering its value through subscription so that the holders of the Sukuk become owners of the assets. The holders share profits and losses on the basis partnership. The Sukuk is tradable at the market price and it is redeemable at a rate agreed upon between the certificate holder and the issuer.
- b) Sukuk of ownership of usufructs of assets: Sukuk are issued by the owner (or usufruct or lessee) of an existing asset with the goal of leasing the asset (or subleasing the usufruct) and receiving the rental from the revenue of subscription, thus the usufruct of the assets passes into the ownership of the holders of the Sukuk. However, when the assets are sub-leased, the Sukuk represents rent receivable, and it becomes non-tradable because rent receivable is a debt owed by the second lessor.
- c) Sukuk of ownership of services: "Sukuk issued for the purpose of providing services through a specified provider (such as educational benefits in a nominated university) and obtaining the service charges in the form of subscription income so that the holders of the Sukuk become owners of these services". It is tradable as long as it is not sub-leased.

Regarding to Indonesia retail Sukuk, it is ijarah Sukuk with the mechanism as follows: the debut benchmark Indonesia international Sukuk is being issued by Perusahaan Penerbit SBSN Indonesia (PPSI-I), the special purpose vehicle (SPV) is set up and wholly owned by the Indonesian Ministry of Finance. PPSI-I will issue trust certificated based on parcels of assets owned by the Indonesian government but transferred to the SPV till maturity of the certificates. The assets will be leased back to the Indonesian government, which will pay a rental to the SPV, some of those proceeds will be used to service periodic payments to Sukuk certificate holders.

2. Musharaka Sukuk: musharaka means sharing of profit or loss by the partners of a joint venture. Thus, partners can hold a musharaka certificate which represent their assets proportion in the venture. The Sukuk can be traded in the secondary market. Thus, the Sukuk holders are entitled to their share in the profits and they bear a loss in proportion to the financial value represented by his certificates. One of the forms of musharaka Sukuk is mudaraba Sukuk. The certificates are based on mudaraba activities. Thus, the Sukuk holders (subscribers) own the assets, while the issuers are mudarib. They are entitled to an agreed ratio of profit, whereas only the subscribers bear the loss. Figure 2 below describes Sukuk musharaka structure.

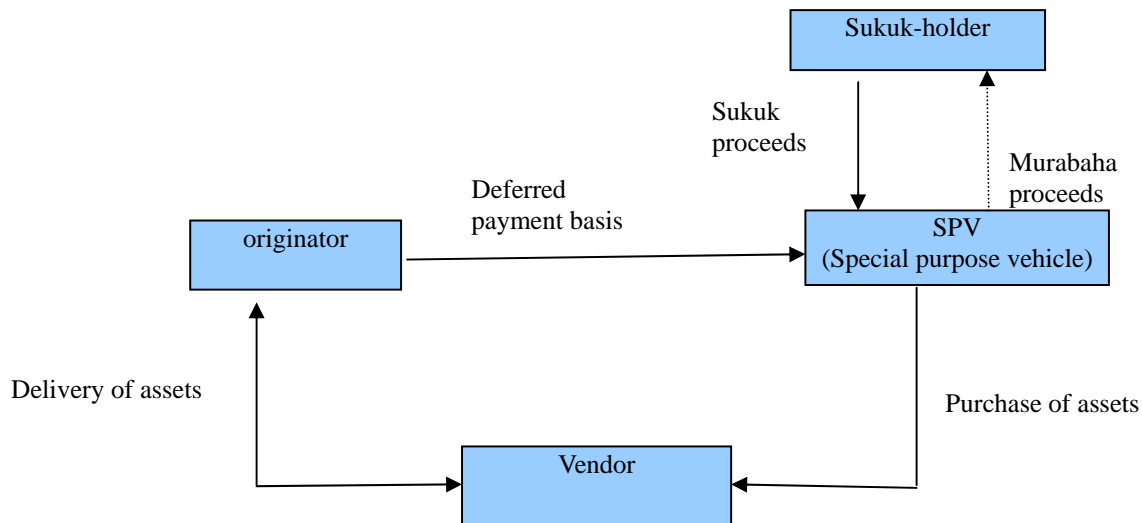

Source: Global Research

Figure 2: Sukuk musharaka structure

Different forms of Sukuk musharaka are discussed below (Usmani, 2006):

- a) participation certificates: Sukuk are issued representing projects on the basis of musharaka by appointing one of the partners or another person to managed the operation.
 - b) Mudaraba Sukuk: Sukuk are issued on the basis of mudaraba. Thus, the issuer is the mudarib, that is a person who manages an operation of the project; the subscribers are the owners of capital, and the realised funds are the mudaraba capital. The Sukuk holders and mudarib share the agreed profit sharing, while only Sukuk holders ear the losses.
 - c) Investment agency Sukuk: Sukuk are issued on the basis of an investment agency. The issuer of the Sukuk is the investment agent; and the subscribers are the principals and the realised funds are the entrusted capital or investment. The Sukuk holders share profit and losses, while the agent is entitled to an agency fee, he or she is not related to profit or loss of the business.
3. Murabaha Sukuk: murabaha is a specific kind of sale where the commodities are sold on a cost-plus basis. Islamic financial institutions usually use this murabaha mode of financing by purchasing goods on behalf on client, and its resale to the latter on deferred payment basis. Murabaha Sukuk are certificates based on murabaha activities. The issuer is the seller of commodity, the subscribers are the buyers of that commodity. The Sukuk holders are entitled to murabaha commodity and its sale price. The Sukuk is not tradable since murabaha activities are based on deferred payment basis, in other words, it is a debt payable by the client. However, trading of the Sukuk is permissible after purchasing of murabaha commodity (not on debt basis) and before selling it to the buyer.
 4. Salam Sukuk: salam is a contract in which advance payment is made for goods to be delivered later on. The seller undertakes to supply some specific goods to the buyer at a future date in exchange of an advance price fully paid at the time of contract. The seller of salam is Sukuk issuer, the subscriber is the buyer of the salam goods. Thus, the holders of Sukuk are the owners of the salam goods, they are entitled to the sale price of the salam goods sold. Salam Sukuk is not tradable during the term of Sukuk since the underlying asset is a debt. This debt will be converted into a tangible asset at the maturity date.

Source: Global Research

Figure 3: Sukuk al murabaha structure

5. Istisna' Sukuk: isti'na is the deferred sale of commodity. So, the purchaser orders to manufacturer to make the required goods. The price is fixed and specification of the goods is settled between parties. Furthermore, it is not necessarily that the price is paid in advance, but it may be deferred to any time according to the agreement of the parties. The supplier/seller is Sukuk issuer; the Sukuk holder owns the product. Istina' Sukuk is tradable when the funds have been converted into assets owned by Sukuk holder.

The Shari'ah Board of the Accounting and Auditing Organization for Islamic Financial Institutions (AAOIFI) advises Islamic Financial institutions and Shari'ah Supervisory Boards to decrease their involvements in debt-related operations and to increase true partnerships based on profit and loss sharing in order to achieve the objectives of the shari'ah (AAOIFI, 2007).

Risk of Sukuk

There are few risks embedded at Sukuk (El-Quqa, 2008; Zaidi, 2007; Tariq, 2004):

1. **Market risk:** interest risk and foreign exchange risk are two amongst market risk that are related to Sukuk. Interest rate risk is the rate of return risk. Sukuk which is based on fixed rate has the same exposure as conventional bonds, that is the price of Sukuk will go down when the interest rate increases. Sukuk certificates are also exposed indirectly to interest rate fluctuation through the widespread benchmarking with LIBOR in their financing operations. I think it shows that the investors treats Sukuk as conventional bonds, i.e. they compare Sukuk with conventional variable (interest). The issuance of Sukuk is meant to be widening investments alternatives for muslims. They are supposed to compare the Sukuk return with profit sharing (equivalent rate) of others Islamic financings. For sovereign Sukuk, the price of Sukuk is influenced by GDP, instead of interest rate. "If GDP growth rose relative to inter-bank rates, demand for the Sukuk would increase given its return, hence the price would rise", and the other way around. Thus, in the case of Sukuk benchmarked against GDP growth, then the Sukuk price is influenced by performance of a country growth (Wilson, 2006). Exchange rate risk arises from unfavourable exchange rate fluctuations when Sukuk is denominated on foreign currency.
2. **Credit and counterparty risk:** credit risk is an investor's risk of loss arising from a borrower who does not make payments as promised. Counterparty risk refers to the risk when the counterparty does not fulfill the contract. Major Sukuk issuance are mainly based on Ijarah, Istina, Salam, and Murabaha contracts. Salam and Istina contracts are exposed to the risk that commodities will not be supplied on time or to the agreed quantity. While Murabaha contracts are exposed to the risk that the client can not make a payment on time.
3. **Price/collateral risk:** the risk of differences the underlying asset fair-market value and the reported values. The assets must be depreciated and the maintenance cost is also the issue. Ijarah Sukuk is most likely exposed by this risk since the depreciation will cause the assets value will fall below the prevailing market values.
4. **Liquidity risk:** the risk relates to the limited growth of the secondary market. Thus, the investors are challenged to trade or liquidate their holdings.
5. **Sharia compliance risk:** sharia compliance risk refers to the loss of asset value as a result of the issuer's of its fiduciary responsibilities with respect to compliance with sharia. Islam is the way of life for muslims, thus, Islamic finance has to reflect the essence of the faith. The challenge here is how to preserve the competitiveness as well as

the rule. Sometimes, the balance between shariah conformity and project feasibility is disturbed, then jurists and shariah consultants play a continuously integral role in the formulation of the Sukuk prospectuses.

6. Operational risks: there are several risks, namely, default risk, coupon payment risk, asset redemption risk, SPV specific risks, investor specific risks, and risk related to the asset. Basically, the risks are attached to the structure of the issuance rather than the underlying Islamic principles.

Risk of Bonds

There are risks associated with bonds (Newman, P. et. al., 1997), those are listed below:

1. Interest rate risk: as mentioned above, the interest risk is the rate of return risk, that is the risk that a bond will have to be sold at a loss. The holding period return is affected by the uncertainty about the future price of a bond. The uncertainty is because of the future interest rate uncertainty and hence prices. [Interest rates](#) and bond prices has negative relationship; when interest rates fall, the price of bonds trading in the marketplace generally rises, and the other way around. "This happens because when interest rates are on the decline, investors try to capture or lock in the highest rates they can for as long as they can. To do this, they will scoop up existing bonds that pay a higher rate of interest than the prevailing market rate. This increase in demand translates into an increase in bond price" (Curtis, n.d.)
2. Reinvestment risk: the risk when future interest rates at which the coupon can be reinvested will be less than the yield to maturity at the time the bond is purchased.
3. Credit or default risk: the risk that the issuer will not pay its obligation. Usually, the lower-quality-rated bonds will pay higher yield than the higher-quality-rated bonds. However, the government bonds will have the least credit risk, even in some countries the bonds do not have credit risk.
4. Call risk: the risk when the issuer retire all or part of a bond at disadvantageous time, that is when the interest rate declines relative to the coupon rate. "this creates an asymmetric risk for the holder who suffers the full burden of any rise in interest rates through fall in price but will not reap the benefit of higher price through lower interest rates".
5. Inflation or purchasing power risk: it arises when purchasing power of investment returns is eroded by increase of inflation. Nominal interest rate usually reflects the inflation.
6. Exchange rate or currency risk: when bond is denominated in foreign currency, then domestic currency cash flows will depend on the foreign exchange rate at the time the payments are received.
7. Event risk: the risk of "the ability of an issuer to make interest and principal payments changes seriously and unexpectedly because of either (1) a natural or industrial accident or some regulatory change, or (2) a takeover or corporate restructuring".

Looking at the risks of conventional bonds and Sukuk, some of them are similar. In this paper, we investigate government domestic retail Sukuk, thus only few of the risks above can be used as variables which affect Sukuk price, namely, interest rate, and inflation. Moreover, I add shariah profit sharing return as proxy interest rate to observe whether retail investors consider others shari'a financial instrument to invest in Sukuk.

Sukuk Challenges

The challenges of Sukuk are coming from legal framework, economic, and regulatory. Hayat (2010) raised the issue of treatment Sukuk under the Islamic law as well as the secular law. El Quqa et.al.(2008), Jobst, et. al. (2008) also suggested that legal uncertainty arising from the fact that the transaction structure needs to satisfy commercial as well as Islamic law, especially in non-Islamic countries. Moreover, the on going efforts from Islamic regulators, such as AAOIFI, are still having differences in interpretation. The need for global standards was needed when "AAOIFI issued a statement on Sukuk in February 2008 amid criticism that majority of Sukuk were structured such that they were not in strict compliance with Islamic teachings" (Hayat, 2010). "Greater standardization would enhance the valuation and efficient pricing of Sukuk and improve secondary market liquidity within regulatory frameworks that are cast in a way to be flexible enough to adapt to the characteristics of new Islamic capital market securities while preserving universal standards of market supervision and financial surveillance" (Jobst, et. al., 2008).

Nasif, et. al. (2009) suggest four considerations in order Sukuk financing to become primary instruments of financing the projects. First, "greater clarity in transaction structures. Improved documentation, increased standardization, and lower overall complexity". Second, "consensus among Islamic scholars around the world, including better issuer and investor education about Sukuk and sharia compliance generally". Third, create a more liquid secondary market. Fourth, a more certain legal framework, especially surrounding the enforceability of collateral.

Regarding to economic and financial challenges, Jobst et. al. (2008) state several points: the identification of underlying asset that meet both shariah requirements and attractive returns; the absence of structural features that are

standard in conventional securities but which are not normally contractually permissible in an Islamic principle; lack of shariah compliant risk management; limited historical performance data on shariah compliant assets; buy and hold strategy, and limited diversify of Sukuk investor create illiquid secondary markets and inhibit efficient price discovery; and tax disincentives.

Methodology

The research employs multiple regression model with retail Sukuk as dependent variable; inflation and interest rate (conventional as well as shariah equivalent rate) as independent variables. Since we use OLS, then assumptions under linear regression model - namely heterocedasticity, normality, autocorrelation, linearity, multicollinearity - are tested in order to obtain best linear unbiased estimators (BLUE).

Data is from 26 of February up till 11 of November, 2010. The detail of data is as followed:

- Monthly data of retail Sukuk 01 (SR01).
- Monthly profit and loss sharing (equivalent rate) as a proxy of shari'a return rate
- Monthly inflation
- Monthly BI certificate - 1 month as a proxy of conventional interest rate

The result is shown at the table below:

Table-1: OLS, using observations 2009:02-2010:11 (T = 22)

Dependent variable: Sukuk

<i>Variable</i>	<i>Coefficient</i>	<i>Std. Error</i>	<i>t-ratio</i>	<i>p-value</i>

inflation	-11.8349	19.0137	-0.6224	0.54146	
shari'a12*	4.77147	91.9772	0.0519	0.95920	
con1**	-160.342	38.0263	-4.2166	0.00052	***

*shari'a12 is profit and loss sharing equivalent rate 12 month

**con1 is conventional BI certificate 1 month rate

Result

From the table 1 above, we can conclude that the signs of variable inflation and conventional interest rate are in line with suggested theory. Conventional bond theory suggests that inflation and interest rate increase, then the bonds price decrease. While shari'a return rate has positive sign, which is not inline with the theory. However, it is not significant, in other words, shari'a return rate has no influence on the price of retail Sukuk. The result is surprising because the price of retail Sukuk is only influenced by conventional interest rate. It means that the investors compare the return of retail Sukuk to conventional interest rate. They are supposed to compare it with others shariah financial instrument, in this case is mudarabah deposito 12 months. This finding is also supported by Syafirdi (2006, cited in Siswanto, n.d.), inflation does not affect the price of Sukuk. It also noted by Dahlan Siamat, the Director of shariah Financing, he said that the investors are keen on conventional interest rate (BI rate-8.25%) and inflation, which is much smaller than retail Sukuk return 12% (Suprpto, 2009). The implications of the result above are discussed below.

First of all, I assumed that the investors of retail Sukuk are devoted Muslims, however, the result does not support it. The investors apparently are not concerned with shari'a instrument, as suggested by Jabeen and Javed (n.d), “not surprisingly when the target investors are muslims and knowing that sharia'h permissibility is an important element in their decision-making, such products would flourish and there is still a huge latent market waiting for it. This product is not confined to the muslim world alone. If Sukuk enable the muslim ummah to rid itself of the yoke of riba and debt-based financing, and develop the taste for risk and reward sharing, this would be considered as a major achievement in history”. It suggests that retail Sukuk is influenced by the same variable as conventional bonds. However, the investors apparently only concern on the return, they do not look at the inflation rate. It is suggested by analyst at PT Mandiri sekuritas “the investors will be demanding a premium of as much as 50 basis points over non-Islamic debt”. It is similar to European investors that in order to consider investing in Sukuk, it should be priced at a premium over conventional bonds. As, we know Europe is not continental which is dominated by muslim. Thus, comparing the Sukuk return with a return of conventional product is making a sense. Moreover, interviewing four SR01 selling agent, two of them said that most of investors are non-muslim, and the other two informed that most of investors are muslim. Thus, we can assume that investors' profile - regards to religion – is around 50 % muslim and 50% non-muslim, if it is the case, then it is most likely a reason of muslim investors is not due to a religious factor but solely due to a economic reason (return). However, I believe that there are huge potential new muslim investors who do not invest their money in the financial instruments. They are

reluctant investing in financial instruments might be the reason of low financial literacy. It is worth it to investigate further.

Godlewski, et.al (2010) study whether Islamic investment certificates are special. They look into two perspectives: first, the opinion of stock markets regarding to differences between Sukuk and conventional bonds; second, whether Sukuk are likely to replace conventional bonds. They conclude several implications, one of them is that “there might be several motivations for firms to issue Sukuk, including religious factors. However, the fact that stock markets negatively perceive Sukuk seems to indicate that the use of these securities should not be favored for economic reasons”. Thus, Zaini's (2007) opinion on the fact that Muslim investors are increasingly choosing Islamic financial products and services over the conventional ones does not happen in Indonesia.

Conclusion

Retail Sukuk is developed by ministry for domestic investors in bond market to strengthen the government's bond against volatility due to foreign investors movement. It helped to finance the budget deficit. The question is that what variables affect the price of retail Sukuk.

This paper will examine what factors that affect individual investors to buy retail Sukuk 01(SR01). Investigating factors that affect SR01 price is crucial because Indonesia, as the world's most muslim populous country, is supposed to have muslim investors who are more concerned to Islamic finance products to invest. Thus, the government has a potential new market segment (diversification of investor base) to finance the budget through domestic market. Moreover, the government does not need to have exchange rate exposure relates to non domestic currency denominated Sukuk.

The result suggests that only interest rate (conventional) affects the price. It implies that the investors are only concern on the return; the religious factor apparently does not come in the picture. I supposed that the potential muslim investors – devoted one, who concern on shari'a compliance of financial investment – are reluctant investing in financial instruments. the reason might be low financial literacy. It is worth it to investigate further.

University of Delhi

M. C. Kapoor
Adjunct Professor, IndianBusinessSchool, Gurgaon

ABSTRACT

The present paper investigates the impact of bank specific factors on the determinants of Net Interest Margin (NIM) for the public sector, private sector and foreign banks operating in India for the year 2010. The calculation of NIM is crucial since it includes important information about the efficiency of the banking system and identifying the determinants of net interest margin would help to provide policy implications for the banking environment. We examine the impact of the recent changes on the NIM by dividing the data into two subparts: Model 1 for public sector, private sector and foreign banks and Model 2 for only public sector banks in India. The results suggest that for Model 1 Asset Quality, Operating Expenses, Capital Adequacy and Return on Assets have a significant impact while for Model 2 Operating Expenses, Capital Adequacy, Return on Assets and Gap are significant determinants of the net interest margin of banks.

Introduction

The banking industry has undergone a rapid transformation in the last decade and the recent trends of shrinking margins and increasing competitive pressures have changed the face of banking industry beyond recognition. Recent changes in the banking business due to rapid technological development, increased competition and diversity in banking operations have made the process of ALM complex. With increasing pressure on the banks bottom lines, ALM continues to be a much - debated topic for both regulators and policy makers.

Though the Asset Liability Management (ALM) process is too complex to practice, it is perhaps the only solution for banks to survive in this rapidly changing environment where the composition, duration and risk profile of their assets and liabilities have an important bearing on their growth and profitability. An efficient ALM technique aims to manage the volume, mix, maturity, rate sensitivity, quality and liquidity of the assets and liabilities as a whole so as to earn a predetermined acceptable risk/reward ratio. The technique views the financial institution as a set of interrelationships that must be identified, coordinated and managed as an integrated system (Moynihan,G.P., Purushothaman,P,Mcleod,R.W. and Nichols,G,2002). In fact a sound ALM process helps the banks to evaluate balance sheet risk and take prudent decisions that enable them to remain financially viable as economic conditions change.

With competition rising in the banking sector more and more focus is on effective asset liability management of banks so as manage the risk and consequently achieve desirable returns. Thus to appreciate the ALM in its existing state in the interest volatility scenario, it is useful to study the relationship between Interest rate risk and maturity gaps as they exist in Indian banks and also the key determinants of NIM . Some of the recent studies on the determinants of NIM are Saunders and Schumacher(2000) , Maudos and Solis(2009) , Kasman et al (2010) .

NIM is an indicator of both performance and efficiency in the banking system. According to RudraSensarma and SaurabhGhosh (2004), a competitive banking system is expected to foster efficiency which should get reflected in lower NIM. Too high NIM is reflective of lack of competition in the industry. However, too low NIM can also put a stress on the profitability of banks. As NIM is an indicator of both performance and efficiency in the banking system, it is interesting to explore its determinants.

In the context of the current international financial crisis, results from the study will allow us to shed light on some of the possible effects on determinants of bank performance and the resulting banking net interest margins. The Indian banking system is an important sector of the economy which is robust and has not suffered much in spite of the successive international and domestic crises that the countries have gone through over the years. According to recent reports two Rating agencies – Care and Fitch, expect FY11 to see a rise in bank non-performing assets. The year 2011 is likely to be a tough one for banks in terms of profit margins. Banks which saw their net interest margins improve in 2010 may see margins come under pressure due to tight liquidity and increasing cost of funds (Hindustan Times, January, 2011). Analysts feel that margins of banks peaked in 2010 and protecting the current level will be a challenge specially for the public sector banks. This means that banks need to cut their operating cost and increase efficiency by generating more fee based income in the coming years. This will help them to increase their profitability in spite of a decrease in NIM.

The rest of this paper proceeds as follows. Section 2 briefly presents the relationship between interest rate risk and Gap analysis. Section 3 reviews the relevant literature. Section 4 describes the data and methodology used for the study. Section 5 presents the results and discussion of our study. Section 6 presents the policy implications and Finally Section 6 concludes.

Financial Risk, Interest rate Volatility and Asset Liability Management

The function of asset-liability management is to measure and control three levels of financial risk: interest rate risk (the pricing difference between loans and deposits), credit risk (the probability of default), and liquidity risk (occurring when loans and deposits have different maturities).

A primary objective in asset-liability management is managing Net Interest Margin (NIM), that is, the net difference between interest earning assets (loans) and interest paying liabilities (deposits) to produce consistent growth in the loan portfolio and shareholder earnings, regardless of short-term movement in interest rates. The rupee difference between assets (loans) maturing or repricing and liabilities (deposits) is known as the rate sensitivity gap (or maturity gap). Banks attempt to manage this asset-liability gap by pricing some of their loans at variable interest rates.

GAP and Net Interest Margin

GAP is defined as the absolute difference between Rate Sensitive Assets (RSA) and Rate Sensitive Liabilities (RSL) for each time bucket. The sign and magnitude of GAPS in various time buckets can be used to assess potential earnings volatility arising from changes in interest rates. Positive GAP indicates that RSA are more than RSL and from an earnings perspective, the position benefits from a rise in interest rates. A negative GAP on the other hand indicates that RSL are more than RSA and from an earning perspective the position would benefit from a fall in interest rates.

If the bank wants to keep its net interest income immune from changes in interest rates it must closely monitor and manage its GAP carefully. Net interest income is defined as the difference between interest income and interest expenses and provides the life blood of a bank's earnings.

$NII = \text{Interest Income} - \text{Interest Expenses}$

The GAP also affects a bank's net interest margin and is defined as follows: -

$$\text{NIM} = \frac{\text{Net interest income (NII)}}{\text{Interest earning assets (EA)}}$$

Or

$$\text{NIM} = \frac{\text{NII}}{\text{EA}}$$

Also, change in net interest income will result in a change in net interest margin, so that symbolically we have

$$\Delta \text{NIM} = \frac{\Delta \text{NII}}{\text{EA}}$$

Substituting the value of ΔNII in the above equation we get

$$\Delta \text{NIM} = \frac{\text{GAP} \times \Delta r}{\text{EA}}$$

Thus, the focal variable of ALM from the accounting perspective is net interest margin in its ratio form (NIM / EA). In this context the ALM objective is to maximize net interest margin for a given level of risk as reflected by the variability of interest rate changes. Management of interest rate risk is one of the critical components of risk management in banks.

Review of Literature

The measurement of interest rate and liquidity risks on the banking book of a bank has had a prominent place in ALM. Some of the early studies include Platt (1986), Farin (1989), and Fabozzi and Konishi (1991). Most of the existing literature in this area suggests that banks may choose to focus on two approaches to measure interest rate risk (Basle Committee, 1997; Dermine and Bissada, 2002). The first approach to measure interest rate risk is with respect to the impact of a change of interest rate on the Profit & Loss account, in other words, is the impact on the net interest income (NII) of the bank. The second approach measures the impact of a change in interest rates on the fair economic value of the equity of a bank.

This study focuses on the first approach. Since NIM is an important measure of efficient ALM in banks, it is important to identify the determinants of NIM. Various studies have been conducted to identify the determinants of NIM. In their seminal work, Ho and Saunders (1981) defined bank as an intermediary between intermediary between lenders and borrowers, and stated that the optimal pure spread depends on four variables: the degree of risk aversion, the market structure (proxy for competition), the average size of bank transactions, and the variance of the interest rate on loans and deposits (market risk). Since then number of studies have been carried out in this direction. Most of the studies in this context have used variables such as bank size (Bikker and Hu, (2002); Ben Naceur and Goaid (2008)), credit risk, and equity (Maudos and De Guevara (2004) & Ben Naceur and Goaid (2008)) as internal determinants of bank performance.

Few studies have investigated relevance of size as a determinant of NIM. Kasman et al (2010) evaluate the effects of financial reforms on the determinants of commercial bank net interest margin in the banking systems of the new EU member countries. The results show that size and managerial efficiency are negatively and significantly related to net interest margins. However, Bikker and Hu (2002) and Ben Naceur and Goaid(2008) find positive and significant relationship between size and bank performance.

Studies have evaluated another variable, equity, as a determinant of NIM. Saunders and Schumacher (2000) carried out a study to identify the determinants of bank NIM in selected European countries and the US during the period 1988-1995 for a sample of 614 banks. They found out that the regulatory components in the form of interest-rate restrictions on deposits, reserve requirements and capital-to-asset ratios have a significant impact on banks NIMs. As Macro interest-rate volatility was found to have a significant impact on bank NIMs, they propose that macro policies consistent with reduced interest-rate volatility could have a positive effect in reducing bank margins.

Doliente (2005) finds that bank-specific factors, such as loan quality, capital, operating expenses and liquid assets, and volatility of interest rates and non-competitive market structure of banking system explained net interest margins for the south east Asian banks. Ben Naceur and Goaid (2008) also find positive relationship and significant relationship between capitalization and bank performance.

Operating costs is yet another variable that finds a significant place in the literature. Maudos and Solis (2009) analyze net interest income in the Mexican banking system over the period 1993–2005. Their study models the net interest margin simultaneously including operating costs and diversification and specialization as determinants of the margin. They have attributed high margins mainly to average operating costs and to market power. They find that although non-interest income has increased in recent years, its economic impact is low.

Few studies find credit risk as an important determinant for NIM. Angbazo, L. (1997) show that the net interest margins of commercial banks reflect both default and interest-rate risk premia. The results in their study state that the net interest margins of money-center banks are affected by default risk, but not by interest rate risk, which is consistent with their greater concentration in short-term assets and off-balance sheet (OBS) hedging instruments whereas (super-) regional banking firms are sensitive to interest-rate risk but not to default risk. Miller and Noulas suggest a negative relationship between credit risk and profitability. Thus we find that size, equity, credit risk, operating costs and inflation amongst others are some of the key variables used in the literature.

Data and Methodology

In this section we discuss the data sources, variables definitions, and the model specification employed in our investigation. Two models were tested in the present paper.

Model 1 includes data from 55 banks (28 Public sector banks, 20 Private sector banks and 7 Foreign banks) operating in India for the year 2010. Model 2 includes only the data for 28 public sector banks. The data for all the banks were obtained from the various issues of Report on Trend and Progress of Banking in India, Statistical Tables Relating to Banks in India and the annual reports of the banks.

The detailed description of the variables used in the study is as discussed in Table 1.

Dependent variable

The dependent variable here is Net Interest Margin (NIM) or spread which is the difference between cost of deposits and yield on loans earned by a bank divided by its total assets. In the Indian banking industry, NIM has come down subsequent to banking sector reforms but the decline has been very slow (RudraSensarma and SaurabhGhosh, 2004).

Independent Variables

As the NIM of a bank is an indicator of bank performance and efficiency, it is very important to study what are the explanatory factors that affect NIM. The seven independent variables considered in the study are:

Book Value of Equity divided by Total Assets (EQTA), Borrowings divided by Total assets (BORTA), Non Performing Assets divided by Total Assets (NPTA), Return on Assets (ROA), Operating Expenses divided by Total assets (OETA), Log of Total assets (TA) and GAP (calculated as the difference between rate sensitive assets and rate sensitive liabilities for 1 year) divided by Total assets.

TABLE 1: DEFINITION OF RESEARCH VARIABLES USED IN THE ANALYSIS AND EXPECTED SIGNS OF COEFFICIENT

S.No.	Variables	Definition	Predicted Sign
1	EQTA	EQUITY CAPITAL / TOTAL ASSETS	+
2	BORTA	BORROWINGS / TOTAL ASSETS	+
3	ROA	RETURN ON ASSETS / TOTAL ASSETS	+
4	NPTA	NON PERFORMING ASSETS / TOTAL ASSETS	--
5	OETA	OPERATING EXPENSES / TOTAL ASSETS	--

6	TA	TOTAL ASSETS (TAKEN IN LOGS)	+
7	GAPIYR	GAP/ TOTAL ASSETS	
8	NIMTA	NET INTEREST MARGIN / TOTAL ASSETS	

Most of the empirical approach is based on the hypothesis that the variables used in the analysis are stationary. It is always useful to provide statistical support for this hypothesis as there is increasing evidence that the variables used are not stationary. The frequency of the series as well as the time period plays a major role in the results of these tests and they cannot be generalized from one case to another. Furthermore, if it were the case that the series are non-stationary, co integration procedures could be used and would provide statistically more reliable results.

Using **EIEWS 7.0**, we model the equation using the Multiple Regression method of estimation. The program will generate the values of α and β on the basis of the actual data. These values of α and β are such that they minimise the error in the model as represented by ϵ_t

When we performed the unit root test for stationarity, we found that out of the seven independent variables identified, six variables (EQTA, ROA, NPTA, OETA, TA and GAP 1 YR) were stationary at level and only one variable (BORTA) was non stationary at level. For the public sector banks all the variables were stationary at level. The dependent variable (NIMTA) was stationary at level for both the models examined. If the series being tested for regression are non stationary at level, but stationary at first difference, then the results could be spurious. As such, we had no option but to drop BORRTA from our analysis for Model 1 and then perform the multiple regression analysis.

The Linear multiple regression model used by our analysis is specified as follows:

$$Y_{it} = \alpha + \beta X_{it} + \epsilon_t$$

Here Y_{it} is the dependent variable (NIMTA) and X_{it} is the set of independent variables (EQTA, NPTA, ROA, OETA, TA, GAPIYR)

The above model can also be written as

$$NIMTA = \beta_1 + \beta_2 EQTA + \beta_3 NPTA + \beta_4 ROA + \beta_5 OETA + \beta_6 TA + \beta_7 GAPIYR + \epsilon_t$$

where

β_1 is the constant and ϵ_t is the error term

This study also tested the assumptions of the linear multiple regression model, viz., multicollinearity.

Results and Discussion

Model 1: Public Sector, Private sector and Foreign banks

Our study tested the variables for multicollinearity. Table 2 presents the results of the correlation among the independent and dependent variables. None of the two independent and dependent variables are highly correlated and hence, there is no problem of multicollinearity in the variables chosen for our analysis.

TABLE 2: CORRELATION AMONG INDEPENDENT AND DEPENDENT VARIABLES

Variables	NIMTA	EQTA	BORRTA	NPTA	ROA	OETA	TA	GAPIYR

Results of the multivariate regression models

Table 3 summarizes the impact of the explanatory variables on the net interest margin. The results show that the data seems to fit the model reasonably well and the explanatory variables present the expected signs and are statistically significant.

Table 4 shows the model summary of the regression for the sample banks. The R-Square of the model equals to 80.48% and the R-Square adjusted of the model equals to 77.62%. This means that 77.62% of the changes in the dependent variable (NIM) are due to the variations of the independent variables used in this model. A few other factors which could probably have an influence on the NIM are management efficiency, liquidity, nature of ownership, and non interest income.

The major findings emerging from the analysis can be summarized as follows:

NIM is not significantly associated with size of banks.

Return on Assets is associated with higher NIM.

Non Performing Assets has a statistically significant impact on NIM.

Higher Capital Adequacy Ratio is associated with higher NIM.

NIM is inversely related to Operating Expenses and they are statistically significant at 5% level.

Gap as a crude measure of interest rate risk is not significantly related to NIM.

Dependent Variable: NIMTA

Independent Variables: (Constant), BORTA, NPTA, ROA, OETA, TA, GAPIYR

Model 2: Public Sector Banks

Tables 5 and 6 summarize the impact of the explanatory variables on the net interest margin. The results show that Operating expenses, Return on assets, Capital adequacy and GAP are the most important drivers of net interest margin. Borrowings, Non Performing Assets and Size have no impact on the NIM of the bank.

The major findings emerging from the analysis can be summarized as follows:

NIM is not significantly associated with size of banks.

Capital Adequacy Ratio is significantly associated with NIM.

Non Performing Assets is not a significant variable in determining NIM.

Operating expenses are an important determinant of profitability.. NIM is inversely related to Operating Expenses and has a statistically significant impact.

Return on assets has a statistically significant impact on NIM.

Borrowings are statistically insignificant and are not related to NIM.

Gap is significant and is related to NIM

TABLE 5: DETERMINANTS OF NET INTEREST MARGIN

Capital Adequacy

In the multiple Regression model, Capital adequacy which is measured by the ratio of the book value of equity divided by total assets (*EQTA*) has a highly significant positive coefficient. In our model we find that the coefficient is significant and positive at 1% for both the models under study. The ratio has a positive relationship with NIM as banks need more interest income in order to maintain high levels of capital. This is consistent with the hypothesis that well-capitalized banks are subject to less expected bankruptcy costs and hence lower cost of capital (Berger, 1995). The ratio is also used as a sign of banks' credit worthiness with a higher ratio indicating that a bank is well capitalized with regard to the solvency risk in the near future. The positive and significant coefficient of equity divided by total assets as a measure of capital adequacy on net interest margin supports the findings of the study by Saunders and Schumacher (2000) and Brock and Suarez (2000). Thus, Capital turns out to be an important determinant of bank margins, in both the models emphasizing the need to maintain relatively high capital adequacy levels to ensure stability and maintain the confidence of depositors.

Asset Quality

The coefficient of NPA/ TA has the expected negative sign for both the models and is significant for model 1. Our results are consistent with the findings of RudraSensarma and SaurabhGhosh (2004) who argue that banks with high NPAs are expected to have shifted their loan portfolio away from risky activities which would have otherwise adversely affected their spreads. The less risky activities where these banks would have moved into would bring them lower returns. Empirical literature also suggests that poor asset quality and low levels of liquidity are the two major causes of bank failures.

Size

The total assets of the banks are taken as a proxy for size in our model. Since all the other explanatory variables were deflated by total assets in the model, we use log of total assets in our calculations. According to empirical researches, size is introduced to account for existing economies or diseconomies of scale in the market. Smirlock (1985) finds a positive and significant relationship between size and bank profitability. Demirguc-Kunt and Huizinga (2000) suggest that the extent to which various financial, legal and other factors (e.g. corruption) affect bank profitability is closely linked to firm size. The coefficient of total asset is insignificant in both our model indicating that size is not a determining variable for NIM.

Operating Expenses

A high NIM alone cannot make a bank profitable as a substantial portion of NIM can be eroded by operating expenses and credit costs, including provisions for bad assets and write-offs (Mint, October 31, 2010). Operating expenses appear to be an important determinant of profitability closely related to the notion of efficient management. Our results show that operating expenses are an important driver of net interest margin as the coefficient of operating expenses is positive and statistically significant at 5% for model 1 and 1% for model 2. The positive and significant ratio indicates that banks with high operating expenses have to strive for higher intermediation margins to cover their higher operating costs. Our results are consistent with that obtained by Kasman A (2010), Brock and Suarez (2000), Abreu and Mendes (2003) and Maudos and de Guevara (2004).

Return on Assets

Return on assets is defined as net profit divided by total assets and measures the ability of the management to convert the assets of the bank into net earnings. (Sarkar et al. 1998). It is a measure of bank profitability and gives an idea as to how efficient management is at using its assets to generate earnings. ROA in many studies emerges as the key ratio for the evaluation of bank profitability (IMF, 2002). The ratio is significant for both the models in our study.

Borrowings

Abreu (2002) found that well capitalized banks face lower expected bankruptcy costs and thus lower funding costs and this resulted into better profitability. Borrowings are not significantly associated with NIM of a bank. The coefficient is insignificant for model 2 and is not stationary for model 1.

GAP

GAP which is calculated as the difference between RSAs and RSLs is used as a crude measure of interest rate risk. Interest rate risk arises in bank operations because banks' assets and liabilities generally have their interest rates reset at different times. This leaves net interest income vulnerable to changes in market interest rates. The magnitude of interest rate risk depends on the degree of mismatch between the times when asset and liability interest rates are reset (Katerina Simons, 2004). Management of Interest rate risk is one of the critical components of market risk management in banks. Excessive interest rate risk adversely affects a bank's financial condition in the current year as also in the future. For Model 1 GAP is not significant. For Model 2 Gap is significant at 5% level of confidence. This finding is in accordance with the interpretation that public sector banks with a greater degree of interest rate risk will require higher net interest margin to compensate for higher risk of default.

Policy Implications

The paper studies the effects of the determinants of bank net interest margins and attempts to identify the factors that affect NIM. NIM is an important indicator of performance of banks in India and has emerged as a key indicator of asset productivity, since a high NIM is indicative of the effective use of earning assets and a sensible mix of interest-bearing liabilities (Sophocles N. Brissimis, Manthos D. Delis, Nikolaos I. Papanikolaou, 2008).

Following the recent economic crisis and the increased pressure on the bottom-line of the banks, the investigation of bank net interest margins is crucial since they include important information about the efficiency of banking systems. Identifying the determinants of net interest margin would help to understand the changing scenario and trends in bank efficiency and provide the policy maker implications for the banking environment. The need for risk management in the banking sector is inherent in the nature of the banking business. Poor asset quality and low levels of liquidity are the two major causes of bank failures. The Basel accords have raised the stakes of Indian banks. Under Basel 2, banks need to maintain a tier 1 requirement of 6% of total capital and 9% of risk weighted assets.

The analysis suggests that banks may require an extra net interest margin to cover the high operating expenses as the results show that this is a very significant driver of net interest margin. Similarly, it will be of interest to policy makers and regulators to understand that higher equity to total assets ratio not only influences the performance of a bank positively but also lowers the need for external funding. The ratio is used as a signal of banks' credit worthiness with a higher ratio indicating that a bank is well capitalized with regard to the solvency risk in the near future. Our results clearly show the importance of capital adequacy rules as a means to prevent banks from taking excessive risks and as a tool for maintaining depositor confidence. Finally, high NPAs in a bank reduce the spread and are associated with low NIM.

Conclusions

We employ a multiple regression model using data from 55 banks for 2010 to identify the determinants of NIM. We find that Capital Adequacy, Asset Quality, Operating Expenses, Return on assets and GAP have a significant impact while borrowings and size of the bank have no impact on NIM.

The above findings also suggest that well capitalized banks face lower probability of going bankrupt. Also, higher bank equity ratios may influence bank performance positively when loan rates do not vary much with bank equity. For example for the year 2010, HDFC Bank had an NIM of 4.2%, probably the highest in the Indian banking industry. IDBI Bank 1.06% NIM is the lowest. However, it is important for the policy makers to understand that though NIM is an indicator of performance of banks, a high NIM alone cannot make a bank profitable as a substantial portion of NIM can be eroded by operating expenses and credit costs, including provisions for bad assets and write-offs.

The public sector banks account for about 75% of the Indian banking industry in terms of assets. Their operating expenses are also higher than their private sector peers. With the slowdown in the borrowers' ability to repay loans, banks are likely to pile up stressed assets in the future. According to a recent report by Care ratings (Economic

Times, June 2, 2010) managing credit growth and asset quality while sustaining earnings growth would be key challenges for the banking industry.

Abstract

The purpose of this research was to identify the main factors of the country and the firm, as well as assess and determine the mathematical relationship of individual exercise, by incorporating debt into the capital structure of companies located in Mexico. The analysis was conducted with the financial information published in the Mexican Stock Market, during the period between 2000 and 2007. An empirical study was performed where long-term debt was the dependent variable and by using the E-views 4.1 program and the technique known as panel data, the mathematical relationship which independent factors execute were estimated, that were previously identified and analyzed. The study results are from theoretical and practical interest, identifying and understanding the relationship of the main factors by including debt in the capital structure, facilitates and contributes to the normative postulates' construction.

Keywords: Capital Structure, Company Factors, Country Factors.

Introduction

The investigation arises from not finding in the company's real world capital structure policy, rule or model for its development, highlighting and raising the need to review the theories, empirical studies, existing hypotheses as well as the assumptions that underline and adopt different approaches to the study of the factors and their relationship to form the structure of capital. The review of theories and empirical studies gave a solid foundation to the questions, challenges and problems that we considered.

Theoretical Framework

The lack or existence of an optimal capital structure for the company, as well as how it should be determined have been one of the most controversial issues in the finance literature since Modigliani and Miller (1958), published their article and presented their proposals for the irrelevance of capital structure on the enterprise value. It's been 53 years since the publication of this seminal work which gave rise to corporate finance we know today and which in turn causes a study of the capital structure of companies to capture and received much attention from the finance and economic areas. Notwithstanding the extensive developed researches, the capital structure theory does not provide conclusive answers.

The theoretical models developed in recent years have tried to validate and generalize, sometimes, the thesis of the irrelevance of (Modigliani and Miller 1958), or some others, to adapt the thesis of maximum debt (Modigliani and Miller 1963). From convergence of both research lines in the decade of the sixties a renewed theory of capital structure emerged, which postulates the existence of an optimal solution to the raised problem.

In the actual investigation were reviewed among others the following theories: optimal capital structure, tax base theory, asymmetric information theory, theory of preferences hierarchy or pecking order theory (POT), which was formally proposed by Myers(1984) and by Myers and Majluf (1984) built on the preliminary work of Donaldson (1961), theory of agency costs and the free cash flows theory, together with empirical studies that support these theories, highlighting among others the study made by (Rajan and Zingales 1995), and the study of (Wald 1999), these studies provided empirical evidence for the G-7 countries. They analyze some institutional

factors of the company, such as: the size of the firm, earnings, growth rate, and risk. As well as in the financial theories' study, knowledge has grown and evolved, however it has not been able to build a model that includes all the factors considered as determinants of capital structure in the various empirical research, citing just to mention some of them those by Filbeck and Gorman 2000, Bradley, Chung 1993, Van Der 1989, Kester 1986, Harrell and Kim 1984.

The empirical evidence suggests that in addition to company specific factors, macroeconomic and institutional factors in each country are important determinants of capital structure. Booth et al. (2001), Antoniou, Guney, & Paudyal, (2008), Bonales and Gaytan (2009), Dias, Thosiro, & Cruz, (2009) and Dias and Toshiro (2009). However, most of the theoretical and empirical debate on corporate finance has been conditioned by well-developed capital markets and financial well-structured architecture (Zingales 2000). Arias et al. (2009) propose that specialized research is needed on this issue about Mexican companies in order to achieve a better understanding of its financial decisions, and be able to design appropriate financial instruments to their needs that enable and facilitate their growth.

The Capital Structure and The Macroeconomic or Institutional Factors of the Country

Recent empirical evidence suggests that country-specific factors are important determinants of capital structure in emerging markets. Booth, Aivazian, Demirguc-Kunt, & Maksimovic, (2001); Antoniou, Guney, & Paudyal, (2008); Gaytan & Bonales (2009); Dias, Thosiro, & Cruz, (2009), and Dias & Toshiro (2009). Suggest that specific factors about explaining the decisions of indebtedness of the company are related to the economic environment and institutional arrangements in each country, as the structure of the financial sector, taxation, the tradition of the legal system and accounting practices generally accepted.

In this study were considered the macroeconomic and institutional variables about countries in which empirical studies have been previously shown to have a significant impact as determining factors in the capital structure of enterprises: i) inflation (Dias, Thosiro, & Cruz, 2009), (Dias and Toshiro, 2009) (Gaytan and Bonales 2009). ii) the interest rate, (Barry, Mann, Mihov, Rodriguez, 2008). iii) the exchange rate (Burgman, 1996). iii) the exchange parity.

Capital Structure and the Enterprise Specific Factors.

It has been extensively searched how to identify the enterprise-specific factors that might be significant determinants on deciding the capital structure as well as the validity of the theories that gives them sustenance. Among the particular characteristics of the company that can act as determinants in the capital structure, Dias, Toshiro and Cruz. (2009), Bonales and Gaytan (2009), and Dias and Toshiro (2009) studied the mathematical relationship between the specific factors of companies established in Mexico and Latin American companies. His mathematical relationship to form the structure of capital, in their empirical studies related to the determinants of capital structure, they found significant evidence on the following factors: i) size, (Vigrén, 2009), (Rajan and Zingales (1995), (Frank and Goyal, 2009), (Titman and Wessels, 1988), (Chung, 1993) and (Ozkan, 2001), (Dias, Toshiro and Cruz, 2009) and (Dias and Toshiro (2009). ii) profitability, (Rajan and Zingales (1995), (Ozkan, 2001), (Frank and Goyal, 2009), (Teker, Tasseven and Tukul, 2009), (Dias, Toshiro and Cruz, 2009) and Dias and Toshiro (2009). iii) risk (Vigra, 2009). iv) growth (Antoniou, Guney and Paudyal, 2008), (Rajan and Zingales, 1995), (Myers, 1977) (Hall, Hutchinson, and Michaelas, 2000), (Dias, Toshiro and Cruz, 2009) and (Dias and Toshiro, 2009).

Objective

Studies on the structure of capital in Mexico are essential, and due to the lack of a robust model to explain the financing decisions of Mexican companies in each sector, this study aimed to identify key institutional factors of the country, as well as institutional factors of the company and its positive or negative relationship with the addition of debt when forming the capital structure used by companies traded steadily in the period from 2000-2007 in the Mexican Stock Market.

Hypothesis

The main factors of national and company's concern that relate to the addition of debt when forming the capital structure used by firms in the areas of trade, services, telecommunications, mining, construction and transformation that are traded on the Mexican Stock Market are: interest rate, inflation, exchange rate and income tax, as well as company size, sales growth, profit and risk.

Methodology

The econometric model of panel data will be used to process information, which includes a sample of factors for a determined period of time, so it combines temporary dimension and cross-sectional data. The model is also known as longitudinal joint, grouped data, combination of data in time series and transversal, micro panel data, event history analysis (Gujarati, 2003).

The panel data technique allows developing and testing complex models, according to Carrascal (2004), applies on the following areas: a) forecast sales, b) studies and forecasting costs, c) Financial analysis, d) Macroeconomic prediction e) Simulation, f) Analysis and evaluation of any statistical data. It also allows to observe the causal inferences of independent factors on the dependent factors, such inferences of causality would be very difficult to understand if isolated it was only applied the technique of "cross-sectional data" or the technique of time series data".

The panel data analysis (or longitudinal) joint simultaneously the cross-sectional study with the time series study which captures the heterogeneity of economic agents and incorporates the dynamic analysis. (Rivera, 2007), (Mayorga & Muñoz 2000).

The key feature of panel data, which distinguishes them from the combinations of cross section, is the fact of having and following the same entities or companies over a sustained period of time (Wooldridge, 2001). In the comments organization, the data for the eight years of each company are located contiguously, the first year before the second. For almost all practical purposes, this is the usual sort of panel data sets. The availability of information is presented, therefore, in two dimensions, generating multiple punctual observations for each economic unit (Mur & Angulo, 2006).

In economics is frequent that data sets combine time series with cross-sectional units or cross-sectional (firms, countries, states, etc.), so that an application of techniques for separate study leaves unanswered questions. The panel data analysis studies the group putting together the cross-sectional data technique with time series. (Rivera, 2007), (Mayorga & Muñoz 2000).

A panel data set (or longitudinal) states simultaneously from cross-sectional data and time series. This is when you have comments on certain characteristics of a set of agents (individuals, countries, companies, etc..) over a continuous period of time. The available information is presented in two dimensions, generating multiple punctual observations for each economic unit (Mur & Angulo, 2006).

The model recognizes two effects, firstly the individual effects which refer to those who affect unequally each of the agents contained in the sample study and second to the temporary effects which affect both all individual units of study that do not vary with time. This allows studying changes in the benefits of a single company over a period of time as well as a variation on the benefits of several businesses together (Pindyck, 2001).

Thanks to this method the effects that are not observable in data purely cross-sectional or time series can be detected and measured, thus they enrich the empirical analysis in a way that would not be possible if only the other methods were used in an isolated way. (Rivera, 2007), (Gujarati, 2003).

General Specification of the Panel Data Model.

The general specification of a linear analysis of panel data on a regression model according to Pindyck and Rubinfeld (2001) is as follows:

$$Y_{it} = X_{it}\beta + \varepsilon_{it} \quad (1)$$

Where the subscript i takes the values $i = 1, 2, \dots, N$ and indicates the cross-sectional unit, $t = 1, 2, \dots, T$ indicates the different periods of time, Y_{it} are the dependent variables or explained (*back*), X_{it} are independent or explanatory variables (*regressors*), β is the vector of parameters to estimate and ε_{it} is the error term or random disturbance. These are the components of classical linear regression model.

If for each unit of cross section there is the same number of temporal observations, that is, if $T_{it} = T$ for each i , we say that the panel data is balanced or unbalanced. Otherwise, the panel is not balanced or unbalanced.

The estimate of β in this model by Ordinary Least Squares (OLS) is consistent and efficient. However, there are generalizations of this model, more common in econometrics, for which the OLS estimates are inconsistent, (as shown below). It is customary for the study of different available estimates assume that the random error is decomposed into two terms, $\varepsilon_{it} = \alpha_{it} + U_{it}$, where α_{it} is the specific individual effect for each unit of cross section and is considered constant over time.

Thus, the general specification of a regression model with panel data to estimate is as follows:

$$Y_{it} = \alpha_{it} + X_{it} + \beta + U_{it} \quad (2)$$

With $i = 1, \dots, N$; $t = 1, \dots, T$.

Where i refers to individual or unit of study (cross section), t to the time dimension, α_{it} its vector of intercepts of n parameters, β is a vector of K parameters and X_{it} is the i -th observation at time t for K explanatory variables. The total sample of observations in the model is given by $N \times T$.

The Specification of Panel Data in Error Terms.

Panel data models can also be interpreted through its error components. The error term U_{it} included on the equation (1), can be broken down as follows:

$$U_{it} = U_i + \delta_t + U_{it} \quad (3)$$

U_i represents the unobservable effects that differ between the units of study but not in time. They are generally associated with entrepreneurship firm (Burdisso, 1977).

δ_t is identified with non-quantifiable effects that vary over time but not among the units of study.

U_{it} refers to the purely random error term.

According to Burdisso, (1997), most applications which include panel data use the error component model known as "one way " in which $t = 0$. Different variants of the "one way" model ($t = 0$) from error components arising from different assumptions made about the term i , so three possible cases can be presented: using a simple model with fixed or random effects.

Alternative Models for Combining Time Series Data and Cross-Sectional.

There are several ways of specialization panel data from the general model. Different variants for the "one way" model ($t = 0$) from error components arising from different assumptions made about the term it . Various possibilities may arise, (Mayorga & Muñoz, 2000):

Regular Term

The simplest case is the one that considers the $i = 0$, so, that there is unobserved heterogeneity among individuals or firms. Given the above, it meets all the assumptions of general linear model, whereby the method of classical least squares estimation produces the best linear unbiased estimator and has the advantage of providing more degrees of freedom.

$$Y_{it} = \alpha_{it} + \sum_{k=1}^k \beta_{kit} + U_{it} \quad (4)$$

Where all coefficients are constant, $\beta_{kit} = \beta_k$ and e_{it} is heteroskedasticity and autocorrelated. However, the presence of random effects invariant on α_i time implies the appearance of persistent unobserved heterogeneity and failure of the assumption of homoscedasticity (constant variance disturbances) and no autocorrelation (variance 0 of the present comments from the same cross unit). As estimated by OLS will not lead to best linear unbiased estimator. Then, there are different frameworks for dealing with these models presented below.

In panel data analysis there are two models: fixed effects and random effects. (Gujarati, 2003), (Mayorga, 2000), (Wooldridge, 2000).

Fixed effects or intra group model (within).

Second possibility is to assume a fixed effect to i and different for each firm and individual effects are independent from each other. Each explanatory variable has a single coefficient (has the same impact on the dependent variable, but each individual or company has a different constant). In this case, the unobserved heterogeneity enters the model constant.

This model considers that the explanatory variables affect both the cross-sectional units and that they differ in characteristics of each other, measured by the intercept. That is why the N intercepts are associated with dummy variables with specific coefficients for each unit, which must be estimated. For the i -th unit of cross section, the equation is:

$$Y_i = i\alpha_i + \beta X_i + U_i \quad (5)$$

Where the subscript i represents a column vector of ones where α_i is an unknown parameter to be estimated. Y and X are the T observations of the i -th unit and U_i the vector $T \times 1$ of associated errors. This model presents a significant loss of freedom degrees.

In the fixed effects model despite the fact that the intersection can vary for each individual, each intersection itself does not vary with time, is invariant over time. (Gujarati, 2003).

Random Effects Model: Generalized Least Squares.

The third alternative is to treat i as an unobserved random variable that varies between individuals but not in time. Unlike the fixed effects model, this model assumes that individual effects are not independent of each other, but instead, they are distributed randomly around a given value. A common practice in regression analysis is to assume that the large number of factors that affect the value of the dependent variables but have not been explicitly included as independent variables of the model can be properly summarized in the random disturbance (Mayorga and Munoz, 2000.) Thus, this model considers that both, the impact of explanatory variables as the characteristics of each bank are different. The model is algebraically expressed as follows:

$$Y_{it} = (\alpha + U_i) + \beta' X_{it} + \varepsilon_{it} \quad (6)$$

Where "i" comes to represent the random disturbance that would distinguish the effect of each individual in the panel. Is the random error which characterizes the i -th observation and is steady over time (Greene, 1999). For estimating purposes stochastic components are included, and the following relationship obtained:

$$Y_{it} = \alpha + \beta' X_{it} + U_{it} \quad (7)$$

Where $U_{it} = \delta_t + U_i + \varepsilon_{it}$ becomes the new term of disturbance, U is not homoskedastic, where $\delta_t, U_i, \varepsilon_{it}$ correspond to the error associated with the time series (t), to the disruption of cross section (U_i) and the combined effect of both (ε_{it}).

In this case, the Ordinary Least Squares method (OLS) may not be an option because no assumptions are known that allow the estimator be consistent. Therefore it is preferable to use the Generalized Least Squares (GLS) whose estimates are higher than OLS when they do not meet the traditional assumptions and are similar on the other hand. An estimate by GLS random effects is a regression of Y_{it} partial deviations over the same partial deviations of X_{it} .

Advantages and Disadvantages of Panel Data Technique

The panel data technique has a number of advantages and disadvantages compared with time series and cross section models. The most relevant according to Baltagi (1995) are the following:

Advantages:

1. The technique allows economic researchers, having a greater amount of observations increasing the freedom degree and reducing the collinearity among the explanatory variables and, ultimately, improves the efficiency of econometric estimates.
2. The technique allows capturing unobservable heterogeneity either between individual units of study as well as time units. Based on the foregoing, the technique allows implementing a number of hypothesis trials to confirm or reject such heterogeneity and how to capture it.
3. Panel data involve and incorporate the fact that individuals, companies, banks or countries are heterogeneous on the analysis. The time series and cross section analysis shall not try to control this heterogeneity run the risk of obtaining biased results.
4. The panel data allow a better study the adjustment processes dynamics. This is mainly true in studies focused on the permanence degree and permanence of certain levels with economic status (unemployment, poverty, wealth).
5. Allows developing and testing relatively complex behavior models compared with time series and cross-sectional analysis. Clear examples of this type of models are those focused on trying to measure technical efficiency on the individual economic units side (firms, countries, etc).

Disadvantages:

Overall, the disadvantages associated to the panel data technique relates to collection and evaluation of statistical information processes related to individual units of study, when the data is obtained through surveys, interviews or using some other means to obtain the data. Examples of such constraints are: coverage of the target population, response rates, confusing questions, deliberate distortion of responses and the high economic costs etc.

E-VIEWS (Econometric Views)

The software used on processing the gathered information to apply the panel data technique, was the econometrics package E-VIEWS (viewer econometric) version 4.1. on its Windows version, originally designed for TSP (*Times Series Processor*). The program can be used for the time series study, timeless series and panel data. (Carrascal, Gonzalez and Rodriguez, 2004).

Software E-Views 4.1 provides several specialized tools that help you work with grouped data and help to operate in any of the temporal dimensions series or cross section, and implement estimating methods that show a joint structure of the data.

Within the statistical estimation there are several factors that help us to interpret the results as the coefficients associated with each of the explanatory variables, its standard or typical estimated deviation, the

statistical error of individual significance and likelihood probability on itself. (Carrascal, Gonzalez and Rodriguez, 2004).

In turn, each estimated equation shows in the bottom part a block of statistics which allows us to partially evaluate executed regression: R-squared, Adjusted R-squared, SD dependent var, S.E. of regression Sum squared resid, Log likelihood, F-statistic, Durbin-Watson stat, Prob (F-statistic).

Source and Data Gathering

Data from company specific variables were obtained from financial statements published in annual financial statements of the Mexican Stock Market, being this a very reliable source, taking on consideration that according to specific laws, companies which are listed on the Stock Market, are required to generate reports at the end of each quarter (Schneider, 2001). The data of macroeconomic variables were obtained from databases and publications produced by the Mexican Bank.

The study sample was not random because there were considered all the companies that consistently chosen by sector were listed in the period 2000-2007. Based on the Stratification published in the Federation Official Journal of June 2009 all businesses are classified as large companies.

On the application of the econometric model the long-term debt was considered as an independent variable (contracted debt). The independent variables are represented by total assets (firm size) risk or capital (equity + minority) Net sales (growth), profit (operating income), income tax (tax rate) interest rate (cost of corporate financing) exchange parity (annual average of FIX exchange rate), inflation (national index of consumer prices).

Each of the variables were individually reviewed, so we could measure whether each variable is or is not individually significant in explaining the behavior of the endogenous variable on the period frame and together to determine changes in the correlations when considering other factors.

Model Specification

It was used the fixed effects model. This model takes into account the unique characteristics of each unit (company) of the cross section, causing the intercept vary for each unit, however, assumes that the angular coefficients are consistent between the units. The estimation was performed using the method of least squares (GLS) because it provides the most robust results for the characteristics of our study sample, at the same time the White contrast was used to identify heteroscedasticity and this was corrected by cross section weighting.

The dependent variable is represented by the long-term liabilities presented by each of the companies in the sample, also, within the regressors and as the independent variables, are the integration of each of the internal factors of the firm that could affect the debt integration in capital structure, which are specified within a common factor, so, EViews will include a single coefficient for each variable; to correct the heteroskedasticity problem the calculation of variances and standard errors consistent to White heteroskedasticity will be included; to avoid the multicollinearity problem, initially each of the variables will be analyzed on a bivariate way and jointly afterwards, adjusted by the exclusion of factors technique; to verify a possible autocorrelation, we will use the statistic from Durbin-Watson.

The model that we will follow is the fixed effect, establishing a ratio of interception by differential intersection dichotomous variables, with the journey across weighting option, using the following equation:

$$Y_{it} = \alpha_1 + \alpha_2 D_{2i} + \alpha_3 D_{3i} + \dots + \alpha_n D_{ni} + \beta_{1i} + \beta_2 X_{2it} + \beta_3 X_{3it} + \dots + \beta_n X_{nit} + \mu_{it}$$

With $i = 1, \dots, N$; $t = 1, \dots, T$.

Where:

i = refers to the individual or unit of study (cross section)

t = time dimension

α = vector of intercepts of n parameters

β = is a vector of K parameters

X_{it} = is the i-th observation at time t for the K explanatory variables

The total sample of observations in the model would be given by: $N \times T$. (Mayorga and Muñoz, 2000) and (Pindyck and Rubinfeld, 2001).

Analysis and Interpretation of Results

The obtained results after applying the statistical tests by using the panel data technique, show that the main factors of national and company's concern relate to the addition of debt to form the capital structure used by business enterprises from the service sector, trade, services, telecommunications, mining, construction and transformation in Mexico, are not the same nor they do not have the same mathematical relation to each of the sectors. This can be seen in the summary tables shown in chart No.1 and No.2.

Null hypothesis was rejected where the various independent variables as determinants of capital structure, are not related to the incorporation of debt used by service sectors, trade, telecommunications, processing, construction and mining in Mexico. $H_0: B_j = 0$ where j corresponds to the independent variable at the significance level of 5%, because the evidence given by the E-views in all cases is less than (5%).

Conclusion

The research focused on a particular object of study which was to identify some key quantitative factors that relate to the addition of debt when forming capital structure, also, identifying the positive or negative mathematical relationships using the statistical technique of "data panel" between the dependent and independent variables, as well as the discrepancies between the factors of service enterprises, trade, telecommunications, processing, construction and mining in Mexico. However, the factors arising from the qualitative characteristics such as culture, power, country risk, and personal values are factors that can influence and change the results, which is why we suggest them to be included on a future research.

Abstract

The present is part of a series of theoretical reviews that will deal with the question of financial efficiency in the United States, Spanish and Mexican market portfolios through time, in order to determine if there's external validity in Sharpe's (1964) and Lintner's (1965) Market equilibrium assumptions or if these can be used as mere neutral views as Black and Litterman (1992) propose for active portfolio management.

Three discrete event simulation using in the Markowitz-Tobin-Sharpe-Lintner (Markowitz, 1987) framework were developed with monthly data of DJIA, IBEX35 and IPC stock members from January 2000 to December 2010. The results were statistically compared with the Sharpe Ratio and showed that, in the short term, the equilibrium assumption doesn't stands, suggesting that the best application of it is the starting neutral view in the Black-Litterman framework for active management. In the long term there's a possible equilibrium that needs further research.

Keywords: Optimization Techniques, Simulation Modeling, General Equilibrium Models.

JEL classification codes: C61, C63, C68

Introduction

From its proposal in 1952, Harry Markowitz's standard portfolio selection model has become one of the key stones in the Financial Economics architecture, especially in the portfolio valuation and the Asset Allocation process among practitioners. From that starting point, several improvements have been made to the original proposal, starting with James Tobin's (1958) "*Liquidity preference as Behavior toward risk theory*" also known as the "*Two fund separation theorem*" that is the starting point of the Markowitz-Tobin-Sharpe-Lintner (MTSL) portfolio model and the so called market equilibrium assumptions proposed separately by Sharpe (1964) and Lintner (1965) in order to approximate the aggregate "rational choice" among investors. This lately lead to the proposal of Sharpe's Capital Asset Pricing Model (CAPM), its nonstandard forms such as Black (1972) zero beta, Amihud and Mendelson (1986) liquidity, Merton (1992) continuous time and Heaton and Lucas (2000) with no tradable assets versions and finally the Arbitrage Pricing Theory (Ross, 1976) that changes the focus of the presence of market disequilibrium in order to the presence of arbitrage, leading to a more general, flexible but not clearly definedⁱ multifactor model used widely today among asset and portfolio managers.

Even Though many of these equilibrium assumptions seem to be far from reality, many practitioners and theorist have use it in order to justify passive managementⁱⁱ and financial asset valuation. On the other side, some other had use them as a neutral views or starting points for quantitative methods of active portfolio management (Black & Litterman, 1992, pp. 29-33). The first approaches that tried to solve the portfolio optimization problem using market equilibrium assumptionsⁱⁱⁱ were made by Treynor and Black (1973) and by Elton, Gruber, and Padberg (1976). The first case is, perhaps, the first approach that solved the quantitative portfolio optimization and active management problem by defining the optimal risky portfolio (in the MTSL framework) as a combination of a

market portfolio (the conformation of a stock index made with a previously determined statistical criteria) and an optimal, efficient but not well diversified^{iv} one calculated using the information ratio. The second approach is a straightforward model that attains the optimal (but perhaps not well diversified in terms of cardinality) portfolio by ranking the Treynor ratio (Treynor, 1965) in the investment universe and determining the optimal investment level with a reference quantity known as the C-cutoff rate (Elton, Gruber, & Padberg, 1976, pág. 1348). After these approaches the most recent development^v is due to Black and Litterman (1992) and Xu & Liu (2011) who propose (the former) the use of market equilibrium assumptions not as a part of the theoretical framework for asset allocation and portfolio management but as a neutral view or starting point for portfolio optimization, using a Bayesian transformation of the inputs in the analysis to achieve the optimal risky asset. The latter propose a portfolio model that contemplates the resolution of a discrete quadratic programming problem using the so called “paring constraints”, related to the minimum investment level among assets and number of trades and assets allowed.

The use of market betas as a measure of asset risk and the development of CAPM is notoriously criticized at the beginning by Black, Jensen and Scholes (1972) due to the lack of statistical significance (t test) of the beta coefficients in the S&P500 index. As an answer to this finding and also as one of the most notorious critiques to CAPM, Roll (1977) observes that this situation comes around due to the fact that the market portfolio is not efficient. This means that it lays in a point below the efficient frontier and outside the efficient set. Because many of the assumptions proposed by Sharpe and Lintner are not achievable in real life capital markets and that the market portfolio is not as efficient^{vi} as it should be compared with the optimal one attained in the Markowitz-Tobin-Sharpe-Lintner (MTSL) framework; and also because this equilibrium assumptions could be used as a neutral view or starting point in the active management process, the main motivation of the present document emerges: There have been previous studies in the US, Spanish and Mexican Stock Markets but these make a static comparison of the efficient frontier against the market portfolio in fixed periods of time.

What had happened for the American market of the 30 blue-chips of the Dow Jones Stock Index, the 35 in the IBEX35 and the Mexican IPC from January 2000 to December 2010 in a monthly period analysis evaluation of the MTSL model?, Have the Dow Jones, the IBEX 35 and the IPC been, as market portfolios, laid in the efficient set? If the answer is no, What would be the explanation of these inefficiencies? and Is it possible that this behavior of financial efficiency and convergence between the market portfolio and an MTSL optimal one can be observed in the long term as part of the Economic Theory would expect? The core subject of the present work will be the first two questions leaving the third one to a proper and more exhaustive review related to Economic Theory, signaling just a few features noted in the empirical results.

The first studies of this kind for the Dow Jones Index were the ones initially made by Black, Jensen and Scholes (1972), latter Frankfurter (1976) studies the effect that has the design of the market portfolio (rules and composition) in the CAPM related portfolio optimization models. He concluded that some better references should be performed in order to make CAPM theoretically and practically correct and that there is no significant impact of the benchmark selection in the linear relation among betas and expected returns in the aforementioned model. Following him, Roll (1977) complements and gives an explanation (as mentioned in latter paragraphs) to Black, Jensen and Scholes findings. Elton and Gruber (1983) repeated Roll's tests in some nonstandard CAPM models such as the one for non marketable assets of Mayers (1972), The International CAPM of Solnick (1974), Friend, Landskroner and Losq (1976) or the inflation and international versions of Grauer, Litzenburger and Stehle (1976) or the one of Chen and Bones (1975). Lately, Kandel and Stambaugh (1989), (1995) propose, following Roll findings, a ratio of relative efficiency between de market portfolio proxy (market index) and the theoretically ones in the efficient set that shares the same risk and/or the same return.

In the Spanish market there are some other empirical studies related to the IBEX35 as the market portfolio. Among them, the works of Ferruz and Sarto (1997), Acosta and Gonzalez (1999) and Jara and Martinez (2000) are focused in the convenience of the use of the IBEX35 as the market portfolio instead de Indice General de la Bolsa de Madrid (IGBM). This result was later confirmed by Lucas who observed that the use of the IBEX35 as proxy of the market portfolio is due to benchmarking for mutual fund performance among practitioners. Gomez-Sala and Yzaguirre (2003) analyze the effect that the changes in the IBEX35 membership have in stock prices and Miralles and Miralles (2005) study the effect of eight European stock indexes in the optimal portfolio calculation from 1995-

2002 also Martínez, De la torre and Bilbao (2010) made a first dynamical and intertemporal approach like the present one for the Spanish stock market^{vii}.

For the Mexican stock market little research has been done related to the geometrical and efficiency relationship between the Índice de Precios y Cotizaciones index (IPC: the market portfolio) and its counterparties in the efficient set. As one of the most notorious developments, the work of Lopez Herrera (2000) can be quoted where similar conclusions than Frankfurter are attained for the IPC and Índice Mexico (INMEX), noting the impact of their stock membership rules in the observed levels of Beta in the short term. For the multifactor CAPM (the conditional model) Del Castillo (2006) concludes about the convenience of the model (and the assumption of market equilibrium) in Mexico if the model is running with non parametric econometrics (kernel regression) using the IPC index, the industrial activity index, the M4 monetary aggregate, the USDMXN percentage variation, the percentage variation of the Dow Jones Index and the spread between the CETES (riskless asset in Mexico) with the Mexican commercial paper as state variables. Finally, and consistently with Del Castillo conclusions, Sansores (2008) remarks that the classical CAPM cannot be applied in emerging economies financial markets due to the limitations in the assumptions for the model, leading him to conclude that it would be better to use a multifactor CAPM such as the one proposed by Fama, MacBeth and Schwert (1977).

From all the aforementioned theoretical reviews a common factor is the observance of the lack of equilibrium in markets due to systemic aspects such as the influence of inflation, tax or other rational or irrational elements and also to the natural financial inefficiency of the market portfolio proxy due to its statistical or market volume calculation parameters, leading to the acceptance of the market equilibrium assumptions only as a neutral or starting view in quantitative models of active portfolio management. Therefore it is of interest to know What had happened from January 2000 to December in the efficiency of the main 30 to 35 blue-chip stocks in the US, Spanish and Mexican market? This first question is part of a serial of future questions on this subject and its relation with passive but, specially, active portfolio management.

The Markowitz-Tobin-Sharpe-Lintner Framework and The Statistical Test

The general Markowitz-Tobin-Sharpe-Lintner framework uses a portfolio optimization algorithm that starts with the derivation of the efficient set through a quadratic programming problem using the specific investment weight in the i^{th} asset $w_i, w_j \in W$ and its expected return μ_i and covariances $\sigma_{i,j}$ for the calculation of portfolio return R_p and variance σ_p^2 :

$$\text{Maximize } \sigma_p^2 = \sum_{i=1}^N \sum_{\substack{j=1 \\ j \neq i}}^N (w_i w_j \sigma_{i,j})$$

Subject to:

$$w_i, w_j \geq 0$$

$$\sum_{i=1}^N w_i = 1$$

$$\sum_{i=1}^N w_i \cdot \mu_i = R_p$$

(1)

With the efficient set, a curve known as the “Capital Allocation Line” that comes from Risk free asset (r_f) to each point ($R_{p,i}$ and $\sigma_{p,i}$) in the efficient frontier (the geometrical representation of the efficient set) is used in order to determine the optimal risky asset W following another optimization problem shown in figure 1:

$$\text{maximize } \theta = \frac{R_{p,i} - r_f}{\sigma_p}$$

Subject to:

$$\sum_{i=1}^N x_i = 1$$

$$x_i \geq 0$$

(2)

FIG. 1 THE MARKOWITZ-TOBIN-SHARPE-LINTNER FRAMEWORK

According to Sharpe (1964) and Linter's (1965, p. 15) equilibrium assumptions, if all the investor are rational, use the present framework in order to value the optimal portfolio and have homogeneous expectations (Samuelson, 1973) the portfolio W would become the optimal one for all agents in the market, defining this one as the "Market Portfolio" M . The hypothetical market portfolio should have all the traded assets in the market (therefore the importance of assuming that all assets are liquid ones) and its conformation is the same one for all $w_i, w_j \in W = M$ with W derived in MTSL framework. That's the key part of this first work: If the optimal portfolio W and Market portfolio M were the same, its Capital Allocation Line slope θ would be the same for both cases through time, assuming that the expectations are homogeneous but dynamic according to economical and social factors reflected in stock (market) prices^{viii}.

In portfolio performance measuring the slope θ of the Capital Allocation Line is known as the Sharpe Ratio (Sharpe W., 1966) or S that lead to the next statement:

$$\forall w_i, w_j \in W = M \Leftrightarrow S_w = S_M$$

(3)

In order to probe (3) a discrete event simulation was programmed in MATLAB and performed using monthly historical data of stock prices and index memberships from January 2000 to December 2010 for the Dow Jones and IPC indexes and from February 2001 for the IBEX35. All data comes from Bloomberg (2010) databases. The time series of returns in the i^{th} assets were calculated directly from asset prices using percentage return formula. The Sharpe Ratio was calculated using the objective function in (2) for both W attained with MTSL framework and M calculated by Bloomberg. The historical values of the efficient frontier of W and M generated during simulation where calculated with 30 month return data^{ix} plotted and visually compared with the Capital Allocation Line and the geometrical location of the market portfolio. In order to determine S_w and S_M values, the US Treasury Bills with three months of maturity, the Spanish Treasury Bills with the same maturity and the Mexican CETES with 28 maturity where used as the risk free asset rate r_f . These values (S_w and S_M) where statistically compared with a one-

way Analysis of Variance (ANOVA 1) in order to confirm the presence of a difference in both time series and to determine the case with the highest financial efficiency level.

The Observed Behavior In The Markets Of Interest

In the case of the Dow Jones it is noted that the market portfolio (light triangle in the 3D plot of figure 2) is considerably below the historical set of efficient frontiers and the optimal risky portfolio (W and dark circle) attained with the MTSL model is notoriously efficient, giving the first suggestion of the lack of efficiency in M and confirming that the equilibrium assumption as long with the one of heterogeneous expectation and rational choice are questioned empirically. This is confirmed with the Sharpe Ratio historical plot (S_W and S_M) in figure 3 whose ANOVA 1 and Box Plot tests are shown in the table and chart of figure 4, confirming the convenience of the interpretation of market equilibrium not as a (theoretical) necessary and sufficient condition for portfolio management but as only a necessary assumption in order to have a reference, neutral view or starting point. Also the behavior of the market portfolio (DJIA) against W suggest the preference of active portfolio management from the passive one due to a much better risk-return trade-off.

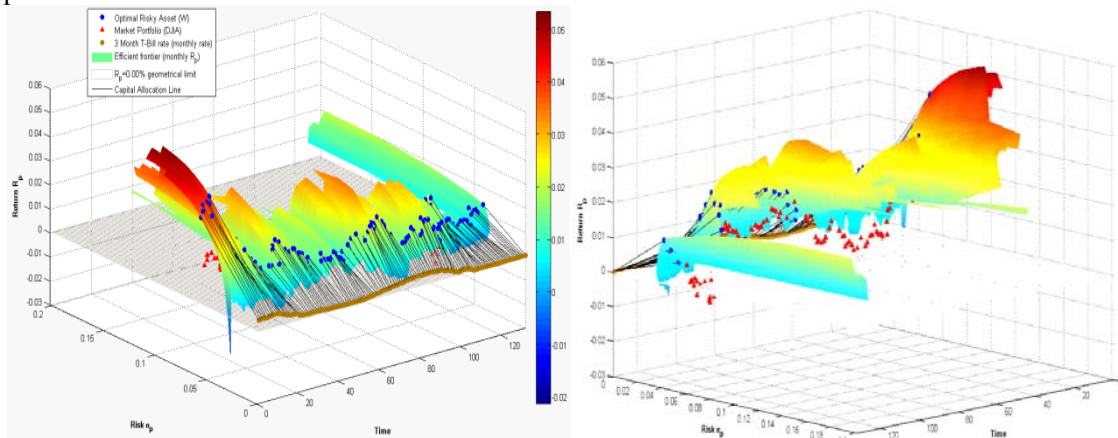

FIG. 2 HISTORICAL EFFICIENT FRONTIERS, OPTIMAL RISKY PORTFOLIO (W) AND MARKET PORTFOLIO FOR THE DOW JONES BLUE-CHIP STOCK MARKET

FIG. 3 HISTORICAL OBSERVED SHARPE RATIOS IN MARKET PORTFOLIO AND OPTIMAL RISKY ONE (US MARKET)

FIG. 4 ANOVA 1 TEST AND BOX PLOT OF THE EFFICIENCY IN THE MARKET PORTFOLIO OF THE BLUE-CHIP STOCKS OF THE DOW JONES INDUSTRIAL AVERAGE.

In the case of the IBEX35 index, the same results were attained, noting that, as in the Dow Jones case, there have been some market portfolios with expected return below to zero, as is the case of year 2010. This is due to the economical situation and market volatility as a result of the speculative attack that the Spanish and Euro economy had in its currency (the euro) and the relative uncertainty about the fiscal and economic growth health in such country. Also, at the beginning of the simulation (year 2002) and in 2005 there have been some notorious jumps in the efficient frontier and also in the Capital Allocation Line slope (Sharpe ratio). Some of the most plausible explanations of this behavior are 1) the behavior of the membership of the delisting process of stocks such as Amadeus Global IT and, 2) the properties of portfolio optimization that leads to extreme investment levels when short selling is not allowed (Black & Litterman, 1992, p. 34) showing investment levels of only three to thirteen assets (in average) each month in the optimal portfolio and 3) the economical cycles of Spanish economy: The 2001-2004 period was conducted by the consequences of the 9-11 terrorist attacks in worldwide markets, the latter corporate scandals such as Enron or world.com that affect worldwide stock markets certainty levels; From 2004 to 2007 there has been a strong economic growth in the country lead by the real estate boom due to global liquidity levels and from 2007 to 2010 there has been a notorious level of volatility due to the restricted levels of liquidity, economic growth and employment in worldwide economies, specially the Spanish one.

For this reason an ANOVA test was performed in three separate stages (for statistical consistency reasons): 2001-2004, 2004-2007 and 2007-2010, leading to the same results of a lack of efficiency in the market portfolio, compared with the optimal one in the MTSL context, as shown in figure 7.

This also suggest the convenience of active management instead of a passive one and the convenience of the equilibrium assumptions only as reference, neutral or starting portfolios for a much complete and specific active portfolio management.

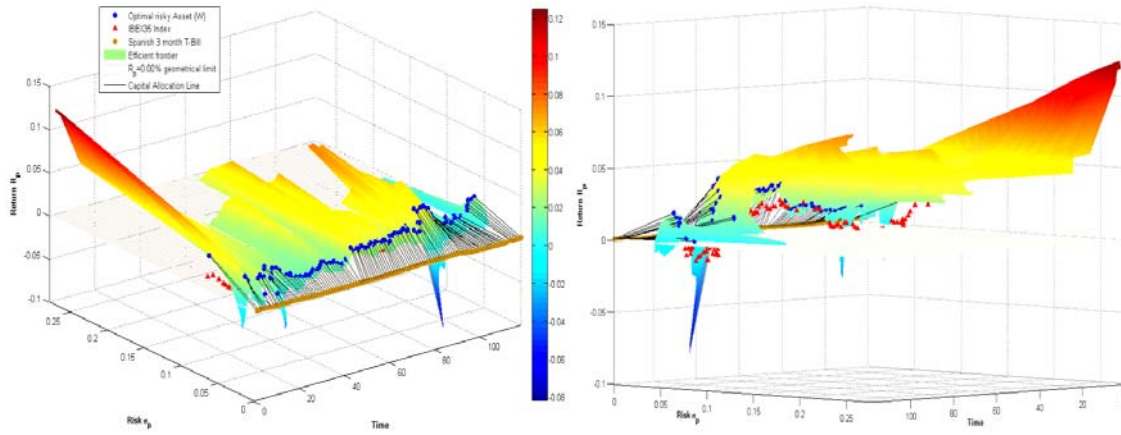

FIG. 5 HISTORICAL EFFICIENT FRONTIERS, OPTIMAL RISKY PORTFOLIO (W) AND MARKET PORTFOLIO FOR THE IBEX35 BLUE-CHIP STOCK MARKET

FIG. 6 HISTORICAL OBSERVED SHARPE RATIOS IN MARKET PORTFOLIO AND OPTIMAL RISKY ONE (SPANISH MARKET)

FIG. 7 ANOVA 1 TEST AND BOX PLOT FOR THE EFFICIENCY IN THE MARKET PORTFOLIO IN THREE SEPARATE PERIODS (2001-2004, 2004-2007 AND 2007-2010) FOR THE IBEX35 BLUE-CHIP STOCKS MARKET IN SPAIN

In the Mexican Stock Market a notorious irregular periods were observed in the investment opportunities set and in the efficient frontier due to several changes in the membership of stock indexes^x. Also the extreme behavior of the solutions of the optimization problem in the MTSL framework was observable were the average number of assets in the optimal risky portfolio was two to nineteen in average. Also, due to the dependency of this stock market to international investors expectations and to the same economical cycles and situations than the previous market in the worldwide economy (except for the Real Estate crisis in Spain), the ANOVA 1 and box plot test were made separately for the 2001-2004, 2004-2007 and 2007-2010 periods, leading to consistent results with the two previous markets, suggesting the lack of efficiency in the market portfolio and the convenience of active asset management instead of a passive one (index or market portfolio tracking), leaving equilibrium assumptions not for realistic acceptance but as neutral or starting view in active portfolio management.

FIG. 9 ANOVA 1 TEST AND BOX PLOT FOR THE EFFICIENCY IN THE MARKET PORTFOLIO IN THREE SEPARATE PERIODS (2001-2004, 2004-2007 AND 2007-2010) FOR THE INDICE DE PRECIOS Y COTIZACIONES BLUE-CHIP STOCKS MARKET IN MEXICO.

FIG. 10 HISTORICAL OBSERVED SHARPE RATIOS IN MARKET PORTFOLIO AND OPTIMAL RISKY ONE (MEXICAN MARKET)

Concluding Remarks

The empirical test performed through monthly discrete event simulation from January 2000 to December 2010 suggest that the equilibrium assumptions do not hold and that the homogeneous expectations does not apply for the modeling of the aggregate decision making process among investors in the US, Spanish and Mexican stock markets. This also confirms Roll’s findings that the possible restriction of CAPM or other multifactor models is due to the inefficiency of the market portfolio proxy compared to the elements of an efficient set conformed with portfolios with the same investment opportunity set.

With these results can be partially concluded that the proposed assumptions of equilibrium and the use of a proxy of the market portfolio for asset valuation and portfolio optimization are only valid not as necessary conditions but as starting point or neutral views for portfolio management. This of course will need further research in light of the results attained in the applied aspects of this practice.

Due to this and for the observable efficiency (Sharpe ratios) of the risky portfolios calculated in the Markowitz-Tobin-Sharpe-Lintner framework in comparison with the market portfolio proxies, an Active Portfolio Management is preferable than a Passive one even if the aforementioned equilibrium assumptions are taken or not as starting point or neutral view of the quantitative model used for this purpose.

Also, as figures three, six and ten suggest, there’s a possible equilibrium (convergence between the optimal risky portfolio and the market one) conditions in the long term that must be studied with a more formal economic theory approach to achieve better conclusions. Also this observation must be supported with more data and stronger simulations, relaxing some of the main MTSL framework assumptions.

End Notes

ⁱ Due to its flexibility and the heterogeneity in investors expectancies and factor selection.

ⁱⁱ Also assuming that there's a form of market informational efficiency (Fama, 1965).

ⁱⁱⁱ This mean by using market risk measured trough asset return's Beta (β) with another or other market or economic factors.

^{iv} Defining "diversification" as a combination of the appropriate (preferently high) number of stocks and financial efficiency.

^v It is important to note that some other portfolio model proposals were made such as Roy (1952) or Konno and Yamasaki (1991) but Elton, Gruber, Brown & Goetzman show that these are asymptotically equivalent to the Markowitz-Tobin-Sharpe-Lintner framework assuming that the asset returns are normally distributed.

^{vi} Financial efficiency in the sense of mean-variance efficiency as proposed in the Markowitz-Tobin-Sharpe-Linter framework.

^{vii} Results that are complemented in the present document with actual data and the comparison in other two markets.

^{viii} This lead to the concept of informational efficiency that is the core issue and not directly tested here but the data will lead to some remarks on this subject.

^{ix} In some cases such as the IPC this lead to some unstable graphical and statistical values due to the lack of historical data as a result of mergers or IPO's.

^x Due to mergers, acquisitions, IPO's of segregated stock of actual members and corporate events related, in cases such as February to June 2001, May to June, December2002 to January 2003 2002 and December 2008 to January 2009 the index had 36 members instead of 35. In the July to November 2002 period, had 37 members and in the March 2004 to January 2005 and June to July 2010 the index had only 33 members.

Comparative Analysis of Islamic Banks and Conventional Banks in the UAE

Abstract

This paper is an attempt to study, analyze and compare performance of Islamic Banks and Conventional Banks in the one of the important GCC Country like United Arab Emirates. Globalization had lead to the increased competition in the financial markets as these act as intermediaries for suppliers and investors. After the Economic recession of 2008 especially people are more cautious and taking precautions to invest into the financial markets. Many regulations are introduced by the government authorities and policies are revised for the safe and transparent methods which lead to the diversification of financial product and services. Islamic banking based on the principle of Shariah is compared with the existing traditional conventional banks in UAE. Data is taken from the annual reports, Income Statements and balance sheet of major Conventional banks of Abu Dhabi, Dubai, Sharjah and the same for the Islamic Banks. Ratio analysis show higher performance and profitability of the conventional banks during 2005 and 2006 and later 2008 and 2009 it was almost stable. The study finds that conventional banks are more profitable whereas Islamic banks are less risky and have high liquidity.

Key words: Islamic Banking, ratio analysis, comparative performance, conventional banking.

Introduction

Banks are one of the most important components of a thriving, developed economy and financial system of a nation. Functional banking system helps to create an effective and successful society. Banks act as an intermediary for the surplus and deficit sides in the society. The increasing competition in the national and international banking markets, the changes towards monetary unions, technological innovations, major changes in banking environment, growing needs of the customers and other challenges of banks to make timely preparations in order to enter into new competitive financial environment had made banks to keep up the pace through offering a wide range of products and services of which Islamic banking is the one of them. Though Islamic banking has a history of more than 3 decades, after the global economic crisis of 2008, there is a lot of importance given to this industry by the specialists in the financial system and academic researchers. There is great focus for the relationship between Islamic banking and financial stability and it was reported by many market research agencies that Islamic banking was more resilient during the crisis and acted as shock absorber. It was concluded by the industry specialists and academic researchers that lack of exposure to the type of assets associated with the conventional bank experienced crisis where as the asset-based and risk-sharing nature of Islamic finance—have shielded Islamic banking from the impact of the crisis. According to the IMF Islamic banking is one of the fastest growing segments in the financial industry tracking a 10-15% growth over past decade. Globally, Islamic banking assets are estimated to grow around 15% year to \$1 trillion by 2016. This high growth expectation is due to the increasing demand from Muslims, growing oil revenues in the middle east countries and attractiveness of Shariah based financial services to non Muslim investors also. There has been a huge demand for Shariah-compliant products not only in the Middle East and other Muslim countries, but also by investors globally, thus making it a global phenomenon. Besides its vast geographical expansion, Islamic banking is witnessing rapid expansion across the whole spectrum of financial activities including retail banking, insurance and capital market investments.

The objective of the study is to compare study and analyze the actual performance of Islamic banks and Conventional banks of the United Arab Emirates. The UAE market is relatively competitive, with a large number of banks serving a limited population. Dubai International Financial Center was established in 2004 with the objective of making UAE one of the major global onshore financial hubs. Apart from this lot of incentives were introduced, most importantly a much more liberal business environment than in the rest of the country, specially in terms of foreign ownership where all the foreign banks are allowed to operate. Both Conventional Banks and Islamic banks are traded in the Dubai Financial Market. From the previous empirical studies and research reports it is evident that the Islamic banks have a small market share in the UAE but the global crisis has lead to the demand of the Islamic banks and the opportunity is utilized by many conventional

banks offering Islamic banking products and services simultaneously along with their conventional products and services. Ex HSBC Amanah.

Review of Literature:

According to (Delis and Papanikolaou 2009) investigations determinants like bank size industry concentration and the investment environment have a positive impact on bank's efficiency. Study done on unbalanced pooled time series dataset of 23 greek banks by (Kosmidou 2008) during the period of financial integration, he used the ratio of return on average assets and for the determinants he classified them into internal and external. The external set included the annual change in GDP, inflation rate, the growth of money supply, the ration of stock market capitalization to total assets, the ration of total assets to GDP and concentration, The results indicated that ROAA was found to be associated with well capitalized banks and with lower cost to income ratios, The results indicated that impact of the growth of GDP and size was positive while inflation had a negative impact. (Medhat Tarawneh 2009) classified the commercial banks of Oman in cohesive categories on the basis of their financial characteristics revealed by the financial ratios. A total of five Omani commercial banks with more than 260 branches were financially analyzed, and simple regression was used to estimate the impact of asset management, operational efficiency, and bank size on the financial performance of these banks. And he found that the operational efficiency, and asset management, in addition to the bank size, strongly and positively influenced regression analysis showed financial performance of the banks. This was agreed with the correlation analysis among the variables of the study, which indicated the existence of positive relationships Local financial institutions, and foreign ones have greater opportunity in economic development in the Arab countries. The development and performance of domestic and foreign banks in Arab gulf countries was studied by (Mazhar M. Islam, 2003) concluded that local and foreign banks in these countries have performed well over the past several years. Moreover, he added that banks in these economies are well capitalized and the banking sector is well developed with intense competition among the banks. Research in the efficiency, customer service and financing performance among Australian financial institutions (Elizabeth Duncan, and Elliott, 2004) showed that all financial performance measures like interest margin, return on assets, and capital adequacy are positively correlated with customer service quality scores. Hypotheses was framed and was concluded that Islamic banks are more efficient than conventional banks in terms of resource use, cost effectiveness, profitability, asset quality capital adequacy and liquidity ratios than conventional banks (Iqbal 2008; Hassan and Bashir 2005). Commercial banks, however, have a more favorable operations ratio (Hassan and Bashir 2005). A cross-country study was done by (Al-Jarrah and Molyneux 2005) on efficiency and it was concluded that efficiency is higher in Islamic banks compared to conventional banks This contrasts with the results of another cross-country study which suggests that Islamic banks have lower efficiency than conventional banks (Abdul-Majid et al 2008a). Both technical and cost efficiency are found to be lower for Islamic banks compared to conventional banks in Malaysia, and the difference is significant (Mokhtar et al 2008). (Wum et al.2007) investigated the impact of factors such as: financial development measured by financial interrelation ratio (FIR), the level of monetary measured by GDP and the level of capitalization, size, age of the bank, business orientation measured by the ratio of non-interest income, and per capita GDP on the Chinese commercial banks.

The results indicated that the higher the levels of financial development, the better ROA performance for banks. The results also indicated a positive impact of per capita GDP on bank performance. However, a negative impact of size and business orientation on the ROA was found. (Ali 1996) compared the relative efficiency of Islamic banking with conventional banking in Bangladesh. He found that the Islamic banks are relatively more efficient than conventional banks. (Samad 1999) evaluated the relative efficiency position of the Islamic bank during 1992-1996, and compared it with the conventional banks in the country. His finding was that Bank Islam Malaysia enjoyed relatively higher managerial efficiency than the conventional banks (Unal et al.,2007) conducted a comparative performance analysis between the Turkish state-owned and private commercial banks during the period 1997-2006. They used net profit-loss, return on assets and return on equity as proxies to measure profitability. To measure operating efficiency they used net profit, net assets efficiencies relative to total employment and total number of branches. The findings suggested that state-owned banks are as efficient as private banks. (Chirwa 2003) investigates the relationship between market structure measured by concentration and profitability of commercial banks in Malawi using time series data between 1970 and 1994. It was found that there was a positive relationship between concentration and performance. (Naceur and Goaid 2001) examined the determinants of the Tunisian deposit during the period 1980-1995. The results indicated that the principal determinants of a bank's performance were by order of importance: labor productivity, bank's portfolio composition, capital productivity and bank capitalization. Banking sector in Saudi Arabia has been examined by (Ahmed and Khababa1999) three measures of profitability as dependent variables; ROE, ROA and percentage change in earnings per share. On the other hand, they used four independent variables. These were: business risk measured by dividing the total loans of the bank by its total deposits, market concentration, the market size measured by dividing the deposits of the bank by the total deposits of the commercial banks under

study and the size of the bank. The results indicated that the business risk and the bank size were the main determinants of the banks' performance. (Kim and Kim1997) conducted a comparative study on the structure-profit relationship of commercial banks in Korea and the U.S. To assess the profitability of the sample banks, they used ROA and ROE as two dependent variables and seven independent variables namely: shareholders' equity to total assets, liquid assets to assets, total loans to total deposits, fixed assets to total assets, total borrowed funds to total assets, reserves for loans to total assets and a reciprocal value of total assts They concluded that the banks in Korea in terms of efficiency and profitability are much behind the US banks. The findings also indicated that the capitalization rate, reserves for loan losses, and the size of the bank were important factors affecting the profitability of the banks in both countries. (Zimmerman 1996) examined factors influencing community bank's performance in California during the early 1990s and concluded that the regional conditions and loan portfolio excessive reliance on lending caused decrease in the overall profitability. Lack of geographic diversification was important factor in community bank's performance. According to (Yudistira 2003), empirical analysis on efficiency provides new evidences on the performance of 18 Islamic banks over the period of 1997-2000. Data for this time period was extracted from balance sheets and income statements of the Islamic banks and was found that there was a small inefficiency around 10% for 18 Islamic banks, which is considerable as compared to many conventional banks. It was also found that Country specific factors mainly determine the efficiency differences across the sample data.

Measure efficiency of Islamic banks in Bangladesh, (Sarker 1999) utilizes Banking efficiency model and claims that Islamic banks can stay alive even within a traditional banking architecture in which Profit-and-Loss Sharing (PLS) modes of financing are less dominated. Further concludes that Islamic financial products have different risk characteristics and consequently need different regulations. (Abdus Samad 2004) in his paper examines the comparative performance of Bahrain's interest-free Islamic banks and the interest-based conventional commercial banks during the post Gulf War period 1991-2001. Using nine financial ratios in measuring the performances with respect to (a) profitability, (b) liquidity risk, and (c) credit risk, and applying Student's t-test to these financial ratios, the paper concludes that there exists a significant difference in credit performance between the two sets of banks. However, the study finds no major difference in profitability and liquidity performances between Islamic banks and conventional banks. Research done by (Kader and Asarpota 2007) utilizes bank level data to evaluate the performance of the UAE Islamic banks. Balance sheets and income statements of 3 Islamic banks and 5 conventional banks in the time period 2000 to 2004 are used to compile data for the study. Financial ratios are applied to examine the performance of the Islamic banks in profitability, liquidity, risk and solvency, and efficiency. The results of the study showed that in comparison with UAE conventional banks, Islamic banks of UAE are relatively more profitable, less liquid, less risky, and more efficient. They conclude that there are two important implications associated with this finding: First, attributes of the Islamic profit-and-loss sharing banking paradigm are likely to be associated as a key reason for the rapid growth in Islamic banking in UAE. Second, UAE Islamic banks need to be supervised in a different way as the UAE Islamic banks in practice are different from UAE conventional banks.

Data and Methodology:

In order to study, compare and analyze the performance of conventional banks and Islamic banks in the United Arab Emirates ratio analysis method is utilized. The use of ratio measures is one of the important and common methods used in the performance analysis in the literature. It was utilized by (O Connor 1973) and (Libby 1975) in the early 1970s. Since then, it has been found in many and recently by Samad (1999). The use of ratio method has many advantages. The most important benefit is that it compensates bank disparities. As Banking firms are not equal with respect to sizes. The use of ratio removes the disparities in sizes and brings them at par. In order to examine whether there is a difference in performance between Islamic banks and conventional banks of United Arab Emirates, secondary data sources published by the banks such as balance sheets, annual reports and the and income statement have been taken. Three major Islamic Banks and three major conventional banks one each from Abu Dhabi, Dubai and Sharjah are taken for the Study and the ratios are calculated for all the three banks individually in both categories and an average of three Islamic banks is compared with the average of conventional banks in each year from 2005-2009. As the data for 2010 for all the banks taken up for study is not available the study is limited for the mentioned period only.

These performance rations are classified into three categories:

- a. Profitability Performance
- b. Liquidity Performance
- c. Risk Performance

Profitability Performance

The profitability ratios are used to assess the performance of the bank with all its expenses and costs during a particular period of time, these are stated to be the basic financial ratios in order to know how well bank is performing in terms of profit. Three ratios under this category taken are as follows

a. Return on Assets (ROA) = net profit/total assets. ROA is a good indicator of a bank's financial performance and managerial efficiency. It shows how competent the management is in allocating asset into net profit. The higher the ROA, the higher is the financial performance or profitability of the banks.

b. Return on Equity (ROE) = net profits/equity. It shows a rate return on base capital, i.e., equity capital. The higher the ROE, the more efficient is the performance.

c. Profit Expenses Ratio (PER) = Profit before tax / Operating expenses.

Higher PER means the bank is cost efficient and is making higher profits.

Liquidity Performance

Liquidity is assumed to be the life of a bank. It means how quickly a bank can convert its assets into cash at face value to meet the cash demands of the depositors and borrowers. The higher the amount of liquid asset for a bank, the greater is the liquidity of the bank. Among the various liquidity measures, this study uses the following ratios

a. Loans to Deposit Ratio (LDR) = Loans/ Total Deposits

Bank with low LDR is considered to have excessive liquidity, potentially lower profits and hence less risk as compared to the bank with high LDR. Higher LDR indicates the stress taken up by the bank by making excessive loans.

b. Loans to Asset Ratio (LAR) = Loans/total assets.

Similar to LDR the bank with low LAR is considered to be more liquid as compared to the bank with high LAR, However high LAR is an indication of potentially higher profitability and hence more risk.

Risk and Solvency Ratios

This category of ratios measure the risk and solvency of the firm, these ratios are also referred as debt of financial leverage ratios. The extent to which a firm relies on debt financing rather than equity financing. These financial ratios are used for measuring loan/credit risk performance of a bank. They are

a. Debt- Equity Ratio (DER)

DER = Total Debt/ Shareholder's Equity.

This ratio is utilized to measure the ability of the bank capital to absorb financial shocks. A bank with lower DER is considered to be better as compared to the bank with higher DER.

b. Debt to Total Assets Ratio (DTAR)

This ratio measures the amount of total debt firm uses to finance its total assets. It is an indicator of financial strength of the bank, It provides information on the solvency and ability of the firm to obtain additional finance for potentially attractive investment opportunities. Higher DTAR means bank has financed its assets through Debt as compared to the equity financing. Higher DTAR indicates that bank is more involved in more risky business.

DTAR = Total Debt / Total Assets

Results and Discussions

Ratios analysis acts a signal for the depositors and gives a clear picture of the performance of the banks A comparative analysis is done for two sets of the banks both Islamic banking and conventional banking. In the operation of Islamic banks principles of shariah where interest is forbidden are been implemented whereas the

conventional banks have the old traditional method of operations with the concept of interest .Different elements of the reports are taken and then plotted against each other to understand the trend.

I. Profitability Performance

Return on Assets (ROA)

TABLE 1: ROA

	ROA	
	Average IB	Average CB
2005	0.03	0.06
2006	0.02	0.03
2007	0.03	0.03
2008	0.02	0.02
2009	0.01	0.01

Figure 1

The results for year 2005, 2006 indicated high ROA for the conventional banks compared to Islamic banks which means higher performance and profitability, but from 2007 there was not much difference between the two banks they had almost the same profitability from 2008 onwards which shows that Islamic banks gained momentum during this period after recession. It is expected that results of 2010 will tell whether the Islamic banks have performed better than the conventional banks? Further it can be seen from 2005 to 2007 ROA was almost stable for the Islamic Banks.

2. Return of Equity (ROE)

TABLE 2: ROE

Year	Average IB	Average CB
2005	0.18	0.24
2006	0.16	0.17
2007	0.17	0.19
2008	0.13	0.12
2009	0.04	0.10

Figure 2

From the study of ROE for both Islamic banks and conventional banks it is found that in 2005 Conventional banks were performing better than Islamic banks but in 2006 to 2008 both were similar in 2009 the Islamic bank has relatively performed poorer.

3. Profit Expense Ratio (PER)

TABLE 3: PER

Year	Average IB	Average CB
2005	2.04	3.02
2006	0.78	1.02
2007	0.85	1.15
2008	0.77	0.66
2009	1.00	0.94

Figure 3

Measure of PER for 2005 in the conventional banks was high and gradually decreased in year 2006 until 2007 where both conventional and Islamic banks had a similar pattern whereas after 2008 the Islamic banks performance increased. It shows that Islamic banks are improving and performing slightly better than the conventional banks and had drawn the attention from the investors.

II. Liquidity Ratio:

4. Loan to Deposit Ratio (LDR)

TABLE 4: LDR

Year	AV I	AV C
2005	0.14	0.62
2006	0.17	0.67
2007	0.16	0.63
2008	0.06	0.70
2009	0.08	0.50

Figure 4

Results reveal that higher value is seen in the conventional banks from the year 2005-2009 which reveals that these banks have taken high risk by providing the excess loans. Whereas the Islamic banking figures are less and show that Islamic banks are risk averse.

5. Loan to Asset Ratio (LAR)

TABLE 5: LAR

Year	AV I	AV C
2005	0.17	0.93
2006	0.19	1.04
2007	0.22	1.05
2008	0.08	1.14
2009	0.15	5.16

Figure 5

Results of conventional banks for the year 2005 to 2008 were gradually increasing but after 2008 it had increased more than 4 times shows higher profitability and more risk and financial stress taken by the conventional banks. Low LAR of Islamic banks shows more liquid and less risky situation. The LAR slightly increased after 2008 which shows the popularity among the people towards Islamic banks and the loans taken from these banks. there is huge increase which shows that financial stress is taken by the conventional banks.

III. Risk and Solvency Ratios

6. Debt to Equity Ratio (DER)

TABLE 6: (DER)

	Av I	AV C
2005	7.24	4.04
2006	6.22	3.59
2007	5.97	5.80
2008	5.00	6.02
2009	4.50	5.56

Figure 6

The above calculations indicate in year 2005 DER of conventional bank was less compared to DER of Islamic banks and had been increasing more and there was slight growth in 2008 and decrease is observed in Islamic banks from 2008 to 2009 which reflects better performance compared to the conventional bank. Thus shows that after the economic meltdown. Islamic Banks have gained importance in the financial services industry.

7. Debt to Total Assets Ratio (DTAR)

TABLE 7 (DTAR)

2005	0.81	0.78
2006	0.62	0.58
2007	0.85	0.84
2008	0.85	0.84
2009	0.45	0.58

Figure 7

The ratio calculation reflected the same results as of DER, In the e year 2005 DTAR was high for the Islamic bank and was almost equal to the conventional banking with a marginal difference the period of 2006 was nearly equal for 2007 and 2008 it was same after 2008 the DTAR ratio is less showing that bank is involved in less risky business there after whereas the higher DTAR of the conventional banks shows that are involved in high risk business.

Conclusions:

After examining and comparing the ratios of the two types of banks it is concluded that the conventional banks are more profitable compared to the Islamic banks. In terms of liquidity Islamic banks are highly liquid, have lower profits and less risk whereas the High LDR of Conventional banks indicates the stress taken by these banks by making excessive loans.

Further Scope:

As the reports of 2010 for all sample banks taken for study are not available the paper is limited to the period of 2005-2009. The sample for the conventional banks and Islamic banks in the United Arab Emirates is taken from the banks of Abu Dhabi, Dubai and Sharjah which can be extended to other emirates also.

Abstract

While global financial deregulation has led to liberalization of financial services and thus to modernization of commercial banking, industrialized economies are facing a financial meltdown. The health of major global banking industry is under severe stress but, that in the context of India continues to be strong. Despite cost prohibitive efforts in the introduction of a range of new products and services, banks in India are striving to emerge from an era of development banking into consumer oriented supermarkets. This paper studies the Indian banking industry with regards to its readiness to move on to the next generation.

Introduction

Following global financial deregulation, developing economies have been engaged in rapidly increasing of the efficiency of various industries in their respective countries. Any attempt to revamp their financial services industry will lead to a major integration of services and the introduction of a range of new products. This will also require a complete overhaul of technology starting from automated teller machines, internet banking, point-of-sale transaction processing, credit card operations, efficient telecommunication service for data transmission, and assisting investors with a whole plethora of alternative investment vehicles. Modernization of the financial services industry will be fruitful only when it is accompanied by adequate risk management. Risk management in the banking industry has thus become a global phenomenon. This is an area where the Bank for International Settlements (BIS) is working with various central banks to ensure the presence of a uniform and harmonized approach.

Literature Review

Banks are exposed to a variety of risks, namely, credit risk, liquidity risk, exchange risk, operational risk, transparency risk, reputation risk, interest rate risk, technology risk etc. The BIS recommends the need for an adequate amount of capital to help banks temporarily absorb any unexpected fluctuation and/or losses. Central banks of countries follow the guidelines of the BIS and introduce befitting policies and procedures in the context of their markets. As more products and services are introduced, the policies must be flexible enough to accommodate the requisite changes. The successful negotiation and implementation of Basel II Accord will lead to a sharp focus on the risk measurement and risk management at the institutional level [Arora, Garg and Ranjan, 2007]. Indian banking industry in general uses a credit committee for decision making and the managements of most banks perform industry study, make periodic credit calls, undertake regular plant visits, and conduct annual review of accounts for credit risk management. Irrespective of the bank size and sector, the credit risk framework follows guidelines provided by the country's central bank, namely, the Reserve Bank of India [Bodla and Verma, 2009]. The information contained in bank financial statements may be used to assess the risk management capabilities of banks and then ascertain the sensitivity of bank stocks to risk management [Sensarma and Jayadev, 2009].

The impact of credit rating on capital adequacy ratios of the state-owned banking industry needs short and long term perspectives [Nachane and Ghoshal, 2004]. The financial services industry is undergoing drastic changes through convergence between sectors and integration of products thereby requiring different type of regulation [Singhal and Vij, 2006]. If Indian banking industry follows the global trend of consolidation, critical issues must be

assessed regarding two important stakeholders, that is, shareholders and managers [Jayadev and Sensarma, 2007]. Operational risk is the risk of loss resulting from failure to administer efficient internal control processes within a bank. The regulators ensure that the management of the banking system is following the guidelines in this regard. Banks in India are directed to follow Basic Indicator Approach (BIA) for operational risk capital charge calculation [Bodla and Verma, 2008]. A survey conducted on select banks in India indicates insufficient internal data and difficulties in collection of external loss data. Hence it is imperative that banks devote time and resources to implement the advanced approach under Basel II [Janakiraman, 2008].

A study of the technical efficiency scores across a set of private and public sector banks reveals that the private sector banks have higher technical efficiency scores than their public sector counterparts [Sinha, 2008]. Management of interest rate risk in the banking system has become significant because there is the possibility of significant basis risk in addition to re-pricing risk [Saha, Subramanian, Basu, and Mishra, 2009]. Agricultural and other priority sector loan exposures may be typically managed on a portfolio basis. This will enable banks to diversify the risk and optimize the profit in the business besides strengthening a bank's relationship with its clients. Transparency in loan decision making process will continue to expand to reach benefits of corporate governance [Bandyopadhyay, 2008]. Finance companies that operate in the unorganized segments must also be required to become Basel II compliant but with a higher capital adequacy ratio [Ghoshal, 2008]. A modified and improved approach for the development of risk assessment must include an audit plan and an outline of the acceptable levels of risk for identifying risk mitigation measures [Khanna, 2008].

A Historical Perspective of the Indian Banking Industry

Following the nationalization of twenty major commercial banks starting in 1969, the government followed policies of financial repression for nearly two decades. The public sector commercial banks experienced rapid expansion of network of branches, including rural areas. They did not have any competition in their deposit mobilization efforts and using the depositors' funds in the disbursement of loans. While employment in the banking industry exponentially increased, the highly educated and motivated bank employees and managers had no discretion or autonomy in their decision making. Interest rates were administered by the Reserve Bank of India for deposits and loans. Direction of credit was also determined by the central bank and the government.

The cost burden continued to increase with high salaries for employees and high interest rates for deposits and that for loans was artificially kept low to suggest development banking. Depositors had no viable and dependable alternative investment vehicles. Commercial credit was at a high and unaffordable cost. Thus, the operating efficiency of public sector commercial banks rapidly declined due to the aforesaid reasons. The banking industry went through a transformation in the last decade due to the financial liberalization efforts of the government. Entry barriers were removed permitting fresh private banks to operate thereby making the industry competitive. Rate deregulation also was introduced in stages. The implementation of Basel I capital adequacy norms led to banks finding avenues for a fresh infusion of capital. Cost cutting was inevitable leading to generating fee based income sources. The public sector commercial banks have yet to fully expand their off-balance sheet activities compared to their traditional fund-based activities [Sinha 2008]. Fig 1 shows that the banking industry in India still commands a major market share in the financial savings of the household sector. While a range of new financial products has become available, the household sector is mostly risk averse and also not so financially literate to assess the relationship between risk and reward. Thus, the imperative for the banking industry is to scan the financial market on behalf of its clients for a superior rate of return for a fee.

Empirical Study of the Banking Industry in India

Any attempt to study the efficiency of individual banks and the effectiveness of the banking system will have to start with the segments within the industry. Our data comprises sector wise standing of the banking industry from 1979 to 2009 divided into State Bank of India & associates, nationalized banks (also known as public sector banks), regional rural banks, private banks, and foreign banks. The regional rural banks were constituted for a specific purpose of

“development of agriculture, trade, commerce, industry and other productive activities in the rural areas, credit and other facilities, particularly to the small and marginal farmers, agricultural labourers, artisans and small entrepreneurs”¹. We included twenty-nine ratios of the industry as a measure of the industry’s readiness to display efficiency, profitability and also proceed with Basel II implementations. The ratios that we studied are: Cash to deposit, Credit to deposit, Investment to deposit, Credit and investment to deposit, Deposits to total liabilities, Term deposits to total deposits, Priority sector credit to total credit, Term loan to total credit, Secured advances to total advances, Investments in non-approved securities to total investments, Interest income to total assets, Net interest margin to total assets, Non-interest income to total assets, Intermediation cost to total assets, Wages to intermediation cost, Wages to total expense, Wages to total income, Burden to total assets, Burden to interest income, Operating profits to total assets, Return on assets, Return on equity, Cost of deposits, Cost of borrowings, Cost of funds, Return on loans, Return on investments, Return on loans adjusted to cost of funds, and Return on investments adjusted to cost of funds. The correlation matrix for select variables is shown in Table 1. If the industry has sufficient products to invest in, its profitability will be visible in its return on assets (ROA). The same will also suggest the presence of liquidity risk, credit (default) risk, operational risk, and interest rate risk. So, we included key independent variables, namely, cost of deposits, cost of borrowing, cost of funding, return on loans, return on investments, intermediation cost, term deposits, priority sector credit, term liabilities, and total liabilities.

FIG 1: SIZE OF HOUSEHOLD SAVINGS WITH BANKS

Hypothesis 1:

$ROA = \alpha$ (constant) + β_1 (cost of deposits) + β_2 (cost of borrowing) + β_3 (cost of funding) + β_4 (return on loans adjusted to cost of funds) + β_5 (return on investments) + β_6 (intermediation cost of funds)

Hypothesis 1A:

$ROA = \alpha$ (constant) + β_1 (cost of deposits) + β_2 (cost of borrowing) + β_3 (cost of funding) + β_4 (return on loans adjusted to cost of funds) + β_5 (return on investments) + β_6 (intermediation cost of funds) + β_7 (Dummy variable for foreign banks)

Hypothesis 2:

$ROA = \alpha$ (constant) + β_1 (term deposits to total deposits) + β_2 (priority sector credit to total credit) + β_3 (term liabilities to total liabilities) + β_4 (secured credit to total liabilities) + β_5 (net interest margin to total assets) + β_6 (non-interest income to total assets) + β_7 (operating profit to total assets)

Hypothesis 2A:

ROA = α (constant) + β_1 (term deposits to total deposits) + β_2 (priority sector credit to total credit) + β_3 (term liabilities to total liabilities) + β_4 (secured credit to total liabilities) + β_5 (net interest margin to total assets) + β_6 (operating profit to total assets) + β_7 (Dummy variable for foreign banks)

Hypothesis 3:

ROA = α (constant) + β_1 (term deposits to total deposits) + β_2 (priority sector credit to total credit) + β_3 (term liabilities to total liabilities) + β_4 (secured credit to total liabilities) + β_5 (net interest margin to total assets) + β_6 (operating profit to total assets)

Hypothesis 3A:

ROA = α (constant) + β_1 (term deposits to total deposits) + β_2 (priority sector credit to total credit) + β_3 (term liabilities to total liabilities) + β_4 (secured credit to total liabilities) + β_5 (net interest margin to total assets) + β_6 (operating profit to total assets) + β_7 (Dummy variable for foreign banks)

India's foreign direct investment policy for the banking industry was fully liberalized in January 2000 and so we studied the same data using the same hypotheses for the years 2000 to 2009 separately. We also realized the need to examine the return on equity (ROE) as one of the dependant variables using similar hypotheses.

Hypothesis 4:

ROE = α (constant) + β_1 (Interest income to total assets) + β_2 (Net interest margin to total assets) + β_3 (Non-interest income to total assets) + β_4 (Intermediation cost to total assets) + β_5 (Wages to total income) + β_6 (intermediation cost of funds)

Hypothesis 4A:

ROE = α (constant) + β_1 (Interest income to total assets) + β_2 (Net interest margin to total assets) + β_3 (Non-interest income to total assets) + β_4 (Intermediation cost to total assets) + β_5 (Wages to total income) + β_6 (intermediation cost of funds) + β_7 (Dummy variable for foreign banks)

Hypothesis 5 (2000 to 2009):

ROE = α (constant) + β_1 (Interest income to total assets) + β_2 (Net interest margin to total assets) + β_3 (Non-interest income to total assets) + β_4 (Intermediation cost to total assets) + β_5 (Wages to total income) + β_6 (intermediation cost of funds)

Hypothesis 5A (2000 to 2009):

ROE = α (constant) + β_1 (Interest income to total assets) + β_2 (Net interest margin to total assets) + β_3 (Non-interest income to total assets) + β_4 (Intermediation cost to total assets) + β_5 (Wages to total income) + β_6 (intermediation cost of funds) + β_7 (Dummy variable for foreign banks)

The public sector banks lacked original equity and so started issuing new equity to the public. The entire State Bank group thrives on government accounts and also acts as an agent of the country's central bank thus, only the newly licensed private banks are funded by original equity. A few public sector banks have initiated the process of initial public offerings to infuse fresh and real equity into their financial health. Table 2 shows the number of issues by the banking industry and the amount of equity obtained from the market for the period 1996 to 2009. Until all banks are uniformly supported by original equity, the return on equity may not be a viable tool for sector-wise analysis. Similarly, we also studied the ratio of loans to deposits but, a high statutory liquidity and cash reserve ratios in the past undermine the relevance of this ratio.

Discussion of Results

Our models yielded expected signs for all the variables consistently. The key variables turned out to be statistically significant amidst development banking policies imposed by the government. This suggests that the country's central bank ensured maintenance of economic standards in its banking industry, however minimum levels such standards reached. Thus, the systemic risk was overall addressed prudently by the regulators. Our first model studied the importance of profitability for banks through return on assets (ROA) despite being under an administered banking environment. Tables 3 and 4 summarize our findings for the entire period of 1979 to 2009 and 2000 to 2009 respectively. The cost of funding has an immediate effect on the rate of return on loans and other investment

securities. As industry gets modernized on a continual basis, banks are likely to resort to inexpensive sources of funding. As and when the country's financial market harnesses its potential to offer short and long term products, banks will fund their own investments in loans through external borrowings. This may be a departure from the vanilla type of banking that the country has followed for two centuries. Traditionally, the Indian banking industry has relied upon domestic deposits as the only source of funding for all types of credit. The depositors with no alternative channel of investment were offered a high interest rate for their savings and term deposits. Besides, a sense of security for their deposits was prevalent as the banking industry represented the government itself. Depositors' overbearing reliance on interest income from transaction accounts left the government and the central bank with the only solution of offering interest rates that had no competitive market factors.

TABLE 2 EQUITY OBTAINED BY BANKS IN INDIA

Year (ending March 31)	Number of issues	Amount raised (US\$ millions)*
1996	17	1,790
1997	10	1,601
1998	8	568
1999	15	1,117
2000	15	927
2001	13	674
2002	14	1,055
2003	13	725
2004	11	1,234
2005	12	2,586
2006	12	2,797
2007	5	504
2008	6	7,760
2009	0	-

*Capital raised in Indian rupees converted and rounded off by the authors into US dollars at the interbank rate as of March 31 in each year. (Source: Securities and Exchange Board of India)

Cost of deposits was thus the primary factor in assessing the economic viability of the banking industry. Profitability increases whenever it is cheaper to borrow from the market than from mobilization of deposits. So, we modified our first model by including the cost of borrowings as an independent variable. The same performance ratio, ROA, was studied in the light of the length of the time period of loans and also the collateral security. The cost of deposit did not register a noticeable level of significance in all our models but the cost of borrowing and the cost of funding turned out to be highly significant. This is due to the absence of the term structure of interest rates in the past due to an administered environment. With the introduction of benchmark rates through short term treasury securities in 1997 and adoption of global standards, the reliance on deposits could be fading. Besides, the intermediation cost and employee salaries played a distinct role in reducing the overall profitability of the industry. We also noticed the return on loans and that on investment both adjusted to their respective costs registering significance. Similarly, our results comprehensively indicate that banks are likely to suffer from interest rate risk unless they are allowed to introduce hedging instruments for protecting themselves.

We ensured that the independent variables were significant by including a dummy variable for the foreign banks as a group and our results reinforced our findings regularly. The foreign banks constituted to be the only unique sector wherein the dummy variable was also significant thereby suggesting that the competitive field was not

open to foreign institutions for a long time. This sector operated strictly under market factors and ensured economic viability. Our final step was to understand how the industry operated with deposits as the major item on liability and the cost of deposits being the most expensive item on the income statement. We juxtaposed the factors of credit such as cash to deposit ratio for systemic health, priority sector credit for complying with development policies, secured credit to maintain safety and soundness, and term loans to total credit for the sake of steady cash flows. All variables registered a high level of significance wherein lies the systemic stability. When the market participants have placed a sizeable investment in banking stocks, the banking industry is under an obligation to cost reduction to render a better return on equity (ROE) consistently. Our scrutiny of the ROE as the variable dependent upon increasing interest income, maintaining a sustained net interest margin, offering more fee-based services, lowering intermediation costs, and reducing the wage expenses. The results summarized in Table 5 emphasize that the market participants do insist upon a satisfactory ROE. In this analysis, the domestic banks were on par with foreign banks.

Conclusion and Future Direction

With the advent of a significant presence of private banks and foreign banks, the Indian banking industry has the potential to become modern and sophisticated. The public sector banks need original equity from the public. If a fresh infusion of capital were to take place, the market will look for a privatized industry. In such an environment, bank managements are certain to be efficient but the responsibility of protecting the investors from the risk of moral hazard solely rests with the regulators. The foreign direct investment (FDI) policy of India permitted a complete ownership of banks by foreign investors since 2000 but there has been only one merger with ING's acquisition of the Vysya Bank Limited. Liberalization efforts have been steady but considerably slowed down due to resistance from pressure groups such as trade unions.

TABLE 5 REGRESSION RESULTS FOR THE INDIAN BANKING INDUSTRY, 1979-2009

Dependent Variable: ROE	Model 5	Model 5A	Model 6	Model 6A

The reason that the financial services industry overall has suffered from the nonperforming assets (NPAs) and also a foreign investor may not fully comprehend what to expect as a measure of performance. In its assessment of Basel core principles as applied to the commercial banking industry in India, the Reserve Bank of India finds banks in India to be compliant with regards to capital adequacy, large exposure limits, and country & transfer risk. They are also largely compliant in the areas of credit risk, problem assets, provisions & reserves, operational risk,

internal control & audit, and abuse of financial services. The concern stems from banks found to be materially non-compliant in addressing risk management process, exposure to related parties, market risk, and liquidity risk. Most importantly, commercial banks are non-compliant in measuring and controlling interest rate risk in banking books. "Our study also reinforces the same point of view but we understand that the regulations may only pave the way for market evolution and infrastructure enhancement. The introduction of real time gross settlement (RTGS) recently is a major step to suggest that India's banking industry is prepared to be modernized which is consistent with industrialized economies. The risk management systems are mostly proprietary and so require each individual bank's commitment to enforce stringent internal control mechanism while bestowing a sophisticated degree of autonomy on the management. Adequate risk management systems determine the health of each institution cumulatively contributing to the robust systemic health. In order to fulfill this area, an expansion of this study must be undertaken from the perspective of each individual major bank under each sector in order to conclude which banks are likely to be fully compliant with regards to risk management systems. Implementation of core banking system is just the beginning of India's banking industry which was necessitated by the advent of rapid technology amidst its consumers. The same customers are engaged in the changing landscape of the whole industry.

Are Spillovers from Japanese FDI larger than from U.S. FDI?

Evidence from Backward Linkages in Mexico's Manufacturing Sector

Leo Guzmán Anaya¹, leo.guzman8@gmail.com

Universidad de Guadalajara, Mexico

Abstract

Previous literature regarding technological spillovers from Foreign Direct Investment (FDI) in developing countries has turned out mixed and contradictory². This has also been the case in empirical studies that specifically compare Japanese and United States FDI Spillovers³. Theoretical contributions suggest that Japanese FDI should generate larger spillovers than U.S. FDI because of the characteristics embodied in each type of investment⁴. Using economic census data from Mexico's manufacturing sector we compare backward spillovers from Japanese and U.S. FDI. Results show that foreign presence in an industry increases productivity within the industry. The backward spillover coefficients were not statistically significant and this may be due to data limitations.

Introduction

Foreign Direct Investment has grown dramatically in the last 35 years, and this growth has been more accentuated in the last 20 years⁵. Even though FDI primarily seeks developed markets, developing countries have increased their participation as host countries of FDI inflows recently⁶. Specifically, the decrease of bank lending to developing economies during the 1980's prompted most of these countries invite Foreign Direct Investment by reducing restrictions on foreign capital, by offering subsidies and tax incentives to foreign investors (Carkovic & Levine, 2002). Görg and Greenway (2003) mention that in 1998, sixty countries made regulatory changes regarding FDI, where 94% were aimed to generate more favorable conditions to foreign investors. Mexico has also eased restrictions on FDI, especially after the debt crisis of the 1980's where foreign investment became the main source of financing after 1988 (Gurria, 1994). The Mexican government has since then pursued active policies to lower the entry barriers to investment from multinational enterprises (MNEs) in the hope that FDI would promote economic development through technological spillovers and faster growth of exports. The country has also transitioned from a highly protective import substitution to an export promotion strategy where FDI plays a central role. Since the middle of the 1980's, and more particularly since the implementation of the North American Free Trade Agreement (NAFTA) in 1994, FDI flows to Mexico increased. After receiving FDI inflows worth around 5.5 billion constant 2000 US

dollars in 1993, the amount in 1994 was over 11 billion US dollars in constant 2000 prices. Even though the increases of FDI inflows to Mexico and other developing countries have boomed since the 1980's, the spillover effects of FDI still remain unclear (Carkovic& Levine, 2002).

The economic foundations to offer special incentives to attract FDI derive from the idea that foreign investment is a composite bundle of capital, know-how, and technology which produces externalities, mainly through technology transfer as well as technology and skill diffusion in the countries that import FDI (Balasubramanyam, 1996). Romer (1993) mentions that there are important "idea gaps" between rich and poor countries, and that FDI may serve as a channel to transfer technological and business know-how to poor countries. Growth theory, which gives importance to Research and Development (R&D), human capital accumulation, externalities, and learning-by-doing, give theoretical bases to the motion that FDI can increase productivity in the host country. However, empirical studies have not always supported this claim.

The present paper uses economic census data from 1999, 2004 and 2009 to test whether the magnitude of vertical spillover from the United States and Japanese FDI differ in the Mexican economy. Two reasons give support to the claim that spillovers from Japan and the U.S. must be different. First, theoretical models on vertical linkages state that the share of intermediate inputs provided by multinational enterprises (MNEs) is positively correlated with the distance between host and home country (Rodrigues-Clare, 1996; Markusen&Venables, 1999)⁷. Larger shares of indigenous sourcing imply more contact between local and MNEs and greater opportunities for knowledge transfer. Therefore, it is expected that Japanese FDI should generate larger vertical spillovers than U.S. FDI.

Second, when it comes to a direct comparison between Japanese and U.S. FDI spillover effects on countries, different theoretical postures can be identified. The first posture claims that Japanese FDI generates larger spillovers than U.S. FDI. This theory is based on the idea that Japanese enterprises invest in sectors that are more suitable for developing countries, in terms of a more accessible, standardized and mature technology that can be easily absorbed by local firms (Kojima 1978, 1982; Kojima & Ozawa, 1984). This theory takes a macroeconomic approach where host economies are expected to increase economic growth and exports. The second posture claims that the spillovers from U.S. FDI are expected to be larger than those of the Japanese counterpart. This posture claims that technology transferred from the U.S. is more advanced than that of Japanese FDI and thus the spillovers expected are larger for the U.S. case (Kim, Lyn, &Zychowicz, 2003). This posture is more applicable to developed countries, which have higher levels of absorptive capacities to benefit from advanced technologies. The third theoretical posture claims that spillovers from Japanese or U.S. FDI depend on several factors (such as domestic government policies, investing firm's internal transaction motives, and nature of the investment project), all of which influence the outcome of the spillovers for each case (Lemi, 2004; Perez, 1998). Since Mexico is considered a developing country, it might be benefiting more from accessible and standardized technology than from the advanced case, due to low levels of absorptive capacity. This also implies that spillovers from Japanese FDI might be larger than from U.S. FDI.

Literature Review

Most empirical work searching for spillovers does so by analyzing changes in productivity of local firms. Intra-industry studies that apply cross-sectional data usually find positive spillovers from foreign presence, which may be due to estimation bias, as mentioned by Görg and Greenway (2001). When panel data estimation techniques are applied mixed results appear⁸. An explanation is that firms within the same industry have incentives for minimizing knowledge transfer within the industry (Kugler, 2001). On the other hand, domestic suppliers might benefit from multinationals presence in several ways. A multinational might help prospective providers setup production facilities; provide technical assistance to improve the quality of their products and thus facilitate innovation; and provide training of employees and transfer of management and organizational knowledge (Lall, 1980).

Recent empirical work seems keener to search for inter-industry spillovers as opposed to intra-industry spillovers. Results from inter-industry studies seem to support the claim that domestic suppliers benefit from foreign presence. Specifically, most studies show that for developing countries, domestic firms usually benefit from spillovers through backward linkages (Blalock & Gertler, 2008; Javorcik, 2004; Javorcik & Spatareanu, 2008; Liu & Lin, 2004; López & Südekum, 2009; Schoors & van der Tol, 2002). For Mexico, the previous study by López-Córdoba (2003) also supports this claim.

Empirically, comparing Japanese FDI and U.S. FDI has provided mixed results. Most studies have searched for macroeconomic spillovers, where contradicting results have been found (Hahm & Heo, 2008; Kim et al., 2003; Kojima, 1985; Lemi, 2004). We will encounter a problem when searching for macroeconomic FDI spillovers as this variable measured in aggregate terms is relatively small (for developing countries it generally represents less than 5% of GDP), so economy level spillovers may be unobservable. This may be a reason for the mixed and insignificant results found in this literature. Microeconomic studies on the other hand, have emphasized intra-industry spillovers and with contradicting results (Banga, 2003b, 2003c; Lee, 1984). One of the reasons for contradicting microeconomic results may be that in an intra-industry setting, foreign firms have the incentive to prevent any kind of positive spillovers to competing firms in the same industry. On the other hand, foreign companies that benefit directly or indirectly may promote spillovers with domestic firms with an input-output linkage so vertical spillovers are more likely to occur (Kugler, 2001).

The present study intends to compare inter-industry spillovers from Japanese FDI and U.S. FDI in Mexico's manufacturing sector.

Empirical Strategy

The Methodology applied to search for vertical spillovers from Japanese and U.S. FDI will follow that of Javorcik (2004) and Liu & Lin (2004). A Panel data estimation technique is applied where output is regressed on capital, labor, and other intermediate inputs. The model takes the following form:

$$\ln Y_{jt} = \alpha + \beta_1 \ln K_{jt} + \beta_2 \ln L_{jt} + \beta_3 \ln M_{jt} + \beta_5 \text{Horizontal}_{jt} + \beta_6 \text{BackwardUS}_{jt} + \beta_{10} \text{BackwardJAP}_{jt} + \alpha_t + \alpha_j + \varepsilon_{jt} \quad (1)$$

Where, Y_{jt} , K_{jt} , L_{jt} , and M_{jt} represent output, capital, labor and material inputs for industry j at time t . All variables are in constant 2010 prices. Output represents gross total output in an industry. Capital is measured as total fixed assets in an industry. Labor is measured by the total number of workers in an industry, and material inputs represent the value of intermediate material inputs used by industry. Horizontal and Backward variables are added to test the effects of foreign presence on industrial productivity.

The Horizontal variable measures foreign presence in the same sector and is defined as the share of industry j 's fixed assets owned by foreign investors⁹. It is defined as:

$$\text{Horizontal}_{jt} = \frac{\text{Total Foreign Fixed Assets}_{jt}}{\text{Total Fixed Assets}_{jt}} \quad (2)$$

The Backward variable is the share of an industry's output purchased by downstream foreign enterprises (Blalock, 2001). It is a proxy for foreign presence in downstream sectors, in other words it intends to capture the effect of foreign enterprises as customers of domestic suppliers. It takes the following form:

$$\text{Backward}_{jt} = \sum_{k \text{ if } k \neq j} \alpha_{jk} * \text{horizontal}_{kt} \quad (3)$$

In equation (3), α_{jk} is the proportion of upstream sector j 's output used by downstream sector k taken from the 2003 IO matrix. Two different measures of the Backward variable are calculated, one for Japanese capital and one for U.S. capital respectively. The direct comparison between the coefficients of both variables will indicate which type of capital is generating larger backward linkage spillovers in Mexico's manufacturing sector.

Estimation was carried out using pooled data OLS regression and panel data fixed effect and random effect econometric techniques.

Data Description

Data for production, capital, labor, and inputs obtained from Mexico's National Institute of Statistics and Geography (INEGI). Specifically, we used Economic Census data for the years 1999, 2004 and 2009 focusing on the manufacturing sector at a three-digit SCIAN disaggregated level. In total, we work with 21 industries of manufacturing activity¹⁰. Foreign Direct Investment data was obtained from Mexico's Secretary of Economy. FDI data however, was classified under CMAP and not SCIAN, so a conversion table from INEGI was used to make the data comparable.

We also used an input-output matrix (IO) provided by INEGI covering the year 2003¹¹. The IO matrix for the manufacturing sector accounts for 21 sub-sectors under three-digit SCIAN classification. Each industry was matched with the IO subsector classification based on its primary three-digit SCIAN code.

Results

Results from the econometric estimation are shown in table 1 using pooled OLS regression and panel data fixed effect and random effect estimations. Results from the three estimation techniques are quite similar. We find that the input variables (capital, labor and materials) are highly significant and positive. Generally speaking, a 1% increase in fixed assets, labor and materials genders a 0.06%, 0.1% and 0.87% increase in manufacturing sector output. The horizontal variable, which includes all foreign participation within an industry, resulted to be significant in all three models as well. The positive sign also indicates that competing firms within an industry have benefited from foreign presence and spillovers have occurred.

The main variables of interest (Backward_Japan and Backward_U.S.) did not turn out statistically significant in any of the three models. However, it seems interesting to point out that the coefficient signs seem to indicate that Japanese FDI has generated positive backward spillovers with the local economy. U.S. FDI on the other hand, seems to be negatively correlated with local productivity, which may indicate that foreign U.S. companies are not creating linkages with local suppliers¹². A reason for the lack of significance in these results may be the fact that shares of foreign presence in an industry had to be calculated using FDI flow data and not economic census data¹³. Since FDI flow data was not under the same classification as census data, conversion tables had to be used and this may have altered the results.

Conclusions

This study employs industry level data from Mexico's manufacturing sector to examine whether backward spillovers from Japanese FDI are larger than their U.S. counterpart. Results obtained from our empirical analysis do not give support to our original hypothesis. Although coefficients from the three regression models applied were

positive testing for backward linkages from Japanese FDI and negative from U.S. FDI, these were not statistically significant.

We believe that the reason for these results stems from the fact that an alternate database for foreign capital origin had to be used and made comparable with production and inputs data. Also, due to the conversion of FDI flows from CMAP classification to SCIAN classification, we had to aggregate the data to three-digit instead of six-digit disaggregated level, which resulted in the loss of observations.

Despite these limitations, our results show that foreign presence in general, increases productivity of firms within that sector. However, these results should be taken with reservation. As mentioned by Aitken and Harrison (1999), horizontal measurements of spillovers may overstate the positive relationship between foreign presence and local productivity. In other words, foreign companies may be attracted to the most productive industries of the economy and not be the cause of high productivity in these industries.

⁴ See: (Aoki, 1986, 1990; Coriat, 1990, 1991; Fujita & Hill, 1995; Graham &Krugman, 1995;Kojima, 1978; Piore&Sabel, 1984;Ravenhill, 1999;Womack, 1990).

⁵ Between 1970 and 2008, world FDI flows grew at an average 9.2%, while world GDP and exports grew at average rates of 3.2% and 6.6% respectively. (UNCTAD, 2008).

⁶ Between 1970 and 1975 developing countries received FDI inflows accounting for 0.56% of their GDP, during the period of 1980 to 1985 the figure jumped to 0.74%, between 2000 and 2005 it increased to 2.84% and in 2008 it represented 3.84% of their GDP. (UNCTAD, 2008).

⁷This has also been empirically tested for Japanese and U.S. MNEs. For U.S. MNEs, Hanson, Mataloni and Slaughter (2003) show that there is an inverse relationship between trade costs and sales of intermediate inputs from headquarters to overseas affiliates. Japanese MNEs also seem to increase local sourcing in their U.S. affiliates due to transportation distance and shipping delays (Chung, Mitchell &Yeung, 2003; Martin &Swaminathan, 1995)

⁸Positive spillovers were found in Görg&Strobl (2002) and Suyanto, Salim& Bloch (2009) for Ghana and Indonesia respectively, while negative results were reported for the cases of Morroco (Haddad & Harrison, 1993), Venezuela (Aitken & Harrison, 1999) and India (Kathuria, 2000).

⁹Initially, the horizontal variable was to be calculated as the share of output by foreign companies over total output. However, due to time constraints the database with this specific information was not made available from INEGI.

¹⁰The manufacturing sector under SCIAN classification has a total of 293 classes; 11 classes were dropped due to missing observations.

¹¹Ideally, it would be better to use multiple IO matrices since relationships between sectors may change over time or with FDI activity. However, radical changes among these relationships are unlikely and we can assume that industrial structures do not change rapidly over time (Javorcik, 2004; Javorcik, Saggi&Spatareanu, 2004). IO matrices for other years were unavailable. While coefficients from the IO table remain fixed for the entire period, horizontal values and output do change over time, so backward values are time-varying, industry-specific variables (Javorcik, 2004).

¹²Significance for these variables was at a 62% interval for Backward_Japan and at a 75% interval for Backward_U.S..

¹³Economic census data reports the share of foreign presence in production, fixed assets, investment, employment, material inputs and total number of companies by country and by industry; however, this data base was not made available in time from INEGI for the submission of this paper. Results should be taken with this caveat in mind.

Investment Strategy of the Temasek Holding

What is sovereign wealth fund?

A sovereign wealth funds (SWFs) are investment funds owned by national governments and financed by the country's foreign currency reserves (dollar, euro, yen), often through their central banks or via direct investments. The funds invested usually the proceeds of non-renewable natural resources or a higher return alternative to holding foreign currency. The term sovereign wealth fund was introduced in 2005, but the first SWF was introduced in 1953 by the government of Kuwait ('Kuwait Investment Authority,' a commodity SWF). Expansion of sovereign wealth funds in recent years has been driven by ballooning East Asian foreign exchange reserves and the need for oil rich countries to invest oil money to provide income to replace that from diminishing oil reserves. These funds are now major players in the world financial markets. The combined assets of the major SWFs (owned by 20 governments) have reached over three trillion dollars, and are expected to reach over 10 trillion dollars by 2012. Although the current total amount makes up only some 3 percent of the world's traded securities, the SWFs already have tremendous concentrated financial power. Over half of the SWF assets are owned by oil and gas exporting nations, and about one third by Australia, China, and Singapore. SWFs are aggressive investors and have bought into firms as diverse as Morgan Stanley, General Electric, and Sony.

Definition of SWFs

Although there exists no commonly accepted definition of SWFs, three elements can be identified that are common to such funds. First, SWFs are state-owned. Second, SWFs have no or only very limited explicit liabilities and, third, SWFs are managed separately from official foreign exchange reserves. In addition, most SWFs share certain characteristics that originate in the specific nature of SWFs. For example, the lack of explicit liabilities (or the stretched out maturity of liabilities) favours the pursuit of long-term investment strategies, as implemented by most SWFs. In this respect, sovereign wealth funds differ from sovereign pension funds that operate subject to explicit liabilities and a continuous stream of fixed payments, making sovereign wealth funds more similar to private mutual funds. Second, the absence of explicit liabilities also has a bearing on the willingness to take risk, as standard portfolio theory predicts a higher share of fixed income securities for funds that are subject to recurring payments. Finally, most sovereign wealth funds appear to have substantial exposure to foreign investments or are even entirely invested in foreign assets.

Who established SWFs?

The main group of countries that have established SWFs are resource-rich economies which currently benefit from high oil and commodity prices. In these countries, SWFs partly also serve the purpose of stabilising government and export revenues which would otherwise mirror the volatility of oil and commodity prices. Another purpose of such funds in resource-rich countries is the accumulation of savings for future generations as natural resources are non-renewable and are hence anticipated to be exhausted after some time. Prominent examples of such SWFs include Norway's Government Pension Fund, investment agencies set up by member countries of the Gulf Cooperation Council, such as the Abu Dhabi Investment Authority which manages the foreign assets of the Emirate of Abu Dhabi in the United Arab Emirates, and the Russian oil stabilisation fund which has recently been partly transformed into a fund for future generations.

A second group of countries, most notably in Asia, has established SWFs because reserves are being accumulated in excess of what may be needed for intervention or balance-of-payment purposes. The source of

reserve accumulation for these countries is mostly not linked to primary commodities but rather related to the management of inflexible exchange rate regimes. As the authorities have become more comfortable with reserve levels, foreign assets have been moved to specialised agencies which often have explicit return objectives and may invest in more risky assets than central banks. Prominent examples include funds that have been operating for decades, such as the Singapore Government Investment Company, but also more recently established funds such as the Korea Investment Corporation, and the investment portfolio of the Exchange Fund managed by the Hong Kong Monetary Authority. Recently also China established a new investment agency, the China Investment Corporation, responsible for the management of a portion of Chinese foreign reserves.

Amount of asset under management of SWFs

Based on a combination of private and official sources, SWFs are estimated to have accumulated between at least USD 3 trillion, compared with around USD 5 trillion in traditional foreign exchange reserves. Comparing the level of traditional foreign exchange reserves with assets managed in SWFs, two observations stand out (see Chart 1). Some countries have been accumulating foreign assets in SWFs for a long time and therefore hold relatively modest levels of foreign exchange reserves (e.g. members of the Gulf Cooperation Council like the UAE and Kuwait). In contrast, other countries have accumulated sizeable holdings of traditional foreign exchange reserves – most likely in excess of precautionary levels – but only recently created SWFs with relatively modest levels of assets under management (e.g. China and Russia). Therefore, many observers expect that these countries may in the future increasingly accumulate foreign assets in SWFs or even shift traditional reserve assets into such funds. Oil exporters, mostly from the Middle East, but also Norway’s sizeable Government Pension Fund, are estimated to account for the largest part of total assets managed by SWFs. A smaller fraction, of around USD 700 billion, is accounted for by Asian emerging economies, most notably Singapore, which has been running SWFs since the 1970s. But also mature economies, other than Norway, have set up SWFs, mostly to save receipts from the exploitation of natural resources. In sum, a plausible estimate of total assets managed by SWFs ranges from USD 3 to 4 trillion.

CHART 1: SWFs VS OFFICIAL FOREIGN EXCHANGE RESERVES

Selected Sovereign wealth funds

Singapore

The Government of Singapore owns two independent SWFs. The first, Temasek Holdings, was founded in 1974 to manage part of the Government's revenues. To satisfy legal requirements in issuing bonds, Temasek first reported its accounts to the public in 2004. Total annualised returns have been 18% per annum since inception and currently the fund has a net asset value of around USD 133 billion. Although Temasek originally invested domestically, foreign investments now account for more than half of its total portfolio, concentrated in emerging Asia, especially China, Taiwan and Korea and, from a sectoral viewpoint, in the financial and telecommunications industries. Temasek claims not to direct the commercial or operational decisions of portfolio companies, except where shareholder approval is specifically required. In 1981 a second SWF, the Government Investment Company (GIC), was set up to manage part of Singapore's foreign exchange reserves. Although its accounts are not published, GIC reports managing a portfolio of more than USD 100 billion. The GIC's investment target is to achieve a real return of above GDP-weighted inflation. GIC claims to have constantly exceeded the benchmark return.

Hong Kong

Reserve management in Hong Kong is centralised in the Hong Kong Monetary Authority's Exchange Fund. The fund is split into a "backing portfolio" consisting of traditionally managed foreign exchange reserves, which fully back the Hong Kong dollar monetary base, and an actively managed "investment portfolio". Management of the investment portfolio is partly carried out by Hong Kong Monetary Authority staff and external fund managers. The latter are responsible for the management of all equity investments, which account for around a third of the investment portfolio.

Russia

Russia introduced a formal Oil Stabilisation Fund in January 2004 with the aim of saving the fiscal windfall gains from high oil prices. Prior to that, Russia used to operate a less formal framework aimed at smoothing the macroeconomic impact of oil price fluctuations ("special reserve"). The Oil Stabilisation Fund is mainly financed from two sources: oil export custom duties in excess of a reference price and the mineral extraction tax. In addition, the unspent fiscal surplus of the previous fiscal year is added to the Oil Stabilisation Fund. Accumulated funds may be used to finance the federal budget deficit if the oil price falls below the reference price. If the Oil Stabilisation Fund's balance exceeds RUB 500 billion, these funds can be used to prepay external debt. Since February 2008 the fund is split into a "Reserve Fund" and a "Future Generations Fund". The Future Generations Fund can invest in sticky assets but has so far maintained a prudent asset allocation. At the same time, the Reserve Fund continues to invest in low-yielding, low-risk government bonds.

Norway

Norway's Government Pension Fund was established in 1990. Since January 2006, this fund includes the Government Pension Fund–Global (formerly Government Petroleum Fund, established in 1990) and the Government Pension Fund–Norway (formerly National Insurance Scheme Fund). The fund receives central government revenues from petroleum activities. As regards its objectives, the fund is used primarily as a savings fund for future generations. Only the expected real return of the fund can normally be transferred to the central government budget and used for general budgetary purposes. The Government Pension Fund–Global attained a portfolio value of around USD 423 billion at end-2009. The day-to-day management is delegated to Norges Bank but the ultimate responsibility lies with the Ministry of Finance, which issues guidelines for the investment of the fund's capital in shares and other securities abroad. Its institutional set-up is often quoted as a benchmark in terms of transparency and accountability. The fund publishes quarterly and annual reports which include a detailed disclosure

of assets under management, the currency and asset class composition of the portfolio down to company level and a standardised reporting of its performance against a benchmark.

Temasek Holdings

Temasek is an investment holding company with characteristic of SWFs and with a portfolio of investments covering a wide range of countries and industry sectors. Temasek was established to create and maximize long-term shareholder value as an active investor and shareholder of successful enterprises. Headquartered in Singapore, Temasek was formed by the Government in 1974 to separately hold and manage its investments in companies and joint ventures (Temasek is wholly-owned by the Government through the Minister for Finance – MOF, under the Singapore Companies Act). This move freed the Government to focus on the economy as a whole and provided an opportunity for a commercially disciplined and independent company to achieve sustainable long-term returns. In addition to managing its inherited portfolio, Temasek also actively invested in other local companies in Singapore for growth and diversification. As Singapore's economy evolved and became increasingly globalized, Temasek began to invest actively outside of Singapore. Temasek has been assigned an overall corporate credit rating of "Aaa" by Moody's and "AAA" by Standard & Poor's. From an initial portfolio of S\$350 million in 1974 made up of various Singapore start-ups, Temasek's investment exposure has grown over the last 30 years into a globally diversified portfolio of about US\$ 133 billion (as at March 31, 2010), covering a range of industries, including financial services, transport and logistics, telecommunications and other infrastructure and engineering services. Total shareholder return of the Temasek Holding since its inception has been 17% compounded annually. Singapore and Asia account for nearly 80 percent of Temasek's investments, while developed markets such as the United States and Europe are a long-standing and growing part of Temasek portfolio.

Financial background

The Temasek had total assets of US\$203.4 billion as at March 31, 2010. The Temasek generated revenue of US\$54.8 billion and profit attributable to equity holder of Temasek of US\$3.3 billion for the year ended March 31, 2010. Temasek's Net Portfolio Value amounted to US\$133 billion as at March 31, 2010, compared to S\$130 billion as at March 31, 2009. As at March 31, 2010, approximately 32% of Net Portfolio Value was in Singapore, 46% in Asia (excluding Singapore and Japan), 20% in the Organization for Economic Cooperation and Development ("OECD") economies (excluding Korea, Mexico and Chile) and 2% in other markets. As at March 31, 2010, the top three sectors (based on contribution of each sector to Temasek's Net Portfolio Value) were financial services, telecommunications, media and technology, and transportation and industrials which comprised 37%, 24% and 18%, respectively. Temasek has delivered a total shareholder return of 17% by market value and 16% by shareholder funds compounded annually since its inception to March 31, 2010.

Strategy of the Temasek

Temasek is an SWF which is managed on commercial principles to create and deliver sustainable long-term value for its stakeholders. Temasek is an active value-oriented shareholder and investor, which seeks to manage its investments to create and maximize shareholder value, balancing risks and opportunities across industries and geographies. Temasek is an active shareholder and aims to achieve sustainable returns by engaging the boards and management of its portfolio companies to foster a culture of integrity, excellence and meritocracy, maintain a clear focus on core competence, customer fulfilment, consistent value creation, and cultivate high calibre board and management leadership. In engaging the boards and management of its portfolio companies, Temasek also aims to institutionalize superior business leadership and sound corporate governance and create strategic options to build significant international or regional brands or businesses.

As a shareholder, Temasek does not participate in the day-to-day management of its portfolio companies. Companies in its portfolio are managed by their respective management, and guided by their respective boards of

directors to deliver sustainable shareholder value. Temasek’s decisions are guided by business tenets and commercial discipline. As the owner of its portfolio, Temasek has flexible investment horizons and the option of taking concentrated risks or remaining in cash. As an active value-oriented investor, Temasek may increase, reduce or hold its investments in companies or other assets, based on its value tests and market opportunities. Temasek may also pioneer innovative products or businesses in order to increase and improve growth and diversification of its portfolio.

Temasek to centre its investment strategies on these four investment themes:

1. Transforming Economies - Tapping the potential of transforming economies like China, India, South East Asia and Latin America, through investments in sectors such as financial services, infrastructure and logistics.
2. Growing Middle Income Populations - Leveraging growing consumer demands through investments in sectors such as telecommunications, media and technology, and consumer and real estate.
3. Deepening Comparative Advantages - Seeking out economies, businesses and companies with distinctive intellectual property and other competitive advantages.
4. Emerging Champions — Investing in companies with a strong home base, as well as companies at inflection points, with potential to be regional or global champions.

In terms of its overall portfolio, Temasek is guided by a directional portfolio mix of 40:30:20:10. This means an exposure to Asia of about 40%, keeping Singapore at about 30%, maintaining OECD exposure at about 20%, and adding exposure of up to 10% to other geographies such as Latin America, the Middle East and Africa. Temasek believes this portfolio mix provides an approximate 50:50 exposure between mature economies and growth regions.

Temasek investment portfolio by sectors

Temasek invests across sectors including financial services; telecommunications, media and technology; transportation and industrials; consumer and real estate; energy and resources; and life sciences. The text below sets forth Temasek’s top three investments by market value (in the case of listed securities) or book value (in the case of unlisted securities) in these sectors, as well as their contribution to Temasek’s Net Portfolio Value (see Chart 2), in each case as at March 31, 2010

CHART 2: TEMASEK’S INVESTMENTS EXPOSURE BY INDUSTRY SECTORS AS AT MARCH 31, 2010

Financial services

Temasek's top three investments in the financial services sector were its minority interest in each of China Construction Bank Corporation ("CCB"), Standard Chartered PLC ("Standard Chartered") and DBS Group. Temasek's investments in the financial services sector comprised 37% of Temasek's Net Portfolio Value.

Telecommunications, media and technology

Temasek's top three investments in the telecommunications, media and technology sector were its majority interest in each of SingTel, ST Telemedia and STATS ChipPAC Ltd. Temasek's investments in the telecommunications, media and technology sector comprised 24% of Temasek's Net Portfolio Value.

Transportation and industrials

Temasek's top three investments in the transportation and industrials sector were its majority interest in each of SIA, Singapore Technologies Engineering Ltd ("ST Engineering") and PSA. Temasek's investments in the transportation and industrials sector comprised 18% of Temasek's Net Portfolio Value.

Consumer and real estate

Temasek's top three investments in the consumer and real estate sector were its majority interest in Mapletree and its minority interest in each of CapitaLand and Singapore Airport Terminal Services Ltd. Temasek's investments in the consumer and real estate sector comprised 11% of Temasek's Net Portfolio Value.

Energy and resources & Life sciences

Temasek's top three investments in the energy and resources sector were its majority interest in Singapore Power and its minority interest in each of MEG Energy Corporation and Niko Resources Ltd. Temasek's investments in the energy and resources sector comprised 6% of Temasek's Net Portfolio Value. Temasek's top three investments in the life sciences sector were its minority interests in each of Amyris Biotechnologies Inc., Bumrungrad Hospital PCL and Interpharma Investments Limited. Temasek's investments in the life sciences sector comprised less than 1% of Temasek's Net Portfolio Value.

Temasek investment portfolio by major portfolio companies

The following table (see Table 1) sets forth the market value (in the case of listed securities) or book value (in the case of unlisted securities) of Temasek's major portfolio companies as of March 31, 2010. These companies accounted for approximately 60% of Temasek's Net Portfolio Value as at March 31, 2010.

TABLE 1: TEMASEK INVESTMENT PORTFOLIO BY MAJOR PORTFOLIO COMPANIES

Company name	(S\$ million)
Singapore Telecommunications Limited	27,273
China Construction Bank Corporation	16,088
Standard Chartered PLC	13,965
Singapore Airlines Limited	9,780
DBS Group Holdings Ltd	9,117
PSA International Pte Ltd	7,985
Bank of China Limited	7,584
CapitalLand Limited	6,591
PT Bank Danamon Indonesia Tbk	4,962
Singapore Technologies Engineering Ltd	4,824
Sembcorp Industries Ltd	3,609

Temasek Portfolio Performance

Temasek’s Net Portfolio Value amounted to S\$186 billion as at March 31, 2010, compared to S\$130 billion as at March 31, 2009 (see Fig.1). As at March 31, 2010, about 77% of Temasek’s Net Portfolio Value comprised listed and liquid assets. One-year total shareholder return for the year ended March 31, 2010 was approximately 42% by market value and 26% by shareholder funds. Total shareholder return by market value takes into account changes in the market value of Temasek portfolio, dividends paid, and nets off any new capital Temasek received. For unlisted investments, the movements in shareholder funds are tracked in lieu of market price changes. Over the medium term, five-year total shareholder return for the year ended March 31, 2010 was 11% by market value and 14% by shareholder funds. Since inception, 36-year total shareholder return for the year ended March 31, 2010 was 17% by market value and 16% by shareholder funds (see Chart 3). The last 10 years Temasek in particular have seen much volatility, starting with the crash of the dotcom bubble in 2000, and ending with the pull-back from the brink of a deep global depression in 2009, punctuated in between by 9/11, SARS and the H1N1 flu pandemic scare.

FIG. 1: DEVELOPMENT OF THE TEMASEK PORTFOLIO VALUE OVER TIME

CHART 3: TEMASEK TOTAL SHAREHOLDER RETURN BY MARKET VALUE

Risk Management

Financial risks of Temasek include market risk due to changes in equity prices, foreign exchange rates and interest rates. To assess its market risk, Temasek uses a VaR statistical model that estimates the potential loss on a portfolio at a given confidence level. Temasek uses an 84% confidence interval, and Monte Carlo simulation based on three years of price data to compute its VaR for a 12-month holding period. As at March 31, 2010, Temasek's VaR was about S\$25 billion. This implies a 16% probability of incurring marked-to-market losses in excess of S\$25 billion, on a Net Portfolio Value of S\$186 billion for a 12-month holding period following that date. The diversified VaR of the top 10 companies contributed over 70% of the total diversified VaR as at March 31, 2010 (2009: 70%; 2008: 67%; see Table 2). Apart from tracking VaR, Temasek also conducts monthly stress tests and scenario analyses to gauge monthly the effect of low probability but high impact events. In addition, Temasek reviews its overall risk position on a monthly basis and provides additional analyses of specific event, industry or country risks. In terms of credit risk management, Temasek conducts periodic reviews of its exposures relating to counterparties, custodians, issuers and countries. Temasek's investment portfolios are typically denominated in the local currency of the countries in which the investments are made. Accordingly, Temasek's returns on these investments, including any dividends received from these investments, are usually subject to foreign exchange rate risks.

TABLE 2: TEMASEK VaR DEVELOPMENT BY SECTOR AND RISK FACTORS

Temasek VaR by Sector	2010	2009	2008
Financial Services	43%	41%	34%
Transportation and Industrials	21%	19%	18%
Life Sciences, Consumer and Real Estate	14%	13%	12%
Telecommunications, Media and Technology	14%	19%	28%
Energy and Resources	7%	7%	7%
Others	1%	1%	1%
Total	100%	100%	100%
Temasek VaR by Risk Factors			
Equity Risk	98%	99%	101%
Foreign Exchange Risk	6%	8%	7%
Interest Rate Risk	3%	5%	0%
Total Diversification Effects	-7%	-12%	-8%
Total	100%	100%	100%

* Diversification Benefits resulting from the interactions between the equity, foreign exchange and interest rate risk factors.

Other sources of risk

As at March 31, 2010, approximately 32% of Temasek's Net Portfolio Value was in Singapore. Any economic recession or other deterioration in one economy - Singapore's economy could materially and adversely affect the Temasek Group's results of operations, financial position and cash flows what creates significant risk for the whole investment portfolio. The Government, as a 100% shareholder of Temasek, through MOF, can exercise control over Temasek's corporate objectives, strategies and actions. While the Government has not taken any actions in the past to influence the corporate objectives, strategies or actions of Temasek, there can be no assurance that the Government will not take any actions in the future to influence the corporate objectives.

Temasek financial condition

The Temasek Group had total assets of S\$284.8 billion as at March 31, 2010. The Temasek Group generated revenue of S\$76.7 billion and profit attributable to equity holder of Temasek of S\$4.6 billion for the year ended March 31, 2010. The Temasek's results of operations are materially affected by conditions in the global capital markets and the economy generally, both in the U.S. and elsewhere around the world. Negative trends in these factors led to declines in Temasek Group's revenue and profit. In the event of extreme prolonged market events, such as the global credit crisis, the Temasek Group could incur significant losses. The following tables (see Table 3 and Table 4) sets forth selected income statement & balance sheet data for the Temasek for the years indicated.

TABLE 3: TEMASEK SELECTED INCOME STATEMENT DATA

(\$ million)	2010	2009	2008
Revenue	76 658	79 615	83 284
Net operating expenses	-72 570	-72 448	-63 125

Current liabilities	42 031	42 558	66 454
Total equity and liabilities	284 793	247 949	295 518

The global economy has experienced stress since the second half of 2007. Since then, concerns over inflation, energy costs, geopolitical issues, the availability and cost of credit, declining business and consumer confidence, and increased unemployment have slowed global economic growth and have resulted in recessions in numerous countries, including the U.S. and many countries in Asia. Global capital markets have also been experiencing heightened volatility and turmoil, and in the second half of 2008, the volatility reached unprecedented levels. The weak global economic conditions continued in 2009. While showing signs of improvement, the macroeconomic environment in 2010 remained for the Temasek difficult. In 2011 economic environment remain challenging with

significant uncertainty regarding the outcome of the debt crisis in Europe, unemployment levels, and the impact of the unwinding of stimulus measures by the U.S. and other governments.

The following chart (see Chart 4) describes mid-term decreasing profitability of the Temasek investment portfolio for the years indicated as an impact of the economic recession and worsened economic condition described above in the text.

CHART 4: TEMASEK PROFIT MARGIN AND ROE DEVELOPMENT OVER TIME

Conclusion

This paper presents information about investment strategy one of the most successful SWFs on the world – Temasek Holding. The paper also analyzes the main investments holdings in the Temasek portfolio. Also we examined historical financial performance and described main risk tools what is used by Temasek. We find that sovereign wealth fund can provide significant performance over long term period and SWF can be significant part of the economy.

Main factor behind the growth of SWFs is the effort by many emerging market countries to accumulate large stockpiles of international reserves by running persistent current account surpluses. Many of these countries, particularly in Asia, now hold more reserves than needed for prudential reasons. As we see in this paper, attempts to diversify these reserves into potentially higher-yielding assets entail transferring them from the control of the central bank to quasi-public entities, such as SWFs, with the mandate to pursue financial strategies aiming at higher long-run returns.

SWFs are fundamentally different from monetary authorities holding official foreign reserves, where liquidity and security issues necessitate a short investment horizon and low risk tolerance. As we see, SWFs typically seek to diversify foreign exchange assets and earn a higher return by investing in a broader range of asset classes.

By definition, the global sum of all current accounts adds up to zero. Hence, the still growing current account surpluses of commodity exporters and Asian countries will be the mirror image of the growing current account deficits of other countries, primarily the U.S. and the EMU. Excess saving and accumulation of foreign assets by surplus countries will be the counterpart to the excess demand and issuance of foreign liabilities by deficit countries.

The result, growing international wealth transfer from debtors in one country to creditors in others will foster the growth of SWFs in to the future.

Financial Wisdoms Reexamined from Stock Market History

*Edwin Hamilton, edwhamilton@yahoo.com
United States*

*Yanli Zhang, zhangy@mail.montclair.edu
Montclair State University, United States*

Charlie Munger once said: if you want to be a better investor, read history, read history, read history. History can provide us a perspective that is often lost in the daily noise and short-term thinking that is so overwhelming today. However, there have been relatively few studies in investment that provide a historical perspective, and for the few that do, they often don't provide a sufficiently long horizon or their perspectives might be biased. It is the purpose of this article to provide an appropriate historical perspective of stock market returns, and use that perspective to guide our thinking about future investment.

Before the recent financial crisis, it has become an almost commonly held 'truth' in the financial community that over a long period of time, equities will deliver better results than bonds. For decades, financial advisors were recommending people to invest a major proportion of their retirement account in stocks if they have a long horizon before retirement. People were educated that for the long term the stock market 'always' outperformed other investments, both from books in academics -- going as far back to Smith (1924) and more recently Siegel (1994), and an overwhelming number of articles in financial media. In fact, it is sometimes believed that this kind of public learning had contributed to the bull markets in the 1920s and late 1990s to early 2000s.

Supposedly based on the history of US stock data all the way back to 1802, Siegel (1994) came to the conclusion that became in fact faith to investors: Ever since Jefferson was president, stocks have generated a remarkable average return of nearly 10% a year. Siegel's conclusion and methodology have been challenged by many afterward (Shiller, 2004; WSJ, 2009a). For another example, in an article in August 2008, John Brennan, chairman of Vanguard Group, said that "financial theory and the empirical evidence suggest that stocks are our best chance at long-term growth", citing evidence that in the long run -- periods of 20 or 30 years or more, stock returns are likely to revert to historical averages of closer to 10% per year (Brennan, 2008). However, after the financial crisis, there has been some change of voices in the financial media that questions the deemed dominant role of stocks in long term portfolio (WSJ, 2009b), even though it has still remained a weak voice.

While Mr. Brennan warned against the loss of perspective from short-term thinking, there is another danger of loss of perspective from looking at nominal stock price histories unadjusted by inflation. Looking at stock market history in nominal price only tell us how much our wealth has grown on paper -- which might look huge, but not how much it is actually worth -- which is often surprisingly much less. That is why it is so important to use inflation adjusted stock price in order to provide the right picture of stock market returns over a long period of time.

For example, The Dow Jones Industrial Average Index (DJIA) is the U.S. stock market price indicator the media most often quote. Its units are U.S. dollars. Figure 1 shows an example of the kind of charts we commonly see in media that describes the history of Dow index. We can see if charting the history of the nominal DJIA, it looks like our wealth has grown enormously in the past decades. For example, in the peak-to-peak 70.3 year interval from September 1929 to January 2000, DJIA rose by 30.9 fold, as seen in Figure 1.

FIGURE 1: DJIA HISTORY

Source: http://en.wikipedia.org/wiki/Dow_Jones_Industrial_Average#History

However, what is not shown in Figure 1 is that over this same period of time, consumer price inflation has also grown a lot. In the same period as in the interval from 9/1929 to 1/2000, consumer price index CPI-U rose by 9.8 fold, as can be seen in Figure 2.

FIGURE 2: CPI-U HISTORY

Source: Bureau of Labor Statistics: <http://data.bls.gov/PDQ/servlet/SurveyOutputServlet>

Thus, we can see, a big part of the stock market appreciation is just the consumer price inflation. After accounting for the inflation, the Real Dow rose by just 3.2 fold in that same period from 9/1929 to 1/2000, as can be seen in Figure 3.

FIGURE 3: REAL DOW HISTORY

The comparison above shows what an extraordinarily different impression using real stock price index versus nominal stock price index makes in our minds in terms of stock market returns and how deceptive nominal stock price can be! Real stock market price history paints a much less optimistic picture of the stock market than the common conception of 10% long term stock market return according to the financial community and the media.

Yet most of time, the communication we receive from the industry insiders or financial media is couched in terms of nominal price indices. No wonder economists recognize that a big problem with our economy is the failure to take account of money illusion -- failure to reckon money as its purchasing power at the time (Shiller, 2009).

Perspective 1: What is the Real Dow Long Term Return?

Choosing the two big peak to big peak intervals as comparable periods (i.e., 9/29-1/66 and 1/66-1/00, together = 70.3 yr), a Quantitation obtains the rate of increase +1.64%/yr compounded annually as the long-term past performance of the Real Dow." The obtained +1.64%/yr looks very solid for the long-term past performance of the Real Dow. It comes from relating two periods/groups; further division into four groups gave +1.61%/year, see in Table 2 here below. Note here that 'the entire price ride' was taken by the composite average DJIA stocks-holder ('the average of everybody'), whose price experience we seek to characterize. His dividends received and frictional costs he paid out are cash flows, separate from the price experience.

The smooth curve in the Real Dow plot below increases at exactly 1.64 %/yr compounded annually (please here ignore the six black triangles and squares). It is scaled such that, over the 9/29-1/00 interval of 845 months, the average of all the 845 differences between the Real Dow and the curve, expressed as factors > 1 , is a minimum. (NOTE: a Real Dow = twice the curve's value, and a Real Dow = half the curve's value, are both a factor of 2 difference -- first is times 2, second is divided by 2.) Thus, this curve is a best-fit, as described, constant rate of increase (exponential) to the Real Dow over the 9/29-1/00 interval. Notably, the Real Dow equalled: $2.53 \times$ curve in 9/29; $\text{curve}/2.57$ in 7/32; $2.06 \times$ curve in 1/66; $\text{curve}/2.38$ in 6/82; $2.55 \times$ curve in 1/00.

FIGURE 4:

If we take into account the dividends and frictional costs, we come to the startling conclusion that “Calculated Certainty Equivalent of the Long-Term Past DJIA is Slightly Inferior To Long-Term TIPS Held to Maturity Yielding ca. 2.7-3.2 %/yr Real Interest Rate”. Guided by Campbell and Viceira (2002) and Goldstein, Johnson and Sharpe (2006), we used the constant relative risk aversion (CRRA) utility function, with the coefficient of relative risk aversion equal to 5. The resulting certainty equivalent ratio = 0.977 (a TIPS held to maturity = 1), which gives the above conclusion.

In reaching this conclusion, we take into account dividends and frictional costs. The average DJIA dividend yield during the 70.3 yr period 9/29-1/00 was ca. 4.2%/yr. Frictional Costs are the expenses associated with stocks-holding and stocks-transaction. Warren Buffett has elaborated at length on frictional costs. As reported, Warren Buffett has three times during mid-1999 to mid-2003 estimated these frictional costs: 1 %/yr, 7-9/1999; 1 %/yr, 7-12/2001; 1.5 %/yr, 5/2003. We accept Buffett's 1-1.5 %/yr frictional costs for the recent U.S. stock market; and we use the same 1-1.5 %/yr for the DJIA stocks, both for recently and for the long-term past. Sum of Both ca. 4.2%/yr dividends minus 1.0-1.5 %/yr frictional costs equals ca. 2.7-3.2 %/yr cash flow. While for TIPS, frictional costs are reckoned zero or negligible for TIPS held to maturity in TreasuryDirect. No wonder Shiller says: “the evidence that stocks will always outperform bonds over long time intervals simply does not exist” (Shiller, 2006, pp198). Moreover, even if history supported this view, we should recognize (and at some level most people must recognize) that the future will not necessarily be like the past.

Perspective 2: Is Buy and Hold the Best Policy?

Another common advice from financial advisers is that individual investors should buy and hold if they have a long term investment horizon, and not try to time the markets or worry about short-term losses. This piece of advice clearly builds upon the above conception that equities will generally in the long run do better than bonds. Not only that, people have been persuaded that the stock market is not really risky if held for the long term, and that a long term horizon would iron out the ups and downs in the markets.

However, the real history as shown in Figure 3 clearly shows that if people just adheres to the buy and hold strategy and get in the market at the peak, it could sometimes take 30 years just to get back to the original level of real purchasing power, such as from 1929 to 1959, and from 1966-1996. Note that this is a much more dramatic picture than provided by the nominal Dow history, which may give a misleadingly optimistic picture of how fast stock market rebounds. Even more shocking, we can see that the Real Dow of 12.4 in June 1982 is even less than that of 56.6 years earlier in November 1925.

It is well known that financial markets are not efficient. It has been said that the aggregate stock market in the United States in the last century has been driven primarily by psychology and fads and has shown massive excess volatility (e.g. Kindleberger, 2005, Shiller, 2004). Buffett describes Mr. Market as an emotionally unstable character, subject to wide mood swings, sometimes to an extreme extent. Since financial markets are made up of the collective actions of all investors, they are invariably influenced by human behavior. Collective herd behavior in the stock market can be so widespread that it leads to wildly inaccurate market valuations, overinflated during euphoria, and underestimated when pessimism overrules. In fact, there's something very hard-wired in human nature and psychology that produces financial bubbles and crises (e.g. Mackay, 1995).

Figure 5 shows clearly 3 asset bubbles in the 80+ year history since the 1920s, and these bubbles have been publicly warned by a Fed chairman. Evidently, in the more than 90 years since the Fed was founded in 1913, a Fed chairman has only 3 times publicly warned that the stock market was overpriced, as seen around 1/1929, 5/1965, and 11/1996 in Figure 5. Note that there is no lack of easy rationalization for a herd behavior periodicity of ca. 3 to 3.5 decades -- people only live so long, and they take their 'lived through it' experience with them; they get replaced with people who, at best, only read/heard about it. After all three Fed chairman warnings, the market crashed sooner or later.

FIGURE 5: FED WARNING

Perspective 3: How did We Get Here and What Does it Mean for the Future?

Another look at Figure 5 gives us the striking impression that the real Dow prices after the 1990s are so much higher and out of line with the previous decades in history. Compare that to a typical chart we read in the media, in there the time span is often much too short to show enough of a historical perspective, and it is often shown in nominal prices and thus doesn't provide the right benchmark across time. Short term thinking dominates what we see and hear every day, to the extent of overwhelming and misleading us, and in-depth historical perspectives in real price terms like these are seldom made available to the public to be seen.

Before the crash of 2008, most of what we heard in the media is that we had been living in the greatest growth era since the 1990s, and this grand growth was continuing. This is an easy conclusion if we simply look at the trend of nominal stock price since the 1990s, out of the context of the longer history. However, if we look at the long term Dow history as shown in Figure 5, we see extremes do commonly end and reverse "naturally", like how markets dropped severely after hitting a lofty point, after the previous two warnings from Fed chairman. The bubble burst because it formed (Sornette, 2004). Thus, looking at Figure 5, one has to wonder about that continuous growth picture painted by the financial industry and media, and whether this kind of dangerously high level can sustain forever or not.

What is the engine that has been powering this greatest growth era of all? We have another chart, shown in Figure 6, which shows that Real Dow price and Real Home price seem to go up together after the mid 1990s. It seems that the increasing home prices and home ownership had been one of the underlying forces for the growth of the economy and the stock market, thanks to the influences coming from the financial industry, main stream media, and the government.

FIGURE 6:

http://homepage.mac.com/ttsmyf/RD_RJShomes_PSav.html (see continuously updated chart here).

On the other hand, what has been financing all this growth in home ownership and home price? Figure 7 shows the personal saving rate and ratio of household debt to personal income. It is quite an alarming picture. Americans have been financing their homes with an ever higher debt level, and the inflated home price has been enabling to get into further debt. This debt-ridden picture provides us with a gloomy picture of what is going to drive future US consumer purchasing power and economic growth.

http://homepage.mac.com/ttsmyf/moPSav_quartDB.html

This sad phenomenon of the public not being rightly informed or even misled is rooted in the incentive structure and institutions of our financial industry, media, and the government (Bogle, 2008). Most of the public rely on the financial media to inform them about the stock market, and financial media rely on financial industry insiders to provide that kind of information or opinion. For these financial industry insiders, it is more often than not in their favor to paint a rosy picture of the stock market so that more money can be made from more enthusiasm and participation in the stock market. The government has also admitted that the promotion of home ownership as 'American Dream' has been seriously misleading and is planning to shift to a more balanced housing policy.

Compensation at American Commercial Banks Before and After the Financial Crisis of 2007-2008

*Richard Lord, lordr@mail.montclair.edu
Montclair State University*

Abstract

Since the onset of the financial crisis in 2007, compensation of the top executives in American banks declined markedly. Bonuses dropped sharply from their peak in 2005, and by 2009 the median executive received no bonus. Option grants had been shrinking since 2002, and the crisis has hastened their decline. Before the crisis, the use of restricted stock grants had been on the upswing. While the level of stock grants was lower after the shock, it remained more robust than the other forms of performance-based compensation. In tests of my first hypothesis I find that while both bonuses and equity grants are insensitive to declines in earnings, the same does not seem the case for the effects of stock returns and revenue growth on compensation. I also find that the crisis has clearly had a major impact in how performance-based pay is granted to American bank executives.

Introduction

Since the financial crisis, which began in the fall of 2007, swept first through the United States then much of the rest of the world, the executive compensation practices of financial institutions has been a burning subject. Even before the collapse, there had been long-simmering resentment over levels of executive pay in general, and in the financial industry in particular. During the crisis in late 2007 and early 2008, governments across the world stepped-in to bailout these institutions, which prompted more criticism of excessive levels of pay financed through the benevolence of tax payers. In the ensuing years there has also been a fierce debate over whether the design of pay packages created incentives for excessive risk-taking by financial institutions.

I examine the relationship between firm performance measures and executive bonuses and equity grants among commercial banks in the United States. I concentrate on two specific executive compensation issues for these institutions. First, are bonuses and equity grants to executives equally sensitive to poor performance as to good performance? Second, has the sensitivity of these pay elements to firm performance changed significantly since the crisis?

In the next section I review the previous literature and present my hypotheses. I then describe the characteristics of the sample. The model specifications to test the hypotheses are described in the fourth section. The empirical results are then presented. Finally, the findings are summarized.

Literature Review and Hypotheses

Murphy (1999) provides a classic study of general executive compensation practices. He notes a rapid growth in stock option compensation through the 1990's. Cai and Milbourn (2010) and Lord and Saito (2010) note that for financial institutions, this trend continued until the dot.com crisis, peaking in about 2002. Since then, the use of restricted stock grants has begun to supplant option compensation. Traditionally, the other widely used form of performance-based compensation was bonuses. The most commonly used explicit basis for bonuses is normally a measure of profitability; earnings per share being the most widely used. Another common measure is growth in revenues. There is also evidence that bonuses are correlated with stock returns (see Hall and Liebman, 1998). Murphy also notes that to some extent most executive bonuses have a discretionary component. In a study of executive compensation before the crisis at the largest financial institutions in the United States, Hodgson (2010) found that the most common explicit performance measure used as the basis for bonuses was return on equity (ROE) and growth in revenue. Murphy notes that most performance-based compensation plans have a major discretionary component. In fact, many are purely discretionary.

There is a long-standing charge that executive compensation is insensitive to poor firm performance. That is, pay rises when firm performance is good, but executives do not feel the pain when performance is poor. The most prominent complaints about this behavior in general have been raised by Bebchuk, Fried and Walker (2002) and Bebchuk and Fried (2004). However, theoreticians in finance, such as Holstrom (1979), Smith and Stulz (1985) and Smith and Watts (1992), have long argued exactly the opposite; that it is necessary to provide convexity in executive pay packages. Because managers tend to hold poorly diversified portfolios, and they are individually risk-averse, they will tend to forgo investment in risky, but value-increasing, projects if they are exposed to downside risk to the same extent as upside payoffs. However, several years before the crisis, John and Qian (2003) warned that aligning the pay incentives of managers of highly levered financial institutions closely with those of their shareholders, would probably create excessive risk-taking incentives.

Since the public ire over the bailouts of Wall Street firms has been so intense, politicians have begun arguing about curbing the amount and design of managerial pay. Recently (June 17, 2009), President Obama stated "... excessive executive compensation – unmoored from long-term performance or even reality – rewarded recklessness rather than responsibility." At about the same time the Department of Treasury suggested guidelines for executive pay by financial firms receiving federal bailout funding (February 4, 2009), which mandated that any compensation above \$500,000 must come as restricted stock grants. This has been discussed as a viable blueprint for wider legislation by many in congress.

There is also a widely-held perception that the pay of bank executives has changed little since the beginning of the financial crisis. The appointment of Kenneth Feinberg as a "Pay Czar" to oversee the pay practices of institutions that received Troubled Asset Recovery Plan (TARP) funding, attests to the presumption that executives would not reduce their compensation. To the contrary there is clear evidence that annual pay for executives in the financial sector declined markedly, though it is beginning to move back up-ward. A recent survey by the Comptroller of the State of New York (Goldman and Moore, 2011), shows that cash bonuses are half of their level in 2006. The deeper concern is that the structure of the compensation packages is not changing dramatically. In an influential study, Hodgson (2010) notes there has been little shift away from short-term compensation targets to long-term goals.

I will test two hypotheses regarding the design of executive compensation among American commercial banks. The first is:

H1: Executive bonuses and equity grants are as sensitive to poor performance as to good performance.

The second is:

H2: The relationship of executive bonuses and equity grants with firm performance are the same during and after the financial crisis (2007 through 2009) as they were in the period before (1992 through 2006).

Sample Sources and Statistics

I will test these hypotheses using a sample of American commercial banks with executive compensation data available on the EXECUCOMP database. This source contains comprehensive information on the pay to the five most highly paid officers for a sample of firms corresponding roughly to the S&P 1,500. The data is available from 1992 through 2009. I will restrict my sample to institutions in the three-digit SIC code 206, which is for commercial banks. It is important to be mindful that much of the popular discussion of compensation at "banks" is actually about large investment banking institutions. So results from my sample may differ from conjectures about such firms.

To gain a notion of the financial performance of these banks throughout the sample, median performance measures for the sample are given in Table 1. The number of firms declines through time because of mergers and acquisitions in this sector. There is a corresponding increase in nominal revenue from 1993 to 2009. The figures for the percentage change in revenue show a period of high growth from 1994 to 2000, three quiet years during the crash of the dot.com bubble, more growth from 2004 through 2007, and then two years of large declines in revenue. There is a similar increase net income from 1993 to 2009. Again, there is a very sharp drop in 2008 and 2009. For such highly levered enterprises, the median level of return on equity is surprisingly stable from 1992 to 2007, hovering around the sample median of 14.10%. This sets off the sharply lower levels of ROE in the last two years.

The median stock return over the eighteen years is 14.27%. Returns in 1995, 1996 and 1997 are incredibly high. Average returns are negative in 1998 and 1999, then there is another five-year period of positive median returns. Not surprisingly, the performance of the shares in 2007, 2008 and 2009 is abysmal.

Data on the annual composition packages for the CEOs in the sample are given in Table 2. For bonuses, option grants and restricted stock grants, the means are much higher than the medians, showing these components of compensation are highly skewed. Nominal salary rises slowly over the period. The mean of bonus payments also rises steadily, but the medians vary more. As noted in earlier studies, such as Cai and Milbourn (2010) and Lord and Saito (2010), there was rapid growth in option grants from 1993 to 2002 in the financial services industry. After that, their use begins to decline. Restricted stock grants were once rare; the medians in all but the last year are zero. But, the means show a clear growth in their use.

In 2008 and 2009 median bonuses for CEOs fall to zero. There is also a noticeable drop in option grants. So the annual pay of these executives did drop sharply during the period of financial crisis. Restricted stock grants also decline, but not as sharply as the other performance based elements of pay. This is probably because of the political lobbying encouraging the use of restricted stock compensation. There is an interesting rise in (mean) salary compensation in 2009. The Comptroller of the State of New York (Goldman and Moore, 2011) notes this shift away from performance-based pay toward straight-salary continued in 2010.

A summary of the composition of annual pay packages for the non-CEO executives in the sample is given in Table 3. Not unexpectedly, the magnitude of the elements of compensation for these lower level managers is notably smaller than for the CEOs. But, the patterns through time are similar. Salary and bonus payments drift up through most of the sample period. Option grants rise sharply, then begin to decline. There is evidence that restricted stock grants begin to increase near the end of the period. Again, there is a sharp drop in bonuses and option grants in 2008 and 2009, and restricted stock grants do not decline as sharply. The jump in mean salary in 2009 is also evident.

The data in these three tables suggest that managerial compensation in the banking sector rose during the period from 1993 to 2006. But, revenues and net income also increased steadily. This seems consistent with recent evidence, such as Hall and Murphy (2003) and Gabaix and Landier (2008), which suggests that levels of executive compensation are highly correlated with firm size. There is also strong evidence that the compensation of most bank executives declined very sharply during the crisis (in 2008 and 2009). This is contrary to the popular perception that the level of pay of managers in the sector was little affected by the collapse.

Model Specification

I first define two base regression models to explain bonuses and equity grants to executives in the US banking sector. The base model to explain bonus compensation is specified as:

$$\text{BONUS} = \alpha_0 + \alpha_1 \text{LBONUS} + \alpha_2 \text{DCEO} + \alpha_3 \text{CAP} + \alpha_4 \text{LREV} + \beta_1 \text{STKRET} + \lambda_1 \text{ROE} + \delta_1 \text{REVGR} + \varepsilon. \quad (1)$$

The dependent variable, BONUS, is the sum of bonuses and payments under long-term incentive plans to a bank executive. The next four terms LBONUS, DCEO, CAP and LREV are all control variables. LBONUS is the lagged bonus for the same executive in the previous year. DCEO is a dummy variable set to one if the particular executive is the corporate CEO in this year, and set to zero otherwise. CAP is a proxy for the firm's capital structure; defined as the book-value of corporate liabilities, divided by the sum on the book-value of corporate liabilities, the book-value of preferred stock and the market value of common equity. LREV, the logarithm of revenues, is a proxy for firm size. A regression model with BONUS as the dependent variable, with only these four independent variables (detailed results not shown), explains over 76% of the variability in executive bonus pay. The three independent variables to proxy the firm performance factors that should influence (or be influenced by) executive compensation are STKRET, ROE and REVGR: STKRET is annual stock return, ROE is return on equity, and REVGR is growth in corporate revenue for the year. BONUS and LBONUS are obtained from the EXECUCOMP database, and all other variables from COMPUSTAT. The ε is an error-term with the usual properties.

A similar base model is specified for annual executive equity grants:

$$\text{EQGR} = \alpha_0 + \alpha_1\text{LEQGR} + \alpha_2\text{DCEO} + \alpha_3\text{CAP} + \alpha_4\text{LREV} + \beta_1\text{STKRET} + \lambda_1\text{ROE} + \delta_1\text{REVGR} + \varepsilon. \quad (2)$$

Here EQGR is the value of annual executive equity grants (stock options grants, at either Black-Scholes, 1973, or fair market value, plus restricted stock grants), and LEQGR is the value of equity grants for the previous year. Both are obtained from EXECUCOMP. All other variables are as defined above. A regression model with EQGR regressed on the four control variables alone (results not shown), explains about 67% of the variability in executive equity compensation.

The first hypothesis is that the effect of the firm performance variables have a different impact on executive compensation when they are negative than when they are positive. To test this hypothesis, I create three one-zero dummy variables. D_STKRET is set to one when stock return is negative, and to zero otherwise. D_ROE is set to one when return on equity is negative, and zero otherwise. D_REVGR is set to one when revenue growth is negative, and zero otherwise. Then, I create a set of three cross-product terms, which are each variable multiplied by the corresponding dummy variable, N_STKRET, N_ROE and N_REVGR, respectively.

The equation to test the first hypothesis for executive bonus compensation for is specified as:

$$\text{BONUS} = \alpha_0 + \alpha_1\text{LBONUS} + \alpha_2\text{DCEO} + \alpha_3\text{CAP} + \alpha_4\text{LREV} + \beta_1\text{STKRET} + \beta_2\text{D_STKRET} + \beta_3\text{N_STKRET} + \lambda_1\text{ROE} + \lambda_2\text{D_ROE} + \lambda_3\text{N_ROE} + \delta_1\text{REVGR} + \delta_2\text{D_REVGR} + \delta_3\text{N_REVGR} + \varepsilon. \quad (3)$$

The corresponding equation to test the first hypothesis for executive equity compensation is:

$$\text{EQGR} = \alpha_0 + \alpha_1\text{LEQGR} + \alpha_2\text{DCEO} + \alpha_3\text{CAP} + \alpha_4\text{LREV} + \beta_1\text{STKRET} + \beta_2\text{D_STKRET} + \beta_3\text{N_STKRET} + \lambda_1\text{ROE} + \lambda_2\text{D_ROE} + \lambda_3\text{N_ROE} + \delta_1\text{REVGR} + \delta_2\text{D_REVGR} + \delta_3\text{N_REVGR} + \varepsilon. \quad (4)$$

The second hypothesis is that the effect of the firm performance variables has a different impact on executive compensation after the onset of the financial crisis at the end of 2007 than they did before. To test this hypothesis, I create a one-zero dummy variable, D_2006, which is set to one in the years 2007, 2008 and 2009, and is set to zero in prior years. I again create three interactive terms, which are the product of each firm performance measure with this dummy variable, T_STKRET, T_ROE and T_REVGR, respectively.

The equation to test the second hypothesis for bonus compensation is then specified as:

$$\text{BONUS} = \alpha_0 + \alpha_1\text{LBONUS} + \alpha_2\text{DCEO} + \alpha_3\text{CAP} + \alpha_4\text{LREV} + \mu_1\text{D_2006} + \beta_1\text{STKRET} + \beta_4\text{T_STKRET} + \lambda_1\text{ROE} + \lambda_4\text{T_ROE} + \delta_1\text{REVGR} + \delta_4\text{T_REVGR} + \varepsilon. \quad (5)$$

The model to test the second hypothesis for executive equity grants is:

$$\text{EQGR} = \alpha_0 + \alpha_1\text{LEQGR} + \alpha_2\text{DCEO} + \alpha_3\text{CAP} + \alpha_4\text{LREV} + \mu_1\text{D_2006} + \beta_1\text{STKRET} + \beta_4\text{T_STKRET} + \lambda_1\text{ROE} + \lambda_4\text{T_ROE} + \delta_1\text{REVGR} + \delta_4\text{T_REVGR} + \varepsilon. \quad (6)$$

I estimate each of these models using pooled cross-sectional data, drawing observations on all of the executive salaries reported for each firm, for each available year between 1992 and 2009. Because the firms in the industry are relatively homogeneous, I do not employ firm-specific or executive-specific dummy variables. For each model I make an initial estimation and identify any outliers that could seriously bias parameter estimates. I eliminate all observations that have residuals with a Cook's D value higher than one, and/or an R-Student value with an absolute value greater than three. See Welsch (1980) for more details on these methods.

Empirical Results

Summary statistics for the fourteen variables used in this study are given in Table 4. There are several interesting characteristics in the data. As expected the financial leverage (CAP) used by these banking firms is very high. As seen above, the management compensation variables (BONUS, LBONUS, EQGR and LEQGR) are highly skewed. The same is true for firm size (LREV). Means for the dummy variables show that 15% of the executives are CEOs, about 33% of observations have negative stock returns, almost 29% have negative annual revenue growth, less than 6% have negative ROE, and about 16% of observations are during the crisis period of 2007 through 2009.

Results for the three models that explain executive bonuses as a function of firm performance are given in Table 5. The estimates for the base model, equation 1, are shown in the first column. All of the control variables are statistically significant. As expected, current bonuses are positively correlated with bonus for the prior year, and with firm size. As was evident in Tables 2 and 3, CEOs receive higher bonuses than other executives. Bonuses are negatively correlated with the use of financial leverage. As anticipated, bonuses are positively related with stock returns and growth in revenue. Surprisingly, they are negatively correlated with ROE. Earnings are usually the fundamental explicit determinant of bonus payments, so a positive relationship was anticipated. However, the results in the other two columns shed some light on the reason for this negative sign.

The results for equation 3 to test the first hypothesis for bonus payments are shown in the second column of Table 5. This specification examines whether bonuses are insensitive to poor firm performance. Parameter estimates for the control variables are similar to those for the base model. Here β_1 on stock return is no longer statistically significant. But, β_2 is negative and significant, and β_3 is positive and significant. Collectively these results suggest that bonuses are little affected by positive stock return, but bonuses decline dramatically when stock prices fall. Earlier, Leone, Wu and Zimmerman (2006) also found that cash compensation was more sensitive to stock price declines than increases for a broader sample of firms. In equation 3, λ_1 on ROE is positive as expected. The parameter estimate on the interactive term, λ_3 , is significantly negative, and of roughly the same magnitude as for λ_1 . This means that when earnings are positive, bonuses rise with ROE, but when earnings are negative, bonuses are flat. This is exactly the relationship between earnings and bonuses described by Murphy (1999). Interestingly, λ_2 on the dummy variable is positive and significant, suggesting managers of firms with negative ROE have somewhat higher bonuses than others. The parameter δ_1 is again positive, suggesting that bonuses rise with increases in firm revenues. Both δ_2 and δ_3 would only pass a confidence test at the 90% level. Since they are both negative, they tell somewhat conflicting stories. The negative sign on the dummy variable, δ_2 , sensibly suggests are lower when firm size declines. On the other hand, δ_3 is opposite the sign on δ_1 and is of a greater magnitude, which might suggest that the correlation becomes negative when revenue declines. But, since the values of revenue growth are, by definition negative in this range, this implies that as firm size declines bonuses rise.

Results for equation 5 to check the second hypothesis, whether executive bonus compensation changed during the financial crisis years of 2007 through 2009, are shown in the third column of Table 5. Again, the parameter estimates on the control variables are similar to those in the base model. The parameter on the dummy variable for the crisis period, μ_1 , is not statistically significant. The coefficient β_1 is positive and significant, meaning bonuses rise with increasing stock returns and fall with declining stock returns. The parameter, β_4 is not significant, which means this relationship is no different during the crisis from the period before. In this model, λ_1 is positive and significant, which implies a positive relationship between ROE and bonuses before 2007. The parameter on the cross-product term, λ_4 , is negative, significant and of roughly the same magnitude as λ_1 , which implies that the linear relationship disappears during the crisis. Clearly, the incidence of negative measures of ROE was much higher in this period; overall only about 5.50% of the observations were negative, but in the three crisis years almost 27% were negative. The coefficient δ_1 on revenue growth is again positive. But, in the crisis period the significant negative magnitudes of δ_4 would suggest a negative relationship between revenue growth and bonuses.

The empirical results for the three models to explain the relationship between executive equity grants and firm performance are given in Table 6. The results for equation 2, the base model, are shown in the first column. The coefficients on all four of the control variables are statistically significant. Equity grants in the current year are positively correlated with those from the previous year, and with firm size. CEOs receive higher grants than other

executives. Grants are negatively related with financial leverage. The signs for these parameters are the same as for the models of bonus compensation. The parameter λ_1 is not statistically significant, suggesting no relationship between ROE and equity grants. As expected, the grants are positively correlated with revenue growth. In this model the curious result is a negative relationship between stock return and equity grants. Normally, equity grants are thought of as a reward for firm performance. But, an alternative view is that they are an incentive for better performance in the future. This might suggest that managers of firms with poor stock performance be given more stock-based pay.

The empirical results for equation 4 to test the first hypothesis, that executive equity grants are equally sensitive to poor firm performance measure as to positive performance, are given in the second column of Table 6. The coefficient estimates on the control variables are similar to those for the base model. As in the base model, the parameter β_1 on stock returns is significantly negative. The coefficient, β_3 , on the interactive term is not statistically significant, meaning that the negative relationship between managerial equity grants and share returns holds equally when returns are negative as when they are positive. The estimate for β_2 is also negative and significant, suggesting that equity grants are somewhat lower when stock returns are negative. The parameter λ_1 is positive and significant, and λ_3 is negative, significant, and of roughly the same magnitude as λ_1 . This implies that managerial equity grants rise with ROE when earnings are positive, but it does not fall with earnings when ROE is negative. This is exactly like the relationship between executive bonuses and ROE. The relationship between equity grants and revenue growth is also similar to that for bonuses. The parameter δ_1 is positive and significant, so when revenues are growing, grants increase with firm size. But, δ_3 is negative and of a greater magnitude than δ_1 . Therefore, because revenue growth is negative in this range, equity grants rise as firm size shrinks. The coefficient δ_2 is significant and positive, suggesting that equity grants are a bit higher when revenues are declining.

Results for equation 6 to test the second hypothesis, that performance is the same during the crisis as before, are shown in the third column of Table 6. Again, the sign of the coefficients for the control variables are similar to those in the base model. In this case, μ_1 is positive and significant, suggesting, that all else the same, equity grants are actually higher during the crisis than before. This is presumably because of the decline in option grants after the dot.com crash near the turn-of-the-century, and the marked increase in restricted stock grants in the last few years. In this specification, the parameter β_1 on stock returns is again negative. The coefficient β_4 is negative, significant and of roughly the same magnitude of β_1 . This means that there is no linear relationship between managerial equity grants and stock return during the crisis. The coefficient λ_1 is positive and significant, and λ_4 is negative, significant and of roughly the same magnitude as λ_1 . This implies that before the crisis there was a positive relationship between equity grants and ROE, but, during the crisis this relationship disappears. The parameter δ_1 is positive and significant, meaning that before the crisis there was a positive relationship between revenue growth and executive equity grants. The coefficient δ_4 is also positive, meaning the positive relationship becomes even stronger during the crisis. Because almost 54% of the firms exhibited declining revenues during the crisis, this implies that equity grants were probably increasing when firm revenues declined.

Summary

Since the onset of the financial crisis in autumn 2007, the annual compensation of the top executives in American banks declined markedly. Bonuses dropped very sharply from their peak in 2005. In fact, the median CEO received no bonus in either 2008 or 2009, and the median of other top officer was also zero in 2009. Option grants had been shrinking since 2002, and the crisis has hastened their decline. Before the crisis, the use of restricted stock grants had been on the upswing. While the level of stock grants was lower after the shock, it certainly remained more robust than the other forms of performance-based compensation.

My first hypothesis is that the compensation of bank executives is not as sensitive to poor firm performance as to positive results. Both bonuses and equity grants are positively correlated with ROE when earnings are positive, but this relationship disappears when ROE is negative. This is thought to be common of the design of bonus contracts. But, it is interesting that equity grants also seem to be insensitive when earnings are negative. The positive relationship between equity grants and stock returns holds equally whether returns are rising or falling. On the other

hand, bonuses are uncorrelated with positive stock returns, but they decline when share prices fall. Both bonuses and equity grants have an interesting relationship with growth in revenues. Both forms of performance based compensation rise when the level of revenues change, be it rise or fall. There is little reward if revenues remain relatively constant. While both bonuses and equity grants are insensitive to declines in earnings, the same does not seem the case for the effects of stock returns and revenue growth on the compensation of bank executives.

The second hypothesis is that the design of executive compensation grants remained unchanged by the crisis. Both bonuses and equity grants are positively related to ROE before the crisis. But, during and after this relationship disappears. Interestingly, before the crisis, equity grants are negatively correlated with stock returns. This may mean that these grants are used primarily as inducements for managers of poorly performing banks to improve. But, during the crisis this negative relationship disappears. In contrast, bonuses are positively related with stock returns, both before and after the crisis. Both bonuses and equity grants are positively related with revenue growth before the crisis. However, after the crisis, the relationship of bonuses with firm growth turns negative, and that with equity grants becomes more strongly positive. Therefore, the crisis has clearly had a major impact in how performance-based pay is granted to American bank executives.

FDI in Banking Services: An Analysis of ‘Behind the Border’ Regulations

*Pralok Gupta pralok07@iimb.ernet.in;
Indian Institute of Management, India*

Abstract

This paper focuses on regulatory barriers affecting foreign direct investment (FDI) in banking services and quantifies such regulatory restrictiveness. It examines the extent to which this restrictiveness is due to ‘Behind the Border’ (BtB), i.e., operational restrictions as opposed to border level, i.e., entry level regulations and estimates changes in such restrictiveness over time (1995-2010) in India. It also examines the relationship between changes in regulatory environment with availability of export credit given critical input role played by banking services in enabling credit facility for goods and services trade. The paper finds that total regulatory restrictiveness affecting foreign investment has reduced over time and ‘BtB’ restrictiveness has also reduced but with a lesser degree. Increased liberalization and consequent reduction in restrictiveness indices is associated with increased availability of export credit. The performance indicators for foreign banks also show their improved performance in the wake of liberalization in India’s banking sector.

1. Introduction

Banking and financial services are the backbone of any economy. Sound and efficient banking and financial services are needed to compete internationally. Banking service is an important producer service as every transaction in domestic or international trade requires credit and financial intermediation. Francois (1990) argues that banking services are complimentary to the production process and efficient banking services can help in scale expansion and technological innovation. A highly regulated banking sector can hurt the efficiency of the entire economic system. It is, however, important to note that uncontrolled and undirected liberalization in banking services can also lead to inefficiencies and can threaten macroeconomic stability. Therefore, while it is important to liberalize banking services to improve efficiency, it is also necessary to have a cautious and well planned approach to liberalization.

This paper estimates and quantifies the incidence of regulatory restrictiveness affecting foreign investment in banking services in India and tries to assess the likely implications of liberalizing these measures for trade and investment flows in the banking services and in related areas of the economy.

This paper contributes to the existing body of literature in many ways. It differentiates between ‘At the Border’ and ‘Behind the Border’ regulations in the banking services and constructs separate indices for these regulatory barriers to assess the actual liberalization of banking services in India. It improves the existing templates of earlier studies, which have focused on overall regulations, to include ‘Behind the Border’ regulations such as freedom to purchase immovable property, tax structure, complexity of tax laws etc. for calculating trade restrictiveness indices. In the process, it also takes into account non-discriminatory regulatory policies affecting foreign firms. Another important contribution of this paper is to do a time series analysis of the incidence of regulatory barriers affecting foreign investment in banking services and liberalization of such barriers, compared to most previous studies which involved only one or two points in time estimations.

The rest of this paper is structured as follows. The next section provides a conceptual analysis of ‘At the Border’ and ‘Behind the Border’ regulatory barriers. Section three reviews the existing literature on regulatory barriers affecting services trade and quantification of such barriers and identifies research gaps based on the literature review. The fourth section provides overview of methodology and data sources used for quantification work. Section five presents results of such quantifying exercise. The last section outlines the policy implications of this research and concludes with a brief discussion of the limitations and possible future extensions of this work.

2. ‘At the Border’ vs ‘Behind the Border’ Regulatory Barriers

Regulations and protectionist measures affecting foreign investment in banking services can be classified into two categories. The first category pertains to restrictions or regulatory requirements which affect the entry of foreign investors in the host country. These are typically border level regulations such as limits on foreign direct

investment, restrictions on the form of entry, and other entry level measures which affect foreign and domestic service providers differentially. The second category pertains to those regulations which affect the ongoing operations of foreign firms after their establishment in the host country. These are termed 'Behind the Border' regulations, and include for instance, licensing and authorization requirements, restrictions on purchase of immovable property, and may or may not apply differentially to domestic and foreign service providers.ⁱ

Conceptually, the difference between these two types of measures, as explained in Deardorff and Stern (2008), is that border regulations restrict the establishment of foreign service providers within a host country, thus reducing the number of service providers and hence the quantity supplied at a given price (an upward or leftward shift of the supply curve), while regulatory barriers which affect ongoing operations do not affect the numbers of suppliers but increase their costs, thereby resulting in a higher price for a given quantity.

Regulatory measures affecting services trade can also be divided into discriminatory and non-discriminatory measures, i.e., measures which apply only to foreign service providers and measures which apply to both domestic and foreign service providers.

This paper differentiates between 'At the Border' (henceforth AtB) and 'Behind the Border' (henceforth BtB) regulations affecting foreign investment in banking services, however, it does not differentiate between discriminatory and non discriminatory regulations, as it is implicitly assumed that even when regulations are non-discriminatory in content and application, they are likely to affect foreign service providers more than domestic providers due to the administrative and procedural complexities they introduce and due to their limiting effect on market contestability.ⁱⁱ

3. Literature Review and Research Gaps

While significant progress has been made in recent years in analyzing barriers to goods trade, there has been relatively little progress in the case of services trade (Deardorff and Stern 2008; Hoekman and Braga 1997). Griffiths (1975) was perhaps the first study to document the barriers to international trade in services. There exist different types of barriers on foreign investment in services trade, in general and more for banking services. Findlay and Warren (2000) in their study suggest that barriers to such trade appear to be substantial, especially on foreign investment. They reported that there is significant discrimination against foreign providers of services as compared to domestic service providers.

UNCTAD (1996) suggest a three part classification system to define barriers affecting foreign investment in services. These are related to restrictions on Market entry, Ownership and Operations of the foreign firms. Using this three part classification system, Hardin and Holmes (1997) list the major restrictions on inward FDI in service sectors for selected APEC countries. They consider restrictions on the level and share of foreign ownership, application of some form of screening or registration process, widespread use of case-by case based assessments, restrictions on ownership and control such as restrictions on Board membership etc. as the primary barriers to foreign investment in service sectors.

With the improved understanding of barriers to services trade over time, attempts have also been made to quantify these barriers. The pioneering work on quantification of regulatory barriers and creation of restrictiveness indices is done by economists and researchers at the Australian Productivity Commission (APC), the Organization for Economic Cooperation and Development (OECD) and the World Bank. These economists estimate restrictiveness indices for various service sectors across countries. The quantitative estimates of the Australian Productivity Commission do not focus specifically on discriminatory policies; rather they are more inclined towards assessing the impact of regulations. The OECD quantification work focuses mainly on entry barriers such as ownership limits, barriers to establishment etc.

An analysis of available literature reveals that the regulatory regimes considered in the existing and ongoing studies do not differentiate between 'At the Border' regulations and 'Behind the Border' regulations. In the absence of such differentiation, it is difficult to assess the trend and nature of liberalization. This is of particular importance for banking services as many of the domestic regulations in this sector are of 'Behind the Border' type. Apart from that, the empirical work on barriers to services trade has focused more on discriminatory policies to assess the impact of imposing such regulatory barriers. The policy indices are constructed by identifying regulatory policies affecting entry and establishment and then determining if policies differentiate between domestic and foreign firms. These studies do not take into consideration nondiscriminatory policies. However, nondiscriminatory policies also have the potential to affect foreign firms

differentially and become de facto discriminatory by increasing fixed or variable costs of production for foreign firms. It is also to be noted that the existing studies have quantified the regulatory restrictiveness generally at a single point of time and cross country comparisons have been made on that basis. These studies have not analyzed the changes in these domestic regulations over the years, particularly for India.

4. Methodology and Data Sources

The empirical analysis on constructing restrictiveness indices primarily builds on the existing work on restriction indices for services by the academics at the OECD, the World Bank and the Australian Productivity Commission. The main studies concerned with restrictiveness in banking services and referred to are 'Restrictiveness on International Trade in Banking Services' by McGuire and Schuele (2000) and 'Modal Estimates of Services Barriers' (OECD Trade Policy Working Paper No. 51) by Dihel and Shepherd (2007). These studies assign weights to different regulations based on either subjective judgments or statistical technique of factor analysis by taking into account the increased cost and inefficiency due to restrictive regulations.

Since the primary aim of this study is to show the role of BtB regulations in total trade restrictiveness, it modifies the available templates of these studies and includes new categories of regulatory barriers to make the restrictiveness indices more comprehensive. As mentioned earlier, it also includes non-discriminatory barriers in the existing templates. Some of these added barriers are licensing procedures, FDI approval process, restrictions on purchase of immovable property, complex tax laws, discrimination in tax treatment of foreign companies etc. It constructs two types of restrictiveness indices – **Total Trade Restrictiveness Index (TRI)** showing quantification of regulatory barriers in both AtB and BtB categories and **'Behind the Border' Trade Restrictiveness Index (BtB Index)**, reflecting the quantification of regulatory regime arising only from BtB regulations.

The restrictiveness indices are calculated by assigning weights to various regulatory barriers. In the literature, three methods are generally used for weighing regulatory barriers; Researcher Judgment, Expert Opinion and Factor Analysis. Deardorff and Stern (2008) argue that the best approach for weighing is judgments of knowledgeable investigators. In their view, factor analysis being purely a statistical technique need not be an improvement on the use of judgment weights. Considering the fact that the weights should reflect the relative economic costs of different types of restrictions, a combination of these techniques have been used in this study to weigh the barriers applicable for banking sector restrictiveness indices. It modifies the available weights of these studies (primarily based on factor analysis) based on researcher judgment to include new set of regulatory barriers. It also relies on expert opinion for weighing these barriers.

The following steps have been followed for constructing trade restrictiveness and 'Behind the Border' restrictiveness indices.

- **Step 1.** Collection of information from different government agencies and regulatory bodies for various regulatory policies pertaining to banking services at different points in time. It also includes information gathering from various other sources such as study reports of the World Bank, the OECD, independent research organizations and various authors.
- **Step 2.** Defining degrees of restrictiveness and assigning scores to each type of regulatory barriers. Scores range from zero for the least restrictive to one for the most restrictive. There is an inverse relationship between regulatory requirements and the score assigned to it for some of the regulations. For example, in the foreign equity limits category, if 26% is the approved limit, we have assigned a score of 0.74 and vice-versa. Other regulations are divided into various degrees of intensity and scores have been assigned from zero (for the least intensity of regulations) to one (for the highest intensity of regulations). For instance, for 'FDI approval process' barrier, 'No automatic approval is allowed' is given a score of 1 due to the highest intensity of restrictiveness, 'FDI is allowed partially through automatic route and beyond a limit through government approval' is given a score of 0.5 due to moderate intensity and 'FDI is allowed through automatic route' is given a zero score due to the least intensity of restrictiveness.

- **Step 3.** Assigning weights to various regulatory barriers based on their economic importance by using a combination of methods as explained earlier.
- **Step 4.** Constructing Trade Restrictiveness Indices (TRI) by multiplying scores obtained in step 2 with weights obtained in step 3. It also includes constructing ‘Behind the Border’ restrictiveness indices (BtB Indices) by separating relevant barriers affecting operations of foreign firms from the total set of regulatory barriers.

It is to be noted that whereas the maximum value of TRI can be 1 (when there are absolute restrictions on foreign firms), the maximum value of BtB Index will always be less than 1 as some of the regulatory barriers considered for the analysis were of AtB type and hence do not figure in calculating the BtB Index. The indices are calculated over a period of time from 1995 to 2010 at four different points of time, i.e., 1995, 2000, 2005 and 2010. The choice of these years comes from the fact that these are the years when significant policy changes have been made in India in banking service sector.

Data Sources

Secondary data sources include information and published reports by government authorities and multilateral, regional and country agencies. These reports include various Government of India publications, Trade Policy Reviews available on WTO website and other notifications and circulars issued from time to time by various departments and Ministries of Government of India. A comprehensive but not exhaustive list of secondary data sources used for quantification of barriers is presented below.

TABLE I: DATA SOURCES FOR QUANTIFICATION WORK

Country Level (Government Sources)	Multilateral Sources	Others
1. Manual of FDI Statistics, Department of Industrial Policy and Promotion, Govt. of India 2. Foreign Exchange Management Act 1999 3. Reserve Bank of India (RBI) Annual Reports 4. Draft Report for Presence of Foreign Banks in India issued by (RBI) 5. Reserve Bank of India website 6. Ministry of Finance, Government of India, website	1. Trade Policy Review available at WTO website 2. UNCTAD Handbook of Statistics 2010 3. OECD Working Papers	1. Indiastat online database 2. Australian Productivity Commission Research Papers

Source: Author's Compilation

Thus, the information regarding prevailing regulatory barriers is taken from a wide range of government and non-government sources. However, most of these documents do not have comprehensive information on various regulations and associated conditions. In case of non-availability of information for a particular regulation, inferences are drawn from other reports and documents, published articles and news paper clippings.

5. Empirical Results

The construction of restrictiveness indices is a difficult task given inherent nature of banking sector regulations. Francois and Hoekman (2010) in their paper highlight various difficulties, such as lack of transparency, non-availability of information etc., in constructing numerical estimates of barriers in services trade in general. We have also faced similar difficulties and challenges while constructing restrictiveness indices for banking services. These difficulties are more pronounced as we construct restrictiveness indices over a period of time. The difficulties and challenges faced are threefold- First, the availability of information on policies is very

limited and imprecise. The policy documents do not have detailed information on various regulations. For instance, the FDI policy available with Department of Industrial Policy and Promotion, Government of India talks about maximum allowable foreign equity but it puts conditions that this limit is subject to requirements as stipulated by the concerned department. The difficulty is that these additional requirements are not easily and publicly available. Second, as various Ministries and institutions of Government of India are involved in liberalization of banking services, it is very difficult to get various policy documents and circulars at one place. Third, the data on service transactions is also very limited. Bilateral services trade data disaggregated at sectoral level is not available. This is precisely because services are not generally observed crossing borders, hence difficult to record. Another difficulty that has arisen in the process of construction was getting industry expertise for weighing various regulatory barriers. As any information on regulatory framework is confidential and strategic, many of the banking experts prefer not to talk on these issues.

Thus, the construction of restrictiveness indices has undergone through many difficult challenges. As mentioned earlier, in the absence of precise information about a particular regulatory barrier, the inferences have been drawn from other available sources such as web postings, news paper articles etc. Of course, this introduces an element of subjectivity in the construction of restrictiveness indices, but this is inevitable given various difficulties as enumerated earlier. The results of construction exercise are discussed in the subsequent paragraphs.

As explained earlier, these restrictiveness indices are split between a **Total Restrictiveness (TR) Index** and a purely **'Behind the Border' BtB Index**. The indices calculated for banking services and the changes thereof over time are given below.

TABLE2: TR AND BTB INDICES FOR BANKING SERVICES IN INDIA

Year	TR Index	BtB Index	% Contribution of BtB in TRI
1995	0.639	0.329	51%
2000	0.522	0.341	65%
2005	0.360	0.254	70%
2010	0.397	0.241	61%

Source: Author's Calculations

GRAPH1: TR AND BTB INDICES FOR BANKING SERVICES IN INDIA

Source: Author's Calculations

From Table 2 and Graph 1, it is clear that there is a decreasing trend in the index value and is mainly due to the increased allowance for foreign equity participation in private banks in India, easing of FDI approval process and the granting of establishment rights to wholly owned subsidiary of foreign banks in India over the period under consideration. The RBI has released a road map for presence of foreign banks in India in February 2005, which proposed significant liberalization of various AtB and BtB regulations. In this road map, the RBI

proposed that presence of foreign banks will be implemented in a phased manner, consistent with India's commitments to the WTO. This road map consisted of two phases, Phase-1 (March 2005 to March 2009) and Phase-2 (April 2009 onwards). In the first phase, foreign banks wishing to establish presence in India for the first time were allowed either to operate through branch presence or set up a 100% wholly owned subsidiary (WOS), following the one-mode presence criterion. For new and existing foreign banks, it was also proposed to go beyond the existing WTO commitment of 12 branches in a year with a more liberal policy for underbanked areas. In this phase, foreign banks already operating in India were allowed to convert their existing branches to WOS while following the one-mode presence criterion. The WOS were to be treated on par with the existing branches of foreign banks for branch expansion in India. However, the Reserve Bank may prescribe market access and national treatment limitation consistent with WTO, as also other appropriate limitations to the operations of WOS consistent with international practices and the country's requirements.

In the second phase, this road map proposed the removal of limitations on the operations of the WOS and treating them on par with domestic banks to the extent appropriate after reviewing the experience with Phase I and after due consultations with all stakeholders in the banking sector. The WOS of foreign banks on completion of a minimum prescribed period of operation are to be allowed to list and dilute their stake so that at least 26 per cent of the paid up capital of the subsidiary is held by resident Indians at all times. However, given the recent financial crisis and risky exposure of the foreign banks, the RBI has not implemented the second phase fully and is adopting a step by step approach.

As far as branch authorization is concerned, the branch licensing procedure is continued to be governed by previous practices. Foreign banks are required to bring an assigned capital of US\$25 million upfront at the time of opening the first branch in India. Existing foreign banks having only one branch would have to comply with the above requirement before their request for opening of second branch is considered. Foreign banks are also required to submit their branch expansion plan on an annual basis. In addition to the parameters laid down for Indian banks, foreign banks are subject to the following parameters while authorizing their branches- foreign bank's and its group's track record of compliance and functioning in the global markets, reports from home country supervisors, wherever necessary, even distribution of home countries of foreign banks having presence in India, the treatment extended to Indian banks in the home country of the applicant foreign bank and the bilateral and diplomatic relations between India and the home country. The branch expansion of foreign banks would be considered keeping in view India's commitments at the WTO. ATMs would not be included in the number of branches for such computation.

It is also to be noticed from Table 2 that though there is a decreasing trend over time, the index value has slightly increased in 2010 as compared to 2005. This is because of the additional condition imposed on FDI approval process in 2010. FDI in banking services in India was allowed fully through automatic route in 2005 (FDI Policy, 2005) but in 2010, the government has stipulated that FDI in banking services is allowed through automatic route only up to 49% and beyond 49% and up to 74%, it is allowed through Government route (Consolidated FDI Policy, 2010).

Table 2 and Graph 1 also reveal that the BtB regulations contribute a significant 51 percent and above of the overall index and this contribution has increased overtime. In 1995, BtB and AtB regulations were contributing almost equally to the overall index. But in 2000 and 2005, BtB contribution has increased to 65% and 70% respectively. It implies that most of the investment liberalization in banking services in India has been in AtB regulations during these years. The main AtB liberalization steps undertaken during this period were- allowing increased foreign equity participation (from 20% in 1995 to 74% in 2005), allowing foreign banks to operate through fully owned subsidiary mode and ease of FDI approval process. However, in 2010, the percentage contribution of BtB regulations in the overall index has come down to 61% from 70% in 2005. This is because of two reasons, first, the government has put conditions on FDI approval process (as explained in the previous paragraph), which is an AtB barrier, thereby increasing the percentage contribution of AtB barriers in the overall index and second, some of the BtB regulations, such as number of licenses to be granted to the foreign banks, corporate tax laws etc., were also liberalized during this period. However, the BtB regulations such as licensing requirements for branch expansion etc. are still prevalent. Thus, there is scope for relaxing some 'Behind the Border' non prudential regulations in banking services, such as branch expansion, licensing etc. which could facilitate trade and investment flows in the banking sector and also indirectly facilitate trade finance and associated transactions in goods.

This paper also correlates banking services liberalization in India and corresponding changes in BtB and TR indices with trade in financial services, availability of export credit and some of the performance indicators for foreign banks. The results are shown as below-

TABLE Error! No text of specified style in document..3: CORRELATION MATRIX FOR BANKING SERVICES

Type of Trade Restrictiveness Index		Export Credit	Financial Services Trade	Foreign Banks Performance (as a %age of total assets)		
				Gross Profit	Net Profit	Net Interest Income (Margin)
TR Index	Pearson Correlation	-.929(**)	-.457	-.689(*)	-.706(*)	-.647(*)
	Sig. (1-tailed)	0	.151	0.014	0.011	0.041
	N	14	7	10	10	8
BtB Index	Pearson Correlation	-.867(**)	-.457	-.625(*)	-.696(*)	-0.56
	Sig. (1-tailed)	0	.151	0.027	0.013	0.075
	N	14	7	10	10	8

** Correlation is significant at the 0.01 level (1-tailed)

* Correlation is significant at the 0.05 level (1-tailed)

Source: Author's Calculations based on data accessed from UNCTAD Handbook of Statistics 2010 and India Statistics Online Database

The results above show that, as expected, there is a negative relationship between the TR and BtB indices and the various measures of trade and performance, i.e., liberalization is associated with improved efficiency and increased trade. For most of the coefficients, the relationship is significant at either a 1 percent or 5 percent significance level.ⁱⁱⁱ These coefficients are particularly high and very significant for export credit which is an important driver of trade in all goods and services. Increased liberalization and consequent reduction in BtB and TR indices is associated with increased availability of export credit. The performance indicators for foreign banks also show the same trend, indicating improved performance in the wake of liberalization in India's banking services.

6. Conclusion and Policy Implications

This study quantifies the qualitative nature of regulatory barriers affecting foreign investment in banking services. It finds that there has been significant investment liberalization undertaken in India in this sector over the past decade or so. However, a greater part of this liberalization has been at the border while many 'Behind the Border' restrictions continue. The latter still constitute a sizeable share of overall restrictiveness in banking services and thus remain a critical factor shaping the overall regulatory environment of this sector in India.

The paper indicates that there are considerable potential gains to be realized from liberalizing banking services, not only from relaxing FDI ceilings but also from liberalizing the overall domestic regulatory environment. It confirms the importance of 'Behind the Border' regulations in opening banking services to foreign investment. The findings suggest that liberalization is probably easier to undertake at the border but more difficult to undertake 'Behind the Border', possibly because the latter measures are often hidden and not explicit and because their ramifications for trade and investment flows may not be well recognized. The findings also suggest that domestic and foreign investors are likely to be affected by similar 'Behind the Border' measures that shape the overall regulatory environment through productivity and efficiency gains, and thus one may need to consider domestic and foreign investment incentives along similar lines. And finally, policy makers need to be cognizant of inter-linkages and spillover effects between banking services and also between the goods and services sectors of the economy when designing policies so as to reap the full benefits of liberalization in the service sector.

The primary limitation of the study comes from a weighing of various regulations which is the usual limitation for any quantification exercise in the area of services trade. Though, the weights are obtained through a combination of methods prescribed in the available literature and by seeking expert opinion, some degree of subjectivity cannot be denied. A second limitation of the study pertains to the availability of data. It proved

difficult to obtain accurate and consistent time series data for many of the regulations. In case of non availability of information from the policy documents, inferences have been drawn from other available resources. A third limitation is that the indices do not capture yearly changes in the restrictiveness indices and attribute all changes to particular points in time (1995, 2000, 2005 and 2010). The latter can, however, be justified as the primary aim is to track how the restrictiveness indices have changed over a period of time rather than capturing exact points in time when these changes may have occurred. Moreover, policy changes in terms of deregulation measures tend to be discrete point in time changes corresponding with specific initiatives and programmes rather than being continuous year on year processes. Nevertheless, the points in time measurement are approximate ones. This empirical work of consisting of time series of restrictiveness indices can be extended to analyzing the price-impact of investment liberalization in banking services. Firm level data can be used to assess the effect of liberalization on productivity and efficiency by comparing the firms that use the banking services intensively and non-intensively. Since data and information on most of the parameters of price-impact analysis is either not available or incompletely available particularly with reference to India, any such analysis is difficult to incorporate in the present study.

Endnotes

ⁱ This distinction is also accepted by Australian Productivity Commission and used in its various studies concerned with services sector liberalization. Australian Productivity Website (www.pc.gov.au/research/memoranda/servicesrestriction/index.html) can be referred for more detail.

ⁱⁱ Similar arguments have been made in several other studies including Deardorff and Stern (2008).

ⁱⁱⁱ An extended correlation analysis of financial services trade by segregating into financial services exports and imports (not included in the table above) further shows that the correlation coefficients are higher and also more significant for exports of financial services as compared to imports of financial services.

Information Transmission Mechanism between Chinese and the US Stock Markets during Financial Crisis: Evidence from Intraday and Overnight Volatility Spillover Effects.

University of International Business and Economics

Abstract

This paper mainly focuses on the intraday and overnight information transmission effects between China and the US stock markets around the crash of September 2008. We employ the FFF regression, the CCF approach and the ARMA-EGARCH-HFV model for high-frequency intraday 5-minute data that covers the period from July 15, 2008 to January 31, 2009. The empirical analyses show that (1) the Lehman Crash does increase the volatility spillover effects, (2) information transmission between different domestic markets can be achieved within 5 minutes and (3) the intraday volatility exhibits the strong intraday periodicity and long-memory features. However, we can effectively filter out the intraday periodicity patterns by the FFF-regression.

Key Words: Lehman crisis; High-frequency financial data; Volatility spillover effect; Intraday periodicity; FFF-regression

1 Introduction

Since 1980s, in the waves of economic globalization and liberalization, financial markets throughout the world have steadily become more open to foreign investors. With open markets, market deregulation and free flow of capitals have further increased the globalization of financial markets. An essential outcome of this force of globalization is increased interdependence of asset prices across international markets. The market crash of October 1987, known as the “Black Monday”, sparked studies about the linkage between stock markets in the world. Hamao, Masulis and Ng (1990), Jeon and Von Furstenberg (1990), Lai, Lai and Fang (1993), Blackman, Holden and Thomas (1994), among others, have empirically found the strong evidences that the co-movements among international stock markets had increased significantly after the crash of October 1987.

In September 2008, huge waves that set off in the United States engulfed the global financial markets. The financial tsunami began at the bankruptcy of the fourth-largest US investment bank *Lehman Brothers Holdings Inc.* on September 15, 2008. Moreover, on the same day, *Bank of America* agreed to acquire *Merrill Lynch & Co., Inc.*, the third-largest US investment bank, with the price of US\$29 per share, a total of US\$50 billion. In order to restore the normal operation of the US financial system, the US government immediately decided to formulate “Emergency Economic Stabilization Act of 2008”, which came up with US\$700 billion to rescue the ailing economy. Unexpectedly, however, the project was rejected via a vote of the House of Representatives on September 29, 2008. The US stock markets were affected by this blow and the Dow Jones Industrial Average plunged 777.68 points in a single day, 684.81 points drop on September 17, 2001 (the first trading day after September 11 attacks), making a record of the largest single-day point drop. Although the US Congress passed the amendment on October 3, the destruction had been done and spread rapidly to the world stock markets with utmost panic. For instance, in the US stock market, the return on Dow Jones Index never fluctuated by more than 4% within a trading day since 2003. Nevertheless, during the two and a half month after Lehman’s bankruptcy, it was on 20 trading days that the fluctuation exceeded 4%. Even the fluctuation went beyond 10% in two days. Paul Krugman describes the worldwide production, financial and consumer crunch following these events as “the beginning of a second Great Depression”ⁱ. The above series of phenomena mark this round of financial crisis a further upgrade of the subprime mortgage crisis that began in 2007. To distinguish them apart, in this paper, we call the new round of financial crisis after September 15, 2008 as “Lehman crisis”.

This paper focus mainly on the intraday and overnight volatility spillover effects between China and the US

stock markets around the Lehman crash. As clearly demonstrated by Ross (1989), asset return volatility also provides a useful signal of information flow, in other words, the direction of volatility also provides a useful signal on information flow.

In recent years, the issue of stock market co-movement between China and international stock markets has gradually attracted academic attention. Hong *et al.* (2004) studied the volatility spillover effect on emerging markets and main international stock markets between January 1995 and April 2003, but no evidence was found of co-movement relationships between Chinese A-share market and other main global markets (the US, Japan and Germany). In contrary, the study of Liu and Chen (2008) revealed that there is significant volatility spillover effect from China to other stock markets (the US, Japan, the UK and Hong Kong) but no evidence is found of spillover effect from the other way round. In addition, some existing studies examined the co-movement relationship in stock prices across markets. Examples include Gu and Lu (2006) and Nishimura (2009).

Compared with these previous research works, our study has the following characteristics. First, comparing the extensive use of daily or weekly data in numerous previous studies, we apply 5-minute data. The financial asset price movement is subject to various information disturbances. Discrete collection of data will inevitably lead to information loss, whereas the application of high-frequency dataset can take full advantage of the information conveyed by the financial asset price variation. Second, we conduct both horizontal and vertical analysis in our empirical study. For horizontal analysis, we perform comparative analysis on the intraday volatility characteristics and volatility spillover effects between Chinese and the US stock markets. For the vertical analysis, the day of Lehman's bankruptcy is taken as a separation point and the information transmission effects is analyzed for two periods, i.e., before and after the crash, which offers objective and scientific evidences to comprehend the influence of Lehman shock on these markets. This paper aims to systematically study the intraday and overnight information transmission effects between Chinese and the US stock markets around the crash of September 2008 by vertical analysis on time series and horizontal analysis on Sino-US stock markets.

The rest of this paper is organized as follows. Section 2 describes the sample data and analyzes its intraday periodicity. Section 3 analyzes volatility spillover effects within Chinese and the US domestic stock market. Section 4 empirically analyzes the overnight volatility spillover effects between Chinese and the US stock market. Section 5 concludes the paper by summarizing the main findings and making some rational judgments about the new future.

2 Data and intraday periodicity

Our primary data set consists of 5-minute returnsⁱⁱ for Shanghai Composite Index (SH), Shenzhen Component Index (SZ), Dow Jones Index (DOW) and Standard and Poor's 500 Index (SP500) from July 15, 2008 to January 31, 2009ⁱⁱⁱ. The trading hours of Chinese stock market are 9:30-11:30 and 13:00-15:00 Beijing time, a total of 4 hours. And the trading hours of the US market are 22:30-5:00 Beijing time, a total of 6.5 hours. Therefore, within a trading day, there are 49 and 78 return observations, not including the overnight return (the close-to-open return during the overnight non-trading hours), for Chinese and the US stock market respectively. In total, there are 6370 and 10536 for the two markets respectively. These data are obtained from Foxtrader and Bloomberg.

The volatilities for data of different sampling frequencies exhibit different dynamic characteristics. Many academic studies indicated that intraday periodicity is one of the most important dynamic features of intraday volatility. Andersen and Bollerslev (1997) found that the intraday return volatility of SP 500 index assumes a U-shaped pattern^{iv} and Andersen, Bollerslev and Cai (2000) found a W-shaped (doubly U-shaped) pattern on the intraday return volatility of Nikkei 225 index^v.

Andersen and Bollerslev (1997, 1998b) demonstrated the failure of standard volatility models in presence of the intraday periodicity. In other words, if we use intraday high-frequency data to estimate the time-series models, such as ARCH-type models, we will get bias statistical inferences. Then, it's necessary to eliminate the intraday periodicity before applying standard volatility models to the analysis of stock market co-movements. Andersen and Bollerslev (1997, 1998b) introduced FFF (Flexible Fourier Form) regression, which was developed by Gallant (1981), into the research of high-frequency financial time series as an effective method to describe and filter out the intraday periodicity.

The n -th return within day t is denoted $n_{(t)}$ ($t=1,2,\dots,T$; $i=1,2,\dots,n$), and generally can be written as

follow:

$$r_{t(i)} = E[r_{t(i)}] + \sigma_{t(i)} s_{t(i)} z_{t(i)} \quad (1)$$

Where $E[r_{t(i)}]$ is the expected 5-minute return, $\sigma_{t(i)}$ represents the intradaily volatility factor, $s_{t(i)}$ is the periodicity factor, $z_{t(i)}$ is an *i.i.d.* mean zero and unit variance innovation term. By squaring and taking logs of Equation (1), we can isolate $s_{t(i)}$, i.e.

$$x_{t(i)} \equiv 2\ln(|r_{t(i)} - E[r_{t(i)}]|) - \ln(\sigma_{t(i)}^2) = c + 2\ln(s_{t(i)}) + u_{t(i)} \quad (2)$$

Where, $c = E[\ln(z_{t(i)}^2)]$, $u_{t(i)} = \ln(z_{t(i)}^2) - E[\ln(z_{t(i)}^2)]$. The dependent variable $x_{t(i)}$ is computed by $E[r_{t(i)}]$ and $\sigma_{t(i)}^2$, hence we need to estimate them in advance. Following Andersen and Bollerslev (1997, 1998b), we replace $E[r_{t(i)}]$ and $\sigma_{t(i)}^2$ with the sample mean of the 5-minute returns, $\bar{r}_{t(i)}$, and reasonable estimator of $\hat{\sigma}_{t(i)}^2$ respectively. Andersen and Bollerslev (1997, 1998b) assume that the this volatility component is constant over the trading day, i.e. $\hat{\sigma}_{t(i)}^2 = \hat{\sigma}_r^2 / n^{1/2}$ and chose a GARCH(1,1) model estimate of daily return volatility $\hat{\sigma}_r^2$. Alternatively, we adopt the daily realized volatility (RV) proposed by Andersen and Bollerslev (1998a). The daily RV at time t is defined as the cumulative sum of squared intraday returns over day t , that is

$$RV_t = \sum r_{t(i)}^2 \quad (3)$$

As clearly demonstrated by many literatures, such as Andersen *et al* (2001), Andersen *et al.* (2003), Barndorff-Nielsen and Shephard (2004), among others, the realized volatility would provide a consistent estimator of the integrated volatility, a natural definition of real volatility as the time interval tents to zero^{vi}.

After introducing $\bar{r}_{t(i)}$ and $\hat{\sigma}_r^2$, treating $\hat{x}_{t(i)}$ as the dependent variable in the regression allows the parameters to be estimated by ordinary least squares (OLS).

$$\hat{x}_{t(i)} = 2\ln(|r_{t(i)} - \bar{r}_{t(i)}|) - \ln(\hat{\sigma}_{t(i)}^2) = \hat{c} + f(\theta; t(i)) + \hat{u}_{t(i)} \quad (4)$$

Where $\hat{c} = E[\ln(z_{t(i)}^2)] + E[\ln(\sigma_{t(i)}^2) - \ln(\hat{\sigma}_{t(i)}^2)]$ and the error term is stationary. To describe the periodicity factor, $f(\theta; t(i))$, Andersen and Bollerslev (1997, 1998b) propose to use the following specification:

$$f(\theta; t(i)) = \sum \sigma_i^j \left[\mu_{0,j} \frac{1}{t} + \mu_{1,j} \frac{1}{t} + \mu_{2,j} \frac{1}{t} + \sum \left(\gamma_{l,j} \cos \frac{2l\pi t}{N_1} + \delta_{l,j} \sin \frac{2l\pi t}{N_2} \right) + \sum \lambda_k I_k(t(i)) \right] \quad (5)$$

Where, $N_1 = (n+1)/2$, $N_2 = (n+1)(n+2)/6$, $I_k(t(i))$ is the dummy variable for "day-of-the-week" effect. For $J = 0$ and $P = 0$, equation (5) reduces to the standard Flexible Fourier Form proposed by Gallant (1981). Andersen and Bollerslev (1997, 1998b) emphasized that, allowing for $J \geq 1$ and thus a possible interaction effect between σ_i^j and the shape of the periodic pattern is important.

Finally, we utilize the estimator of the periodicity factor $\hat{s}_{t(i)}$ to calculate the periodicity-free intraday return series. That can be obtained as follows: $\tilde{r}_{t(i)} = r_{t(i)} / \hat{s}_{t(i)}$ ^{vii}. For simplicity, the following omits the tilde symbol.

Figure 1 plots the average 5-minute volatility pattern (average absolute 5-minute return for each 5-minute interval) within a day and the autocorrelations for the 5-minute volatility at lag of 10 day (i.e. 490 periods for Chinese equity market and 780 periods for the US equity market). It is obvious that the volatility patterns of SH series and SZ series are nearly the same, so are the patterns of DOW and SP500 series. In the left figure, consistent with the study of Andersen and Bollerslev (1997) and other earlier studies, the intraday volatility from the US stock market has shown an extremely significant U shape even during this period of financial crisis. It is noteworthy that the intraday volatilities of SZ and SH series are approximately U-shaped but decline gradually when approach closing. This is a unique phenomenon during financial crisis and ignored by previous studies^{viii}.

In the right figure, the intraday volatility series for both Chinese and the US stock markets exhibit U shape within each one-day (one day is equivalent to 49 periods for Chinese while 78 periods for the US market) cycle, in conformity with the intraday trend of volatilities for 5-minute return shown in the left figure. For the presence of significant intraday periodicity effect, the results from traditional time series models such as ARCH-type models will be distorted. It is necessary for us to filter out the intraday periodicity.

In addition, the autocorrelation function declines slightly and largely stay beyond the 5% critical value (the horizontal dotted line in the figure right). It is suggested that the intraday volatilities reveal long memory characteristics. In the US stock market, this is even more apparent.

Figure 1 Intraday 5-minute average volatilities and autocorrelation function with 10 day lag

Notes: The image left graphs the intraday trend of the 5-minute average volatility and the image right graphs the autocorrelation function with 10 day lag. In both images, the left scale shows volatilities of SH and SZ return series and the right scale shows volatilities of DOW and SP500 return series. The dotted line in the image right represents the 5% critical value.

In following procedures, we apply FFF regression to the original series and filter out their intraday periodicity. The FFF regression estimates can be very sensitive to value of J and P in equation (5). The choice of J and P is carried out among $J = 1, 2$ and $P = 1, 2, \dots, 20$. To determine the optimal value for J and P , we test all the potential optimal models, a total of 42, and obtain the optimal one by minimizing the Akaike information criterion (AIC). Consequently, for SH and SZ, we choose $J = 1, P = 2$ and for DOW and SP500, we choose $J = 1, P = 1$.

Figure 2 shows the intraday-periodicity-free 5-minute average volatilities extracted from the index return series within a day (left image) and the intraday-periodicity-free autocorrelation function at lag of 10 day (right image). As shown in the figure, FFF regression captures the features of the intraday volatility and effectively eliminates the intraday periodicity effect. Nonetheless, for the existence of long memory characteristics, it is important to be careful in modeling the volatility series.

Figure 2 Intraday 5-minute average volatilities and autocorrelation function at lag of 10 day

excluding intraday periodicity

Notes: The left image shows the trend of 5-minute average volatilities within a day and the right image plots the autocorrelation function with 10 day lag. The left scale shows volatilities of SH and SZ return series and the right scale shows volatilities of DOW and SP500 return series. The dotted line in the image right represents the critical value at 5% significant level.

3 Intraday volatility spillover effects within Chinese and the US domestic markets

3.1 Methodology

In this section, we apply the two-step procedure developed by Cheung and Ng (1996). Step one: estimate appropriate volatility model for each univariate time series to obtain their standardized residuals. Step two: the cross-correlation function (CCF) of squared standardized residuals are used to detect causality-in-variance^{ix} between two different time series.

Suppose the intraday return series $r_{l,t(i)}$ ($l = x, y$; $t = 1, 2, \dots, T$; $i = 1, 2, \dots, n$) on either of the two stock markets can be written as following:

$$r_{l,t(i)} = \mu_{l,t(i)} + \sigma_{l,t(i)} z_{l,t(i)}, \quad E(z_{l,t(i)}) = 0, \quad \text{Var}(z_{l,t(i)}) = 0 \quad (6)$$

Where, $\mu_{l,t(i)}$ represents mean equation (conditional mean) that is specified as an ARMA model in our research, $\sigma_{l,t(i)}^2$ represents variance equation (conditional variance) that is specified as a Chung-type FIAPARCH model^x to capture the asymmetric and the long memory property of intraday volatility for stock index return series. Given equation (6), an estimable ARMA(1,1)-FIAPARCH(1,1) model can be specified as follows:

$$r_{l,t(i)} = c_l + \phi r_{l,t(i-1)} + \varepsilon_{l,t} + \theta \varepsilon_{l,t(i-1)}, \quad \varepsilon_{l,t(i)} = \sigma_{l,t(i)} z_{l,t(i)}, \quad z_{l,t(i)} \sim WN(0,1) \quad (7)$$

$$\sigma_{l,t(i)}^2 = \sigma_l^2 (1 - \beta) + (1 - \beta L - (1 - \alpha L)(1 - L)^d) (|\varepsilon_{l,t(i)}| - \gamma \varepsilon_{l,t(i)})^\delta - \sigma_l^2 + \beta \sigma_{l,t(i-1)}^\delta \quad (8)$$

Where, σ_l^2 is the unconditional mean of $\varepsilon_{l,t(i)}$ and L is the lag operator i.e. $L^k y_t = y_{t-k}$. We estimate the FIAPARCH model and obtain the square of standardized residuals i.e. $\hat{z}_{x,t(i)}^2 = (r_{x,t(i)} - \hat{\mu}_{x,t(i)})^2 / \hat{\sigma}_{x,t(i)}^2$ and $\hat{z}_{y,t(i)}^2 = (r_{y,t(i)} - \hat{\mu}_{y,t(i)})^2 / \hat{\sigma}_{y,t(i)}^2$ to detect the volatility spillover effects. Let us define $\rho_{xy}(k)$ as the sample CCF of $\hat{z}_{x,t(i)}^2$ and $\hat{z}_{y,t(i)}^2$ at time lag k .

$$\rho_{xy}(k) = \text{Cov}_{xy}(k) / \sqrt{\text{Cov}_{xx}(0) \times \text{Cov}_{yy}(0)} \quad (9)$$

Where $\text{Cov}_{xx}(0)$ and $\text{Cov}_{yy}(0)$ are the sample variance of $\hat{z}_{x,t(i)}^2$ and $\hat{z}_{y,t(i)}^2$. $\text{Cov}_{xy}(k)$ is the sample cross-covariance. The appropriate CCF-statistic proposed by Cheung and Ng (1996) is given by the following formula.

$$CCF - \text{statistic}(k) = \sqrt{T \times n} \rho_{xy}(k) \xrightarrow{a} N(0,1) \quad (10)$$

Cheung and Ng (1996) proved that the CCF-statistic given in Equation (10) follows an asymptotic standard normal distribution under the null hypothesis as the sample size $T \times n$ goes towards infinity. Consequently, the hypothesis test to determine whether volatility-spillover or a lead-lag relationship exists between the variables at time lag k . If the null hypothesis, $H_0: CCF - \text{statistic}(k) = 0$, cannot be rejected, there is no evidence of volatility spillover effects and *vice versa*.

3.2 Empirical results

Since it is possible that the standardized residuals $z_{l,t(i)}$ do not follow the Gaussian distribution, parameters for ARMA-FIAPARCH models are estimated by using quasi-maximum likelihood (QML) estimation and the test results are presented in Table 1.

Parameter d reflects the long memory feature of the variables. Thus, the intraday volatility follows a short-memory process when $d = 0$ and a long-memory process when $d > 0$. As indicated by Table 1, parameter d for each model is significantly positive at the 1% significant level, suggesting the long memory characteristics of the intraday volatility for both Chinese and the US stock market.

The asymmetric effects of return volatility can be tested by the hypothesis that $\gamma = 0$. If $\gamma > 0$, bad news effect on stock market will be greater than good news effect and vice versa. As a result, the parameter γ is statistically significant at 1% level for all the four markets. This indicates that volatility is significantly asymmetric in both Chinese and the US stock markets and therefore bad news increases volatility more than

good news.

In addition, the null hypothesis that $\delta = 2$ cannot be rejected, which means that parameter δ and σ^2 are identical.

We calculated Ljung-Box statistics Q_m for the square of the standardized residuals in CCF test and found that for each m equaling 1,2,...,100, series Q_m statistics cannot reject the null hypothesis of no autocorrelation at 5 percent level of significance. Table 1 only shows the Ljung-Box statistics with lag 10.

Notes: ***, ** and * denote the significance level at 1, 5 and 10 percent, respectively. Standard errors are in parenthesis. *L.L.* denotes log likelihood. Q_{10} is the Ljung-Box statistics with lag 10 for standardized residuals squared.

In the following part, we investigate the intraday volatility spillover effect by use of CCF approach. We set the cutoff point at breakout of Lehman's bankruptcy (September 15, 2008) and divide the timeline into two parts, the pre-crisis period which lasts from July 15, 2008 to September 14, 2008 and the post-crisis period from September 15, 2008 to January 31, 2009.

Table 2 presents the CCF test results for pre and post crisis periods. Lags are measured in 5 minutes, and the reported range is limited to 5 lags ($k = 0\sim 5$)^{xi}. The CCF test at lag zero is not a strict causality relationship test but does provide some information about contemporaneous relationship. Significant CCF statistics at lag zero implies strong contemporaneous correlation relationship between SH and SZ, and between DOW and SP500. It seems that there exists no intraday lagging volatility spillover effect. It is well known that the volatility is directly associated with the flow of information. In this sense, either in Chinese or in the US stock market, the information transmission within the domestic stock market is completed in 5 minutes. In recent years, frequent innovation and rapid development of the communication technique facilitate the information transmission among the markets and these market information produce direct effect on the behavior of investors. For the availability of data, we can only use the market data of 5-minute frequency. We need data of even higher frequency, such as 1-minute data, for further research on the micro structure of Chinese and the US stock markets.

Moreover, in comparison of the CCF statistics for Chinese and the US stock markets, we conclude that the information transmission in the US domestic stock market is more efficient than that in Chinese market and the

crisis improve the information transmission effect within domestic stock markets to a certain extent.

5	1.766	0.510	-1.077	-1.091	-1.206	-1.167	0.640	0.810

Notes: ***, ** and * denote the significance level at 1, 5 and 10 percent, respectively. The test statistic shown in the table is the CCF-statistic(*k*) defined by Equation (10). The “*lag*” represents the one-way effect from SH to SZ or from Dow to SP500 while the “*lead*” represents the corresponding reverse effect.

4 Overnight volatility spillover effects between Chinese and the US stock markets

In the previous section, we discuss the intraday volatility spillover effects within the domestic stock market of China and the US respectively. In this section, we will turn to the international co-movement issues between Chinese and the US stock market. As mentioned earlier, the direction of volatility also provides a useful signal on information flow. Regarding this, the intraday volatility of the US stock market during the closing time of Chinese stock market might convey some material information which will transmit to Chinese stock market and surprise its opening price. A transmission like this increases the close-to-open volatility in Chinese market. Contrariwise, intraday volatility of Chinese stock market might influence the overnight volatility of the US stock market. Accordingly, this section investigates whether there is overnight spillover effect between Chinese and the US stock market and if there is, how the effect changes around Lehman crisis.

4.1 Methodology

What we extracted from the FIAPARCH model above was the 5-minute volatility whereas what we need in this section is the daily volatility calculated from open-to-close return series. Similar to the daily realized volatility (RV) in equation (3), we define the daily high-frequency volatility (HFV) at time *t* as below:

$$HFV_t = \sum \hat{\sigma}_{t(i)}^2 \quad (11)$$

Where, $\hat{\sigma}_{t(i)}^2$ denotes the estimator of the *i*-th high-frequency volatility at the *t*-th trading day. In the test results above, we found the parameter δ for FIAPARCH model is 2. Hence we apply the conditional variance in this paper.

As a result, we find no long memory feature with the overnight volatility^{xii}. Furthermore, the logarithm of realized volatility (RV) and high-frequency volatility (HFV), which calculated from intraday high-frequency return series, is approximately normally distributed^{xiii}. Nelson (1991) proposed EGARCH model via the logarithm of the conditional variance and the variable in the model can be positive or negative. This enable us to introduce the logarithm of HFV into the variance equation and extend the basic EGARCH model to an improved one — ARMA(1,1)-EGARCH(1,1)-HFV model which captures the overnight volatility spillover effect of stock market *y* on another market *x*:

$$r_{x,t(night)} = c_x + \phi r_{x,t-1(night)} + \varepsilon_{x,t(night)} + \theta \varepsilon_{x,t-1(night)} + \delta D_{x,t}, \varepsilon_{x,t} = \sigma_{x,t} z_{x,t}, z_{x,t} \sim WN(0,1) \quad (12)$$

$$\ln(\sigma_{x,t}^2) = \omega_x + \beta \ln(\sigma_{x,t-1}^2) + \gamma z_{x,t-1} + \alpha |z_{x,t-1}| + \lambda \ln(HFV_{y,t-1}) \quad (13)$$

Where, $r_{x,t(night)}$ denotes the overnight return of stock market x at time t . $HFV_{y,t-1}$ denotes the high-frequency volatility of stock market y at time $t-1$. We also include a dummy variable for the trading day following a weekend or holiday in the conditional mean equations to capture potential “day of the week” effects. represents a dummy variable that takes a value of 1 on days $D_{x,t}$ is the dummy variable for state closing, which equals 1 if the stock market x is closing at time $t-1$ or 0 otherwise. In the expanded EGARCH specification of equation (13), the estimate of parameter λ can be interpreted as the percentage change in volatility of stock market x when the 1% change in volatility of stock market y occurs. If the return series on stock market y is in fact volatile, such volatility may lead to greater volatility in stock market x . Therefore, the parameter λ is expected to be positive.

We have to take the time difference problem into consideration for our analysis on the volatility spillover effects within a trading between different markets. In a day, the trading hours of Chinese stock market always precede that of the US stock market and there is no overlap between the two.

Since the empirical study of this section focuses on daily data, we must take the time difference between these markets into consideration. As far as transaction time in the same day is concerned, market hours in China do not overlap perfectly with that in the US. Then the order of the time is $USA_{t-1} \Rightarrow CHN_t \Rightarrow USA_t \Rightarrow CHN_{t+1} \Rightarrow \dots$. To this end, we must use $\ln(HFV_{SH,t})$ or $\ln(HFV_{SZ,t})$ to test $\ln(HFV_{DOW,t})$ or $\ln(HFV_{SP500,t})$ when analyzing the volatility spillover effect of SH or SZ on DOW or SP500. Otherwise, serious errors may arise.

4.2 Empirical results

Table 3 reported the test results based on ARMA-EGARCH-HFV model. We are most interested in the parameter λ estimate on China’s volatility shocks but found no evidence of significant volatility spillover effects during the pre-crisis period. This is suggesting that there is no effective information transmission from the USA to China, in line with the study of Hong *et al* (2004), Liu and Chen (2008) and Nishimura (2009). In the post-crisis stage, a fundamental change happened to the parameter λ . The volatility spillover effects from DOW and SP500 to SH are 1.262 and 1.340 respectively, which are both significant at 1% level. It’s obvious that the new round of financial tsunami following Lehman crash on September 15, 2008 has direct impact on the co-movement relationship and improves the information transmission effect among the international stock markets^{xiv}. The overnight volatility spillover effects are significantly positive, perfectly in line with our expectation. This indicates the positive direction of the volatility spillover effects. In other words, the volatility in a stock market shocks that of another stock market. Aside, SZ blocks the influence from DOW and SP500. Perhaps, this can be interpreted as lower level of liberalization in Shenzhen stock market than in Shanghai stock market.

Notes: ***, ** and * denote the significance level at 1, 5 and 10 percent, respectively. Standard errors are in parenthesis. *L.L.* denotes log likelihood. Q_{10} and Q_{10}^2 is the Ljung-Box statistics with lag 10 for standardized residuals and standardized residuals squared, respectively.

5 Conclusions

This paper studies the intraday and overnight volatility spillover effects around the Lehman crisis by using the high-frequency data from Chinese and the US stock market. The main findings are as follows: (1) By application of ARMA-EGARCH-HFV model into overnight spillover effect tests, we found that the volatility spillover effects between Chinese and the US stock markets become more significant after Lehman crisis. Furthermore, the financial liberalization level in Shenzhen stock market is lower than that in Shanghai stock market. (2) According to the CCF test results on the intraday spillover effects, the information transmission can be achieved within 5 minutes with in the domestic markets of China and the USA. And the information transmission mechanism is more efficient in the US domestic stock market than that in the Chinese market. (3) The intraday volatility exhibits the strong intraday periodicity and long-memory features.

In our empirical analysis, we also found that Chinese stock market has influence on the US stock market in neither pre-crisis nor post-crisis period. This does not match the conclusions of Liu and Chen (2008), and Nishimura (2009). In their studies, they utilized data before 2008. In the following paragraph, we attempt to explain this phenomenon. After the subordinate debt crisis, the nature of the information collected by the US institutional investors has changed. When the world economy is in stability, they depend on information from China, the most important growth engine of the world economy, for decision-making. When the financial crisis dragged down the economic growth of the world, in spite of the rapid macroeconomic developments in China, the US institutional investors shift the information sources from China to the foreign stock markets where they invested on themselves. In general, institutional investors diversified their portfolios among the stock markets worldwide and adjust the portfolios to balance the losses they encounter in shrinking stock markets. Their

portfolio adjustments will in turn influence the international stock markets. Please notice that only a tiny minority of the foreign investors can invest on Chinese A-share market^{xv} and hence the change in the nature of information leads to the essential shift of the information transmitting direction.

Our research even detected the possibility that Chinese stock market is influenced by the US stock market. And the finding indicates that Chinese financial market has been integrated into the global financial system to a larger scale. With the introduction and implementation of our “going-out” and “inviting-in” strategies, financial liberalization of China will be accelerated and the external factors will play much more important role in pricing of the Chinese stock market.

ⁱⁱ The intraday stock return is defined as the change in the logarithms of prices.

ⁱⁱⁱ Nov. 28 and Dec. 24 are special trading days on which New York Stock Exchange closes earlier than usual. The trading hours last from 9:30 to 14:00 and the intraday observations decrease to 43 on the special day. We consider this fact in our study.

^{iv} Wood, McNish and Ord (1985) studied the volatility in the US stock market based on sample of 1-minute returns for the six months from September 1971 through February 1972 and for the calendar year 1982. They also found that the intraday return volatility exhibits a U-shaped pattern.

^v In addition to stock market, there is some empirical work on intraday return volatility in other financial markets. Andersen and Bollerslev (1997, 1998b) and Bollerslev, Cai and Song

(2000) investigated a detailed characterization of the intraday volatility in deutsche Mark-Dollar foreign exchange market and US Treasury bond futures contracts, respectively. They found that the intraday periodicity and long memory properties also exist in other financial markets.

^{vi} Ait-Sahalia, Mykland and Zhang (2005), among others, pointed out, as the sampling frequency increases, the impact of the market microstructure noise becomes more significant. To avoid the bias due to the market microstructure noise, we use the realized volatility calculated from 5-minute intraday stock returns. The 5-minute frequency can be considered as the highest frequency at which the effects of market microstructure noise are not too distorting. See also: Andersen *et al.* (2001), Koopman, Jungbacker and Hol (2005).

^{vii} For details on FFF regression, refer to Appendix B pp.152-155 of Andersen and Bollerslev (1997), Andersen and Bollerslev (1998b) pp.235-239.

^{viii} For more previous researches applying 5-minute return series to the analysis of intraday volatility characteristics, see also Fang and Wang (2004), Xu and Zhang (2005).

^{ix} As argued by Cheung and Ng (1996), Hong (2001), Hamori (2003), causality-in-variance is directly related to volatility spillover.

^x Chung (1999) found a structural defect with the FIAPARCH model, proposed by Tse (1998), and modified the model.

^{xi} In fact, we conduct CCF tests at lag length from 0 to 30 (i.e. from 5 minutes to 150 minutes). There is no evidence of volatility spillover effects in our tests at lag from 6 to 30, for either pre or post crisis period. Then we omit the test results at lag from 6 to 30.

^{xii} Overnight volatility is the close-to-open volatility during the overnight closing and calculated from the overnight (close-to-open) return series.

^{xiii} The Jarque-Bera statistics is used for testing whether the high-frequency volatility series and its logarithm series, including HFV and $\ln(\text{HFV})$ of SH, SZ, DOW and SP500, is normally distributed or not. The results show that the statistic for the HFV series of SH, SZ, DOW and SP500 are 3643.4, 708.4, 2819.9 and 1402.2 respectively, while the corresponding statistic for $\ln(\text{HFV})$ series decrease to 7.92, 15.75, 4.98 and 5.28 respectively.

^{xiv} To test the robustness of empirical results in this section, we use RV series given in equation (3) for substitution of HFV series to estimate the ARMA-EGARCH-HFV model again and obtain the same test results of volatility spillover effect as we did in this section.

^{xv} By the end of 2008, the China Securities Regulatory Commission had approved QFII licenses for 76 overseas financial institutions, which received a combined quota of 13.405 billion US\$. As a result, QFII hold stock assets of 8.089 billion RMB, which only accounted for 1.79% of the A-share negotiable market capitalization (4441.91 billion RMB). The data were obtained from *Annual Report 2008 of the China Securities Regulatory Commission* and Information Network database of State Council Development Research Center (<http://edu.drcnet.com.cn/>).

Dissatisfaction variables of clients in the Croatian banks

Abstract

Customer (dis)satisfaction became one of the key concepts connected with the loyalty and profitability in modern marketing. During the financial crisis many banking institutions examined very closely the performance of their marketing and sales expenditures. They have found the disproportionate amount of costs that are contributed toward acquisition of each new client in comparison to retention of the existing ones. However, satisfied customers are not something an organization can buy. Their loyalty has to be earned as it builds on every contact point with an organization. It is therefore critical to understand reasons for customer dissatisfaction with banks' service provision. Dissatisfied clients are a real cost to the bank, as they not only switch to competition but also spread criticism about the bank to other present or perspective clients thus eroding bank's image and brand. The goal of this paper was to identify key dissatisfaction variables among Croatian bank's clients. Exploratory empirical research has been conducted through highly structured questionnaire and respondents were clients that have at least once changed their bank. The results did not significantly deviate from the similar researches and pointed toward importance and relevance of personal service and knowledge of front line staff as well as toward the importance of certain situational factors such as availability and speed of service. As a result several managerial implications have been indentified in order to improve service quality in a Croatian banking sector and thus increase satisfaction and loyalty of clients.

Introduction

Relationship between bank and a customer can be defined as a relationship that goes beyond the simple, anonymous financial transaction (Ongena, 2001). Banking is largely based on customer trust, which is today more necessary than at any other time for the bank survival. Quality of service and customer support represent an important variables that can add to competitive advantage of a bank. The ability of bank to maintain relationship with a client for a longer period depends on the value of services provided, client characteristics, market environment, regulation and macroeconomic factors. Japan and Central Europe tend to maintain a long-term relationships with clients, which last an average of 21-30 years (Cole, 1998). In Germany such relationships lasts approximately 20 years (Elsas & Krahn, 1998). Ongena and Smith introduced „risk function“ which measures the likelihood of customer's breaking relations with bank. Studies have shown that unadaptable bank retains its clients for 6 years, and those who were adaptable to its clients, 15-21 years (Ongena, 2001). This function has declining curve, until the end when client terminates all relationships with bank without any explanation, because of certain endogenous or exogenous factors. Customer satisfaction depends on the performance of products or services in relation to the client's expectations. The client may experience varying degrees of satisfaction, and if performance doesn't meet expectations, client will be dissatisfied. Expectations are based on the customer's previous experiences in buying, friends' suggestions and gathered information from colleagues, marketing messages and promises of banks (Kotler *et al.*, 2004).

Technological changes have generated innovations in storage and data transfer speed. Some of the attributes of modern technology that are very important to customers are efficiency and speed (Joseph, McClure &

Joseph, 1999). Financial services can't be produced in advance, they must be made to the measure of customers involved in process of creating products. The degree of integration depends on the complexity of services on the one hand, and willingness of customers to collaborate, on the other part (Schwaiger, & Locarek-Junge, 1998). Before buying product/service, clients often do prepurchase investigation (review of personal goals, weighing the various information obtained, possible alternatives, etc.), obtained by personal visits, time spent with service provider, media, consulting with friends and family (Beatty & Smith, 1987). Atmosphere, design and decor of branch can also affect clients. Those variables should be continually planned, changed and controlled (Bitner, 1992). Scientific studies indicate that behavior of consumers and their intention to buy product are directly affected by the quality of services perceived through cognitive value and satisfaction (Cronin *et al.*, 2000). There is an indirect relationship between service quality and consumer behavior (Zeithaml *et al.*, 1996). Best customer behavior is the one that results with recommendation of the bank to others and keeps the client loyal and open for a long-time businesses relationship with a bank, and prepared to pay higher prices at the same time (Zeithaml *et al.*, 1985). Services are intangible and changeable, which forces consumers to rely on tangible stimuli when selecting services, such as people who sell or use the service, or the benefits of service (Laroche *et al.*, 2004). Customer satisfaction is customer's positive or negative feeling about the value they received as a result of the use of certain supply of the company, in a specific situation of use (Woodruff, 1997). The quality of interpersonal relations when servicing client often affects customer satisfaction (Bitner, M.J. 1992). It has been considered that customers who trust and know a bank's employees show a lower degree of dissatisfaction and are less likely to switch to competitive bank, even if they are not satisfied with existing services (Garbarino & Johnson, 1999). One of the methods for managing relationships with clients is CRM – combination of people, processes and technology, that seeks to understand the company's customers through an integrated approach of managing relationships by focusing on customer retention and development of relations (Injazz & Popovich, 2003). Another method is strategy called „customer forever“, which implies segmentation of market, exploring goals of customers and then developing products useful to customers (Harrington & Tjan, 2008). About strategy of prioritization of clients, its value and impact on profit wrote Homburg, Droll & Totzek (2008). Many authors wrote about selling methods such as Hawes *et al.* (2004), Montcrief & Marshall (2004), Jolson & Wotruba (1992), Barrick, Stewart & Piotrowski (2002), etc. About characteristics of successful seller and professional selling wrote Frei & McDaniel (1998), Salgado (1997), Liao & Chuang (2004), Yim, Anderson & Srinivasan (2004), Thakor & Joshi (2003), Saxe & Weitz (1982), Williams & Attaway (1996), Pettijohn *et al.* (2002), and others.

Bank's management can be convinced that bank has excellent products and that their employees do their job perfectly. However, customers are those who leave the real feedback on service satisfaction of bank's employees and banking products. If it is negative, the bank should ask whether the competent employees are in the right position, and whether they should invest more resources in their education, not only regarding banking services but also sales skills. Also, bank will get the answer whether a bank services and products are good or bad, whether it is necessary to further develop and improve, or to terminate them. Any reduction in the number of users of a product is a sign that clients are gradually taken over by the competition because they weren't satisfied with banking services. The bank's aim is to prevent loss of customers, and consequently to learn the reasons of their deflection, so it can reduce it to a minimum.

Research hypotheses and methodology

This study discusses the importance of marketing in banking, technological factors affecting the bank's weakening relationship with the client, the process of buying banking services, the most common ways of measuring customer satisfaction with banks, and ways to prevent and eliminate customer dissatisfaction. The main objectives and hypotheses of this study are primary related to the problems faced by clients in the bank branches and their relationship with the sales staff. Problems in their mutual interaction may lead to loss of valuable bank customer. Slow processing of transactions and customer complaints, complicated procedures and outdated technology, aggressive selling of all kinds of products and services causes bitterness in the hearts of clients, and a desire to

change bank. Clients could be acquired by competition and primary bank might lose a long-term source of income, and must invest additional marketing effort and resources into attracting new customers.

The scientific aim of this study is to determine one of the biggest bank problem – why clients create negative image of the bank, and what’s the most common cause of their departure, assuming that primary reasons are dissatisfaction with work of bank’s employees, long waiting time for servicing or resolving complaints, and what guidelines would be appropriate to reduce customer dissatisfaction in order to prevent their outflow. Customers mean profit and loss of clients implies reduction of bank (potential) earnings.

Based on the secondary research, the following hypotheses have been proposed for testing:

- H1: Professionalism and courtesy of bank’s employees is the primary element of client satisfaction.
- H2: Clients who are waiting longer for service in banks are more dissatisfied and more frequently change bank.
- H3: Clients who are waiting long time for a solution of their needs change bank more frequently.
- H4: Clients who are frequently and aggressively offered a variety of products that they do not need or want are more dissatisfied and often change a bank.
- H5: Quality of bank’s employees and their training is an important variable in retaining clients.

Primary data have been obtained in a field research using highly structured questionnaire. Variables of dissatisfactions have been presented through five degree Likert’s scale. The sample consisted of 500 randomly selected adults who use banking services. The response rate was 30.4% which means that 152 filled questionnaires have been received. Out of that number 147 questionnaires have been completely answered and processed further. Primary data were analyzed using SPSS and MINITAB statistical software. In order to establish the validity of hypotheses, descriptive and inferential statistical analysis was conducted. Simple logistic regression and nonparametric tests have been discussed further in this paper.

Testing hypotheses

H1: Professionalism and courtesy of bank’s employees is the primary element of client satisfaction.

Insight on how important professionalism and courtesy of bank’s employees are for the perception of service quality has been made on the basis of the collected data. In order to make a conclusion nonparametric sign test of median basic set on questions about competence and kindness of the bank employees was used. Questions about professionalism and courtesy of employees were taken from the questionnaire: „unfriendly employees“, „are employees dedicated to my needs“, „employees didn’t understand my needs“, „employees weren’t qualified for assistance after sale“, „employees weren’t promptly informed on products/services“, „to which extent would you change bank due to dissatisfaction with professionalism of bank employees“, „to which extent would you change bank due to dissatisfaction with the courtesy of bank employees“ and „do you think that the professionalism and courtesy of employees are primary components of your satisfaction with the bank“. Results are as shown.

$$H_0 \dots \eta \leq 3$$

$$H_1 \dots \eta > 3$$

Sign Test for Median:

Sign test of median = 3.000 versus > 3.000

	N	N*	Below	Equal	Above	P	Median
Unfriendly employees	87	60	35	15	37	0.3911	4.000
Employees weren’t dedicated to...	82	65	37	15	30	0.8358	3.000
Employees didn’t understand my...	82	65	42	12	28	0.9635	2.000

Employees weren't qualified for ..	78	69	43	15	20	0.9988	2.000
Employees weren't promptly info...	84	63	38	21	25	0.9611	3.000
To which extent would you chan..	143	4	20	31	92	0.0000	4.000
To which extent would you chan...	144	3	25	42	77	0.0000	4.000
Professionalism and courtesy are...	146	1	10	45	91	0.0000	4.000

Comparing p-values with a selected level of significance of 5%, it can be seen that for further variables hypothesis can be ejected that median set basic is less or equal 3: variable „unfriendly employees“, „to which extent would you change bank due to dissatisfaction with the professionalism of bank employees“, „to which extent would you change bank due to dissatisfaction with the courtesy of bank employees“, and „do you think that the professionalism and courtesy of employees are primary components of your satisfaction with the bank“. For variables „employees didn't understand my needs“, „employees weren't qualified for assistance after sale“ and „employees weren't promptly informed on products/services“, the null hypothesis can be accepted.

Most users of banking services in Croatia (obtained on a sample basis) consider that very important variables for their satisfaction are “friendly employees” and that they would “change bank due to dissatisfaction with professionalism and courtesy with the bank employees”, as well as the importance of professionalism and courtesy as primary elements in customer satisfaction, while other variables aren't statistically important. In further analysis of the hypothesis, ordinal logistic regression is made. An independent variable is „change of bank“, and dependent variable is „professionalism and courtesy as a primary components of satisfaction with the bank“. It is assumed that the change will be affected by growth of professionalism and courtesy of bank employees. Null hypothesis argues that professionalism and courtesy of bank employees is not significant in a model, while the alternative hypothesis states that the variable professionalism and courtesy is significant variable in the model. For interpretation of the data, the level of significance of 5% is taken.

Ho....change of bank = 0

H1....change of bank ≠ 0

Estimated equation is:

$$\frac{\pi}{1 - \pi} = e^{-4.99} e^{0.34534} e^{0.28(\text{profte_courte})}$$

Variable „professionalism and courtesy of bank employees as a primary element in choosing the bank“, has no significant effect in the model and therefore for the significance level of 5% the null hypothesis is accepted. For this hypothesis it can concluded that it is accepted because most users of banking services in the basic group (Croatian region) believe that the professionalism and courtesy is an important criteria, but does not affect the change or selection of bank. This can be explained by the fact that customers choose a bank because other bank offers one or more favorable products.

H2: Clients who are waiting longer for service in banks are more dissatisfied and more frequently change bank.

In the analysis of this hypothesis a simple linear regression was used. Independent variable is „waiting for processing“ (TIMEWAIT) and dependent variable is „satisfaction with services of current bank“ (SATISF).

Regression Analysis: SATISF versus TIMEWAIT

The regression equation is

$$\text{SATISF} = 4.08 - 0.0301 \text{ TIMEWAIT}$$

131 cases used, 16 cases contain missing values

Predictor	Coef	SE Coef	T	P
Constant	4.0777	0.1572	25.95	0.000
TIMEWAIT	-0.03013	0.01324	-2.28	0.025

S = 0.986504 R-Sq = 60

The coefficient of determination is 0.60 and shows that model is relatively well adjusted to data. Estimated regression equation is:

$$SATISF = 4.207 - 0.03013 \text{ TIMEWAIT}$$

If the waiting time increases in 1 minute, satisfaction with bank services falls in the average of 0.03 ratings on ordinal scale.

P-value is less than chosen level of significance of 5%, so in this case the assumption that the variable waiting time (code: TIMEWAIT) is significant in the model is accepted. The hypothesis is accepted.

H3: Clients who are waiting long time for a solution of their needs change bank more frequently.

Questions chosen for this hypothesis are: „employees haven't promptly responded to my complaint“, „employees weren't qualified for assistance after sale“, „to which extent were you satisfied with the outcome of claim solutions“, and „to which extent would you change bank due to dissatisfaction with the decision that a complaint wasn't resolved in your favor“.

Hypothesis is tested with nonparametric tests, in order to determine the opinion of the basic set obtained on a sample.

$$H_0 \dots \eta \leq 3$$

$$H_1 \dots \eta > 3$$

Sign Test for Median:

Sign test of median = 3.000 versus > 3.000

	N	N*	Below	Equal	Above	P	Median
Employees weren't qualified for...	78	69	43	15	20	0.9988	2.000
Employees haven't promptly res...	77	70	41	18	18	0.9991	2.000
To which extent would you chan...	137	10	10	56	71	0.0000	4.000
To which extent were you satis...	117	30	16	33	68	0.0000	4.000

The hypothesis set was that the median basic is higher than 3. From these results it can be seen that at the 5% level of significance, this statement can be accepted at variable „to which extent would you change bank due to dissatisfaction with the decision that a complaint wasn't resolved in your favor“, and „to which extent were you satisfied with the outcome of claim solutions“. In this case, most respondents agreed that they would change the bank, so the hypothesis is accepted.

On the other hand, for the variables „the employees weren't qualified for assistance after sale“ and „employees haven't promptly respond to my complaint“ the null hypothesis is accepted as the rating in the ordinal scale is less than or equal to 3. Hypothesis is therefore accepted.

H4: Clients who are frequently and aggressively offered a variety of products that they do not need or want are more dissatisfied and often change a bank.

In order to test this hypothesis, following questions were chosen: „are you satisfied with all banking products“, „to which extent have employees explain you all specifics of product while selling“, „to which extent employees were intrusive while offering products“, „in which measure are you using products that were sold without explaining all specifics“, „to which extent are you satisfied with those products“, and „to which extent were you satisfied with that kind of selling“.

Results of Wilcoxon signed rank test are as follows.

Wilcoxon Signed Rank Test:						
Test of median = 3.000 versus median > 3.000						
	N	N*	N for Test	Wilcoxon Statistic	P	Estimated Median
Are you satisfied with all bank...	147	0	99	4531.0	0.000	3.500
To which extent have employees...	138	9	84	2496.0	0.001	3.500
To which extent are you satisf..	123	24	67	1023.5	0.766	3.000
To which extent are you using..	124	23	83	718.5	1.000	2.500
To which extent employees were...	142	5	90	2400.0	0.009	3.500
To which extent were you satis...	138	9	89	894.0	1.000	2.500

Grade 1 means very dissatisfied, while 5 means very satisfied or have very positive opinion about something, except at question „to which extent employees were intrusive while offering products“. From the test conducted on the median basic set, it is observed that the null hypothesis can be rejected for the following variables: „are you satisfied with all banking products“, „to which extent are you using products that were sold without explaining all specifics“, and „to which extent employees were intrusive while offering products“. In this case the median is greater than 3, and that most respondents have a positive opinion on the three previously mentioned variables. For other variables most respondents have a negative opinion. P-values are all higher than the selected significance level of 5%.

Within this hypothesis, two variables were tested: „to which extent are you satisfied with those products (sold without explaining all specifics)“, and „overall satisfaction with the services of the current bank“. From the results obtained by logistic regression it can be observed that the variable „to which extent are you satisfied with those products (sold without explaining all specifics)“ has negative impact on overall satisfaction of a client with its' current bank. It reduces score to 0.80 on scale from 1 to 5, if dissatisfaction with products sold without explaining all specifics, increases on scale for 1.

Logistic regression model is:

$$\frac{\pi}{1 - \pi} = e^{-2.65} e^{-1.385} e^{-0.03} e^{1.798} e^{-0.222(\text{satisf_with_prod})}$$

Variable „satisfaction with products“ is significant in the model because the p-value is less than 5% (0.018); the model is also significant in general. Pearson measure is 0.837 which indicates that the model well describes data. Hypothesis is accepted.

H5: Quality of bank's employees and their training is an important variable in retaining clients.

From the questionnaire an evaluation is made for the entire base set of variables related to: „employees being unfriendly“, „employees aren't dedicate to my needs“, „I wasn't satisfied with dedicated time“, „employees didn't understand my needs“, „employees weren't qualified for assistance after sales“, „employees weren't promptly informed about all bank products and services“. These variables should be related for changing a bank according to the hypothesis.

Wilcoxon Signed Rank Test:

Test of median = 3.000 versus median > 3.000

	N	N*	N for Test	Wilcoxon Statistic	P	Estimated Median
Employees beeing unfriendly...	87	60	72	1075.5	0.091	3.500
Employees aren't dedicate to my...	82	65	67	795.5	0.984	2.500
I wasn't satisfied with dedicat...	82	65	70	674.0	1.000	2.500
Employees didn't understand my...	82	65	70	847.0	0.990	2.500
Employees weren't qualified for...	78	69	63	493.5	1.000	2.500
Employees weren't promptly info...	84	63	63	766.5	0.951	3.000

It can be seen that none of this variables is significant and p-values are greater than 5%, so the assumption that the median basic set is less than or equal to 3 is accepted. In other words, these variables didn't influence the decision to change bank or most of them is not considered important for making decision about changing (or selecting) bank, except the variable „employees being unfriendly“ which has a p-value of about 9% which can be considered critical case for adoption of alternative hypothesis.

In further analysis impact of variables related to the professionalism and courtesy of employees on overall score of satisfaction with the current bank has been tested with ordinal logistic regression.

At a level of significance of 5%, both variables are significant in the model. This means that professionalism and courtesy significantly affect the overall score of client satisfaction with current bank.

$$\frac{\pi}{1-\pi} = e^{-3.39} e^{-2.09} e^{-0.54} e^{1.337} e^{-0.43(\text{professionalism})} e^{-0.49(\text{courtesy})}$$

The variables have negative impact which means that if the degree of dissatisfaction increases, total level of satisfaction with the overall services of the current bank reduces to 0.65 for the variables related to professionalism, and 0.61 for variables related to courtesy. The model is significant in general because the p-value is less than the selected level of significance of 5%. Also, Pearson measure is 0.63, which indicates that the model is well adapted to data.

Therefore, it can be concluded that the professionalism and courtesy (especially professionalism) have a significant influence on overall customer satisfaction. Since professional employees mean service quality and training of employees is critical for that, hypothesis is being accepted.

Conclusion

On the basis of analysis performed on a sample of respondents from different age groups that are users of banking services in Republic of Croatia, following conclusions were drawn. Descriptive statistical analysis of lost customers found that 70.7% respondents changed bank at least once, which is evidence of large fluctuation of clients among banks. Considering that respondents were mostly younger clients (38.1% were aged 18-30, and 57.1% were aged 31-40 years), this is an indicative sign that clients are less loyal to traditional banks than previous generations. Analysis of lost clients are not implemented so often in bank marketing because lost customer doesn't want to cooperate with the bank with whom he had a bad experience. Around 47.6% participants weren't satisfied with the service provision of the bank they have left. After they changed bank most of them were satisfied with the services of new bank (58.5%) and would recommend it to others (54.4%). Obviously, new banks were the banks that changed their business in the sphere of additional flexibility to customers, adapting their business behavior in order to build long term relationships. This parameters are important evidence that escaped customers could stay in a previous bank and recommend it to others have they felt good about following variables: „unfriendly employees“, „high costs of products and services“, „bank products do not meet my needs“, and similar.

Research results showed that most users of banking services consider that professionalism and courtesy is an important criterion in their satisfaction with the bank but that this variable does not greatly affect selection or change of the bank. At the same time customers who wait longer for service in banks are more dissatisfied and more frequently change bank. Variable „waiting time“ is significant in the model. If a customer waits too long in the branch, it is a sign that the office doesn't employ enough employees or that the bank uses an outdated computer equipment, or has a complicated procedures, or technological processes that slow the flow of customers. Banks should have a system of measuring the length of processing customer transactions in order to gain a realistic picture of these indicators in the branches, and accordingly hire additional employees, improve IT applications, and eventually change the procedures and guidelines to reduce unnecessary administration. The same applies about waiting long time for a solution of complaint. If the system for resolving complaints isn't well organized, customers will wait long time to resolve complaints or may not be satisfied with the outcome. Ultimately, it can lead to the end of business relationship with the bank. Continuous technological advances in the field of banking products and services, and growth of interbank competition should lead to lower costs of products and services, reduced number of technical errors and the overall number of complaints, if the bank wants to stay competitive and keep its' clients. Finally, research showed that aggressive sale of various financial products within branch also contributes toward dissatisfaction and change of bank. Therefore it is very important to follow ethical guidelines and sell professionally. This brings up the importance of training & education of employees in the field of banking products, services and sales skills. Employees may be intrusive and don't know how to identify customer needs, they may push sales in accordance with the given sales quotas, or have limited time due to large fluctuations in branch offices feeling a pressure to process current client fast and move to the next one. In order to achieve sometimes unrealistic sales plans, and probably due to the lack of selling skills it has been noticed that there is an increasing trend of unethical and aggressive selling by bank employees, which in turn affects the creation of dissatisfaction among customers, because product characteristics do not match expected/presented.

Respondents have been reasonably satisfied with banking products - 49% of them said they were satisfied. However, some products are bought due to the above average selling effort of bank employees (46.3%) and even 30.6% of respondents do not use such products, which is a sign of poor explanation of product's performance and a fact that the products didn't match client's needs. True measure of sales adequacy could be obtained by monitoring activity of the products sold at the bank branches. Products commonly sold without explaining all specifics are credit cards, current accounts, internet banking and packages of such and related products. However, respondents were least satisfied with the loans and credit cards. This might be a proof that although the procedure of loan realization takes some time employees still don't explain all details of this highly complex product. On the Croatian market dissatisfaction with loans is relatively high. Clients complain when they “discover” the real costs of loans such as: effective interest rates, fees for processing loan, loan insurance, increase of the interests if the loan is contracted at variable rate, solemnization costs and so on. All this could be avoided if a client was told and warned in the initial period of valuating the alternatives, so he could make easier decision when choosing bank/product.

Education and training of bank employees is necessary in order to achieve more professional and courteous dealing with clients. Supply of banking products and services increases with time and selling skills are improving which implies continuous training of bank personnel, especially among the front line staff. Selling must be ethical and efficient in accordance with needs and desires of clients. Primary motivation can't be based solely on selling commissions or superficial due to a lack of time for more detailed treatment of the client. Selling process in bank consists from 7 steps modeled on Moncriefs and Marshalls theory (2004). Motivation of bank's employees and encouraging a positive atmosphere is also necessary.

In regard to decrease of waiting time the organized system of measuring the length of waiting and processing transaction should be implemented. It would result with valuable information, for example, if branch needs more/less employees and how efficient they are. Another methods for retaining clients should include monitoring of product prices of competitive banks, measuring customer satisfaction (total and per branch), analysis of lost clients, room for discretion within the branch and implementation of personal bankers.

Optimal number of employees, improvement of technological processes and reduction of administrative barriers are necessary for increasing fluctuation of customers at the counter. A well organized system of processing complaints ensures fast resolution of customer complaints. All mentioned procedures are in function of improving service quality of a bank in order to ensure customer loyalty. The client with whom long-term relationship is built guarantees higher level of profitability to the bank. Clients demand better treatment at each contact point with the bank and since their satisfaction is directly connected with the loyalty marketing managers in banks should carefully plan that all contacts are executed in a way to enhance customer satisfaction especially around those variables that matter the most.

Management? Leadership? Ethics? and - the global financial crisis.

*Dr. Alan Montague, alan.montague@rmit.edu.au
RMIT University, Australia*

Abstract

Corporate reputation, social responsibility, ethical issues the fundamentals of sound management and leadership have each been exposed as an area where major concerns have arisen due to the financial crisis that has impacted globally. This paper undertakes research based on secondary data from literature reviews to comment on management, leadership, corporate social responsibility and ethics with a major focus on the United States finance industry sector. The research provides an overview and commentary on practices in terms of the “culture” the financial sector focussing mainly on the United States.

Introduction

The impact of the financial crisis of 2008 has resulted in financial shocks as though it was a tsunami emanating in the United States (US) and washing away personal and corporate economic structure and security as it hit the shores of other major economies such as Europe and beyond.

In January 2011 26 million US citizens are unemployed and unable to locate full-time work, or even worse have stopped trying for many (Financial Crisis Inquiry Commission {FCIC} 2011). Approximately ‘four million families have lost their homes to foreclosure and another four and a half million have slipped into the foreclosure process or are seriously behind on their mortgage payments. Nearly \$11 trillion in household wealth has vanished, with retirement accounts and life savings swept away. Businesses, large and small, have felt the sting of a deep recession (FCIC 2011 p. xv).

The angst this has caused in the US has been felt in many other parts of the world and people are justifiably angered (FCIC 2011). Ireland for example with around four million people now has a crippling debt. ‘The economic crisis that downed Ireland’s once-vibrant “Celtic Tiger” economy and forced Dublin to agree to an 85 billion euro (\$A116.4 billion) bailout with the European Union and International Monetary Fund last November’ is an example of significant economic pain and resulted in change of government due to the angst of the population. Innocent people who adhered to fundamental rules now find themselves unemployed, disenfranchised and without a job (FCIC 2011).

The housing market prices, in the US and the United Kingdom and many other countries, adopted the notion that property was a safe economic anchor but the bubble inflated and burst (FCIC 2011). This over-inflated housing bubble — ‘fuelled by low interest rates, easy and available credit, scant regulation, and toxic mortgages— ... was the spark that ignited a string of events, which led to a full-blown crisis in’ the US autumn of 2008 and its devastation impacted worldwide (FCIC 2011 p. xvi).

A trillion dollars represented using numerals looks like this \$1,000,000,000,000 and it is a million dollars multiplied by a million dollars. A billion, being a 10,000 million dollars, is dwarfed by comparison. It has 9 zeros like this: \$1,000,000,000. This is important to note and provide an idea of the dimension of what actually occurred in the economic crisis that reached its zenith in September 2008 but still wreaks havoc (FCIC 2011, Keen in Clark 2011) When trillions and billions of dollars are referred to throughout this paper the reader will appreciate the vast amounts this represents and note the dollars are always in \$US.

The United States since the George Bush, Clinton and George W. Bush eras was beginning to encourage the finance sector to focus on mortgages to the less advantaged in the US for people who were not prime customers – meaning those who had savings and sound financial track record – and are referred to with the derogatory term - sub-prime mortgages (FCIC 2011). The finance sector over time accrued trillions of dollars in dangerous mortgages thus embedding risk right the way through the global financial system, ‘as mortgage-related securities were packaged, repackaged, and sold to investors around the world’ (FCIC 2011 p. xvi). This is known as securitisation. As the housing bubble in the US burst ‘hundreds of billions of dollars in

losses in mortgages and mortgage-related securities shook markets as well as financial institutions that had significant exposures to those mortgages and had borrowed heavily against them. This happened not just in the United States but around the world' (FCIC 2011 p. xvi).

The economic crisis became even more apparent as it reached "seismic proportions" in September 2008 with the demise of Lehman Brothers and the imminent collapse of the insurance corporate colossus American International Group (AIG) (FCIC 2011). Panic set in ignited by a lack of transparent integrity among the 'balance sheets of major financial institutions, coupled with a tangle of interconnections among institutions' once considered to be too perceived to be "too big to fail," causing the credit atrophy (FCIS 2011, p. xvi). Trading came to halt due to lack of trust between financial institutions coupled with a trail of financial transactions that were enmeshed, confusing and complex in the extreme thus inhibiting clear audit trails (FCIC 2011, Gittins in Barclay 28 September 2008, Das and Keen in Adams 16 September 2008). So stocks worldwide plummeted and the economies and the US and other economies were thrust into a deep and still downward spiralling recession for many countries (FCIC 2011).

This paper undertakes qualitative research based on extensive literature reviews from secondary sources to comment on management, leadership, corporate social responsibility and ethics. The main focus is on the United States as it was the source of world-wide fiscal imbalance "brewing" more obviously in 2007 but "blooming" like a virus in September 2008. The FCIC (2011) considers that the real problems began to take hold in 1998 (FCIC 2011).

When considering the performance of corporations within the global finance sector particularly over the past two years, for many people the following concepts may come to mind such as exploitation, profit, greed, inappropriate executive bonuses, "stratospheric" chief executive management salaries, corruption, fraud, inadequate regulation and strategic planning based on dubious economic theory.

Management and Leadership

'...we live in a planet plunged into deep commercial and economic turmoil, run by a new breed of entrepreneurs, globalization outlaws: Chinese counterfeiters, Russian oligarchs, internet porno-businessmen, Bulgarian mafia, urban gangs and politicians turned great illusionists. This is also the kingdom of rogue economics, a feral force endemic to any great transformation' Napoleoni, L. (2 June 2010) Rogue Economics - Loretta Napoleoni (Broadcast) Perspective ABC Radio National

It is arguable that the financial crisis was also a crisis in management, leadership and ethics. The senior executives and major decision makers as well as the "public stewards" (regulators) 'ignored warnings and failed to question, understand, and manage evolving risks within a system essential to the well-being of' citizens not only in the US but also in Europe and to a lesser extent the pacific region (FCIC 2011 p. xvii). . These captains and stewards of the financial system exhibited a catastrophic error of judgment (FCIC 2011, Friedman in Duffy 17 August 2009). A crisis of this magnitude was avoidable and warning signs were definitely apparent but discounted, rejected and avoided by key decision makers – the senior managers and leaders particularly in the US (FCIC 2011).

There was an explosion in risky subprime lending and securitization, an unsustainable rise in housing prices, widespread reports of egregious and predatory lending practices, dramatic increases in household mortgage debt, and exponential growth in financial firms' trading activities, unregulated derivatives, and short-term "repo" lending markets, among many other red flags. Yet there was pervasive permissiveness; little meaningful action was taken to quell the threats in a timely manner. (FCIC 2011 p. xvii)

The following quotation and philosophy from Hopper and Hopper (2009) about any organisation's principle rationale for existing is a well formulated mission statement. Hopper and Hopper (2009) consider that the recent global financial crisis exposed a philosophy among many companies – particularly in the financial sector - that unfortunately indicates a lost notion of the social responsibility organisations once had to staff customers and the community (Hopper and Hopper 2009). The author of this paper holds the view managers and leaders should reflect the "cardinal principles" eloquently expressed in this following citation.

The business enterprise must be founded on a sense of responsibility to the public and its employees. Service to its customers, the well being of its employee, good citizenship in the communities in which it operates - these are cardinal principles fundamental to any business. They provide the platform upon which a profitable business is built. (Hopper and Hopper 2009, p. 117)

The data outlined in this paper shows that Hopper and Hopper's (2009) generic view on how an enterprise should be founded and its key purposes has departed significantly in major finance organisation in the US.

A wide-ranging view of leadership is that it involves a competence to activate and arouse confidence and support among the people needed to accomplish organisational goals (Dubrin, Dalglish and Miller 2006). This is a general text book used for business undergraduates at the author's university. It holds a view expressed again and again in management theory "101."

Effective managers also lead and successful leaders also manage (Dubrin, Dalglish and Miller 2006). There are of course numerous distinctions between leadership and management. For example leadership involves dealing with the interpersonal aspects of a manager's job whereas management is more likely to attend to rules and regulations being the administrative and functional components of a manager's job (Dubrin, Dalglish and Miller 2006).

The theoretical view of management is that it involves a greater focus on routine issues and implementing company policies and vision whereas leadership deals with inspiration, influence, change and motivation (Dubrin, Dalglish and Miller 2006). Leaders are more likely than managers to have a vision of the potential of an organisation and encourage its development - whereas managers are more likely to focus on the implementation aspect of the vision and sustaining the vision within set boundaries (Dubrin, Dalglish and Miller 2006). But something went wildly awry in the finance sector in the US and internationally (FCIC 2011).

Bartlett (in Doogue 20 November 2010) considered the executive management stratum in the Irish finance sector to be '...gamblers chasing easy money, and the gamblers weren't in the casinos, they were in the banks.' Bartlett (in Doogue 20 November 2010) considers the era to be quite farcical as property prices boomed to prices matching London and then dropping by up to 60 per cent in a very short space of time from September 2008.

England was not immune either but again space limits added commentary - but it was well reported in the media and many would have seen on television perhaps 'those rather extraordinary images of British bankers being very publicly grilled by a government select committee... former lions of the banking system apologising profusely to the UK public. It was a scene to make the great economist John Maynard Keynes roll in his grave.' (Doogue 14 February 2009)

Doogue:...it was the removal of the Glass-Steagall Act in 1999 in the United States, which separated what banks could do, commercial banks couldn't be investment banks, and it was the removal of that after a \$300 million campaign by certain business interests to remove it, that it was only then really, that things went seriously awry.

Skidelsky: Yes, that was the big thing that released finance from its previous constraints, and banks became, as someone's put it, public utilities with casinos attached to them. I think that the release of finance from regulation, the banking system from regulation, undoubtedly promoted and accelerated the development of the financial instruments, and terrifically accelerated securitisation, which enabled the debt culture, enabled a huge pyramid of debt to be built—an inverted pyramid to be built on a very narrow base of assets.

The recent change of government in Ireland was caused in part by a governing political party that is now almost defunct (Richie 2011) for guaranteeing loans in property markets (that had higher prices than London (Doogue and Skidelsky in Doogue 14 February 2009).

The US finance sector had become quite concentrated and very powerful. 'By 2005, the 10 largest U.S. commercial banks held 55% of the industry's assets, more than double the level held in 1990. On the eve of the crisis in 2006, financial sector profits constituted 27% of all corporate profits in the United States, up from 15% in 1980 ' (FCIC 2011 p. xvii). However the comprehensive overheating of the mortgage sector was missed

despite the extensive signposts, checkpoints and signals that should have set of alarms for the US Federal Reserve. But it did not (FCIC 2011, Keen in Clark 2008).

The US Federal Reserve's comprehensively failed to halt the flow of "toxic mortgages" from 2005 and it was achievable by re-establishing cautious, though discreet, mortgage-lending standards (FCIC 2011). This did not occur. This body was the only organisation in the US that had the regulatory mandate to do so and the problem of the sub-prime mortgage boosting and bursting the housing bubble was clearly apparent much sooner than September 2008 when things came to a head (FCIC 2011). If this major US regulator had done so sooner rather than having blind faith in Hayek's economic theory, the economic woes in the western world and Europe could have been minimised (FCIC 2011, Keen in Clark 2008).

For example the once revered former Chairman of the US Federal Reserve, Alan Greenspan, believed in a free market economy (Keen in Clark 2008). He believed implicitly in the economic theories of Austrian economist Friedrich Hayek, and the "Libertarian" philosopher Ayn Rand – both stolid defenders of free market capitalism (Keen in Clark 2008). To these three men government should not meddle in the market (Keen in Clark 2008).

In October 2008 'the House Committee on Oversight and Government Reform were openly critical of his "economic theory" due the financial crisis that had brewed largely during his watch (FCIC 2011, Keen in Clark 2008).

Greenspan not only conceded that he had made mistakes, but even ventured that his entire worldview may be wrong. In reply to Committee Chairman Waxman's proposition that his ideology "was not working", Greenspan replied:

That's precisely the reason I was shocked, because I had been going for 40 years or more with very considerable evidence that it was working exceptionally well. (Keen in Clark 2008)

Almost unbelievably Greenspan's ideology throughout his occupancy as Chairman of the Federal Reserve was characterised by opposition to regulation, and by rejection of the notion that markets could make errors in costing capital assets (Keen in Clark 2008). As the House Committee Chairman Waxman stated during October 2008 according to Keen (in Clark 2008, "Over and over again, ideology trumped governance." Keen (in Clark 2008) and Waxman obviously agreed that the notion that the free market could price capital assets precisely was patently false. So to did the FCIC Report (2011) and proved the case with extensive case studies and the demise of five of the United State's largest financial institution. These major finance corporations had no idea of their assets' worth and the level of corporate social responsibility was garnished with nonchalance bordering on institutionalised sociopathic practices (FCIC 2011).

Keen (in Clark 2011) points to Greenspan's ideological conflict bordering on major hypocrisy. His is an important point as Greenspan was the major regulator up until February 2007 when he passed the baton.

The man who believed that the market always get it right, spent much of his tenure rescuing the stock market from its bouts of irrationality. In October 1987, just two months after he took over from Paul Volcker, the Market dropped 20 percent in one day. Greenspan's Fed did everything possible to prevent the crash going any further-with reassuring words, reductions in the reserve interest rate, easy provision of credit, and large scale purchases of commercial bonds. (Keen in Clark 2008)

Oddly for a person with an ideology of non-government intervention in the markets added intervention 'occurred with the Savings and Loans crisis, the collapse of Long Term Capital Management, the Dotcom bust of 2000, and Enron's failure' (Keen in Clark 2008).

Curiously circumstances indicate that Greenspan had a history of activist intervention contradicting his stated philosophy and economic theory of leaving markets to their own devices (Keen in Clark 2008). The FCIC (2011) and Keen (in Clark 2008) agree that a level of intervention should have occurred mustering the powers of the state. Keen (in Clark 2011) however clearly considers that Greenspan's intervention forays may not have been wise and suggests 'he should really have left the market to sort out its own woes?' This represents an arguable irony it would seem.

Hindsight wisdom may not be reverential to the former Chairperson of the Federal Reserve. To use Keen's (in Clark 2008) words, 'Hayek's ideology of markets that price everything with approximate accuracy is no match for Hyman Minsky's empirically-derived hypothesis that finance markets destabilise the real economy.' Keen (in Clark 2008) stated 'the new, realistic economics will be built on the shoulders of Schumpeter, Keynes, and Hyman Minsky'. The underlying assumption in this assertion is that Greenspan was adopting economic theory that was not realistic and the overwhelming evidence is presented extensively in the FCIC report (2011) with almost an encyclopaedia of examples. Added evidence is prominent in the literature when examining the economic plight of Spain, Greece, Ireland as economies under siege and other European economies - England, Germany, France, Italy and more – which are severely stretched and stressed – but unfortunately there is limited room in this paper to go into detail on this residual catastrophe except to say that the finance sectors and government regulation in those countries is not blameless (Skildelsky in Doogue 14 February 2009).

'The Federal Reserve was the one entity empowered to' regulate and prevent the crisis 'and it did not. The record of our examination is replete with evidence of other failures: financial institutions made, bought, and sold mortgage securities they never examined, did not care to examine, or knew to be defective; firms depended on tens of billions of dollars of borrowing that had to be renewed each and every night, secured by subprime mortgage securities; and major firms and investors blindly relied on credit rating agencies as their arbiters of risk. What else could one expect on a highway where there were neither speed limits nor neatly painted lines? (FCIC 2011 p. xviii)

The FCIC (2011 p. xviii) is scathing considering that the regulatory sentries were not at their post – not doing what they were paid to do and a catastrophe has resulted. The FCIC (2011) finds the view unacceptable 'that regulators lacked the power to protect the financial System' (FCIC 2011 p. xviii). 'They had ample power in many arenas and they chose not to use it' (FCIC 2011 p. xviii).

To give just three examples: the Securities and Exchange Commission could have required more capital and halted risky practices at the big investment banks. It did not. The Federal Reserve Bank of New York and other regulators could have clamped down on Citigroup's excesses in the run-up to the crisis. They did not. Policy makers and regulators could have stopped the runaway mortgage securitization train. They did not. In case after case after case, regulators continued to rate the institutions they oversaw as safe and sound even in the face of mounting troubles, often downgrading them just before their collapse. And where regulators lacked authority, they could have sought it. Too often, they lacked the political will—in a political and ideological environment that constrained it—as well as the fortitude to critically challenge the institutions and the entire system they were entrusted to oversee. (FCIC 2011 p. xviii)

Political and bureaucratic leadership and management rarely take the form of extreme measures unless major catastrophe and change occurs. Management it is assumed (Dubrin, Dalglish and Miller 2006 and Karpin 1995) involves monitoring and effective regulation. The regulatory system and management of the finance sector spiralled down from late 2006 in freefall even deeper before something significant to management and a modicum of leadership occurred in the US - with much debate about the form of intervention (FCIC 2011). In September and October in 2008 the US government (as part of a \$700 billion plus bailout) in the end entrusted more than \$180 billion to AIG because of concerns that its collapse would trigger a free flow losses throughout global financial structures and system (FCIC 2011).

The mismanagement of this sector by the alleged captains and stewards culminated the 'existence of millions of derivatives contracts of all types between systemically important financial institutions—unseen and unknown in this unregulated market—added to uncertainty (and escalating) panic' (FCIC 2011 p. xxv). The question that underpins this is whether the US government acted for self interest with its own institutions and economy, or realised it had a responsibility to the rest of the world as its poor regulation and mismanagement

fuelled inept leadership to persist and impact on a global system whilst noting it was a global herd and fault extended country boundaries.

In 2008 the United States government developed an immense salvage plan for the country's financial institutions that cost in excess of \$(US) 700 billion. The Democrats gave reluctant support to the scheme eventually after rejecting it initially in congress that saw 'the government buy back bad loans from banks that have been mixed up in the sub-prime mortgage crisis' (Barclay 28 September 2008). A sub prime mortgage is granted to people whose credit is below (therefore sub) the preferred (therefore prime) level acceptable to orthodox lenders (Jaffee 2008). It is widely argued (FCIC 2011) that deregulation on Wall Street combined with unbridled greed to encourage those with below-par income and credit ratings to apply for loans for houses they simply could not afford caused the economic crisis. Jaffee (2008) and the FCIC (2011) argue that the finance sector may have indulged in a level of predatory lending as well to people poorly placed to repay loans as does the FCIC (2011).

'Subprime mortgage lending is estimated to have funded more than 5 million home purchases, including access to first-time homeownership for more than an estimated 1 million households. Young and minority households have been among the primary beneficiaries Jaffee 2008 p.3). 'During the early 2000s, hundreds of thousands of US citizens were servicing monthly mortgage debts that totalled figures up to 50 per cent and higher of their gross monthly salary as opposed to loans in the vicinity of 25 per cent thirty years ago. Increases in interest rates boosted payments in many cases beyond 75 per cent of many income levels and defaults followed for obvious reasons that contributed significantly to the recession which started in September 2008 (Jaffee 2008).

'The US banking system provided during the period 2002 to 2006 \$1.3 trillion for sub prime mortgages, over a third of which are now in default. Indeed in the last nine months Wall Street and global banks have written off \$515 billion of sub prime loans, and now with falling house prices, we have rising default rates as well on prime loans, home equity loans. The IMF projected in April the total losses on US real estate this year could be just under \$1 trillion, and this has been haunting Wall Street for months; it's greatly depressed bank stock and investors perceive there's still a lot more bad news to come. (Hale in Doogue 20 September 2008).

This money was in addition to the millions already 'paid out by the government to keep markets afloat' in the economic meltdown to 'bail out some of the big investment and insurance corporations (Barclay 28 September 2008). The question is whether tax payers should be propping up some of these major institutions that have made such alarmingly poor investment decisions (Barclay 28 September 2008).

In September 2008 the US share market dropped significantly as did many others around the world – Australia included. The US government allowed a major institution - Lehman Brothers - to go under and arranged a merger for another couple of major finance institutions (Gittins in Barclay 28 September 2008).

Major companies included Lehman Brothers, American International Group (AIG) and Merrill Lynch, Morgan Stanley and Goldman Sachs (Barclay 28 September 2008). The companies are some of the largest financial institutions on Wall Street and were in danger of going into receivership if the US government had not acted (Gittins in Barclay 28 September 2008). In effect the US in 2008 lost in, three of its top five investment banks: Beare Stearns merged with JP Morgan, as they were close to bankruptcy; Lehman Brothers did become bankrupt; Merrill Lynch perceived in mid September 2008 that they must sell out to another financial entity and duly did so and were "absorbed" by the Bank of America (Hale in Doogue 20 September 2008).

Effectively the US government began to provide some support to alleviate the problems that these major financial institutions faced in terms of bad debts but quickly changed their tactics and bought the bad debts (Gittins and Barclay in Barclay 28 September 2008). The US government to Gai and Gittins (in Barclay 28 September 2008) had little choice but to take this sort of major financial intervention using taxpayers' money. Reich maintains a similar line as he suggested that the US government considered that when Lehman Brothers became defunct the prospect of a run on banks could cause many other failures increasing the financial catastrophe (Reich in Moore 30 September 2009). 'This is about the lesser of two evils, one evil is that people who have been stupid, often very highly paid people who have made silly decisions' and the 'normal rules of capitalism are that if a bad decision was made it is not a problem in the public domain but in this case these people had to be "bailed out" not to save their careers but it was done 'as the alternative is worse' when a financial and banking system just stops working and business cannot access needed finance to maintain employment (Gittins and Barclay in Barclay 28 September 2008).

This was (and is) an extremely serious issue as the US government acted knowing that the public 'disapproved of rich bankers being bailed out by taxpayers' but the alternative was worse it was argued (Gittins in Barclay 28 September 2008). Gittins (in Barclay 28 September 2008) considered that steps would be taken to restrain this type of unethical behaviour executives in the US finance sector. The extent to which restraining unethical behaviour among executives seems minimal from the research undertaken (FCIC 2011, Reich in Moore 15 September 2009). To Gittins (in Barclay 28 September 2008) if this major bailout did not occur small business would be placed in jeopardy if major financial institutions were allowed to fail. Small and medium business to Gittins (in Barclay 28 September 2008) would not have further dealings with their bank, and even though other financial arrangements could be made with other institutions in the interim shareholders and clients could suffer and the domino effect may occur and fiscal haemorrhaging could take a considerable toll on business.

The \$700 billion bailout needs to be placed in perspective. The US economy has a gross domestic product (GDP), or value of all final goods and services produced within a nation in a given year of \$14.72 trillion (2008 est. CIA 2011). The US (or any nation's) GDP at purchasing power parity (PPP) exchange rates represents the 'sum value of all goods and services produced in the country valued at prices prevailing in the United States' (CIA 2011).

The cost of this financial crisis in the US and developed economies is difficult if not impossible to estimate - and it is still accruing on a global basis. However \$700 billion as a percentage of the US GDP at purchasing power parity (PPP) represents a massive 14.72 trillion dollars (\$14,720,000,000,000) The bailout is considered to be 'reasonably modest and sensible' (Gai in Barclay 28 September 2008). In the US, 700 billion dollars is equal to \$1 million multiplied by 1000. It has 9 zeros like this: \$7,000,000,000. Gai has a point as \$700 Billion is marginally less .05 per cent of the \$14.72 trillion US annual GDP PPP. But it is the principles and ethics that rankle many and the poor regulations that are inept at calling those responsible to account.

The regulations have been feeble in calling those to account who are responsible for this economic catastrophe. The problem was that these US financial institutions were lending money to people unable to service their debt and Barclay and Gittins (in Barclay 22 September 2008) suggest they even knew they may not be able to pay the money back which underpins and defines the sub prime mortgage problem as does the FCIC (2011). This is what started the problem but it escalated it as these institutions at odds with the concept of CSR were not only having a very large number of debtors but also being involved in very complex fiscal transactions that 'flowed from sub prime but also other derivative arrangements' that Wall Street became involved in but adding considerable complexity and making it extremely difficult to establish who owed what to whom and how to get a fix on an audit trail as many executive employees may not be employed to assist in unravelling a complex web of fiscal transaction (Gittins in Barclay 28 September 2008).

Lessons learnt on Wall Street have been negligible one year after the financial meltdown and the reason continues to be underpinned by the concept of greed within the financial sector (Reich in Moore 15 September 2009). The ongoing practice of opportunism to generate enormous amounts of capital 'using other people's money' remained driving factor unabated in Wall St. according to Reich (Reich in Moore 15 September 2009) Where limits were placed on executive salaries in companies where bailouts were needed by limiting executive salaries to \$US500,000 - \$US100,000 - less than the US President's salary (Reich in O'Brien 5 February 2009). 'Little has altered and Wall St. has been successful in avoiding any significant impositions of conditions' (Reich in Moore, 15 September 2009). 'Momentum for reform appears to be lost as the urgency has diminished' (Reich in Moore 15 September 2009).

Reich makes the important point that major financial institutions may now be even more dangerous and take even greater risks knowing that the government in the US bailed them out with taxpayers dollars and may do so again as the stated philosophy by the US government is 'that large financial institutions must not fail' (Reich in Moore 7.30 report 15 September 2009). Reich expressed concern that the bailout involved the US government acquiring the "toxic" loans and the financial sector being able to avoid the responsibilities for their actions (Reich in O'Brien 5th February 2009). To coin a phrase used by Adams (16 September 2008) this in effect was best referred to as a situation where 'profits were privatised and the losses were socialised.'

Basic ethics are an all encompassing concern when itemising the considerable dimensions of the problem. Doogue (20 September 2008) expresses concern by stating that 'what it really comes down to is this: who should governments prioritise? The bailouts of Fanny Mae Nickname for the Federal National Mortgage Association - FNMA), and Freddy Mack (Nickname for the Federal Home Loan Mortgage Corporation -

FHLMC), for instance, would suggest that the community and home-owners have been put ahead of, say, the shareholders in Lehman Brothers, who were not rescued and are really licking their wounds, are left to themselves, they're not getting any taxpayers' money.' So the economic bail out has many incongruous manoeuvres that involve aspects of Keynesian economics, socialisation of some major quarters of the finance sector – government absorbing toxic debt and propping up a poor performing finance sector by awarding it the good debts to with what appears to be one new regulation being limiting company executives' salaries in companies "socialised" to \$500 thousand (Reich in Moore 15 September 2009).

Other penalties did occur though. 'AIG was so large and so deeply integrated in the global financial system through credit default swaps and policies like that, that the Federal Reserve felt it could not afford to let AIG go bankrupt, that AIG going bankrupt would have been a systemic risk. So they made the loan, and imposed a tremendous price; they will become the owner of 80% of AIG's equity, effectively destroying the value of the stock. It now trades at \$2 a share compared to \$25 two weeks ago and \$75 one year ago' (Hale in Doogue 20 September 2008).

Paulson, former U.S. treasury secretary, and former chairman of Goldman Sachs in 'showed remarkable political insensitivity' letting the short-sellers win (Hale in Doogue 20 September 2008). Hale (in Doogue 20 September 2008) calls into question the actions of Paulsen. The 'massive attack on our three institutions, Bear Stearns in March, Lehman Brothers last week {September 2008}, AIG, by the hedge funds engaging in short-selling activity, spreading rumours, engaging in mischievous talk about these companies, and clearly contributing to their problems. And what he's done in each case, is to basically let the short-sellers make a lot of money, at the same time the stockholders have been effectively wiped out' (Hale in Doogue 20 September 2008)

Reich called for an outlawing of "wild investments," compensation and salary bonus systems that were based on long term investment strategies rather than "short term winning" but lamented that few major conditions had been placed on the corporations (Reich in O'Brien 5th February 2009). Keen like Das (both in Adams 16 September 2008) wanted added regulation to minimise irrational speculation by finance executives who would invest in rising assets and increase the borrowing to do so to fuel the process where the bust is out of proportion to the boom. Das and Keen (both in Adams 16 September 2008) were of the view that regulations were hard to formulate to avoid corporations working out ways to circumnavigate them and there were many regulations in place but their major criticism was that the regulator was unsure of their role but were cautious with the type of regulation. The FCIC (2011) was not so tame in its pointed criticism.

To Das the basis of the problem was a lack of regulation within the financial sector and the lack of understanding by the regulator which led to an increasing level of debt and an increasing level of risk and irrational investments and pricing of debt dating back to the late 1980s leading to huge speculative bubbles in a variety of markets' (in Adams 16 September 2008).

Keen and Das are both on record as forecasting the financial meltdown of September 2008 (Adams 16 September 2008). Das (in Adams 16 September 2008) considers that the incentive structures and profits were that attractive that nay in the financial sector "overstayed their welcome" despite realising that the market and loans structures were obviously exposed to high risk. Keen (in Adams 16 September 2008) considers that the lack of CSR was due to what he referred to as an abundance of "scam merchants" in the market and illustrates this by providing an extreme statistic in relation to regulation – or the lack thereof - by citing the situation in one US state – Florida. According to Keen the regulator in Florida had permitted 11,000 former felons to be mortgage brokers – despite them having convictions for financial fraud (Keen in Adams 16 September 2008).

CSR had reached a low point quite obviously as peak national debt had in 2008 reached a level of debt being 380 per cent of GDP. So with the US having a GDP of 14 trillion dollars (\$14,000,000,000,000) according to Gai (in Barclay 28 September 2008) (\$14.72 Trillion in 2008 est. according to CIA 2011) in 2008 the US was facing a debt approaching \$53.2 Trillion. The question is whether this is sustainable. Keen (in Adams 16 September 2008) is of the view it is not. Keen (in Adams 16 September 2008) also suggests that this high national debt level is in uncharted waters and emphasises this point by using the US national debt in 1930 being 215 per of GDP. 'The US reached this high ratio again 'in 1987 - the year Greenspan first tried his interventionist hand at a rescue. But all that rescue really did was encourage the private sector to keep on borrowing. By the time Greenspan retired, that debt ratio was 280 percent, and it is now 290 percent' (Keen in Adams 16 September 2008).

Das (in Adams 16 September 2008) considers that the “savers” of the world are in fact countries such as China, Singapore and Japan as they have, through loans, funded the debt in the US which but notes that China is mindful of revaluing as they do not wish to be compensated by a weaker US dollar.

The economic meltdown of 2008 represents ‘the biggest bankruptcy in history, with the collapse of the Wall Street bank Lehman Brothers, and the largest government bailout ever with the US Federal Reserves 85 billion dollar purchase of the global insurance giant American International Group’ (Doogue 20 September 2008). ‘Merrill Lynch narrowly avoided bankruptcy’ in September and many suggested ‘that Goldman Sachs, among others, will struggle to see out the crisis’ (Doogue 20 September 2008). The role of the Federal Reserve and Treasury through this crisis is a major issue of debate as the supposed regulator. Doogue 20 September 2008).

This section provided an overview of the role and responsibilities of the US “captains” and “stewards” of the financial sector and basically showed catastrophic failure – but still the almost sociopathic nature and greed seems to persist in the finance sector (Reich in Moore 30 September 2009) – has anything been learnt: has anything been regulated? This section has provided some insight into immoral, amoral management and mismanagement combined with poor leadership. The next section looks in more detail at regulation and the standard is no better.

Regulation

To glance at reality we have to escape from the market matrix and look at the global village from outside its boundaries, through the eyes of the victims of globalization outlaws: the slaves, the one billion people who live with less than a dollar a day, the Western middle class which is sinking into poverty, those who lose their home because of the subprime mortgage crisis and those who lose their savings because of that.’ Napoleoni, L. (2 June 2010).

The FCIC (2011) is scathing as it states that the regulatory sentries were not at their post – not doing what they were paid to do and a catastrophe resulted. The FCIC (2011) finds the view unacceptable ‘that regulators lacked the power to protect the financial System’ (FCIC 2011 p. xviii). ‘They had ample power in many arenas and they chose not to use it’ (FCIC 2011 p. xviii).

To give just three examples: the Securities and Exchange Commission could have required more capital and halted risky practices at the big investment banks. It did not. The Federal Reserve Bank of New York and other regulators could have clamped down on Citigroup’s excesses in the run-up to the crisis. They did not. Policy makers and regulators could have stopped the runaway mortgage securitization train. They did not. In case after case after case, regulators continued to rate the institutions they oversaw as safe and sound even in the face of mounting troubles, often downgrading them just before their collapse. And where regulators lacked authority, they could have sought it. Too often, they lacked the political will—in a political and ideological environment that constrained it—as well as the fortitude to critically challenge the institutions and the entire system they were entrusted to oversee. (FCIC 2011 p. xviii).

The FCIC (2011) concluded extensive failures in financial regulation, monitoring and supervision culminating in sheer devastation and instability in the US and international financial markets. The FCIC (2011) is highly critical of former Federal Reserve chairman Alan Greenspan and key institutions for a naive and broad philosophy accepting blindly that financial institutions could effectively police themselves coupled with the notion that is now easily proven to be false premise that markets would self correct. To draw an analogy to represent the incredulity of these dual notions it is akin to considering that a living organism can inflict a major wound and heal repeatedly in a new strengthened form.

The FCIC (2011) considers that successive US administrations (G. Bush, Clinton and G.W. Bush) and Congresses, enthusiastically propelled by the omnipotent financial industry, were in full support of the notion of industry self correction and self policing. This resulted in stripping “key safeguards” essential to avoiding catastrophe that eventually saw the loss of trillions and trillions of dollars of dollars in the US alone (FCIC 2011). Even worse the US government permitted financial firms to pick their preferred regulators and rating agencies culminating in the ‘race to the weakest supervisor’ (FCIC 2011 xviii).

Dramatic failure in risk management and corporate governance within important financial institutions was a key cause of this crisis (FCIC 2011). The FCIC (2011) and Das (in Adams 16 September 2008) consider that executive managers within the finance held the utopian view that a preservation instinct was operative inside major financial firms. The view was that this alleged safety mechanism was ‘shielding them from fatal risk-taking without the need for a steady regulatory hand, which, the firms argued, would stifle innovation’ (FCIC 2011 p. xviii). The numerous firms acting recklessly with inappropriate exposure to risk of a scale never seen before in economic history backed by too little capital to balance that risk was a recipe for disaster (FCIC 2011, Das in Adams 16 September 2008) - if not a strategic plan to induce economic crisis in global proportions as occurred. The financial crisis provides an example of a deep-seated herd instinct among regulators and senior managers in the finance sector that epitomises groupthink, rigid paradigm obfuscation underpinned by myopia and greed all within an astonishing toxic mix in an overheating cauldron with no evidence of a significant and objective backward step.

Many of these institutions grew aggressively through poorly executed acquisition and integration strategies that made effective management more challenging. The CEO of Citigroup told the Commission that a \$40 billion position in highly rated mortgage securities would “not in any way have excited my attention,” and the cohead of Citigroup’s investment bank said he spent “a small fraction of 1%” of his time on those securities. In this instance, too big to fail meant too big to manage. (FCIC 2011 p. xix)

The quick deal, the short-term gain, the excitement of the gamble, and the view that the payoff was inevitable and the risk minimal (FCIC 2011, Keen in Adams 16 September 2008). The industry was disconnected from quality service. Institutionalised self seeking activities were the norm with the bottom line as the only issue of the quality service agenda and devoid of customer consideration and the public at large (Hopper and Hopper 2009). Improper consideration in relation long-term consequences was the new norm and fanned by the corporate boardroom saturating all ranks with the mortgage broker charged notion to gather an ever growing number of mortgagees regardless of their capacity to service a loan (FCIC 2011, Hopper and Hopper 2011).

The research, much of which cannot be documented in this limited study space, reveals astonishing examples of cited by the FCIC in relation to “governance breakdowns and irresponsibility” (FCIC 2011). Three excellent examples of institutionalised ineptitude are: AIG’s senior management’s lack of knowledge of the terms and extreme risks being a \$79 billion exposure to derivatives and mortgage-related “securities” (FCIC 2011). The second is the “sky is the limit approach” by Fannie Mae’s mission to establish much greater market share, increased profits, and bonuses leading to heightened, if not stratospheric, exposure to loans with greater risk as the “housing market was peaking” in the US: (FCIC 2011): and the rest is history. The last example is the expensive surprise when Merrill Lynch’s top echelon of their management structure finally comprehended that the company held \$55 billion in “super-senior” and supposedly “super-safe” mortgage-related securities that resulted in billions of dollars in losses (FCIC 2011).

In the preceding years before the crisis reached its crescendo the number of key financial institutions, and too many households, borrowed to the maximum leaving all parties very susceptible to financial anguish or devastation if the worth of investments turned down even marginally and this is exactly what happened (FCIC 2011).

The US government was poorly prepared and ill equipped for the crisis, and its knee jerk and contradictory reaction added to the ambiguity and panic in the financial sector. To be more specific ‘key policy makers—the Treasury Department, the Federal Reserve Board, and the Federal Reserve Bank of New York—who were best positioned to watch over our markets were ill prepared for the events of 2007 and 2008’ (FCIC 2011 p. xxi) .

There was a notion within the major financial institutions that “risk” had been “diversified” but the FCIC report (2011) considers that it had been concentrated (FCIC 2011). These institutions considered they were defraying risk of the debt by drawing in other financial institutions based in the US, or in Europe for example, but they were merely subcontracting the risk to a third party (securitisation) but the mortgagee was still their client. This calls into question just how detached from their clients these institutions had really become?
