Abstract

Identifying pathways for small to medium sized enterprises (SMEs), as potential entrants to the international market place, encourages evaluation how entrepreneurial activity can overcome encountered barriers to economic development. In an expression of commitment to improving the socio economic welfare of Indigenous people the Australian Government is encouraging Aboriginal involvement in entrepreneurial ventures, and integrating this notion in a local housing construction business has potential to improve the persistent poor living conditions in remote Australian Aboriginal communities. This paper describes an accommodation building programme initiated by the Yolngu people of East Arnhem Land of Australia, and with illustrations shows location and achievements. Revealing how the literature specified barriers to Australian Indigenous entrepreneurship were overcome provides a pathway worthy of consideration by rural Indigenous communities intending to engage in entrepreneurship, with vision to extend the life cycle of the firm into international markets.

Keywords: Indigenous; entrepreneurial; Aboriginal; housing; Australia; Internationalisation,

Introduction

Entrepreneurship, small and medium sized enterprises (SMEs), and international business are inextricably bound. The entrepreneurship literature has focussed on individual aspects (Brockhaus, 1980; Kirzner, 1979), while international business has concentrated on the company in traditional approaches (e.g., Uppsala model, Johanson and Vahlne, 1977; innovative based model, Cavusgil, 1980; internalisation theory, Rugman, 1980; eclectic paradigm, Dunning 1980; industrial network approach, Johanson and Mattsson, 1986) to provide assumptions about market conditions and competitive advantage. Emergence of the world economy has rapidly promoted interest in international entrepreneurship to better understand how firms are to acquire superior financial performance in perspectives that are refuting the applicability of the traditional frameworks (McDougall, Shane and Oviatt, 1994; Oviatt and McDougall, 1994). Indeed, connections between SMEs and their contribution to the free market economy and productivity are being observed in arrangements significantly different to the extent literature (OECD, 2005; Kukoc and Regan, 2008; Stringfellow and Shaw, 2008). The progression of SMEs in environments of accelerating product volatility and competitive change oblige hastening of design and productive processes in the pursuit of new customers (Nummela, Saarenketo and Puumalainen, 2004; Lutz, Kemp and Dijkstra, 2010). But operating in these domains compels SMEs to innovate, and acquire knowledge, skills and abilities by engaging talented employees as a source of competitive advantage (Hartmann, Feisel and Schober, 2010; Lewis and Heckman, 2006). Sustainability in the new market conditions is concomitant on capability and resources, and acquiring them can become a substantial barrier for SMEs in a globalised world.

Despite a proliferation of interest in investigating SME entrepreneurial behaviour for coping with the complexities of entry to globalised markets the evidence shows the process is precarious. In fact, there is only a

generalised understanding how SMEs pathway through experienced market entry barriers (Coviello and Jones, 2004, Dijkstra, Kemp and Lutz, 2006, Stringfellow and Shaw, 2008). Evaluating a great deal of research from the 1980s, has led commentators to identify barriers that can hamper entry of entrepreneurial firms to the market as structural (McAfee, Mialon and Williams, 2004), and strategic (Robinson and McDougall, 2001). Lutz, et al. (2010) found this too blunt an instrument and in a study with 1170 SMEs were able to identify 23 items, which were factor reduced to the seven most important dimensions (i.e., capital, distribution, strategic action, research and development, advertising, government regulations and product differentiation), that are likely to hamper the entry of a SME to the market. Other scholars (Oviatt, Shrader and McDougall, 2004; Zahra and George, 2002) earlier proposed the prime factors determining the rate of global market entry are contained in the three dimensions of environmental influences, organisational attributes, and the personal characteristics of the entrepreneurs. Other attempts (McElwee and Warren, 2000; Ram and Carter, 2003) to precisely identify market barriers have specified staff training, insufficient infrastructure, limited social and economic capital, strategic planning and business acumen. The relationship between entrepreneurial activity and national economic growth (Van Stel, Carree and Thurik, 2005; Acs and Storey, 2004) provides strong incentive to determine if some of the numerous overlapping identified barriers can be reduced in number. Dacin and colleagues (2010) succinctly state this view when they write "... entrepreneurship researchers and practitioners could benefit from a stronger dialogue and understanding of entrepreneurial failure." (p. 51).

The phenomenon of the increasing rate of internationalisation of SMEs challenges the different viewpoints of the traditional theories of international entrepreneurship. Barriers to market entry constitute an important issue in entrepreneurship, and relevance for the salient dimensions might be availed in the considerable work that has been done by scholars in the Australian Indigenous entrepreneurship literature. This information has potential to yield valuable insights how entrepreneurs of SMEs might better understand the distinct elements that place their firm at a disadvantage when operating in the international sphere.

The primary purpose of this paper is to report the achievements of an Indigenous building construction programme. The pursuit of this vision is through the medium of a fledgling business venture that amalgamates the milling of timber and an inaugural house construction business venture by the Yolngu clan, who are the Indigenous people in the remote region of East Arnhem Land in the Northern Territory (NT) of Australia. Detail is given about the venture partners together with identified barriers to Australian Indigenous enterprises that were surmounted by the participants to facilitate the Indigenous entrepreneurial project.

The manuscript is presented in seven parts. After the Introduction (the first part) is highlighted key core elements of the entrepreneurial building programme. The third section of the paper presents with text and a table indicators of socio economic inequality (the forecasted drivers of entrepreneurial activity), Australian government strategies for addressing Indigenous disadvantages, the literature identified barriers to Australian Indigenous entrepreneurial venturing, and how these obstacles were circumvented by the Yolngu Gumatj clan. In the fourth part of the manuscript the programme context is described, and this is followed by the results as text and illustrations. The final sections (six and seven) draw out some of the prominent features of the regional impending entrepreneurial activities and the forces that have played a central role in formulating the local operational framework.

Pillars of the enterprise

The intensity of Australian Indigenous entrepreneurship is a function of political, personal and contextual criteria. Australian Aboriginal affairs policy shifted focus from assimilation to a policy construct of self determination during the late 1960s by the Holt Coalition Government (Smith, 2006). This radical departure, from the previous Colonial policy of assimilation (Anderson, 2007), was adopted in 1972, to lessen Indigenous Colonial dependency, to install within the Aboriginal people a degree of political autonomy, and to introduce new arrangements for an opportunity for self management by Indigenous people. The legislation, which was pivotal in removing the previously imposed harsh restrictive controls on Indigenous commercial activity (Sanders, 2002), had been preceded by the Commonwealth Capital Fund for Aboriginal Business Enterprises. This funding initiative, which was devised by

Coombs (1993) in 1968 to alleviate Indigenous rural unemployment, enabled government agencies to provide finance for Aboriginal enterprises. Subsequent Commonwealth political actions have directed attention to recognition of self determination and self management of Australian Aboriginal people. Notable, was the establishment of Indigenous Business Australia (*Australian Government, 2007*), which was a political endeavour to demonstrate commitment to facilitating Indigenous entrepreneurial partnerships with Australian business. Practical endeavours by the government to successfully develop Australian Indigenous enterprises can be found in reports (*Submission, 2001; Cape York, 2005*), the publication of brochures advising how to initiate a business as well as rebranding employment facilities (e.g., Indigenous Training Employment Centre) to give assistance in generating Indigenous business proposals. Despite these various political initiatives there is scant literature about successful Indigenous Australian entrepreneurs (Martin and Liddle, 1997; Foley, 2006a; Whitford and Ruhanen, 2010).

There is substantial evidence from Western based studies providing intuitive appeal that personal attributes are likely drivers of entrepreneurial behaviours (Shaver and Scott, 1991; Pearson and Chatterjee, 2001; Dana, 2007). In spite of these findings their relevance is restricted in Australian contexts as most Indigenous adults in remote regions of Australia do not articulate well in English literature, as their spoken English can be a second or third language, while their numeracy competencies are also extremely lower than non Indigenous Australians, particularly in the NT (Bradley et al., 2007; Elliott, 2009; Hughes, 2009). And although there is a deficit of evidence about outcomes of Australian Indigenous business ventures (Foley, 2003; Furneaux and Brown, 2007), Russell-Mundine (2007) has reported the success rate of Indigenous tourism enterprises, which is one of the more popular and prominent forms of Australian Indigenous businesses (*Open for Business, 2008*), is abysmal. Consequently, understanding how to facilitate entrepreneurship with Indigenous Australians might be better served by examining anecdotal or historical information where success in Indigenous entrepreneurial activity has been recorded, and this approach is adopted by outlining the business activity that has been undertaken by the Australian Indigenous Yolngu people across hundreds of years. Currently, the Gumatj clan of the Yolngu people of East Arnhem Land of the NT of Australia are one of the contemporary leading Indigenous entrepreneurial groups (e.g., Yothu Yindi international musicians). Later, in the paper, is described how their forebearers, who occupied the land some 50,000 years ago, were undoubtedly, the first Australian international traders. The personal attributes that link the historical periods of past and present may be a legacy of commitment to secure better living conditions by engaging in entrepreneurial action.

Despite widespread support for Australian governments to reduce the inequality between Indigenous and non Indigenous Australians limited progress is often recorded. For instance, some evidence (Altman, Biddle and Hunter, 2005; 2008) has been presented to show improvement across some socio economic indicators, but other concerns have been raised about monitoring techniques (Pholi, Black and Richards, 2009) or how 'closing the gap' is affected by variations in social and economic conditions (Hunter, 2009a). There are also structural impediments (e.g., layers of bureaucracy) that appear to have strangled the strategic Indigenous Housing and Infrastructure Programme that was an initiative from the 2007 Intervention (Maddison, 2008). An ambitious \$A 672 million project, that was to address chronic housing problems of Indigenous people in remote communities of the NT became an embarrassment to the current Australian government (Mercer, 2009) as while 10 to 20 percent of the funds had been consumed in administrative arrangements a minimal amount of the house construction programme was completed by the close of 2009 (Toohey, 2009). Understandably, this presents an opportunity for Yolngu people to undertake entrepreneurial engagement in housing construction and reduce their dependency on government welfare.

Creating the entrepreneurial business of housing construction, by the Gumatj people, who are one of the prominent 13 Yolngu clans in East Arnhem Land, is embedded in existing social structures and cultural connections with the country. The process of forming a business group within the arrangement of the clans aligns nicely with the concept of community based enterprise as defined by Peredo and Chrisman (2006: 309) as "... a new enterprise embedded in existing social structures.". And while the immediate goal of the business is to pursue economic benefits and regular skilled employment for the participants there is also opportunity to yield substantial advantages to others (both within the clan and the wider community) who may live in the constructed dwelling. However, an overt focus on economic features to the detriment of "socio cultural and environmental issues" (Whitford and Ruhanen, 2010: 491) may account for the failure of many Indigenous entrepreneurial ventures (Peredo and McLean,

2010). An important feature of the Yolngu entrepreneurial business venture is an opportunity for the Indigenous people to work on their ancestral lands, with which the clan has maintained strong and religious connections (Altman, 2003; Yunupingu, 2009) for over 55,000 years. Harvesting the timber for the housing construction is done by the Yolngu, not by employing modern 'efficient' clear felling methods, but by the selective removal of mature trees and allowing adjacent trees to mature. The reoccupation of their land and undertaking the entrepreneurial activity within the savannah forest employs a core business strategy of integrating conservation development and ecological sustainability.

It is widely recognised that certain concepts are linked with business success. Some of these concepts, such as the management of people, access to funding, linkages with industry, appropriate production processes as well as effective systems for sales and marketing might be conveniently grouped into a construct of business acumen. A lack of acumen, creativity, vision and innovation has often been associated with the failure of Australian small business and particularly Indigenous endeavours (Ivory, 1999; *Submission*, 2001; Flamsteed and Golding, 2005; Foley, 2006a). To optimise a successful outcome for the Indigenous business endeavour of housing construction the Gumatj Corporation adopted a strategy that accommodated a diverse set of macro environmental conditions, social arrangements and cultural values that are vital for fostering entrepreneurial activity (Tsang, 1996; Rahman, 1999; Morris, 2000). For instance, industry links were made with Forestry Tasmania to provide training and instruction in the timber production processes, the Architectural School of the University of Tasmania provided construction drawings and milled timber lists initially for the bunk house (and subsequently for a four bedroom home), political support was sought from the three levels of government (Federal, State, Local) to ensure provision of field service and a reduction in bureaucratic procedures, and Fairbrother Builders as specialists in building and construction supervised the building of the bunk house, while the Gumatj Corporation provided most of the funding from mining royalties. There were some subsidies from the Commonwealth government's Jobnet work programme. Furthermore, the land on which the venture was undertaken was owned by the Gumatj clan.

A latent dimension of the entrepreneurial enterprises is contemporary Yolngu hold a business legacy from their traditional society. There is historical evidence the Dutch explorer Jan Van Carstens, explored the shoreline of East Arnhem Land in 1623, to be followed by a notable Australian seafarer Abel Tasman in 1644, and later in 1803 the British explorer Mathew Flinders engaged with the Indigenous people of Arnhem Land. Business activity was heightened in the 17th century when the Macassarese, from Malaysia, Indonesia, and Sulawesi (Celebes) traded with the local Yolngu clans (Worsely, 1955; Rose, 1987; Trudgen, 2000), in addition to regional trade between the clans (Berndt and Berndt, 1999). Clearly, the Yolngu employed business concepts long before the management/business texts were written, and international trade only ceased in 1907 by direction of Australian governments (Ivory, 1999; Anderson, 2007). Nearly a century later particular arrangements of entrepreneurial activity have emerged, predictably as forecasted by Dana (1995), who contended Indigenous communities respond quite differently to traditional entrepreneurial frameworks when an opportunity is presented. The business enterprise being undertaken by the Yolngu is in a remote region of Australia, and geographical points of interest, that will be nominated in the paper, are shown on the map, that is presented as Figure 1.

Note: Locations  = Garrathiya, P = Port Bradshaw, and M = Milling site.

FIG.1: REGION OF THE CASE STUDY AND PLACES OF INTEREST

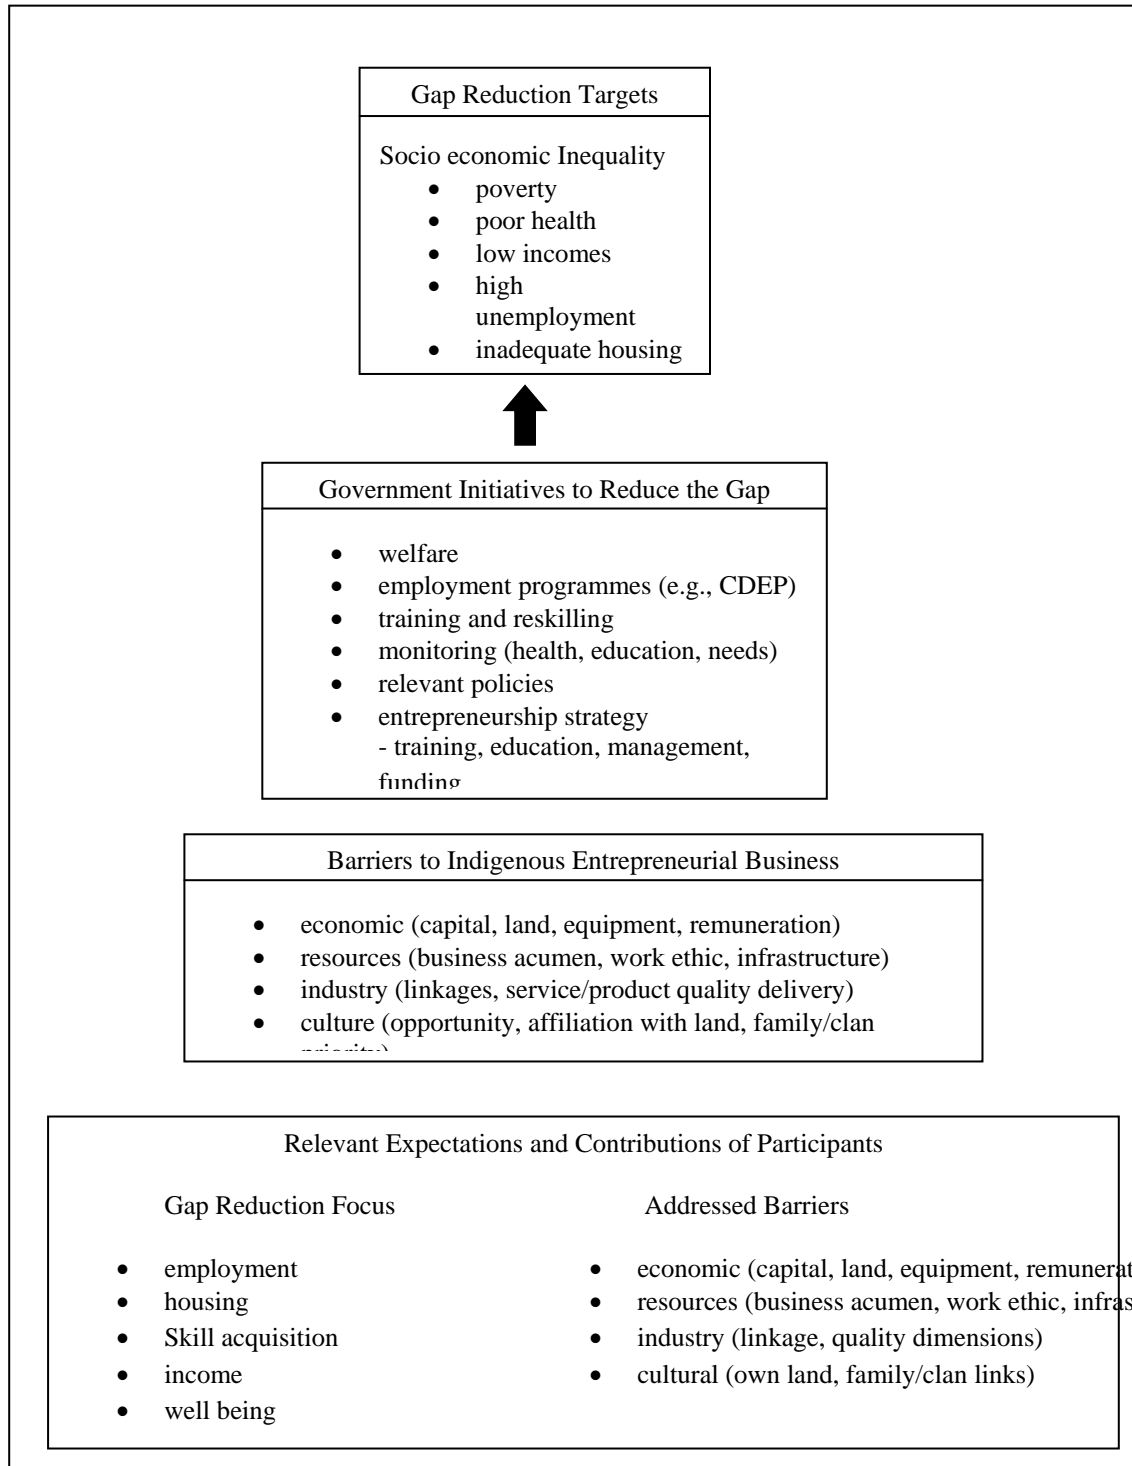

Australian Indigenous entrepreneurial barriers

Indigenous entrepreneurship operates in a setting of three contextual sectors. A primary contextual sector is the notion of closing the gap in socio economic disadvantage of Indigenous Australians (Altman, 2009; Pholi et al.,

2009). In this sector is contained the persistent manifestations in Indigenous communities (Gray and Hunter, 2002; Altman et al., 2005) of lower incomes, higher unemployment rates, extreme poverty, poor health quality, inadequate housing, relatively low levels of formal education and high incarceration rates, which are states the Australian government is committed to improve (Hunter, 2009a). The second sector represents the initiatives that demonstrate the Australian government's commitment to close the gap in Indigenous disadvantage in the broad fields of health (e.g., child mortality, life expectancy), education, and employment. The government agenda to address the inequalities between Indigenous and non Indigenous Australians, which is contained within policy formulation, performance monitoring and reporting (*Indigenous Education*, 2007; Pholi et al., 2009), can be articulated as welfare, employment and training programmes incorporating entrepreneurial support as well as indicators to assess the effects of these interventions. A third important sector is the barriers that are encountered by programmes that are installed to reduce the socio economic inequality experienced by Indigenous citizens. These barriers have been regularly specified in the literature (*Submission*, 2001; *Cape York*, 2005; *Open for Business*, 2008).

Commitment by the Australian Federal Government to encouraging Indigenous entrepreneurship is driven by a belief financial independence will provide relief from a number of endemic disadvantages. This notion has recently attracted a flood of discourse about 'closing the gap' in socio economic disadvantage between Indigenous and non Indigenous Australians, and the material embraces a wide range of issues. For instance, higher rates of poverty (Altman, 2000, Hunter, 2009b), poorer health (McDonald et al., 2008; Pholi et al., 2009), inequality in income and employment (Hunter and Taylor, 2001, Hunter, 2009a), fewer job opportunities (*Cape York*, 2005; Cutcliffe, 2006), inadequate housing and infrastructure (Tripcony, 2000; Altman and Jordan, 2009; Toohey, 2009), and inequality in education and training (Hughes, 2009; Wallace et al., 2009) are listed in the top rectangle of Figure 2. These dimensions, which reveal the inequality between Indigenous and non Indigenous Australians, provide what Peredo and colleagues (2004) contend are the initiators or motivators for Indigenous people to improve themselves beyond economic circumstances and align with "... the larger agenda of rebuilding their communities and nations and reasserting their control over their traditional territories." (pp.5). A pragmatic assumption of the Australian government is the differences in these indicators, between Indigenous and non Indigenous society are likely to be reduced by a variety of policies that can generate employment opportunities. The major streams of this notion are shown in the second from top rectangle of Figure 2. The focus of this paper is on the entrepreneurship strategy.

FIG. 2: A FRAMEWORK FOR THE GAP REDUCTION WITH AN INDIGENOUS HOUSING CONSTRUCTION BUSINESS VENTURE

Despite a range of initiatives to stimulate Australian Indigenous owned and operated businesses few are successful. Indeed, Buultjens and colleagues (2010) state Indigenous tourism, the most prevalent of all Australian Aboriginal small businesses, is "... extremely fragile and tenuous." (pp. 598), with the majority not surviving for five years. Delineation for their likely failure is provided by Russell-Mundine (2007) who tabulated the four dominant barriers; 1) economic (capital, land), 2) resources (business acumen, work motivation), 3) industry (industry requirements versus delivery capacity), and 4) cultural values. Identification of these obstacles to successful entrepreneurship, sharpened by evidence of Australian Indigenous chronic poverty as well as knowledge these people are often deprived from improving their lifestyles, relevant policies and programmes have been installed by Australian governments to encourage and support Aboriginal entrepreneurship. Currently, the Australian government provides resources in terms of training, industry assistance and access to finance under conditions of stringent commercial eligibility (Foley, 2006b; *Australian Government*, 2007) to Indigenous communities, and especially those in remote areas. But many of the people lack personal and contextual attributes, that are vital for governance and compliance with regulatory requirements (Foley, 2003; 2006b; Furneaux and Brown, 2007; Buultjens et al., 2010). A summary of the inhibitors are presented in the third rectangle of Figure 2.

In the fourth (bottom) rectangle of Figure 2 is outlined the entrepreneurial strategy for balancing Indigenous expectations of gap reduction and overcoming the barriers in their Indigenous setting. In the left hand side of the rectangle is captured the gap reduction targets that were the focus when the Gumatj Indigenous people undertook modern dwelling construction systems in their natural homelands. The right hand side of the rectangle shows the barriers they were able to overcome. Some barriers were reduced through political connections and industry affiliations through the leadership given by the clan leader Galarrwuy Yunupingu. Other barriers were sidestepped by importing external resources that provided specific expertise for the duration of the project. Some barriers, such as capital (financial and social) were provided by the Gumatj Corporation, and clan members, or natural resources (land, timber) were available, and more specific details follow.

Methodology

Site

The construction site of the five room bunkhouse is at the Garrathiya cattle station. This location is just over 100 km by road south, south west of Nhulunbuy, and 20 km west of Port Bradshaw. The harvesting of the timber for the construction of the bunk house was undertaken in the savannah forest some 10 km north of Garrathiya. However, access between the two destinations was by the unsealed East Arnhem Road and a bush track (and across creek beds) for a distance of some 20km.

Participants

There were four key groups of participants. Forestry Tasmania provided on site personnel who gave instruction, training and supervision how to operate the Lucas mills, and how to size and grade the sawn timber. The second key group was the School of Architecture, of the University of Tasmania, that designed and prepared the construction plans as well as the quantity list of timber sizes for the bunk house. Subsequently, the School of Architecture has completed a set of plans for the construction of a timber four bedroom house. The third group was Fairbrother Builders, a Tasmanian firm that specialises in building and construction. Fairbrother Builders supervised the construction of the bunk house and provided training and guidance for the 18 Gumatj workers at the project site. The fourth set of participants was the Gumatj people. There was one group of 10 Yolngu people who selected and felled the trees and milled the logs for timber that was used in the construction of the bunk house. There was a second group of 18 Yolngu people who intermittently worked at Garrathiya constructing the bunk house.

Apparatus

The milling of the timber was undertaken by a team of 10 Yolngu people. One group of four members felled the trees (two are certified timber fellers), dragged the 13 metre logs by end loader to a docking station where

the ends were trimmed square and the log was cut into two logs each one of 6.1 metres length. These logs were then transported by the front bucket by the end loader to one of two Lucas mills. Each Lucas mill is operated with a team of three Yolngu people. These people debark the log, fasten the log to the bed of the Lucas mill with wooden wedges and then mill the log to the required size (e.g., 150mm× 75mm, 75mm× 25mm). The sawn timber is stacked for drying and the stacks are bound with steel strap for transporting to the construction site.

A Lucas mill has a number of favourable features. The mill is manufactured in Australia for a price of about \$19,000, so it is readily available for a reasonable price. A second feature is a Lucas mill can be dismantled in about 20 minutes, transported on a motor truck to a new location where it can be reassembled in about 30 minutes. Another aspect is a Lucas mill can saw logs up to 6.1 metres in length, and mills can be coupled in line to cut longer length logs. The relative ease of adjusting the circular saw blade horizontally and vertically is a fourth desirable feature. Rotating the blade is undertaken with a small joy stick and the depth or width of the saw cuts is done by the team members adjusting moveable parts.

Sawing the log requires the operator to walk the length of the log pushing a horizontal bar. On this bar is the motor and the saw blade assembly. The horizontal bar has wheels at the ends, and these wheels are guided to run on beams that run the length of the Lucas mill. Figure 3 shows these components as an operator mills a log. After the log is debarked it is fastened to the bed of the Lucas mill with timber wedges. The operator makes horizontal or vertical cuts by setting the blade and walking the length of the Lucas mill pushing the horizontal bar. When the scantling (scrap) or timber planks are cut the two assistants remove the sawn material.

FIG. 3: OPERATING A LUCAS MILL IN THE SAVANNAH FOREST OF EAST ARNHEM LAND

The timber being milled is *Encalyptus Tetradonta*. This timber, which comprises most of the savannah forest of East Arnhem Land, has the tradename of NT stringy bark. The timber is relatively dense at 1.4 tonnes per cubic metre when 'green'. When cut the timber is a deep red chocolate brown, similar to the heart wood of Western Australian jarrah, and dries to a deep brown colour. Mature trees grow to about 0.3 metre diameter at the bowl, the distance to the first branch is about 15 metres, and as the trunk only tapers slightly the sawn timber is knot free and there is little wastage.

Results

The five room bunk house (with verandahs) at Garrathiya (translated as the land of the cycads, which abound in the area) was constructed in two and one half months. On the morning of the 25th May the first footing was set, and the building was officially unveiled on the 7th August 2009, to an audience of a variety of stakeholders. In addition to Federal and local members of government, with representatives of their Departments (e.g., Families and Housing Community Services and Indigenous Affairs, Department of Employment Education and Workplace Relations), there were columnists of the National and State media, the business partners, and a number of invited guests, which included the Gumatj representatives and employees who harvested the timber and built the carbon neutral timber dwelling of 20 tonnes. Both authors were present on the first day and at the official opening, while the second author visited the building site a number of times during the construction period. Figure 4 shows the building on the opening day.

FIG. 4: THE BUNK HOUSE AT GARRATHIYA

Additionally to the bunk house the Yolngu employees at Garrathiya earlier completed a six room dormitory, the associated kitchen, and the ablution block. These three units, which are connected by concrete pathways, and are about 200 metres from the bunk house, were commenced in early 2009. These separate sets of structures were undertaken with an arrangement with the Jack Thompson Foundation. The buildings are of a timber internal structure clad with colour bond, and have a capacity for 12 residents. This accommodation will attain greater significance when the Garrathiya cattle station, which has Braham cattle, begins production of cryovaced beef products for the nearby outstations.

The bunk house was constructed for a modest cost of less than \$ 200,000 despite the immaculate presentation of an extremely high quality residence. Site construction of contemporary accommodation or houses in the East Arnhem Land region is normally undertaken by non Indigenous non local companies. Often the framework, including the roof structure, is galvanised steel members and the cladding is various types of factory sheeting. Hence, as almost all of the resources are non local the construction cost of a four bedroom house is of the order of \$800,000. The Yolngu employees who constructed the bunk house (and completed the dormitory complex) are preparing to commence the construction of two four bedroom houses at Dhanaya, which is in close proximity to Port Bradshaw. These two houses are programmed to be completed by mid 2010, each for a price of \$325,000. It is then intended to move the building team to the outskirts of Nhulunbuy and construct four more of these types of houses on Yolngu land at Gunyangara (Ski Beach).

In addition to the building construction less tangible achievements have emerged. One of the construction workers (Russell), who left his truck driver position on a Community Development Employment Projects to work at Garrathiya, said when interviewed "I feel very happy and proud to be building in our country." While Samuel made some toys for his children from 'off cuts' of the building materials. Moreover, the Gumatj Corporation has a contract for milling mature trees on the next Rio Tinto Alcan mining tenement of over 800 hectares, which is a substantially novel approach as previously the forest was bulldozed into windrows and burned. And the attaining of on the job skills and knowledge in sustainable harvesting, milling and building construction is expected to realise further business opportunities. Finally, potential exists for entrepreneurial ventures in the collection and sale of seeds and bark for painting, the sale of sawn timber to the Nhulunbuy and adjacent communities, processing of timber for veneers and furniture as well as carbon credits.

Discussion

The evidence of this case study reveals the involved Aboriginal people pragmatically embraced entrepreneurship. Their motivation to engage in a business venture was driven more by the need to provide better accommodation rather than an emphasis on formulating a project strategy aligned with business models or commercial undertakings as identified in the relevant literature. At the core of the venture was a goal to build quality accommodation for five clan members who worked at the Garrathiya cattle station. These Yolngu people had been living in 30 year old sea containers, which would have been unbearably hot in the summer 40°C temperatures. From interviews with the timber millers and those Yolngu who constructed the bunk house it became evident they sat easily with the separation of commercial objectives and cultural features. The employees perceived their community position as the workers and willingly abdicated commercial challenges to the clan leader. At the periphery of the core aim of the project was the attainment of economic rewards, an opportunity to work on their own ancestral lands with their clan members, the circumstance of being able to readily go hunting or fishing, the chance to gain valuable job skills as well as being able to enjoy a variety of cultural specific benefits. Seldom are these prevailing features the foundation of non Indigenous business ventures that have become dominated by modernisation theory as outlined by Peredo and colleagues (2004). For example, rather than a monetary bonus at the completion of the building of the bunk house all members went hunting and fishing for two weeks before commencing the two house construction project. Collectively, these generalisations may provide a better understanding of the motivations and the salient strategies

for Indigenous entrepreneurship. This knowledge extends the boundaries of the paradigm of *perceptions of risk* being a driver of entrepreneurship as promoted by Dana (2007).

It should not be construed that the Yolngu people do not entertain planning. On the official opening day of the bunk house discussions with some of the members revealed they had identified a vital key component of the construction business. The proposal to build two houses at Dhanaya, and a further four at Gunyangara was dependent on a supply of milled timber, but there were only two certified timber fellers and one qualified end loader operator. And there was also the contract with Rio Tinto Alcan to remove marketable logs from the 800 hectares mining tenement during the next two years. While engaging an endloader operator from within the community was not seen as a major problem finding other clan members who would be prepared to undertake a technical training course to become responsible certified timber fellers was a more difficult undertaking. There was consensus this was to be resolved by the clan leader. Clearly, there was partitioning of levels of formality. Observing the timber milling and working on the bunk house construction showed the Yolngu people operated in an informal climate. Once the task was understood supervision was distant, and despite a total of 18 Yolngu members being identified as the bunk house construction cadre seldom was more than nine on site. Yet the bunk house was completed in the planned time, which is an expression of formality. And there were other formal dimensions of the project, that were performed by the clan leader Galarrwuy Yunupingu (as a former Australian of the year [1978], and was Chairman of the powerful Northern Land Council for two decades), who had political connections, access to resources and was the pivotal leader – manager of the community. McAdam et al. (2008) distinctly identified the role of leadership is vital for the introduction of new products.

Endeavours by Australian governments to improve Aboriginal housing have been elusive. Some of the numerous reasons for the prolonged failure to provide suitable living conditions of Aboriginals have been presented as inadequate maintenance, intergenerational living and overcrowding, low levels of tenant upkeeping responsibility, a lack of property rights, low socio economic power, a reliance on welfare and an awareness how to gain support from political and Church groups (Tripcony, 2000). Frustration with the inability of the Australian Federal government and the NT administration to deliver suitable Aboriginal housing the Yolngu clan leaders have established a *Dilak* that would operate as a ‘Yolngu Parliament’ for direct dialogue with the governments to close the gap in Aboriginal disadvantage, and in particular housing (Robinson, 2009; Rothwell, 2009). Potentially, the Gumatj Corporation could construct houses for their clan in the Nhulunbuy region at a considerably lower cost than external contractors, with the added advantages of local meaningful job creation, and a likelihood these dwellings will be more responsibly administered by the tenants and the Gumatj Corporation. Furthermore, this entrepreneurial model may be adopted for similar or other projects. For instance, the Rirritjingu clan has ambitions to provide better housing at Wallaby Beach (where some of the original mining houses of 1972 are now occupied by Yolngu people), and dwellings at the now pristine Galura (East Woody Beach), through their Bunuwal Industrial Corporation, that is now headquartered at Yirkala. Although these endeavours may only resolve the chronic housing problem and some of the social inequalities of the Aboriginal people of East Arnhem Land other Indigenous people in remote areas may become encouraged to walk the path of self determination in their acclaimed style of entrepreneurship.

Conclusion

The business venture model employed by the Gumatj Corporation in the remote region of East Arnhem Land is a novel and promising framework for Australian Indigenous entrepreneurship. A partnership of important stakeholders had prioritised redressing of a chronic community housing situation in contrast to economic development paradigms that have key elements of monetary income and economic growth. But how the supporting partners will be rewarded in the future is yet to be disclosed, as the Gumatj Corporation is resource rich and other capitalistic arrangements may evolve. An additional line of enquiry of tenant commitment to reducing degradation of dwellings provided by government programmes, and reluctance to maintain presentable home sites attracts attention by the frequent reporting of squalid conditions of Aboriginal housing in remote areas of Australia. Such investigation may disclose why government provided housing is perceived as an instrument of assimilation to wean Indigenous people from

cultural values, and the accumulated debris is not of their making, but *white man's rubbish*. Insights into this rationale may arise when Indigenous people build houses with materials from their traditional homelands for tenants of Aboriginal people. Although the findings of research might contribute to less criticism of Australian Aboriginal housing the evidence may lead to a better understanding of the relativity of transactional opportunity and cultural priorities within the framework of Indigenous entrepreneurial enterprise, which is recognised as the foundation for socio economic development of remote regions of the nation.

A salient observation was the Gumatj Corporation employed an entrepreneurial organisational arrangement governed by community based ideals. Reducing the chronic dwelling disadvantage of the local Indigenous was approached by preserving the secondary economic conditions within a framework for the more important cultural and environmental values. The normative literature advanced in leading Western business schools suggests small businesses are informal, have few rules and regulations, with ad hoc budgeting systems and small cadres of clerical support. Furthermore, these entities often evolve into larger organisations by transforming sequentially through relatively predictable development stages (e.g., pre bureaucratic, midlife to maturity). These periods of change involve variations in organisational rules and activities. Few of these characteristics were observable in the Gumatj dwelling construction programme. Instead, the Gumatj leader reconstituted the fabric of the clan workforce into three satellite entities with external supervisors who were responsible for 1) preparing the dwelling plans and inventory lists, 2) supervising of the dwelling construction team, and 3) training and supervision of the timber milling group. When the tasks were completed the external supervisors were shed and the Yolngu workers returned to the main labour pool, later to be assigned to small group projects (e.g., fencing construction, furniture making). The inaugural entrepreneurial business entity was not required to transform to a more complex organisation with features of written rules, manuals and procedures and job descriptions, an unsuitable framework for the oral culture of Yolngu society where few people have the necessary English reading competencies. Also, the simple structure enabled the maintenance of the dominant familial priority which endorses decision making authority to remain with the clan leader. While further research is warranted the evidence of this case study demonstrates the prevailing Western business/management assumptions may not capture how Australian Indigenous entrepreneurial venturing develops.

The results of this study reveal the importance of competencies to overcome market entry barriers for SMEs. A prominent aspect is the Gumatj SME as a social hybrid commercial venture was pursuing critical community benefits. Thus, the focus was in contrast to the traditional SME, which typically operates in a competitive market place when endeavouring to facilitate economic development activities. The extant literature advances a perspective, that competitive markets normally impose sanctions on entrepreneurship and SMEs and obtaining profits, reducing unemployment while increasing dynamics in the economy are the only relevant issues. But these factors were not the fundamental goals of the Gumatj SME, but rather social entrepreneurial purpose. Specifically, the key objectives were to reduce a substantive social problem that was not being satisfactorily resolved by government and public resources, and achievements were not for the personal economic benefit of the employees. Yet with these goals the Gumatj SME overcome entry barriers with leadership, familialism, and social capital. Although these mechanisms might be associated with structural characteristics of resource allocation, technological usage, and market advantage; or strategic dimensions of exploiting internal strengths, responding to environmental opportunity, and developing a sustainable competitive advantage they were evolutionary. The dominant social community enterprise, without conscious design employed mechanisms for market entry serendipitously overcame market barriers that have been identified as structural and strategic typologies.

Analysis of Food Security Situation In An Oil And Gas Producing Environment: Evidence From Warri And Environs, Delta State, Nigeria

Ben U. Omojimite
buomojimite@yahoo.com
Delta State University, Abraka, NIGERIA

Abstract

This study attempts to investigate whether there could be food insecurity incidence in an ‘oil city’ of Warri, Nigeria. The paper also examines the determinants of food insecurity among the households studied. The socio-economic characteristics of 260 households were collected by means of a structured questionnaire. A food insecurity index was constructed and was used to assess household food insecurity incidence. The results obtained were analysed by means of tables and percentages and found that on the average the incidence of food insecurity is high in the study area, implying that the benefits of oil and gas activities in Warri do not actually benefit all in the communities studied. Also, a logit model was specified and tested to determine the factors that affect food insecurity in the study area. The results of the two approaches used in this study reveal that the age of household heads, sex of household heads, the type of occupation of household heads and dependency ratio all exacerbate food insecurity in the study area. The level of educational attainment of household heads, the nature of occupation of household heads and income of household heads tend to reduce the probability of households being food insecure. The study recommends food aid and food subsidy to the vulnerable in the area. It also recommends expanded educational facilities to enable inhabitants attain higher levels of education.

Key Words: Food security, Logit model, food security index, Warri, Nigeria

Introduction

Food in adequate quantity and quality is to humans as petrol and oil is to the combustion engine. Food is necessary to sustain life, stimulate growth and keep humans healthy. As food digestion takes place within the human body the nutrients from the food are derived, used or stored in the human body. Food nutrients provide the human body with power which could be converted to work. Work creates wealth and wealth determines the rate and character of development of a nation. There is therefore a positive link between availability and access to good food and the level and pace of development of a people.

Food is necessary for healthy living and a pleasurable living conditions. Good food in adequate supply provides all the nutrients needed for an active living. This in turn reduces ill-health, work stoppages and consumption expenditure on health at the household and national levels. It could be argued therefore that adequate supply of good food would reduce national budget on health care delivery thereby freeing more resources for the development of the other sectors of the economy.

Given these linkages between food security and development of nations, the global concern over food security is easily understood. In Nigeria the concern over food security has recorded several dimensions. First, there is the phenomenon of rising food import bills in the past three decades (Omojimite, 2010), necessitating the allocation of high levels of foreign exchange to food imports. Second, there is the concern over the problem of malnutrition. The World Health Organization (FAD) proposed minimum daily intake of basic nutrients per capita. Meeting these minimum requirements, especially in the rural communities and the urban poor, remains a challenge till date. Third, over reliance on external sources to meet domestic food demand may actually diminish domestic efforts in local food production. Besides there may be real danger if the food exporters fail to supply or if the level of inflation rises in food exporting countries.

Several studies have investigated the food insecurity problem in Nigeria (Olayemi 1996; Makinde, (2000), Adeyeye (1992), Omonona et al (2007). Most of the earlier studies focused on the quantitative measurement of food security by using consumption expenditures. Apart from Omonona et al (2007) attempts to study the food security phenomena on a case by case basis is sparse. This study aims at filling such gaps by focusing on the food security situation among household in an oil and gas producing environment in Nigeria. Warri harbours a large number of oil workers whose wages are usually higher than those in other professions. The consumption behavior of workers whose wages are relatively higher has spill over effects on others living within the same environment. This in turn would have implications for the food security situation in such environments. The findings of this study would therefore be of benefit to food policy makers in designing differential food policies for such environments. The objective of this paper therefore is to empirically analyze the impact of the oil and gas production on the food security situation in Warri and environs in Delta State, Nigeria. The remainder of the paper is structured as follows. Following this introduction section 2 presents the conceptual framework and literature review. Section 3 describes the methodology adopted for the study. Section 4 analyses and discusses the results while section 5 concludes.

2: Conceptual Framework / Literature Review.

Although the concept “food security” is not a new phenomenon in many countries, it has commanded a global attention within the past three decades. According to the World Food Summit in 1996, “food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food for a healthy and active life” Gurkan (1995) defined food security as a “state of affairs where all people at all times have access to safe and nutritious food to maintain a healthy and active life. The description above clearly brings out three main components of food security namely food availability, food access and food utilization. At the national level, food is available if it is physically present from all sources including cultivation, processed, manufactured or imported. Food import is widespread in Nigeria, suggesting that domestic food production lags behind domestic demand for food. Food access refers to “the way in which different people obtain available food” according to the International Federation of Red Cross and Red Crescent Societies (2002). Some of the channels through which food is accessed includes but not limited to: home production, purchase, barter food aid. According to the International Federation (2002), food utilization refers to the way people use food such as the method of preparation, storage facilities and the health status of the individuals concerned.

Food availability is determined by several factors including climatic conditions which affect agricultural outputs. It is also affected by the availability of foreign exchange for food imports and food aids especially to developing countries. From the above, food availability depends on both internal and external factors. Very often the concept is used at the national or regional levels. Nevertheless it could also be used in reference to household food security situations.

Food access concerns the demand for food. Food demand is affected by economic as well as consumer preferences. Food must first of all be available before access to it. The key in food access is affordability. For the household the quantum of resources available determines the overall access. Food access could also be enhanced by physical and social infrastructures such as good network of roads and storage facilities. These facilities facilitate the distribution of food items from one region to another as well as permit the preservation of food for a longer period of time.

Food utilization varies from one community to another. It refers to the manner in which persons prepare their food and feeding practices. It is determined by the quantity, quality and a variety of dietary intake and general health conditions.

According to Omonona et al (2007), the food security situation in a country is a measure of the strength or weakness of the agricultural sector. For example in Nigeria food insecurity problems have been attributed to several factors (Olayemi 1996). These include inadequate budgetary provisions to the agricultural sector especially during the military regimes, bottlenecks in distribution, storage and marketing. It is also argued that the advent of petroleum oil as a major revenue earner shifted attention away from agriculture that led to declining productivity in the agricultural sector.

Nwaniki(2008) observed that the root cause of food insecurity in developing countries is the inability of people to gain access to food due to poverty. Nigeria is ranked one of the poorest nations of the world. The poverty level is aggravated by high level official corruption, widespread unemployment and natural resource constraints.

Again, Omonona et al (2007) noted that poverty limits economic access not only in monetary terms but also in terms of access to land, credit facilities, good health facilities all of which affect the food security status at the aggregate level.

Idachaba (1989) noted that the growth rate of population is higher than the growth rate of food production thereby creating a shortage in food supply. This has led to rising prices of food items which has reduced access to adequate food especially in the rural areas. Also inflationary pressures in food exporting countries has sparked off domestic inflation that has made food increasingly inaccessible to the vulnerable groups.

3: Research Methodology

3.1 Area of Study

The area selected for this study is Warri metropolis and the adjoining towns all in Delta State of Nigeria. Warri is often regarded as “oil city” because, together with the adjoining towns of Ekpan, Ogonu, Effurun, Warri DSC/ Aladja, Okumagba layout, Enerhen and Agbara, harbours a large number of oil and gas workers. The combined population of the eight settlements is put at about 480,000 of which about 11,000 people are directly or indirectly employed in the oil and gas industry.

3.2 The Data

In generating, the data for this study 300 households were randomly selected from the eight communities listed above. The number selected from each community depended on the population of each of the communities. The streets in each community were clearly marked out and equal number of households were randomly selected from each street. A structured questionnaire was the instrument used to generate the data. A pilot study was successfully carried out using thirty copies of the instrument in the neighbourhood of the study area to enable us validate the instrument. The instrument was distributed to a total of 300 households in the eight communities (see table 1). 260 questionnaires were recovered. The questionnaires were administered by 8 assistants. The instrument (questionnaire) enabled us to collect information on household monthly income, monthly expenditure, occupation, age, and sex of household heads and household dependency ratio. Secondary data on food production and intake were obtained from the Nigerian Bureau of Statistics.

Table 1: Distribution of Questionnaires

Location	Distributed	Recovered	% Recovered
Ekpan	45	38	84.44
Ogonu	40	36	90.00
Effurun	35	28	80.00
Warri urban	35	31	99.60
Dsc/ Aladja	30	27	90.00
Okumagba L/Out	40	36	90.00
Enerhen	40	33	82.50
Agbasa Warri	35	31	88.60
Total	300	260	

Source: Compile from field survey 2010.

3.3 Method of Data Analysis

The responses on the questionnaires were sorted into the socio-economic groups as indicated earlier. Two approaches were used in carrying out this study. First, to enable us determine the food security situations in each socio-economic group, in the study area a food security index was constructed using the following formula.

$$Fi = \frac{\text{per capital food expenditure for the } i\text{th household}}{\sqrt[2]{\text{mean per capital food expenditure of all households}}}$$

Where Fi = food security index (Omonona et al, 2007)

When $Fi \geq 1 \Rightarrow$ food secure household and;

$$Fi \leq 1 \Rightarrow \text{food insecure household}$$

Applying this formula on the data generated from the questionnaire we are able to establish a food security line. The food insecurity incidence is then constructed for each socio-economic group. This permits a classification of each group either as food secure or food insecure. These information are presented in tables with percentages added. Second, an analysis of the determinants of household food security in the communities was undertaken to enable us see the relationship between socio-economic characteristics of households and their food insecurity situation. Gujarati (2003) noted that when the dependent variable is dichotomous the use of the logit or probit model should be preferred to the linear regression model. Following other researchers (Hosmer and Lemeshew 1989; Ojogho 2010; Veen and Gebrehiwot 2011), we specify a logit model that will enable us assess the effects of socio-economic characteristics on food security and the probability of a household being food insecure. Assuming the probability of a household being food insecure is determined by an underlying response variable that capture the true economic status of a household, the underlying response variable R is the case of binary status could be defined by the multivariate logit regression relation $R_i = \sum X_i \beta_j + e_i$, where $\beta_j = \beta_1, \beta_2, \dots, \beta_j$ and $X_i = 1, X_{i2}, X_{i3}, \dots, X_{ik}$

The logistic expression are given as $\text{prob}(R^* = 1) = 1 - F(\sum X_i \beta_j) = \frac{e^{\sum X_i \beta_j}}{1 + e^{\sum X_i \beta_j}}$ and

$\text{Prob}(R^* = 0) = F(-\sum X_i \beta_j) = \frac{e^{-\sum X_i \beta_j}}{1 + e^{-\sum X_i \beta_j}} = \frac{1}{1 + e^{\sum X_i \beta_j}}$ where F is the cumulative distribution function for μ_i, \dots , $\text{prob}(R_i = 0/\beta_j X_i) = F(-\sum X_i \beta_j)$ and $\text{prob}(R_i = 1/\beta_j X_i) = 1 - F(-\sum X_i \beta_j)$. The likelihood function is given by

$$L = \prod_{Y_i=0} [F(-\sum X_i \beta_j)] \prod_{Y_i=1} [1 - F(-\sum X_i \beta_j)]$$

while the log likelihood function for the expression is $H(\beta) = \log L(\beta) =$

$$\sum_{i=0}^n y_i \log [1 - F(-\sum X_i \beta_j)] + (1 - y_i) \log F(-\sum X_i \beta_j)$$

where μ_i , in F , follow a logistic cumulative distribution, X_i are characteristics of households, and β_j are the coefficients for the respective variables in the logit function. The probability of a household being poor and the corresponding change in probability due to unit change in a variable X_i are given as:

$$\text{prob}(R_i = 1/\beta_j X_i) = \frac{e^\varphi}{1 + e^\varphi} \text{ and } \frac{d[\text{prob}(R_i = 1/\beta_j X_i)]}{dX_i} = \beta_j (1 - p)p$$

where φ is $\sum \beta_j X_i$, P is estimated value of the probability due to a variable, β_j is estimated regression coefficients (Ojogho 2010; Veen and Gebrehiwot 2011).

4. Presentation of Data and Analysis of Results

Table 2: The Food Insecurity Line for the Households

Deciles	Mean per capita food expenditure (MPCFEM (₦))
First	2,320.52
Second	3,931.33
Third	4789.32
Fourth	7232.54
Fifth	10,231.24
Sixth	13,534.55
Seventh	18,423.24
Eighth	24,297.31
Nineth	32,341.51
Tenth	43,562.32
Total	16,056.4
2/3 MPCFE*	10,704.27

Source: Authors calculations from field reports

From the table above, the food security line is N10,704.27. Using the decision rule (fi) established above, any household whose mean per capita food expenditure falls below ₦10,704.27 are classed, as food insecure while households whose mean per capita food expenditure is above ₦10,704.27 are food secure. From all the households studied the food insecurity, incidence is calculated to be 0.41 using the household income and expenditure information derived from the questionnaire used for this study.

The demand for food especially in the study area may be influence by several factors. These include the income of the household, the area located, sex of the head of the household, the size of the household as well as tastes and preferences of the household members. These considerations informed the inclusion of the variables, in our questionnaire. In presenting the data, households are classified as food secure and food insecure depending on whether their mean per-capita food expenditure is above or below the food insecurity line as defined earlier. In the first segment of the analysis we employ tables and percentages in presenting and analyzing the results of our findings. In the second segment of the study, we present and analyze the results of the logit model.

4.1: Household Heads and their Education Status

Table 3 below present the data on the educational status of households

Table 3: Distribution of Households Heads by Educational Status

Educational status	Food secure		Food insecure		Food insecurity incidence
	Frequency	Percentage	Frequency	Percentage	
No formal Education	7	3.85	8	10.25	0.62
Primary	25	13.73	9	11.4	0.34
Secondary	28	15.38	20	25.64	0.51
Tertiary	122	67.3	41	52.56	0.35
Total	182	100.00	78	100.00	0.41

Source: Field survey 2010

Table 3 above presents the distribution of household heads by levels of educational status and the food insecurity incidence. From the table, food insecurity incidence is highest (0.62) for households whose heads are without formal education and least (0.35) for households whose heads have tertiary education. These findings tend to suggest that higher incomes that are associated with higher educational status reduce the incidence of food insecurity.

In the table, households are profiled into food secure and food insecure. Household heads among the food secure group are made of 67.03% for those with tertiary education, 15% for those with secondary education, 13.23% for those with no formal education. On the other hand in the food insecure group 51.56% of Household head had tertiary education. Household heads without formal education constitute 10.25%, for primary and secondary education the corresponding figure is 11.54% and 25.64% respectively.

Table 4: Distribution of Households by size

Household size	Food Secure		Food Insecure		Food Insecurity Incidence
	Frequency	Percentage	Frequency	Percentage	
1-4	113	62.0	26	33	0.45
5-7	64	35.0	42	53.20	0.68
6-10	5.4	3.0	7	9.80	1.00
Above 10	0.00	0.0	3	4.00	
Total	182	100.00	78	100.00	

Source: Field Survey 2010

Table 4 presents the distribution of household by size. Food insecurity incidence rises with the size. Food insecurity incidence rises with the size of the households ranging from 0.45 to 1.00 for household groups 1-4 and 6-10 persons per household respectively. The food insecure group recorded 33% for the 1-4 household members and 53.20% for households with 5-7 members. Households with 6-10 members were 9.80% while households with members above 10, were 4%.

Table 5: Distribution of Household heads by Occupation

Occupation	Food Secure		Food Insecure		Food Insecurity Incidence
	Frequency	Percentage	Frequency	Percentage	
Oil workers	115	63.20	33	42.30	0.35
Traders	33	18.13	22	28.20	0.36
Civil servants	29	15.93	18	23.10	0.42
Unemployed	5	2.74	5	6.40	0.31
Total	182	100.00	78	100.00	0.41

Source: Field Survey 2010

In table 5 the occupations were classified as oil workers, Traders, civil servants and the unemployed. The oil and gas group of workers account for 63.20% of the food secure group while traders and civil servants accounted for 18% and 15% respectively. For the food insecure group 42.30% were oil and gas workers while traders and civil servants accounted for 28.20% and 23.10%. The food insecurity incidence is highest in the civil servant group (i.e. 0.42). oil workers and traders recorded 0.35 and 0.36 respectively.

Table 6: Distribution of Households by Monthly Income

Monthly household income (N'000)	Food Secure		Food Insecure		Food Insecurity Incidence
	Frequency	Percentage	Frequency	Percentage	
20 – 40	37	20.32	16	20.51	0.40
41 – 60	21	13.20	20	38.46	0.61
61-80	21	11.53	11	14.10	0.43
81 – 100	24	13.20	9	11.53	0.33
100 and above	46	25.27	7	8.97	0.26
Total	182	100.00	28	100.00	41.00

Source: Field Survey 2010

Table 6 presents the distribution of households by monthly income. From the table we observe that the incidence of food security declines as income rises. The highest income group, i.e.. 100,000 naira and above recorded the least incidence of food insecurity. As income rises, food security incidence rises, reach a peak and thereafter declines. Among the food secure group 25.27% (which is the highest) falls within the highest income group N100,000:00 and above. The middle income group (40,000 – 60,000) were 11.53% which represents the least in that income classification. For the food insecure group the percentage points declines as income rises. This implies that the number of food insecure households declines as income rises.

Table 7: Distribution by Age of Households Heads

Age of Household Head	Food Secure		Food Insecure		Food Insecurity Incidence
	Frequency	Percentage	Frequency	Percentage	
21 – 30	33	18.13	24	30.67	0.30
31- 40	55	30.22	13	16.76	0.30
41 – 50	40	21.98	17	21.80	0.32
51 – 60	25	17.74	12	15.38	0.46
61-70	20	10.99	9	11.54	0.52
70 and above	9	4.94	3	3.55	0.45
Total	182		78	100.00	0.41

Source: Field Survey 2010

Table 7 above summaries the age distribution of household heads and the food insecurity incidence. The table reveals that food insecurity incidence increases with the age of household heads. Between the age 21 – 70 years the incidence increased from 0.30 to 0.52. The age group 21 – 70 year has some distinctive features. At the lower segment of that age bracket, wages are relatively low as they constitute the lower cadre of the labour force. Family sizes are also small within the age group 21 to 30 years. These help to explain the level of food insecurity incidence observed in the table 7. Within the age bracket 41 to 50 years household head's incomes would have risen and at the same time responsibility for a larger family size would increase food insecurity incidence as recorded on the table. Between 60 and 70 years most household heads would have gone on retirement with the attendant lower incomes an increase in food insecurity incidence.

Among the food secure group 30% of the households fall within the age group 31-40 years. Thereafter the percentage declines as the age of household heads increases. This picture is also replicated in the food insecure age groups of household heads.

Percentage of household heads in the food insecure group declined from 30% for the (31-40) age group to 3.55% for the age group 70 years and above.

Table 8: Distribution of Household Heads by Sex

Sex	Food Secure		Food Insecure		Food Insecurity Incidence
	Frequency	Percentage	Frequency	Percentage	
Male	151	82.97	61	78.21	0.37
Female	31	17.03	17	21.79	0.46
Total	182	100.00	78	100.00	

Source: Field Survey 2010

Tables 8 presents the distribution of households heads by sex and food insecurity incidence. Clearly the table reveals that food insecurity incidence is highest wherehouseholds heads are female (0.46). Among the food secure households 82.97% of the householdheads are males while only 17% are females. On the other hand among the food insecure households 78.2%of the household heads are males while 21.79% are females.

Table 9: Distribution of Household by dependency Ratio

Dependency ratio	Food secure		Food Insecure		Food Insecurity Incidence
	Frequency	Percentage	Frequency	Percentage	
No dependency	63	34.62	18	23.08	0.30
Less than 1	54	29.67	12	15.39	0.32
Equal to 1	27	14.84	7	8.97	0.39
Greater than 1	38	20.87	41	52.56	0.48
Total	182	100.00	78	100.00	0.41

Source: Field Survey 2010

From table 9, food insecurity incidence increases from 0.30 for no dependency to 0.48 for greater than 1 dependency ratio. Here dependency ratios isdefined as the proportion ofhousehold members that are not working to those that are working. From table 9, 34.62% of households have no dependants.

4.2 Interpretation of the Result of the LogitModel

Table 10: Definition of Variables used in the EstimatedlogitEquation

Variable	Definitions	Symbols
Food insecurity (dependent)	P = 1 if food insecure = 0 otherwise (food insecurity estimates)	P
Explanatory variables		
Sex of household head	Sex = 1 if male = 0 otherwise	SHH
Education level of household head	= 1 if primary = 0 otherwise	EHHP
	= 1 if secondary = 0 otherwise	EHHS
	= 1 if tertiary = 0 otherwise	EHHT
Age of household head (years)		AHH
Per capital income of household head (₦)		PCIH

AHH	0.031	1.452	0.812	0.005
PCIHH	-0.000417	-1.660	0.160	-0.00006
Constant	-2.763			

Count $R^2 = 0.84$, $R^2_{MCF} = 0.41$

* $\frac{dy}{dx}$ is for discrete change of dummy variable, **Significant at 5% level, ***significant at 1% level (see table 10 for meanings of abbreviation)

Table 11 reveals that household head who are civil servants (OHCS), household dependency ratios (HDR), household size (HHS) and age of household head (AHH) are positively related to the probability of a household being food insecure. On the other hand, household heads who are oil and gas (OHG) workers, the level of education of households heads (EHH), Age of household heads (AHH), income of household heads (PCIH) all have negative relationship with the probability of a household being food insecure.

Table 11 shows that occupation (i.e. oil and gas workers), education (i.e. primary, secondary and tertiary) are determinants of food insecurity as all these variables are significant. The respective probabilities of primary EHHP (0.461), secondary EHHS (0.321), tertiary EHHT (0.128), oil and gas OHOG(0.221) and Trader (OHT 0.211) all have low probabilities of a household being food insecure. Thus the more education one acquires, the higher the probability of reducing food insecurity incidence. The income of household heads is also found to be a significant determinant of food insecurity.

The logit value of the household size was 1.723, with a partial coefficient of 0.321. This implies that as the size of household rises by a unit on the average, the estimated logit increases by 0.321 and adds 0.036 to the probability of a household being food insecure for every unit change in household size.

5: Research Findings and Conclusion

The study reveals that food insecurity is lower for those engaged in the oil and gas sector. This category of persons earn relatively higher wages than the other groups studied. Food insecurity incidence is highest for civil servant (including teachers, 0.42) and lowest for the unemployed (0.31).

Food insecurity incidence decreases with the level of education. It is highest for those without formal education (0.62) and lowest for those with tertiary education.

The study also revealed that food insecurity incidence decreases as the level of income increases. It decreased from 0.61 to 0.21 for the income group 21,000 – 40,000 and 81,000– 100,000 respectively. The study also revealed that food insecurity incidence is higher in households where the heads are female. These findings were also supported by the results of the logit model that we estimated.

The food insecurity incidence has a direct relationship with the size of the household. The study revealed that small sized households recorded an incidence of 0.27 while large size households had food insecurity incidence of 1. The study also found that food security incidence increases with the age of the head of the household. Again the results of the logit model supports this finding

The food insecurity incidence for the entire households survey was 0.41. this shows that in general, although the oil- sector drives the economy of the study area, the food insecurity incidence in the area is high.

The study also found that food insecurity incidence increases with the level of dependency ratios. It rose from 0.30 to 0.48 for dependency ratio of zero dependency ratio and ratio of greater than 1. The results from the logit model also supports this.

From the findings of this study the following recommendations are made.

First, since the oil sector wages are relatively higher in the areas studied with its attendant inflationary effects, a programme of food subsidy or food aid should be put in place for the benefit of low income earners and other vulnerable groups in the area and be funded by government. Second, for the public servants in the area, government should provide special allowances to augment their earnings. Third, since food insecurity incidence was found to increase in female headed households, appropriate legislations should be made at the local council level to discourage broken marriages.

In conclusion, although this study has its own limitations in terms of the number of households covered, attempts should be made to carry out case by case studies across different geo-political areas. The present study has revealed that socio-economic factors such as the level of educational status, monthly income, size of the households, occupation of household heads all affect food security situations.

Abstract

Global mining corporations have contributed significantly to Australian economic development and national infrastructure, and it is touted they are one of the few organisations delivering training and employment opportunities for Indigenous people in the remote mining areas. Persistently advanced is globalisation will enable these marginalised people to substantially reduce their socio economic disadvantage, but the evidence is they continue to have unsuitable housing, poorer health status and lesser life expectancy, while greater access to wealth is linked to substance abuse, which manifests as heightened violence, greater incarceration, and more suicides than experienced in the non Indigenous population. In this paper is reported findings from a four year study with Indigenous people, who have exercised an opportunity for engagement in an educational programme and employment in a mainstream job in a remote Australian mining operation. The results demonstrate allowing global mining corporations to operate in remote regions of Australia may lead to a resurgence of interest in Indigenous employment, but an expectation their representation in the mining workforce will increase and/or their social disadvantage will be significantly reduced is worthy of revisitation.

Introduction

Australia is an ancient geographical continent with an abundant supply of minerals. These minerals, and the associated exploration and processing industry, account for eight per cent of the Australian gross domestic product (Martinez-Fernandez, 2010; Roarty, 2010). The abundance of minerals has led to national prosperity, and from exporting these resources has substantially contributed to satisfying the international demand for metal based (i.e., bauxite, iron ore, manganese) and energy (e.g., coal, gas, uranium) commodities. Nevertheless, the Australian governments and the resource industries have long been criticised for failing to positively engage with Indigenous people on whose land the mining operations are conducted (Buultjens et al. 2010, Lockie et al. 2008). Indeed, Australian Indigenous people unfavourably present against the social indicators of a developed society compared to the non Indigenous population.

Australian legal developments have underpinned a resurgence of interest in improving the socio economic status of Indigenous people in remote regions where mining operates. Following the 1992 Mabo decision, which gave Indigenous people a legitimate claim to land ownership (Crawley & Sinclair, 2003), the 1993 Native Title legislation was enacted with a feature the Traditional Land Owners were able to negotiate land usage with the miners. A common thread of these land use agreements, in addition to the financial dimensions, is the provision of education and vocational training for Australian Indigenous people (Barker, 2006; Tiplady & Barclay, 2007). Despite the opportunity for involvement in these work integrated learning schemes the majority of the Indigenous population has a preference for welfare or government subsidised work systems (Altman, 2009; Altman & Gray, 2005), and few Australian Aboriginals are employed in mainstream mining jobs (Brereton & Parmenter, 2008; Pearson & Daff, 2010a).

Aspirations of the mining industry, the Australian governments, and Indigenous people lack consensus. The mining companies argue that Indigenous people can acquire personal wealth and better social conditions by working

in the industry, but the lack of coherent policy by governments for the engagement of Australian Aboriginals ignores inter cultural identities of these people (Dillon & Westbury, 2007; Trudgen, 2000). Australian Indigenous people have strong spiritual and religious connections with the country and would prefer to live on their ancestral land in the hybrid economies, that include wildlife harvesting (Altman, 2003; Foley, 2006). In short, many Indigenous people in remote areas, where resource extraction is undertaken, find the prospect of mining operations unattractive (Pearson & Daff, 2010a). These conflicting ideologies have spawned considerable public debate focusing on Australian government pragmatic initiatives, such as welfare or subsidised paid work schemes, for improving the well being of Indigenous Australians (Anderson, 2007; Hunter, 2007). Arguably these imposed systems have not necessarily led to favourable outcomes. The imbalances are demonstrated as gross Indigenous inequalities in economic, health and social issues, which abound in remote communities where mining is being undertaken (McDonal et al. 2008; Pholi, Black & Richards, 2009; Rowley et al. 2000).

This paper reports on these notions to demonstrate the disadvantage of Australian Indigenous people in mining contexts. Paradoxically, while the Australian government expresses an enthusiastic commitment to improving the socio economic status of Indigenous people, substantial imbalance exists compared to non Indigenous people. And the mining and mineral sector, which generates enormous revenues, contributes to the paradox as the rhetoric from some of the world's largest resource companies has not led to equality for Indigenous Australians.

Australian Resources Sector Contribution

The Australian minerals industry makes a significant contribution to the economic growth of the nation. From 2006 the minerals industry in the domains of exploration, extraction, and processing has accounted for eight percent of the Australian gross domestic product (ABS, 2009; Martinez-Fernandez, 2010). In fact, the Australian minerals sector is in the top five world producers of most key mineral commodities (e.g., bauxite, coal, iron ore), and this activity accounts for the direct employment of some 170,000 people, and nearly twice as many in indirect employment (Roarty, 2010). Undeniably, the mineral resources (including gas) are major contributors to the Australian economy, often demonstrated by reassessments of the brought revenues, economic developments and contribution to the mineral and energy needs of the contemporary world society. Nevertheless, negative criticisms of the impacts of mining are beginning to resonate in the wider community.

Mineral extraction projects and their associated activities have been the focus of international and national concern. A recent international crisis was the substantive oil spillage in the Gulf of Mexico. Similar in disaster type, but with lesser impact in the world media, was the Montara drilling rig explosion (with accompanying crude oil leakage) in the waters off the northwest coast of Australia. Both events generated strong negative perceptions of the petroleum industry. In addition to potential environmental degradation, and the gradual unsustainability of mining (as the resource is not renewable) assessments of mining operations have been undertaken to examine health, safety, and social impacts. These assessments, which are within the gambit of corporate social responsibility (Jones, Marshall & Mitchell, 2007; Lockie et al. 2009) "...are a means of integrating development into core business strategies and can assist in building the companies and the communities..." (Esteves & Vanclay, 2009, p. 137). However, there are emerging growing concerns that some of these assessments have insensitively failed to allow those people (often in Indigenous communities) who will be most affected by the mining operations in remote regions of Australia (Arbeláez-Ruiz, 2010; Harvey & Brereton, 2005; Lockie et al. 2008) to have a stake in the decision making.

A resurgence of interest in the engagement of Indigenous communities with the Australian mining industry has mainly been driven by legal developments. In 1788, when Captain Phillip sailed the First Fleet into Botany Bay in New South Wales of Australia, the British Crown acquired sovereignty over several parts of Australia under the notion of *terra nullius* (vacant land belonging to no one). This condition persisted until 1992, compelling Indigenous people, who had lived in the region of the mining operations to be displaced and excluded (Crawley & Sinclair, 2003), although some were employed in menial jobs (Barker, 2006). On the 3 June 1992 the notion of *terra nullius* was declared, by the High Court of Australia, to be irrelevant in a judgement commonly referred to as *Mabo* (*Mabo*, 2009). The action had been led by Eddie Mabo, David Passi and James Rice, all from the Meriam people of the

Murray Islands in the Torres Strait, who challenged the state of Queensland, which had annexed the islands in 1879. The Mabo decision provided underpinning for Native Title legislation that profoundly changed relationships between mining companies and Australian Indigenous people. By demonstrating that the Meriam people had lived on the Murray Islands in a subsistence economy prior to European contact the court accepted native title rights by reason of long possession.

In 1993, the Keating government introduced the *Native Title Act* (2009) to deal with implications of the Mabo decision. The Act set forth procedures for dealing with native title claims, and retrospectively validated the interests of non Indigenous Land Owners. In a historic compromise Australian Indigenous groups agreed to the validation feature of the Act in exchange for guaranteed rights of the Traditional Land Owners to negotiate land use agreements. Coupled with pressures from international groups (e.g., U.N.), peak industry bodies (e.g., International Council of Mining and Metals), and the Australian government has led to policy commitments by the miners to not only deliver direct financial benefits to the Traditional Land Owners, but also sponsorship of long term benefits to the Indigenous communities in the region of the mining operations. A common feature of the land use agreements is employment and training provisions with an assumption that there will be greater indigenous representation in mainstream community jobs and in the mining sector.

Economic Engagement and Impacts

In spite of the phenomenal economic contribution of the Australian resources sector, few Indigenous Australians benefit in the distribution of the wealth. The point was succinctly put by Muir and Evans (2005) when they wrote that mining operations generate massive revenues for governments yet little of the money is invested in improving the lives of the regional residents. More objective data show that Indigenous employment in the Australian mining industry is low (Brereton & Parmenter, 2008), often the enjoyed occupations are low skilled (Tiplady & Barclay, 2007), overall the Indigenous unemployment rate in Australia approaches 20 per cent with even higher values in remote regions (Altman, 2009; Gray & Hunter, 2005), and consequently, long term welfare dependency or government subsidised work schemes (e.g., Community Development Employment Programme) have become attractive to Indigenous people.

Despite the Australian government policy of social inclusion Indigenous people are the most disadvantaged minority group in the nation. The notion of social inclusion is a conviction held by the Federal government Australian citizens "...should have the opportunity to participate in economic, social and community life..." (Brown, 2009, p. 4). Yet there is widespread evidence that Indigenous Australians continue to experience low labour market participation (Daly & Hunter, 1999; Gray & Hunter, 2002; 2005), and this vulnerability to unemployment manifests as lower consumer spending capacity (Altman, 2009; Giddy, Lopez & Redman, 2009), poorer houses and unsanitary living conditions (Toohey, 2009; Tripcony, 2000), lower health status and life expectancy (McDonald et al. 2008; Rowley et al. 2000), educational disadvantage (Bradley et al. 2007; Hughes, 2008), higher levels of poverty (Cechanski, 2002; McGrath, Armstrong & Marinova, 2006), as well as, social disorganisation expressed as family violence, unacceptable incarceration rates and suicides (*Anglicare*, 2009; Edney, 2001; Krieg, 2006). Disturbingly, available wealth is being channelled into extensive substance abuse and the ill effects on health and social adjustment in Aboriginal communities.

Mitigating circumstances have been advanced for substance abuse by Indigenous people. The misuse of tobacco, alcohol, recreational drugs and petrol (Lee et al. 2008; 2009), by Indigenous Australians is believed to reflect their struggle from colonial times in the pursuit of self determination (Maddison, 2008). Prior to the 1967 Referendum (which introduced the Federal government affairs policy of self determination), Indigenous people were embedded in the colonising forces of assimilation, which restricted their movement from government centres and missions, and excluded them from mainstream services, and created a raft of socio economic disparities (Smith, 2006). The policy shift to self determination removed the strict restraints on Indigenous people, which led to a rural exodus back to their ancestral lands where they resided in small remote communities called outstations (Coombs, 1974). It has been estimated that 25 per cent of the 0.6 million Indigenous population live in 1200 of these relatively small centres across 86 per cent of Australia (McConvell & Thieberger, 2001). Living in these rural communities

enables reinvigoration of their customary sector of the economy, which is based on wildlife harvesting (Altman, 2002; 2003), in enduring spiritual relationships and religious connections with the ancestral land of some 50,000 years of heritage. However, an absence of meaningful jobs in the remote communities has compelled Australian governments (when endorsing the policy of social inclusion) to provide welfare, which some Indigenous leaders (Pearson, 2007) claim has led to the collapse of social norms, and the rise of violence, alcoholism, child abuse and suicide. Paradoxically, the provision of wealth from government subsidised work, welfare or in some instances paid employment, which is designed to improve the socio economic status of Indigenous people, when coupled with full citizenship rights (1967 Referendum) has provided a pathway to engage in substance abuse.

Methodology

Site

The study site was the Gove Peninsula and surrounding region in an area about 150km from Nhulunbuy. Included in this zone are a number of Indigenous outstations such as Dhalinbuy, Dhanaya, Garrathiya, Galupa, Gunyangara, and Yirrkala, which are shown on Figure 1. The populations of these outstations range from a nominal 20 people at Galupa to over 600 at Yirrkala, with some 100 inhabitants each at Dhalinbuy and Gunyangara. Population numbers are fluid as the Indigenous people frequently move about the Northern Territory (N.T.). Even Nhulunbuy, which is a 'closed' mining town of some 4000 people (mostly non Indigenous) has a transient population component of fly in fly out employees. The town of Nhulunbuy is 15km to the east of the largest bauxite refinery in the southern hemisphere, which is 20km north of the minesite crusher. Bauxite ore is transported from the crushing station to the refinery by a conveyer belt system. Nhulunbuy which has all the facilities and infrastructure of a contemporary Australian town (e.g., hospital, shopping complex, airport, water and drainage, electricity), is 680 km east of Darwin, the capital of the N.T.

FIGURE 1: REGION OF THE STUDY AND PLACES OF INTEREST

A unique feature of the Gove Peninsula is the recorded history. In the 1600s the Indigenous Yolngu people traded with the Macassans from Sulawesi (formerly Celebes), and other European seafarers (e.g., Jan Van Corstens, 1623; Able Tasman, 1644; Matthew Flinders, 1803), until the trade was terminated in 1907 by the South Australian government. A Methodist Church Mission, which was established in 1934 by the Reverend Wilbur Chaseling, was closed in 1975 when the Yirrkala Dhanbul Community Association was founded. From 1942 to 1945 some 4000 military personnel (some were Indigenous Yolngu) were stationed in the region with a flotilla of PBY Catalina flying boats based in Melville Bay (adjacent to Gunyangara). During this period high grade bauxite ore was found at the now Gove airport, and during the 1960s a mine site and a refinery was established with the first consignment of alumina exported in 1972. The initial town for the construction workers was Birritjimi (Wallaby Beach) was built east of and adjacent to the refinery, but today only some 15 houses remain as the land has been transferred back to the Traditional Owners, the Rirritjingu clan of the Yolngu people. The town site of Nhulunbuy was designed in 1968 (*Town*, 1968), and progressively built to skirt Mount Nhulan (Mount Saunders).

Participants

The participants of the study are Indigenous Australians. More specifically, they are the Indigenous Yolngu people of East Arnhem Land of the N.T of Australia whose forbearers occupied the land 50,000 years earlier. The respondents are identified as a cohort group as different samples been employed in a variety of studies and reports that are acknowledged in this paper.

Procedure

An array of literature was used to provide information about a range of Indigenous socio economic disadvantages. Some of this literature is about Indigenous people of the N.T, but most is about Yolngu who have lived on the Gove Peninsula.

Results

The results are presented in three parts. First, is the social problem of substance abuse, which is a notable contribution to the high levels of anti social behaviour in Nhulunbuy, Yirrkala and the smaller, closer outstations. Second, are the night patrols and the significant associated infrastructure that has been acquired to support the service necessary to alleviate the consequences of substance abuse. Third, is the central information of two confidential Nhulunbuy police reports, that delineate the numbers of suicides and attempts, which are persistent social dislocation behaviours in the region.

Substance Abuse

Indigenous substance abuse in East Arnhem Land has escalated since the establishment of the mining operations. Prior to the early 1960s the only non Indigenous founded settlements were Yirrkala Mission and the military facilities during the Second World War. With the construction of the minesite and refinery in the late 1960s a number of Indigenous Yolngu were employed in labouring type jobs, but without retail outlets and being prior to Indigenous rights, payment in money was unappealing. At the Yirrkala Art Centre old film can be viewed to show at the close of work many Indigenous people sitting on benches drinking alcohol (beer). Today there are a number of liquor outlets in Nhulunbuy, and also at the Gunyangara Yacht Club where both non Indigenous and Indigenous people can consume alcohol.

In addition to alcohol, substance abuse presents as misuse of social drugs (e.g., Cannabis), petrol, glue /paint, tobacco and Kava. Cannabis usage, which is prevalent in the Indigenous communities on the Gove Peninsula

(Pearson & Daff, 2010b), can lead to mental disorders, psychotic illness, and depression (Degenhardt, Hall & Lynskey, 2003; Lee et al. 2008; Hall, Degenhardt & Teeson, 2004). In Nhulunbuy *Opal* fuel was introduced in February 2008 (*Arafura Times*, 2008) to replace 91 octane grade fuel, which has aromatics sought by hard core sniffers. In the one hardware store in Nhulunbuy all pressurised cans of paint are secured (by law) to deter purchase by juveniles. Yolngu people have a high smoking rate, which contributes to lung cancer and cardiovascular disease. Recently, the Chief Executive Officer of Miwatj Health Aboriginal Corporation stated the Yolngu on the Gove Peninsula have the highest rate of lung cancer of all Australian Indigenous groups, but it is unclear if the cause is from camp fire smoke or smoking of tobacco. In 2010 the Nhulunbuy shopping precinct was designated a non smoking area (*Arafura Times*, 2010a). The following year the *Menzies* School of Health was the recipient of a Federal grant of \$761K to investigate how to reduce tobacco consumption among Indigenous people (*Menzies*, 2010). Kava is an illicit substance, registered as a dangerous drug that continues to be of concern to the Nhulunbuy police (*Arafura Times*, 2003; 2010b). Nevertheless, despite endeavours to control the abuse of alcohol with a permit system being introduced in 2008 (*Arafura Times*, 2008) it [alcohol] is a significant social problem.

Night Patrol

In 2004 the number of inebriated Indigenous men wandering the Nhulunbuy streets on a nightly basis was a community concern. Following a town meeting of the Combined Reference Groups (business, government and industry representatives) a social impact assessment was undertaken of the nightly Indigenous anti social behaviours. The problem was referred to an anti social behavioural committee, and the resolution was the notion of a night patrol service to provide appropriate cultural assistance to those Indigenous people who were at risk. The service was initiated by elder Indigenous ladies from Yirrkala in February 2005.

When the night patrol service began there was minimal infrastructure to ensure the safety of vulnerable Indigenous people. Those who were injured had to be taken to the hospital as they could not be taken home where there was a threat of physical violence. Delivering the client to the police was an unattractive strategy as when in custody constant surveillance was required and Nhulunbuy only had eight police staff. Consequently, suitable facilities were constructed, and operational frameworks have been developed to provide minimum requirements for the management of night patrol services in Nhulunbuy (*Night Patrol Services*, 2010).

Today Nhulunbuy has a special care centre that is administered by the N.T. government and the Nhulunbuy Corporation Limited. This facility, which cost of \$1 million to establish (and operate), provides; 1) a safe haven for night patrol clients, and 2) a sobering up shelter. Residential rehabilitation provides treatment for alcohol or other drug abuse. The community patrol now operates from the special care centre.

Suicide

The current suicide rate for the N.T. is 66 per cent greater than the national rate. Table 1 presents a summary of actual and attempted suicide numbers for two confidential Nhulunbuy police reports (Fuller, 2005; Wurst, 2009), to show the trends are increasing. More disturbingly is the higher incidents of attempts and threatened. Trends are difficult to quantify because in periods of nil suicide reports were not prepared while latter reports are more comprehensive. Most (87%) of the attempted and actual suicides are from Indigenous Yolngu residents from Gunyangara, Nhulunbuy and Yirrkala. Hanging is the most prevalent method used.

TABLE 1: SUICIDE DATA NORTH EAST ARNHEM LAND

2006	N.R.	N.R.	Nil
2007	30	57	2
2008	41	77	6

Note. N.R. = Not reported

Discussion

The literature linking Australian mining and Indigenous engagement is in two main streams. One stream promotes the commodity worth to an international mineral consuming marketplace; and the economic contributions in terms of earnings, government revenues, direct and indirect employment levels, rural and regional development as well as other associated financial benefits (*Australian Energy Statistics*, 2010; Roarty, 2010). The quantity of publications and enthusiasm for this literature far outweighs the ascribed negative outcomes of environmental degradation; health, safety, and social impacts; the fact mining is unsustainable as eventually the resource is depleted; or contribution of the product and operations to greenhouse gases (Esteves & Vanclay, 2009; Lockie et al. 2009). The second stream of the relevant literature is in terms of corporate social responsibility to better engage Indigenous communities (Barker, 2006; Harvey & Brereton, 2005), employment systems (Jones et al. 2007), and other social features to integrate sustainability into the mining operations (Brereton & Parmenter, 2008; Tiplady & Barclay, 2007). Despite several studies of major health and social problems common in Australian Indigenous populations researchers are yet to investigate connections between the low status of Aboriginal well being and their living in rural settings where mining operations are being conducted.

Nhulunbuy as a greenfield town provides opportunity to broadly present a historical account of Indigenous health and social issues after 38 years of mining operations. The documented history reveals a substantial feature of the rich heritage of the Indigenous Yolngu of East Arnhem Land is linked to their engagement with non Indigenous Australians. Early records show the Yolngu people traded with European and Asian seafarers (Berndt & Berndt, 1999; Worsely, 1955), from the 1860s to the early 1900s they had disastrous confrontations with the pastoral companies that occupied Yolngu land from 1861 to 1908 (Trudgen, 2000), and when a large group of Indigenous people from the Yirrkal Church Mission assembled at Gove airport to be told their land was to be used for mining (Yunupingu, 2009). There is no evidence in any of these accounts that alcohol consumption by Indigenous people was condoned by the church, or that substance abuse (i.e., cannabis, solvent sniffing) was a social issue prior to the arrival of mining personnel. Yet there is recent medical research (Lee et al. 2008; 2009), and mining data (Pearson & Daff, 2010b) to show heavy cannabis use and the depressive symptoms are common in the Aboriginal communities on the Gove Peninsula. And a recent report by Anglicare (*Anglicare*, 2009), compiled from the responses of a wide body of stakeholders, stated substance abuse (i.e., alcohol, cannabis and other drugs) was a significant concern for the Aboriginal communities on the Gove Peninsula.

Mining provides extensive wealth that attracts substance abuse, which is linked with social disorders. The annual revenue of the Nhulunbuy mining operations is constantly recorded to be about \$1 billion (*East Arnhem*, 2010), and much of this money is distributed in the community as the town boasts the highest per capita income in the nation. At these mining towns relatively low skilled jobs can attract high remuneration rates. Taylor (2011) reports low skilled Indigenous people in Western Australian mining towns can earn \$100,00 per annum in landscape work (e.g., lawn mowing, whipper snapping, mulching). A link with consumer spending capacity and dysfunctional

social activity is given by Mercer (2010) who reports people living in mining communities in Queensland and Western Australia are prone to violence and anti social behaviour that has been fuelled by alcohol and drugs. A claim wealth acquired by workers at Western Australian minesites appears to be linked to organised crime is supported by the police seizing large quantities of drugs from fly in employees (Eliot, 2010). More credible are the findings of medical studies demonstrating that heavy, persistent substance misuse in N.T. Indigenous communities is associated with mental and physical health as well as social problems (Lee et al. 2008; 2009; Rowley et al. 2008). Clearly, the isolated communities in remote Australia, many near mineral extraction facilities, are targets for suppliers of illicit substances, while alcohol is readily available at commercial outlets within the townsite shopping precincts.

Conclusion

Systematic longitudinal research to present links between living in Australian mining regions and experienced socio economic disadvantage by the inhabitants is lacking. Although there has been a number of recent co relational one shot designs of studies assessing physical and mental health problems, and social dislocations of people living in Australian mining contexts there has been a lack of enthusiasm for longitudinal causal investigations. Longitudinal evaluations can take a reasonably long time whereas academics, politicians, bureaucrats and the public in general have shorter attention spans. More often there is not any scientific original data. During the 1980s and the 1990s environmental and social agendas began to emerge hence, before these times the emphasis was on the commercial priorities, and today 'lunar landscapes' are a feature of defunct mining regions. Thus, greenfield towns like Nhulunbuy or revitalised towns to provide infrastructure and accommodation for the workforce were founded on commercial and technical priorities. Impact reviews are often undertaken a long time after the mining operations have been installed when the social problems manifest.

This paper has presented information about an Australian mining town and socio economic problems. A greater focus has been made on the Indigenous people who live in the remote Gove Peninsula of the N.T. of Australia where the mining operations have been conducted for 38 years. Employing an array of public literature an inescapable conclusion is that there are damaging social, mental and physical effects being experienced in the mining town and in the nearby regions. In particular the Indigenous people do not present favourably against any of the indicators of health, employment, housing, incarceration, poverty or longevity. Yet Australian mining is profiled by financial contributions to the international and national arenas rather than the equality of Indigenous Aboriginals on whose land the mining is conducted. Balancing economic and productivity arguments within a much broader ethical and moral interface with all stakeholders is a worthy visionary challenge.

Shadow economy in the wood industry in Slovenia

Jože Kocjančič
Štefan Bojnec
University of Primorska, Slovenia

Abstract

This paper investigates the impact of the reduction in the number and size structure of large enterprises in the wood industry on the dynamics of the shadow economy in the wood industry in Slovenia. The empirical results show that the dynamics in the reduction of the number and size structure of large enterprises in the wood industry significantly contributes on the increasing share of the shadow economy in the wood industry. The most important decision factors to participate in the shadow economy are the level of taxes and contributions, opportunities for better earnings and tax regulations. The estimated share of the shadow economy in the wood industry is 21.7%. As the basic solutions to reduce the share of the shadow economy and to speed up the dynamics of the entering of small enterprises in the wood industry are improved regulation system to provide better incentives to operate within the formal sector and better access for necessary financial capital at acceptable guarantees. As important are also good practices by the state institutions by providing incentives for entrepreneurship and encouraging decisions for the setting up of an enterprise.

Introduction

This paper investigates the impact of the changes in the number and size structure of large enterprises in the wood industry in Slovenia on the share of a shadow economy and the most frequent reasons for operation in the shadow economy. The previous studies have largely investigated the shadow economy for the manufacturing sector activities as a whole. Few studies have investigated the shadow economy in the literature (e.g. Glas 1991; Kukar 1995; Ott 1998; Feige et al. 1999, 2008; Fleming et al. 2000; Smith 1994; Flajs and Vajda 2004; Schneider 2005, 2007; Nastav and Bojnec 2007, 2008; Nastav 2009). In addition to the review of the previous studies on the shadow economy, in the empirical part we analyze the results of our research on the sample of micro and small enterprises, which operate in the wood industry in Slovenia. The empirical results indicate in what degree and in which ways the changes in the number and the importance of large enterprises in the wood industry have determined the changes in the shadow economy.

Theoretical background and main stylized facts

In general two main streams of literature exist regarding the definition of the shadow economy. The first view considers the shadow economy as an unregistered economic activity, while the second view basis on a temporary characteristics of economic behaviors (Fleming et al. 2000). The aims to generalize different definitions of the shadow economy in most cases are based on these two streams of literature. Thomas (1999) suggests that for the shadow economy activities are considered all those activities, which are not, but should be included into the national revenues. Schneider and Enste (2000) define the shadow economy as all economic activities, which should be calculated in the national gross domestic product, but due to different reasons are not. Smith (1994) defines the shadow economy sector as legal or illegal, on market demand based production and service activities, which were avoided in the estimations of the national gross domestic product. Nastav and Bojnec (2007) under the term of the shadow economy include all those economic activities, which are legal, but are not under a control of institutions, which are managing with them.

The main reasons for the shadow economy in developed and transition economies as well as in developing countries are higher taxes and contributions for social insurance, tax moral of the people and the degree of the state

regulation. Higher taxes and contributions explain 35 to 38% of the reasons for the appearance of the shadow economy, more strict tax regulations 8 to 10% and tax moral 22 to 25% of the reasons for the shadow economy (Schneider 2005).

Impact of the shadow economy on the economy

The shadow economy has both negative and positive impacts on the economy and society. These impacts are reflected in a form of less charged taxes of responsible institutions, in impacts on less competitive enterprises, which are operating in the formal sector of the economy as well as on the side of consumers, which usually do not have guarantee for products and services. On the other hand enterprises, which are operating in the shadow economy, they operate with lower costs and they can employ more people, which might do not find employment in the formal sector. Consumers can have lower costs for purchases of goods and services, which are caused by bureaucratic and administrative barriers and might not pay value-added taxes. The shadow economy can also play a specific incubator role for small enterprises at the early stages of the operation in the shadow economy (e.g. Schneider and Enste 2002; Smith 2002; Nastav and Bojnec 2008).

Shadow economy in Slovenia and in some developed countries

As can be seen from Table 1 in most of developed countries the share of the shadow economy is between 8% and 30% of gross domestic product. Moreover, the share of the shadow economy in developed countries is lower than in transition economies and in developing countries. The shadow economy in general represents a part of gross domestic product, which should be considered in formulation of the economic policy.

TABLE 1: SHARE OF THE SHADOW ECONOMY IN SOME DEVELOPED COUNTRIES

Country	Share of the shadow economy in % in gross domestic product in the period 1999–2003
Greece, Italy,	24–30%
Sweden, Norway, Denmark, Ireland, France, Spain, Netherlands, Germany, England, Portugal, Belgium, Finland	12–23%
Japans, Austria, Switzerland, USA	8–11%

Source: Schneider 2007.

Slovenia as a former socialist transition country and since 2004 the member of the European Union (EU) is rarely included in the comparative studies of the shadow economy. Most often Slovenia is analyzed in studies of the shadow economy in transition countries or in associated members of the EU. Empirical results of the shadow economy in different studies often vary due to different used definitions and methodologies, which very often prevents direct comparisons of the results. The study conducted by Schneider and Enste (2003) reports that 26.7% of gross domestic product in Slovenia is generated by the shadow economy in the period 2000–2001. They consider as the shadow economy all those economic activities, which are administratively organized and should be normally taxed. In the study conducted by Schneider (2004) using the sample of ten new members of the EU there is also included estimation of the share of the shadow economy in the officially reported gross domestic product in Slovenia in the period 1999–2003. According to this estimates the share of the shadow economy is between 27.1% and 29.4% and tends to increase.

Nastav and Bojnec (2007) report that the share of the shadow economy in registered value added by different economic activities in Slovenia vary and tends to increase. In 1995, the average estimate of the share of the shadow economy in gross value added in Slovenia was between 18.9% and 20.8% and increased by the year 2000, when it was between 20.4% and 22.5% of the registered gross domestic product.

Shadow economy and dynamics of enterprises

European Commission (2004) and OECD (2002) argue that there is a direct association between micro and small enterprises on one hand and the shadow economy on the other. The finding is based on a fact that small enterprises are more flexible and easier avoid unfavorable legislation and administration limitations and therefore easier hidden a part of their activities, which are performed in forms of the shadow economy. Moreover, high taxation obligations and other regulatory and administration limitations are causing the increases in the share of informal economic activities, which are performed in the shadow economy (Johnson et al. 2000). In a spite of these facts there is not possible to associate a positive association of the dynamics of entry and exit of enterprises only with the impacts of these factors. Taxation limitations, labor market regulations, administrative transaction costs, investment climate, income inequalities and some other factors can also have impact on the dynamics of entry and exit of enterprises as well as on the share of the shadow economy (Schneider and Enste 2002, Bartlett et al. 2005).

The relation between the rate of unemployment and the dynamics of entry of new enterprises particularly with an aim to establish self-employment can also have positive effects on the dynamics of entry, and vice versa (Audretsch et al. 2005). First, a positive effect is from unemployment of individuals, who are willing to establish own enterprise in the case of low opportunity costs for entry into self-employment (Evans and Leighton 1990). Second, a negative association effect is from high rate of unemployment, which has for implication the higher share of activity, which is conducted in the shadow economy, and which is associated with low rate of the dynamics of entry of new enterprises. Third, positive dynamics of entry of new enterprises have impacts on the reduction of the shadow economy and the rate of unemployment (Storey 1991).

Wood industry

Wood industry is by statistical economic activities included among manufacturing activities. Its main activity is production of processed wood and wooden plates, then production of furniture, construction furniture, and other products made from wood. For wood industry in Slovenia typical is a high concentration of enterprises: 1% of enterprises contribute 25% of total revenues and the first 3% of the largest enterprises contribute 50% of total revenues in the wood industry in Slovenia.

In 2006 in the wood industry in Slovenia operates 2,586 enterprises and individual entrepreneurs (SURS 2007), which means 14.2% share of all enterprises in the manufacturing activities. In the same year the gross value added per employee in the wood industry on average amounted to 19,403 euro, which is a bit more than 67% of value-added per employee in the manufacturing activities, which on average achieved 26,974 euro, and only a bit less than 64% of gross value added per employee in the economy as a whole, which on average achieved gross value added per employee 30,408 euro (SURS 2008).

The comparison of the wood industry in Slovenia with the wood industry in the EU-27 shows that Slovenia with 19,403 euro of value added per employee achieved a bit less than 75% of average value added per employee in the EU-27, which amounted to 25,885 euro. The wood industry has important contribution in the Slovenian economy employment and value added, but the labor productivity in the Slovenian wood industry on average is lower than in the EU.

Methodology and data

The collected data from the existing secondary data bases are analyzed by descriptive statistics and multivariate factor analysis. In addition, at the end of 2008 and at the beginning of 2009 the primary data for the sample of enterprises were collected using the written questionnaire, which was sent by post-mail with a pre-paid post mark and envelope. The written questionnaire contains from a short, mostly closed-type of questions. The possibility for a selection of answers was based in a form of question, which is known as a Likert's scale-type. The respondents were asked to select one out of five possible answers. The selected answer indicates the degree of agreement or disagreement with the possible opinion (Easterby-Smith, Thorpe and Lowe 2005).

We include statistical population of micro, small and large enterprises, which operate in the wood industry in Slovenia. In 2007, the statistical population contains 3,324 micro and small enterprises and 18 large enterprises (Table 2). The in-depth investigation of statistical population is based on a statistical sample, which includes 700 statistical units in population of micro and small enterprises, which represents almost 21% of total population of micro and small enterprises in the wood industry in Slovenia. On the written questionnaire, which was sent to 700 in the sample of randomly selected enterprises, we received 168 completed answers of enterprises. This means that we received 24% of successfully completed written questionnaires. Among the participating enterprises are by legal-organizational forms 60.7% independent entrepreneurs, 33.9% associations with limited responsibility and in 3.6% share-holding company.

TABLE 2: POPULATION OF MICRO, SMALL AND LARGE ENTERPRISES IN THE WOOD INDUSTRY BY STANDARD CLASSIFICATION OF ACTIVITIES, SLOVENIA, 2007

	Number of enterprises		Number of employees	
	DD20	DN36	DD20	DN36
Micro enterprise (0 – 9 employees)	1,520	1,568	3,030	3,139
Small enterprise (10 – 49 employees)	119	117	2,326	2,524
Total micro and small enterprises	1,639	1,685	5,356	5,663
Large enterprises (more than 250 employees)	6	12	3,385	5,212
Total population	1,645	1,697	8,741	10,875

Note: Standard Classification of Activities DD20 – Manufacture of wood and wood products; DN36 – Manufacture of furniture, manufacturing not elsewhere classified.

Analysis of the shadow economy in Slovenia

We investigate the impact of the changes in the number and size structure of large enterprises in the wood industry in Slovenia on the share of the shadow economy and on the most frequent reasons for participation in the shadow economy. The starting point of the analysis is theoretical and empirical findings of the shadow economy (e.g. Schneider 2004, 2005, 2007; Feige and Ott 1999; Nastav and Bojnec 2007, 2008; Nastav 2009).

Analysis of the impact of the dynamics of large enterprises on the share of the shadow economy

The presence of the shadow economy is visible particularly in activities, which require relatively smaller investments into technological equipments and buildings. In a difference from the formal sector, which is burdened with taxes and regulations, the shadow economy is dynamic and adjustable (Schneider and Enste 2002).

We investigate the impact of the reduction in the number of large enterprises on the share of the shadow economy in the wood industry using the data collected with the written questionnaire. We find that the reduction in the number of large enterprises in the wood industry determines the number of people working in the shadow economy. The average value of 3.89 by the Likert's scale – from 1 as very unimportant to 5 as very important – shows relatively important positive impact of the reduction in the number of large enterprises on the increase of the shadow economy (Table 3). Similarly, the reduction in the size structure of large enterprises on the shadow economy in the wood industry shows relatively important positive impact on the increase in the shadow economy with the average value of 3.82. Therefore, the reduction in the number and in the size structure of large enterprises in the wood industry increases the share of people working in the shadow economy.

TABLE 3: ANALYSIS OF RESPONSES FOR IMPACT OF REDUCTION IN THE NUMBER AND THE SIZE STRUCTURE OF LARGE ENTERPRISES ON THE SHARE OF THE SHADOW ECONOMY IN THE WOOD INDUSTRY IN SLOVENIA, 2009

Interval of opinions for its average value (Likert's scale from 1 to 5)					
Notes on opinions: 1 – very unimportant; 2 – unimportant; 3 – neutral; 4 – important; 5 – very important					
Opinions	N	Average value	Modus	Median	Standard deviation
Impact of reduction in the number of large enterprises on the share of the shadow economy	165	3.89	4	4.00	1.093
Impact of reduction in the size structure of large enterprises on the share of the shadow economy	165	3.82	4	4.00	0.977

Table 4 shows the important impact of labor price on the share of the shadow economy as well as on the dynamics of entry of small enterprises in the wood industry. Therefore, the labor price through the structure of labor costs and value added per employee has important impact on the shadow economy. Enterprises, which operate in the shadow economy, can avoid a part of operational costs, which can increase their competitiveness as well as can provide a source of income for people, which might do not find employment in the formal sector of the economy. Moreover, the labor price in the structure of costs and value added per employee with taxes and contributions has impact on the taxation burden of enterprises, which operate in the formal sector of the economy. Due to this, they can become less competitive in comparison with the informal sector and its expansion.

TABLE 4: ANALYSIS OF OPINIONS FOR IMPACT OF LABOUR PRICE ON THE SHARE OF THE SHADOW ECONOMY AND DYNAMICS OF EXIT OF SMALL ENTERPRISES IN THE WOOD INDUSTRY IN SLOVENIA, 2009

Interval of opinions for its average value (Likert's scale from 1 to 5)					
Notes on opinions: 1 – very unimportant; 2 – unimportant; 3 – neutral; 4 – important; 5 – very important					
Opinions	N	Average value	Modus	Median	Standard deviation
Impact of price of labor on the share of the shadow economy	156	3.85	4	4.00	0.772
Impact of price of labor on dynamics of exit of small enterprises	165	3.49	3	3.00	0.712

Table 5 shows that the impact of the shadow economy on competitiveness of small enterprises in the wood industry is relatively strong with their impact on the reduction of competitiveness of the small enterprises that operate in the formal sector of the economy. Due to less paid taxes the shadow economy enterprises are more competitive vis-à-vis enterprises, which operate in the formal sector, which pays taxes and thus have higher costs of operation. Therefore, the increased share of the shadow economy with its supply of products and services has modest to important impact on the reduction of competitiveness of small enterprises, which operate in the formal sector of the wood industry.

TABLE 5: ANALYSIS OF OPINIONS FOR IMPACT OF THE SHADOW ECONOMY ON COMPETITIVENESS OF SMALL ENTERPRISES IN THE WOOD INDUSTRY IN SLOVENIA, 2009

Interval of opinions for its average value (Likert's scale from 1 to 5)					
Notes on opinions: 1 – very unimportant; 2 – unimportant; 3 – neutral; 4 – important; 5 – very important					
Opinion	N	Average value	Modus	Median	Standard deviation
Impact of the shadow economy on competitiveness of small enterprises	162	3.65	4	4.00	1.112

Analysis of factors of the shadow economy and its share in the wood industry

Reasons for operation in the shadow economy

The reasons to operate in the shadow economy might be different by countries and within a certain countries by individual branches. Table 6 presents the opinions of the respondents on the nine frequently reported reasons as important for decision of an individual to work in the shadow economy in the wood industry. The average value of the respondents' opinions on the important factors for decision to work in the shadow economy in the wood industry in Slovenia vary by questions, but the highest opinion values are found when the higher level of taxes and contributions, followed by opportunities for better earnings and state tax regulations.

TABLE 6: ANALYSIS OF OPINIONS ON FACTORS IMPORTANT FOR DECISION TO OPERATE IN THE SHADOW ECONOMY IN THE WOOD INDUSTRY IN SLOVENIA, 2009

Interval of opinions for its average value (Likert's scale from 1 to 5)					
Notes on opinions: 1 – very unimportant; 2 – unimportant; 3 – neutral; 4 – important; 5 – very important					
Opinions	N	Average value	Modus	Median	Standard deviation
Rate of value added per employee	162	3.61	4	4.00	0.954
Low value added	159	3.60	4	4.00	0.835
Lack of establishing capital	162	3.30	4	3.00	0.918
Degree of the branch competition	159	3.23	3	3.00	0.885
Level of taxes and contributions	162	3.96	4	4.00	0.905
Tax regulations	159	3.91	4	4.00	0.786
Opportunities for earnings	162	3.93	4	4.00	0.962
Law tax moral of people	159	3.58	4	4.00	1.021
Lack of suitable employment	156	3.06	3	3.00	1.120

Dynamics in the share of the shadow economy in the wood industry

The opinions on the dynamics of the shadow economy in the wood industry are based on the answers by the respondents on the three questions: the share of the shadow economy in the wood industry has declined, has remained at a similar level, and has increased. Table 7 indicates some differences in the average value of the responses on the individual question. The highest average value 4.37 is given to the statement that the share of the shadow economy in the wood industry has increased, while the average value of 3.61 is given to the statement that the share of the shadow economy in the wood industry has remained at a similar level. The frequency distribution and the average value of the opinions suggest that the share of the shadow economy in the wood industry has remained at a similar level or has a slightly increased.

TABLE 7: ANALYSIS OF OPINIONS ON THE DYNAMICS OF THE SHADOW ECONOMY IN THE WOOD INDUSTRY IN SLOVENIA, 2009

Interval of opinions for its average value (Likert's scale from 1 to 5)					
Notes on opinions: 1 – very unimportant; 2 – unimportant; 3 – neutral; 4 – important; 5 – very important					
Statements	N	Average value	Modus	Median	Standard deviation
Reduction in the share of the shadow economy	24	3.46	4	4.00	0.721
Stagnation in the share of the shadow economy	84	3.61	3	3.00	0.865
Increase in the share of the shadow economy	57	4.37	4	4.00	0.587

The average share of the shadow economy in the wood industry by the opinion of the respondents is around 22% (Table 8). According to some other estimates the share of the shadow economy in the registered gross domestic product in Slovenia was between 18.9% and 20.8% in 1995, and between 20.4% and 22.5% in 2000 (Nastav and

Bojnec 2007). Therefore, the wood industry in Slovenia with the share of the shadow economy, which is close to an average in the economy, is not an exception by the share of the informal sector of the economy.

TABLE 8: ANALYSIS OF OPINIONS ON THE SHARE OF THE SHADOW ECONOMY IN THE WOOD INDUSTRY IN SLOVENIA, 2009

Opinion	Interval of opinions for its average value				
	N	Average value	Modus	Median	Standard deviation
The share of the shadow economy (in %)	165	21.73	30	22.00	9.936

Common factors to work in the shadow economy

With the factor analysis we aim to identify whether exist common factors, which explain how changes in the number and size structure of large enterprises in the wood industry in Slovenia causes on the share of the shadow economy. In the factor analysis are included 168 enterprises in our sample. The factor model is estimated in two steps: with principal axis factoring and maximum likelihood method with estimation of factor weights with using rotations.

In the factor analysis are used the following indicators: impact of the reduction in the number of large enterprises on the shadow economy, impact of reduction in the size structure of large enterprises on the shadow economy, impact of value added per employee on decision to work in the shadow economy, impact of capital profitability on decision to work in the shadow economy, impact of establishing capital on decision to work in the shadow economy, impact of competition on the share of the shadow economy, impact of level of taxes and contributions on the share of the shadow economy, impact of tax regulations on the shadow economy, impact of better earning on decision to work in the shadow economy, low tax moral of people, availability of working places, impact of price of labor on the shadow economy, impact of price of labor on the number of small enterprises in the wood industry, and the impact of the shadow economy on competitiveness of enterprises, which operate in the formal sector.

With the factor analysis we define two common factors, which explain differential in the share of the shadow economy in the wood industry in Slovenia. The variables used are based on the opinions of the respondents. Two common factors explain around 45% of variance in the dynamics of the shadow economy in the wood industry in Slovenia (Table 9).

The first common factor for the role of general enterprise environment factors explains a bit less than 30% of variance for the share of the shadow economy in the wood industry. The greatest impact in the first factor shows variables for the impact of competition in the wood industry, impact of reduction in the size structure of large enterprises, impact of reduction in the number of large enterprises, and impact of value added per employee on the share of the shadow economy in the wood industry. The reduction in the number and size structure of large enterprises in smaller extent causes the dynamics of entry of new small enterprises in the wood industry, but indeed increases already a strong competition as well as causes reduction in the rate of value added per employee. Due to this an important part of labor surplus decides for operation in the shadow economy due to lower operation costs. In a case of restructuring of supply of existing small enterprises towards foreign markets with higher processed products this would be a way to achieve higher value added products, which would reduce competition for products and services with lower value added. This would have positive implications on the dynamics of entry of small enterprises and on reduction of the shadow economy in the wood industry.

The second common factor for the role of the state on the shadow economy explains additionally a bit more than 15% of variance for the dynamics of the shadow economy in the wood industry. The greatest impact is on variables the impact of taxation regulations on the shadow economy and to a lesser extent the impact of level of taxes and regulations on the share of the shadow economy and opportunities for greater earnings. Importance of tax regulations implies that the enabling environment should be more institutionally friendly towards small enterprises with more friendly legislation and advice activities, which would reduce the identified negative impacts and create positive synergies to reduce the shadow economy in the wood industry.

TABLE 9: SHARE OF EXPLAINED VARIANCE OF FACTORS OF THE SHADOW ECONOMY IN THE WOOD INDUSTRY IN SLOVENIA, 2009

Factor	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of variance	Cumulative in %	Total	% of variance	Cumulative in %
1	4.176	29.826	29.826	3.680	26.282	26.282
2	2.133	15.234	45.060	1.792	12.803	39.086
3	1.444	10.316	55.377			
4	1.194	8.531	63.907			
5	0.947	6.763	70.670			
6	0.860	6.146	76.816			
7	0.773	5.520	82.335			
8	0.650	4.645	86.980			
9	0.604	4.317	91.297			
10	0.484	3.455	94.752			
11	0.284	2.031	96.783			
12	0.203	1.452	98.234			
13	0.140	1.003	99.238			
14	0.107	0.762	100.000			

Estimation method: principal axis factoring and maximum likelihood method.

Conclusion

The research has confirmed the importance of the reduction in the number and the size structure of large enterprises on the share of the shadow economy in the wood industry in Slovenia, but less on the dynamics of entries of new enterprises in this branch. This implies that a great proportion of people who lost employment in large enterprises prefer to operate in the shadow economy rather than to establish own enterprise. The reasons for operation in the informal sector are particularly in relatively high taxation burdens and administration barriers. Moreover, labor costs in the structure of value added per employee have important impact on the share of the shadow economy in the wood industry. This branch on average experiences relatively low value added per employee and cannot compete by wages in other branches, which causes outflow of qualified and skilled labor from the wood industry or they decide to work in the shadow economy. This increases the importance of the informal sector of the economy. Incentives for entries of small enterprises and providing easier access for necessary financial means would create incentives for innovation towards products and services with higher value added products and services and provide opportunities for more competitive relative wages to keep the best qualified and skilled labor in the formal sector as potential for recovery and development of the wood industry.

The research has contributed to science and theory in the area of investigation of the impact of the restructuring of large enterprises on the market dynamics of small enterprises focusing particularly on the shadow economy in the wood industry in Slovenia. Literature so far has focused on more aggregated manufacturing activities in Slovenia. The research contribution is based on own conducted quantitative analysis using secondary data and primary collected survey data. As implications for theory and practice we have provided the empirical associations and links between the analyzed variables in order to identify, measure and provide implications and proposals for reduction of the shadow economy and provide incentives for a greater dynamics of micro and small enterprises. The share of the shadow economy in the wood industry in Slovenia has not declined and for its reduction would be valuable to promote taxation and other economic policies, which would not be oriented only on control over the tax collection, but particularly on providing incentives for switch of the shadow economy activities from the informal economy into the formal economy by entry and growth of enterprises in the formal economy. As limitations and future research possibilities are in a fact that our research investigates only the impact of the

dynamics in the number of size structure of large enterprises on the shadow economy in the wood industry in Slovenia.

Financing Sustainability for Cities in Emerging Economies: The Philippines Experience

Robert W. Taylor, taylorr@mail.montclair.edu
Montclair State University

Abstract

Sustainability is a noble goal for any society but to make it operational requires both political will and financial capacity. This is especially true in emerging economies where efforts placed at growing the economy are paramount and other aspects of sustainability, the environment and social equity, are often minimized. Cities in these countries are particularly vulnerable to risks associated with environmental degradation and social conflict. Often, sustainability planning can limit some risks and vulnerabilities and make these places more resilient. This paper discusses various strategies that cities in emerging economies can undertake to finance their sustainability, with an emphasis on Philippine cities. Sustainability projects, as defined in this paper, are smaller-scaled initiatives that are cost-effective and emphasize revenue generating capacities and suitable return on investment or private-public partnerships that utilize newer or unconventional technologies. The goals of these sustainability projects are reduce urban vulnerability and reduce poverty and environmental degradation.

Introduction

Today, nearly 50% of world's population lives in cities. By 2030, this percentage will increase to 60% and cities of the developing world are expected to absorb 95% of this growth as a result of rural to urban migration, transformation of rural settlements into urban ones, and natural population increase. Although comprising only 3% of the earth's land area, cities consume 75% of global energy, create 80% of global greenhouse gas emissions, and intensely concentrate industry, people, materials and energy (Davis, 2008; Schulz, 2002).

The Asian region alone will add an additional 1.5 billion people to its urban regions by 2020 (ADB, 2001). This wave of urban expansion, led by China and India, is restoring Asia to global prominence which it enjoyed before the European and North American industrial revolution. Nearly 2.5 billion Asians will live in cities by 2025, accounting for almost 54% of the world's urban population (Dobbs, 2010). Also, most of this urban growth will occur in large urban regions or mega-cities that consist of populations of over 10 million people. By 2015, the Asian region will have 13 such mega-cities.

One of the countries in Asia that is rapidly urbanizing is the Philippines. In 1980 only 39% of the population lived in urban areas. By 2020 this is projected to increase to 73%. There are currently 136 cities in the Philippines. The top ten cities by population are listed in Table 1. As can be seen, six of the top ten cities are located in the National Capital Region of Metro Manila. Metro Manila accounts for 33% of the national Gross Domestic Product (GDP) making it a dominant metropolitan region (www.nsc.gov.ph). Another important index of Philippine urbanization is metropolitan status. There are twelve metropolitan areas in the Philippines of which the top ten are illustrated in Table 2.

Philippine cities are tiered according to governmental independence and funding levels from the central government. The basic urban unit is the Local Government Unit (LGU) of which there are 1,494 in the Philippines. These LGUs have significant powers to conduct their own business and provide direct services to their citizens as outlined in the Local Government Code of 1991.

Without proper management planning, Philippine cities constitute a major environmental hazard. Yet, through the implementation of sustainable projects some of the risks and vulnerabilities of these cities can be minimized. Compact development planning, settlement patterns that encourage resource and energy efficiency, green building construction, renewable energy technology, and innovative waste management solutions all can make these cities more resilient. Sustainability planning is the most cost-effective strategy for the long-term viability of Philippine cities. In the short run, cities must become extremely creative in designing ways to finance sustainability. This paper explores the various strategies to finance sustainability projects in Philippine cities.

Defining Sustainability Projects

It is necessary to define what constitutes a project that meets the criteria for a sustainability project as discussed and developed in this text. While capital-intensive large-scale infrastructure projects are sustainable, i.e. sewage treatment plants, fixed rail public transit, etc, the funding for these projects is beyond the scope of this text. Instead, the emphasis on sustainability projects in this chapter is on smaller, more labor-intensive and lower cost projects. These are the projects that would be advocated by E. F. Schumacher in his “small but beautiful” thesis. These projects are ones that can generate a significant amount of environmental improvement without major capital outlays. Also these projects emphasize revenue producing capacity, tend to advocate public-private partnerships, and stress creative financing packages that utilize private market mechanisms.

Table 1: TOP TEN PHILLIPPINE CITIES BY POPULATION

City	Region	Population (2007)	Area (km ²)	Population Density (per km ²)
Quezon City	NCR	2,679,450	161.12	16630.15
Manila	NCR	1,660,714	38.55	43079

Current Local Government Funding

Local governments receive their funding from a variety of sources. Figure 1 provides a broad summary of the funds that flowed to Local Governments in 2007 to finance their operating, debt servicing and infrastructure needs. Regular income is sourced mostly from the national government in transfers and locally generated receipts from real property taxes, fees, business taxes, licenses and economic enterprises.

The Local Government Code of 1991 has placed the Philippines in the forefront of fiscal decentralization in East Asia. While this seemingly provides an incentive for cities to develop creative strategies for funding development, this has not materialized. Although this text does not use the legal definition of cities that the Philippine government uses but instead relies on a wider conceptual definition of cities as densely-populated urban communities, it should be pointed out here that there is some discrepancy between the fiscal capacities of these

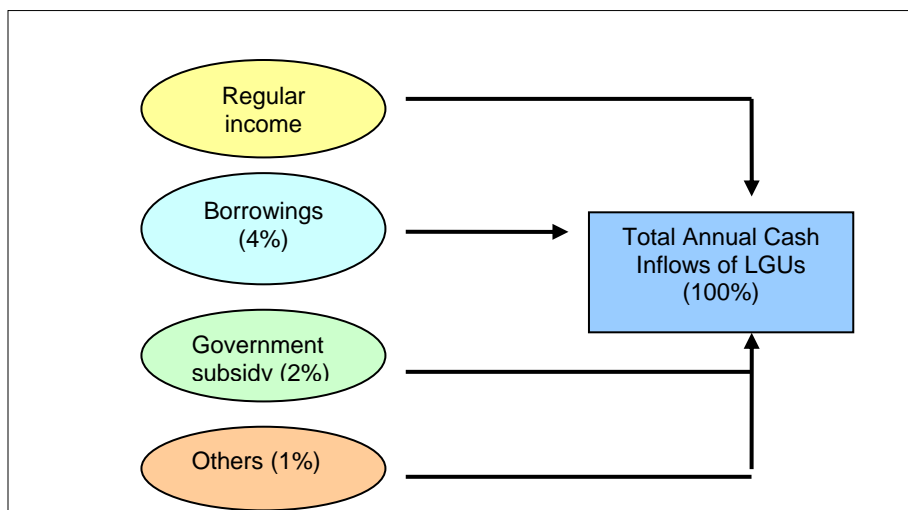

various subunits of government. Highly urbanized cities possess more fiscal autonomy than independent and component cities and considerably more than municipalities. Table 3 shows the ratio of local own revenue to total local revenue in percentage from 2003 to 2006. It shows that revenue derived from local sources, i.e. real property taxes, user fees, business taxes, license fees, economic enterprises, etc. are significantly greater in cities than in either municipalities or provinces. Figure 2 shows this discrepancy graphically.

TABLE 3: RATIO OF LOCAL OWN REVENUE TO TOTAL LOCAL REVENUE (%) IN LOCAL GOVERNMENTS

Year	Total	Provinces	Cities	Municipalities
2003	30.5	12.6	50.7	18.9
2004	31.9	13.8	52.2	19.2
2005	32.3	14.6	52.6	20.1
2006	31.2	13.6	51.6	18.7

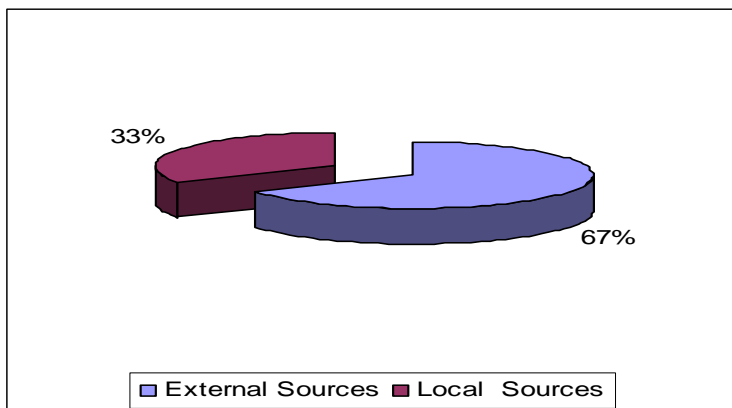

FIGURE 2: LOCALLY DERIVED REVENUE SOURCES

Source: Draft Report 2010 NSSMP

The main bulk of revenue for cities and urban municipalities in the Philippines is the Internal Revenue Allotment (IRA) which is an intergovernmental fiscal transfer from the central government as provided in the 1991 Code. Figure 3 shows the distribution of 2007 local government income. The IRA distribution to local governments is 40% of national internal revenue taxes and is allocated as follows: 23% to provinces; 23% to cities; 34% to municipalities; and 20% to barangays. These shares are weighted according to population (50%), land area (25%); and equal sharing (25%). Legally defined cities are favored in this formula as they proportionally more revenue even though they make up fewer of the local government designations.

FIGURE 3: 2007 DISTRIBUTION OF LOCAL GOVERNMENT INCOME

Source: Draft Report 2010 NSSMP

Through the devolving of responsibility from the central government to the local governments as provided in the 1991 Code, local governments are required to provide more services which necessitates more local fiscal expenditures. Increasingly, a fiscal gap is developing wherein local operating costs are rising faster than local revenue capacity. Already, local governments rely on the IRA as their main revenue source and this dependence is growing. Hence, local governments have four choices before them: 1. they can increase their local own-revenue sources; 2. they can reduce local expenditure responsibilities; 3. they can call for a structural adjustment in intergovernmental responsibilities (a move back to centralization); or 4. they can request an increase in the IRA contribution to say 60%. It is beyond the scope of this text to discuss all of the above options as many would require structural changes. For the purposes of this text, it is assumed that funding for sustainability projects will not be derived from the IRA or from existing local revenue sources, i.e. property taxes, license fees, etc. Hence, the funding for sustainability projects must come from creative funding strategies. The Asian Development Bank has recognized that local governments in the Philippines need to become financially independent and have created the Local Government Financing and Budget Reform Program which aims to improve revenue generation and budget processes of local governments. The following funding strategies are designed specifically to fund sustainable projects. These projects are ones that use nature to mitigate human impacts (bio-mimicry engineering), maintain or restore ecosystem services, foster energy efficiency and renewable energy, and reduce material and toxic waste.

Local Government Bonding

Bonding is a funding mechanism where an investor loans money to an entity that borrows it for a specified period of time and at a certain interest rate. These borrowed funds are returned to the investor on a specified maturity date. There are two types of bonds that local governments can float. One is a general obligation bond where the full faith and credit of the local government backs up the solvency of the security. These types of bonds are not allowed in the Philippines. A second type of local government bond is the revenue bond which are not backed up by the full faith and credit of the local government but instead are paid back through user fees. These types of bonds are best used financing business improvement districts, housing, redevelopment districts and capital-intensive city services such as sewage treatment or water supply projects. In the Philippines local governments must meet three basic conditions for bond issuance. First, the project must be revenue-generating; second, it must be part of the local development

plan; and third, the bond amount must be within the limitations on debt service capacity and maximum borrowing limits as stated in the 1991 Local Government Code. Local governments can use revenue bonds to accomplish some of the goals of sustainability planning.

While there are examples of local government revenue bond floats in the Philippines, it is a financing mechanism that has not been well developed. There are a number of reasons for this situation. First, there is no adequate rating system available to the investor that can provide an impartial rating as to the quality of the bond. And second, there is not bond insurance program established that could reduce some of the risk to the investor. As a result, the investor must approach a local government revenue bond with a caveat emptor approach that requires the investor to undergo a good deal of due diligence before purchasing. This means that the interest rates on these bonds are generally too high for them to effectively sustain various improvement projects. Government investment institutions such as the Development Bank of the Philippines and the Land Bank can offer a local government a better rate. Yet, because of the large amounts of revenue local governments require for sustainability and local improvement projects, national government institutions cannot meet this huge requirement. Hence, local governments need to develop their local bonding capacity to fill this huge need.

The obstacles to local government revenue bonds financing are significant. Besides general issues related to the fear of the investor that change of political leadership could jeopardize repayment of the security, to the need for more education to make bonds a viable source of capital funding, bonding have encountered local opposition where they have been proposed. The *Philippine Inquirer* recently reported a situation in Mindanao where local opposition has attempted to thwart a major in his use of revenue bonding to finance the construction of a new municipal market. The Mayor used the services of a financial adviser from Makati to provide a study justifying the use of bond floatation to fund the infrastructure project. A local finance committee submitted a counter study indicating that securing a loan from a government financial institution would result in less costs and easier terms since the local depository bank is guaranteed payment from the national governmental bank. While this case points to the notion that private investors are taking more risk and require a higher return on their investment than funding from the national government, nevertheless, the national government cannot provide all of the funding for such projects if every local government goes to the national government for a loan. Perhaps it would be more prudent for the national government to provide a bond insurance program with an appropriate transparent bond rating system so that private investors can have some of their risk hedged which would result in local interest rates required and provide lower borrowing costs to the local government. Generally, an investor would require an internal rate of return of 10%. This would make bonds too expensive for many local governments. If the internal rate of return can be reduced to 5% with an incentive package built in, i.e. reduced risk through insurance and some tax holiday for the investor, then revenue bonds become a viable source of capital projects for local governments.

User fees are the primarily source of revenue to pay off revenue bonds. When an investor or a local government analyzes the potential success of a bond float, it must assess whether the capital project or service can pay for itself through user fees. Hence, only projects that meet certain criteria or profitability can be considered. While this limits some projects, it is believed that sustainability projects will pay for themselves over a longer time frame. What often hindered the capacities of green projects are they that require more up-front investment than traditional projects, but begin to accelerate their investment return after seven years or so. For instance, green building projects might require more initial investment but after the seventh year or so they exponentially provide a return to the investor. Hence, revenue bonding provides an excellent source of revenue for these projects as repayment requires are extended over a longer period of time.

Impact Fees and Transfer of Development Rights

Urban development by its very nature impacts urban ecosystems. The notion of ecosystem services is basic to sustainability planning for Philippine cities. Ecosystem services provide life sustaining systems and services, i.e. purifying air and water, regulating climate, mitigating droughts and floods, and detoxifying and purifying water (Salzmann, 2003).

Maintaining urban watersheds and preserving local vegetation are simple but significant measures to maintain urban ecosystems. There are various strategies designed to maintain the sustainability of these ecosystem services. One way is to regulate environmental impacts. This places a strong reliance on governmental regulatory regimes. The advantage of this approach is that it establishes environmental standards that local development must meet. The disadvantage is that it requires a well-paid, well-trained and non-corrupt civil service. Another approach is to create market mechanisms and institutions that can capture and maximize ecosystem service value. In this

approach, appropriate instruments are developed whereby investors are paid to preserve or restore urban ecosystems.

One approach for cities to take is to create a dedicated fund to preserve or restore ecosystems by having the private developer pay for development impact. These fees would be determined by analyzing the impact of the development on a local area and to affix a fee accordingly. Another approach, and one that is advocated in this text, is to compensate the owner of environmentally fragile urban land, i.e. wetland, open space, deep-sloped land, by transferring development rights from the environmentally-fragile land to land that offers more development potential. This land use development technique must be done by utilizing local government's zoning capacity or police power. It is accomplished in a transfer of development right through a development certificate to the property owner in lieu of the owners loss of development right on his/her land. In this manner, the local community maintains the integrity of a valuable ecosystem service but does not "take" the value of the owner's property.

While transfer of development rights is one example of the use of market mechanisms in maintaining ecosystems, in this case with the help of the local government, other examples can be created for local governments. The key to this strategy is first to identify the ecosystem service to be protected or preserved, create a valuation for it, develop a market instrument to convey its value, and use local regulatory power to enhance its value. Examples of this strategy abound. The preservation of local wetlands by providing trade-able credits to owners that could be sold to developers or to non-governmental groups, charitable organizations, or outside donors. The same approach could be used to preserve urban watershed. And finally, the use of carbon credits to fund renewable energy projects is one which has already been discussed but also demonstrates the viability of this approach.

Special Assessment Districts and Tax Increment Financing

Special Assessment Districts are public projects that provide specific benefits to both particular properties and to their communities. It requires a local ordinance to create a Special Assessment District. A Special Assessment District can be established for a number of purposes. It can be designed as a business improvement district or a historic district. As a finance tool for sustainability it can be set up to demonstrate various innovative technologies in building construction, landscaping, creating zoning applications for green space integration, etc. The first step is to delineate the specific geographic area of the district. The next step is to get property owner buy-in. Owners would not be persuaded that their properties would gain in value as the District prospers. A Special Assessment District Plan would be created, generally initiated by a local NGO, which would establish the goals and objectives of the District and the purposes to which the funding would be designated, and the financial plan to repay the loan.

A revenue bond float would fund the improvements and the District property owners would pay a user fee based on a percentage of each property's assessed value at a specified rate, similar to a property tax. These user fees would pay off the bond. It is assumed that District improvements will lead to property value increase. The idea of tax increment financing, which is used in the United States to fund urban area improvement, is based on fees charged to the property owner on before and after value of their properties as established through a detailed assessment process. This is a creative tool that could be utilized to showcase whole areas of cities that desire to redevelop around the concept of sustainability.

Real Estate Investment Trusts

Real Estate Investment Trusts (REIT's) are a new form of financing and investment tool that has recently been implemented in the Philippines through the Real Estate Investment Trust (REIT) Act of 2009 or Republic Act 9856. The law establishes a framework and a set of guidelines for the creation of stock corporations that aim to be traded publicly and used to finance a wide range of infrastructure projects as well as provide a stable rate of return to their investors. It is well recognized in the Philippines and alluded to earlier in this text that more complex capital markets and instruments need to be developed in the Philippines. This is particularly true of infrastructure projects that support sustainability aims. In a REIT, a publicly traded company's stock is registered with the Securities and Trade Commission and traded on the Philippine Stock Exchange. The requirements for a REIT are specific. They must have a minimum paid-up capital of P300 million with at least 1000 stockholders. At least 75% of the deposited property of a REIT must be invested in income-generating real estate, and 90% of their distributable income must be sent as dividends to their stockholders not later than the last day of the fifth month following the close of the fiscal year. Investors are provided incentives through certain tax incentives that are included in the Act. REITS can be used to support a variety of sustainability projects that utilize green building and energy conservation technologies.

Also, housing is a major consideration for environmental improvement for cities. Though REIT's that invest in moderate income new housing, a major source of un-sustainability can be removed or reduced. REIT's can be combined with national tax policy to provide an instrument for the construction of lower income housing. Instead of the government building public housing, a lower-income housing REIT could integrate favorable national tax policy or incentives for investors. While the REIT structure in the Philippines is geared toward equity REIT's, mortgage-based REIT's can invest in housing mortgages are popular in other national markets. Using the REIT structure and financial instrument to finance lower income housing could go along way to alleviate the environmental problems associated with informal settlers in Philippine cities.

Public Private Partnerships

The major assumption of this chapter is that if cities are to engage in sustainability planning they will need to create new funding instruments or, at the least, significantly extend existing funding opportunities utilizing public-private partnerships. Local governments already have maximized their use of traditional revenue sources based on immediate local needs. Figure 4 shows how local governments spend their revenue. Projects that utilize sustainability planning features must seek their funding from the private sector in creative public-private arrangements.

Source: Draft Report 2010 NSSMP

A model of the sustainability funding process is provided in Figure 5. This model is based on tapping into new sources of revenue for projects, mainly from the private sector, either NGO's, businesses, or private banks.

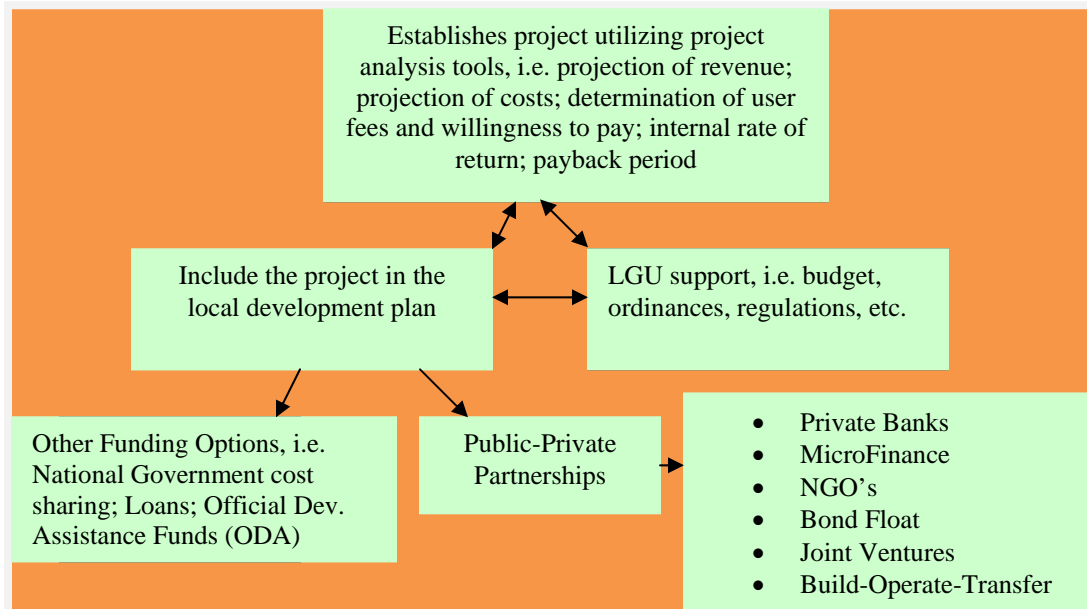

Joint Ventures

Cities can enter into Joint Venture (JV) agreements with another party to undertake a sustainability project. The private sector partner must contribute assets and share in the risks of the project and are bound by certain restrictions. First, the undertaking should be within the expressed or implied power of the local government. Second, the project should be within the territorial boundaries of the local government or grouped local governments if several local governments are grouped as partners. And lastly, the project must be included in the local development plan. It is the responsibility of the local government to validate the authority of the contracting official; subject the project to general review and approval; consist of terms that are not disadvantageous to the local government; and local government personnel should not have a direct or indirect financial or material interest in any transaction that requires the approval of their office.

An example of a sustainability project that the city could undertake with a private entity is to develop a joint venture with an Energy Services Company (ESCO). An ESCO is a private company that undertakes energy audits and implements energy use reduction programs for their clients. These clients can be public, such as schools, government buildings, etc. or private buildings, i.e. housing, commercial buildings, shopping malls, etc. ESCO's generate their fees based upon their capacity to reduce the energy usage of their clients, saving them money and also reducing their carbon dioxide footprint. For instance, an ESCO will be asked by a client, let's say a local government, to conduct an energy audit of public buildings with the intent of developing a program to lessen energy

usage and costs. The ESCO will first report on small changes that can be made such as moving to compact fluorescent or LED lighting. But the main thrust of a ESCO is to develop a plan for long term energy savings which requires possible capital investment in “big ticket” items like compressors, transformers, and photovoltaic systems. The ESCO structures a capital funding program for its client where major equipment is financed over a 10-15 year

FIGURE 5: MODEL OF SUSTAINABILITY FUNDING PROCESS

Source: Draft Report 2010 NSSMP

period through a loan provided by either the ESCO directly or a third party, i.e. bank, etc. The ESCO is committed to the energy reduction plan that they have outlined and is contained in a long-term contract. The ESCO receives its profit based on a percentage of the cost savings on energy use of the client over the term of the contract. Since the ESCO generates its revenue stream based on the initial or base energy audit, if it miscalculates the energy savings from its capital investment program over the term of the contract, it will be at risk. Under the ESCO joint venture, the city transfers most of its financial risk for borrowing to the ESCO, while the ESCO gains a stable revenue stream in its public client. This type of program provides a good solution to cash-strapped cities that want to reduce its energy usage and carbon footprint.

NGO Partnerships

Cities can partner with NGO's to accomplish many sustainability projects. An example is the work of Sustainable Project Management (SPM), a Geneva-based NGO, in Smokey Mountain, a two million ton garbage dump in Tondo, the city of Manila. For over 40 years it served as a waste disposal facility for Metro Manila and attracted a huge squatter community who scavenged the garbage for their livelihood. SPM was invited by the parish priest of Smokey Mountain to help develop a solution that would address the long-term environmental and health risks associated with the community's exposure to the mountain of waste, while improving the livelihood of the vast population that relies on the waste business. It sought both to alleviate poverty and improve the local environment.

SPM's strategy is to develop a strong public-private partnership that enables it to facilitate and implement its projects. One of its partners, the Manila Eco-aide Association asked SPM to assist them in upgrading their operations and to organize their Eco-waste program and information campaign in Tondo. To accommodate the wastes that are generated and then segregated, a two-story building Materials Recovery Facility was constructed with a \$229,500 grant from The Asian Development Bank (ADB). Another partner, the Kababaihan group agreed to implement a information and education campaign for the project. And finally, a major corporation, Unilever, agree

to have its company's waste hauled, sorted and recycled at MRF. Initial products from the Facility were donated for the construction of the Church of the Risen Christ in Smokey Mountain.

The Smokey Mountain Remediation and Development Program (SMRDP) was launched under the guidance of SPM. The Program incorporated three projects. The first project was to establish an information and education campaign. It provided ecological solid waste management training workshops that provided useful information to barangay council members, city of Manila public service representatives, and a large number of local partners. A second project was the development of a Material Recovery Facility (MRF). It met with the Department of Science and Technology to discuss the relocation and transfer of the bioreactor. It met with the National Housing Authority and Home Guarantee Corporation to discuss use of the property. In 2005, the MRF was set up in barangay 129 in Tondo. A third project was to establish a skills training and capacity building program. A key element to this program was the creation of a micro-financing capacity for sustainable enterprises. And lastly, the fourth project was to set up an outreach component to share the lessons of Smokey Mountain with other LGU's program.

The program meets the basic criteria for sustainability. It provides livelihood capacity for low-income people in Smokey Mountain and it improves the local environment. The program demonstrates how partnerships can facilitate initiatives. SPM was able to partner with important government offices, business sectors and other NGO's. This move created a comprehensive project that integrated education, technical support, financial support, and community participation.

The most successful of the initiatives and projects launched by SPM is the Materials Recovery Facility. Both the Asian Development Bank and Unilever Philippines were significant partners with SPM in its implementation and success. It has helped to provide both an improved environment and livelihood for Smokey Mountain residents. Its success points to the importance of lining up good sponsors and funding for the initiative. Community cooperation is also very important. Having a continuing community education and information program in place, with reinforcement such as prizes and public recognition, also is a key to a successful program. Without community participation, sustainability projects are doomed.

Finally, the issue of housing should be addressed. It is not the scope of this report to discuss the intricacies of the housing redevelopment program at Smokey Mountain, but it does show both positives and negatives. One important positive is that the housing project kept people in place and did not relocate them to provinces that might not be able to accommodate their skill base as scavengers. Of course, they could be effectively relocated to an area that contains a waste facility. A recent review of the housing program stated, "when the SMDRP was first launched, the government promised to transform the garbage dump into a paradise, with adequate housing, jobs, and livelihood training. The current condition of Smokey Mountain indicates otherwise. The promised jobs have not materialized, and the housing is substandard and costly" (Suarez,2008).

Conclusion

Cities do not have the necessary revenue stream in their traditional funding sources to finance many sustainability projects. Also, large infrastructure projects such as new waste treatment and water treatment and supply plants will need special financing that is not the subject for discussion in this chapter. Sustainability projects advocated in this text are smaller initiatives that are cost-effective and tend to emphasize either revenue generating capacities and suitable return on investment or private-public partnerships that utilize newer or unconventional technologies.

Already, a number of public-private partnerships are well utilized in the Philippines. An example is the Build-Operate-Transfer (BOT) partnership. In this type of arrangement, the private sector builds an infrastructure project, operates it and eventually transfers ownership of the project to the government. In some instances, the government becomes the firm's only customer and promises to purchase a minimum, predetermined amount of the project's output. This ensures that the firm recoups its initial investment in a reasonable time span. In order to improve the flexibility of the BOT arrangement, other modalities like concession agreements, management contracts and franchise agreements can be considered as BOT variants under the law.

Traditionally, the Philippines has relied on Official Development Assistance (ODA), funding either in loans or grants from international organizations or foreign governments. This funding has usually be sourced through Government-Financial Institutes (GFI) such as the Land Bank and the Development Bank of the Philippines. Some private financing institutions (PFIs) also offer loans using ODA funds (borrowed by these private banks from GFIs on a wholesale basis) supplemented by their own funds. The MDFO of the Department of Finance (DOF), on the other hand, provides a mix of grants and loans to LGUs (depending on income class) to finance revenue generating projects, social infrastructure and environmental projects. In 2007, the government appropriated a total of P1.1 billion to MDFO to be used for lending operations to local governments. Generally, the loans to LGUs by either the GFIs or MDFO have a repayment period of 15 years with a three-year grace period on the amortization of the

principal. Although LGUs are allowed to borrow, the Local Government Code (LGC) puts a ceiling on debt servicing which should not exceed 20% of their regular income.

And finally, for sustainability projects to be implemented, they need to utilize the Microfinance apparatus established in the Philippines under the Banking Law of 2000 and its succeeding circulars. Microfinance is “the viable and sustainable provision of a broad range of financial services (savings and credit) generally, by the private sector to poor and low-income households engaged in livelihood and micro-enterprise activities using non-traditional and innovative methodologies and approaches (e.g. non-collateralized cash-flow based lending). Sustainability projects must be built on a wide-range of support of the local community. Private banks, thrift banks, credit cooperatives and micro-finance NGO’s can provide a unique service in providing financial services to local entrepreneurs in their desire to improve their communities through the development and implementation of sustainability projects.

**Business Sustainability
In the Economic Uncertainty:
A Case Study of Siam Commercial Bank in Thailand**

ABSTRACT

This paper presents a case study of the Siam Commercial Bank (SCB) by investigating why and how SCB implemented organizational restructuring during the uncertain economic environment, and gives an overview of the Thai commercial bank industry. This paper presents and discusses SCB's strategy implementation in its organization during 1997-2010 with SCB's HRM role. This case study is aimed to provide some guidelines for other companies in developing and choosing strategies for their business sustainability in the global change, and in choosing the implementation of their organization structure for competitive markets, and to use HRM as an organizational support for their employee capacity building.

KEYWORDS: Business Strategy, Organizational restructuring, Organizational Structure, Human Resource Management

1. Introduction

Back in 1997, the Thai economy faced a number of challenges arising from the global economic slowdown, political uncertainties, and Thai baht appreciation. The result directly affected the financial and banking industry. The first alternative for Thai businesses operating in the turbulent economic situations with higher level of market competition was to formulate new corporate strategy to implement their business plan adjustment and organizational restructuring.

In today's dynamic business environment in Thailand, it is necessary for organizations to constantly go through organizational renewal and restructuring. However, organizational restructuring always have an impact on the companies' employees in terms of positions, benefits, job responsibilities, etc. Moreover, the result of restructuring might cause employee's psychological stress and other related symptoms. Most employees received the company's news and information in an unclear manner or through rumours such as "our company is going bankrupt, selling all businesses" or "our company will put pressure on employees to do difficult work, and so that, they will be resigned". Thus, in order to reduce employee problem between the employees and companies, most companies tried to adopt new policies, plans and activities.

The Siam Commercial Bank (SCB) is one of Thailand's largest banks in term of market capitalization, which had been affected from the Thai economy's fluctuation. Thus, in order to sustain its business, the Bank had been constantly restructuring its organization along with its business expansion. The Bank's organizational restructuring was able to change its culture which had never changed in more than 90 years. Furthermore, the Bank's employees came from all regions of Thailand, people strongly hold on to their societies and local cultures. In addition, the Thai in all regions of Thailand have lived in different types of society, culture, and economy in their local communities (Siengthai & Bechter 2001). As a result, SCB had some employee group who resisted its organizational restructuring. Thus, the Bank utilized human resource management (HRM) to solve and prevent the employees' problems.

2. Organizational restructuring and HRM

This section reviews the findings of previous relevant studies on organizational restructuring and HRM practices.

Organizational restructuring is one type of management tools used to eliminate the weaknesses in firm and the development of a strong organization. Firms implement organizational restructuring to cope with the intensification of the economic change, the growing globalization of business, poor operating performance and stock returns, financial distress. Informational and political factors are forcing organizations to consider new ways of organizing and responding to the competitive dynamics of the external environment (Lewin & Johnston 1996, Pettigrew & Massini 2000, Lin, Lee & Gibbs 2008). The successful implementation of the organizational restructuring could change work process, organizational structure and organizational culture, reduce expenses, compete in the business world, and develop employees. In the UK, organizations changed to propose that in 1988, a major organizational crisis emphasized change in organization and management. Thus, most commercial organizations have changed their structure and culture, and designed business strategies by increasing their competitiveness in market environment (Edwards, Woodall & Welchman 1996). The organizational restructuring efficiency and effectiveness has been reflected by the quality of strategy implementation. Furthermore, in order to prevent errors in the implementation of the organizational restructuring. The strategy implementation will identify factors, and check situation of organizational restructuring and business processes.

Although, most companies succeeded to achieve their businesses growth by implementing organizational restructuring, but the outcomes of organizational restructuring also had rapidly changed and affected some employee groups led to employee panic, internal conflicts, employee resistance, and employee dissatisfaction. HRM has a very important role in creating understanding of organizational restructuring between the employees and company according to HRM strategy, HRM planning, HRM policies and practices. In a relationship between HRM and organizational restructuring, HRM has an important role in stimulating employee involvement in the change of business process of the organization (Dooreward & Benschop 2003).

3. The Economy of Thailand

Before 1997, the Thai government emphasized on achieving the newly industrializing country status by transforming the Thai economic structure from agriculture to manufacturing. The Thai economy had then been called the emerging tiger in Asia. As a consequence of the economic plans, Thailand's Gross Domestic Product (GDP) increased about 7-9 percent annually from the late 1980s until 1996. In 1997, the Thai economy started to experience financial crisis. After that, it has been continually fluctuating due to changes in the global economy and ongoing Thai political problems. Even though, in 2002, Thailand succeeded to recover its economy from financial crisis, and grew at 7.1 percent in 2003. Nevertheless, Thailand has a strong economy based on agriculture, food processing, and tourism industries, these three industries are the main sources of Thailand's income and can persist while global economy keeps changing.

5. Context of the Study

Before financial crisis in 1997, most commercial banks in Thailand never changed their corporate strategies because they were family businesses. During the financial crisis in 1997, Thai bank's business performance was at its worst, due to financial problems, leading to the growth of non-performance loans (NPL).

In order to sustain Thai commercial bank industry and Thai economy, Thai government and Bank of Thailand (BOT) changed the regulation of Thai commercial banks' shareholders by eliminating foreign investment barriers and allowed the foreign investment groups to hold up to 100 % of Thai banks' shares. As a result, the foreign investment groups acquired five small Thai commercial banks. For example, Standard Chartered Bank acquired Nakornthon Bank in 1999, GE Capital acquired Bank of Ayudhaya in 2007, UOB acquired Radanasin Bank in 2003 and Bank of Asia in 2005 which merged both banks under the name UOB in 2008. CIMB Bank Bernhard acquired Bank Thai in 2009.

Even though, foreign investor groups acquired five small Thai commercial banks. The Ministry of Finance approved new licenses for commercial bank in Thailand, namely, Thanachart Bank, TISCO Bank, Kiatnakin Bank, and Land and House Retail Bank.

This has led to change Thai bank's market capitals in terms of innovation products, business styles, capitals, high competition, banking technologies, and human resource management.

Overall, Thai commercial banking industry has high opportunity to create business performance because Thai market has large scale of retail group and the strength of the Thai economic structure can drive the Thai banking industry growth.

SCB was one of Thai commercial banks which were hit by the financial crisis which put SCB on the verge of bankruptcy. It started in January 1906 in the reign of King Rama V as the first local commercial bank in Thailand. Based on SCB's determination over 100 years, it has emphasized Thai owner's bank. Furthermore, the Bank by the top management level chose to implement its organizational restructuring with continual business expansion strategy for its business sustainability during 1997 – 2010 by relating the global economy and the Thai economy situations at that time.

In order to explain SCB's employee to understand why SCB continued to implement its organizational restructuring, Dr. Vichit Suraphongchai, SCB's Chairman of the Executive Committee gave to speech in SCB's Forum that:

“The change program is the project to change ourselves and the project will build the future of SCB. Someone asked whether SCB can stop this project, this answer is that we cannot stop this project. We must continue to change in order to sustain our bankChange is natural. Change is necessarily. Change is our future, and we must continue to change our bank.”

3. Research methodology

The respondents were randomly sampled in SCB from the top management and middle management levels by using Taro Yamane's method ($n = N/1+N(e)^2$). These 291 sample respondents represent the managers all business units. Approximately 95 percent of the sample respondents participated from the beginning stage to implement SCB's organizational restructuring in 2001. A total of 56.27 percent of these respondents represented managers in the lower rank in the top management group, and a total of 43.73 percent represented middle management level.

This paper applied grounded theory method in data collection which involved in-depth interviews and open-ended questionnaire survey with some individual sample respondents and the analysis secondary data. The use of both in-depth interviews and questionnaires can consider useful in maximizing the strengths and minimizing the weakness of both techniques to ensure that the findings are more reliable. Furthermore, the respondents were very cooperation to answer questions based on their experiences working in the current position, job responsibility and business target. Interviews were tape-recorded and written in the questionnaire. Each interview session approximately took 45-60 minutes.

6. The corporate strategy implementation in SCB during 1997-2010

Based on the financial crisis in 1997, SCB had high volume of NPLs and lost money from exchange currency rate. During that time, the Bank's value per share had been 8.60 Thai baht in SET, and it had low capital value. Therefore, the Bank must be increased its new capitals but it failed to increase new capital at first. In 1999, it decided to enlist in the Government's Tier 1 Capital Support Program, and succeeded to participate in this program in the same year. Furthermore, the Bank succeeded in increasing its new capital from domestic and global investors.

Regarding the result of the financial crisis, SCB learned of its weaknesses from the financial crisis as follows: one large customer group, low quality in risk management, wrong investment in non-core bank businesses, unpopular SCB brand, conservative bank, and employee management based on line management only.

SCB's lessons learned from the financial crisis leads to the decision of the top management level to change its corporate strategy by focusing on restructuring all business organizations in 1999. In the following sections, this study analyzes the result of in-depth interviews and SCB's annual reports during 1997-2010.

6.1 The Economic Recession in 1997-1999

All Thai business industries had been affected by the Thai economic recession. Many companies closed their businesses which caused significant unemployment level in the urban areas. All Thai commercial banks had serious problems caused by an increase in NPL volumes. In 1998, SCB had a lot of financial problems. In order to sustain its business, the Bank decided to propose early retirement programs by offering pension plan depended on the calculation based on length of service and the amount of last month pay received. As a consequence of SCB's financial problems, most of the top management team members resigned from SCB also. The then mismanagement of business led to increased NPL, and some lost business areas. Therefore, the Bank closed some branches, and tried to stop its NPL. In addition, SCB made a mistake in investing in non-core banking business. Thus, the Bank emphasized cash expansion to sell all non-core banking businesses. In 1999, it succeeded to increase its new capital by participating in the Government's Tier 1 Capital Support Program. As a result, the Bank had a strong capital base, and it was the first bank to meet 100 percent mandatory provisioning requirement. In the second half of 1999, SCB started to develop its business for business expansion plan in 2000. Meanwhile, all SCB's competitors stopped expanding their business, and stopped their services in some business areas because they had several problems, and their capital did not support the 100 percent of the loan-loss provision.

In brief, during this period, SCB's strategies had emphasized cost reduction strategies and developed a strong capital base by implementing several strategies, namely 1) early retirement program (lay-off strategy), 2) changes taking place at the top management level, 3) closing low profit branches or loss-making branches, 4) selling non-core businesses, 5) decreasing cost operations, and 6) controlling and managing NPL.

6.2 The Economic Renewal in 2000-2002

The result of Thai economy grew 4.5 percent in 1999. In the economic renewal, SCB emphasized its organizational restructuring based on building the strength of its business. In 2000, SCB continued to rapidly expand its business because it expected the Thai economy to boom again. In 2001, in order to ensure the successful implementation of organizational restructuring, SCB established a new unit under the name "Change Program Project" to manage and control the implementation of the organizational restructuring only. Based on new SCB's business strategy, in order to implement new concept of banking service, the Bank tried to change its culture from "customer walk-in" to access banking services to the Bank's employees approaching customers. As a result, in 2000, the Bank started to sustain its business by showing its net profit, and in years later, the Bank was able to achieve its business expansion, as shown in Appendix Table 1.

One of the branch managers working in Bangkok's Vicinity area who agreed with SCB's organizational restructuring strategies explained that

"Organizational restructuring is the best strategy. SCB can adapt itself in the present situation by restructuring organization and reprocessing work. The results of restructuring enable SCB success in running business in the crisis time, economic change and the future. Furthermore, the Bank can transform business threats into business opportunities. Consequently, SCB has many banking products to support customer requirement and increase customers' volumes. In addition, rewards from other financial institute given to the Bank can guarantee success in its business performance."

While, all SCB's competitors still stopped expanding their businesses. In addition, in order to develop and create new banking products and services, SCB created a new appearance by creating SCB brand together with redesigning physical branches based on the purple color. In 2002, to continually expand new retail group and volumes of loans, increase SCB's loan-loss coverage ratio, and control its NPL volumes, the Bank chose to reserve to fully accommodate any potential deterioration of Problem Classified Loans by setting aside a huge provision for loan-loss of about 24.8 billion baht. Therefore, the Bank reported a net loss of 12.5 billion baht but it succeeded to expand its loans in the short-term and long-term.

In the economic renewal period, SCB continued to build the strength of its business by implementing organizational restructuring, namely, 1) developing new culture (change culture), 2) re-building SCB brand and

branch redesign, 3) focusing on the retail group, 4) expanding retail distribution, and 5) controlling NPL volumes, cost and budget.

6.3 The Economic Growth in 2003-2006

During 2003-2006, the Thai economy continued to grow by an average of about 5.7 percent. All SCB's competitors began to expand their businesses which led to high competition in the banking market. Thus, the Bank emphasized its business sustainability and continual organizational restructuring to achieve business recovery and business expansion. In 2003, SCB could protect its market share and prevent its competitors' business expansion. Furthermore, the Bank quickly increased its business by expanding its business channels. In 2004, it underlined its organizational restructuring by focusing on growing its business, improving the quality, developing human resource, and implementing the premier universal bank. Furthermore, SCB replaced new core bank system to support customer volumes more than 10 million accounts. In 2005, the Bank started to change its branch services to the premier universal bank concept by setting its business performance standards with respect to service quality and employee performance as World Class Standard, Customer Engagement (CE), and Customer Satisfaction Score (CSS). Moreover, in 2005, SCB started to pay a dividend to shareholders, and in 2006, the Bank held the second highest market capitalization among the Thai Financial Institutions, and the third biggest banks in Thailand.

According to the result of the strong SCB's capital, the Bank decided to invest its money in Asian markets such as in Cambodia by using owner strategy in 2002-2003, in Vietnam by using joint venture strategy and providing banking knowhow in 2004, and in the People's Republic of China by using alliance strategy in 2005

In the economic growth period, SCB succeeded its organizational restructuring by aiming several business strategies, namely, 1) restructuring its organization, 2) changing branch banking concept, 3) recognizing the premier universal banking, 4) expanding business to SME sector and large industry, 5) continuing the launch of new banking products, 6) increasing customer loans, 7) recruiting employees, 8) replacing and implementing new core bank system with new business process, 9) expanding investment and service in other region, and 10) developing human resource.

6.4 The Economic Decline in 2007-2010

During 2007-2010, Thai economy continued to decline due to the Thai political instability, and the global economic uncertainty. Especially, in 2009, Thai economy grew -2.3 percent. During this period, the Bank's competitors quickly expanded their businesses because they believed that the Thai economy will rebound soon and some of them already lost their market share to SCB, as shown in Appendix Table 2.

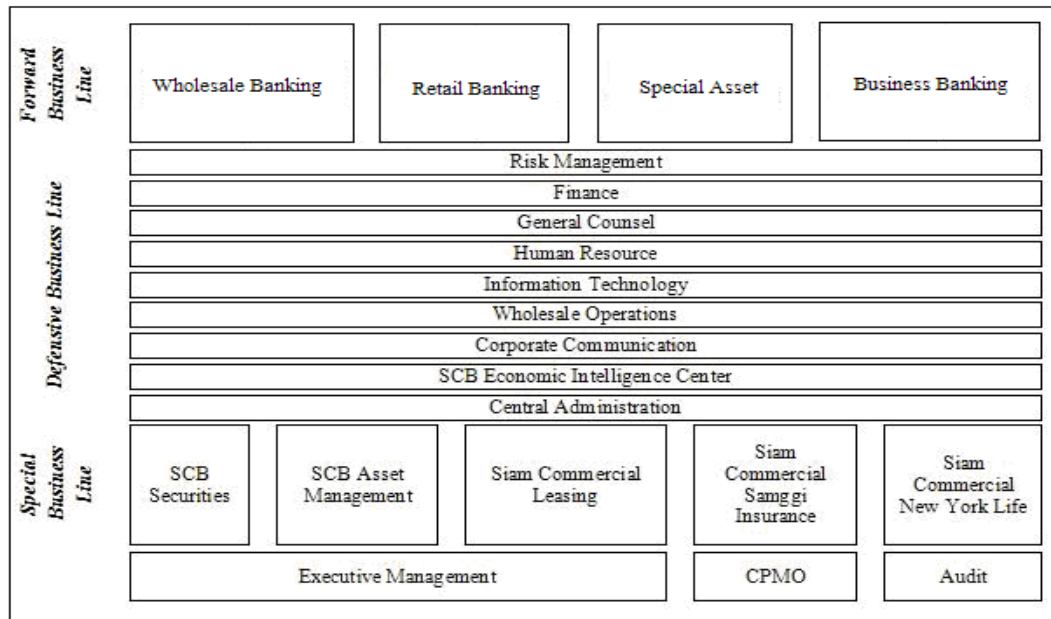

In order to sustain SCB's business during the Thai economic decline period, the Bank has been continuously restructuring its organization based on its strategies of the business expansion and customer retention. There were seven business activities, namely, 1) maintaining the customer loyalty, 2) increasing services and banking products quality, 3) expanding new market and new customer groups, 4) maintaining employees and delaying recruitment, 5) controlling costs and budgets, 6) maintaining SCB brand, and 7) implementing shared service strategy.

In 2007, the Bank succeeded in gaining market share in the SMEs sector and hire-purchase businesses. In 2008, the Bank stressed its business by adjusting risk level related to business situation. It showed its net profit at baht 21.4 billion a 23.4 percent increase. It was the highest in SCB's history. In 2009, the Bank assigned cost reduction strategies for HO offices and business expansion strategies for all branches. For business expansion strategy, the Bank aimed to maintain its customer base, and expand market share in the blue chip, public sector segments, and mortgage. The Bank showed its net profits at baht 20.8 billion, and in 2010, the Thai banking market continued its fierce competition. The Bank started to offer customer benefits in terms of special interest rates, credit line expansion, and long-term loan agreement. Therefore, SCB showed its net profits in 2010 at baht 24.2 billion. During 2007-2010, SCB achieved the highest market capitalization among Thai Financial Institutions.

Furthermore, SCB developed its structure related to its business in the Thai economic uncertainty and high market competition. The Bank started to redesign its organization in 2001 by changing from divisional structure to conglomerate structure. In 2010, according to the Thai economy uncertainty, the Bank redesigned its organization again by proposing three main structures, namely, the first component is a forward business line which covers four business groups, and creates aggressive business strategy and increase business efficiency by expanding customers' base, new bank products and market share, and building customer relationship. The second component is a special

business line which covers five subsidiary companies. Their business products and services are different SCB's business and outside BOT's justification. The five subsidiaries have provided products and services as leasing, assurance, insurance, investment, and stock exchange, and the third component is a defensive business line which covers nine business groups. The defensive business line has provided the Bank's IT, legal, financial system, infrastructure, risk management and control system, internal audit, HR, and communication for SCB and SCB group subsidiaries business based on shared service strategy.

Figure 1: SCB's Organizational Structure

Overall SCB's business sustainability is achieved. The Bank is able to operate its business in the economic uncertainty by implementing continuously its organizational restructuring with various business strategies in order to increase its business efficiency and organizational efficiency, even though, the Bank had some employees' problems.

7. The role of HRM in SCB's business sustainability

The achievement of SCB's business sustainability is reflected in the Bank's ability to generate the business efficiency, and organizational efficiency and effectiveness. These outcomes also had rapidly changed and affected employees' job responsibilities, behavior, culture, and livelihood led to employees panic, internal conflicts, employee resistance, and employee dissatisfaction. Furthermore, in order to support SCB's business strategy, the Bank continued to recruit many employees from all regions of Thailand and specialists from other banks and financial institutions. They have lived in different types of society, culture, and economy in their local communities.

Therefore, SCB's top management levels chose the role of HRM for its employees' motivation to appreciate SCB's corporate culture changed. Consequently, SCB's HRM has played a difficult role into integrating different cultures and attitudes between two generations of employees. The difference in the generations caused internal conflict and job stress in organization. The old generation employees like to maintain their old way of brotherhood and non-confrontation society, but the new generation employees like Western culture, because they believed Western culture enables the company progress. This suggests that the ethnic and cultural diversity of Thailand exist among different population and cultures in each region (Lawler & Siengthai 1997).

In order to verify SCB's HRM development in the Bank's business sustainability, this paper found that each SCB's business stage has used different HRM role related to its business strategies at that time.

7.1 The organizational restructuring stage

There was a panic among most SCB's employees who believed that the Bank was on the verge of bankruptcy. In addition to this, the Bank emphasized cost and budget reduction by offering the early retirement program. As a result, more than 1,200 employees joined this program. In addition, the Bank tried to explain to the employees about its situation by increasing the communication between the top management and all employee levels. As it was difficult to communicate to all employees in all provinces of Thailand, the top management tried to increase the cycle of communication to SCB employees. This study found that, the Bank designed HRM strategies to strengthen internal communication system, and set up conditions of the early retirement programs by screening employees who are qualified to join this program, and induced employee participation in the Bank's activities. At the same time, the Bank persuaded its specialist groups, and expert groups to remain with SCB.

7.2 The Bank's business rehabilitation stage

The Bank has entirely restructured its organization in order to rehabilitate its business with changed business plans. Some employee groups resisted this policy because it changed business processes and authorization, and corporate culture. This paper analyzed HRM role in this stage, and found that SCB's HRM strategy was formulated to emphasize internal communication to enhance all employees understanding of the Bank's targets by using both formal and informal communication channels including several media, channels, and SCB forum. Furthermore, in order to encourage employees to willingly participate in SCB's business rehabilitation, even though, the Bank could not adjust employees' salaries and other benefits, the Bank continually used HRM practices to encourage employee participation, through consultation, and brainstorming activities. Most of the Bank's employees are pleased to participate in SCB's business rehabilitation.

7.3 The Bank's business expansion stage

The Bank succeeded to retain its business with strong capitalization. As a consequence, the Bank must expand its businesses in other business areas and customer groups by increasing the number of new branches and launching new banking products. Thus, the Bank recruited a lot of new employees from universities, other companies, and other financial institutions, and motivated all employees to increase their job efficiencies. Thus, the Bank used HRM strategy to determine qualifications of candidates for recruitment, and to persuade new employees to work for SCB. Furthermore, in order to support the Bank's business in short-term and long-term plans, the Bank set human resource development plan in its organizational restructuring strategy. It approved a lot of budget in each year for its employee development by offering internal and external course training programs. The Bank emphasized HRM policy and practices for employee evaluation and employee motivation. Based on SCB's employee motivation, the Bank had encouraged its employees to create the job efficiency by offering many employee benefits. Regarding SCB's employee evaluation, the Bank set standard for employee evaluation by using key performance indicators (KPIs), World Class Standard, CE, and CSS.

7.4 The Bank's internal conflict stage

In order to motivate the Bank's employees to generate their performance, the Bank had offered individual benefits based on each individual performance. As a result, the Bank had high internal competition. The result of internal competition encouraged some employee groups to generate their benefits and the Bank's benefits. Whereas, some employee groups resisted and denied the internal competition and consequently tried to interrupt the Bank's restructuring into the process organization because they could not adjust themselves into competition, and held old culture (brotherhood culture). In addition, the internal competition was an important factor led to change in SCB culture. The Bank had realized employees' conflict; meanwhile, the Bank wanted to succeed its business sustainability. Thus, the Bank set criteria to evaluate teamwork and individual performance based on HRM practices such as KPIs, World Class Standard, CE, and CSS. The Bank had surveyed teamwork and individual performance by using outsourcing companies. Furthermore, the Bank had offered benefits and awards for the best individual and teamwork performance. As a consequence of the implementation of SCB performance standard, the employee conflict had been extremely reduced.

7.5 The Bank's business retention in the worst economic stage

In this stage, in order to sustain SCB's businesses, the Bank implemented several business strategies. This paper found that SCB aimed to use cost reduction strategy for business units at HO, and used business expansion strategy for the branches. The role of HRM was to explain to all employees at HO, branches, and the Bank's subsidiaries so that they clearly understand the Bank's policies. Furthermore, the Bank used lay-off program with the severance pay based on the Labor Law of Thailand. HRM practices were to set the criteria of evaluation to measure the employee performance. In addition, HRM strategy and policy have emphasized employees' understanding and the enhancement of employees' skills and attitudes by offering training courses for employees of all business groups in order to build competitiveness and business opportunities.

7.6 The Bank's business success stage

SCB already succeeded to expand its businesses during the economic growth during 2003-2006 and retain its business during the worst economic situation by implementing organizational restructuring. The Bank continues to use the role of HRM to constantly develop employees' skills, retain employees, evaluate employee performances, and decrease employees' conflicts. Furthermore, the role of HRM arranged human resource according to business plans and economic situations. Nowadays, SCB constantly develops HRM's software application to support HRM's plans and practices based on each employee profile under the project name "SCB Space".

In brief, SCB has emphasized the role of HRM along with the Bank's implementation of the organizational restructuring. The result of success of SCB's organizational restructuring has resulted in the Bank's success in improving its human resource efficiency. Furthermore, the role of HRM was significant in improving organization's communication with the employee and reduced the employee resistance by enhancing the understanding and employee participation in the Bank's organizational restructuring.

8. Conclusion

The result of the successful bank business sustainability has been clearly due to the organizational restructuring with business expansion plan. As a result, the Bank has succeeded to retain its business in the economic recession and decline, and expanded its business in the economic renewal and growth. The Bank increased its business efficiency to improve revenue and profit growth, market share growth, market capitalization growth, customer satisfaction, and competitiveness. During 2003-2009, the Bank had continually generated its benefits, and constantly approved a dividend payment starting in 2005.

Meanwhile, the result of organizational restructuring has been successful to a large extent. The Bank has been able to increase and develop organizational efficiency and effectiveness. The human resource efficiency is evidenced in organizational commitment, employee engagement and loyalty to create strategies and plans to build upon the Banks' business efficiency in terms of revenue growth, market share expansion, and customer satisfaction. For increasing and developing human resource efficiency, the Bank has developed HRM strategies, policies and practices to develop and enhance employee efficiency. Furthermore, the Bank's organizational structure has been redesigned. It consists of three main lines of businesses, namely, forward business line, defensive business line and special business line to support the Banks' strategies and businesses in all economic situations.

The five key factors have powered to push SCB's successful organizational restructuring and corporate performance. This study finds that, first, the corporate strategy and policy had been proposed and distinctively implemented for the organizational restructuring. Second, the top management level had been involved in the organizational restructuring program. Third, the plan of the organizational restructuring was aligned to the Bank's business plan. Fourth, most employees have high organizational commitment and loyalty, and participated in the organizational restructuring. Fifth, the Bank had established a separate unit called "Change Program Management Office" to manage the organizational restructuring, and approve the organizational restructuring under "Change Program Steering Committee".

Abstract

Innovative energy research and development plays a key role in addressing global and national energy challenges. Increasingly, decision makers are recognizing that to meet the energy challenge, cooperation between government, science and industry (triple helix partners) is necessary. Today, energy research is often conducted in various collaboration forms involving helix partners. Though a partnership brings with it significant synergies and benefits, such collaboration is a complex phenomenon which is difficult to define and poses difficult policy and organizational problems as well as management challenges. In the current study, we provide an insight into successful research collaboration designs and discuss challenges associated with them. In particular, we present issues relating to organization, financing, and personnel management in energy collaborative research which are based on preliminary findings obtained through analysis of publicly accessible data and extensive personal interviews with key personnel in leading energy research organizations in Australia, Japan and USA.

Keywords: energy, research collaboration, triple helix

Introduction

Energy research plays a key role in addressing global challenges relating to sustainability, global warming and climate change, in addition to addressing national challenges relating to competitiveness, energy supply security and sustainable development (EU, 2010). Though universities have historically been the core provider of research, the landscape of university research is changing as the scale and cost of research rise rapidly (Smith, 2001). Today, energy research is no longer the exclusive domain of institutes of higher education, whose main goals include the promotion of academic education and training in addition to basic research (often done according to scientific interest). Other research providers include 1) national/regional/governmental research centers, whose main aims are the promotion of the national research agenda which normally have a strong economic rationale as their basis (for example the Commonwealth Science and Industrial Research Organization CSIRO in Australia and the National Energy Technology Laboratory NETL in the USA); 2) Private research centers, which include private/non-profit research institutes, firms or universities pursuing research according to economic and non-economic interests of their organizations (for example the Fraunhofer Institutes in Germany and Japan Coal Energy Center JCOAL in Japan); and 3) Industry, characterized by economic value driven research aimed at the creation of financial economic gains (Porath, 2010).

Unlike product research and development, energy research goals often involve achieving wider social, economic and environmental objectives (for example to encourage economic development and technology leadership, to reduce CO₂ emissions etc.) in addition to innovative research. Increasingly, societal and energy decision makers are realizing that to achieve real, sustainable energy technological breakthroughs and competitive advantage, cooperation between government, industry and science is essential. Such cooperation could also allow the reaching of new summits of economic growth through utilization of research capabilities linked to economic ventures and interests (EU, 2006). Recognizing this potential, energy research activities today are increasingly being conducted in various collaboration forms between government, science, and industry, so-called triple helix interactions (Etzkowitz & Leydesdorff, 2000), and are usually characterized by complex hybrid networks between different helix actors (Heimeriks et al., 2003).

However, collaboration is a complex phenomenon that is difficult to define. Though it serves many different purposes, it also poses difficult policy and organizational management problems (Smith, 2001). Helix research partnerships are highly challenging as they require cooperation between separate entities from different “cultural” backgrounds (i.e. governmental, scientific or industrial), with different aims and different sets of values (Porath, 2010). For example, a potential conflict point between scientific and industrial partners is the conflict between publication (academia) and confidentiality (industry), which is further complicated should the research project be both publicly and privately funded (i.e. financed through both government and industry partners) as placing the outputs of research into the public domain is one of the defining requirements of publicly funded research activities (Smith, 2001). If this is not resolved through well-defined contractual terms and management systems, it could lead to premature termination or collaboration and/or failure to reach research objectives. In addition to the challenge of facilitating sustainable and successful cooperation between partners with different purposes and goals, energy research partnerships, in particular large research projects involving multiple partners, often involve (industrial) partners who are also market competitors. Hence, firms trying to collaborate under such an atmosphere where co-opetition issues are very strong will have to lay down a strict set of cooperation rules in order to avoid conflict (Porath, 2010).

Failure to address the significant challenges (some of which are mentioned above) faced by such collaborative partnerships could ultimately lead to project failure (for example Lhuillery & Galiab, 2006; Lhuillery & Pfister, 2009). Faced with the potential for such (economically and socially) expensive failures, an urgent question for both scholars and practitioners is how energy research partnerships involving different partners can be designed, organized and managed to facilitate successful and sustainable collaborations.

Though much progress has been made in research management, even leading practitioners recognize that there remains much to learn (Kirkland, 2005). Especially in collaborative research, though there is wide consensus that collaboration offers powerful solutions to problems of scarce resources, excessive competition, quality control and scale of problem (Smith, 2001), the abyss between research management and organizational character of different partners are difficult to overcome as these are cultural differences which are harder to define and therefore harder to solve, hence making management of research partnerships even more challenging. Nevertheless, the development of collaborative research, its increased usage in particular for energy research and innovation promises great rewards to those able to understand its formation and function mechanisms, and the ability to control the cooperation in order to achieve the targeted goals (Porath, 2010). This leads us to the objective of our current paper, to provide an insight into successful research collaboration designs and identifying challenges associated with them, while highlighting the importance of the institutional environment following an intensive benchmarking process of leading energy research providers in different countries¹. In particular, our present paper presents issues relating to collaboration organization, research financing and personnel management in the field of energy collaborative research which are based on preliminary findings obtained through analysis of publicly accessible data and extensive personal interviews with key personnel in leading energy research organizations in Australia, Japan and USA.

The Importance of Institutional Environment

Like firms (Lin, Peng, Yang & Sun, 2009), research providers and how they design and manage collaborations differ across institutional frameworks. Strategy scholars have increasingly highlighted the importance of institutional environments (for example Oliver, 1997; Peng & Heath, 1996) as being more than background conditions in which decision making and management processes take place. They argue that institutions directly determine the resources that an organization has access to in its struggles to formulate and implement strategy (Ingram & Silvermann, 2002). Considering that institutions differ profoundly between different economies, be it formal institutions (such as laws, rules and regulations) or informal institutions (such as cultures, norms and values) (Peng, Sun, Pinkham, & Chen, 2009), different institutional environments would have a significant influence in shaping research organizations, the direction of their research activities and the modes of research collaborations.

As a key helix player, the government shapes the institutional framework of the energy research landscape in which collaborative research activities take place. Its most fundamental role is the reduction of uncertainty for

different actors by conditioning the ruling norms of behaviors, defining the boundaries of what are legitimate and setting strategic directions (Peng et al., 2009). Today, government and its agencies have developed new expectations of publicly funded research, as research is expected to make an explicit contribution, either socially, economically or environmentally. Through policy intervention, directed funding and other incentives, it significantly influences the direction of energy research to address the nation's energy priorities by placing funding with those research providers most likely to address the relevant issues (Smith 2001), as well as creating the environment and conditions for collaborative research between different research providers. This is illustrated for example through the directed funding of energy research and collaboration projects by the German government in its Energy Concept 2010 (BMW, 2010) and its 5th Energy Research Program (BMW, 2005), and by the USA government in its Advanced Energy Initiative (Li, Jenkins-Smith, Silva, Berrens, & Herron, 2009). Though it is an important player in promoting energy research collaborations through the creation of the collaborative research environment, the government does not necessarily have an active role in the managing of the project, often playing at most a supervisory role as it has a specific interest to show that fair play and transparency regarding public funds and their allocation has been maintained (Porath, 2010). As mentioned earlier, its main interest is in promoting the research to match the nation's needs and priorities, to meet its social, economic and environmental objectives, as well as to stimulate economic growth through linking research capabilities to economic ventures and interests.

The Benchmarking Process

We obtained an insight into how leading energy research organizations strategically organize their research collaborations and the challenges they face through analysis of publicly accessible data and extensive personal interviews with key personnel in numerous global research organizations. In this way, we are able to obtain qualitative information and feedback which will be otherwise not possible through using the more familiar benchmarking process of gathering quantitative performance indicators on a range of issues (Kirkland, 2005). The importance of the institutional framework in shaping energy research and collaborations has been discussed above. In the following sections, we will first introduce different general forms of research collaboration which we have identified in our benchmarking process. Following that, we will focus on triple helix research collaboration (i.e. organizational level collaboration), in particular on issues relating to collaboration management, research financing, and personnel management in research partnerships in leading energy research organizations in Australia, Japan and USA, as well as the corresponding challenges faced by each collaboration form. Note that the aim is not to present a representative sample. Rather, our intent is to gain insights into a range of research collaboration approaches, and hence stimulate different examples of good practices.

General Forms Of Research Collaboration

Research collaboration forms differ in their level of intensity. At its most basic level, research collaboration occurs between researchers, not organizations. However, societal and energy decision makers often refer to collaboration at other levels: between departments, disciplines, organizations, sectors, or between nations, which in its structure is more akin to a partnership, an alliance or understanding than traditional inter-researcher collaboration (Smith, 2001). Through our benchmarking process, we identified the following forms of research collaboration with differing levels of intensity and strategic significance (see Figure 1).

FIG.1: Research Collaboration Forms (Level of Intensity)

Peer to peer level research collaboration is pervasive in traditional university based research and is the essential building block of research activity, often originating from professor-research assistant/student relationships (Smith, 2001), as well as between academic and/or industry researchers with similar or complementary research interests.

Increasingly, with the growing demand for interdisciplinary capabilities to solve multidisciplinary issues, team level collaboration are being encouraged and promoted as the creativity essential to new knowledge production and innovation is frequently the outcome of the collectivity – the sum is greater than the individual parts (Smith, 2001, p. 135). Hence, bringing together research expertise from appropriate areas provides a competitive edge (i.e. bringing together researchers from different departments to solve multidisciplinary challenges. The Inter-departmental Organization for Environment and Energy in the Tokyo Institute of Technology, Japan, is such an example). As such, such team collaboration is often encouraged through funding initiatives by the government and public agencies in numerous countries. An example is the directed funding of collaborative research centers in universities by the German Research Foundation (DFG, 2011).

Organizational level research collaboration (for example between scientific and industry partners) enable research partners to secure access to resources otherwise unavailable to the organizations working in isolation (Smith, 2001). Such organizational level research collaboration offer significant benefits to collaboration partners. In a time where public funding has been scaled back in numerous countries, such collaborations allow scientific partners to obtain the financial resources necessary to carry out its research activities, and engage in knowledge transfer and in providing a pool of knowledge and expertise on which the economy can draw on. For the industry partners, collaboration with scientific partners allows them access to a free flow of basic knowledge, and the academy also provides a good support basis for further work and solving applied problems. Moreover, there is reduced strategic risk as the academy is not going to compete with the firm in the market. Additionally, there is also a reduction of risk and costs faced by being involved in a research or by investing in research infrastructure (Porath, 2010).

National level collaborations are often highly strategic in nature and set the stage and provide support for other forms of collaboration and technology transfer. An example is the cooperation of Germany with other European countries in the European Research Zone, where the German government promotes national level collaborations through creating the necessary framework conditions, supporting joint measure for the establishment and extension of international research alliances, initiating new collaboration initiatives, as well as helping to solve individual collaboration problems, if and when they arise (BMBF, 2011).

Triple Helix Research Collaboration In The Energy Context

As mentioned above, in addition to innovative research, energy research goals often involve achieving wider strategic social, economic and environmental objectives. Societal and energy decision makers are realizing that to achieve such goals and address a nation’s energy challenges, cooperation between government, industry and science is essential. This is because bringing together a mix of different disciplines and cultures from these three different players can lead to a “bigger bang for the buck” and the multiplier effect from this synergy can achieve more than organizations working independently (Alcock & Woodley, 2002, p. 28). As a result, energy research collaboration increasingly involves all three helix players (i.e. public agencies and multiple industry and scientific partners), with

the government playing a key role in promoting such organizational level collaborations between industry and science. Advantages include a reduction of research costs as research is shared between multiple partners. Furthermore, it allows partners to continue with other research projects and to spread their risks (Porath, 2010). Additionally, the scope of research covered in such research collaboration will also be wider than would optimally be expected from a single research provider (Kamien & Zang, 2000). An example of such multiple partners research collaboration is the German Centre for Energy Resources in Germany. The center carries out research addressing strategic energy issues and comprises of multiple scientific and industry partners, and is funded through both public and industry partners. The collaboration allows industry competitors to cooperate in strategic research development and gain access to multidisciplinary scientific resources. Moreover, it also allows the government to achieve its social, economic and environmental objectives, while strategically addressing the nation's energy challenges.

However, despite its potential, the growing importance of collaborative research involving multiple partners from different backgrounds aggravates the problem of research management. Main problems include: 1) If firms are technologically close enough to cooperate, they are close enough to be competitors in various ways, leading to co-opetition issues, 2) partners from different backgrounds have different sets of goals and values, as well as organizational and management cultures, 3) potential conflicts relating to publication versus confidentiality and intellectual property rights (Porath, 2010).

To address the above challenges in research collaboration, leading research organizations have developed alternative forms of research partnership programs. As organizational level research collaboration is fast becoming the norm in energy research, in the following sections, we will present insights drawn from three leading energy research organizations in Australia, Japan and the USA on how they address organization, financing and personnel issues in such research partnerships, and illustrate the corresponding challenges facedⁱⁱⁱ.

Australia

Concerned that there was not enough ready uptake of research innovation by the industry, the cooperative research centers (CRCs) program was established in 1990 by the Australian government to improve the effectiveness of Australia's research and development. CRCs are devoted to strengthening collaborative links between industry, research organizations and government agencies to achieve outcomes of national, economic and social significance. CRCs aim not only to resolve national challenges. Their goals also include the transfer of knowledge between researchers and industry, and the development of industry ready graduates. As such, it is a form of research collaboration actively utilized by the Australian national science research organization.

Organization: CRCs are based on strategic collaboration between multiple partners. They aim to bridge the gap between scientists, research institution, government agencies and private industries. CRCs are accountable for their own direction, progress and outputs. Each CRC is given a seven-year life span and is reviewed regularly (one, three and five years) to ensure they are meeting their key objectives.

CRCs are like virtual organizations, with researchers dispersed throughout the country depending on the location of research partners. As such, one of the biggest challenges in collaborative projects is a lack of clarity about who does what. Research objectives which are too board and which change along the way further complicate the matter. Additionally, due to its virtual nature, researchers' loyalties often lie with their home institutes, even though they know that their funding comes from the CRC. Furthermore, with multiple stakeholders and interests in a CRC, another main challenge is the management of intellectual property (IP) issues (for example the question of who's going to own what, and who can use what).

To overcome the above challenges, a CRC is set up as a complete separate company, much like a small-medium enterprise (SME). All partners are in the company with rights to IP and technology transfer. Each CRC has a board with an independent chairman, and each company/group of companies and each research organization/group of research organizations are represented on the board. However, non-research organizations are usually the majority on the board so as to ensure industry focus in the research undertaken. Board members are required (by law) to operate in the best interests of the CRC.

Furthermore, a CRC also tries to employ some independent employees who do not have divided loyalties. These include the CEO and core management and support staff. They will be employed directly by the CRC and are

not from any participating scientific institutions or companies. Moreover, to avoid conflict of interest, the CEO reports directly to the board, and not to anyone else. 100% of the funding goes to the CRC and the CEO is responsible for distribution of funds according to delivered results. In this way, the CEO has control over the funding and hence a lot of leverage in “encouraging” partners to cooperate with each other and to deliver research objectives as planned.

To ensure research quality, an international panel of experts (the research advisory committee) carries out periodic review of research results delivered by each CRC (for example every 2-3 years). However, though the panel of experts works with the CRC board to resolve research issues, they give their report directly to the government. This external review process thus encourages the CRC virtual team members to bind together.

Additionally, as different partners have different motivations for joining the CRC, there is a need to balance the different motivations and avoid conflict of interests. Each CRC thus works hard in separating research objectives from commercial objectives, and structuring relationships according to objectives.

Financing: CRCs are unincorporated joint ventures consisting of multiple partners. Competitive funding rounds are held by the government every 12 months, with the federal government funds seen as the “glue” attracting contributions from participants - approximately one-third from government and two-thirds from participants. There is upfront industry commitment of funds and resources based on legally binding agreements. This, together with government funding, represents a significant united funding base for each CRC. On average, each CRC has an annual budget of AUD\$7 million to cover operating costs and wages for staff (Alock & Woodley, 2002), which include cash and in-kind contribution by other core participants including companies, government agencies and universities.

Personnel: Generally, a CRC employs 100-200 people. However, as mentioned above, most people are not employed directly by the CRC (except for the CEO and core management and project support assistance staff) and most of the research is carried out by partner institutes and universities sitting in different locations.

Japan

A country with a different institutional environment is Japan. As a culture relatively high in uncertainty avoidance (according to Hofstede’s cultural dimensions), Japanese triple helix partners have developed an alternative form of energy research collaboration to address the nation’s energy priorities and challenges. As a country highly dependent on imported energy resources, the government plays a key role in directing the direction of energy research and in facilitating energy collaboration between scientific institutions and the industry. Our research with a non-profit energy research organization on their research collaborations with government, scientific and industry partners reveal the following insights.

Organization: Originally established and funded through the government, the research organization is today a private non-profit organization. As the organization addresses energy issues of national strategic importance, its chairman comes from one of the biggest power station in Japan while its president comes from the ministry.

The organization is funded 100% through a membership program. Board members include (special) members, chairman and president who sit together twice a year to discuss research priorities and progress. Additionally, members also sit on the organization’s committee of trustees.

To avoid conflicts, all IP rights belong to the industry partners. The research organization often takes on an intermediary role in bringing together market competitors to collaborate on research projects. For example, it drafts research proposals together with member companies to apply for research funds from the government, and undertakes the project planning and coordination when funds have been approved. In such a way, market competitors could collaborate together with the research organization on research projects whereby it takes over the project coordination and controlling. In such a way, all IP generated through the projects will be shared peacefully between the different partners as they’ll get government funds to subsidize their research.

Financing: Financial support is obtained through a membership program. Members are divided into four categories (special, class 1, class 2 and class 3). Members from different categories pay different amount of annual membership fees. In return, they obtain different level of research support and have access to different amount of information and research results.

Personnel: Personnel consist of both full-timers and part-timers (volunteers). The organization capitalizes on its members for research personnel resources and has an active and sustaining personnel exchange program with its industry members. Only coordination staffs are employed full-time by the organization itself. Other full-timers consist of external engineers and researchers on the exchange program (usually staying with the research organization for two to three years. When one engineer/researcher leaves, he will be replaced by another from the company/institution).

Interestingly, the research organization does not have its own research facilities or equipment to run tests and experiments. Only managing personnel sit in the organization's office and it collaborates with member companies for utilization of research facilities and equipment.

USA

The USA is the largest energy consumer in the world. The Advanced Energy Initiative, unveiled in 2006, aims to reduce the country's dependence on foreign energy and to promote the use of clean-energy technology (Li et al., 2009). However, despite calls from various sources for increased commitment to energy R&D to reach the above goals (Friedman, 2007), there has been a general historical decline in federal funding (Nemet and Kammen, 2007). Together with the deregulation of electric utilities following the Public Utility Regulatory Policies Act (PURPA) of 1978 (Russo, 2001) and the Energy Policy Act of 1992 (Li et al., 2009), these developments in the institutional environment have led to different forms of research collaborations between helix partners as they restructure and strategically position themselves in the energy market. The insights obtained through our research and interview with a leading non-profit energy research provider are presented below.

Organization: The research organization has developed a mechanism for a group of interested companies (especially local small-mid size energy distribution companies) to engage in research collaboration to address common issues using a consortium approach. Such a collaborative approach allows the participating companies to leverage their investments (in terms of funds and personnel) to minimize risks and improve the potential for success. Moreover, as each company has limited resources, this approach ensures minimized administrative and transaction costs while enabling them to address their most critical needs. Furthermore, it facilitates consensus building on projects that will impact regulatory issues (Snedic, Bernstein & Fiore, 2008).

In this form of collaboration, a group of interested companies come together to form a not-for-profit corporation. The board of directors consists of one member from each participating company. Its role is to provide strategic guidance on program priorities and set long-term goals and objectives, in addition to establishing procedures and program oversight. A technical project committee, comprising of representatives from member companies who typically meet in person twice a year, works closely with the research organization to identify challenges and issues that are to be addressed in the program, as well as specific topics that will be the focus of individual research projects.

To avoid conflicts between member companies, the corporation formed attempts to retain the IP for projects they fund (typically monetized later on through licensing arrangements).

Financing: Research funding is provided by the companies in the consortium. The number of customers that each company has determines the funding level for each participating company in the partnership. Funds received by the partnership from a member are held in trust by the partnership until the member directs the partnership to allocate a specific dollar amount to a specific project. As such, a participating company has the option to fund or not fund an individual project which the partnership will undertake. Each member will invest in the projects they wish to fund. Once participating companies elect to move a project forward and the scope of work is finalized, the project participants may elect to seek additional and/or leveraged funding outside the partnership (for example from public agencies).

Personnel: The not-for-profit corporation formed in the consortium approach has no employees. It is a virtual organization. The research organization is contracted to be the administrator of the partnership. Hence, in addition to providing research capabilities, its role includes the overall program management, back-office activities (for example financial accounting and contract administration), and commercialization activities (for example manufacturer identification and selection). However, research projects decided upon by the partnership are given out

on a competitive basis. Hence, external research providers could also bid for research projects given out by the partnership (though the research organization remains the main research provider for the partnership).

Conclusion

Innovative energy research and development plays a key role in addressing global challenges relating to sustainable development and climate change, in addition to national challenges of competitiveness, energy supply security and sustainable development. Increasingly, decision makers are recognizing that to meet the energy challenge, cooperation between government, science and industry is necessary. Today, energy research is often conducted in various collaboration forms involving government, science, and industry partners. However, such collaboration is a complex phenomenon which is difficult to define. Though it serves many different purposes and brings with it significant synergies and benefits, it also poses difficult policy and organizational problems as well as research management challenges. Through an intensive benchmarking study of research collaboration forms practiced by leading energy research organizations, we seek to identify factors which contribute to sustainable and successful research collaborations involving multiple partners, highlighting the importance of the institutional environment in which collaboration takes place. In the current paper, we share insights on different research collaboration designs as practiced by three leading energy research organizations in Australia, Japan and USA and discuss the corresponding challenges faced. Bear in mind that research management is an activity which has grown rapidly over the past two decades (Kirkland, 2005). Though our benchmarking exercise provides a snapshot and overview of current collaborative practices, we expect collaborative research management practices to continue to evolve as they react to changes in institutional environments and other challenges.

Abstract

The possibility to realize sustainable production and consumption systems is coming to the fore as an important policy object and the literature is increasingly focusing on how firms are improving their environmental performance. However, changes in dynamics of production and trade in the global economy call for a Value Chain (VC) perspective in order to effectively understand the trajectories of the greening of industries. This paper contribute to the literature by expanding the knowledge on environmental upgrading and analyzing the conditions that may enable economic and environmental upgrading at the VC rather than at the firm's level. Leveraging on the Global Value Chain (GVC) and on environmental managerial literatures, the paper develops a theoretical framework to analyze environmental upgrading trajectories, namely process, product, functional and intersectoral and their implications in terms of firm's green strategies. Theoretical insights are complemented by the analysis of significant case studies in the home-furnishing industry.

Introduction

The importance of the environmental agenda for the industry has been rising exponentially at the international level in recent years. Both managers and policy makers are increasingly recognizing the business opportunities linked to the introduction of products and practices that reduce the impact on the environment. On the one hand, increasing consumers' awareness on the environmental impact of their consumption choices and their willingness to contribute to reduce the ecological footprint creates new market opportunities for companies. On the other hand, increasingly restrictive policies that punish environmentally harmful behaviors and the actions of NGOs and other environmentalism groups that raise the attention on firms' polluting behaviors, encourages firms to control the effects of their activities on the environment in order to reduce reputation risks and avoid additional costs.

Academics and practitioners are increasingly focusing on which strategies are implemented by firms to reduce their environmental impacts. However, in order to understand the trajectories of the greening of industries to focus on single firms is not enough anymore: the disintegration of production and the integration of trade that is increasingly characterizing the global economies call, instead, for a value chain perspective (Feenstra, 1998; Gereffi, 2005). Increasingly, production activities of developed countries' firms are delocalized or delegated to developing countries' suppliers. To reduce their impact on the environment, therefore, firms increasingly need to deal with activities spanning outside their boundaries. To become environmental leaders means increasingly to organize green value chains while taking advantage of the international division of labor.

Despite the literature on the management of supply chains activities to achieve environmental improvements is growing, it is still sparse and not focusing on the peculiarities of the global dimension of the current competitive arena nor on the economic gains that firms can achieve through these green strategies. This paper sets out to fill in the gaps in the literature by investigating the possibility to achieve combined economic and environmental upgrading in a globalized setting. In the first section, the paper presents the managerial studies focused on business approaches to environment and in the second the global value chain theoretical framework. In the third section, we propose an integrated theoretical framework leveraging on the literature on green strategies and on the global value chains and, in the fourth section, we apply it to the analysis of successful case studies in manufacturing industries in Italy. Conclusive remarks are then discussed.

Green strategies

Academics' and practitioners' contributions on the importance for firms to control the environmental performance of production activities have mushroomed in recent years. More and more their analyses are asserting, on the one hand, the importance for firms to consider also the activities performed by their value chain partners, on the other hand, that those activities may represent a source of innovation and competitive advantage rather than a burden. If in the past the focus was mainly on the analysis and the design of policies to boost more environmentally friendly production and consumption systems, more and more lead firms are considered as the potential actors of the change. Thanks to their market power and their capabilities, lead firms may be powerful spurs for the reduction of environmental impacts also at their suppliers, transferring environmental standards and best practices of the North to the South (Jeppesen and Hansen, 2004; van Tulder, 2009). By rethinking the production process according to the life cycle approach (LCA), reducing wastes and energy consumption along the value chain and by incorporating the environmental considerations into the design of new products, those firms are seeking not only to obey to the legislation or to protect from NGO's criticisms but also to achieve a competitive advantage.

The managerial literature is increasingly addressing the potential link between economic and environmental benefits or, more in general, benefits for the society. Contributions focusing on the Corporate Social Responsibility (CSR) have highlighted why and how multinationals are increasingly responding to their stakeholder's expectations in considering environmental and social impacts of their and their suppliers' activities. Using the corporation as the focus of the analysis, these contributions have addressed the challenges and opportunities of the integration of environmental thinking into supply-chain management, focusing mainly on stakeholders' management. The contributions of Porter and Kramer (2002, 2006) took this literature a step further by connecting environmental and social activities of firms to their core businesses and strategies. Starting from the identification of different justifications to the CSR for the companies, the authors focused on the interdependencies between the companies and the society, identifying three general categories of social issues in which economic, social and environmental benefits may co-exist. Focusing on the elements of the competitive context *à-la-Porter*, firms can "identify areas of overlap between social and economic value that will most enhance its [...] competitive advantage" (Porter and Kramer, 2002). To achieve these goals firms have to pursue a strategic approach to CSR and environmental activities, which adds to the firm's value proposition and is strictly connected to its overall strategies. Similarly, the strategic management literature has focused on different economic advantages and different strategies the firms can implement to achieve social and economic goals. Environmental management strategies are usually distinguished by the intensity of the investment to reduce the impact on the environment and the attitude toward external stakeholders' pressure. Buysse and Verbeke (2003), for example, through an empirical examination of Belgian firms, empirically identify three dominant strategies, which closely resemble those predicted by theoretical contributions in the environmental resource based view literature, namely *reactive*, *pollution prevention* and *environmental leadership*. The latter strategy is that in which environmental concerns are the most pervasive in the firm's strategy, and in which other stakeholders than regulation are considered important for strategy setting. Similar classifications of firm's environmental strategic stance have been elaborated based on how deeply environmental issues are integrated within the firm's overall strategy and how many decision areas they affect (Lee and Rhee, 2007). Lee and Rhee (2007) expand the previous classifications by explicitly considering the consideration of the activities of the value chain partners in the strategy setting process. Other than the *reactive* and *proactive* strategies, they identified also the *focused* and the *opportunistic* categories, identifying firms that focus, respectively, on environmental activities inside or outside the company, i.e., engaging in supply chain management activities.

If the majority of the contributions on environmental strategies simply describe firms' attitude and actions without considering the economic motivations of their activities, Orsato's contributions focused specifically on the competitive advantage sought by firms through environmental improvements. Based on Porter's competitive advantage models, Orsato (2006) proposed four general types of competitive environmental strategies, depending on the firm's competitive focus and its competitive advantage. When the focus is on organizational processes and the company competes offering the lower costs *eco-efficiency* is a strategy that ensures economic gains while reducing the impact on the environment, reducing waste and the use of resources and of energy along the value chain. When

the competitive advantage the companies seeks is differentiation, *beyond compliance leadership* will rather be a better bet, enabling them to leverage on the final markets thanks to eco-labeling or marketing instruments that make consumers aware about its efforts. The third strategy identified by Orsato is *eco-branding*, a strategy in which the company seeks to differentiate from competitors by offering eco-friendly products and services. The premium-price the consumer may be willing to pay for those products will represent a clear economic advantage for the firms that produce products with less harmful raw materials or in a more environmentally sound manner. Finally, the *environmental cost leadership* is intended to compete on lower prices, but implying more radical modifications than the eco-efficiency strategy, by revisiting the products or services. Firms' characteristics such as size and managers' attitude, the structure of the industry and the types of markets will likely affect the choice between one strategy and the others (Orsato, 2006; Lee and Rhee, 2007; Murillo-Luna et al., 2008).

Despite the great contribution in the understanding of how firms can gain from the reduction of the environmental impacts, these contributions barely focus on the strategy implications of considering activities of value chains partners. Branching from Supply Chain Management, a new stream of literature has developed, focusing around what has been named Green, Sustainable, or Environmental supply chain management (GSCM). Empirical and theoretical contribution within this stream of literature have addressed the topic of how to integrate environmental thinking into supply-chain management, analyzing the specific strategies of lead firms in aspects, such as eco-design, waste management and green operation to improve the environmental performance of their suppliers (Srivastava, 2007; Seuring and Müller, 2008). Those contributions highlight the pivotal role of lead firms in fostering environmental improvements at suppliers. They suggest that, in order to effectively enable such changes in the supplier's activities, these firms enact knowledge transfers and technical cooperation on innovative activities that add to the reciprocal dependency, shifting from arm's length toward more complex governance structures (Geffen and Rothenberg, 2000; Meyer and Hohmann, 2000; Goldbach, 2003; Simpson and Power, 2005; Simpson et al., 2007). Despite the intentions, those studies focus just on first-tier relations rather than taking the whole value chain as the main objects (Seuring, 2004; Seuring and Müller, 2008). Furthermore, those contributions very often miss to consider the economic side of these environmental improvements, lacking in particular in the analysis of the overall firms' strategy rather than single aspects (e.g., eco-design, supplier management,...), which is rather a strength of the managerial literature. Conversely, the managerial literature lacks in the analysis of value chains strategies, despite external stakeholders, including customers and suppliers other than regulation, are pointed to in many contributions as key players in spurring environmental strategies (Buysse and Verbeke, 2003; Chan, 2010). On top of that, both literatures miss in capturing the specificities of the geography of production: a thorough analysis of environmental dynamics within value chains cannot abstract from considering the globalization of the production and consumption systems. Globalization poses specific challenges to firms that aim to reduce the impact of their products on the environment, adding to the complexity of coordination because of higher distances and because of differences in the business habits and environmental legislation, especially when it comes to trade between firms from the North and the South. The more production is fragmented among actors globally dispersed, the more firms are compelled to shape their environmental strategies explicitly considering the global dimension of production, both to reduce the environmental problems linked specifically with global logistics and production and to take advantage of the economic opportunities of the international division of labor. In this paper, we suggest that the use of the Global Value Chain framework may well complement these insights from these GSCM and the managerial literatures, filling in the existing gaps in the knowledge of environmental and economic upgrading in a context of fragmentation of production at a global level.

Competing in global value chains

The global value chain approach (GVC), which developed since the mid '90s, is emerging as a key tool in analyzing the division of labor between independent actors from developed and developing countries, focusing on the role of global players in shaping the development trajectories of such chains, their governance structure and innovative activities (Gereffi and Korzeniewicz, 1994; Gereffi, 2005; Gereffi et al., 2005). The GVC framework is primarily interested in understanding the nature and the content of inter-firm linkages that span international borders, taking

the step from the recognition of a disintegration of production, moving from a model of vertically integrated firms to the development of complex forms of coordination between independent actors globally dispersed. Value chains are analyzed along four main dimensions: i) an input-output structure, which encompasses all the activities of the value chain; ii) a geographical configuration, giving and account on where activities are located; iii) an institutional context, encompassing government and non government agencies but also rules that govern society and the economy, and iv) a governance structure (Bair, 2009).

We believe that the GVC would be a useful framework to understand the possibilities to achieve jointly economic and environmental improvements for several reasons. First of all, the GVC framework enables to focus on the role of lead firms in shaping the development of value chains and governing the flows of products and knowledge. Since its earlier contributions (Gereffi and Korzeniewicz, 1994; Gereffi, 2005), this literature focused on the role of lead firms, as “key drivers in the formation of globally dispersed and organizationally fragmented production and distribution networks” (Gereffi et al., 2005). By focusing mainly on low-tech manufacturing industries, empirical contributions identified two main typologies of lead firms and therefore two forms in which global players explicitly coordinated activities of first and second tier suppliers: buyer-driven and producer-driven chains. Later contributions characterized different typologies of coordination mechanisms taking place within GVC, namely market, modular, relational, captive and hierarchy, but still underlined the pivotal role of lead firms in shaping global production networks (Gereffi et al., 2005). The rise of global and regional production networks significantly affected developing countries, with positive and negative impacts on their production and consumption patterns. Lead firms proved to be key actors of this process, by managing global value chains that represent a significant proportion of global trade and by imposing standards in their industries. By requiring developed-countries’ environmental standards to all suppliers and by transferring technology and knowledge, lead firms may decisively contribute also to the environmental improvements at their suppliers and beyond (Jeppesen and Hansen, 2004; van Tulder, 2009). If it is argued that environmental upgrading in the North is mainly driven by stakeholders and competitive pressures, in the South market and lead firms have the potential to be the main drivers of the change (Jeppesen and Hansen, 2004). The GVC literature seems an appropriate framework to understand environmental upgrading also because it has an explicit focus on activities spanning international borders yet acknowledge the importance of local and national institutions and of geographically rooted competitive advantages. As it was already argued, the fact that both the environmental impacts and the economic gains take a global dimension put specific challenges to the strategic approach of firms.

Furthermore, much of the theoretical and empirical contribution of the GVC literature have explicitly focused on the opportunities in terms of learning and market access for developing countries’ suppliers as they participate in value chains lead by developed countries’ firms, which is referred to as *upgrading* (Gereffi, 1999; Ponte and Ewert, 2009). Economic upgrading has been defined as ‘the process by which economic actors – nations, firms and workers - move from low-value to relatively high-value activities in global production networks’ (Gereffi 2005). Upgrading imply therefore going up on the value ladder, moving away from the “low road” in which competition is high and entry barriers low (Giuliani, Pietrobelli, and Rabellotti 2005) and that does not represent a sustainable strategy in the long run (Kaplinsky and Morris 2003). Four typologies of economic upgrading have been identified (Humphrey and Schmitz 2002; Barrientos, Gereffi, and Rossi 2008):

- Process upgrading, transforming inputs into outputs more efficiently;
- Product upgrading, moving into more sophisticated and advanced product lines;
- Functional upgrading, performing higher value-added activities such as marketing or logistics;
- Intersectoral or chain upgrading, moving toward different chains, more technologically advanced.

The insights developed within this stream of the literature are particularly instructing because they suggest different categories of (economic) upgrading, or downgrading, and because they link the upgrading possibilities of firms with different governance structure of the value chain implemented by lead firms (Ponte and Ewert, 2009). If by now the literature has focused mainly on economic upgrading (Gereffi, 2005), it is recently enlarging to take into account also the social dimension of upgrading, considering the impacts of the inclusion in global value chains on the entitlements of workers and the quality of employment, and inquiring into the conditions leading to a joint improvements of the competitiveness of firms and the social conditions of workers (Barrientos et al., 2010).

Green strategies, environmental and economic upgrading: an integrated framework

We aim at further the GVC analytical tool to include the environmental dimension. In this setting, we define environmental upgrading as the process by which economic actors move toward a production system that avoid or reduce environmental damage of their products, process or managerial systems.

As previously described, the literature emphasized different approaches a firm can follow to transform its business into a green one. However, given the high fragmentation of production, the point is to understand how firms may reduce the impact of all the activities performed to realize their products, including that of suppliers and sub-suppliers, therefore moving the focus from firm's level strategies to value chain levels. The firms – specifically those specializing in products for final markets – are asked to develop interactive relationships with their suppliers as well as with other key players in the value chains – from universities to other KIBS and final users' association – to create and share new environmental knowledge and jointly develop green products or processes. According to Jeppesen and Hansen (2004), lead firms can promote environmental upgrading through standard setting, monitoring and control and technical collaborations. The possibilities for a lead firm to ensure the environmental upgrading of its suppliers will depend on the balance between the lead firms' market power and the suppliers' bargaining power. But which strategies do the firms implement to reduce the impacts along the entire value chain, or in other words, which environmental upgrading trajectories can lead firms implement in their VC?

We assert that the managerial literature on environmental strategies can incorporate the framework of global value chains to improve the understanding of the consequences of the green strategies toward a higher level. More specifically, we observe interesting convergences between the GVC concept of upgrading and the theoretical framework on green strategies outlined by Orsato (2006, 2009). In both the approaches, it is highlighted that the value creation (and achievement) can be related to the strategic control of products and/or processes. While the former is focused on how those product and process upgrading can effect the repositioning of the observed player (the lead firm) into its value chain – globally considered – the latter depicts the environmental competitive advantage into the 2 by 2 matrix of Porter's basic strategies. In our view, the two approaches can be considered as complementary: by adopting one of the green strategies described by Orsato, a firm can not only redesign its competitive advantage, but also upgrading its position into the value chain it belongs to.

More specifically, the firm can improve its process by transforming it into a more sustainable one saving energy or reducing material use. Similarly, it can improve its product through new design or the use of new components and materials. In terms of functional upgrading, the firm can include into its organization a specific function that is primarily devoted to set up, manage and monitor the implementation of its environmental strategy. Such function can integrate, support or lead the activities of other specific functions such as R&D or design department, supply management or manufacturing department. Even the inter-sectoral upgrading can be lead by new green approaches, since the firm can be interested in including into its range of activities new ones related to specialization not previously covered (such as in the case of Tetrapack and its involvement in recycling processes, see Orsato, 2009). The process(es) considered can be either within the firm's organizational boundaries or – from a broader sustainable approach – shared with suppliers, retailers and/or customers. The power of the GVC framework is that it enables to capture the overall improvements in the chain, without limiting just to the changes in the focal firms activities. Adopting a GVC framework in the analysis of environmental upgrading means also considering the geographical dimension of the value chain. From this point of view, in adopting a green strategy – in terms of both products and processes – the firm has to consider how the entire value chain impacts on the environment. This means considering not only suppliers, but also retailers, customers, technology and machinery providers as well as related industries that will be involved by the production of the “green” product or by the new green process put in place.

The process upgrading - defined in the GVC literature - in environmental terms can refer to the strategies of Eco-efficiency. A firm can transform its internal processes by redesign them on the basis of new environmental standards or goals. The strategy defined as “beyond compliance leadership” can also be referred to the process-upgrading framework, but it can also induce the firm to develop new functions and play a new role in the value chain (functional upgrading). The outcome could be efficiency or differentiation i.e. a better corporate image. The product upgrading - defined in the GVC literature - in environmental terms can occur in terms of the strategic approach of Eco-branding or Environmental cost leadership. No matter the strategic focus on costs or differentiation, through one of those two strategies a firm can increase the value achieved within the value chain and reinforce its competitive

position. By considering the corporate strategy option, the environmental cost leadership can also affect the industries in which the firm competes (inter-sectoral upgrading). The two upgrading options of functional and inter-sectoral upgrading can in fact refer also to the corporate strategy options. Approaching the environmental sustainability do not only transform the business the firm competes in, but also can modify the firm's approach to its competitive arena, by opening up new opportunities of business to cope with the sustainability requirements.

Fig. 1 summarizes how environmental upgrading in value chains and firm's strategies can match according to the framework we propose. Green strategies thus can lead a firm to reach economic upgrading benefits in terms of higher position in its value chain. This result can be obtained by focusing on product or process environmental upgrading, which can also produce a functional upgrading or extend the firm's competitive domain (inter-sectoral upgrading). However, managerial studies in environmental innovation stressed that green product innovation usually requires also a transformation in business process both internally and within the value chain. Consistently with those contributions, we argue that there is not linearity from process to product upgrading, as stated in the GVC framework, when considering the "green option". Rather, as also proposed by Orsato (2009), the distinctions among the green strategies is not fix, while the two dimensions of upgrading are reinforcing each other and push the value chain to a step forward. The concept of upgrading can help the firm understanding the opportunities related to the adoption of an environmental strategy, where the definition of the competitive focus (organizational process vs. products or services) becomes the second strategic decision to make. By coupling economic and environmental upgrading a firm can increase its power within the value chain – due to its new competences, market relationships or technology control. However, in the case of environmentally-based strategy, the green innovation on products or services requires to increase the level of cooperation among the players in the value chain and, hence, the role of standards can have a crucial importance as well as the relational dimension (GVC governance).

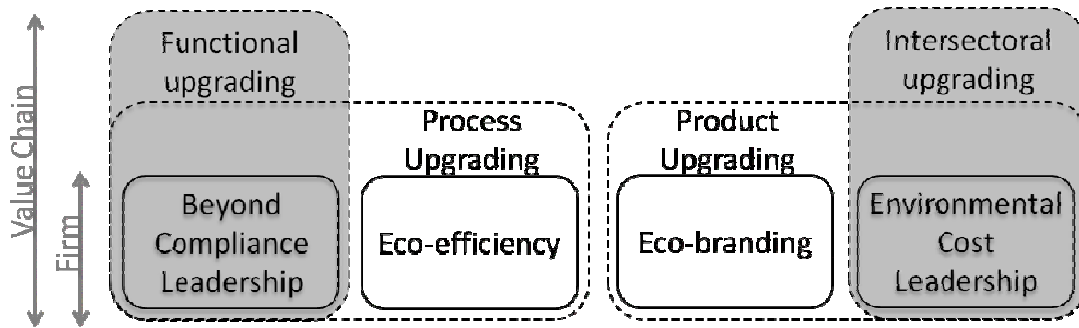

FIGURE 1: THE PROPOSED FRAMEWORK FOR ENVIRONMENTAL UPGRADING STRATEGIES.

Case studies

In the following we present four case studies, one for each environmental upgrading strategy identified above, which aim to illustrate the proposed framework and how the four strategies may interact in an empirical setting (Siggelkow, 2007). The narrative is based on interviews with entrepreneurs and managers of firms that successfully reduced their environmental impacts while achieving economic advantages. Given the purpose of developing theory on green strategies, we purposely selected firms that put the environment at the core of their business and of their communication effort. The firms have been selected by considering their investments in the green domain as a strategic asset of their strategies. All firms are specialized in the same industry, the home-furnishing and are located within the same geographical area – the Northeast of Italy.

Friulintagli: process upgrading

Friulintagli is specialized in the production of paper and veneer wrapped profiles and doors, furniture elements and flat packed furniture. Established in 1968 as an artisan furniture manufacturer, it is now a leading firm in the European market, employing 850 workers in the development and production of large quantities of low-costs products for

mass retailers. The company started to consider its environmental impact as a direct consequence of the requests of its main customer, IKEA, which was concerned in increasing environmental performance of its value chain. If at the beginning the environmental strategy of Friulintagli was “reactive”, with respect to the customer’s requests, it may now be defined as “proactive”, being at the core of its business strategy.

The company heavily invested in its production process to achieve environmental sustainability, which allowed it obtaining process certifications such as ISO14001 (eco-efficiency). Friulintagli have optimized its logistic, improved its manufacturing efficiency and lessened considerably its production wastes. Other than reducing the use of energy, it is increasing the share of energy coming from renewable sources. In order to achieve those environmental goals it heavily invested in equipment and machinery and revisited the way it manufacture its products. For example, it acquired photocell-equipped machineries that enable to reduce the energy consumption by ensuring that machinery works just when needed and substituted machineries’ engines and the existing lighting systems with more energy-efficient ones. Furthermore, it substituted the existing boilers with more efficient ones, which enables to lower emissions and recycle chips – waste from the production process. Finally, it adapted its production process to use glues and varnishes that are less toxic than traditional.

By reducing energy and materials used in the production process and improving the logistic and the waste management, Friulintagli is an example of how it is possible to both reduce the ecological footprint and improve the production efficiency, which allow the company remaining competitive with respect to firms located in lower-costs countries.

ILCAM: functional and process upgrading

ILCAM is a group based in Gorizia, in North-East Italy, with subsidiaries in Slovenia and Romania, which is specialized in the production of furniture frontals and components. In 2009, the group employed 760 people and its turnover was 99.6 MI Euros, realized mainly in foreign markets.

ILCAM started along a sustainability path because it was a specific request of its foreign buyers. Being a highly automated company whose competitive advantage is the ability to keep prices low, it introduced several process and organizational environmental innovations, by investing in more efficient machineries and by optimizing its production processes. ILCAM revisited its logistical and packaging systems, to reduce waste and the use of nonrenewable materials. Moreover, it modified its equipments to use water-borne varnishes, which are less toxic and polluting than traditional ones, and substituted PVC and traditional glues to the advantage of new materials, which ensured lower levels of formaldehyde emissions (beyond compliance leadership strategy). However, ILCAM is also a case of functional upgrading in that it performed more value-added activities to reduce its environmental impact. To comply with customer’s requests, the group decided to use FSC certified wood, i.e., wood from forests certified as responsibly managed. Since, at that time, it was difficult to supply the needed quantities of FSC certified wood on the market, the company decided to manage the forestry and sawmills steps of its value chain internally, through its own subsidiary in Easter Europe that underwent the FSC certification process.

ILCAM can be considered an example of functional upgrading, in which the firm performs new value-added activities in order to improve its environmental performance. It is interesting to notice that those activities were upstream the value chain (raw materials) rather than downstream (marketing and design), how is it most common in economic upgrading cases. The inclusion of environmental concerns in the business activities, in fact, may spur firms to be directly involved in the management of raw materials and the initial steps of its value chain.

Valcucine: product upgrading

Valcucine is a leading company specialized in high-end and design-driven kitchens and parts thereof based in Pordenone, in Italy. It is a small yet very successful enterprise: in 2009, it employed 171 persons and had a turnover of 36.4 MI Euros, almost half sold in foreign markets. Thanks to the attitude of the entrepreneurs, the tension toward the reduction of production and consumption’s impacts on the environment characterized the firm’s activities since its foundation in 1980 but grew in the years until becoming one of its core competitive advantages, strongly built in its corporate culture and brand (eco-branding strategy).

Since the company relies on external suppliers for most of the production activities, it invested mainly on the product to reduce its environmental impacts. Thanks to its design and R&D effort, Valcucine introduced several product innovations, consisting of the use of recyclable and recycled raw materials, the reduction of toxic emission due to the varnishing, the development of recyclable products and products using less energy and materials to be

produced. Furthermore, the company strives to reduce the impact of the products during their use at the final customer, by installing just highly-efficient electronic appliances and lighting systems and ensuring a longer-than-usual product's durability. Among its most interesting and break-through product innovations is the development of kitchen's doors, worktops and base units that allow a reduction up to 70% of the raw materials used, which is now used in the majority of its products. Similarly, it developed a 100% recyclable kitchen, thanks to the use of recyclable materials – glass and aluminum – and to an innovative design that facilitate disassembly.

Valcucine is a case in point of how a firm can upgrade by introducing new products, reducing the impacts on the environment while achieving economic advantages through a differentiation strategy. Thanks to the careful design and the R&D effort, the environmental upgrading takes place not only at the lead firm, but also at the suppliers, which are asked to produce products more efficiently or employing less-polluting raw materials.

Aquafil: product and inter-sectoral upgrading

Aquafil is a global Italian-based company specialized in the production of Nylon yarns and a European leader in fibers for carpeted floors. Formed by twelve companies located from North America to Asia, in 2009 Acquaafil group had a turnover of 337,887 Ml Euro. It started to develop a green strategy in the mid- 90s, driven by the requests of its main client, Interface – a US based multinational company leader in the production of carpets and products for the residential markets. The Interface's CEO Ray Anderson asked to all its strategic suppliers to take the opportunities of a sustainable strategy. Giuseppe Bonazzi, President of Aquafil decided to accept the chance and to turn its company into a green one.

Being a chemical-based company, Aquafil invested in many directions to reduce its business environmental impacts. From 2008, Aquafil published its sustainability report that summarizes all the results the group has achieved in terms of environmental benefits – lower pollution, reduced use of resources, energy production, etc – and clarify the sustainable strategy adopted. A key investment was to develop a new product line – the Econyl – a recycled polyamide, which in 2009 was awarded the “Sustainable Product” approval by UL Environment, being Aquafil the first manufacturer in the world to be allowed using this certification mark for these products. The core idea at the basis of this product is that of reducing the impact on the environment of carpets dismissed i.e. due to building renovation. This product, usually produced many years ago, is difficult to transform because of the chemical materials used in their original production. Through its R&D, Aquafil was able to develop a new recycling process that allow the company obtaining safe new inputs for new polyamide, also with limited impacts in terms of water use, waste, CO2 emissions and energy saving. According to the sustainability report, “Econyl 70 contains 70% post-industrial recycled material and 30% virgin raw material and makes Aquafil market leader for recycled products.” (p. 22). Many Aquafil's customers – Interface among them – shared this sustainable vision and developed entirely new carpet lines based on this new recycled material. Among the many green projects promoted, Aquafil invested also in energy production and management through a cogeneration plant (in 2006) that allow the company managing energy more efficiently.

Such case study can be considered a successful example of product upgrading in terms of environmental cost leadership, where the company develops a completely new product pushed by a new environmental-friendly approach. At the same time, it can also be explained as a case of inter-sectoral upgrading. The development of such new product asks Aquafil to enter into a new sector – the recycling industry – since the company had to design the reverse supply chain for used carpets as well as invest in new technologies and processes for recycling.

Conclusions

In this paper, we proposed an integrated framework to understand how firms may achieve jointly economic and environmental improvements managing their value chain. Differently from the previous literature, which studies strategy from the firm's point of view, we focused on the entire value chain, to understand the trajectories of greening in the context of “disintegration of production and the integration of trade” (Feenstra, 1998) that characterize the global economy. In particular, leveraging on the managerial literature on environmental strategies and on the GVC, we identify four environmental upgrading trajectories for a value chain that may correspond to four firms' green strategies, supporting the evidence with case study analysis. Future research should improve this study by investigating the impact of the geographical dimension of the value chain on green strategic options of firms and

related environmental upgrading trajectories. Furthermore, in depth-studies and quantitative research may improve this study, exploratory in nature, by better characterizing each of these upgrading trajectories and by assessing their recurrence in developed and developing countries and identifying under which conditions we may expect one strategy or the other to arise.

On Affective Rationality in Assessing Alternative Energy Options: Evidence from Germany

Roh Pin Lee, roh-pin.lee@der.tu-freiberg.de

Michael Nippa, nippa@bwl.tu-freiberg.de

Technische Universität Bergakademie Freiberg, Germany

Abstract

Debates about energy are often loaded with emotions, which pose a significant challenge to societal and energy decision-makers as they have to consider affective decision-making in the energy context. Drawing on studies on affective rationality, we develop and empirically test a model of how affects toward energy sources influence energy judgments. Findings highlight the importance of the contextual environment in affective evaluation. While positive affects toward renewable and negative affects toward fossil energies were predictable, mixed results toward nuclear energy were not. The study utilizes the concept of affective rationality to better understand affect-loaded decision-behaviors in the energy context.

Keywords: affective rationality, energy, decision-making

Introduction

Continued global population growth, rapid industrialization and modernization, in particular in the BRIC economies, together with globally increased standards of living (e.g. housing, mobility, and computerization) will continue to drive the demand for energy-related services and amenities around the world. Sources to satisfy this immense energy hunger are limited mainly to fossil energy sources, nuclear power, and renewables, with fossil fuels currently dominating the world's energy supply mix (EIA, 2008). However, since the Club of Rome raised considerable public attention with its report "Limit to Growth" (Meadows et al., 1972), modeling the consequences of a rapidly growing world population and finite resource supplies, there is increasing global awareness about the scarcity and finiteness of fossil energy sources. Today, this concern has broadened to the carbon impacts from fossil sources and their role in global warming and climate change (e.g. Dincer, 2000; IAC, 2007), in addition to issues of concern regarding nuclear energy such as plant safety (e.g. Chernobyl), radioactive waste disposal, and potential of military or terror threats (EIA, 2010). Such concerns have led to numerous fierce and frequently highly emotional debates in both national and international arenas about what should or could be the right answers to the energy challenges of competitiveness, energy supply security and sustainable development.

Such affect-loaded energy debates have two major implications for scholars, societal and energy decision-makers. First, in the controversial field of energy policy and management, there is a need to more thoroughly understand "affective rationality" (Slovic et al., 2007). Scholars in numerous fields (e.g. Damasio, 1994; Finucane, Alhakami, Slovic & Johnson, 2000; Kahneman, 2003; Loewenstein, Weber, Hsee & Welch, 2001; Thaler & Sunstein, 2008) are increasingly highlighting the explanatory power of affective rationality, which emphasizes the interplay of affect with rational reasoning in influencing and guiding judgments and decision-behaviors. Second, management and policy decision-makers can neither ignore public opinion nor -consequently- affective decision-making. Public opinions are critical components in the socio-political and economic-ecological contexts in which energy decisions take place (Leiserowitz, 2006). A failure to understand and address public energy concerns and their acceptance of corresponding energy innovations can have dire consequences, as illustrated by the anti-coal movements in the USA (Sheppard, 2009) and Australia (Williamson, 2009), and more recently by the large scale protests against nuclear energy and transport (Slackman, 2010) in Germany. Therefore, in order to avoid misunderstandings and escalations, gaining insight into people affects toward different energy sources and potential moderators of their affects are essential.

Though numerous studies have investigated citizens' knowledge, attitude and perception of energy, such studies have either been too general to enable an insight into how affect influences people's judgment and decision-

making, or they have focused mainly on affect towards nuclear power. To fill the aforementioned gaps, the objectives of our study are the investigation of affective responses toward a full range of energy sources, and investigating the impact of important moderators on affect. By addressing these research objectives this paper contributes to insights into affective rationality in the controversial fields of energy policy and management. By putting affects of public citizens in the spotlight, the present study thus contribute to efforts by societal and energy decision makers to develop sustainable energy policies and energy investment decisions which will be supported by the majority of their stakeholders, facilitate better strategic planning and budgeting efforts as well as more efficient channeling and investment of funds in energy research and development, in addition to the development of better targeted programs to change stakeholders' opinions by communicating convincing arguments.

Literature Review

The field of judgment and decision making has long neglected the influence of “hot processes” i.e. the experiential system on decision behavior in favor of a focus on “cold”, deliberative, and reason-based decision making i.e. the analytic system (Shafir, Simonson & Tversky, 1993). One reason is partly because “hot processes” are viewed primarily as biased and leading to irrational choice behavior (Peters, Västfjäll, Gärling & Slovic, 2006). However, decision scholars are increasingly emphasizing the importance of affect in guiding judgments and decision-behaviors and frequently speak of “affective rationality” (Slovic et al., 2007). Though analysis is certainly important in some decision-making circumstances, reliance on the experiential system i.e. affect is a quicker, easier and more efficient way to navigate in a complex, uncertain and sometimes dangerous world (Slovic et al., 2004). Slovic and colleagues (2007) propose the “the affect heuristic”, arguing that especially when the required judgment or decision is complex or mental resources are limited, affect may serve as a cue for many important judgments. In their “risk-as-feeling” hypothesis, Lowenstein and his colleagues (2001) show that when emotional reactions to risky situations diverge from cognitive assessments, emotional reactions often drive behavior. Scholars in numerous fields (e.g. Damasio, 1994; Kahneman, 2003; Thaler & Sunstein, 2008) now recognize that the experiential mode of thinking and the analytic mode of thinking are continually active and interact in “*a dance of affect and reason*” (Slovic, Finucane, Peters & MacGregor, 2004, pp.314).

Additionally, researchers have observed important moderators of affect, especially in the field of risk perception. One such significant moderator of affect is gender, where evidence from numerous studies on people's risk perception shows that women express far greater concern than men with regard to a large number of health and environmental hazards (Davidson & Freudenburg, 1996). Additionally, scholars also observe that the knowledge which a person gains through his/her participation in certain activities, e.g. research field, appears to moderate perceptions to energy technologies and associated hazards (Barke, Jenkins-Smith & Slovic, 1997). However, research on moderators of affective responses in the energy context has mainly focused on nuclear power and environmental risks (e.g. Davidson & Freudenburg, 1996; Barke et al., 1997). To the best of our knowledge, potential important moderators on affective responses to multiple energy sources have not been empirically tested.

Aware of the crucial role of the general public and their influence on energy debates and decisions, large scale surveys on citizens' attitudes and perceptions of energy-related issues have been carry out in numerous countries such as in the European Union, USA and Australia (EU Commission, 2007; Jenkins-Smith & Herron, 2007; Ashworth et al., 2009). However, these surveys were too general and provided limited insight into public's affective responses toward different energy sources. Furthermore, the influence of potential moderations such as gender and knowledge on perceptions and attitudes toward energy sources was not investigated in the above mentioned studies. Our present study thus addresses the aforementioned gaps by focusing on two specific research questions, namely, investigation of 1) affective responses towards alternative energy sources and 2) factors which potentially influence affective responses towards different energy sources.

Research Model and Hypotheses Development

Evidence from accumulated studies on affective decision-making suggests that affect plays an essential role in influencing judgments and decision behaviors (e.g. Alhakami&Slovic, 1994; Finucane et al., 2000; Loewenstein et al., 2001). The key role of affect in influencing judgments and decision outcomes have been illustrated in studies on decision-making under risk and uncertainty, where public perception and judgment of an energy source have been shown not to be holistic i.e. they differentiate between risks and benefits associated with an energy source/technology. To further complicate matters, energy risks and benefits are multidimensional constructs encompassing social, economic and environmental aspects (e.g. Fischhoff et al., 1984; IAC, 2007). Hence, people's judgment of the risks and benefits of an energy source is expected to be influenced by their affect toward that particular energy source. Additionally, as the experiential mode of thinking and the analytic mode of thinking continually interact in a dance of affect and reason (Slovic et al., 2004), we expect the decision outcome (e.g. risk and benefit judgments of energy sources) to have an influence on a person's perception of a stimulus through continuous feedback.

Furthermore, institutional and cultural environments as well as a country's level of development may also have a significant influence on its citizens' perceptions and affects toward energy sources (e.g. Kasperson, Renn, Slovic, Brown, Emel, Goble, Kasperson&Ratick, 1988; Peters & Slovic, 1996), as illustrated by Germany, a prime example for developed and highly industrialized nations. Germany has shown remarkable developments in its energy mix as well as changes in public opinion. The complex mixture of industrialization, increase in living standards, environmental awareness and concern, development of energy prices, and dependence on international energy imports have led to changes in public opinion and accordingly, the political landscape in Germany. Today, there is increasing demand and push for "green" energy from both politics and society. Oil no longer plays a role in the country's energy generation and nuclear shows a slight decrease in importance. Though coal still dominates as the key energy generation source, natural gas and renewables have increased in importance (Gabriel, 2008). However, as energy issues of competitiveness, supply security and sustainable development are related to complex assessments of energy benefits and risks, there is an on-going debate in Germany among different interest groups regarding the ideal and feasible energy mix and its corresponding energy technologies.

The example of Germany thus illustrates how the level of economic development and the institutional and cultural environments set the context for affective evaluations for different energy sources. Moreover, energy decision-behaviors are expected to be influenced by affective responses toward energy sources. In addition, as noted in the literature review, factors such as gender and knowledge could be important moderators of perceptions of energy sources and associated technologies. Thus, drawing on the aforementioned insights and evidence from previous studies, we propose the following model on how energy sources are affectively evaluated (see Figure 1).

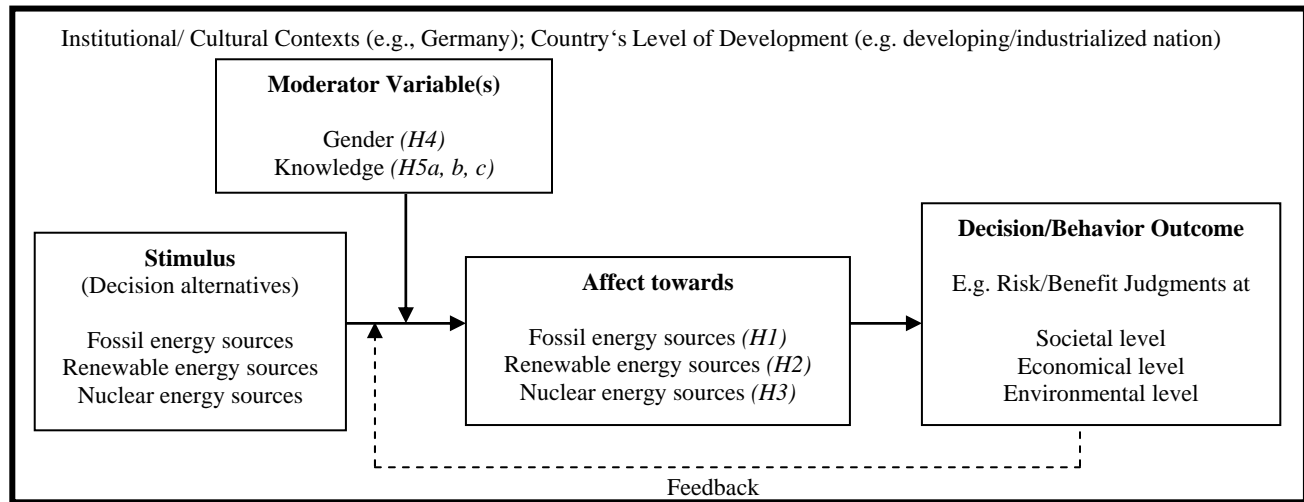

FIG. 1: CONCEPTUAL RESEARCH MODEL

Based upon our general research model, we will formulate our hypotheses in the following paragraphs.

Fossil fuels (e.g. coal, oil and natural gas) continue to dominate as the key energy sources in industrialized economies, and this trend is accelerating as energy demand rapidly increases in developing and industrializing nations (EIA, 2010). However, the continued heavy dependence on fossil energy sources is fiercely debated. Among the reasons are the scarcity of resources, increasing prices due to increasing global demand and supply instability and shortages, exploitation of deposits in areas threatening ecological heritages and environmental concerns such as greenhouse gases emissions (e.g. Dincer, 2000, Keating, 2001). Like many countries, fossil energy sources dominate Germany's energy mix. Ecological risks and harms associated with fossil fuels have received widespread attention in Germany and the general population have been fiercely against developing fossil deposits and associated energy technologies (e.g. carbon capture and storage technologies). Intensive media coverage of such struggles has highlighted the potential risks associated with such energy sources. As such, for an industrialized nation and post-materialistic society such as Germany, we postulate that peoples' affects toward fossil-based energy sources would be predominantly negative. This leads us to our first hypothesis:

Hypothesis 1: Affects toward fossil-based energy sources (coal, oil and natural gas) will be negative.

Renewable energy sources (e.g. wind, solar and biomass) are generally regarded to have no or only little adverse impact on the environment (Hansla, Gamble, Juliusson&Gärling, 2008). However, this may not be always true. For example in the case of wind energy, large scale wind farms will have an impact on the community through noise pollution and changes to the natural landscape. Moreover, renewables such as wind and solar power are intermittent technologies that can be used only when resources are available. Furthermore, energy from biomass has been rather controversial as a result of the food versus fuel debate. Nevertheless, despite potential negative impacts, renewable energies are generally considered as "green", replaceable and environmentally friendly (Hansla et al., 2008). Similar to the global trend, the share of renewables in Germany's energy mix has been increasing since the early 1990s, and renewable energies are projected to be the cornerstone of the country's future energy supply (BMW, 2010). The German public and the mass media tend to view renewables positively. As such, we propose that affects toward renewable energy sources will be positive:

Hypothesis 2: Affects toward renewable-based energy sources (wind, solar and biomass) will be positive.

Around the world, energy generation from nuclear power is attracting renewed interest as countries look to increase the diversity of their energy supplies and provide a low-carbon alternative to fossil fuels (EIA, 2010). However, there is considerable uncertainty and controversy surrounding nuclear power due to issues of concern such as plant safety (e.g. Chernobyl), long-term radioactive waste disposal and terrorism (EIA, 2010). Such issues

continue to raise public concern worldwide and contribute to the negative image of nuclear power in the public's mind. Similarly, in Germany, despite the apparent benefits of nuclear power (e.g. low electricity production cost, reliable and relatively clean source of energy), nuclear energy tend to be viewed negatively by the general public. Large-scale protests have been staged against nuclear energy in the country with widespread coverage by the mass media. As such, we would expect negative affective responses toward nuclear energy:

Hypothesis 3: Affects toward nuclear energy will be negative.

In the following section, we will focus on potential moderators of affects toward energy sources.

Evidence from accumulated research findings show that women tend to exhibit higher levels of concern toward technology and the environment than do men, especially toward nuclear and other technologies that are often seen as posing risks of contamination (e.g. Barke et al., 1997; Davidson &Freudenburg, 1996). As such, we would expect gender to significantly moderate people's affect towards different energy sources:

Hypothesis 4: Women differ from men in their affects toward different energy sources

Besides gender, researchers observe that the knowledge which a person gains through his/her participation in certain activities e.g. field of research also appears to moderate perceptions and affect towards energy technologies and associated hazards (Barke& Jenkins-Smith, 1993; Barke et al., 1997). This suggests that the knowledge that one has is associated with the discipline in which a person is active is. We propose that such moderating effect of discipline may already manifest itself at an earlier stage, when people engage in learning activities in their field of study in school, leading us to formulate the following hypothesis:

Hypothesis 5a: Knowledge gained through field of study will moderate affects toward energy sources.

In addition to education (i.e. field of study), experience (defined as active acquisition of knowledge e.g. through interest, work experience, participation in events and interaction with experts) and exposure (defined as passive acquisition of knowledge e.g. through familiarity by living near power plants or having family/friends working in energy sectors) to energy sources and related issues could also add to one's knowledge. Previous studies suggested that knowledge gained through experience and exposure influence people's perceptions of energy sources (e.g. Ashworth et al., 2009; Finucane et al., 2000; Zarnikau, 2003), leading us to formulate the following hypotheses:

Hypothesis 5b: Knowledge gained through experience will moderate affects toward energy sources.

Hypothesis 5c: Knowledge gained through exposure will moderate affects toward energy sources.

Method

Research approach

The underlying continuum, based on our proposed model, is the respondents' types and degrees of affect toward different energy sources. Word association technique is used to elicit images and affects toward seven energy sources. This technique minimize the researcher bias typically imposed in closed questionnaires (Leiserowitz, 2005), and studies using this technique have demonstrated a strong relationship between imaginary, affect and decision making (e.g. MacGregor et al., 2000; Slovicet al., 2007). In our study, respondents are asked to provide the first three images that come to their mind for each energy source, and to rate each image from very positive (+3) to very negative (-3) with neutral in between. To obtain an overall index for each energy source, the scores for the images generated it by each participant are then averaged in our analysis. Additionally, respondents are requested to provide demographic information relating to age, gender and knowledge. The questionnaire was back-translated between English and German to ensure consistency.

Sample

234 students from a leading German university in the field of natural resources and energy participated in the survey on their perceptions toward alternative energy sources in 2010. 95 responses were excluded from further analysis as respondents were unable to complete the word-association exercise or refused to provide information

necessary to test the study's hypotheses. Of the 139 completed questionnaires which are subjected to analysis, males constituted 52.5% of the sample and the majority of the students (72%) are from business studies.

Results

In the center of the study stood an investigation into the types of affects associated with seven energy sources i.e. coal, oil, natural gas, solar, wind, biomass and nuclear. From the 139 questionnaires analyzed, a total of 2,659 images of the seven energy sources and their corresponding affective ratings were elicited, an average of 2.7 images per respondent per energy source. Of special interest are the affects related to the elicited images.

On the whole, the mean affective ratings for the seven energy sources ranged from medium to weakly negative/positive, suggesting that respondents did not hold strong affective views toward different energy sources. Affective ratings for fossil energy sources (i.e. coal, oil and gas) tended toward the negative, providing support for hypothesis 1, with medium negative affective ratings for oil ($m=-1.29$) and coal($m=-1.03$), and weak negative affecting rating for natural gas ($m=-0.38$). Support for hypothesis 2 is provided by the positive affective ratings observed for renewables. Respondents felt most positive about solar ($m=1.19$), followed by wind ($m=0.52$) and biomass ($m=0.34$). Surprisingly, though mean affect for nuclear was negative ($m=-0.56$), which supported hypothesis 3, an almost equal distribution of positive and negative affective ratings was observed for nuclear power, suggesting that affect towards nuclear energy is not consistently negative (see Table 1).

TABLE 1: MEAN AFFECTS (S.D) TOWARD DIFFERENT ENERGY SOURCES

	Coal	Oil	Gas	Wind	Solar	Biomass	Nuclear
Affect(s.d)	-1.03(1.30)	-1.29(1.39)	-0.38(1.68)	0.52(1.40)	1.19(1.30)	0.34(1.55)	-0.56(1.53)

N=139

The second objective of the present study is an investigation of potential moderators of affect toward energy sources. Gender and knowledge are observed to be important moderators of affect and perception in previous studies. The present study utilizes the ANOVA analysis to investigate these two factors as moderators of affective responses toward the seven energy sources.

Partial support for hypothesis 4 is provided by substantial affect variation found between female and male respondents towards nuclear energy ($F = 20.12$, $p<0.01$), with women exhibiting significantly higher mean negative affect ($m_w=-1.14$) than men ($m_m=-0.46$) towards nuclear energy. However, no significant differences are found between female and male respondents in their affects toward the other energy sources (see Table 2).

TABLE 2: EFFECTS OF GENDER ON AFFECTS <MEAN (S.D)>

Gender(N)	Coal	Oil	Gas	Wind	Solar	Biomass	Nuclear
Female(66)	-1.06(1.09)	-1.19(1.36)	-0.55(1.76)	0.56(1.37)	1.13(1.24)	0.52(1.72)	-1.14(1.38)
Male(73)	-1.00(1.48)	-1.38(1.41)	-0.23(1.60)	0.49(1.45)	1.24(1.35)	0.17(1.37)	-0.46(1.48)
F-Value	0.06	0.60	1.22	0.08	0.25	1.74	20.12**

Total N=139 Significance:* $p<0.05$ ** $p<0.01$

Advancing previous studies, our study tested the influence knowledge bases i.e. field of study, experience and exposure on affective responses toward seven energy sources. Our findings provided partial support for hypothesis 5a that field of study moderates affects toward energy sources. Substantial variation in affects toward nuclear energy ($F = 3.16$, $p<0.05$) is observed, with business students exhibiting the highest negative affect towards nuclear power at -0.77 , while business engineering and engineering students exhibited significantly less negative affect of -0.40 and -0.41 toward nuclear energy. Surprisingly, those from the field of studies natural sciences and others exhibited positive affect towards nuclear energy at 0.19 and 1.22 respectively (see Table 3).

TABLE 3: EFFECTS OF FIELD OF STUDY ON AFFECTS <MEAN (S.D)>

Field of Study(N)	Coal	Oil	Gas	Wind	Solar	Biomass	Nuclear
Business (100)	-1.02 (1.34)	-1.33 (1.34)	-0.44 (1.71)	0.53 (1.41)	1.24 (1.17)	0.30 (1.60)	-0.77 (1.57)
B.Eng. (13)	-1.31 (0.75)	-1.03 (1.27)	-0.01 (1.53)	0.76 (1.49)	1.40 (1.50)	0.99 (1.12)	-0.40 (1.31)
Eng. (13)	-0.32 (1.50)	-1.29 (1.64)	0.28 (1.51)	0.08 (1.30)	0.44 (1.53)	0.28 (1.45)	-0.41 (1.07)
Nat. Sciences (7)	-1.09 (0.94)	-1.19 (1.51)	-0.86 (1.77)	0.52 (1.73)	0.93 (1.80)	-0.48 (1.79)	0.19 (1.45)
Others (6)	-1.03 (1.30)	-1.33 (2.14)	-1.08 (1.56)	0.83 (1.09)	1.89 (1.56)	0.64 (1.30)	1.22 (0.98)
F-Value	0.57	0.14	1.10	0.48	1.76	1.14	3.16*

Total N=139 Significance: *p<0.05 **p<0.01 B.Eng=Business Engineering; Nat. Sciences= Natural Sciences

Similarly, findings suggested that experience significantly influence respondents' affects toward nuclear energy. Respondents that rated themselves as having more extensive experience with energy related issues exhibited significantly less negative affects toward nuclear energy ($m_{\text{more extensive experience}} = -0.18$) as compared to the other two groups ($m_{\text{less extensive experience}} = -0.89$; $m_{\text{same experience}} = -0.80$; $F = 3.22$, $p < 0.05$), providing some support for hypothesis 5b (See Table 4). However, our analysis shows no support for hypothesis 5c, suggesting that the level of exposure has no significant impact on affect towards energy sources in general (see Table 5).

TABLE 4: EFFECTS OF EXPERIENCE ON AFFECTS <MEAN (S.D)>

Experience (N)	Coal	Oil	Gas	Wind	Solar	Biomass	Nuclear

Discussion

Our first research question attempts to determine empirically whether and how affective responses toward different energy options differ in Germany. Our findings show that affective responses toward renewables (i.e. wind, solar and biomass) tend to be positive while affective responses toward fossil energy sources (i.e. coal, oil and gas) tend to be negative. Used as a heuristic (Slovic et al., 2007), affect towards an energy source could consequently guide energy judgments and decision-behaviors. Both observations from Germany and evidence from international studies provide support for the key role of affect in influencing and guiding energy-related judgment and decision behaviors as proposed in our research model. Positive affects observed for renewables would explain the strong German public support for renewable energy sources observed in the Eurobarometer study (EU, 2007), and the willingness of energy consumers in the USA to pay a premium for electricity from renewable sources (Borchers, Duke & Parsons, 2007). Similarly, negative affects to fossil energy sources would explain the German public's resistance to fossil related technologies such as CCS technologies (Fröhlingsdorf et al., 2009), in addition to the high level of perceived risks from fossil energy sources and the resulting limited support for fossil-related energy technologies by the public in both USA and Australia (Ashworth et al., 2009; Jenkins-Smith & Herron, 2007).

Surprisingly, our results regarding nuclear energy show a rather equal distribution of negative, neutral and positive affects. This appears contra-intuitive in the public opinion sphere, especially in view of the recent anti-nuclear mass protests in Germany. However, as proposed in our conceptual model, affect could be influenced through continuous feedback by several aspects including complex risk/ benefit judgments, and by moderators such as gender and discipline in addition to contextual conditions. These could have contributed to the rather equal distribution of affects toward nuclear energy observed in our study, as well as findings from previous studies (e.g. Jenkins-Smith, 1993; Peters & Slovic, 1996) that imagery to nuclear issues are not consistently negative.

Extending previous studies, our second research question investigates potential important moderators of affect in the energy context. Our findings suggest that gender and knowledge play a significant role in moderating affect, especially towards nuclear energy. Consistent with previous studies that documented moderating effect of gender and discipline (e.g. Barke et al, 1997), our results show that women, business studies students, and those having less extensive experience with energy-related issues tend to exhibit stronger negative affects toward nuclear energy, indicating that respondents are far from homogeneous in their affective responses toward energy sources. An explanation for the observed gender difference could be that women, being generally more risk adverse (Slovic, Flynn, Mertz & Mullican, 1993), may be especially influenced by the potential risks posed by nuclear e.g. in view of devastating accidents such as Chernobyl. Our results also suggest that the moderating effect of knowledge manifests itself earlier (determined by field of study) than previously assumed. Interestingly, though experience is found to be a significant moderator of affect to nuclear energy, no differences are observed for other energy sources. This appears to contradict studies which found that intensive exposure to information about energy issues could lead to shifts in perspectives and attitudes for energy sources in general (e.g. Ashworth et al., 2009; Zarnikau, 2003).

In our study, except for nuclear, no gender and knowledge effects are found for other energy sources. This is surprising considering the potential risks/benefits associated with fossil and renewable energy sources, and suggests that there are aspects about nuclear energy that distinguish it from other energy sources. Hence, a promising avenue for future research will be the investigation of what makes nuclear energy distinct from other energy sources in people's minds, especially in economies with different contextual conditions.

In addition, interestingly and much to our surprise, exposure to energy-related issues is not found to have an impact on affect for all seven energy sources. We would expect a person living near a nuclear plant (for example) to have more motivation to actively search for intimate knowledge of associated risks/benefits by virtue of proximity and access. Yet an effect on affective responses from differing levels of exposure to energy-related issues could not be observed. One potential explanation may be that respondents failed to differentiate between experience and exposure. Alternatively the results may simply suggest that exposure, and experience to a lesser extent, does not matter. Either way, further research is needed to better understand the role of experience and exposure (as bases of knowledge) in moderating affect in the energy context.

Conclusion

Decisions about energy options and technologies are frequently influenced by affect-loaded discussions. As such, management and policy decision-makers can neither ignore public opinion nor -consequently- affective decision-making. Our findings support a model of affective evaluation that emphasizes the role of affect in energy decision-behaviors. Furthermore, it highlights the importance of the level of economic development and existing institutional and cultural contexts on respective decisions, and of specific factors such as gender and knowledge (through field of study, experience and exposure) as moderators of affective responses.

Though our study provides valuable insights into public's affective responses towards different energy sources and factors which could potentially influence such affective responses, there are some limitations which require further study, yet at the same time offer opportunities for future research.

First, as Germany is a prime example of a developed and industrialized country, our findings regarding affective responses to different energy sources would most likely apply to other Western democratic countries with similar institutional and cultural environments and level of development (e.g. USA, France, UK). Especially in economies with different level of development, institutional and cultural environments from western industrialized

nations, we expect public affective responses toward different energy options to differ significantly from post materialistic economies where environmental issues are often highly salient in both politics and society. Hence, a replication of our present study in for example China, Indonesia or India may provide valuable insights into how public perceptions and affective responses toward different energy sources differ among countries with different contextual conditions. This will contribute to a better understanding of how global citizens differ in their acceptance and support of different energy options, with implications for global sustainable development efforts.

Second, current high profile occurrences (e.g. Gulf of Mexico oil spill and nuclear protests in Germany) may have influenced survey responses to various energy sources. As we did not control for this in the present study, it would be worth repeating surveys on affective responses to different energy sources frequently or developing methods to control for possible biases.

Third, we distinguish between (active) experience and (passive) exposure to energy-related issues in our study. However, respondents may have had difficulties distinguishing between the two (complicated) concepts. In addition, it is not possible to determine whether subjective assessments of experience and exposure by respondents are comparable. Future studies could avoid these problems by providing objective questions to assess experience and exposure which are quantitatively measurable.

Furthermore, it may be possible that in assessing affect towards an energy source, what we actually measured is the dominant affect felt by the respondent toward the risks and benefits perceived (whichever is more salient) for that energy source. A deeper understanding of which dimensions of different energy sources (e.g. environmental, societal or economical) are most salient to the general public, and their corresponding influence on general affect and perception toward the energy sources would have wide-ranging implications for societal and energy decision-makers. Future studies could thus develop efforts to investigate this potential relationship.

Finally, drawing on evidence from studies in the field of ethical marketing that there are distinctive segments of ethically orientated consumers (Auger, Devinney, Louviere & Burke, 2008), and that variations in attitudes towards social and ethical issues occur across countries (Auger, Devinney & Louviere, 2007), it may be fruitful for future studies to investigate whether there are distinctive segments of “ethically orientated energy consumers” in different countries with varying contextual conditions.

Practical implications of our findings are manifold. A better understanding of public opinions about alternative energy options, and their acceptance and support for innovation in corresponding energy technologies could facilitate better strategic planning and budgeting efforts, as well as more efficient channeling and investment of funds in energy research and development. It is thus of considerable interest to societal and energy decision-makers to find out what are the public’s affective responses to different energy sources, and what are the potential moderators of their affect. Our study contributes to these efforts and to insights into affective rationality in the controversial fields of energy policy and management by empirically investigating affective responses to a full range of energy sources (fossil, renewable and nuclear) and important factors moderating such affects. Furthermore, it highlights the importance of contextual conditions (level of development, institutional and cultural environments) in the proposed energy affective evaluation model. By putting affects of public citizens in the spotlight, the present study thus contribute to efforts by societal and energy decision makers to develop sustainable energy policies and investment decisions which will be supported by the majority of their stakeholders, and to the development of better targeted programs to change stakeholders’ opinions by communicating convincing arguments.

Toward modern Logistics: comparisons between Logistics and Green Logistics

PhD. Antonio Mihi Ramírez, amih@ugr.es
PhD. Víctor Jesús García Morales, victorj@ugr.es
University of Granada (Spain)

Abstract

In the early researches on Logistics the reverse return was omitted, but development of Reverse Logistics in the company in recent years has been very significant mainly due to the possibility of gaining competitive advantage through it (Fleischmann et al., 2000; Pohlen and Farris, 1992, Rogers and Tibben-Lembke, 1999; Stock, 1992, 1998).

In this paper we analyze from the perspective of Operations Management what these two functions of the company are and the most relevant differences between Logistics and Reverse Logistics in order to better understand both functions of the organization like important source competitive advantages for the organization.

1. Logistics and Reverse Logistics

Logistics function is part of a series of primary activities that make up the value chain of a company and can therefore be a source of competitive advantage.

Concept of integrating perspective of cost management and provision of services to primary problem of transport of goods is what man has called Logistics (An and Fromm, 2005; Andel, 1995). In addition, Logistics has many meanings, one of them is which is responsible for the efficient distribution of products within a certain company at a lower cost and excellent customer service (Bienstock et al., 1998; Bowersox, 1974). Logistics thus seeks to strategically manage the procurement, movement, storage of products and inventory control, and all the associated information flow, through which the organization and distribution channel is channeled in such a way the present and future profitability of the company is maximized in terms of cost and effectiveness (Bienstock et al., 1998; Bowersox and Closs, 1996; Bowersox, 1974). Also, Logistics coordinates and determines in good form right product, right client, right place and right time (Majumder and Groenevelt, 2001; Brandeu and Chin, 1989).

In general, authors who have studied the concept of Reverse Logistics (e.g. Fleischmann et al., 2000; Rogers and Tibben-Lembke, 1999; Stock, 1992, 1998; Pohlen and Farris, 1992) usually define it without the reverse flow. Therefore, we propose a definition of Logistics in which clearly integrate both functions, so relying on the definition of Rogers and Tibben-Lembke (1999) we can define Logistics as the process of planning, development and efficient flow control materials, products and information from the place of origin to final consumption of consumer needs are satisfied, recovering residue obtained and managed in a manner that is possible reintroduction into the supply chain, giving added value or getting a proper elimination. In this definition we present the two flows within the logistics function of firms. Moreover, in the definition of Reverse Logistics we can consider 6 elements:

1. Some authors define Reverse Logistics as a task or a set of skills, but most of them do it as a process. Concept of process is much more general and it includes tasks and activities to investigate a specific goal. Indeed, Reverse Logistics uses different skills for specific activities, but it is not only a set of skills, so it is a process adapted to the objectives of Reverse Logistics (Soto, 2005).

2. Most authors agree that inputs used are waste products, used products or parts of products, previously rehabilitated, waste and no waste. These inputs identify Reverse Logistics process but we must also take account of the packaging, information, processes, inventory, raw materials and finished goods. It is a complete reverse flow of goods into the supply chain.

3. Tasks and activities that are undertaken with the inputs are very similar to those in traditional (direct) Logistics, but Reverse Logistics includes additional tasks and have greater uncertainty in the frequency with which they are carried out and the amount of product used. Among these activities, which are discussed in detail below, are (Soto, 2005): Planning, implementation and operational efficiency and cost effective flow of goods, the collection,

transport (including packaging), storage, processing, reduction, management, shipping, and product adaptation. These tasks and activities seem similar in Logistics and Reverse Logistics, but systems what are incorporated in both functions are quite different.

4. Authors state that objectives of the Reverse Logistics is the reuse, recycling, remanufacturing, shipping, reduction and recapture value of the inputs, and all these activities must be included in the definition.

5. Authors agree that Reverse Logistics process starts from the consumer, including return from the distributor, retailer and consumer.

6. The main factor to consider if the Reverse Logistics is a process or not is to know whether the goods have been returned to the point of origin.

Over time, several authors in their investigations have addressed the topic of Reverse Logistics, one of the first research is by Stock (1992) which analyzes, among other things, Logistics related to the return of products from consumer to producer, recycling, reuse of materials and components, and waste disposal operations overhaul, repair and remanufacturing. This paper begins to use and the concept of Reverse Logistics.

Another significant research is by Thierry et al. (1995, 117) they define the concept of recovered product management, which aims to "recover as much economic value (and ecological) as possible, thereby reducing the final amounts of waste." These authors defend the idea that companies should develop an effective policy for the management of recovered products, without significantly affecting its cost structure. In their paper are classified and analyzed for the first time the options available to businesses to efficiently manage the flow of products from consumer to producer, suggesting a number of factors that favor the implementation of a recovery system out-of-use.

Carter and Ellram (1998) conducted a comprehensive review of the literature on Reverse Logistics till date, analyzing the main contributions made in three distinct themes:

1. General and theoretical developments;
2. Transportation and packaging;
3. Final markets.

They point out that most of the studies analyzed are "descriptive and anecdotal," and published in trade journals, detecting the absence of theoretical developments that build a framework for research.

Stock (1998) recovers the topic of Reverse Logistics in what purports to be a White Book on this subject. Author analyzes the role of Logistics in areas such as product returns, reduced waste generation, recycling, repair and remanufacturing through developing management models that combine engineering and logistics business decision models in order to capitalize on the return flow of life products.

Dowlatshahi (2000) brings together the studies and work done on Reverse Logistics into five categories:

1. General concepts: Noteworthy among others, the research work of Giuntini and Andel (1995), Koepf (1993), Krupp (1993), Melbin (1995), Willits and Giuntinni (1994).
2. Quantitative models: highlight the work of Guide et al. (1996), Clegg et al. (1995), DiMarco et al. (1994), Krupp (1992), Shu and Flowers (1995).
3. Distribution, storage and transportation: They are the works of Handel (1995), Dawe (1995), White (1994), and Witt (1995).
4. Company profiles: Here are the works of Hefling (1995), Phelan (1996), and Russel (1993).
5. Industrial applications highlight the work of Byrne and Deeb (1993), Kroon and Vrijens (1995), Pohlen and Farris (1992), Thierry et al. (1995), Webb (1994).

Dowlatshahi (2000) detected certain deficiencies in these works, mainly with regard to the existence of a common framework on which to sustain, that is, a theory of Reverse Logistics has not be developed to give substance to the various elements that compose. Dowlatshahi (2000) goes a step further in this direction, identifying strategic and operational factors considered essential for effective development of systems for Reverse Logistics. Among the strategic factors points to the cost of these systems, the quality of recovered products, customer service, environmental and legal constraints. Among the operational factors Dowlatshahi identifies the functions of logistics systems, transportation, storage, production (remanufacturing and recycling), packaging, etc.

Along with the theoretical development of the concept of Reverse Logistics there have been few empirical studies that have allowed building a framework and analysis of the topic much more appropriate. These

case studies are characterized by the use, design and resolution of the models, different techniques of operational research.

Bloemhof-Ruwaard et al. (1995) analyzed for first time the relationships and interactions between operational research and environmental management from two perspectives:

1. The impact on supply chain and discuss how environmental issues affect the planning of production, distribution, inventory, location and overall, the set of logistics activities.
2. The environmental impact on the chain, looking at how operations research techniques can contribute to a better formulation and resolution of environmental issues. In this pioneering work, and concluded on the importance of recovery has recovered products in managing the supply chain.

Fleischmann et al. (1997) compiled a set of quantitative models designed for the analysis of the inverse function of direct logistic, grouped into three distinct categories:

1. Distribution systems.
2. Inventory management.
3. Models for production planning.

This paper refers to more than 30 quantitative models, mostly designed and resolved through operational research techniques. The authors conclude that Reverse Logistics is a young scientific field in which the contributions are still too biased. They indicate that there is a huge imbalance between the large number of empirical studies related to the reuse or recycling of products and the few, for the moment, theoretical developments that provide a comprehensive overview of this issue.

More recently, Fleischmann (2001) studies, among other things, how can describe the characteristics of Reverse Logistics systems through quantitative models and, thus, improve our decision making process.

Development of Reverse Logistics is becoming a reality. We can find development of doctoral theses (Fleischmann, 2001; Krikke, 1998; Thierry, 1997), publications in prestigious academic journals (European Journal of Operational Research, International Journal of Production Economics, Interfaces, Omega, etc.), opening new research or the creation of specific research groups on this subject (Revlog European Working Group, RELOOP, Reverse Logistics Executive Council), among others, and all of them are contributing to Reverse Logistics begin to gain importance within the academic and professional world.

In the definition of Council of Logistics Management 2003 on the logistics, and clearly shows interest on return flows (reverse), as organizations began to take special interest in being competitive in a way that would allow them to manage the delivery effective products and otherwise to once again returns in the retail channel, all this emphasis on time and resources to this industry within the concept of Logistics is already known as Reverse Logistics. During the nineties the Council of Logistics Management started publishing studies where Reverse Logistics was recognized as relevant for business and for society. In 1992 the Council of Logistics Management published the first known definition of reverse logistics (Stock, 1992, 12): "... The term commonly used to refer to the role of logistics in recycling, waste disposal and handling of hazardous materials; a broader perspective includes everything related to logistics activities carried out in reducing input, recycling, substitution and reuse of materials and their disposal. "

At the end of the nineties, Rogers and Tibben-Lembke (1999, 43) described Reverse Logistics including the purpose and processes (logistics) involved: "The process of planning, implementing and controlling efficient and cost effective flows raw materials, in-process inventory, finished goods and related information from the point of consumption to the point of origin with the purpose of recovering the primary value or dispose of them properly. "

However, the European Group on Reverse Logistics, Revlog (1998), went beyond the definition of Rogers and Tibben-Lembke (1999) using the following definition: "The process of planning, implementing and controlling the flow of raw materials, inventory in process and finished goods from point of use, manufacture or distribution to a point of recovery or proper disposal, "as we see this definition is broader because it refers not to the point of consumption and while accepting even more flows because a party does not necessarily return to the same point it left.

Yet another definition to clarify this concept is that of the Reverse Logistics Executive Council (2003), "Reverse Logistics is the process of moving goods from their typical final destination to another point, in order to

capture value that would otherwise not be available for the proper disposal of the products, which introduces the concept of value recovery of the components in the chain (one of the most important concept.)

In the literature on supply chain, the concept of Reverse Logistics has been associated with the product life cycle (Tibben-Lembke, 2002) guaranteed returns (Teng et al., 2005) operating systems (Knemeyer et al., 2002; Tibben-Lembke, 2002; Tibben-Lembke and Rogers, 2002). Also discussed the strategic advantage (, Tan et al., 2003; Stock et al., 2002), the implementation of case studies (De Koster et al., 2002; Ritchie et al., 2000) technology information (Daugherty et al., 2004), the e-recycling (Nagurney and Toyasaki, 2005), and strategies of green supply chain (Sheu et al., 2005, Simpson and Power, 2005).

As for the activities of Reverse Logistics, design quality, quantity and time of the flow of returned material is a very important part of the Reverse Logistics (Srivastava and Srivastava, 2006). On the activities of Reverse Logistics in the literature on this topic speaks of a location that facilitates processing of raw materials, access to end markets or the location of waste (Pushchak and Rocha, 1998; Appa and Giannikos, 1994; Giannikos, 1998; Brandeau and Chin, 1989; Schmenner, 1982). We can observe the flow of reverse logistics activities in Figure 1.

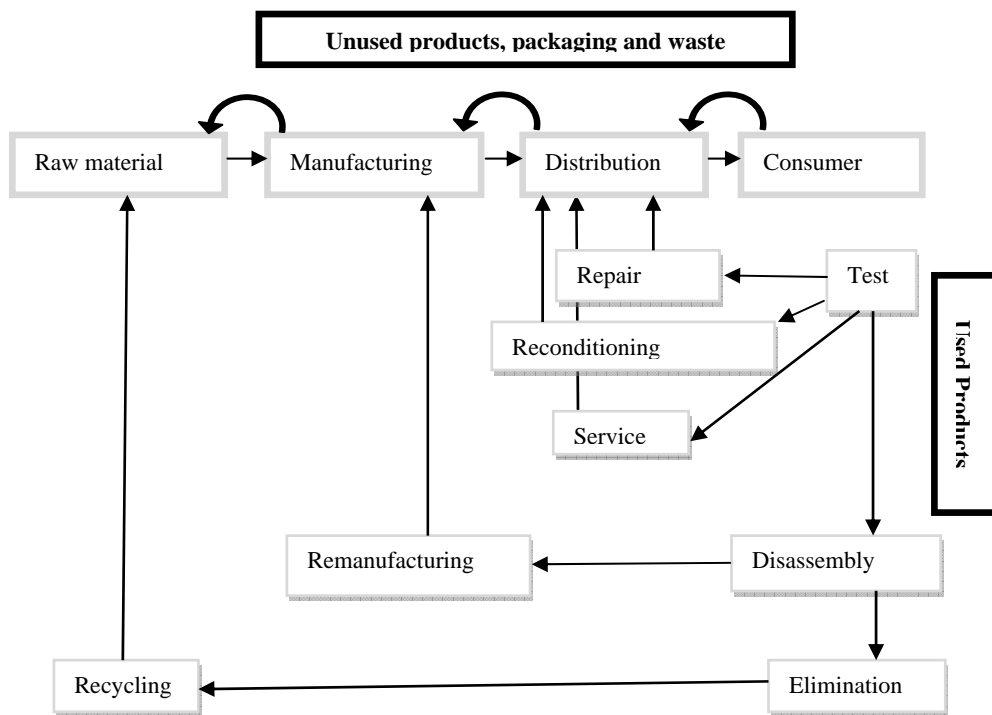

FIG 1. FLOW REVERSE LOGISTICS ACTIVITIES- (KRUMWIEDE AND SHEU, 2002; SRIVASTAVA 2008)

Thus, the recovery process would consist of the following stages (Srivastava, 2008): collection, inspection / management, preprocessing, location and distribution, determination of capacity; remanufacturing.

Collection is the first and most important stage in the recovery process, where products are located, selected, collected and, if required, transported to facilitate remanufacturing and get back to work with them (Srivastava and Srivastava, 2006) . The products used come from many different sources, Cairncross (1992) suggests based their classification as it does reach the consumer or the manager of the waste.

Inspection / management can be done at the time of collection or after (post-harvest positions or in positions to

facilitate the refactoring). The items collected need to be sorted normally. The inspection requires skills in management of used products (Ferrer and Whybark, 2000). This can be combined or not with the pre-processing.

The pre-processing ranging from how to sort, separate, partially or completely disassembled to minor repair and overhaul activities. It can be carried out at collection centers or positions to facilitate remanufacturing, depending on technological and economic factors.

Location and distribution (design of the network), is the most important area of Reverse Logistics. In many cases, recovery networks are not configured independently, but are the logistical structures.

Capacity decisions, focus on providing the right amount (how much) in the right place (eg, facility location) and at the right time (when). The capacity is determined by the size of the physical facilities are built (Schroeder, 1993). In general, decisions on the ease of location depend on the estimated returns, costs, competitive behavior and strategic and operational considerations. Strategies on the installation of new capacity are also more complex the more you increase regulation and consumer demand for recycled / reused (Srivastava and Srivastava, 2006). Bellmann and Khare (1999, 2000) developed the concept of critical mass of returns for a recycling / remanufacturing cost. They affirm that the efficiency of Reverse Logistics could be increased by ensuring that product design takes into account the requirements of a post-using/post-recollecting, a management and recycling.

Remanufacturing is the process of disassembling used items, inspecting and repairing / re-working components, and using these in the manufacture of new products (Majumder and Groenevelt, 2001). The product is considered remanufactured if its primary components come from used products (after making sure that those are functional). Consumer preferences, environmental activism, and legislative pressure are forcing companies to manufacture environment-friendly (Majumder and Groenevelt, 2001).

It looked so far, we see that Reverse Logistics and Logistics show remarkable differences, which are convenient to analyze in the next section.

2. Differences between Direct Logistics and Reverse Logistics

There are many differences between Logistics and Reverse Logistics justifying the development of different theories for each area. Several authors point to as the Reverse Logistics affects different areas of the company (Van der Laan and Salomon, 1997; Krikke, 1998; Thierry et al., 1995). We focus on operations management to present these differences. Within this, we can talk about differences in 6 areas:

1. Location and logistics network design: optimization concerns the localization of products and the ability to facilitate the flow of goods. Demand and operating costs are considered inputs in the traditional logistics model. To Reverse Logistics the demand is envisaged in distribution facilities but also includes receiving the products. Logistics in the direct flow or Direct Logistics is a launch system (pull), while the Reverse Logistics is a launch system and push (push). Traditional Logistics entire system adapts to the need to serve the customer. Reverse Logistics, the extended producer responsibility, cannot influence the amount of waste supplied to the reverse logistics system (push), and must be matched with demand (pull). Eliminating this waste can be an escape, but is limited by law (Krikke 1998). Networks in Reverse Logistics systems have a high degree of uncertainty in the supply, in terms of quantity and quality of products returned by consumers. This is critical for proper structure, since, for example, that increased product quality justifies higher costs of transport, to even make it unfeasible for the low value of the goods transported. Moreover, if it is not known but the number of products, is increasing uncertainty in the design and network planning logistics (Fleischmann et al., 1997).

2. Prediction: To estimate the magnitude, location and quality of returned products is a difficult task in Reverse Logistics. In addition, the lack of secondary market information makes more difficult to estimate the number of buyers in these markets.

3. Inventory Control: The efficient management of inventories of returned products is also important and more difficult because: a) lack of certainty on the quantity of products to receive, b) the difficulty of identifying products, for example, bar code deteriorated, c) sometimes the product is accompanied by other promotional product that really is another new product with a new code, and in return, only get the product without the promotion, inventory

with the new code of both, which creates complications in the inventory balance. Therefore, reverse logistics must be adjusted control mechanisms (Krikke 1998).

4. Remanufacturing: Includes the three subsystems of disassembly, remanufacturing and reassembly. The problem arises in the remanufacturing products are manufactured with 3 components: a) components that are derived from recovered products, of unknown quantity; b) components are always buying new; c) components that can be purchased new or obtained from returned, depending on the availability and cost.

5. Operations that are necessary to convert a returned product in a new one depend on the conditions of actual product (which returns for a new one). Companies do not know the quality of the product until you are returned and checked, and may decide to re-use after a certain number of tests, in contrast with traditional manufacturing, as there are no well-determined sequence of steps in the remanufacturing, which increases the uncertainty (Fleischmann et al., 1997).

6. Disassembly operations are a new activity that is not present in Direct Logistics. Some authors call "Manufacturing." Here we must consider several issues, if necessary this disassembly, the quality of components, the level of disassembly, damage to the product after use. To address this problem the companies working in the disassembly process design.

7. Inverse distribution: The design of a distribution network is also a problem that requires specific solutions. The new products should, for example, be easily arranged on the pallets, which allow companies to better plan the capacity of their vehicles. Returned products should correspond to a few or only one unit of product, and also often do not come well packaged, so that to establish a distribution network is more complicated. The uncertainty in the supply, in terms of quality and quantity, is more difficult in Reverse Logistics (Fleischmann et al., 1997).

In addition, Tibben-Lembke and Rogers (2002) note other differences between Direct and Reverse Logistics are analyzed in Table 1.

TABLE 1 DIFFERENCE BETWEEN LOGISTICS AND REVERSE LOGISTICS

Logistics	Reverse logistics
Forecast / relatively simple planning	More difficult to forecast
One for long transport	Many for transport
Uniform product quality	Non-uniform product quality
Clear destination/route	Unclear destination/route
Uniform product packaging	Often damaged product packaging
Standardized channel	Channel not standardized
Clear choices	Unclear provisions
Price relatively uniform	Price depends on many factors
Direct distribution costs closely monitored by the accounting systems	Less visible reverse flow costs directly
Consistent inventory management	No consistent inventory management
Manageable product lifecycle	The most complex product lifecycle
Simple negotiation between the parties	Negotiation complicated by additional considerations
Known marketing methodology	Marketing complicated by several factors
Readable information in real time for each product	The less transparent process visibility

Thus, as many authors have suggested, Reverse Logistics planning is more difficult than for Logistics because of the degree of uncertainty that presents Reverse Logistics (Flapper, 1995, Guide et al., 2000). In the remanufacturing is not only necessary to plan customer demand, which is always changing, but also planning the availability of product to be remanufactured. However, you can see some general trends. Reverse Logistics flows tend to follow the flow of Direct Logistics, with some variations (Tibben-Lembke and Rogers, 2002). For example, the huge influx of holiday sales of the new product, followed by a wave of post-holiday return product. When sales and promotions are scheduled, the marketing department is already working with Logistics to ensure that the

Logistics function can meet the demand created by marketing efforts. Like traditional Logistics, Reverse Logistics can benefit from information about these plans. When the big sales of an item is expected to be followed by large volumes of returns, can be organized to advance the relocation of this material returned. The prognosis is complicated by the fact that different products have different rates of return. Customer decisions to return a product will be influenced by factors related to product usability, clarity of instructions, buyers remorse, which can vary significantly from one product to the next from the same manufacturer (Tibben- Lembke and Rogers, 2002).

As Fleischmann et al. (1997) note, one of the biggest differences between Direct and Reverse Logistics is the number of points of origin and destination. Direct Logistics usually the product moves from one source to many destinations, the reverse movement of a product is on the contrary, from many sources to a destination. In theory, it may seem that the combination of forward and reverse transport would be savings in transport, why send a second transport to collect a returned product, once you have been sent there to deliver a new product. Not so for two reasons: first, because the independence of the Logistics and Reverse Logistics system avoids the difficulties presented when trying to create coordinated transportation schedules acceptable to both systems, so the savings is combined transport limited (Fleischmann et al., 1997). The second reason is because the physical linkage of both is difficult, so the flow of returned material requires different stops to be picked up at the different locations and stops, for example, refurbishment, while the new product also requires of several stops at various points where it is stored, so that the combined flow of both transport becomes more complex and could be longer.

The new product comes fully packed with protections for transportation, allowing easier handling of it, may also be palletized, deposited in warehouses and counted more easily. In contrast, most products in the reverse channel may not have a complete package. If the product is not sold, returned to the retailer, and can be damaged during their return to manipulate it, or the customer can open curiosity to examine it, and do not return the package correctly. Even if the packaging is correct, the shipment of the returned product is more complex than the case of a new product (Tibben-Lembke and Rogers, 2002). The new product is normally shipped in large quantities. The large number of cases that go to a particular destination allows pallets with ease. In contrast, most returns are in small packages (about 1 pallet per week). With these small volumes is more difficult to create a well-trained pallet that is easy to manipulate. The result is that most pallet arriving at the return centers consist of haphazardly stacked and damaged merchandise. The greatest damage is that if the product falls off the pallet damage to more fragile containing the pallet, and also because the product, not being packaged properly, it is easier to fall or be beaten, damage (Tibben -Lembke and Rogers, 2002). Besides being poorly packaged, its identification more difficult.

To facilitate the Reverse Logistics system, you may need to spend significant time determining where and how to send a particular article. Some merchants require the manufacturer to certain products are "demarcated", i.e., that all information on the identity of the seller of the product is removed before re-sold. The seller could also allow the sale of products demarcated certain intermediaries, and not others. By contrast, traditional Logistics rarely happens (Tibben-Lembke and Rogers, 2002).

The new product, having a uniform quality, would have a uniform price, but the reality is that the new product price is not the same for all retailers. Likewise, the seller sells the same product to different customers at different prices, depending on the type of customer, its importance, the amount of purchase, and the total amount of orders placed by the customer, among other factors. The price range for the reverse flow is even greater by the fact that not all reverse flow product is top quality. When the returns center the company has received and identified the product, determine which companies try to sell it. The company knows the prices paid intermediaries in the past, for the different conditions of the product. At present, the agent might want to pay a different price for different reasons. If the intermediary has a large volume of a particular product by hand, might not be interested in buying more. Also, the role of the life cycle, which we review below, plays an important role. Some brokers specialize in products for domestic markets, for example, others, products for least developed countries, then it is hard to tell whether or not it will appeal to a particular broker. In reverse flow, not being new products, brokers often want to inspect before bidding on them, restricting the number of intermediaries that a company may be bidding for a particular batch of articles. If the intermediary often cannot bid on the items, he will not do so in the future. The company has estimated that small group of intermediaries are those who offer higher prices for a particular item or lot of items, with specific conditions, and offer it to those (Tibben-Lembke and Rogers, 2002).

In direct channel, it is important to fill orders quickly to keep the customer satisfied. In reverse flow, the

ultimate destination is the intermediate product (from the standpoint of the retailer). However, the broker has placed orders for these products, so if the return process is slow, these "customers" will not complain. Thus, for seasonal or seasonal products, when returned, the season or the season may have already passed, so the product is worth considerably less than if it had been resold during the season, in this case there is already a significant loss of value that the broker gets a little later. For technology products, however, this loss of value if it is considerable, given the relatively short life cycle of these products (Tibben-Lembke and Rogers, 2002).

Also direct Logistics Cost is not necessarily the same than Reverse Logistics, as we have seen, and the best performance in Direct Logistics need not be the best for Reverse Logistics. Direct Logistics, costs are well defined and well understood. The accounting system is designed to handle the cost includes the development and displacement along the canal. Companies specializing in Direct Logistics are not usually very effective in managing detailed product non standardized traveling back by the company and the channel. Inventory costs can change the sorting, transporting, handling and storing these products. Table 2 shows some of the ways that reverse logistics costs may differ from Direct Logistics costs. The new product is not subject to refurbishment or re-packaged. Now the product to be resold at a cost greater than the new product. However, the increasing cost of reused product could still be less than manufacturing a new product.

TABLE 2. REVERSE LOGISTICS COSTS

Reverse logistics of costs:	Compared with the direct logistics costs is:
Transport	Greater
Inventory maintenance costs	Minor
Losses (steals)	Much less
Collection	Larger (less standardized)
Sort, diagnostic quality	Much greater
Handling	Much greater
Obsolescence	May be much higher
Reconditioning/re-packing	Significant for logistics reverse, does not exist in logistics network
Changes in the value of the product	Significant for logistics reverse, does not exist in logistics network

(Tibben - Lembke and Rogers, 2002)

In traditional Logistics the cost of ordering is an important factor that determines how often to order the product, and volume. In Reverse Logistics, the largest cost is the cost of transport. This is due in part to the fact that shipments are smaller here. For example, a store could get a lot of new product every week, but the material can be returned only two pallets at the same time.

The traditional order quantity and methods to manage it require a certain distribution and information about the uncertainty of demand, such as mean and standard deviation of demand per week. None of these scenarios is given in Reverse Logistics. In traditional inventory models, the uncertainty is in the amount of product that will be demanded and the price at which the product will be sold is assumed to be known. Reverse Logistics, the arrival of the returned product is often random, and the price is also unknown. The result is that traditional models of inventory management cannot be applied to these situations.

As Tibben-Lembke (2002) suggests, the product life cycle plays a distinct role in Reverse Logistics than Logistics. Changes in the product life cycle involve specific changes in the configuration of Reverse Logistics. This is especially when the demand drops and the product moves towards the end of the cycle of life. So, if you know that the product will be manufactured, the value on the secondary market will be low. But if it is known that a new product model will be manufactured, the value in secondary markets will be high, since interest in product is still high, and the retailer will want to offer a version of a popular product and a lower price.

In traditional Logistics, where provider and buyer negotiate a sale, negotiations are about to ship the product at a future time. In Reverse Logistics negotiation is more complicated than traditional Logistics since product quality is not uniform, and the potential buyer might want to inspect the product before placing your bid (Rogers and Tibben-Lembke, 1999). In addition, vendors may require that the product is demarcated, or could

restrict the set of intermediaries that the product could be sold. Direct Logistics, the seller can sell to any company wanting to make an order, Reverse Logistics, however, vendor will only sell to those brokers that you trust, usually based on a long history of past transactions. In addition, in determining the price, another point of negotiation is to include a manufacturer's warranty, which is rare with the new product. The product will sell a low price at the retail level, so it is sold to middlemen cheaper, while including a warranty is sold to middlemen at a higher price (Tibben-Lembke, 2000). The dealer usually does not like to buy small quantities of product from different backgrounds, but prefers to buy large quantities in a small number of items. Possessing large quantities available increases the value of the product. However, if a large quantity of a product is available, it could be because the product did not sell well in the retail channel, which will cause the secondary market value is very low.

3. Conclusions

In this paper we proposed to clarify the concepts of Logistics and Reverse Logistics, setting out the main similarities and differences between the two functions of the organization. To better understand the concept of Reverse Logistics, one must begin with the traditional logistics, which is used in the direct flow of goods from manufacturer to consumer. When analyzing the Logistics and Reverse Logistics noted that although the Reverse Logistics from traditional Logistics, both functions show remarkable differences in the processes they employ, in costs in the management and the requirements posed. Reverse Logistics includes additional tasks and have greater uncertainty in the frequency with which they are carried out and the amount of products used, is also planning more difficult, but the reverse logistics is also very necessary to deal with the new environment of high uncertainty in which businesses operate.

Ethically Constrained Optimization of Dynamic capabilities: Institutional Matrix and Strategic Organizational Renewal Towards Global Sustainability

Frederick Ahen, *Frederick.Ahen@tse.fi*
University of Turku School of Economics, Turku, Finland

Abstract

The pursuit of efficiency and profitability does not preclude the introduction of innovative, disruptive business models embedded in ethical preferences to keep abreast of new scenarios. In fact, the evolutionary dynamics of the business environment and firms' actions as adaptive systems need to be consistent with the managerial decisions to deploy resources that are specifically in tune and shaped for future challenges and opportunities. Simply put, the normative questions are back in the board room in search of strategic answers to the changing global business environmental turbulence, technological revolution and novel consumer demands backed by strong institutional arrangements. This conceptual contribution via *meta*-theoretical analysis seeks to theorize how dynamic capabilities of organizations are now reconfigured towards a new consumption pattern in response to institutional changes. The systematic analysis offers illustrative cases from the pharmaceutical industry and puts forward objective policy recommendations, managerial implications, and concludes with directions for future research.

Introduction

The pursuit of efficiency and profitability does not preclude the introduction of innovative and disruptive business models and product re-engineering embedded in ethical preferences to help organizations keep abreast of new scenarios constrained by issues of sustainability. In fact, the evolutionary dynamics of the business environment (Baum and Singh, 1994) and organizations' actions as adaptive systems (March, 2006) need to be consistent with the managerial decisions to deploy resources that are specifically in tune and shaped to meet current and future opportunities and challenges. Simply put, the normative and sustainability questions are back in the board room in search of strategic solutions to the changing global business environment backed by strong institutional arrangements. Here, global consumers' demand for corporate social and environmental responsibility, and the need for ethical response and sustainable technological revolution (Campbell, 2007) seem to constrain how firms seize opportunities, capture value, and strategize via resource configuration to meet the new demands that are skewed towards emerging markets as well as markets at the bottom of the pyramid (Prahalad, 2005; Yunus, 2010).

Following Nielsen (2003), the main premise of this paper is that organizations as social arrangements (with a shared purpose and interest) and ethics (as moral principles that are praiseworthy because they are socially desirable) are two concepts that are inextricably bound, and hence, cannot be separated. Drawing heavily on the works of Adam Smith, *Theory of Moral sentiments* (1759) and *An Inquiry Into the Wealth of Nations* (1776), all on ethics and organizations, Nielsen compellingly articulates his thesis that just as "it may not be possible to have an operational organizational theory without an at least implicit ethical or normative foundation; it is also not possible to actualize social ethics without an organizational form" (2003: 476). Implied here, however, is that different organizations may optimize different factors taking into account the spatial and temporal dimensions of the organizational life cycle. Optimization of, for example, shareholder value under certain constraints (such as environmental sustainability) that affect the broader society is simply complex but not impossible and it is based on the individual proclivities and values of the managerial owner. The gap between what is constrained and what is optimized strikingly differs under different institutional environments or societies and types of organizations over time. This poses great challenges for organizations and the societies which sustain them. For Smith business owners should pursue self-interest that does not hurt other constituents but rather increases their welfare.

The purpose of this theoretical contribution is two-fold. First, it seeks to explore the common theories in current strategic management and organization discourse and how they may be pulled together to explain strategic renewal in organizations and how dynamic capabilities lead to sustainability and value creation in the context of emerging economies. Second, it seeks to develop a wider framework that allows a complex but comprehensive and sophisticated reinterpretation of the theories and their practical application within varieties of institutional contexts.

What is the relevance of such theories if they cannot be linked to the overall sustainable need of the present era and its social trends in terms of market and social institutions? To this end, the temporal dimension and contextual utility of this new framework are made explicit in the analysis. This study is important because while the focus of dynamic capabilities seems to centre on adaptation, market dynamism (Porter, 1985; Eisenhardt and Martin, 2000; Augier and Teece, 2008) and long-term competitive advantage, the research on sustainability seems to be more of an interesting rhetoric about the sensitivity to scarce resources and social justice. This leaves the ethical man mostly out of the discourse. Nevertheless, both fail to identify the time logic, systemic variables and the institutional elements which constrain organizational strategic decision making towards the maintenance of competitive advantage in order to ensure that sustainability happens in the first place, while taking society into account. This provides a match between social and economic interests. The implication is that there are substantial opportunities for a pragmatic multidisciplinary approach in enriching and coalescing different theoretical strands into a systematic framework that takes into account current global phenomena in emerging economies.

Three principal themes run through this paper: One, the normative and ethical concerns about social and environmental sustainability constrain how dynamic capabilities, business models and firms' resources are directed towards a new form of competition and adaptation. This describes a shift from the firm centeredness and resource based view (which precludes ethics and stakeholder questions but places emphasis on efficiency no matter the social cost towards the extension) to the dynamic capabilities with the ethical entrepreneur with his innovative co-evolutionary posture. On this, illustrations from the pharmaceutical industry are offered throughout the paper.

Two, the paper focuses on Williamson's (2000) path-dependence account of the political, economic and judicial systems of each society which consist of "a web of interconnected formal rules and informal constraints that together make up the institutional matrix which have led economies onto different paths of development and hence general welfare of their people". These same institutional changes shape the markets especially in terms of the type of new innovations and product architecture as well as strategic decisions by individual managers in response to the sustainability and poverty issues at the bottom of the pyramid. Thus, institutions also determine the form of capitalism (Hall and Soskice, 2001). It is argued that environmental turbulence and institutional dynamics (Scott, 2001; DiMaggio and Powell, 1983) now affect managerial decisions in ways that turn business leaders into entrepreneurial managers (Penrose, 1959; Saravasthy et al, 2008; Dimov, 2007). This leads to the design of new mechanisms (via product architecture and renewable innovations) and the effectuation of strategic changes (Saravasthy et al, 2008) aimed at meeting the current sustainability demands in order to anticipate the future concerns and expectations of consumers and stakeholders (Freeman, 1984) especially in once neglected markets in emerging economies which hold huge potential for business growth and expansion.

The third part analyses how different organizations optimize distinct mechanisms, processes and innovations at different historical points (Nielsen, 2003). It is argued that an organization's resource endowment and pursuance of dynamic capabilities *per se* would not translate into higher performance and greater wealth creation relative to its competitors (Augier and Teece, 2008; Ambrosini and Bowman, 2009). Rather, when managerial entrepreneurs search for opportunities with the willingness to take risks, considering the ethical, normative and sustainability issues in their reconfiguration of resources, they stand a greater chance of achieving success and having a sustained competitive advantage in this era. This conjecture is supported by the fact that given the new consumption patterns, such capabilities are designed in response to institutional changes (industry standards, governmental regulatory frameworks), cultural-cognitive changes (Scott, 2001) as well as social pressures consisting of the society's demand for ecologically sensitive technologies, production and distribution systems and respect for human rights. In essence, this study looks at how formal and informal institutional structures (Williamson 1975; DiMaggio and Powell, 1983), which represent culture crystallized by social arrangements, shape prevailing conditions, systems and processes in various organizations and how organizations in turn adapt to their dynamically changing environment.

Central questions

The above considerations lend themselves to the following questions:

- Why does ethically constrained optimization of dynamic capabilities in organizations within diverse institutional contexts represent both an analytical and practical (*gestalt*) shift from firm centeredness to an

amalgamation of strategic management theory, ethical philosophy, organization theory (OT), and entrepreneurship?

- Why is strategic organizational renewal towards “glocal” sustainability and ethical concerns regarded as both corporate responsibility (CR) and innovative adaptive approaches toward sustained competitive advantage via institutional legitimacy?

Methodology of Analysis

Theories and paradigms in strategic management abound but so too do their levels of fragmentation and disconnectedness (Tsoukas and Knudsen, 2003). There has however been a shortage of the much needed relevance of these theories to both policy makers and practitioners, thus, emphasizing the gap between theory and practice (Starkey and Madan, 2001; Abrahamson and Eisenman, 2001) as well as the lack of steam for the furtherance of scientific knowledge in the above mentioned theories (Miner, 1984; Pfeffer, 1993). It follows that a deeper reflection about the validity and relevance of knowledge (Miner, 1984; Leedy and Ormrod, 2005) and its purpose for understanding the organizations vis-à-vis their external environment should be encouraged. This is because how knowledge is generated and how the validity of such knowledge and elegant theories is scrutinized are challenging questions that need further enquiry. Such thoughtful contemplations lend themselves to *meta* questions whose very essence goes beyond the generation or testing of organizational theories. Rather this process of raising critical questions and engaging in reflexivity about the validity of knowledge, its purpose, and for whom it is practically relevant “makes the generation of theory itself an object of analysis” (Tsoukas and Knudsen, 2003:5).

Here, the analytical shift from non-pragmatic approaches to pluralism (interdisciplinary approach) allows for the translation of relevance into practicality and that is put into context in terms of its useful application by practitioners and the extent to which it generates more explanatory notions and questions for the furtherance of scientific research. Reflexivity in the process of probing allows the detection of biased assumptions about sustainable corporate practices, sometimes viewed as a cost, which underlie some theories. Moreover, *meta* theoretical analysis helps to understand how some notions are more persuasive than others in explaining social and organizational phenomena. Many theories and constructs in organizational and strategic management theories present a high level of incommensurability, due to the lack of general consensus. The presence of ambiguity in several constructs and how they are viewed from the micro or structural levels also present a problem (Tsoukas and Knudsen, 2003). This is the bridge that the foregoing contribution attempts to build via *meta* theoretical analysis. Clearly there is a theoretical and empirical link between the notion of ‘ethically constrained dynamic capabilities’ and neo institutional theory to explain how sustainability issues present an emerging new form of competition for which an organizational renewal is a prerequisite. The conceptual framework of *meta* theoretical analysis is able to draw together the resource based view (Barney, 1991; Wernerfelt, 1984), by extension the dynamic capabilities perspective, entrepreneurship and organizational behavior on the micro level, and institutional analysis on the structural level. This aims at bridging the micro-macro gap with what happens in organizations in practice; thereby doing justice to the questions of relevance in the theoretical framework. The analytical framework attaches much importance to the issues of sustainability in emerging markets and the role of the entrepreneurial manager in actualizing those issues.

Theoretical and Practical Perspectives

Over half a century ago, Bowen’s (1953) systematic account of the importance of organization-society interface accentuated his definition of corporate social responsibility (CSR) as “the obligation of those businessmen (and women) to pursue those policies (based on norms and moral principles), to make those (strategic) decisions or to follow those lines of action (strategy implementation and new business models) which are (socially) desirable in terms of the objectives and values of our society” (Bowen, 1953: 6). No longer are the reduction of negative externalities and other impacts of the firm or social responsibility decisions and actions on society and the environment deemed a public good at the non-affordable private costs which put the firm at an unfair disadvantage

against its competitors. Ethical behaviors such as the limitation of pollution was once considered a cost that puts the firm at disadvantage until the huge boost from environmental laws and stakeholders' support for environmental causes (Ruckelshaus, 1993). Such a reductionist view in which the firm exists only to maximize profits at the expense of its employees, consumers etc, as was sustained in the past by Friedman (1970), Jensen (2002), Sundaram and Inkpen (2004), Levitt (1970), and Drucker (1974) does not reflect present realities where social responsibility is no longer viewed as a problem that needs to be solved by governments. This also demonstrates the link between organizations and public policy. There is now a socially responsible movement of creative capitalists who will only put their investments where their values direct them (Davis and Thompson, 1994). For the modern firm, it is rather about legitimacy and proper use of political power in a competitive environment (Scherer and Palazzo, 2007; Mitchell, 1989). As many firms adopt the approach of sustainability there is considerable evidence to substantiate the fact that it is to the competitive disadvantage of the firms that ignore these normative and ethical concerns. This constrains how dynamic capabilities and firms' resources are optimized and directed towards a new form of competition and adaptation. Vogel (2005) argues that the institutional environment will decide whether there is market for such virtues. It is argued here that renewal is not only about markets but about organizations adopting innovative mechanisms as a social contract without rendering their dynamic capabilities obsolete and non-competitive.

Social responsibility towards communities and employees via better employment conditions increases motivation and employee satisfaction leading to higher productivity and performance (Porter and Kramer, 2002). Adherence to environmental standards via energy cost reduction, lower pollution level, and disruptive business models, which take advantage of economies of scale for markets at the bottom of the pyramid and emerging markets, reduce poverty and increase economic development (Yunus, 2010; Meyer, 2004). Processes embedded in ethical preferences – low-cost and energy-saving product development through cutting edge innovative processes are gradually becoming the rule rather than an exception. For example, the application of human genomics and molecular modeling in the pharmaceutical industry aims at reducing time and cost of the drug development process and life cycle. This also increases safety conditions for trial subjects in developing nations as well as for final consumers.

The **first proposition** from the above theoretical analysis is that: *Organizations which do not consider ethical questions in the optimization of dynamic capabilities and effectuation of organizational renewal run a high risk of creating a competitive disadvantage that renders them obsolete in what they can offer market and society given the institutional and market dynamics. Therefore, the greater the ethical preferences in the optimization of dynamic capabilities (sustainable innovations) are, the greater will be the organization's level of legitimacy in society and hence its sustained competitive advantage.*

Organizational Culture and Institutional Change

The organisational culture is defined variously as shared patterns and meanings, values (ethical or unethical), beliefs and ideologies which underlie internal behaviour and managerial decisions as well as the way organisations react with and adapt to their external environment (Schein, 2004; Smichich, 1983; Hofstede et al, 2002). What is important here is that managerial belief systems, vision, and values affect decisions. This in turn will affect response to the changes in the institutional matrix to either enable or inhibit organisational renewal towards sustainability as Linnenluecke and Griffiths (2009) maintain. To the extent that we wish to understand what is optimized in organisations and the institutions which constrain such optimization, the link must be drawn between the former and the latter. Changes in institutional matrix (of socio-economic and political dimensions) refer to the “fundamental and comprehensive changes introduced to the formal and informal rules of the game that affect organizations as players” (Peng, 2003: 275). Scott (2001:48) views institutions as composing of social structures that have attained a high measure of acceptance and stability. These comprise cultural-cognitive, regulative and normative building blocks coupled with “activities and resources (that) provide stability and meaning to social life”. For Hofstede et al (2002: 800) “institutions are the crystallization of culture, and culture is the substratum of institutional arrangements.” Hence any attempt to claim causality link between the two is a useless endeavor (Peng and Pleggenkuhle-Miles, 2009). Institutions have near spontaneous origins in their creation and diffusion via various modes including relational systems, symbols, routines and social artifacts; they may be formal or informal institutional structures

(Williamson, 1975; Scott, 2001). These social structures are imposed and sustained over time by the actors from the individual level to organizational level as a social behavior. Once they attain a status of inertia, they become normal behavioral patterns which are via the process of socialization re-enacted and continuously routinized and taken for granted. Powell and DiMaggio (1991) offer a fresh look at institutional theory from a sociological point of view with the rejection of rational actor models which view institutions as independent structures. Rather, their more socially embedded and holistic approach of neo institutionalism takes into consideration the “cultural-cognitive explanations and an interest in properties of supra-individual units of analysis that are irreducible to aggregations or direct consequences of individuals’ attributes or motives (1991: 8).”

Explaining organizational isomorphism

For DiMaggio and Powell (1983), four analytical tools are used to aid understanding and explaining the reasons and means by which certain cultural practices and structures govern social behaviors with such a strong rigidity to mutations in a particular population (e.g., in an industry) that they dictate the population’s isomorphic nature. These devices include ‘carriers’, ‘mechanisms’, ‘field logics’ and ‘source of influence’. Mechanisms and carriers refer to the nature of the reified beliefs (or forms of social facts) which present themselves in the form of rules and regulations and particular cultural elements such as norms, values and the mechanism via which they are diffused across organizations. For DiMaggio and Powell (1983), institutional isomorphism is created either via coercive, mimetic, or normative modes. These are, however, not mutually exclusive but are analytically linked. Coercive isomorphism is created through political influence and formal authority or governance systems, thus, formally imposed pressures on one hand and soft “forces of legitimacy in terms of fairness and reasonableness” on the other. The normative refers to the moral principles imposed by society via its informal structures. While state legislations and other formal regulations as well as ratified standards by agencies with legal authority may represent powerful coercive forces, they nonetheless do not amount to the only elements of coercive power. Social pressures and public opinion about organizational conduct may govern isomorphism. This is also because stakeholders in particular and society in general attach reputational value to organizations and this social construction may have either positive or negative ramifications on a firm. Mimetic behavior on the other hand is prevalent under conditions of uncertainty, vagaries and ambiguity. Actors may mimic or emulate a market leader as the archetype in the population either inadvertently or on purpose. For example, in pursuit of legitimacy, organizations may embark on sustainability programmes by copying other successful organizations.

Implied here are three considerations for **proposition 2**: *The optimization of dynamic capabilities is constrained by (i) changing industry specific norms, (ii) new formal rules by governments about sustainability issues, and (iii) the opportunity seeking motive of the firm to pursue competitive advantage which in turn is dependent on ethical managerial decisions to meet social and environmental demands with sustainable innovations.*

Why do organizations engage in ir/responsible business?

In a ground breaking article, Campbell (2007) argued compellingly that institutional environments are the inhibitors or enablers of responsible or irresponsible behavior. This is consistent with the view of Jackson and Apostolakou (2010) and Williamson (1975). Campbell cites both private and public regulatory frameworks under which the organization operates, the presence or absence of nongovernmental organizations (NGOs) which monitor firm behaviour, institutionalized norms within which corporate actions are deemed acceptable, and the pattern of behavior that is consistent and accepted in a particular industry. He further asserts that organized dialogues among organizations and their stakeholders are among the reasons for responsible and ethical behaviour. What is missing, however, is the role of organisations in the context of weak or strong institutions. By strong institutions I refer to the ability of the formal structures to enforce rules and regulations and the informal institutional environment to organize its influence against what is deemed unacceptable corporate behavior. The entry into new markets through legitimate means and institutional recognition by regulators and governments is always a prerequisite. This is readily verifiable from Global Compact (2010) and United Nations Millennium Development Goals by the sheer number of pharmaceutical companies that are taking the initiative to contribute to poverty eradication efforts in the health sector in developing economies in order to appear socially responsible and not as exploitative entities. This is also a way of demonstrating the new trend whereby economic activities of organizations are socially embedded especially

now that there are such partnerships between business entities and NGOs to embark on R&D to produce drugs for neglected diseases etc. Typical cases are those of GlaxoSmithKline and Bill and Melinda Gates Foundation (see the websites). The increasing phenomenon of organizational search for legitimacy, power and influence through their role as political actors is explained by the neo institutional theory and CR in the works of Campbell (2007), Scherer and Palazzo (2007), Mitchell (1989) and Crane and Matten (2007).

It seems plausible from the foregoing analysis that when sustainability plays the central role in a firm's strategic operations and the development of its dynamic capabilities, there is an implicit need for organizational renewal vis-à-vis other organizations in the same population which affects managerial decisions to effectuate and configure firms' internal resources to meet the stakeholder demand (Saravasthy et al, 2008). Markets have evolved significantly, but so has competition increased in several industries to meet today's CR demands which are modeled to capture emerging needs. Strategic goals towards engineering and product design as well as changing core competencies that are geared towards innovations at lower social costs, higher positive externalities and cost-effective processes become the core of management thinking. At the same time, strategic renewal of internal capabilities and social demands are pressuring firms towards a more transparent and accountable governance which lead to positive social impact both for internal stakeholders in particular and society at large (Lee, 2008; Peng and Pleggenkuhle-Miles, 2009).

What is optimized and what is constrained?

Different organizations naturally optimize distinct mechanisms, processes and innovations at different times, for example, shareholder value, legitimacy, power, family wealth etc. under particular constraints (Nielsen, 2003) such as issues of sustainability and social pressure. Again what is optimized and what is constrained according to Nielsen have varied across space and time, the type of organizations as well as the social and institutional context. Simply put, the mantra is "with the occasion and place comply". Ethically constrained dynamic capabilities towards sustainability and CR via processes embedded in ethical preferences and social concerns are overwhelming issues which are generally accepted across the board. Such change processes spur innovation and they are the key sources of sustained competitive advantage of organizations (Augier and Teece, 2008; Porter 1985; Drucker, 1974). The space between what is optimized, e.g., dynamic capabilities, and what is constrained, e.g., sustainability and social justice, is filled with conflict (Nielsen, 2003) of ethical and normative nature. Weaver, Trevino and Cochran (1999) imply that managers with higher ethical commitments are directed by their ethical preferences more in practice than firms that engage in ethical actions as an *ad hoc* program in responses to external pressures. This perhaps explains why some firms strategically renew their capabilities to allow them to offer the optimal value propositions to emerging markets while others stick to the old books.

For March (2006), organizations characteristically pursue intelligence. Thus, they seek to adopt courses of action that will eventually lead them to outcomes that are deemed satisfactory in the long term, taking into account any changes in their hopes, beliefs, value system and ethical preferences as well as the interpretations of these over a period of time and the dilemma over all the above. Important here is the fact that rational technologies permit firms to survive day by day. Rational technologies involve an attempt to understand complex changing systems of causal factors on the basis of imperfect, ambiguous, and contested knowledge of the environment (March, 2006). This process also involves the anticipation and shaping of the environment that is also characterized by other organizations which seek to equally and concurrently 'anticipate' and 'shape' their environment. This means there is a process of confronting inconsistencies in preferences, benchmarking across organizations and making intertemporal appraisals. It follows that adaptive systems are sustained by a process of exploration and exploitation. Therefore, theory, ideology and technologies of rationality in organizations (involving abstractions, values-based decisions) are embedded in a philosophy which holds that the implementation of organization's decisions or strategies (Porter, 1985) should be the "product of the mind and choice", not magic or tradition (March, 2006). This way of reasoning answers many questions about a firm's decisions in response to a dynamic environment but it leaves other theoretical problems if not practical ones unanswered.

McKinley and Mone (2003) pose the question about the inconsistency of competitive strategy. Porter (1985) asserts that organizations must establish unique positions using the metrics of cost leadership, product or service differentiation, pursue sustainable competitive advantage and the possibility of a long-term survival in a dynamic

and competitive market. This is made possible via organizations' core competencies (bundle of skills and expertise) that are unique and inimitable (Prahalad and Hamel, 1990). On the other hand, the neo institutional theory (Meyer and Rowan 1977; DiMaggio and Powell, 1983) holds the premise that organizations' conformity to institutionalized practices is to gain legitimacy and reduce uncertainty rather than to improve technical and financial performance. While McKinley and Mone (2003) view competitive strategy and neo institutional theory as incommensurable, it can still be argued that firms remain institutionally isomorphic due to the market environment or the legal framework that constrains them to mimic each other to attain legitimacy. On the other hand organizations pursue differentiation and other strategies which accentuate their uniqueness in terms of core competencies and dynamic capabilities to attain higher performance while conforming to the expectations of their context. Alexander and Rudolph (1985) and Donaldson (1995) question in their neo-contingency model, in which they theorize how organizations adapt to contingencies (e.g., environmental state, manufacturing technology or firm size), why some organizations continue to exist, while others get extinct under similar environmental conditions. Peter Drucker (1974) poses the same questions. It seems plausible that organizations are both shaped by their environment and they can in turn also use their internal structures to shape the environment. Thus, both are reciprocally dependent. This means that questions of operational efficiency based on capabilities and high quality skills will in turn adapt to environmental dynamics, e.g., sustainability demands. This leads us to the extent to which environmental changes influence internal structures and resource endowment and how they are renewed over time to adapt.

Analysis of Concept of Sustainability

Two levels of analysis are pursued here; the organizational level and the broader structural level of the institutional environment. At the former, organizational culture, dynamic capabilities and the entrepreneurial manager are the focus of analysis, while at the latter three key characteristics of institutions are used with the theoretical lenses of institutional theory (Scott, 2001; DiMaggio and Powell, 1993).

Defining sustainability and environmental turbulence

The concept sustainability has a long history of activism and environmentalism to its present prominence across the globe (Linnenluecke and Griffiths, 2009). A report *Our Common Future* published by the World Commission on Environment and Development (WCED), a UN established body, defined sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987: 43). Its main content as espoused by NGOs, business leaders and civil society was for businesses to pursue their interests while taking into account social and environmental impacts. Sustainability practices refer to the efficient and effective application of innovative *modus operandi* in the use of human, environment and time as limited resources. Sustainability is a buzzword now on corporate websites to indicate organizational commitment to stakeholders' environmental needs. It is known to allow the firm and national economies to enjoy a competitive advantage in the long term since it systematically protects their eco-systems.

Employees working under conditions conducive to productivity certainly have the motivation and cutting edge skills to implement sustainable agenda which is woven into the corporate strategy of the organization through their expertise. Equally important are the national laws which fight against discrimination against women and minorities at work places as well as coercive ways to increase the work-life balance of employees in all industries by treating workers with dignity. This can be achieved through innovative waste disposal and recycling techniques, renewable energy that reduces different forms of pollution while cutting costs, or new production engineering which all aim at reducing the carbon footprint and protecting the fragile ecosystem and its inhabitants (Global Compact, 2010). Sustainable strategies increase firm competitiveness and adaptability to the changing environment and respond to social demands. The governments in developing and emerging economies see this as a way of ensuring that current wealth creation activities are not in any way impeding future generators from creating worth for themselves. This in part explains why there seem to be systemic changes across the board to adapt to this new way of strategy implementation.

Dynamic capabilities of organizations

The resource based view (RBV) (Barney, 1991; Wernerfelt, 1984) traces its origin from Edith Penrose (1959). It essentially states that the heterogeneity and immobility of different organizational endowments will translate into valuable resources which will sustain over time the competitive advantage to earn “super profits or above-average profits” as consistent with Barney (1991), and Priem and Butler (2001). While this notion holds all things static, its shortcoming is that it does not explain how future valuable organizational resources can be generated, nor does it explain how the current stock of resources can be reconfigured to suit the dynamic needs of the market and society. Besides, it fails to see that the firm confronts not only markets but institutions. From where the static nature of RBV ends, dynamic capabilities take over to explain the evolutionary nature, time and context of the organizational direction in relation to the organizational environment and the role of the organization-society interface.

Augier and Teece (2008: 1190) define dynamic capabilities as “the particular (non-imitable) capacity a business possesses to shape, reshape, configure and reconfigure assets so as to respond to changing technologies and markets and escape the zero profit condition”. More to the point, it refers to the ability of the organization to anticipate, seize opportunities and adapt to its environment in a way that permits it to exploit both the internal and external enterprise-specific competencies and deal with the organization’s dynamic environment (Augier and Teece, 2008). Thus, beyond the mere possession of competencies in the short term, the long-term survival is attained by learning and new innovative attributes, continuous process of renewal, and superiority in an organization’s value propositions. These attributes must be able to capture potential opportunities at a rate that is quicker than the competitors’ and concurrently effectuating organizational renewal through entrepreneurial leadership. In effect, it has been found that CR in itself provides new business opportunities via innovation (Hockerts and Morsing, 2008).

Teece et al’s (1990, quoted in Ambrosini and Bowman, 2009) working paper presented in Finland was the first contribution towards the theory of dynamic capabilities. In it, they point out that (p. 11) “our view of the firm is somewhat richer than the standard resource-based view...it is not only the bundle of resources that matter, but the mechanisms by which firms learn and accumulate new skills and capabilities, and the forces that limit the rate and direction of this process”. The refined version of these ideas was formally published in 1994 by Teece and Pisano. Ambrosini and Bowman (2009) and Teece and Pisano (1994: 537) assert the primary importance of the dynamic nature of the external environment as well as the role of strategic management which essentially concerns the process of “adapting, integrating and reconfiguring internal and external organizational skills, resources and functional competencies toward the changing (market and institutional) environment(s)”. The core message here is to perceive the organizations as systems which are embedded in socio-economic, political and technological realities as well as the managers’ cognition. This adaptation is a process of renewal towards sustainability as echoed in the title of this paper.

Summary of previous studies

There seems to be an element of value co-creation in Teece and Pisano’s conceptualization of dynamic capabilities view (DCV). The ethical posture of the manager is crucial in strategic decisions (Augier and Teece, 2008). DCV consists of knowledge articulation, processes and operational routines. Capabilities are not machines and robots. They are competencies and core skills that employees are endowed with in order to implement desired sustainable processes. Pointing to a more sociological aspect of it in OT, it becomes evident that its ethical nature should always be taken into consideration. The ethical posture of the manager is crucial in strategic decisions for the optimization of dynamic capabilities in the light of markets and institutions. This thus seems to be missing in all the five most cited works on dynamic capabilities in Table 1 below.

TABLE 1: SUMMARY OF DYNAMIC CAPABILITIES AS A THEORETICAL FOUNDATION FOR SUSTAINABILITY

Study	Type of study	Definition
Teece and Pisano (1994)	Theoretical contribution on dynamic capabilities providing key conceptualization.	As adapting, integrating and reconfiguring internal and external organizational skills, resources and functional competencies toward the changing (market and institutional) environment(s) (p. 537).
Eisenhardt and Martin (2000)	Theoretical contribution on specific and identifiable processes, exploiting dynamic capabilities	Dynamic capabilities are a set of specific and identifiable processes such as product development, strategic decision making, and alliancing. They are neither vague nor tautological.
Zollo and Winter (2002)	Empirical contribution on mechanisms through which organizations develop dynamic capabilities.	A learned and stable pattern of collective activity through which the organization systematically generates and modifies its operating routines in pursuit of improved effectiveness.
Helfat et al (2007)	A book on understanding strategic change via dynamic capabilities.	“The capacity of an organization to purposefully create, extend, and modify its resource base” (p. 4).

Figure 1 presents a model of ethically constrained optimization of dynamic capabilities towards sustainability. The cusp refers to a threshold or a transition from one historical point to another where environmental turbulence and internal pressures force organizations to renew their structures in order to adapt to the external environment. The optimization of dynamic capabilities is strongly influenced by environmental turbulence, which consists of external forces such as environmental changes (climate change and air pollution), human rights issues, and pressures from external stakeholders (e.g. consumer demand for eco-friendly technologies, new industry standards and governmental regulations). The optimization is also influenced by internal pressures such as demands from internal stakeholders (for e.g. gender equality and employee safety and transparency in corporate governance). This changes the dynamics of the nexus between the firm and society. Environmental turbulence must not be construed only as market and institutional disorder but also as new opportunities especially in emerging economies constrained by the larger society of which the firm is part. This means the ability of the firm to adapt strategic decisions and reconfigure resources and capabilities via managerial entrepreneurship underscores the creation of competitive advantage in new markets in emerging economies. As Helfat and Peteraf (2009) put it, DCV is the Holy Grail which attempts to answer the specific question of firm’s sustainable competitive advantage in a changing environment. This “inside out” view fails to consider the ethical constraints which lead to the successful optimization of dynamic capabilities.

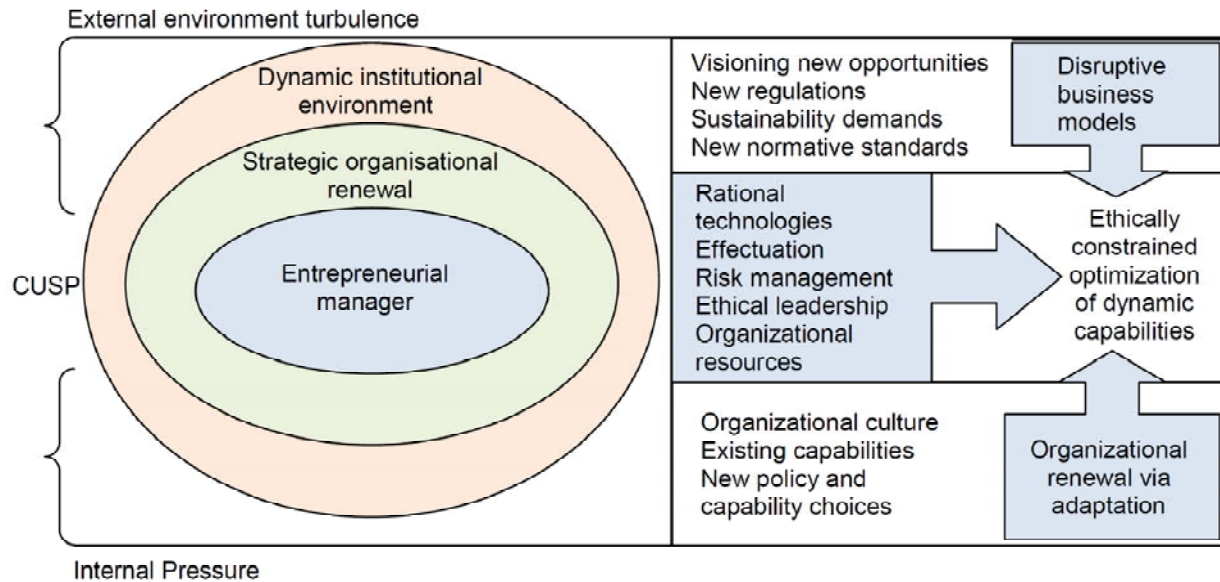

FIG. 1: A MODEL OF ETHICALLY CONSTRAINED OPTIMIZATION OF DYNAMIC CAPABILITIES TOWARDS SUSTAINABILITY

The dynamic capabilities and managerial entrepreneurship allow for creativity in developing sustainable and cutting edge products and services that in turn allow organizations to differentiate or become cost leaders or present unique value propositions to consumers and other stakeholders. These unique and compelling messages represent the cornerstone of firms' reputation as they search for both market and institutional legitimacy via mimetic, coercive or normative mechanisms depending on the industry, sector, circumstances and context (DiMaggio and Powell, 1983). Implied here is that isomorphism does not preclude organizational uniqueness and the creation of competitive advantage due to inimitability of dynamic capabilities constrained by the ethical decisions of the managerial entrepreneur to use business solutions for social issues at profit. Defining socio-economic or technological problems worth solving for profit is a win-win initiative. This however requires dynamic capabilities, strategic decisions and relationships for building the needed novel technologies in managing complex operations under different institutional milieus which present marketing opportunities. Markets and rent seeking matter but institutions may be everything. Addressing it may be non-trivial.

Balancing Entrepreneurship, strategic renewal and sustainability at the bottom of the pyramid

Changes in organizations may also involve superficial façades and genuine deceptions, to paraphrase Starbuck (2010). It is undeniable that persuasive apparatuses to deceive stakeholders pervade organizations. Implied here is that before substantive changes and learning can be very effective, firms must diligently unlearn as well as learn about the changes in industry and institutions (Cohen and Levinthal, 1990; Nyström and Starbuck, 1994). This is easier and practical via collaborative efforts with governments, NGOs and other non business actors with knowledge of the special needs of certain market segments. High profits stem from moving away from the zero sum trap (Augier and Teece, 2008). However, this is also dependent on partial monopolies based predominantly on location-specific advantages in neglected markets of developing economies, sustained reputation and licenses etc (Starbuck, 2010). How Western and Emerging Economies' pharmaceutical organizations can capture the profitable and scalable emerging markets remains a question? This requires a process of visioning new opportunities i.e. 'sensing', 'seizing' and capturing these markets in the long term. This is what Louche, Idowu & Filho (2010) refer to as corporate responsibility that moves from mere risk management to innovativeness and value creation. Such organizational changes are also performance driven Donaldson, (1999).

Recent changes that have transformed the pharmaceutical industry besides scientific and technological advancements are the structure of the markets as well as their geographical configuration. Pharmaceutical firms can now access several types of technical support and knowledge (research centre, laboratories, and engineering and design centers even in developing economies; Malhotra and Morris, 2009). Knowledge-based operations have become as mobile as the physical activities and this is no different in developing economies. It is maintained here that an economically flourishing society is clearly a precondition for markets to thrive (Lee, 2008) due in part to a growing middle class and the existence of scalability; volume and potential consumers both in the middle and at the bottom of the pyramid markets. This in essence becomes the rationale behind the architecture of novel demand-based products that are also contextualized. Since the dawn of the millennium, the world has been undergoing very profound changes in its socio-economic, climatic, market and institutional underpinnings. Such changes have deeply affected ideologies, systems, and organizational thinking in terms of the markets firms operate in and organizational responses to their environment. These changes include policy reforms, liberalization of markets, and privatization, as well as the architecture of new technologies to meet the contextual demands of the new markets. Such changes are also based on both technical and non-technical innovations aimed at achieving a competitive advantage (Porter, 1985) not only based on the ability to create entry barriers etc but based on sustainable innovations of a different kind. These innovations are based on the principle of faster, cheaper, and sustainable products and services that are commercially viable and aimed at matching the developmental agenda of these economies at profit. These forms of demand are predominantly in energy, education, health, transport, atypical financing, agriculture and less of luxury, entertainment and pure rent seeking. The business model innovation also requires the optimization of dynamic capabilities and substantive organizational renewal to incorporate ideas of collaboration between businesses and NGOs and governments. The business model innovation here according to Casadesus-Massanell and Ricart (2011) refers to as consisting of ethical preferences and consequences which are enveloped in three main choices of asset choice, policy choice and governance choice. Such models must characteristically be aligned with the firm's goals in ways that yield expected results. They also need to be auto-reinforcing, complementary such that they promote synergy, robust enough to fend off quick imitation by players, and they should increase bargaining power and limit firms' complacency and substitution by rivals (Casadesus-Massanell and Ricart, 2011). In the same vein, Chesbrough (2010: 362) argues that the fundamental "role of leadership is to ensure effective governance of business model experimentation" in emerging markets. For Kosonen and Yves (2010) strategic sensitivity to various developments requires leadership unity to make quick decisions and fluid resources that are easily and readily configured and deployed to capture emerging opportunities.

Operations in these markets are no longer going to be based on rent seeking and exploitation. Such a shift in thinking requires strategic organizational renewal (Agarwal and Helfat, 2009) that will be balancing the external demands of social good with firms' success (sustained growth and survival). Both incremental and radical innovations will then be required to meet the new market opportunities (Dimov, 2007). As Eggars and Kaplan (2009: 473) conclude on cognition and renewal, "managerial cognition and (ethical decisions) organizational orientation are important factors in understanding firm response to new technical opportunities". This is consistent with Bansal (2003) who argues that managerial values lead the firm to certain consequences and are constrained by institutional

pressures to affect CSR directions. Waldman asserts that organizational values and belief systems affect the processes by which firms identify and set agendas (Waldman et al, 2006).

I define strategic renewal as the profound organizational changes at varying degrees of transformations in a firm's dynamic capabilities and other resources that allow it to adapt productively and maintain competitive advantage over a long period of time. This process consists of shaping and being shaped by the environment constrained by market opportunities and challenges on one hand and institutional constraints and enablers on the other. All these are centered on the ethical sensibility of the entrepreneurial manager.

As an inductive theory building exercise after the *meta*-theoretical analysis, key terms are hereby defined. The reference to varying degrees of changes describes removal and replacement of old business models and the institutionalization of a new mindset, as well as structural and technical changes. The transformation is rather slow, relatively minor, but substantial enough to adapt to while in some cases very radical transformation in terms of organizational structure, culture, and capabilities is required to exploit the new windows of opportunity which promise scale. For Agarwal and Helfat (2009) major transformations may also present themselves as both large and multidimensional, making the firm less useful in serving the radically changing markets that affect business models, technological capabilities and the organizational mindset. Agarwal and Helfat (2009: 282) define strategic renewal as 'the process, content and outcome of refreshment or replacement of attributes of an organization that have the potential to substantially affect long term prospects'.

Key findings, implications and relevance

On the basis of the *meta*-theoretical approach, a reflection on common traits and comparison of theoretical perspectives of seminal works on dynamic capabilities and neo institutional theory is made. How to make sense of them even though they appear irreconcilable at some points when explaining organization-society interface? All this is done in the light of how the process of organising is enacted in response to external dynamics. As indicated in the title, the optimization of dynamic capabilities is a means of outcompeting rivals in ways that are partly dependent on managerial ethical decisions and external pressures within industry and in the wider institutional environment. What is constrained in current business discourse and practice? The building of dynamic capabilities also denotes an intertemporal choice whereby context and lifecycle of products and services matter in managerial decision in order to capture institutional needs and correct organizational renewal. The possession of core competencies such as skills and expertise alone are meaningless in some contexts unless such technical and rational technologies are linked up with the contextual value co-creation process via alliances to produce sustainable results. Adaptation may also mean the application of rational technologies and intuition to anticipate potential threats and opportunities (environmental turbulence) and being prepared with the organization's capability to cushion shocks or capture opportunities. Ethical and rational technologies alone do not guarantee long-term sustainable actions. The institutional elements of regulatory and normative standards serve as checks and balances to create order in society and markets and to constrain adherence to established rules or emerging standards and demands whilst making transaction costs bearable. This is how strategic management, ethics and the institutional environment in which they are embedded are brought together to make sense of the process of organizing in a new era.

Theoretical contribution of the present paper lies in the gap it fills in bridging the contingency theory with a population type of theory through a meaningful analysis which can be applied in empirical work. The managerial implications concern the applicability of this original notion that if development of dynamic capabilities such as expertise and cutting edge technologies are embedded in ethically shaped rational technologies, they stand to adapt in the environment by way of legitimization and institutional recognition which represents value for both the organization and the consumer or the broader society. While Teece et al (1997) and Eisenhardt and Martin (2000) do a great job with their insightful scientific contributions, the present paper contributes something unique because missing in their analysis is the institutional environment of regulatory, normative, and ethical posture of decision makers which are the sources of influence to shape dynamic capabilities. Beyond the aforementioned, the study offers a new perspective and *meta*-theoretical reflection about the existing theories that they are not redundant but they can be reinvigorated in fresh global discourses (Peng and Pleggenkuhle-Miles, 2009) to give them practical relevance, which in fact is the very essence of scientific research. The ultimate objective of research is the search for truth or a better understanding and making sense of data. Here, the pursuit is not after generalizations but

applicability and relevance. The wide spectrum of theories reviewed presents a drawback of being too broad, but on the other hand it provided different perspectives and new theoretical lenses through which to see ethical questions in the pharmaceutical industry. Such a process of *meta*-theoretical analysis encourages pragmatism and reduces parochialism in theoretical choices. The crystallization of culture in organized and social arrangements translates into institutions and that helped to contextualize and focus on the pharmaceutical firms and how they ethically strategize to build their capabilities.

Conclusions and Directions for Future Research

Beyond the boundaries of strategic management theories, a more pragmatic look at other theories helps to explain that the firm's success depends to a large extent on how it employs its endowments, managerial expertise, relational assets, core competencies, and other intangible resources in a way that coincides with the expectations and concerns of society and the dynamism of markets and institutions. This is the firm-society interface which makes dynamic capabilities from management theory and neo institutional theory from sociology interesting. The discussed theories expose practical mechanisms by which society and organizations shape and engage each other. On this basis, we can conclude that: Ethical leadership fused into managerial entrepreneurship in an innovative organizational culture within an enabling institutional context allows new advancement in organizational renewal and R&D, new business models, entry into new markets with "smarter, better and cheaper" technologies and environmentally safe products. This permits sustained competitive advantage. This is clearly an area of inquiry and practice that changes society and the business landscape but most importantly puts the entrepreneurial manager at the centre of the discourse of change.

On the macro level, questions of legitimacy and legal constraints are solved when firms bend no rules, while the rate of dynamic capabilities' optimization increases firm performance and adaptation as a self-sustained and competitive entity vis-à-vis rivals in a dynamic environment. Managerial entrepreneurship enables creativity and innovativeness among employees while diversifying firm resources into emerging markets to solve socio-economic snags at profit. This increases the organisation's chances of survival and adaptability both in the industry and in the larger environment. It follows that the institutionalization of ethical obligation and voluntary actions by organizations towards sustainability reflects the current world order of popular culture that demands ethical actions from organisations albeit the presence of institutional structures that are the main determinants of the extent to which organizations live up to such an order.

That notwithstanding, unethical ideas and rational technologies, thus organizational actions that are not sustainable and dynamic will hardly create value for firm and society as a whole, thereby inhibiting the firm's long term sustainable competitive advantage in this speedily changing market environment. Sustainability is therefore a common denominator of issues pertaining to social responsibility towards employees in a firm as part of a larger society and the environment. Normative concern about environmental sustainability constrains how dynamic capabilities and firms' resources are directed towards a new form of competition and adaptation. This represents the *gestalt* shift (practical and theoretical) in existing theories and their socio-political relevance as well as their managerial implications. The ideas presented here are logically linked, the examples are meaningfully engaging and the process of inquiring and untying the knot of strategic management and ethics theories is pragmatic as a nuanced research into existing knowledge. The model presented herein is still in the phase of development, that notwithstanding it is an attempt to grasp the organization-society interface and the role of ethical managerial decisions. While neo institutional theory seems to answer most of the questions, it faces a bigger dilemma where corporations seem to be even more powerful than certain countries where they operate. There is the need for comparative institutional analysis that allows for theorizing under what conditions firms operate sustainably in countries where institutions are weaker but the market abounds. From here, research will be directed towards this perspective. Campbell (2007) does not say to what extent the presence of NGOs influences firm's actions. I conjecture that the presence of stakeholders and NGOs *per se* does not translate into a formidable force or urgency to coerce organizational change. The greater the power of NGOs' constellations, the greater their influences; but that

influence is empowered by their organizational power to pull fragmented groups together in order to garner more institutional power and support.

Jackson and Apostolakou (2010) and Hall and Soskice (2001) posit that variations in national institutional environments affect the strategic coordination of corporate entities which are put into two groups of unique models of market actors: liberal market economies in the Anglo-Saxon economies and coordinated market economies in the continental Europe. Considerations about developing economies are either taken for granted or their former colonizers' economic systems are used as a proxy to analyze such markets. Nevertheless, most emerging markets operate under completely different socio-political and economic conditions. As Mangham (2003) maintains, unregulated capitalism produces a different ethical climate from regulated capitalism in that managerial values-based decisions are irreducibly social and never idiosyncratic. Going forward, I am persuaded that a comparative institutional analysis of organization-stakeholder relations and what motivates certain forms of innovations in developing economies will provide empirical exposures about how well we understand the emerging markets. Here, the transaction cost economics perspective will help explain governance choices and actions of organizations under conditions of uncertainty in developing economies. This is because hitherto the concept has been applied to advanced countries with stable market and institutional conditions which makes contractual choices feasible (Hoskisson et al, 2000).

Reaching out to Markets at the “Base of the Pyramid”: Ten Latin American Business Cases

*César Antúñez-de-Mayolo, cantunezdemayolo@pad.edu
PAD School of Management – Universidad de Piura, Peru*

Abstract

Based on qualitative research, the author studied the experiences of ten firms, each one operating in a specific country in Latin America, among Peru, Mexico, Guatemala, Colombia, Ecuador, Chile and Argentina, from different industries and at different stages of implementation on their Base of the Pyramid incursions. Through an analysis, the author uncovers what factors were critical for the decision making processes of the studied firms and what other factors were at that moment underlying, but afterwards help to reinforce the value proposition. One of the conclusions of the study is that the person and its needs should be the drivers to develop creative solutions to address low-income consumers' problems.

Objective and methodology

The objective of this article is to find, through theoretical and qualitative research, common factors among firms that have been attending consumers from markets at the Base of the Pyramid (BoP) in Latin America. The author selected ten examples of firms operating in seven different countries in the region, from various industries and with different sizes and levels of maturity and deployment on their BoP incursions.

World Poverty

Conventional definitions of poverty had been referring to a shortfall in income levels (Akindola, 2009), until Rowntree (1901) started studying those aspects of poverty not related to income, which he called 'secondary poverty', referring to habits and behavioral patterns that affect the commodity composition of a family's consumption. Those patterns are related to a 'culture of the poor', concept first suggested by anthropologist Oscar Lewis, based on ethnographic studies he conducted with families in Mexico, Puerto Rico and New York in the 1950s and 1960s (Lewis, 1959, 1961, 1966).

Nobel Prize laureate Amartya Sen (1999) suggests that we need a much deeper understanding of the multidimensional nature of poverty and that the poor cannot reach development because they do not have enough liberty, as they lack the opportunities to increase their income on their own. Sen (2009) indicated that we must learn to identify and remove the constraints that prevent those in poverty from realizing their full potential.

Growth and Inequality in Latin America

In 2010, real world GDP is estimated to have expanded by 3.9 percent, but by 5.7 percent for Latin America and the Caribbean (World Bank, 2011). As with other developing countries, the economies in Latin America had 'decoupled', and will continue to boom even as the economies of the United States and other rich countries grapple with recession (Bishop, 2008).

General economic progress does not improve the levels of the very poor (Todaro, 1997), and some developmental economists contend that the growth processes typically 'trickle-up' to the middle classes and especially the very rich (Norton, 2002). The first calculations of inequality across world citizens were done in the early 80s (Berry, Bourguignon & Morrison, 1983; Grosh & Nafziger, 1986). Since then, Latin America has had the world's worst income inequality (The Economist, 2011; Lopez & Perry, 2008). With a Gini Coefficient¹ of 0.53 in the mid-2000s, Latin America was 18 percent more unequal than Sub-Saharan Africa, 36 percent more unequal than East Asia and the Pacific, and 65 percent more unequal than the high-income countries (López-Calva & Lustig, 2010). According to

some researchers, inequality in Latin America is the result of state capture by elites, capital market imperfections, inequality of opportunity, labor market segmentation, and discrimination against women and nonwhites (Atal et al., 2009; Barros et al., 2009).

A new survey by the World Economic Forum points that widening economic disparities and failings in global governance are the two main global risks over the next decade (World Economic Forum, 2011).

The Base of the Pyramid

The presence of multi-dimensional personalities means that not every business should be measured by the single objective of profit maximization, since businesses have a key role in society (Yunus, 2007). However, the main attention of businesses to poverty had been regarding Social Responsibility Programs; until 1999, when C.K. Prahalad and Stuart Hart wrote an article titled 'Strategies for the Bottom of the Pyramid: Creating Sustainable Development' (Prahalad & Hart, 1999). This work was the first that introduced the BoP concept, attempting to raise awareness of the world economic pyramid and the vastly untapped market of 4 billion people living on less than \$1,500 Purchasing Power Parity (PPP) ² per capita income. The poor at the base of the global socio-economic ladder, primarily transact in an informal market economy, due to the cost, complexity and unfamiliarity of transitioning to the formal economy (London, 2007), and the BoP perspective relies on the view that unmet societal needs are also potential business opportunities (London & Hart 2004; Prahalad, 2004; Prahalad & Hart 2002; London, 2010).

The BoP perspective relies on a proposition of mutual value creation: the greater the ability of the enterprise to meet the needs of the poor, the greater the return to the partners involved. However, profit, rather than any other measure of corporate activity, is the first estimate of how much value a business creates for society and we should encourage businesses to make profit, even if we think about other goals (Wilson & Wilson, 2006).

According to the BoP literature, a BoP venture is a revenue-generating enterprise that either sells goods to (BoP-as-consumer) or sources products from (BoP-as-producer) those at the base of the pyramid, in a way that helps to improve the standard of living of the poor (Prahalad & Hammond 2002; Prahalad & Hart 2002). An specific BoP venture can adopt either or both, approaches (Anupindi & Sivakumar, 2007), and in order to evaluate a BoP venture's impact on poverty alleviation, we should consider respect, dignity, inclusion, choice, security, and transparency, among other aspects of well-being that must be measured (London, 2007).

Base of the Pyramid and Core Competences

A Core competence of a company is a form of economy of scale that results from a company's ability to excel in certain aspects (Milgrom & Roberts, 1992). According to Prahalad and Hamel (1990), a core competence provides potential access to a wide variety of markets, should make a significant contribution to the perceived benefits by customers of the end-product, and should be difficult for competitors to imitate. As in any other business ventures, an enterprise getting into BoP markets should first focus on its core competences.

Base of the Pyramid and Inclusive Scheme

Co-creation business logic implies that the most competitive business models will emerge from a deep understanding and dialogue with front-end users or producers, which in the cases under study comprises the BoP. This requires 'honest and open' long-term relationships (Grönroos, 2000; Normann, 2001). Corporations that succeeded at BoP, have the capabilities of investing or developing associations, developing new competences and experimenting in new and untested markets (Hart & Milstein, 1999).

Base of the Pyramid and Innovation

Market creation is fundamentally different from market entry. According to Simanis (2010), even considering the BoP's 'basket' of compelling needs, the BoP is not actually a market. In order to 'create' a market, firms should focus on products or services that could be 'embedded' into the BoP consumers' lives.

Consumer Needs at the Base of the Pyramid and Wrong Assumptions

Before thinking about consumer needs at BoP markets, we should first think about a *wrong assumption*, which usually blocks managers from thinking about poor people as consumers. As an example, some of these wrong assumptions with reference to poor people are: 'they don't need to use a mobile phone', 'they would not pay for glasses', 'they would not use make-up', or 'they are not capable of investing money with success'.

Base of the Pyramid in Latin America

The World Bank has emphasized the importance of making markets work for the poor, and the need for those in poverty to actively contribute to this process (Narayan et al., 2000; The World Bank, 2001). The World Resources Institute (WRI) conducted a study with the International Finance Corporation to better understand the size and aggregate purchasing power of the BoP. It identified nearly 4 billion people at the BoP across Africa, Asia, Eastern Europe, Latin America and the Caribbean (Hammond et al., 2007). Using data from household consumption surveys, the report estimates total annual household income at the BoP at \$5 trillion PPP (or \$1.3 trillion when adjusted to U.S. dollars). In another study with the Inter-American Development Bank (IDB), WRI also relied on household survey data to examine the BoP in 20 countries in the Latin America and the Caribbean region, finding a BoP population of 361 million in the region, with an aggregated annual income of \$510 billion (World Resources Institute, 2006).

The Selected Cases

Through in-person and telephone interviews, we used the case research method (Yin, 1984) to collect the data and analysis of the ten firms. That kind of research is qualitative, which is useful for studying phenomena in their natural settings, attempting to make sense of, or to interpret it in terms of the meanings people bring to them (Denzin & Lincoln, 2000). Our analysis is divided in the following parts: *Company Background*, *Consumer Needs and Problem*, *Wrong Assumption*, *Value Proposition*, and *Results*.

Global Alimentos (Peru, Packaged Foods)

Company Background

In 1996, Maltería Lima (ML), a firm dedicated to processing malt, corn and other cereals, mostly for a brewing Peruvian group -Corporación Backus (CB)-, launched a barley cereal in form of flakes, which competed successfully with oats, under the brand 'Angel'. That cereal was consumed almost exclusively at breakfast and as the consumption of oats, it needed to be cooked. 'Hojuelas de Cebada Angel' reached a market share of 30% among the Peruvian oats category, competing with Quaker Oats and other imported cereals. In 2003, ML launched an instant corn cereal, 'Hojuelas de Maíz Angel', attempting to compete with Kellogg's and Nestle. By then, ready-to-eat cereals in Peru were mostly distributed at supermarkets, and because of price and accessibility barriers, practically out of low-income consumer's shopping lists. In 2004, CB was acquired by a larger foreign brewing group, interested just on beer-related businesses. As a spin-off from ML, its cereals unit was sold to two seasoned ex-executives from that firm, who founded Global Alimentos (GA). Even though they didn't have the economic resources from CB, that venture brought them plenty of flexibility and independence in terms of investment and

priorities. With a project for a high-quality and low-price instant cereal already launched, they reinforced the value proposition of the product and practically, created a market.

Consumer Needs and Problem

The consumer needs addressed were nutritive feeding, good taste and to share good moments in family, during breakfast. The problem is that low-income Peruvians couldn't afford to buy good quality cereals for their breakfast.

Wrong Assumptions

Some executives thought that low-income Peruvians won't appreciate instant cereals, so they don't deserve the opportunity of tasting good quality cereals, and that low-income housewives don't value their time, so they don't have problem about investing too much time cooking cereals for breakfast. Regarding consumer acceptance, it was thought that a small serving size for corn flakes at an accessible price, wouldn't be attractive.

Value Proposition

GA executives realized that low-income Peruvians don't have an 'atrophied' palate to appreciate ready-to-eat cereals, but an 'sleepy' palate. Also, they realized that low-income housewives value their time. The product is manufactured at state-of-art facilities, with top quality ingredients, a valuable vitamins & minerals fortification, comes in different forms and flavors, and is also available on small individual sizes (22 grams), with an underlying message that 'you don't need to eat more for good nutrition and satiety'. The price was really competitive -the equivalent to ten cents of dollar for the individual size- and all the sizes come in bags instead of boxes -saving more money-, with a similar expiration time-frame.

Results

The market in Peru grew from 1,000 TM a year (2003) to 5,000 TM (2010), and besides absolutely leading the category in Peru, GA now exports to 14 countries in Latin America and have more than 20 different varieties of ready-to-eat cereals, all under the brand 'Angel'.

El Trome (Peru, Newspaper)

Company Background

Founded in 1839, 'El Comercio' (EC) newspaper, with a line of independent journalism and with no political affiliation, gained trust and credibility and was the leading newspaper in Peru among top socio-economic levels (A and B). However, by 2001, EC group depended on a single product and segment, and wanted to compete in the low-price segment of newspapers, niche then dominated by some empty content newspapers, offering entertainment for a low-price (50 cents of Nuevo Sol, equivalent to 14 dollar cents), with useless information and plenty of slang and nude women.

Consumer Needs and Problem

Through consumer research, EC executives realized that low-income consumers need not just information and entertainment, but education and usefulness. Since low-income Peruvians don't have too much time for reading, they are not interested on political analysis or complex schemes, and as they don't have too much money to spend, they demand more for what they pay.

Wrong Assumption

Low income people just need slang and informal style communications, with empty content and just entertainment. They wouldn't appreciate a more valuable newspaper.

Value Proposition

They launched a newspaper named 'El Trome'³, that brings more value, and for all among the family (not nude girls, as is common in the category), with selected information and entertainment articles, and straight educational and utility articles, with practical issues and 'hands on' tips-. The price was 50 cents of Nuevo Sol, while "El Comercio" cost 2 Nuevos Soles).

Results

In Lima, average annual readership went from 1.95 million (2000) to 5,15 million (2010), accounting 'El Trome' for 2.95 million readers, becoming the newspaper with more sales worldwide, among Spanish media.

Yaqu Soluciones (Peru, Utility and Construction)

Company Background

Yaqu Soluciones (YS) was founded in 1999 and its main activity was to sell water tanks and other systems related to water supply. In 2003 YS decided to offer those products and systems to low-income consumers, piloting projects at shanty towns in the Peruvian departments of Lima and Ancash, with support from the Fund for the Americas and the NGO Being.

Consumer Needs and Problem

There is a lack of water supply and sanitary facilities (neither piped water nor public sewage network available), and a need of additional cleaning of waste.

Wrong Assumption

Low-income Peruvians don't appreciate a toilet service like high-income customers do; cesspool or other common solutions are enough for them, and they are not willing to pay for such a more practical system.

Value Proposition

A water supply system, with a sink, shower and toilet, was developed using a digester and a water tank, for areas where regular supply is via a delivery truck and toilet service is not available. The complete system costs around US\$ 1,090.

Results

In years 2004 and 2006, YS won the prestigious award "Creatividad Empresarial", for their creative systems. However, they have just focused on very small niches, lacking a good financing system.

Crosland (Peru, Motorbikes)

Company Background

Founded in 1962, Crosland imported diesel Rolls Royce engines for boats operating in the fishing industry, as well as pumping equipment and power generators. They also manufactured alternators, which were applied to generators

and hydroelectric plants. In 1992, Crosland started importing 3-wheelers motorbikes⁴, but they didn't know how to sell that vehicles.

Consumer Needs

There was an opportunity to provide efficient and cheap transport solutions for low-income people living in places not easily accessible. Regarding the 3-wheeler's owners, the primary need is to make some profits.

Wrong Assumption

3-wheelers could be sold only through a formal distribution network (exclusive distributors).

Value Proposition

Crosland maximizes the value of the Bajaj 3-wheeler, as an efficient transportation alternative, with a more powerful engine, lower parts costs, better durability and better public preference than competitor's products. The price is ranged between US\$ 3,000-3,500 per unit. They started using informal distributors, whom are very close to the potential clients and work with a very low margin. Regarding the service component, Crosland developed 120 sales outlets, 350 spare parts agents, and 160 authorized service centers, continually training the network and creating a spare parts loyalty program, with points and prizes.

Results

In 2010, Crosland leads the 3-wheeler market, with the brand Bajaj, with more than 18,000 units a year, reaching a 25% of market share.

Banco de Antigua (Guatemala, Banking)

Company Background

Banco de Antigua (BA) was founded in 1997, and through commercial and corporate banking, it was focused mostly in medium and high income people. In 2008 BA was acquired by Canadian banking group Scotiabank, turning it into a more solid institution, with higher expansion opportunities. That allowed BA to focus in other segments and consumers in Guatemala.

Wrong Assumption

Since low-income consumers don't deal with banks, it will be almost impossible to reach them.

Needs and Problem

In 2008, BA executives noticed that low-income entrepreneurs and consumers, first of all, want to progress, and since they don't have time, they don't visit banking offices. Traditional banks in Guatemala offered long credit validation processes, mostly at the banks facilities. On the other hand, for low-income Guatemalans, it was difficult to demonstrate the existence of sources of income, since they live under informality.

Value Proposition

BA invested on updating their technological platform and training their personnel, to offer short processes and better accessibility, bringing credits without collaterals or guarantee. BA re-formulated their processes, including their recruitment and training process, creating a sales force with a strong focus on autonomy, speediness and customer service.

Results

BA has been positioned as one of the leaders in consumer finance and micro lending, with 56% of their portfolio composed by small business credits and 31% by consumption credits. From 2007 to 2010, the total number of credits was duplicated, reducing the risk exposure to the tenth. On December 2010, the firm Pacific Credit Rating rated BA with 'Grade of Investment', due to their credit risk control and all their solvency indexes, with top results among the sector.

Frogtek (Mexico, IT Services)

Company Background

Frogtek is a social enterprise founded in 2008 by people with strong technical background, focusing on developing smart-phone technology to improve the operations of micro-retail supply chains in Mexico and Colombia. They realized the opportunity when personnel from Frogtek's main investor, Women's World Bank, were making 'due diligences' with PDAs tools to store-keepers, for credit approvals, and they became aware of the opportunities among low-income business-to-business customers.

Wrong Assumption

Since good shopkeepers have memorized almost all their products' prices and are very customer oriented -they know their customers preferences, birthday, credit profiles, etc.- they are not interested on tools to improve the way they do business. On the other hand, they wouldn't afford paying for sophisticated technological devices.

Needs and Problem

The main need is business development. Most of these business-owners do not know their break-even sales level and cannot analyze an investment opportunity, nor optimize their purchasing decisions. All of these limitations combine to keep micro-retailers operating in a sub-optimal manner, reducing profits, limiting growth and making life more difficult for their suppliers. In addition, corporations selling through these channels don't have accurate information regarding sales and related factors, as they do have with supermarkets channels.

Value Proposition

The product is a point-of-sales software application that allows micro-retailers to record all store expenses and revenues directly on a mobile phone. An external bar code reader connected to the phone via a wireless connection allows micro-retailers to record transactions at the product level. In exchange, micro-retailers gain access to financial reporting, personalized recommendations and additional value-added services. The hardware and software is very accessible and the only required equipment than a smart-phone. The price is US \$400, which could be charged in 4 or 5 parts.

Results

Until now, Frogtek have been selling the product in a few Mexican markets with success. A recent survey with Frogtek's customers shows that they have improved their income, without stocking out of products anymore, and that they now know their margins, having also separated their personal income from the business's flows. Frogtek is now focusing on building a strong sales-force, and plans to sell systematic market research data from the micro-retail channel to large corporations.

Aliar (Colombia, Food Processing)

Company Background

Aliar was founded in 2007 as a firm dedicated to cultivate agricultural products, and to process and market high quality food, based on pork and related meats, following the highest standards of sanitation and hygiene, to bring a better nutrition to the great part of Colombians.

Consumer needs and problem

The key need to attend is nourishment, since 6% of Colombians suffered nutritional deficiencies, with no access to protein from meat nutritive feeding, with good taste and hygienically presented. In 2008, the per-capita consumption of meats was 42.5 Kg. in Colombia, 86 in Brazil and 81.3 in Chile. Regarding pork, Colombian per-capita consumption was 4.5 Kg., while Brazilian was 13.4 and Chilean 20.2. Besides, among Colombians, there are cultural barriers among pork's meat, viewed as a non-healthy, and associated with some kind of mortal bacteria.

Wrong Assumption

Since low-income Colombians don't appreciate pork, they wouldn't appreciate a high quality pork meat. It is almost impossible to bring accessible meat-processed products.

Value Proposition

Aliar launched a brand, calling it 'La Fazenda'. They use the whole pig, without missing any single part. In that way, they could offer more value for the whole animal, bringing quality at low prices. That let the consumer to tryout different products on different occasions and budgets, making it faster to familiarize with the meat of pork. Aliar strongly focused on a vertical integration, and under the concept 'from soil to the basket', invested on crop production of corn and soy, seed development, as well as in state-of-art facilities for pork feeding and treatment, and even started launching their own retail stores.

Results

Currently, Aliar sow more than 30,000 acres of corn and soy, has a grain treatment plant for more of 12,000 tons, and produce 2.700 pigs per week. La Fazenda is becoming a meaning of quality, and the per-capita consumption of pork meat in Colombia has started to grow, from 4.5 Kg. in 2008 to 6.7 Kg. in 2010.

Universidad Politécnica Salesiana (Ecuador, Education)

Company Background

The Universidad Politécnica Salesiana (UPS) was created in 1994 in Ecuador and, according with the policies for the Salesian⁵ presence in higher education in the world, offers to the youth a high quality formation, which helps the insertion to the labor market and motivate a responsible social commitment that surpasses the immediate market needs, and transcend to a necessary change to improve the quality of personal and social life. In 2002, the UPS authorities realized that in order to expand their presence among marginal areas in Ecuador, they should adopt an on-line education approach.

Consumer needs and problem

Low-income Ecuadoreans targeted by UPS were specially the most marginalized; as the indigenous and peasants who live in remote zones and couldn't access to high quality education.

Wrong Assumption

It is almost impossible to bring marginalized Ecuadoreans who live in remote territories, a good quality professional education. Furthermore, they don't have neither the interest nor the skills to participate via virtual sessions.

Value Proposition

UPS brings high quality education for low-income young Ecuadoreans, who have limited possibilities to achieve high value professional degrees. Through semi-virtual and pure on-line options, UPS aims to impact on self-improvement of their students, creating habits of reading and self-education. UPS value the multi-cultural nature of the indigenous, and offer loans with very flexible payment options.

Results

The students, in special the indigenous, were more proud of their ethnic origin and start viewing their relations with their families and the community in a more positive way. Currently, UPS offers 24 different pre-graduate and 18 post-graduate programs, and is positioned among the top ranked universities in Ecuador.

Hipermercados Líder (Chile, Retail)

Company Background

Líder is the supermarket and hyper-market chain from Chilean-North American group D&S, currently owned by Walmart. Líder's first retail format was created in 1995 as Ekono Líder, with basically large storehouses with low-cost products, sold by bulk. In 2001, D&S executives realized that they weren't serving correctly to low-income consumers, or as they called, 'emerging' consumers.

Consumer needs and problem

Housewives from low-income families struggle to save money by buying more with less, in order to take care of their families. Those ladies, as well as her families, need to find all their products in a whole place, saving time and money, but also need to be respected and appreciated while shopping.

Wrong assumption

Low-income consumers just look for low prices, not regarding on the service.

Value proposition

D&S launched Hiper Mercado Líder (HML), a Hyper-Market based not just on product variety, but on customer service and in-store support. The format has large stores (around 110,000 ft²), with a broad variety of products and sections -as grocery, home, electronics, appliances, fashion, hardware, toys, pharmacy, movie rentals and coffee shops-, with a strong financing system through its own credit card -Presto-, and with even insurance products -through Presto Insurance Broker-. They try to bring always more value for less, as by offering high quality perishable products. The credit process to get the Presto credit card is easy and fast accessed, with a friendly debt renegotiation. HML also has a Loyalty Program, under the name of 'My Club'.

Results

In 2010, HML has 67 stores and since 2005, Presto is the number one independent credit card -non from a bank- in Chile, reaching in 2009 more than 1.5 million cardholders. The loyalty program 'My Club' has more than 4 million members, who account for 75% of all the transactions. Thanks to HML, which accounts for more than 60% of D&S

sales, the group has more than 33% of market share, and Líder is recognized as the tenth brand among the 100 leading Chilean brands.

Edenor (Argentina, Energy)

Company Background

Edenor is the largest electricity distributor in Argentina in terms of number of customers and electricity sold (both in GWh and Pesos). The concession, with a 95-year term, covers the north of Buenos Aires (corresponding to 25% of the city) and the north-east of Greater Buenos Aires, representing Buenos Aires and Greater Buenos Aires, 40% of the Argentinean power market. In 2003, Edenor executives wanted to increase their pay electricity usage among low-income consumers.

Consumer Needs and Problem

After the Argentinean crisis in 2002, over 20% of the population was unemployed. For these people, food and health was the priority, with services such as electricity often not paid. Some low-income Argentinean inhabitants opt to 'hang', making their own connections to obtain the service at no cost. Such action is illegal and penalized, but was very common in this situation. Low-income consumers from Buenos Aires need electric fluid at low cost, with a way that they can control it.

Wrong Assumption

Low-income consumers in Buenos Aires prefer rather 'hanging' electricity instead of paying for it, and they don't value the cost of energy from the utility operator.

Value Proposition

A system with a prepaid-card-based power meter, which works as a 'dual-body' meter: part of the meter -installed within the house- has a keypad and a meter, where the customer enters the code that appears on the card, bought from a vending machine. The other part of the meter is installed outside the house, usually on an elevated line pole. The minimum amount to re-charge the card is one dollar.

Results

Edenor discovered the fact that there was willingness among low-income consumers to remain within the formal system and avoid breaking the law. The main financial benefit for Edenor was saving on costs associated with disconnecting bad debtors or illegal users. Even though this figure was not significant for the pilot test, it was very significant when projected for those 200,000 users with permanent difficulties. The company earned the confidence of low-income consumers: for 93% of their customers the prepaid system helped their household economy, for 52% the system was very good, and for 71%, purchasing electricity in installments was very convenient.

Key Findings

By extensively reviewing the abovementioned cases, it can be concluded that there is always a strong presence of the *wrong assumption*, which is connected to the needs and problems of the low-income consumers. However, in the decision making phase, when the company executives are studying the opportunity and have not yet decided to make the incursion, there is always an *underlying factor*, which is strongly related with the way low-income consumers actually will react while interacting with the product or service. We summarize the ten cases in Table 1, which shows such connection of those underlying factors with the needs. If we don't think of the low-income consumers as second-class consumers, and see on them the same aspirations and needs as more wealthy consumers

have, we could tailor a more powerful value proposition, in connection with the firm's core competences. The key issue is that BoP consumers want to be treated as persons, as any of us want. If we see persons instead of just consumers, then the energy, commitment and resources a firm employs on that business endeavors will have an extra driver, since we need to make a profit, but serving more.

TABLE 1: ANALYSIS OF THE TEN FIRMS

Company	Wrong Assumption about BOP consumers / markets	Key Needs & Consumer Drivers	Underlying Factor	Key attributes on Value Proposition
Global Alimentos	"They couldn't value high quality cereals" "Less product isn't enough"	Nourishment, Taste	"They also value their time" "Bags are as good as boxes"	Package format, Size, Variety
El Trome	"Just want entertainment, with empty content"	More for less, Information, Utility	"They appreciate a newspaper that they could share with the family"	Hand-on tips, straight style
Crosland	"They would just buy from formal distributors"	Progress, transportation	"There is people with not capital but willing to rent the 3-wheelers"	Customer service, financing system
Yaqu Soluciones	"Don't appreciate a piped-water and sewage service like high-income customers do"	Water supply and sanitary facilities	"They gain social respect"	All-in-one solution
Banco de Antigua	"Can't be reached, at a reasonable cost"	Progress	"They want to be respected"	Quick credit approval, customer service
Frogtec	"Don't appreciate technology support"	Progress	"They quickly adapt to technology"	No hardware required (just mobile phone)
Aliar	"Couldn't afford a high protein meat"	Nourishment, Taste	"They start tasting pork with more frequency"	Hygienic, Variety
Universidad Politécnica Salesiana	"Can't be educated" "Can't use technology"	Progress	"They reinforced their ethnic origin"	On-line, Academic excellence
Hipermerc. Líder	"Just want to buy cheap"	More for less, Self respect	"They value their time and want to be respected"	Financing, Services
Edenor	"It doesn't matter how cheap we can go regarding the electricity cost, since they could always steal it"	Accessible electricity	"They don't want to steal electricity"	Flexible pre-paid card

Limitations of the Study and Future Research

Although this research provides relevant and interesting insights to understanding the role of firms in venturing into BoP markets, it is important to recognize the limitations associated with the study. From the methodological point of view, the framework is a theoretical research and should be validated with empirical data, with quantitative analysis.

Abstract

The University of the Philippines Mindanao and Curtin University have been organising small-scale vegetable farmers in Mindanao into cluster marketing groups to improve their access to markets and returns from the sale of their vegetable products using the 8-Step Clustering Approach for Agroenterprise Development developed by the Catholic Relief Services (Philippines). This paper reports on an action research investigation with around 30 marketing clusters. Cluster marketing has led to: better and wider market access, improved prices, reduced costs, improved human capital and social capital, and higher incomes. However, the current process may not lead to sustainable cluster marketing without support and may lead to dependency. This paper discusses strategies to overcome key challenges identified and deficiencies in the current process and suggests changes to the 8-step process so that it may improve the chances of cluster success and sustainability.

Introduction

Smallholder vegetable farmers in the Philippines struggle to compete in an increasingly globalised environment, particularly with the entry of the Philippines and China into the World Trade Organisation and the increasing sales of vegetables through supermarkets rather than traditional wet markets. While the presence of high value chains would seemingly provide an opportunity for smallholder farmers, the need for consistency of supply, quality assurance and traceability are serious hurdles to their participation. Traditional supply chains operate in an environment of diseconomies of size, poor infrastructure, poor access to inputs, credit and information, and high transaction costs (Murray-Prior, 2008). In these markets there is little incentive or ability to provide market signals for quality and consequently quality is poor and highly variable. In the past, smallholder farmers in the Philippines were organised into cooperatives, but many of these cooperatives were unsuccessful (Murray-Prior, 2008). Many of these failures appear to be related to lack of a comparative advantage for the cooperative over alternative marketing arrangements and difficulties in maintaining trust in the cooperative and its management. However, poverty, illiteracy, low status and low power also make it difficult for smallholder farmers to collaborate successfully.

The University of the Philippines Mindanao and Curtin University (Perth, Western Australia) have been organising small-scale farmers in Mindanao into cluster marketing groups to improve their access to markets and returns from the sale of their vegetable products. Cluster marketing groups are formed by growers who commit to work together to market their product (Montiflor et al., 2008). Clusters are either area based, where neighbouring

farmers combine to market one or more vegetables; or commodity based, where farmers agree to plant a particular vegetable crop and combine their product for sale. The clustering has been based on the 8-Step Clustering Approach to Agro-enterprise Development for Small Farmers developed by the Catholic Relief Services (CRS-Philippines, 2007). This paper reports on some initial findings of an action research investigation funded by the Australian Centre for International Agricultural Research that seeks to overcome the key challenges for cluster marketing groups and suggest changes to enhance the 8-step process to improve the chances of cluster success and sustainability.

Method

The methodology used to investigate the CRS clustering approach involves an integrated Participative Action Learning and Action Research Process with over 30 cluster marketing groups in Mindanao in Davao City and the provinces of Bukidnon and South Cotabato. The CRS Clustering Approach to Agroenterprise Development is referred to as the 8-step clustering approach (CRS-Philippines, 2007), the 8 steps of which are summarised in Fig. 1.

It begins with identifying the project site, building partnerships with farmers and other stakeholders such as local businesses, local government and NGOs and forming a working group. Step 2 is a participatory process in which the working group identifies the community's resources, products, and production and marketing practices and then decides on the product or products that will be the focus of the cluster group. Step 3 involves the working group undertaking a market chain study. Farmers are trained in market chain studies and conduct market visits in which they develop understanding of the chains for their selected products and conduct initial negotiations with potential buyers.

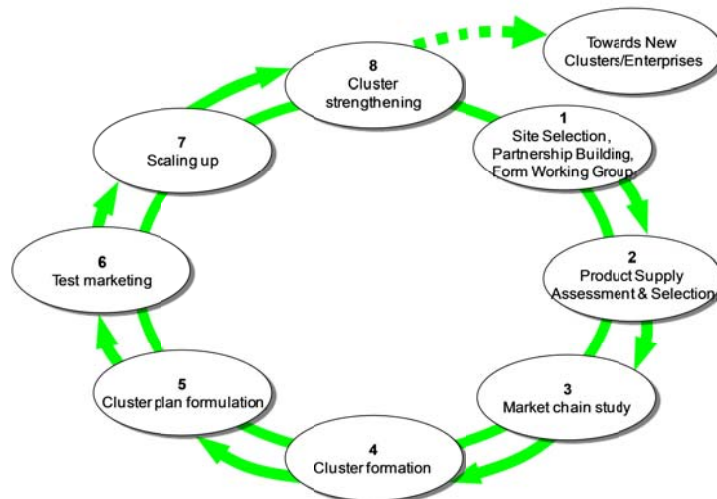

FIG. 1: 8-STEP PROCESS OF THE CLUSTERING APPROACH TO AGROENTERPRISE DEVELOPMENT

Step 4 is the cluster formation phase, in which interested farmers are invited to participate and are provided an orientation on what has been found from the previous phases. The cluster is then formed, leaders selected and a basic cluster agreement and objectives are agreed. Step 5, or cluster plan formulation involves planning a planting and harvest calendar for the products of the cluster and deciding on the test marketing plan which consolidates market, supply, management and financial plans. The test marketing activities of Step 6 involve at least four trial product deliveries. After each, meetings are held to assess performance and adjust the plan to enable improvements. After the test markets are judged successful, the next Stage 7 involves planning and conducting a scaling up process. Readiness for scaling up is appraised against criteria that assess cluster willingness, level of product supply, market performance, management performance and financial trends for the cluster. Scaling up involves producing more products or additional products to supply the existing markets or to more diversified markets. The final step of cluster strengthening involves undertaking activities that expand cluster capacity and networks with other clusters

and businesses. The objective is to improve cluster maturity. Detailed information about the CRS clustering approach can be found in the booklet entitled 'The Clustering Approach to Agroenterprise Development for Small Farmers: The CRS-Philippines Experience' (CRS-Philippines, 2007).

Action Research on the CRS Clustering Approach

The University of the Philippines Mindanao through its UP Strategic Research and Management Foundation (Upstream) has taken over some existing CRS clusters and facilitated the establishment of additional cluster marketing groups in Davao city, Bukidnon and South Cotabato. These groups have been taken through the CRS 8-step process by field officers from Upstream, which is essentially a Participative Action Learning process for farmers. At the same time, research officers from the University of the Philippines Mindanao are involved in an Action Research process which documents each group's activities and investigates issues as they arise; such as problems with and solutions to the financing issue and changes and improvements to the clustering process. Surveys have been conducted of farm household resources and production activities and the relationships between farmers and wholesalers and traders, farmers and the cluster, clusters and traders, wholesalers and institutional markets and back the other way. Case study reports are prepared on each cluster and on selected farmers within the clusters. Findings from these investigations, discussions between the researchers and field officers and evidence from the literature and experiences of the researchers, field officers and farmers are used to identify and evaluate changes to the clustering activities and process.

This combined Participative Action Learning and Action Research process has identified that an enhanced clustering process has to incorporate processes that overcome issues such as: input financing arrangements to replace loans from informal moneylenders and traders; risks associated with production failures; maintaining relationships with buyers; and building group resilience and independence so that donor agencies have an exit strategy.

What to do about the input financing problem

Smallholder farmers in the Philippines and elsewhere have limited or no access to the formal lending sector. Thus they have to rely on informal moneylenders including local traders, landlords, commodity wholesalers and other village moneylenders (Robinson, 2001; Llanto, 2007). These loans are often at rates well above those charged by commercial microfinance institutions (Robinson, 2001; Llanto, 2007) because the markets sometimes have characteristics of monopolistic competition (Robinson, 2001). However, when smallholder farmers market their produce through a cluster marketing group, such as those created using the CRS 8-step clustering process, the farmers may not have access to loans from local traders and commodity wholesalers. These lenders often loan money for inputs on the expectation that they will be able to buy and market the product at prices which are advantageous to them and sometimes threaten smallholders with not lending money or buying their product if they sell through a cluster. This appears to be a fairly common phenomenon (Llanto, 2007).

Some authors (Llanto, 2007; Campaigne & Rausch, 2010) suggest that lending to farmers who are connected to an integrated supply chain is more feasible. Some of the cluster groups from the Bukidnon and South Cotabato provinces have had access to finance through microfinance institutions, partly because they are organised groups. However, their outcomes have been mixed (Axalan et al., 2010; Real et al., 2010). When production fails due to weather or disease problems, farmers who have loans from microfinance institutions face additional burdens which can affect both the viability of the cluster and its marketing arrangements and also lead to default on repayments by farmers. In Bukidnon (Real et al., 2010), squash, sweet pepper and bitter melon clusters were unable to meet their contractual obligations to deliver produce due to disease and weather problems. Since the loans had been obtained because the farmers were members of a cluster marketing group, some clusters had farmers who withdrew because they expected they would be liable to repay the loans of cluster members. On the other hand, members of a sweet pepper cluster in South Cotabato who received loans from a microfinance institution had fewer problems, partly because they did not have the same level of production failures, but also because of the way in which their loans were structured (Axalan et al., 2010). Other clusters from the Davao City area do not have access to microfinance and therefore have to self finance or obtain some funding from informal money lenders.

In light of the literature on microfinance, there are some possible lessons to be drawn from these examples. Firstly, microfinance loans can increase the risk to farmers because they lead to greater investment in inputs, which may not be recovered if production problems occur. Often farmers involved in new cluster marketing groups are involved in learning about and implementing many new and interrelated behaviours. Adopting new behaviours and crops is inherently risky, but in this case farmers are adopting new marketing arrangements, often growing new or expanded areas of crops, and are learning to cooperate to produce, market and deliver their crop to a particular market at the particular time. If farmers in the early stages of the clustering are provided with loans, the combination of these risks can leave farmers and clusters in a perilous financial position, as happened to the clusters in Bukidnon.

Secondly, in one case the loan was linked to a particular crop and marketing arrangement (Real et al., 2010). The microfinance institution lent the money on the expectation that the crop would be sold through a particular agent who would deduct loan repayments and pay the farmers the remaining money. When production difficulties arose, the agent didn't accept the clusters' product and hence repayments were not made. Since the repayments had been linked to a particular crop and payment arrangement, the farmers did not feel as obligated to repay from other sources.

Thirdly, some of the loans made to clusters in the Bukidnon province were based on overoptimistic assumptions about yields and prices (Real et al., 2010). As indicated above, in the early stages of clustering, farmers are learning and adopting many new skills and behaviours and the likelihood of failure is high. Consequently, budgeting for loans must be conservative to allow for the level of production and price risk. This decreases the risk of over indebtedness. Also our experience is that loans should only be made for physical inputs such as seed, fertiliser and pesticides and that the farmers need to finance part of the crop out of their own resources. Hermes and Lensink (2007) suggest that credit rationing can increase the likelihood of loan repayment, which is consistent with this view. In addition, there is some evidence from our clusters that loans are only necessary for crops that are more expensive to grow and not for all crops, at least in the initial trial stages of the process. As farmers gain experience with crops and cluster marketing and expand production, loans may become more necessary.

Fourthly, a comparison of the lending strategies followed by the microfinance institutions in Bukidnon and South Cotabato and their successes and failures supports some of the principles underlying the Grameen Bank and the Association for Social Advancement methods (Llanto, 2007). These include compulsory savings or capital build-up, progressively larger loans based on demonstrated competence, and financial education for loan recipients in budgeting, saving and managing debt (Llanto, 2007; Cohen, 2010).

Finally, donor agencies need to be careful when promoting and supporting loans to cluster marketing groups, because it can lead to the impression that the loans are a gift. Farmers are used to charitable institutions providing gifts and even where the loan is provided by a microfinance institution, if it is linked to the support of the donor agency for the cluster marketing group, it can be perceived as a handout. Our experience with loans to the Bukidnon clusters suggests this was a contributing factor to problems with repayment by at least some farmers.

Risks associated with production failures

Vegetable farming in the Philippines can be a risky business with production quantity and quality varying widely due to climatic conditions and pest and disease outbreaks. Dry periods can lead to poor crop emergence and growth, while wet periods can dramatically affect flowering, product quality and yield. Wet weather also intensifies fungal diseases, which can increase costs of control and/or dramatically reduce yields. Similarly, poor seed selection can result in disease outbreaks (as occurred for the bitter gourd cluster), while pest and disease outbreaks can occur as a result of climatic conditions, poor rotations or poor crop hygiene. These variations in yield and quality not only reduce farmer returns, but also make it more difficult for clusters to be consistent suppliers to institutional markets.

One strategy to manage the risk is to adopt lower input and lower yield production systems that require lower financial outlays and reduce yield variability. Many clusters are in relatively remote areas, so imported fertilisers and pesticides are expensive and difficult to obtain reliably. Consequently farmers have been investigating use of organic and 'natural farming' (Jensen et al., 2006) systems. These systems use local inputs, such as organic fertilisers, pesticides and composts. Further investigation is needed to see what effects these systems have on levels and variability of yield and quality.

Another strategy is for the cluster to only commit a proportion of their expected yield to a particular buyer, particularly if this is an institutional buyer who wants consistent supply. A common figure is 60% of a conservative estimate of yield, although this varies depending on the crop and the number of buyers. This strategy has additional advantages in that farmers are then free to sell their surplus product to other buyers, particularly if there is a spike in prices. They can also maintain their relationships with traditional buyers who provide other services such as credit. It also spreads their risk if one of their buyers defaults or refuses to accept product for whatever reason.

Maintaining relationships with buyers

Modern value chains have mostly been developed in advanced economies and are therefore suited to medium to large farmers because they require consistent quantity and quality of supply and processes for ensuring food safety. Smallholder farmers in the Philippines have little understanding of these markets because they have traditionally only dealt with local traders, rarely visit the wet markets where most of their product ends up, and almost never interact with institutional markets associated with value chains. The clustering process tries to overcome this deficiency by training farmers to conduct their own market chain studies, including talking to buyers from the various markets. Farmers are also taught negotiating skills, which improves their confidence and ability to negotiate prices, volume and quality with institutional and other buyers. However, smallholder farmers generally take some time to develop their knowledge of market operations and requirements and this can create misunderstanding and conflict between the cluster and buyers - especially institutional buyers. Conversely, institutional buyers often come from cities and have little understanding of the constraints faced by smallholder farmers which exacerbates misunderstanding and conflicts with smallholder farmers. This combination has led to the breakdown in relationships between buyers and clusters and smallholder farmers.

One additional strategy to reduce the effect of this issue that forms part of the clustering process is the series of test marketing activities that are conducted as part of Step 6. After each trial, the performance of the clusters trial product deliveries is evaluated in terms of the quantity and quality of the product that was delivered versus what was planned. However, there can still be misunderstandings between the cluster and their buyer and sometimes the donor agency has to facilitate a discussion about the causes of the misunderstanding. Sometimes the problem is with the farmers, but equally sometimes the problem is with the buyer who can try to take advantage of the farmers, possibly because that is what they have been used to doing.

This is a learning process for both sides and it appears that in some cases it requires a couple of years, including periods where the cluster sells to other buyers, before a sustainable relationship is achieved. In other situations, a sustainable relationship may not be possible due to a whole range of reasons. The donor agency that is facilitating this process needs to have patience and to act as an honest broker by not taking sides and attempting to identify the root causes of the problem. It is important for farmers to be involved in discussions and negotiations with the institutional buyers as this is the only way in which understanding and mutual respect can be gained and sustained. One method that has helped is for the buyer to be taken to the farms where the product is grown to give them an appreciation of some of the difficulties faced by the farmers in getting a quality product to market.

Enhancing the clustering process

Cooperatives and cooperative marketing arrangements have a poor record in the Philippines. Many of these cooperatives were set up for political reasons such as agricultural development, pacification of revolutionary activities and distribution of subsidised inputs. Most failed when institutional supports were removed. Outside support can enhance the chances of success of smallholder cooperatives (Murray-Prior, 2007), but it can encourage dependency which means the cooperatives are not sustainable once external support is withdrawn (Shigetomi, 2006). If cluster marketing is to be a successful alternative, processes have to be developed that develop resilience in the groups so that they can survive with minimal external support. This also implies building in an exit strategy to the clustering approach to agroenterprise development. In this section we discuss this issue with a view to hypothesising a framework for the clustering approach to agroenterprise development that will develop resilience and build in an

exit strategy for any donor agency using the process. It is based on our experiences with the CRS 8-step process, other experiences with collaborative marketing groups and the literature on this issue.

Two key factors important to the success of cluster marketing arrangements are a comparative advantage over alternative marketing structures and trust in their fellow cluster members and its management (Murray-Prior, 2007). The clustering approach addresses the first of these issues through its focus on developing a marketing plan and its test marketing activities. The group is unlikely to form unless they see a comparative advantage for cluster marketing over their existing marketing arrangements. The second issue is addressed in a number of ways (CRS-Philippines, 2007). Firstly, the process is participatory and transparent and considerable effort is devoted to activities including involving cluster members in conducting the market chain investigations and development of the production plans, and keeping records on deliveries and payments that are accessible to all members. The cluster agreement, cluster enterprise plan, review of test marketing activities and business policies and systems are all developed by members. Regular meetings of the cluster are a feature and the leadership team is elected by the members. Numbers in each cluster are normally kept to 15 or less so that trust can be maintained through group pressure. In addition, the clusters and their leaders receive training in group processes and leadership. The evidence from the trust measures collected by the research officers indicate that currently cluster members have high levels of trust in their cluster.

While comparative advantage and trust are essential to the successful operations of cluster marketing groups they are not sufficient, nor are they guaranteed in the long run. We propose a framework that builds on and enhances the processes outlined in the CRS 8-step process. It incorporates three phases: Phase 1 - Establishment; Phase 2 - Building Resilience; and Phase 3 – Implement an Exit Strategy. Each of these phases is a type of Participatory Action Learning cycle and contains a series of steps that may be repeated depending on the maturity of the group.

Phase 1: Establishment

This phase essentially follows the first six steps of the CRS process (CRS – Philippines, 2007) with minor modifications and normally takes from 1 to 2 years. In Step 1 (Site selection, partnership building and formation of working group), greater emphasis needs to be put on investigating input financing arrangements, both the existing informal lending arrangements and potential microfinance lenders if farmers are not involved with them already. Orientation needs to be provided on saving, loans and financing alternatives in addition to the orientation on marketing that is currently provided.

In Step 2 (Product supply assessment and product selection), potential crops and products should be considered rather than decided on. This product selection is to be re-evaluated in Step 3 (Market chain study) which is expanded to include an investigation of input requirements for particular crops, potential sources and costs of those inputs and the ability of farmers to finance these inputs. At this stage financial institutions may be invited to contribute to the discussion as part of the consideration of the risks associated with growing and financing potential crops.

Similarly in Step 4 (Cluster formation), the normal process of orientation on marketing basics and clustering needs to be broadened to include briefing on production issues, sources of inputs and financing implications of particular crops. At this stage it should be emphasised that individuals will have to self finance, or arrange their own loans through the finance institution, and that financing is not the responsibility of the cluster. In this context it is interesting that there is evidence in the literature that individual-based lending is more profitable and that the Grameen Bank and BankSol (from Bolivia) are now using individual-based loans (Hermes & Lensink, 2007). Step 5 (Cluster plan formulation) would then proceed essentially as normal. The Test marketing step (Step 6) would go through a number of stages including:

- Assessing cluster commitment and capability of members
- Identify information and training needs and conduct trainings to overcome deficiencies
- Evaluate buyers and establish a good working relationship
- Make refinements to agroenterprise plan.

The next step is a linking step to Phase 2 (Building Resilience) in which the group decides whether to stop or continue deliveries and whether it is ready for scaling up. The criteria for these have been outlined in a table on

page 122 of CRS-Philippines (2007) and the group and the group facilitators use these criteria to decide whether they are ready for the next phase.

Phase 2: Building Resilience

The focus of Phase 2 is essentially cluster strengthening and capacity building – an expansion of Step 8 (Cluster strengthening) in the CRS process. In our experience, groups will often go through periods of decline in activity, often caused by production or marketing problems. Marketing problems may sometimes be caused by a lack of capacity and immaturity in the cluster, but can also be caused by buyers not paying or complying with their agreements. For instance, some problems experienced by cluster groups with key markets include buyers' cheques not being honoured, buyers who won't accept their product because of problems with their processing activities and buyers who try to decrease prices or change quality specifications without consultation with the farmers. Problems like these have the potential to cause a collapse of the cluster, but equally if the donor agency is able to support the cluster in developing strategies to deal with these problems, the clusters develop confidence in their own abilities and are in a better position to deal with future issues without assistance. Kaganzai et al. (2009) argue that this 'repair and maintenance' support from donor agencies may be necessary in the scaling up phase of collaborative marketing groups. In fact, it could be argued that one of two of these difficult periods is part of the process of developing resilience. Production problems have been overcome by approaches including establishing links with seed companies to provide better quality seed and changing production practices with the assistance of local government advisers. Marketing problems have been solved by farmers going out and identifying new buyers and markets and subsequently diversifying their markets. In this Phase the role of the donor agency is to provide assistance when the cluster is struggling, to help enhance their networks and to build capacity. Less direct assistance is provided and the group is encouraged to draw on their own resources. The steps in this process are essentially an adaptation of the steps in the Establishment Phase. They include:

1. Revisit the product supply assessment step and assess training a support needs to produce the product.
2. Undertake a further market chain study with a view to assessing their performance in meeting their markets' needs, identifying additional markets and selecting the focal market chains. At the same time the other elements of the supply chain need to be reviewed including input supply, financing, logistics and packaging. Once again training and support needs are identified.
3. Review cluster membership and structures. This involves assessing commitment of existing members, recruiting new members and perhaps splitting the cluster to create additional clusters. This is also an appropriate time for the group to investigate acquiring a legal status. A mature group will be legally registered and will have appropriate management and control procedures in place.
4. Assess information, training and support needs and conduct trainings and capacity building activities to meet these needs. The donor agency will have an important role here because of their familiarity with the knowledge and skills required to enhance member and leader capacities and their links to other training organisations.
5. Formulate cluster and operational plans.
6. Conduct and review marketing activities.

One issue that has been identified for some institutional markets is that clusters have to combine their product so they are able to supply the volume and variety of products required. Clusters in the Davao region have established a federation to supply one of these markets. Currently, they have a comparative advantage over other suppliers to this market and are receiving higher prices for their product. However, the issue for the future is how to structure and fund this arrangement. The current model of clusters with 15 or less members minimises the problems with trust in the cluster, but combining clusters creates a much larger group with members from different areas and will potentially create jealousies and a lack of trust unless transparency is maintained. These larger groups 'are likely to have governance and cooperation problems ... [because their] ... members are smallholder farmers who lack the literacy, numeracy and management skills to govern a complex organisation' (Murray-Prior, 2008, p. 17). The other issue is how to fund this structure. Since the small clusters do not buy the product and collect relatively small service fees from their members, corrupt practices are less likely to arise and become a problem. However, the marketing

managers for the combined cluster federation will have a greater opportunity and incentive to be involved in corrupt practices, which if they occur, will probably lead to the collapse of the arrangement. Further investigation of this issue is required.

Phase 3: Implementing an Exit Strategy

Sustainability of cluster marketing arrangements is problematic as in the past many such groups have failed when the donor agency withdraws. Some contributors to this problem include: donor agencies taking control of marketing and hence replacing the middleman; donor agencies providing too many gifts and creating a 'handout mentality'; competition between donor agencies; donor agencies focussing on 'favourite' groups who have a 'reputation' for success; and a failure of donor agencies to develop exit strategies. Markelova and Mwangi (2010) call for donor agencies to develop viable exit strategies from the onset of their project in order to lessen dependency issues and that capacity building and effective participation are important parts of this process. This has been one reason for the decision to emphasise the Building Resilience and Exit Strategy phases in the revision of the CRS process. The Exit Strategy phase is expected to be implemented in years 4 or 5.

The CRS clustering process already includes a number of criteria for assessing cluster maturity, so the focus here is on how these can be incorporated into a process for implementing an exit strategy for the donor agency. These criteria are summarised in a matrix on page 140 of CRS-Philippines (2007), with maturity indicators for: organisational development, market position, supply capacity, business management capacity and financial resources. Minor refinements could be made to these indicators but are not discussed here. Similarly levels of performance required to proceed to graduation have been identified, but are also too lengthy to report here. The normal activities of the cluster marketing group outlined previously would continue, but would be augmented by specific steps for this phase which could include:

1. Workshop to assess maturity for graduation or exit of the donor agency. This would involve the farmers in rating their group on the maturity indicators and comparing and discussing their ratings with the donor agency team. Initially it is expected that the groups would not achieve high enough levels to graduate and the workshop would be used to identify strengths and areas for improvements along with planning for how these might be overcome.
2. Training in business planning and development of business plan. Each cluster or association of clusters would be expected to develop its own business plan as part of the exit strategy. Training in business planning would be the beginning of this process which would be facilitated by the donor agency.
3. Strengthen links with supporting institutions. While the donor agency should exit from its intensive support role, any farmer group will still need support or links with research and extension agencies, training agencies, microfinance institutions and markets. Similarly, formal and informal links with other clusters will be beneficial and should be encouraged. This is also an appropriate time to discuss the exit strategies with other donor and development agencies in the area, with a particular focus on not creating a dependency (as suggested by Markelova and Mwangi, 2010), but still providing an opportunity for capacity building in other areas, e.g. Landcare.
4. Group formulates business plan for their afterlife.
5. Participatory evaluation of the clustering process, their involvement in the process and the donor agency performance. Preferably this would be facilitated by an independent agency so that the results would be less biased and the donor agency could learn more from the experience.
6. Organise a graduation activity. This activity would signify the completion of the project and provide acknowledgement of the cluster groups achievements.

It should be made clear to the farmers from the beginning of the establishment phase that the donor agency will be providing support for a finite amount of time and that the cluster marketing group will need to build its resilience and become self sustaining.

Conclusions

Many donor agency development activities fail because they do not focus on an exit strategy from the initial planning stages. The CRS 8-step clustering process is expanded to three phases: Establishment, Building resilience, and Implementing an exit strategy so that the focus will be on the cluster marketing group becoming self sustaining. The process also needs to address access to finance from the formal lending sector, but this must be handled with care as it can increase risks for farmers and the donor agency must ensure that farmers do not get the perception that the loans are a gift. Building long-term relationships between cluster marketing groups and institutional buyers in the Philippines is a difficult process. A donor agency will have to invest considerable time and effort in facilitating this process and organising activities that build capacity and relationships between the smallholder farmers and institutional buyers, so that the cluster can undertake these activities after the donor agency exits.

India - US Knowledge Initiatives on Agriculture - A Way Ahead

RaveeshAgarwal, raveesh15@rediffmail.com
CCS University, Meerut, India
Monica Thiel, mt2652@gmail.com
United States Department of Agriculture (USDA), USA

Abstract

Agricultural education needs to be globally competitive. The true initiatives related to it by any government not only address the need of emerging market, society and country but also for the whole world with all the promises for a better today and tomorrow. This paper attempts to understand the important role played by the formal sector engaged in designing and implementing knowledge initiatives for agriculture in the US and focuses on various initiatives taken by the Indian and the US government. In the changed context, these initiatives focus on the challenges and designs a sustainable agriculture education framework to attain excellence in agricultural education, enhance employability of the graduates, develop human resources to fulfill commitments towards the millennium development goals, and improve the quality of life through sustainable rural development including innovative agricultural extension, and agri-business programs. Finally recommendations are given by researchers to gain the competitive advantages.

Key Words: Agriculture, Competitive advantage, Education, Knowledge, Sustainability

Introduction

Agriculture is the backbone of the Indian economy. As we enter the new millennium, the entire Indian economy is still being sustained by agriculture, which is the mainstay of the villages. Agriculture for India represents India's sovereignty, India's emergence as an independent country, and as a core component of our claims to a Super Power status. Yes, India is an agriculture power. Agriculture is a way of life, a tradition, which, for centuries, has shaped the thought, the outlook, the culture and the economic life of the people of India. Agriculture, therefore, is and will continue to be central to all strategies for planned socio-economic development of the country. But the socio-economic and agro-ecological situations with regard to Indian and American farming are vastly different. In the US model of agriculture, less than 2-3% of the American population depends on farming whereas in India, approximately 65% of our population continues to depend on farming and allied activities for their very survival. In India, agriculture is a way of life connected closely with knowledge evolved over centuries of experiential learning from nature, connected deeply with the culture of Indian peoples and their livelihoods. On the other hand, in the US, agriculture is an industry that is driven mostly by big agribusiness corporations. For the sustainable development of agriculture in any economy whether it is the US or India, knowledge and information is necessary for advancing the agricultural sector and sustainable agriculture. How sustainable agricultural development is defined will determine the capacity of education required for sustainable agricultural development. Historically, agricultural development is defined within rural development, human health and wellness, and farming. This paper focuses on various initiatives to promote agricultural education by the Indian and US government with recommendations by researchers to gain the competitive advantages.

Overview of Agricultural Knowledge Initiatives in India

The Indian government has taken several steps to ameliorate the conditions of farmers particularly small and marginal farmers. With vision is "to link India's small farmers to global supply chains in agriculture, so that nobody will go hungry in the country". The Indian government has also conceptualized several schemes for the benefit of the agrarian community and proved that the economy is capable of propelling itself at a much faster

rate if unnecessary barriers are removed. Key agricultural knowledge initiatives in India can be broadly classified into three categories:

- Government initiatives
- Government initiatives with other countries
- Private sector initiatives and Non-Government Organizations (NGOs) initiatives

Indian Government Initiatives

India's new agriculture policy seeks to promote technically sound, economically viable, environmentally non-degrading, and socially acceptable use of country's natural resources such as land, water and genetic endowment to promote sustainable development of agriculture. In order to sustain these efforts and to keep the momentum, some of these initiatives, programs, and schemes are related to Minimum Support Price, Investment in Agriculture, Credit Flow, Debt Waiver, National Food Security Mission, Rashtriya Krishi Vikas Yojna, Eastern India Initiative, Pulses and Oilseeds Villages, and National Horticulture Mission, etc.

In order to rejuvenate and reform existing agricultural extension support systems and to overcome systemic constraints being faced by the extension machinery in the country, Support to State Extension Programs for Extension Reforms scheme is under implementation in 591 rural districts of the country. The scheme has been recently strengthened to provide Specialist and Functionary Support at State, district, and Block levels and innovative support through a Farmer Friend (FF) at village level (one FF per 2 villages) to promote Farmer-to-Farmer learning. Around 10000 Farm Schools have already been set up. Besides this, Agriculture Clinics and Agriculture Business Centers (ACABC) schemes encourages setting up agriclinics and agribusiness centers by unemployed agriculture graduates. Under this scheme, 21579 agricultural graduates have been trained and 7667 agri-ventures have been set up. On the mass media front, tens of thousands of location specific agriculture related programs are telecast by Doordarshan Kendras and All India Radio every year. The Kisan Call Centers provides critical location specific information on a real time basis to the farming community through a toll-free, countrywide common number 1-800-180-1551. Kisan Knowledge Management System (KKMS) is being developed to provide instant information back up to the call centre agents while replying farmers' queries. Over 46 lakh calls have been received up to March 2010 through 25 KCCs located across the country.

Knowledge Incubator's Research in the area of Agriculture

There are various research institutes and universities in India that are imparting education to villagers through its various programs. Some of these research institutes and universities and their programs are as follows:

Indian Agriculture Research Institute

Initiatives are related to Crop improvement: Seed science and technology, Crop protection: agriculture chemicals, Entomology, Nematology, Plant pathology, Basic Sciences: Biochemistry, Microbiology, Nuclear research laboratory, and Plant physiology, Unit of simulation and informatics, Social sciences, and Agricultural economics.

Tamilnadu Agriculture University

Major Areas of Research are Weather, Soil, Water, Seed, Farm Enterprises, Nutrition, Post Harvest Technology, Bio Technology, Bio-Fuels, etc. Other areas are related to Dryland Agriculture, Watershed Management, Disaster Management, Integrated Farming, Organic Farming, Nutrition, Green Manuring, Bio Technology, Bio-Fuels, etc. Similarly there are various other initiatives to promote technologies related to Crop Production, Crop Protection, Crop Management, Seed Technologies, Bio Waste Management Technologies, Crop Improvement, Sustainable Agriculture, Organic Farming, Indigenous Farming, and other special technologies related to SRI-Systems of Rice Intensification, Precision Farming, Good Agricultural Practices, Good Laboratory Practices, and Good Manufacturing Practices, etc.

Anand Agriculture University

Various Initiatives in the area of Anubhav liquid bio- fertilizer, Anubhav Seeds and Seedlings, etc.

Chaudary Charan Singh Haryana Agriculture University (CCSHAU)

Crop hybrids and Varieties available with CCSHAU are High quality protein, baby corn and winter maize hybrids, Barley variety for malt quality, Guar varieties for industrial gum content, Commercialization of Medicinal crop varieties of mulahatti, isabgol, perwinkle&dhaincha, Male sterile lines, disease resistant hybrids of bajra and other crops, etc.

Jawaharlal Nehru Krishi Vishwa Vidyalaya

The initiatives are related to Basic Science: Physiological manipulations to break the yield barriers; Production of bio input from biodiversity, Genetic Potential Enhancement: Genetic enhancement of yield potential; Genetic stabilization of yields; Genetic improvement in input use efficiency; Plant biotechnology; Development of varieties of minor expoided vegetables (Kakora, Suran, Colosasia, Dolichus bean, winged bean etc.), Production System Development, Natural Resources and Environment Protection, Alternate Land Use System, Tree crop soil interaction studies, Agro techniques for vegetable cultivation and storage, Socio Economic Studies and Policy Research, Dynamic of socio economic changes and their impacts on technology dissemination, Agro technology generation for small and marginal farmers, etc.

Birsa Agriculture University

Steps in the area of Seed production: Breeder and foundation seed production of Rice, Wheat, Soybean and Groundnut etc as per need of Jharkhand state and eastern region, Enriched Vermicompost Production, etc.

Indian Government Initiatives with Other Countries

The Government of India places high priority on reducing poverty by raising agricultural productivity. Hence, policy makers in India took many initiatives in the form of tie ups with other countries to build a solid foundation for a highly productive, internationally competitive, and diversified agricultural sector. One of such initiative is “Indo-US Knowledge Initiative on Agricultural Research and Education.” The U.S.-India Agricultural Knowledge Initiative is helping Indian farmers improve marketing for their products, linking them with new technologies and extension and research facilities and helping them meet international standards for export. Some of the other efforts towards promotion of organic exports include attempts to collaborate with all the major organic importing countries.

Private sector Initiatives and Non-Government Organizations (NGOs) Initiatives

These initiatives are in the form of either taken individually by private sectors and NGOs or in the form of public-private partnership where the private sector can help identify research areas that have the potential for rapid commercialization, with a view to develop new and commercially viable technologies for agricultural advancement. There is a strong presence of Non-Government Organizations (NGOs) in India as active promoters of Organic farming in different agro-climatic regions. In India, the private sector is also recognizing its presence in the development of agriculture by providing education or through another measures. Wal-Mart, PepsiCo, and Tesco are just a few of the multinationals already betting on the country's ability to develop the as-yet unrealized potential of its farm sector. One of the steps taken by Indian Farmers Fertiliser Cooperative (IFFCO), a fertiliser producing and distribution cooperative, is planning to set up an institute at its plant in Paradeep in Orissa. In the proposed institute, farmers would be trained on best crop practices of cereals, pulses, oilseeds, vegetable, and horticultural crops etc. Similarly one of the major steps are taken by ITC. ITC's Agri Business Division, one of India's largest exporters of agricultural commodities, has conceived e-Choupal as a more efficient supply chain aimed at delivering value to its customers around the world on a sustainable basis.

The e-Choupal model has been specifically designed to tackle the challenges posed by the unique features of Indian agriculture, characterized by fragmented farms, weak infrastructure and the involvement of numerous intermediaries, among others. Launched in June 2000, 'e-Choupal', has already become the largest initiative among all Internet-based interventions in rural India. E-Choupal services today reach out to over 4 million farmers growing a range of crops such as soybean, coffee, wheat, rice, pulses, and shrimp in over 40,000 villages through 6500 kiosks across ten states (Madhya Pradesh, Haryana, Uttarakhand, Karnataka, Andhra Pradesh, Uttar Pradesh, Rajasthan, Maharashtra, Kerala and Tamil Nadu). E-Choupal also unshackles the potential of Indian farmers that have been trapped in a vicious cycle of low risk taking ability, low investment, low productivity, weak market orientation, low value addition, low margin, and low risk taking ability. Consequently, farmers and Indian agribusiness sectors became globally uncompetitive, despite rich & abundant natural resources.

Overview of Key Sustainable Agricultural Education Programs in the US

The United States Department of Agriculture's (USDA) Education and Research Alternative Farming Systems Information Center offers many training resources, publications, news feeds, education directory, and organizational links for farmers, ranchers, researchers, instructors, parents, and students to learn about sustainable agriculture (USDA Alternative Farming Systems Information Center Website). The USDA can prioritize agricultural farming research, education, and extension by emphasizing strategic participation and measurable accountability from the government, private sector, and local rural communities.

The Sustainable Agriculture Research and Education (SARE) program can serve as an example. The SARE program focuses on participation between farmers, ranchers, and educators, sustainable agriculture systems, local farm outreach and education, and consistent and well-coordinated program monitoring and evaluation. The EPA is focusing on a "holistic multi-media approach to environmental protection and public health relative to agriculture" (EPA, 2006). "Because agricultural operations tend to be multi-media operations functioning as a system, their problems and solutions are often multi-media in nature. Our challenge will be to use existing authorities while crossing programmatic and organizational boundaries to help the industry address environmental protection concerns" (EPA, 2006).

Sustainable Agricultural Education Challenges in India

It is here the challenge arises considering the imparting knowledge and agriculture education to rural people and implementation of the technology at various levels in India to rural communities. The need of the hour is not only imparting education, knowledge and application of the technology, but the adoption of appropriate education and technology, which would suit the particular level of Indian rural communities. In India, the farming practices are too haphazard and non-scientific and hence need some forethought before implementing any new measures. Required measures are essential in areas related to enhancing agricultural productivity, competitiveness, and rural growth, improving access to assets, sustainable natural resource use, land, and rural finance, strengthening accountability for service delivery, and strengthening institutions for the poor and promoting rural livelihood, etc.

Sustainable Agricultural Education Challenges in the US

The National Sustainable Agriculture Coalition (NSAC) is an alliance of farm, rural, and conservation groups and was organized to critically evaluate federal farm policy, agricultural research policies and programs and to advance the public good from federal funds. (NSAC, 2009). Historically, the United States Department of Agriculture (USDA) focuses on yield and production research and education. In addition, USDA funding in agricultural sustainability plays a small role. For this reason, the USDA requires a major shift to address current and future challenges. Agricultural research and education necessitates a strategic agenda to invite greater competitive capacity and infrastructure programs, risk management, internal coordination, comparative

technology assessments, evaluative metrics which emphasize outputs and inputs, along with a strong collaboration with the industrial or private sector, and interagency bodies within local, regional, national, and international levels.

The NSAC proposes “heightened attention to the statutory requirement that all such grants where applicable are consistent with the development of systems of sustainable agriculture. We further suggest that sustainability as an organizing principle for competitive and special grants should be expanded beyond agriculture to also include the food systems as a whole and to community and economic development” (NSAC, 2009). Generally, the USDA focuses more on the food system and rural economic development instead of sustainable agriculture and farming. However, the NSAC has a good point due to the lack of consistency within the USDA to advance systems of sustainable agriculture as described in Section 1405 of the National Agricultural Research Extension, and Teaching Policy Act of 1977. Thus, an effective and a competitive US agricultural sector mandates responsibility and transparency from the farmers, ranchers, and the USDA.

Many government agencies such as the EPA focus on “increasing education, incentives and funding opportunities for agricultural compliance with environmental protection goals” (EPA, 2006). Increasing education is a noble and necessary role, but without educational performance at the center of sustainable agriculture, it can easily become program funding maintenance. Adding integrated agricultural practices and systems to address the “uncertainty about the specific impacts of climate change” (NSAC, 2009) is vital for effective sustainable agricultural education. The goal of USDA’s climate change adaptation strategy is “to create the knowledge and technologies to ameliorate the detrimental effects of climate change and to take advantage of elements of climate change that may be potentially beneficial to agriculture, forestry, and rangeland, and natural resources management” through “a suite of strategies, sustainable practices, management actions, economic costs and benefits of producer and market responses, management actions, metrics, and life-cycle analysis” (GAO, 2009). Although, “outreach partnerships to provide training on risk management strategies to small farms and beginning limited resource producers” (GAO, 2007) is targeted for 2011, both strategies fail to address integrated performance and risk management approaches to determine the effectiveness of its multiple programs.

The US and other nations have underinvested in agricultural R&D. This may be due to agriculture’s low economic output in comparison to other industrial sectors. According to a 2008 income estimate from the Cornell Program on Dairy Markets & Policy, The Food, Conservation, and Energy Act of 2008 has consistently focused on large farms and not small farms (Novakovic, 2009). Results of farm competitiveness indicate that larger farms were more internationally competitive than smaller farms within the arable sector (Latruffe, 2010). However, in the agricultural food sector, size is not an issue as in the farming sector (Latruffe, 2010).

The Office of Economic and Community Development (OECD) reports “data on private research investments have been particularly difficult to obtain, even in relatively short time series, since the information is proprietary and even public companies are not obliged to publish the relevant information, in their annual reports, in a way that would be useful to economic researchers” (Alston, 2010). Thus, little is known about the benefits of private R&D for farmers, ranchers, consumers, and agribusiness education and “the dynamic structure linking research spending, knowledge stocks, and productivity” (Aston, 2010). Overall, agricultural research and development lacks a strong mechanism for enforcing agricultural research and development for pure technical and scale efficiency change.

There are a plethora of US government agricultural programs to assist small and beginning farms and ranches, and socially disadvantaged farmers or ranchers. However, there is a lack of participation and collaboration with interdisciplinary and multi-stakeholder research and strategic education processes. Furthermore, many USDA programs have focused on Food and Nutrition and health, plant health and production and plant products, animal health and production and animal products, food welfare programs, food safety, forest management, rural economic development, bio fuels, renewable energy, land grant universities, agriculture economics and technologies, rural communities, and environmental natural resources instead of farming. The USDA recently announced that the funding of research, education, and extension grants will provide the Agriculture and Food Research Initiative (NIFA) to address five societal challenges in “childhood obesity, climate change, food safety, global food security, and sustainable bio energy” (US Office of Communications, 2010). Perhaps, resource constraints and competing program requirements limit necessary education and training constrain the program’s ability to fully incorporate all of the service delivery actions.

USDA Secretary “Vilsack” acknowledges “In the past 40 years, the US lost more than one million farmers and ranchers. During that period, income from farming operations, as a percentage of total farm

household income, plunged to half of the previous level. Today, only 11 percent of family farm income comes from farming. In order to maintain viable households, rural Americans have been forced to seek alternative sources of support, and benefits such as health insurance. We need to reverse population declines, increase educational opportunities and opportunities for our young people in rural America. It's not just about the economic connections that rural America provides, but it's about the value system that it provides. We need to develop new strategies to bring prosperity back to rural America in a sustainable and significant way" (US Office of Communications, 2010). Secretary Vilsack further addressed that the 2012 Farm Bill will emphasize "broadband, renewable energy and bio-fuels, regional food systems and supply chains, forest restoration and private land conservation, ecosystem market incentives" (US Office of Communications, 2010).

On June 10, 2010 the USDA Risk Management Agency (RMA) reformed the Federal Crop Insurance Program's risk management tools to increase program sustainability and to reduce the Federal deficit. This program will assist farmers and ranchers to protect and manage their risk more effectively by receiving access to critical risk management tools. However, nothing is mentioned in detail if farmers and ranchers will receive education and training in how to better manage their risk (US Office of Communications, 2010).

Currently, there is a shift from US support and funding for R&D in the US towards developing countries. Most of the farms in the developing countries are very small (CSAW, 2010). Additionally, there are components that contribute towards a reduction in agricultural production such as climate change, land degradation, etc. Furthermore, due to the biological nature of the agricultural sector and its primary role in supporting human wellness it is essential to prevent further decline of R&D. The lack of R&D in the US agricultural sciences is leading to smaller and fewer US university agricultural science departments and programs. Will this trend lead to fewer US agricultural education and social returns? The agricultural industry structure is not similar to other industry structures in that it is significantly impacted by climate change, distance from markets, etc. Furthermore, the USDA should move away from a production/yield-oriented focus and more towards a sustainable agriculture systems focus (NSAC, 2009).

The Government Accountability Office (GAO) reports "USDA support programs may have unintended consequences, including incentives for producers to grow crops on land prone to drought or erosion. Without better oversight to ensure that farm program funds are spent as economically, efficiently, and effectively as possible, we pointed out that the USDA has little assurance that these funds benefit the agricultural sector as intended" (GAO, 2007). The GAO recommends the "USDA (1) track annually native grassland conversion to cropland to develop a comprehensive and current source of information in those geographic areas where such conversions can occur and (2) study the extent to which farm program payments and conservation programs, such as the CRP, may be working at cross purposes and report its findings to the Secretary of Agriculture and the Congress" (GAO, 2007). If the internal coordination of the USDA agricultural support programs are not effectively managed, then perhaps the USDA's education and training support for farmers and ranchers may likely have similar unintended consequences and cross-purposes. The Federal Agriculture Improvement and Reform Act of 1996 permitted flexibility in land conservation systems and provided farmers to self comply with conservation systems, (GAO, 2003). Furthermore, the USDA Natural Resources Conservation Service (NRCS) staff have difficulty in acting as advisor and enforcer to provide "assistance to farmers most of the year in the small communities where the field staff live and work and then have to cite some of the same farmers for noncompliance, which may result in the loss of their farm program benefits" (GAO, 2003). Moreover, training has "not been available since the mid-1990s, which has led to errors in assessing and reporting on compliance" (GAO, 2003).

Sustainable Agricultural Education as Competitive Advantage

Education is essential to increasing the competitive advantage of the US agricultural sector through entrepreneurship and incentives. Agricultural education and training requires an interdisciplinary education within the field of sustainability. The focus and concept of productivity within the USDA demands a new definition for the 21st century. The US agricultural sector can no longer afford to solely focus on agricultural production. Rather, the focus should include sustainable production, consumption and competition within an interdisciplinary framework.

Although the practice of sustainability may appear similar due to current marketing, integrated reporting, etc, the philosophy, incentives, and self-interest divide sustainability into different theories. This is why mixed methods risk-based data collection of interlinked systems within sustainable agriculture is necessary to address educational orientation, interpretation, and dissemination of sustainable data, and consensus capacity for effective systemic analysis. Generally, agricultural education is best served by formal, non-formal, organizational trainings, and online distance learning programs. However, the content of the education should not be limited to the agricultural sciences. Other disciplines are critical to effectively create innovative mechanisms to advance the educational capacity in sustainable agriculture. Therefore, agricultural education and training requires an interdisciplinary education and framework within the field of sustainability.

The US agricultural adult workforce is a dual workforce and consists of “(a) those engaged in agricultural institutions and businesses that serve producers and (b) the agricultural producers themselves, not to mention (c) entrepreneurs and the self-employed, both farmers and agribusinesses” (Rivera and Alex, 2008). Additionally, the agricultural workforce can be divided into four major categories “(a) those currently employed in agricultural institutions and (b) those self-employed or working on farm, there are (c) those preparing to enter the workforce and (d) those in transition from one agricultural job in farming or support services to another, or who are underemployed in the agricultural labor force” (Rivera and Alex, 2008). Agricultural workforce and interdependent sustainability indexes and data collection are necessary to develop flexible human resources in conjunction within a changing and continuous process at all levels of the public and private sectors. Overall, because agriculture is dependent upon a changing environment, risk management is essential to the core development of human resources. Therefore, high quality human resource development is essential for educating the agricultural workforce on risk management. Additionally, funding for education for sustainable development should include funding and technical training, educational outreach through local schools and universities, multi-media forms, and monitoring and evaluation.

Sustainable Agriculture Education Framework

Effective sustainable agricultural education frameworks should not utilize a one size fits all agricultural education program because each program plays a different role and should avoid comparing the agricultural programs with each other. Instead, a sustainable education framework should first implement program design to identify farmers, establish clear program goals, conduct strategic and other planning, second assessing needs to identify agricultural, farming, and learning needs, third tailoring services to ensure developmentally appropriate services, develop theory-based education approaches and evaluate content of services, fourth deliver frequent and ongoing services to ensure communication consistency and implement multiple channels to obtain community support, and fifth implement program evaluation and monitoring to collect output and outcome data, and conduct formal research and evaluation (GAO, 2004). Therefore, effective education frameworks require “theory-based educational approaches” (GAO, 2004). Self-certifying education does not necessarily lead to better learning and outcomes.

The education framework can address questions such as: what are the drivers of sustainable agricultural production and consumption? What are the sustainable agricultural patterns and impacts? What is the role of the farmer? The education framework should identify sustainability drivers with program priorities, prioritizing integration and risk efforts and opportunities and evaluate sustainability impacts such as natural and energy sources and consumption within strategic parameters. Overall, the education framework should develop an integrated and systemic view across the agricultural value chain with education and knowledge transfer flows and processes that align government, business, and farmer value drivers to design new processes or move existing processes to increase sustainable impacts.

Additional questions can further develop a sustainable agricultural education framework such as, Are coordinating and lineage efforts between agricultural programs strong? Do programs incorporate key agricultural education/evaluation actions? Or, do they leave others with limited information of program results? Do agricultural programs systematically collect data on agricultural education services or farmers? Do any of the agricultural programs conduct regular or nationwide impact evaluations of the sustainable agricultural education efforts and require a longer-term evaluation strategy? Does available research provide adequate information concerning if the programs have met their sustainable agricultural education goals? Will a cross-program and integrated approach to sustainable agricultural education / training is helpful? Does the education

framework provide opportunities to explore options to collect reliable data on services rendered and identify lessons learned?

Recommendations

Formal theoretical education can positively persuade agricultural technology, performance, and management practices. However, spending time off the farm may improve the farmer's abilities and education practices to share information and knowledge. Research and development is vital to advance the agricultural sector. However, sophisticated and demanding buyers of agricultural products are essential to the competitive advantage of the agricultural sector. The US farming sector cannot control labor, land, and capital assets, and is dependent upon the US consumers' demand for agricultural products.

Government subsidies can appear to simulate growth and create a dependant agricultural sector. However, government subsidies can duplicate private sector efforts. Government support or subsidies "misallocation of resources due to wrong government competitiveness may result in a misallocation of resources due to wrong government interventions" (GAO, 2007). Additionally, farmers and ranchers with good credit can receive private loans without government rural loan programs. Thus, government intervention can negatively impact the competitive advantage of the US agricultural sector. Therefore, sustainable agricultural education concerning a farmer's risk management and aversion from government subsidies is vital to the advancement of the agricultural sector with further research of government intervention to understand the impact of agricultural policy reforms and to advance the agricultural sector.

Federal Executive Order (EO) 13508 consists of "representatives from the US Environmental Protection Agency and the departments of Agriculture, Commerce, Defense, Homeland Security, Interior and Transportation-and charged it with developing a coordinated strategy "to protect and restore the health, heritage, natural resources, and social and economic value of the nation's largest estuarine ecosystem and the natural sustainability of its watershed" (EO 13508, 2010). EO 13508 focuses on restoring clean water, recovering habitats, sustaining fish and wildlife, conserving land and increasing public access, expanding citizen stewardship, developing environmental markets, responding to climate change, strengthening science, and implementation and accountability. There is an educational component to EO 13508; it will "initiate a robust elementary and secondary environmental literacy initiative", "support and enhance outdoor student environmental education programs", "provide high-quality professional development, tools, and resources for educators," and encourage the creation and maintenance of green schools, including schoolyard habitat and green facilities programs. (EO 13508, 2010).

Unfortunately, the focus is solely on the environment and with only the environment sphere creating environmental, social, and economic value. The focus should be on the systemic relationships of the environment, social and economic to effectively protect and restore the Chesapeake Bay watershed. Thus, education in sustainable development should not be an outcome of the strategic plan for EO 13508. Rather, education in sustainable development should be the driver for the strategy of EO 13508. This is why it is imperative for researchers and educators to analyzed and initiate sustainable agriculture trends.

Integrated Reporting is a good tool to advance sustainable agriculture and education. Sustainable agricultural education requires a stronger education framework. The education framework should focus on the interdisciplinary systemic relationships that impact sustainable agriculture. The International Integrated Reporting Committee along with the International Accounting Standards Board and the US Financial Accounting Standards Board, and the International Organization of Securities Commissions has launched Integrated Reporting. Integrated Reporting incorporates social, environmental, and governance (ESG) company performance alongside business and financial data (BSR, 2010). Although integrated reporting focuses only on the social, environmental, and governance spheres, it is a trend that will significantly impact sustainable agricultural education.

Integrated Reporting is a tool that is interdependent with business strategy and it is a mechanism that can assist agricultural education to develop local, national, and global farming educational business strategies and risk management. Thus, farmers can develop and implement "local sustainability reporting that prioritizes frameworks, internal coordination, and external engagement. Employing this type of approach helps companies manage costs while addressing the original motivations behind producing the report" (BSR, 2010). However, the focus of ESG in Integrated Reporting is a weakness due to different conceptual theories and practices of ESG and ethics.

Conclusion

Sustainable Agricultural Education has a reciprocal value relationship in sustainable development for both countries. Effective sustainable agricultural education should not focus on the grant and grantees use and performance of the grant. Furthermore, effective sustainable agricultural education should include inputs and outputs to ensure that the grantee not just the grant funding drives competition and is required by other sectors. Alternately, effective sustainable agricultural education cannot focus on managing program grants or the staff skills to manage grants. Rather, it must determine how the grant will be used to advance competitive advantage and to prevent maintaining society's dependence upon funding to achieve competitive and effective educational outcomes. Overall, effective sustainable agricultural education frameworks should ensure that sustainability standards are appropriate to the scale of farming, and incorporate training and technical assistance for beginning, small, and mid-size farms, and farmers with limited resources through public, private, and rural community partnerships. This can prevent "Farmers (who) have deliberately chosen alternatives to the industrial agriculture and food chain that privileges uniformity over diversity, centralization over widespread ownership and control, and sterilization over natural habitat" (NSAC, 2008). Thus, Indian and US policymakers should promote incentives and enforcement of mandatory requirements instead of voluntary agricultural practices and self-compliance to encourage the agricultural workforce to develop innovative sustainable agricultural education and practices.

Abstract

This paper reports on the development and facilitation of an intensive postgraduate unit (IS6) at Curtin University. IS6 aimed at enhancing Information Systems students' appreciation and awareness of their industry's impact on the environment, and their ultimate responsibility towards their communities and society. Throughout the seminars, students were keen to demonstrate awareness and sensitivity to the importance of sustainable development and business strategies in such a crucial time for people, planet and profits. Indeed, students were able to display an understanding of the fundamentals of Green IT, applying conceptual tools and frameworks to critically analyze and apply business decision-making practices and policies, translating theories, concepts and analytical techniques learnt into practice. The paper reports on quantitative and qualitative data collected throughout the semester from eighteen students, the diverse assessment methods applied, the three written journals, students' individual oral presentations including peer-evaluation and report writing of an IT Sustainable Strategy. This comes in addition to the feedback provided through informal channels and more importantly through 'eVALUate', a feedback system adapted by Curtin University. The preliminary outcome, though limited to Australian higher education, yet reveals a shift in the students' mindsets towards appreciation of the big picture, thus moving from merely concentrating on their software and hardware development into establishing the link between their specific industry and the society and environment.

Introduction

It is time for practitioners and academics to think seriously about the role they play in the world aiming towards acting in a more sustainable manner towards their stakeholders. As Newton (2003) posits sustainable development is seeking to protect and preserve the environment not only for this generation but for the seventh generation. Jagers (2009, p.182) indicates that sustainable development enhances the means for doing so in a 'manner consistent with their [World Trade Organization and human rights] respective needs and concerns at different levels of economic development'. In this regard, Epstein & Roy (2001) define five major components for businesses to organize their sustainability and economic matters: (1) corporate and business unit strategy, (2) sustainability actions, (3) sustainability performance, (4) stakeholder reactions, and, (5) corporate financial performance. According to Epstein and Roy, these major components play an important role not only for economic, finance and business structure, but also extend to cover recent attention paid to the power of shareholders. This comes as we are recently reminded by Amann et al. (2009) that sustainable development had 'led shareholders to be more attentive to the concerns of all stakeholders – personnel, clients and suppliers, investors and non-governmental organizations – [which] conveys the expectations of society as well as the environment of the company' (Amann et al. 2009, p.338). Weybrecht (2010) argues that this circumstance had led to huge competition not only between organizations and firms, but also between countries and societies, as majority of organizations and firms started to integrate sustainability into their strategy. Weybrecht highlights the importance of inclusion of sustainability in strategy, noting that organizations and firms who are successful are building a business case for sustainability 'that suits the unique needs of their project, their initiative, their division or even their whole company' (Weybrecht 2010, p.21).

Sustainable development is unlimited to businesses; higher education, specifically business schools had commenced to very seriously and carefully evaluate and think about the importance of sustainability. This shift in their thinking does not limit the incorporation of sustainable strategies at the higher education institutions' policies, but rather extends to include the introduction of units (courses) aiming at the education of future leaders and employees thus incorporating such topics in their degrees. One of the units (courses) that form a part of the postgraduate studies including the students of Information Systems (IS) and Information Technology (IT) is the subject of this paper. This paper starts with the provision of a brief literature review, and then provides an empirical evidence of students' mindsets shift through the analysis of the quantitative and qualitative data. This data was collected throughout the semester from eighteen students, through diverse assessment methods, the three written journals, individual oral presentations including peer-evaluation and report writing of an IT

Sustainable Strategy. All this is coupled with data provided by the feedback through informal channels and more importantly through 'eVALUate', a feedback system adapted by Curtin University.

Background and Literature Review

What is Sustainability?

In 1983, the Sustainability concept was founded and addressed by Gro Harlem Brundtland, from the World Commission on Environment and Development meetings. In 1987, the Brundtland's report was released to alert the global world to the urgency of marking progress towards economic development, since people have become required to use our world in a way that will not detract from the future. Loorback et al. (2010, p.140) posit that sustainability can be defined as 'work together with suppliers, partners, and clients for a profitable position in the market by applying alternative fuels for sustainable energy and transportation'. While Weybrecht (2010, p.14) indicates that sustainability, for business sector, can be defined as 'adopting business strategies and activities that meet the needs of the enterprise and its stakeholders today while protecting sustaining and enhancing the human and natural resources that will be needed in the future'. Therefore, businesses and higher education globally and locally, should consider sustainability innovation in their strategies and curriculum to protect the environment not only for the current generation but also for the seventh generation according to Newton (2003).

Providing an endless list of positive consequences when applying sustainable business strategies; Rainey (2006) posits that applying sustainability in business strategies enhances business performance thus contributing to cost reduction and efficiency improvement, which enhances reputation, recruiting and retaining excellent people, gaining better access to investors' capital, and reducing a company's liabilities. Nidumolu, Prahalad & Rangaswami (2009, p.58) argue that sustainability is not the 'burden on bottom lines that many executives believe it to be. In fact, becoming environmentally-friendly can lower your costs and increase your revenues. That is why sustainability should be a touchstone for all innovation'. Henceforth, sustainability innovation should be spread out to organizations' strategies and even to education curriculum to generate future labour and leaders who understand the environment requirements ensuring the safeguard of those sources for the future generation.

The importance of sustainability to business has become an important public concern both locally and globally. This comes as evidence is mounting that the development and application of sustainable business strategies has the ability to provide a high quality of life for the current and future generation. Though literature seems to be over-flowing with ideas, frameworks, tools and models relating to the sustainable business, yet, there seems to be a misunderstanding of the true meaning of sustainability. Blowfield & Murray (2011, p.23) tried to tackle this issue by stating that sustainability as a concept is unlimited to capturing the environmental business rationale, 'but the triple bottom line was developed to add this by encouraging companies to think in terms of adding economic, social and environmental value'.

In conclusion, the expedition towards more sustainable strategies is an essential and a goal of great importance; therefore, businesses should understand where they are now and where they want to go. There is a need for them to understand their goals and objectives prior to developing and applying sustainable strategies for their businesses. Indeed, bearing in mind Kendall & Kendall's (2010) confirmation that sustainability will benefit not only the company's shareholders but the society as well; novel aim contemporary businesses should be aiming towards.

Sustainability and the field of IS and IT?

The field of IS and IT, Green IT, seems to gain favour with business strategists forming a major part of their Information Systems Management Strategy. Sustainability and Green IT are very essential in the Information Systems Management Strategy, since the present generation does not own the planet and its resources, but are allowed to use, holding it in trust on behalf of future generations (Weybrecht 2010). It was noticed that individuals, businesses, communities and societies seem keen to study and address the critical issues behind the current sustainability issues to allow them to move on to prevent the coming critical crisis. This is crucial, especially with Starik et al. (2010, p.377) stating that 'Climate change continues to alter global ecosystems, most obviously resulting in melting icecaps and glaciers. Biodiversity losses are resulting in a mass extinction of species both on land and in the sea, while toxic pollutants, most visibly at the time of this writing; the Gulf oil spill and hazardous waste are becoming ever present not only on land and in the sea, but also in the air we breathe. Human population increases by more than 200,000 net each and every day, primarily in

developing countries, while human over-consumption of fossil fuels, potable water, meat and fish, primarily in developed countries, increasingly cause problems both within and around us’.

European Greens (n.d.) suggest that green economic vision puts social and environmental justice and equity within nations and between nations at the centre, just use of the earth’s resources (e.g. reducing the gap between rich and poor). Every person has the right to meet their basic needs: clean air, water, food, soil, shelter, energy, health, freedom, every human being has a right to solidarity, democracy, self determination, autonomy, responsibility, dignity, self fulfillment, and the economy should enhance wellbeing rather and not detract from it. Furthermore, the European Greens (n.d.) argue that the green economy should play central role for investments in sustainable development and green technology, and should create new opportunities, in particular on the labour market, making it possible for everyone to exploit his or her talents. Therefore, the key to greening the economy is to make it less intensive in its use of natural resources, but the most essential is to have the proper incentives starting with the appropriate leadership. This leadership that allows for the development and application of sustainable business strategies to all departments within the business including the IS/IT.

This paper provides a simple outline as how the readings, case studies and assessments design of ‘IS6’ postgraduate unit (course) had played a role in attempting to shift the students’ mindsets becoming more aware in respect to sustainability and IT development strategy. The most important aspect was the concluding remarks by students following their attendance and completion of the IS6 unit (course), was their feedback and reflection that organizations and firms should integrate sustainability within their strategy that is aimed at IS/IT department to allow them to be more competitive in the marketplace locally and globally simultaneously.

Sustainability, Green IT and Education – The design of IS6 unit (course)

The economic crisis in 2008/2009, did not only raise the alarm about lack of sustainable practices in our finances, but had alerted businesses towards issues beyond finance and profit, who started to struggle coping with the increased IT/IS cost and their environmental footprint influence. Arevalo (2010) urges businesses to pay more attention to the issue of sustainability and global social responsibility. Arevalo providing empirical evidence, argues that relationships between environmental and economic dimensions of sustainability have been solidly specified, but relatively little attention has been given to the social sphere concluding that there is a transformative effect on citizenship that can result from the teaching and learning that is facilitated by voluntary corporate social responsibility initiatives. These initiatives can only become serious and acted upon if they are incorporated within the company’s strategy. Kaefer (2009, p.4) indicate that ‘IT contributes 2% of world wide CO₂, and IT energy consumption is growing at 12% annually while a Google search needs on a average the same energy as a 11W energy saving lamp in one hour (11Wh)’.

Therefore, businesses seem to have started moving and quickly towards adopting a sustainable strategy, this is coupled with actions by higher education to incorporate sustainability and Green IT as parts of their teaching and learning materials, acknowledging their importance for the global and local businesses. This interest by businesses and higher education has come in the form of introducing some new concepts. For example, ‘Green IT’, is a concept that brought with it the ‘ecological impact of IT into the public and academic focus’ (Schmidt et al. 2009 , p.400). Marques (2009) reviews an important paradigm shift that is currently spreading amongst humanity, instigating a critical analysis of the way we used to perceive matters in past centuries, and encouraging an entirely opposite way of approaching the essentials of contemporary life. To clarify this perceptual change, Marques discusses different areas such as education, and economics amongst others. In this respect Walck (2009) confirms that majority of academics globally and locally are shifting towards green and sustainability in the management and Information Systems curriculum.

These specific units (courses) must be mapped properly, ensuring the proper linkages are established between the material provided, assessments and the unit (course) outcomes. Designers of such units (courses) should always pose the questions, as to what outcomes might be desirable from this unit (course), and what assessments should be included in these units (courses) to meet students, university and marketplace requirements simultaneously. This has increased in its importance especially with the latest developments in the market, and environment that pose great challenges to the humankind. To meet these increased challenges, and at Curtin University, the IS6 unit was designed providing pointers to and examining the strategic development issues that need to be taken into account to allow the future IT business leaders to act responsibly towards achieving their goals as stewards of the planet, people, and their profit.

The aims of IS6 unit were: (1) to provide students with some understanding of issues relevant to Organizational Sustainable Strategy, (2) to provide students with some understanding of issues relevant to Green IT, and, (3) to establish the link between the two areas. As for the learning outcomes of IS6 unit those were: (1) students to demonstrate initial awareness and sensitivity to the importance of sustainable development and business strategies in such a crucial time for people and planet and ultimately profit, (2) students to display an understanding of the fundamentals of Green IT, and, (3) students to apply some of the ever-increasing and changing conceptual tools and frameworks to critically analyze and apply business decision-making practices and policies in a comprehensive manner that would allow to issues other than profit to be considered, and, (4) students display proper abilities to translate theories, concepts and analytical techniques learnt into practice.

The IS6 unit (course) topics were: (1) the changing landscapes history and strategic implications – Green IT, (2) overview: Risk society, stewardship, strategic thinking and business strategy for the digital world, (3) stewardship and financial decision-making (in relation to IT), (5) strategic thinking and sustainable business development strategy (sustainability, innovation, change), and, (6) sustainable development and business success (benefits and limitations) security issues and concerns. In addition, assessments were designed to ensure that the unit's (course) aims and objectives were achieved. This will be elaborated upon later in the paper.

Method

Research question and objective

This paper will answer the question: 'what are the benefits and consequences of teaching Sustainability and Green IT for Postgraduate students of IS and IT?' The main purpose of this paper is to report on data collected during the teaching of sustainability and Green IT for Postgraduate students in Australia and whether such teaching will change students' attitudes towards the subject of sustainability in there IS/IT field. This data was collected through the assessments that were originally set to assist the IS6 postgraduate students to achieve the unit outcomes.

Methodology

The mixed-method approach was deemed appropriate for the analysis and reporting of data in this paper. A mixed method approach allows researchers to reduce the gap in the finding, since the qualitative research and quantitative have their place in research and each have their strengths and weakness (Teddlie & Tashakkori 2009). Kumar (2005, p.13) indicates that researchers should not 'lock' themselves into solely quantitative or qualitative research, and 'neither one is markedly superior to the other in all respects'. The teaching and learning feedback should be only gathered through the mixed-method approach. Furthermore, Walker (1997) and Green (2008) confirm that each of the techniques has its shortfalls, and in combining both the shortcomings of each will be reduced.

In this paper, data was collected through the quantitative and qualitative techniques, from our records, and students' feedback (both formal and informal). The students' feedback was collected over two periods in the semester. The first was through the informal feedback while students were still undertaking the unit (course). This 'informal feedback' is a teaching and learning initiative, when during the semester students, were asked to provide their anonymous feedback on the unit using the model 'Continue, Stop, Start' (CSS). By completing the CSS students are usually given the chance to provide their comments of what they want the lecturer to continue, to stop and to start doing, thus providing the chance for both the students and the lecturer to benefit from the course, enhancing the methods of teaching and learning. The second was at the end of the semester through the University's formal feedback (eVALUate). This 'eVALUate' is applied at Curtin University at the end of each semester, when students voluntarily and anonymously provide their feedback on the unit and the teaching staff.

Through the analysis of the collected data it was noticed that students were interested in and keen to study the material that formed the IS6 unit, which, according to them had enhanced their knowledge, challenged their beliefs, and encouraged them to seek more articles and material to support the ideas that have been planted through the first session of this unit. What became apparent that students came to enhance their abilities, including critical thinking to their writing and reading skills? Some of students' comments (informal and formal feedback) will be elaborated upon in the discussion section of this paper.

Participants

The IS6 participants were a mix of students, where some have a solid work experience in the field, while others were students who have elevated through their undergraduate studies at the university without any exposure to work in their field. This in itself was a challenge that the lecturers had to deal with, through the scaffolding offered to those who were finding it difficult to think of the practicality of the issues under discussion. Another challenge was the different backgrounds of these students. Some students completed their undergraduate studies moving into post-graduate studies at the same university, while others had only joined the university merely to obtain their post-graduate qualifications bringing with them diverse ideas and real-life experiences relevant to culture. Students were also derived from different majors.

Table 1 shows some demographic details of the IS6 students (e.g. qualification types, students' number, gender, nationality, work experience etc...).

Table 1: Demographic details of IS6 students

Qualification	Number	Gender	Nationality	Work Experience	Final Unit
Master of Commerce (IS)	2	None	Asia, Mauritius	1 Middle, 1 Low	None
Master of Information Systems	8	1 Female	6 Asia, 2 Middle East	1 Middle, 7 Low	5
Honors	1	None	Asia	1 Middle,	None
Postgraduate Diploma of Commerce (IS)	6	1 Female	5 Asia, 1 South Africa	1 High, 5 Low	2
Master of Logistics	1	None	India	1 High	1
Total	18				

Gender and Nationality were key variables when it came to comparing students' participation, oral presentations and reports writing. Differences were noticed, female students' participation, oral presentations and reports writing were of a higher quality when compared to the majority of male students in the class. Nonetheless, the experienced male students were able to add value to the class debates and discussions (either face to face or online) through sharing their experiences, videos and articles. As for students' nationality, this was another interesting difference, especially with students sharing their countries' perspectives in relation to sustainability as a whole, sharing their stories, videos, and articles in the discussion forums on the blackboard.

To properly examine as to whether IS6 has achieved its aims and outcomes, assessments were designed. These assessments were all required to be submitted on individual basis. This was coupled with several group activities throughout the semester in the classroom. As the IS6 was discussing sustainability, no paper was used in this unit, but rather electronic drop box facility was provided for students to drop their assignments in and lecturers feedback was communicated in the same manner, in addition electronic blackboard provided the readings and case studies material. These assessments were: (1) three reflective accounts/journals to be done individually, (2) individual oral presentations of an IT Sustainable Strategy proposal, and, (3) reports writing of the IT Sustainable Strategy that students proposed in their second assignment using the frameworks and tools provided, and most importantly those that the students themselves were able to locate through their ongoing research throughout the semester. Table 2 provides a breakdown of the marks allocated to each of these assessments.

Table 2 – Assessment Activities for IS6 unit

No.	Assessment Activity	Percentage %
1	Three Reflective Journals	30%
2	Individual Oral Presentations of a IT Sustainable Strategy	20%
3	Reports Writing on Your IT Sustainable Strategy	50%
	Total	100%

The three-part reflective accounts/journals (individual assignment) were designed to provide student(s) with valuable experience in critically, creatively and reflectively, reviewing and recording key points and their

thoughts about material from textbook(s), journal articles and the internet. In addition, this assessment encouraged student(s) to always endeavor to keep themselves up-to-date with their readings and their ongoing search in the World Wide Web in relation to the topics under study. It is worthwhile to note here that the reflective accounts/journals were not meant to only form a summary of the readings but student(s) were encouraged to provide their own opinions, and reactions to the material provided in these sources, reflecting on the contents and providing additional evidences from the literature they sought. The fact that these were three-part reflective accounts/journals has played a positive role, as students built on the feedback provided to them on their first and second to provide, and especially those who needed scaffolding throughout, a well-written account/journal on their third submissions.

The second assessment was in the form of oral presentation. This individual oral presentation was designed to promote student presentation skills and their arguments abilities as they were faced with questions from the audience (classmates and lecturers). These presentations provided a brief, concise and succinct account of their major IT sustainable development strategy for a company of their choice. The method adopted in running those presentations also enhanced the learning of those students. Thus, and in order to achieve this aim, and maintain interest, students were provided with marking guides to assess their peers' performance allocating marks. These marks were taken into account when evaluating the overall mark of each of the students. The fact that students were allowed to assess their peers was taken seriously by students, who were also generous with their remarks on what went well, wrong, and who could have been done better.

The third individual assignment aimed at providing students with the ability to write professionally and academically. The proper way to achieve such aim, communicating with their lecturers was through writing a report enhancing their analysis of the company's present strategy, their recommendations through the use of different frameworks, tools and models. In some cases students were courageous to even suggest the deletion of stages in some of the models, and addition of others. All this was derived from solid research and understanding. In this paper, only the first assignment of these course assessments (i.e. reflective accounts/ journals by students) will be explored.

Discussion

Using reflective journals, individual oral presentations, and reports writing assessments for IS6 was considered an effectual way to encourage students to participate, engage, and to understand the main concepts of IS6 unit (course). The development and the facilitation of IS6 was a great challenge not only for students but lecturers. At the beginning of the semester, and following the ice-breaker activity, it became evident that the majority of students were unaware of the role that IS/IT might play in the increase of carbon footprints, and how their sustainable strategies might reduce such an impact. It seemed hard to convince and influence students about the importance of the sustainability and green IT concepts in the business and education sectors. One of the students comments sums up this suspicion:

'Please don't get me wrong, I support green IT, but there is something that I am still unsure about green IT. Guess that you still haven't brain washed me to that extent' (IS6 Student 1).

The individual reflective/accounts journals were considered a valuable tool to engage students in the learning activities, to improve their understandings of IS6 objectives, and to improve their communication skills as the same time. This echo Clarke (2003, p.5) that reflective/accounts journals promote professional development of students, and enables them to make the links between theory and practice and 'encourages them to evaluate their teaching performance'. Furthermore, Cunliffe (2004, p.408-418) posits that using this method in business education can develop 'collaborative, responsible and ethical ways of managing organizations', 'and not thinking about thinking, but thinking about self from a subjective process'. This was evident in some of the comments provided by the students either in their individual reflection specifically in their conclusions. From these comments:

'The learning experience helps me to improve communication skills and start to think more critically'. (IS6 Student 2).

'I was taught a lot of things about green IT and some new aspects in these seminars.' (IS6 Student 3).

Following the introduction of IS6 to our postgraduate students with a request to students to read and search for articles, in relation to sustainability and Green IT, it was revealed to the lecturers/unit leaders that students started to change their way of thinking becoming more aware of how businesses should integrate sustainability into their core business strategy and practices. Following the examination of their first individual reflections, the lecturers/unit leaders adopted new techniques and tools to enhance students understanding of Sustainability and Green IT encouraging them to extend their research gaining more insights into the topic and the meanings of those concepts. Students appreciated this fact commenting:

'Our brain has been washed to green'. (IS6 Student 4).

'Improve [our] reading skills, analyzing and reflecting from journal readings. (IS6 Student 5).

The change did not stop in shifting the students' mindsets, but rather it was very interesting to read in their accounts/journals that they feel the importance of the topics covered in this unit calling for a change into the way businesses are conducted.

'Commitment and cooperation is a major factors that will influence successfulness of sustainability whether it is from the inside of the company such as top management, staff or even other organization could help promote and increase credibility toward the sustainability plans and process'.(IS6 Student 6).

Patenaude (2011, p.270) posited the need for a 'proportion of academic research to become informed by real world problems as faced by communities and businesses, inter-institution spaces for the incubation and exchanges of ideas, innovations and people, as well as neutral hubs of research, teaching and expertise are needed'. Sustainability and Green IT should not be limited to businesses but rather to higher education, who should contribute to society's eagerness to understand, develop and implement sustainable business strategies by introducing new units (courses) including these aspects. This has the potential in changing students' perceptions towards sustainability, a percentage of which will become the future chief executives. Therefore, higher education has the responsibility to apply sustainability philosophy into their units (courses) including Accounting, Marketing, Management, Information Systems, Economic and Business in general. This was a call by IS6 students:

'...Each and every one of us will have roles to play in helping environment, but it will needs to start with understanding the big picture which can be done through education and proper realization of the result so they can feel what they earned even though most of them is intangible.(IS6 Student 7).

'There are many helpful tools and aspects of environmental issues in terms of learning sustainable business IT strategies. This unit helped us to improve the research skills by reading many articles concerning on the environmental, social, political and technological issues. As we've done some case studies during the seminars...' (IS6 Student 8).

Table 3 eVALUate Full Unit Report

eVALUate quantitative items	Unit Agreement (%)
The learning outcomes in this unit are clearly identified.	80%
The learning experiences in this unit help me to achieve the learning outcomes.	90%
The learning resources in this unit help me to achieve the learning outcomes.	90%
The assessment tasks in this unit evaluate my achievement of the learning outcomes.	90%
Feedback on my work in this unit helps me to achieve the learning outcomes.	90%
The workload in this unit is appropriate to the achievement of the learning outcomes.	90%
The quality of teaching in this unit helps me to achieve the learning outcomes.	90%
I am motivated to achieve the learning outcomes in this unit.	100%
I make best use of the learning experiences in this unit.	100%
I think about how I can learn more effectively in this unit.	100%
Overall, I am satisfied with this unit.	90%

Table 3 above provides the quantitative items of ‘evaluate’, the students’ overall satisfaction was 90% which is well above the satisfaction rate at the university level. Though the students expressed, and verbally, their concern about the number of readings and assessments the above table provides a 90% satisfaction with the workload, feedback and assessments. This is a testimony that students have appreciated the efforts exerted by the unit controllers in developing and facilitating the unit.

Finally, and in light of the comments detailed above, an issue such as sustainability and business strategies directed to the IS/IT is of great importance. Thus academics and practitioners should engage in a dialogue on how best higher education can serve organisations in enhancing their understanding of such an important topic during uncertain times. Though the topic is challenging, and might be met with suspicion and cynicism by students at start, yet when evidence is provided change happens. One final issue, the lecturers/unit leaders should be keen and have the conviction of the necessity of sustainability, displaying knowledge and passion, otherwise it would prove to be difficult to become agents of change.

Conclusion

This paper presented an Australian higher education perspective in relation to Sustainability and Green IT concepts. From the analysis of the quantitative and qualitative a shift in the students’ mindsets was witnessed towards the knowledge, awareness and importance of sustainability and green IT including the necessity to

develop sustainable business strategies, ensuring their implementation in businesses. The data provided evidence that the design of IS6 assessments that took into account the Curtin graduate attributes had enhanced students' understanding of the main concepts of 'Sustainability' and 'Green IT'. Indeed, had changed their minds towards the necessity of sustainability in the IS/IT field. Further, the way these assessments were designed allowed students to enhance their communication skills from critical thinking, written, oral presentations, and research and information technology skills. Comments from students, some of which were highlighted in this paper are strong evidence on this conclusion.

Now, the responsibility lies in the hands businesses and the top management of higher education to continue their engagement and efforts to protect, sustain, and enhance the human and natural resources which are needed in the future through becoming aware of the necessity of development and implementation of sustainable business strategies including those directed to IT/IS. Further research will be carried out when this unit (course) is run again at Curtin University, which is expected in semester 2, 2011, which might provide strength to such empirical evidence.

Abstract

In this paper, we conduct a systematic research studies on China's clean development mechanism (CDM) market. By employing a generalized autoregressive conditional heteroskedasticity model containing regime switching on distributions (SWGARCH), we empirically test the market price of carbon trading by analyzing the statistical characteristics. The findings show that at the peak of the financial crisis, the distribution of certification emission reduction (CER) price return rate switched frequently between normal distribution and t distribution, and the fluctuation spread switched between different levels. After the peak of the financial crisis, the switching frequency fell and the price also leveled off. Finally, we discuss the future trend of sustainable development of China's CDM market.

Key Words: China's CDM; SWGARCH model; future trend

1. Introduction

The trading activities on the greenhouse gas (GHG) emissions have become prevailing in recent years because extreme weather events, such as tsunami and icy snow calamity, have occurred frequently. On February 16, 2005, "Kyoto protocol" took effect, which makes GHG emission reduction in industrialized countries binding. In addition to regulating the abatement of GHG emissions in developed countries before 2012, "Kyoto protocol" set down three flexible market mechanisms—Emission Trading(ET)、Joint Implementation(JI) and Clean Development Mechanism(CDM). To reach the abatement goal, firms can buy additional allowances from the markets if the given amount that they can emit does not satisfy their actual needs and sell allowances if they have excess allowance, besides investing in technical progress leading to fewer emissions.

Under CDM, firms in developed countries assuming the obligation of emissions reduction can cooperate with developing countries in projects by technology transfer or capital investment to offset the amount of emission reduction with Certified Emission Reductions (CERs). Developing countries can sell their emissions reduction to developed countries since they are not obligated of reducing emissions before 2012.

China is currently the second largest emitter of GHG in the world. Its fast growing economy has resulted in excessive consumption of resources and deterioration of the environment, which poses a serious threat to sustainable economic development. Therefore, how to develop the economy harmoniously is the major concern of China in the long run. Chinese government has made a bold commitment that the emission of carbon dioxide per unit of GDP will drop by 40% -45% compared with that in 2005 by 2020. The key to achieve carbon emission reduction is to minimize the cost of reduction. The best way for China is to participate in the trading system of CDM project actively. However, there are few participants currently in China's carbon trading market. In addition to investing in the financial instruments of low-carbon plate and the concept of low-carbon, domestic financial institutions seem not well prepared for the carbon trading era. Moreover, as the world's largest supplier of carbon emission allowances,

China does not have its own carbon trading system as Europe and the United States. So, what China needs to do is to improve domestic carbon trading system and establish a well organized market to facilitate carbon trading activities.

In this paper, we conduct a systematic research on China's CDM market. The organization of the paper is as follows. Section 2 briefly reviews the relevant literature. Section 3 analyzes the development of China's CDM market. Section 4 empirically tests the market price of carbon trading by investigating the statistical characteristics by employing a GARCH model containing regime switching on distributions (SWGARCH). In the last section, we discuss the future trend of sustainable development of China's CDM market.

2. Literature Review

Following an early theoretical discussion of trading theory of sewage drainage (Dale, 1968), quite a large number of qualitative studies on carbon emissions trading have been conducted. Stern (2007) points out serious consequences of global warming and the relationships between human activities become more and more intriguing.

Croker (1996) presented the possibility of applying property rights to air pollution prevention and established the theoretical basis for carbon emissions trading. Stavins (1995) examined the trading issues of emission allowances when considering the transaction costs, believing that deal costs can decrease trading efficiency. Cason and Gandgadhara (2003) tested and confirmed the Stavins point that non-zero transaction cost tended to increase the trading price of emission rights. When the marginal transaction cost declines, the initial allocation of emission rights will deviate from the efficient equilibrium. Moreover, the transaction price could fall close to the equilibrium price with zero transaction cost and trading volume will also increase; when the marginal transaction cost keeps unchanged, the transaction price, trading volume and market efficiency will not change no matter what the initial allocation is.

As "Kyoto Protocol" took effect On February 2005, the global carbon trading grew rapidly as a result of the three flexible trading mechanisms. At the same time, literatures focus on the study of carbon trading mechanisms. These include Sven Bode (2006), Cames and Weidlich (2006), Grubb (2004), Neuhoff (2006) discussing trading mechanisms design in developed countries; and M. Germain et al. (2007), Wang et al.(2005), Li (2006), GAO (2007), Bi et al. (2009), the State Council Development Research Center Research Group (2009) specifying on the problems of using CDM in China and other developing countries. All argue that CDM provides a good opportunity for both the developed and developing countries' emission reduction and sustainable development. Besides, many Chinese researchers have done numerous studies on China's CDM, including the industrial and regional distribution of CDM projects, the existing problems in current CDM market and the potential risks of CDM projects (Zhang and You, 2008; Chen and Liu, 2009; Miao, 2008; Kong and Lu, 2006; Ma, 2009; Cui, 2005; Wang and Zhao, 2009; Zhuang, 2008). The majority of them indicate that firms are main players in the international carbon trading market and have the primary responsibility for global carbon emissions. A flexible market mechanism gives an incentive to firms to produce fewer emissions by investing in and using more efficient technologies. It is worthwhile to note that enterprises are subject to significant risks during both production and emission trading process.

CDM projects are all long-term ones. Thus, CER price volatility is important because volatility forecasts are central to calculating optimal hedging ratios and options prices. Until now most literatures on the carbon emission allowance price dynamics have concentrated on EUA rather than CER. We can classify them into four categories according to the research methods. The first one uses a diffusion process with "jump" to depict the data generation process (Yang et al.,2008; Tuthill,2008; Seifert et al., 2008; Daskalakis et al., 2009). The second one decomposes EUA price process into a mean component, a GARCH component and a jump component. Gronwald and Ketterer (2009) use the Autoregressive Jump-Intensity (ARJI)-GARCH model developed by Chan, and Maheu (2002) examines the EUA futures price series. The third one is to let the innovations of GARCH model conform to some mixed distribution to identify the fat tail, clustering and jump in the EUA price process (Paolella and Taschini, 2008; Sanin and Violante,2009). The fourth group introduce Markov regime-switching model to embody the characteristic of jump of the EUA price process (Benz and Trück, 2009). In addition, Chevallier et al. (2009), Chevallier (2009),

Chevallier and Sévi (2009) argue that there exists jump in the EUA price process, but they do not model it. A limited number of literatures study CER price dynamics. Maria et al. (2010) proved that there existed a co-integration relationship between EUA and CER price processes and CER price was a follower to EUA price. Hence, the dynamics shown by EUA price should be found in the price process of CER as well.

The price process of carbon emission allowance shows characteristics including fat tail, clustering and jump (regime-switching or structure changes). The existence of “jump” has been a common knowledge. However, the understanding of “jump” is limited on the concept of mean and variance. Actually, “jump” in the CER price process may be more complicated. It is known that demand and supply in the carbon market is created by policy and scheme rather than coming into being spontaneously. Except economic factors such as macro-economical situation and energy prices, climate change, new energy technology and politics all play vital roles in the price dynamics of the carbon emission allowance. For instance, Conrad, Rittler and Rotfuß (2010) indicated that the decisions of the European Commission on second National Allocation Plans have a strong and immediate impact on EUA prices. In addition, there exist more uncertainties in the price of CER than EUA. First, EU ETS has been confirmed until 2020 but contracting parties under Kyoto Scheme have not come to consensus with respect to new compliance stages, which leaves CER unsecured by law after the year 2012. Second, EU ETS is a cap-and-trade program which means that the total supply of EUA is decided once the cap is published but the supply of CER is based on CDM projects which contain large risks for that they are affected by too many uncertain factors. Therefore, CER price process may exhibit more sophisticated “jump”, associated with events such as financial crises, institutional reform, etc.

The Markov-switching model family focuses on capturing dramatic breaks in the data series. Hamilton (1988) established the first Markov-switching model to study short-term interest rates. Hamilton (1989) introduced the model to identify the long-run trends in gross national product and the business cycle. Cecchetti, Lee, and Mark (1990) used it to explain mean reversion in equilibrium asset prices. Partly in response to Lamoureux and Lastrapes’ (1990) argument that ARCH and GARCH models always provided worse multi-period volatility forecasts for stock price series than constant variance model because of non-linearity in the stock-market volatility. Hamilton and Susmel (1994) and Cai (1994) introduced Markov-switching parameters to ARCH. Especially the latter exerted a vital influence to the later researchers. Dueker (1997), Gray (1996), and Haas et al. (2004) extended the Markov-switching approach to GARCH models further. Particularly, Dueker’s (1997) model simplified the model specification and demonstrated more flexibility. Therefore, we will construct a Markov-GARCH model containing switching in the tail thickness, clustering and distribution to prove that changes indeed take place in these areas in the CER price process.

3. Development of China’s CDM market

3.1 The current status

China’s carbon dioxide emission volume currently ranks the second in the world. Major market imperfections like irrational energy structure, low efficient energy consumption and high proportion of GHG emissions make China’s CDM investment attractive. At present, China’s CDM projects are mainly distributed in wind power, hydropower and energy efficient sectors. FIG.1 shows the number of projects approved by the CDM EB (by type of emission reduction) so far. FIG.2 shows the expected annual emissions reduction of projects approved by the CDM EB (by type of emission reduction).

FIG.1: NUMBER OF APPROVED PROJECTS BY TYPE

FIG.2: ANNUAL PREDICTED EMISSION REDUCTION OF PROJECT APPROVED BY TYPE¹

The ratio of renewable energy and energy efficient projects has increased. But the amount of CERs produced in hydropower, solar and biomass projects are still very small. By January 1 2009, renewable energy and energy efficient projects accounted for about 39% and 8.13% respectively in those projects developed and registered in the CDM EB. Rapid development of China's wind power project directly enlarged the scale of renewable energy projects. The number of energy efficient CDM projects has grown fast, the majority of which are from the electricity sector (energy-saving power generation project) and cement, steel sectors. CDM projects of the HCF-23 Decomposition and N₂O decomposition elimination have produced a large number of CERs because of its low investment costs. However, the ratio of these projects among all the CDM projects registered by CDM EB decreases gradually. As China's energy structure is coal-dominated, there is great potential in China's coal mine methane area. The number of projects and the volume of annual CERs have grown significantly. Hydropower, wind power and

energy-saving power generation projects take the largest share among the projects being developed. In addition, biomass CDM projects are also numerous.

CDM projects show some regional features because of its resource dependence characteristics. Hydropower projects are concentrated in China's southwestern regions such as Yunnan and Sichuan provinces, which are rich in water source. Wind power projects are mainly located in Inner Mongolia. And energy efficiency projects are evenly distributed in the provinces like Shanxi, Jiangsu and Shandong because there are many energy-intensive businesses and large-scale manufacturing in these areas.

3.2 Issues in current CDM Market

Although China's CDM market develops pretty fast, there two types of issues we have to address. First of all, we have no pricing right on CERs. CDM market is a buyer's market, where demand is generated through political negotiations. Besides, the buyers are developed countries undertaking GHG emission reduction obligations and they value CDM emission credits from their own benefits. If the demand terminates, the amount of CDM emission reductions generated will make no sense. Whether CDM is legal or not in the post-Kyoto era presents the greatest risk to CDM participants. If there are voluntary markets as a supplement, the situation will be much better, where CDM emission credits can still be recognized and transferred.

Secondly, China is the largest supplier in the short-time but may not last long. Currently, China occupies the biggest proportion among the CERs sellers. In 2008, China's market share accounted for 84%, far more than other developing countries. It is expected that, by 2012, China can obtain 1.8 billion tons of carbon trading allowances through CDM. Although optimistic in the short-term, we can not ignore the hidden problems. China's current CDM projects are concentrated in a number of areas with lower-cost, but those that really need new technology are unappealing. HCF-23 decomposition projects are usually priorities due to the lower capital investment and high outputs. These projects registered account for the largest share, about 32.02% per year. New energy and renewable energy projects follow. All of them are resources-related projects with low investment, low technology, and stable income which are more preferred by investors in developed countries.

In the process of carrying out CDM projects, there exist the following issues. First, the unique character of China's carbon market is that the government set an unwritten guide price for CERs. Article 15 of *China's Clean Development Mechanism Project Operation and Management Measures* asserts that the transaction price is decided by the National CDM Project Board. On the one hand, as the market is still not mature and project sellers have no advantage, Chinese government should interfere in the CER price. However, on the other hand, this may lead to the deviation of CERs price from EUAs, which might have negative effect on China's carbon trading. Therefore, the market shows a mixed reaction to the guidelines.

Second, most of the participants in CDM projects are only for financial purposes. Many foreign buyers bear the purpose of reducing emissions. These include firms with emission reduction obligations under the European Union emissions trading system. In addition, for the image of social responsibility or preparing for implementing low-carbon businesses in the future, some firms tend to trade in voluntary markets such as the Chicago Climate Exchange. However, more and more Chinese firms are involved in CDM projects because they can produce additional cash flow. Statistics shows that Chinese firms participating in CDM projects are mainly concentrated in the areas of energy production. Projects in this field are capital-intensive and require intensive investment at the beginning. Nevertheless, if the situation changes such as China begins to undertake emission reduction obligations in the post-Kyoto era, these firms will have to improve their technology through appropriate means of financing to obtain additional capital.

Third, Chinese government pays insufficient attention to CDM development. Most of the government agencies still put GDP in priority. The government should compromise between the current situation and the arrival of low-carbon economy and direct the government expenditure to new energy and environmental protection industry to help them get new technology. The future of CDM is still uncertain. Because of the financial crisis, many firms in developed countries are still suffering. In addition, a large amount of international capital flows into China, which has intrigue many developed countries. This can be reflected in recent international trade frictions. Therefore, we can not rely solely on external forces to promote CDM projects. If our government can make sufficient effort to

promote the development of low-carbon economy, China is bound to spearhead in the world in the future.

Although CDM projects have brought benefit to firms, they can easily mislead us at the same time. Developed countries can reduce their costs by purchasing emissions credits from developing countries. Despite that China's domestic carbon market has not started, a large number of Chinese firms have reaped huge benefits through CDM projects. As a result, the public are easily misled by such cases and consider it as free lunch. However, based on the above analysis, it is not difficult to conclude that CDM is a double-edged sword in the long run.

4. Empirical test

Due to the volatile nature of CER prices, it is imperative for relative firms to manage the market risk of CERs. The study of the volatility and the risk characteristics of CERs are of great practical significance for Chinese firms to manage risk of carbon trading.

4.1 Methodology

Markov regime switching model uses Markov chains to depict the phenomenon of structural changes in the economic system. Hamilton and Susmel (1994) introduced the ideas of Markov regime switching model into the ARCH model to specify a SWARCH model. According to them, if S_t is set to be a state variable, then the conditional variance h_t is actually specified to be a function of p most recent state variables:

$$h_t = f(S_{t-1}, S_{t-2}, \dots, S_{t-p}) \quad (1)$$

However, when we introduce the ideas of Markov regime switching model into the family of GARCH models, a problem arises-- the conditional variance h_t would be a function of entire history of the state variable even though it was assumed to be GARCH(1,1) process (Dueker, 1997), namely:

$$h_t(S_t, S_{t-1}, \dots, S_0) = \gamma(S_t) + \alpha(S_{t-1})\varepsilon_{t-1}^2 + \beta(S_{t-1})h_{t-1}(S_{t-1}, \dots, S_0) \quad (2)$$

Dueker (1997) introduced a collapsing procedure developed by Kim (1994) to solve the problem. He supposed that there exist two states, state 0 and state 1, during every period and h_t is a function of the most recent two state variables S_t, S_{t-1}

$$h_t^{(ij)} = h_t(S_t = i, S_{t-1} = j | \Omega_t) \quad (3)$$

Then GARCH equation will be :

$$h_t^{(ij)} = \gamma(S_t = i) + \alpha(S_{t-1} = j)(\varepsilon_{t-1}^{(j)})^2 + \beta(S_{t-1} = j)h_{t-1}^{(j)} \quad (4)$$

$$h_t^{(i)} = \sum_{j=0}^1 P(S_{t-1} = j | S_t = i, \Omega_t) h_t^{(ij)} \quad (5)$$

Such that $h_t^{(i)} = h(S_t = i | \Omega_t)$, Ω_t is the information set in time t . Dueker (1997) further let h_t to be a function of S_{t-1} such that GARCH process can be written as:

$$h_t^{(0j)} = h_t^{(1j)} = \gamma + \alpha(S_{t-1} = j)\varepsilon_{t-1}^2 + \beta(S_{t-1} = j)\hat{h}_{t-1} \quad (6)$$

$$\hat{h}_t = P(S_{t-1} = 0 | \Omega_t)h_t^{(i0)} + P(S_{t-1} = 1 | \Omega_t)h_t^{(i1)} \quad (7)$$

We develop Dueker's model to specify a GARCH (1, 1) model switching between normal distribution and t distribution. We call it Markov Regime Switching GARCH Model (MSGARCH) model. We will fit it using CER price data series. In addition, we will also fit a ARCH(2) model, a GARCH(1,1) model and a SWARCH(2) model from Hamilton and Susmel (1994) to prove that the MSGARCH model above is appropriate to fit CER spot price yield series in the secondary market by comparing the outputs of all of the four models.

4.2 The empirical analysis

4.2.1 Data

The data² used in the paper is CER spot closing price from the Bluenext Exchange in France from August 12, 2008 to March 17, 2010³. We use P to represent the sample series. The log return rate in t period is computed by equation (1):

$$\text{The log return rate in } t \text{ period} = (\ln P_t - \ln P_{t-1}) \times 100 \quad (8)$$

Table 1 demonstrates the descriptive statistical analysis for the sample. The skewness is -0.330, less than zero. The Kurtosis is 4.64, larger than that of normal distribution, 3. P value of JB statistics approximate to zero. So, the null hypothesis of normal distribution is rejected.

TABLE 1: CONDITIONAL VARIANCE

	$S_{t-1} = 0$	$S_{t-1} = 1$
$S_t = 0$	h_t^1	h_t^2
$S_t = 1$	h_t^1	h_t^2

FIG.3 shows CER daily closing price series. FIG.4 shows CER daily return rate series squared the squared series. CER spot price had been falling and fluctuating violently from second half year of 2008 to late in March, 2009. It was because that industrial production declined so much that global energy consumption shrank seriously and demand for CER dropped significantly under the impact of financial crisis. The price leveled off gradually after April, 2009 with the rebound of demand for energy. Therefore, CER price dynamics might have taken place regime-switching during the sample period under the impact of financial crisis.

FIG.3: CER DAILY CLOSING PRICE

FIG.4: CER DAILY RETURN RATE AND THE SQUARE

Furthermore, we split the sample to two sub-samples. The first one is from August 12, 2008 to April 30, 2009. The second one is from May 1, 2009 to March 17, 2010. Table 2 shows descriptive statistics for the two sub-samples. We may observe that the maxima and minima of sub-sample 1 are just that of primitive sample. The standard deviation of sub-sample 1 is larger than that of sub-sample 2, which means that CER secondary market price in the first sub-sample period fluctuates more violently. In terms of kurtosis, sub-sample 1 is 3.892, larger than that of sub-sample 2, 3.458. With respect to distribution test, P value for JB statistics of sample 1 is 0.024 while that of sample 2 is 0.108. Thus, we reject the null hypothesis of normal distribution for sub-sample 1, but accept it for sub-sample 2 under the level of 0.05. Therefore, there are significant differences in statistical features between the two sub-samples. Regime-switching may have taken place in fluctuation spread, distribution, kurtosis and tail thickness. MSGARCH model may be fit to the sample.

TABLE 2: THE DESCRIPTIVE STATISTICAL ANALYSIS FOR THE SAMPLE

Mean	Max.	Min.	Std. Dev.	Skew.	Kurt.	Sample Volume	JB	JB p value
-0.136	9.443	-10.22	2.658	-0.330	4.679	406	54.69	0.000

4.2.2 Results

We estimate ARCH (2) model, GARCH (1, 1) model, SWARCH (2) model and MSGARCH models under the assumption that random disturbances follow t distribution. The result is demonstrated in Table 3. Only for the MSGARCH model, all parameters are significant at 1%. In addition, MSGARCH model's log likelihood is the largest but AIC the least. Therefore, our MSGARCH model fits CER price data the best.

According to MSGARCH model's parameters estimation results in the last column of Table 3, p_{00} and p_{11} is respectively 0.917953 and 0.786970 ($p_{11} = 1 - p_{01}$) respectively. It indicates that state 0 shows a stronger persistence.

TABLE 3: ESTIMATION RESULT

parameters	ARCH(2)	GARCH(1,1)	SWARCH(2)	MSGARCH
μ^0	-0.007642 (0.124183)	0.012988 (0.104007)	0.178385 (0.134281)	0.333606** (0.016328)
μ^1	n.a.	n.a.	-0.593009 (0.359671)	-1.06272** (0.018573)
γ	3.727330** (0.559043)	0.191022 (0.117432)	2.829771** (0.466714)	0.157025** (0.020511)
α	0.371781** (0.133868)	0.130763** (0.046051)	0.091623 (0.068864)	0.195966** (0.020936)
β	0.150899 (0.081123)	0.851653** (0.043704)	0.015737 (0.052150)	0.764054** (0.017589)
n	6.565710** (1.955538)	7.268948** (2.468718)	31.56016** (69.01678)	3.468332** (0.041738)
p_{00}	n.a.	n.a.	0.969967** (0.023401)	0.917953** (0.024088)
p_{01}	n.a.	n.a.	0.053598 (0.039801)	0.213030** (0.016928)
g	n.a.	n.a.	2.973315** (1.020502)	n.a.
<i>Log likelihood</i>	-938.4996	-927.6770	-929.0232	-924.5812
<i>AIC</i>	4.67079	4.594468	4.649909	4.593996

Notes: It's standard deviation in the parenthesis. * indicates significance at 5%; ** indicates significance at 1%.

In another word, when the return rate follows t distribution, it is more likely that regime-switching will take place in the next period. When it is in state 1, the return rate follows t distribution with a freedom 3.468332 and the tail is fatter, namely, a higher probability for extreme values. Holding h_t constant, it will lead to a growth of 136.2% for the conditional variance if it switches from state 0 to state 1:

$$\left[\frac{n}{n-2} - 1 \right] \times 100\% = \left[\frac{3.468332}{3.468332 - 2} - 1 \right] \times 100\% = 136.2\% \quad (9)$$

The estimator for ARCH item coefficient in the GARCH process is $\alpha \left(1 - \frac{2}{n} \right) = 0.195966 \times \left(1 - \frac{2}{3468332} \right) = 0.082963$. So the ARCH item coefficient in the GARCH process switches from 0.195966 to 0.082963 when it switches from the state 0 in t-1 period to the state 1 in t period. Hence, the disturbance from t-1 period makes a more significant effect on the conditional variance in t period when it is in state 0 in t-1 period than in state 1.

4.2.3 Smoothed Probability

In the model involving regime-switching, state variables are unobservable. However, we can compute the probabilities for each state according to the model and sample information. Compared with filtered probabilities, smoothed probabilities utilize sample information more efficiently. Thus, we compute smoothed probabilities for state S_t in order to analyze the volatility of CER price in the sample period. FIG.5 and FIG.6 are smoothed probabilities when CER return rate is in state 0 and state 1 respectively. Combining them with FIG.3 and FIG.4, we can infer that there exists regime-switching indeed during the sample period. However, generally regime-switching takes place more frequently at the peak of financial crisis (August, 2008-March, 2009) and state 1 occurs with a higher probability, which means CER price fluctuates more violently and the risk is larger. It take place less frequently after the peak of financial crisis (March, 2009-March, 2010) and state 0 occurs with a higher probability, which means CER price fluctuates more moderately and the risk is smaller.

FIG.5: SMOOTHED PROBABILITY FOR STATE 0

FIG.6: SMOOTHED PROBABILITY FOR STATE 1

The fluctuation of the CER price in the secondary market demonstrates a characteristic of regime-switching under the influence of many factors. Therefore, we specify a MSGARCH model with distribution switching in order to fit CER price data and then compare the estimation result with an ARCH(2), a GARCH(1,1) model and a SWARCH(2) model. It is proved that the MSGARCH model works the best. At the peak of the financial crisis, the distribution of CER price return rate switched frequently between normal distribution and t distribution and the fluctuation spread switched between different levels. After the peak of the financial crisis, the switching frequency fell and the price also leveled off. Using the conditional variance gotten from MSGARCH model to compute the hedge ratio might reduce the risk effectively and maximize the profit.

5. A few words about the future trend of China's CDM market

The top priority for Chinese government is to improve the efficiency of social resources allocation by taking into account the comprehensive economic, social and environmental factors as well as developing the low-carbon economy. The industrial economy in China is now experiencing unprecedented growth. The fast growing economy has resulted in excessive consumption of resources and deterioration of the environment, which poses a serious threat to sustainable economic development. Therefore, how to develop the economy harmoniously is the major concern of China. Traditional resource allocation does not consider the destruction of industrial pollution emissions on the environment. As a negative economic externality, air pollution reduces the whole allocation efficiency to some extent. When we take the environmental factors into account, emissions allowance as a kind of scarce resource can be traded in the market. The Coase theorem shows us that, carbon trading can integrate the social resources and make the external costs internalized, which contributes to the overall allocation efficiency of resources.

As a player in the international game of climate change, China should adapt the low carbon era proactively based on precise risk assessment and rational prediction. Gaming depends on fair rules. International regulations solving the climate problem is still in primary stage and thousands of international negotiations have not generated new legally binding international agreements. In this situation, as the largest developing country, China should take great advantage of its international influence, act a positive role in the climate change negotiations, and promote the formulation of legally binding international agreements.

Although global climate game will eventually be a win-win cooperative game, the benefit distribution among participants is still a problem. How much each participant can gain from the game will ultimately depend on the competitiveness. In response to the challenge of global climate game, China should eventually resort to technological advances and market-oriented mechanisms. The technological progress will enable us to control more available resources, while market mechanism can allocate resources more effectively. China needs to make full use of technologies from developed countries and strengthen research and development abilities on renewable energy, carbon capture and carbon storage technology. In terms of the construction of market mechanism, China must not only develop domestic carbon credit trading markets positively and normatively, but also encourage banks and other financial institutions to enhance finance innovation, manage climate change risks effectively and participate in generating international rules of carbon credit transactions. Meanwhile, China needs to explore effective market incentives and monitoring mechanisms which are supported by technology and funds from developed countries. The bottom line is that China must guarantee the future development rights while reducing emissions.

CLIMATE CHANGE: AMERICA, INDIA AND CHINA

By

V. Ranganathan, Professor, IIM, Bangalore.

Abstract

All the three countries US, India and China have abundant coal and a large coal based electricity program. All of them face stiff choices between low cost and carbon footprint in their future electricity generation program.. Of this US had maximum Carbon emissions, followed by China and then India. This year, 2011, has seen the tipping point where China has overtaken the US for Carbon emissions. For India energy intensity has actually decreased, as evidenced by energy-gdp elasticity figure changing from 1.2 to 0.8 over the last couple of years. However while China is seen as making efforts to reduce emissions—in fact it has outmaneuvered US industries by offering lower cost emission reduction equipment—India is often accused of not playing the ball. The paper addresses different approaches of the three countries to the Climate change issue and in particular outlines the dilemma that India faces in reaching its twin goals of inclusive economic development, which require low cost energy strategies and compliance to climate change agenda, which requires low carbon energy strategies.

Introduction The concept of sustainable development cautions that mankind should not consume excessively today because it will leave less for our posterity. Output is created using manmade and natural capital, and while the former is amenable to market logic, the latter is consumed excessively since there is a market failure; the natural capital has no price tag since it is somewhat a public good, with characteristics of nonexcludability and to a limited extent non-rivalry. We say limited extent, because upto the point of its absorptive power (of pollution, which indicates its use), nature is a free resource with characteristics of non-rivalry, but beyond this, it becomes a scarce resource, albeit with no market price, and therefore manifests as an external diseconomy. Pollution being a public (dis)good, and also having a positive correlation with output and GNP, it suffers the fate of the ‘tragedy of commons’, impelled by prisoner’s dilemma behavior: i.e. collectively we realize that pollution is bad but individually we have something to gain by polluting, and inexorably driven to a nonoptimal outcome induced by noncooperative behaviour. The IGES white paper (2008) gives specific policy guidelines for Asia, emphasizing that climate change policies must align with sustainable development.

The intergovernmental panel on climate change (IPCC) brought out a report [IPCC AR-4 (2007)] and made the point that climate change is for real and quick action is called for by all countries acting in concert. However, the report also came under dim light for some plagiarisms which were deliberately contorted relating to Himalayan glaciers likely to melt by 2035. In the Climate Change debate, the following questions are pertinent:

1. Is the temperature rise a real trend?
2. Is the temperature rise caused only by human efforts or exogenously?
3. Will the temperature rise cause adverse consequences? If so, what are they at global, national and local levels? How far is it possible to relate local emissions and global emissions to local (including national) and global consequences?

4. For mitigating global level adverse consequences, what global level cooperation is required? (It is here that environment becomes a public (dis)good).

IPCC's answer to the first question is that it is a real trend. It has categorized various regions of the world as having temperature falls/rises and according to IPCC, a 2 to 3° rise in the last 34 years is corresponding to danger levels. According to US National Climatic Data Centre "during the past century, global surface temperatures have increased at a rate near 0.06°C/decade (0.11°F/decade), but this trend has increased to a rate of approximately 0.16°C/decade (0.29°F/decade) during the past 30 years".

IPCC has produced models of causation to prove that human activity has caused the temperature rise. But other scientists, organizations of NGOs have differed with this assessment. For instance, the NIPCC (2009) report says that 'a comparison of 'fingerprints' from best available observations with the results of state-of-the-art GHG models leads to the conclusion that the (human-caused) GHG contribution is minor', and that 'sun and associated atmospheric cloud effects are responsible for much of past climate change'. This report damns the IPCC report in every respect, temperature rise, glacier melting, sea ice, extreme weather, biological effects and species extinction. Thus it is the very antithesis of IPCC report, and has the support of Liberty Institute, a market oriented think tank.

In terms of impacts, India and other developing countries seem more vulnerable to them; sea level rise would submerge Bangladesh and even otherwise make its water saline, and cause migration to India. Erratic monsoons could have catastrophic effects on food production. But unless all the people are able to see the link between climate change and carbon emissions, the imperative of survival today, will force the developing countries to delay the low carbon trajectories. For the same reason that poor people do not use compact fluorescent lamps and still use incandescent lamps, even though the former may pay for the incremental cost within about 2 years, people will not use low carbon paths and will opt for emission intensive coal energy to fuel their development.

The plight of the poor developing countries clearly show the answer to the question no.4; viz. it is the burden of developed countries to reduce emissions to forestall climate change. The developing countries' stance is that they have a mandate for development to become as well off as the developed countries, and correspondingly have a right to the common resources of the globe, such as nature, which translates as an implicit right to emit an equivalent quantum of green house gases on a per capita basis.

We now proceed to show how the action has proceeded in tackling climate change at global level, and how the developed world is shirking this responsibility. Subsequently we will concentrate on the approaches of US, China and India towards tackling this issue.

The Kyoto Protocol was signed in 1997 and executed from February, 2005. This envisaged mandatory emission reductions for 37 developed countries and voluntary reductions for

developing countries, based on ‘common but differentiated responsibilities.’ These reductions could be achieved by countries, by 3 ‘flexibility’ mechanisms, viz. emissions trading, clean development mechanism (CDM) and Joint implementation (JI). Kyoto expires in 2012, and this is one reason for the Carbon market to collapse, since there is uncertainty about the post Kyoto regime.

The main tool most governments in the developed world are counting on to cut emissions and drive investment into climate-related industries is carbon trading, also known as cap and trade. The European Union established its system six years ago. Its goal is to cut emissions by one-fifth from 1990 levels by 2020. Carbon trading has run , into obstacles in Europe, where the system has been rocked by extreme volatility, computer attacks, tax fraud, recycling of used credits and suspicions of profiteering.

There are two options for cutting down emissions, viz. levying a carbon tax and the carbon trading (cap and trade). In the latter, caps of emissions are set, industries are given allowances, and these allowances are traded. If allowances are auctioned, then the price is the same as carbon tax. If allowances are given away by Governments, Government does not get the revenue, and therefore there is no compensating effect of reducing other taxes. Under certainty, both are equivalent. However, under the real world conditions of uncertainty, Carbon tax will work better than cap and trade, in cutting down emissions. A carbon tax will work like an advalorem tax, which will shift the supply curve upwards, and thereby reduce the output which has the pollution externality. Using tax to restrict bad things (apart from the traditional purpose of raising revenues to Government) was first suggested by Pigou. The Carbon tax was strongly advocated by Joesph Stiglitz (2006) and supported by Maniew (2007). On the other hand, the cap and trade has volatility because the Governments can increase the Carbon quotas for their industries thereby depressing the price of carbon.

The CDM works on the principle of a carbon trade between developed and developing countries, taking advantage of the low cost of carbon abatement in developing countries. Even if the system does not reduce actual emission in developing countries, because proving additionality is extremely difficult, it still benefits the developed countries, because once their industries buy the Certified Emission Reductions (CERs), they can use it as a shield and go on themselves emitting carbon. So, it appears that CDM is a clever trick for the developed countries to pretend that they are reducing emissions, without actually doing so, and paying a small price for it, in buying the CERs. They are really not interested in finding out if the CERs are genuine or fake. A good part of the CER money is recycled to the developed countries, as payment to the consultants who will prepare the project report and verify that the reductions are real. And because the additionality criterion and the corresponding various benchmarks are all too complicated, they ultimately become judgmental and require the MNC consulting firms to navigate through the labyrinth of CDM bureaucracy.

The Copenhagen Accord in 2009 realized that a legally binding treaty may be impossible to be reached, and instead sought an Accord. In this context, it is useful to understand the subtle differences between Accord and Agreement. An accord is a consensus decision reached which is politically and morally binding but not legally binding, whereas an Agreement is one that is legally binding. Such an agreement becomes a Treaty. A treaty implies seriousness on the part

of countries to comply with its provisions and corresponding incentives and disincentives to achieve the provisions contained in it. Such a treaty may also be a sine qua non for a carbon market to function. However, such a treaty is unlikely to be achieved unless developing countries also agree to reduce their emissions. Fig. 1 shows the CO₂ (or equivalent) emission by various countries from 1990 to 2030. It is clear that as on 2010, USA and China are the top emitters at 5,000+ million metric tons, then comes OECD Europe followed by Russia and India and Japan are below the level of Russia.

The Cancun summit in Dec. 2010 witnessed divisions in agreeing to a legally binding agreement between countries. US, China and India did not want, while the rest of the countries were for signing legally binding restrictions. In the BASIC group, consisting of Brazil, South Africa, India and China, which started with a common climate agenda, Brazil and South Africa opted for legally binding agreements isolating China and India which were opposed to that move. India's position was that while it will make domestic commitments suo motu, it has not yet reached the stage to make international commitments. There were also divergences on issues of Measurement, Reporting and Verification (MRV). US thought that China and India would fudge the figures and hence insisted on presence of external observer, which China did not agree. India was also cool to the US proposal, but later brought out a mechanism which essentially agreed for transparency to be introduced by external participation. Essentially major emitters will voluntarily make data on emission available in periodic intervals, through a process called International Consultation and Analysis (ICA); criticism within India is that this compromise removes the distinction between Annex 1 and non-Annex 1 countries. (for the latter the reductions are voluntary and domestic).

The broad divergence between developing and developed countries is that it is the latter that were responsible for global warming and so they must cut emissions. The developing countries are later beneficiaries of development through intensive energy use and so they must have this till they reach developed country levels of standard of living. Now let us analyse the approach of US, China and India towards the climate change measures.

US, China and India: All the three countries, are rich in coal; reluctant to give it up. All three are faulted for the failure of Kyoto Protocol to bring results, US being a non-signatory and China and India being not required of mandatory reductions of GHG.

Table 1 below presents the Energy-Environment related resource availability and production and consumption for the 3 countries, US, China and India. The average energy consumption per capita in the US is about four times that of China's. China is the world's largest producer and consumer of coal, with more than 70 percent of its energy consumption dependent on coal. In contrast, coal accounts for about 20 percent of energy consumption in most developed countries, complementing oil and natural gas. According to the World Energy Council, as of 2009, China held an estimated 114.5 billion short tons of recoverable coal reserves, the third-largest in the world behind the United States and Russia. In 2009, China, typically a net coal exporter, became

a net coal importer from countries such as Indonesia, Australia, Vietnam, and Russia. In September 2009, the China Coal Transportation and Distribution Association stated that China signed a \$6 billion loan-for-coal agreement with Russia for 15 to 20 million tons of coal for 25 years. While coal consumption fell 0.2% in 2008-09 to 3.28 billion metric tons of oil equivalent, China's and India's respective coal consumption rose by 10% and 7% ahead of their GDP growth (Business Week (2010)).

Table 1

	Units	US	China	India
Recoverable coal reserves	Billion tonnes	250	114.5	62.3
Coal Production	bt	1.097	3.4	0.613
Coal consumption	bt	1.052	3.5	0.681
Total energy consumption	Quadrillion btu	97.73	85.1	13.5
Per capita energy consumption	Million btu	250	64	17
Energy intensity	Btu/\$ (2008/2007)		11,450	6,500
Energy related CO ₂ emissions	Million tons	5,300	6,534	1,494
Per capita CO ₂ emissions	tonnes	17.5	4.9	1.31
CO ₂ intensity	Tones/1000\$		0.9	0.48

Source: US Energy Information Administration

From Table 1, it is clear that all three countries have big stakes in coal. Coal fuels 45% of electricity production in the US, about 60% in India and about 83% in China. In terms of energy consumption, US and China consume much more energy than India, and this inequality is exacerbated when it comes to per capita energy consumption. In terms of emissions, China has surpassed the US in absolute energy consumption, while India consumes about a little more than one fifth of China.

US's position: The US has an all or nothing approach and says that unless China and India agree to cut emissions, it will not do so and it will not allow even other aspects like funds for GHG reductions to reach a conclusion. This is articulated by Mankiew (2007) where he says, "Any long-term approach to global climate change will have to deal with the emerging economies of China and India. By some reports, China is now the world's leading emitter of carbon, in large part simply because it has so many people. The failure of the Kyoto treaty to include these emerging economies is one reason that, in 1997, the United States Senate passed a resolution rejecting the Kyoto approach by a vote of 95 to zero." Considering that both electricity and transport sectors contribute significant GHG emissions in the US, their reluctance to reduce emissions is understandable. The difference between the Bush Jr. administration and Obama administration is one of form, and not of content. While the former bluntly rejected Kyoto with 100% support of the Senate, the latter is playing the game 'only if you do first', especially with respect to China and India.

China is emerging as a global power and it has to wear two opposite hats. As an economic powerhouse it would like to take a leadership and statesmanlike role supporting GHG reduction. But it is also the leader of developing countries, and in this role it has to oppose GHG reduction if it were to champion the cause of developing countries, which incidentally benefits China itself in the process, in economic terms. Thus there is a conflict between its economic interests and global ambitions to be a leader. China also sees CDM as an opportunity to seek funds transfer from the West, and is channeling these private sector inflows into Government flows by specific taxes on the CDM recipients and using these tax revenues to subsidize renewable energy technologies to undercut the western manufacturers in the supply of equipment for these technologies. This has gone to such an extent, that the US administration is looking at bringing a case against China, including accusations about manufacturing subsidies for wind turbines, before the World Trade Organization.

Investment in clean energy in China rose 30 percent last year, to \$51.1 billion — by far the largest figure for a single country — and represented more than 20 percent of the total global investment of \$243 billion, according to Bloomberg New Energy Finance.

China is developing and investing in clean and renewable energies such as solar, wind, nuclear and hydropower but its coal production and consumption are also significantly increasing, as seen in fig. 1.

Fig. 1

India's emissions are much lower, a fifth of China and its energy-gdp elasticity is falling from 1.2 to 0.8, its economy being less energy and therefore emission intensive. The only energy resource available relatively in abundance in India is coal, apart from large hydro potential which is lying unutilized in the North East Brahmaputra basin and in the Northern State of Jammu and Kashmir. Coal is the preferred fuel for producing electricity whose demand has been rising at

around 9% per annum. India's emission is one fourth of the global average (Jyoti and Kirit Parikh (2002)).

Conclusion: Thus, while US is using China and India as a shield for its reticence towards emission reduction, China is actually increasing its emissions and at the same time benefitting from the CDM scheme by taxing the profits from these revenues and using these tax receipts to subsidize its renewable energy technologies, which it sees as a growing market. It is also getting good press because it is effectively competing in green technologies even though it is hurting the Western green industry, which it undercuts. On the other hand, India though no where consuming energy or emitting pollution as much as China, and far far from the US, it is still seen as a bellicose actor by the global media and is seen as torpedoing the Cancun process. Thus there is a great need to improve for India its finesse in handling the energy-environment issues relating to climate change.

Issues and Trend in the Payment of Compensation in the Oil Industry in Nigeria, 1969-1997

*Aghalino Samuel Ovuete , aghalinosamuel@yahoo.com
Department of History and International Studies,
University of Ilorin, Ilorin- Nigeria*

Abstract

This paper examines the issue of the payment of compensation to victims of oil pollution and other forms of environmental modification occasioned by oil exploration and production in the oil-bearing enclave in Nigeria. It is asserted that the intractable problem -of the payment of fair and adequate compensation could be traced to the colonial origin of the oil industry as epitomized by the skewed template of laws that undermine the interest of victims of the negative externalities from the oil industry. In this guise, this study is predicated on analysis of the legal framework for compensation payment in Nigeria. Furthermore the actual payment of compensation practice by oil firms is evaluated in the light of the reality on ground in Nigeria. It is found that while there is a semblance of attempt to pay rates higher than those of the Federal government in Nigeria by the oil firms, it is observed that even at that, the rates paid by the oil industry do not reflect market price and they also fall short of international standard. In our conclusion, we emphasized the need for the oil firms to address the inadequate compensation regime being perpetuated in order to redress the incessant community agitation and youth restiveness in the oil-bearing belt of Nigeria

Introduction

The payment of compensation is one of the intractable problems facing the oil industry in Nigeria. The internecine crisis between the oil firms, the host communities and the federal government could be traceable to the issue of neglect which is synonymous with the low compensation paid to the victims of negative externalities from the oil industry.

These externalities are in form of oil pollution, gas flaring and other forms of environmental modification. Bearing in mind that it is difficult to engage in oil business without one form of environmental pollution, the framers of the 1969 Petroleum Act insisted that in an event of untoward modification of the environment, fair and adequate compensation should be paid to the victims. It is therefore a statutory obligation for oil firms to engage in best oil field practice to avoid polluting the environment. However, evidence on ground would seem to suggest that the issue of compensation is a thorny one.

Opinions are divided on the adequacy or otherwise of the compensation paid by the oil firms to the victims of oil spillage. On the one hand, oil firms claim that they are paying adequate compensation. Indeed, it is asserted that they pay rates higher than the official ones. On the other hand host communities insist that the rates paid by oil firms are not just enough and that the oil firms violate existing regulations in the payment of compensation. Seen against this background, this paper examines the issue of compensation in the oil industry. It is opined that the controversy surrounding the payment of compensation dates back to the colonial period. Consequently, our discussion is predicated on this colonial antecedence. The legal framework for compensation-is given some attention against the backdrop of compensation practice by oil firms. The conclusion drawn from this study is that the attitude of oil firms to the issue of compensation must be understood from the neocolonial nature of the oil industry. Besides, it would appear that legislative bottleneck and the paternalistic attitude of the judiciary are some of the observable limitations to the actualization of fair and adequate compensation in the oil industry.

The Payment of Compensation: Colonial Antecedence

An appropriate understanding of the issue of compensation must commence from the perspective of the colonial origin of the oil industry. Thus, a linkage must be drawn from the past and its influence on the present state of affairs in the oil industry. The point to emphasize is that the British colonial masters created a template of law, which made it possible for foreign firms to operate, as they deemed fit. Consequently they enjoyed massive fiscal incentives while exploiting oil concessions. Nigeria (www.lilt.list.edu/critique/fall2002/docs/jagbonifo.pdf). The people of the Niger Delta who as it were, are stakeholders in the oil industry were never compensated for oil found in their soil.

It is within this context of first, uncontrolled exploitative activities and skewed colonial State laws to protect British domination of Nigerian economy and perpetuation of the patron-client relationship that the present day lukewarm attitude of oil firms must be located. Agbonifo has shown that enamored by its imperial privileges, the Transnational National Corporations (TNCs) resorted to wanton exploitation of the people and environment, destroyed forests, farmland and constructing overland crude oil pipelines without any regard for the well being and safety of local peoples. In this process the local people's right to safety of life and property were undermined (www.lit.listedu/critique/fall2002/docs/jagbonifo.pdf). This approach by the TNCS backed by the colonial state is not surprising. As it were, colonialism was, first and foremost, interested in extracting the surplus generated in Nigeria for the benefit of the metropolitan economy (Akin, 2002:53-56).

Indeed, although oil prospecting commenced in Nigeria as early as 1937 legal framework for oil operation in the period immediately following independence was predicated on ownership by the federal government of mineral resource located anywhere in the federation. Specifically the Mineral Act of 1969, enacted to amend and consolidate all the existing legislation relating to mines and minerals vested ownership of mineral resources including petroleum on the federal government¹. This Act was a timid copying of the vesting of natural resources in the Crown. The point here is that because Nigeria was a conquered territory, the people of Nigeria were not entitled to any form of compensation from the exploitation of their resources by the colonial masters.

Ordinarily, one expects that after independence, there should have been a semblance of freedom for the owners of the resources. Rather, in post colonial Nigeria, the elite failed to grasp the essence of colonialism as an apparatus of exploitation and alienation. They accepted hook, line and sinker the erstwhile dominant colonial theory and form of property ownership. The point may be raised as to why it took the people of the Niger Delta so late to realize that they have been paid little or no compensation for their oil wealth. It must be conjectured here that at the initial period of the oil industry, they were highly enthused as to the prospect of the transformation of their region. Their hope was robust, as this was ignited with promises of gainful employment, provision of basic amenities, better quality of life and assurance of building of cottage industries that would employ their sons and daughters (Aghalino, 2004:56). This optimism possibly made the people to pay little attention to the issue of compensation.

It is arguable that without a prospect of the transformation of their region, the people of the Niger Delta would have confronted the oil industry head long from the on-set having earlier on been victims of the greed of the colonial state. On the whole, it was not until the early part of the 1960s that some bite was given to the issue of fair and adequate compensation from the oil industry. A potent manifestation of the evolving wave of discontentment was the Isaac Adaka Boro revolt (Maier, 2002:124). Appalled by the insensitivity of the oil firms, Adaka Boro and his cohorts revolted against the state and the oil firms. It must be reiterated that if the legal framework put in place to redress the issue of compensation were adequately adhered to by the oil firms, the incessant crises would have whittled down appreciably.

Legal Framework for Compensation

There are extant acts and statutory provisions that enjoin oil firms to pay one form of compensation or the other to victims of oil pollution. These includes: The Petroleum Act, 1969, Oil Pipeline Act, 1958, Petroleum (Drilling & Production) Regulations, 1969, Public Lands Acquisition Miscellaneous Provision Decree (1977) and later Land Use Act, 1978. In all, there are three strands under which victims of oil pollution may seek payment of compensation from the oil industry. These are the statutes, the common law and rules of international law (Ekpu, 1996:258). Each of these sources obligates operators in the petroleum industry to provide compensation in appropriate cases for damages resulting from oil pollution. In point of fact, section II (5) of the Oil pipeline Act reads as follows:

The holder of a license shall pay compensation to any person suffering damage other than on account of his own default or on account of the malicious act of a third person as a consequence of any breakage of or a leakage from the pipeline or any ancillary installation for any such damage not otherwise made good.

Paragraph 36 of schedule 1 of the petroleum Act, 1969, provides in general terms the obligation of license holders. It states that:

The holder of an oil exploration license, oil prospecting license or oil mining lease shall, in addition to any liability for compensation to which he may be subjected under any other provision of this Act, be liable to pay fair and adequate compensation for who owns or is in rightful occupation of the
Licensed or leased land

(cited by Etikerense, 1990:288).

The other important provision in this Act is contained in Regulation 23 of Petroleum Drilling & Production Regulation). It states that: If the licensee or leasee exercises the right conferred by his license or lease in such manner as unreasonably to interfere with the exercise of any rights, he shall pay adequate compensation therefore to any person injured by the exercise of these just mentioned rights. Certain part of this Act needs amplification. For example, one note that the words "shall ensure" is rather whimsical and bogus to command compliance. First what is fair? Is what is fair to the oil firms, fair to the victims of oil pollution? And what is the machinery for ensuring that a fair and adequate compensation is paid! Second, is what to be paid determined by the oil firms or by government or by both? Are the victims not supposed to be involved in determining what is fair and adequate? The inability to integrate major stakeholders in determining what to be paid as compensation has always been a sore point in the tripartite relationships in the oil industry (Aghalino,1999:102).

It must be noted that even when oil companies consent to pay compensation there is always the procedural problem. Issues are raised as to the extent of the areas polluted, categories of damage to be compensated and at what rate. There is also the problem of whom to pay. In most cases, the oil companies prefer paying directly to the victims of oil spillage. This option is understandable because it would appear it costs less to pay directly as they lacked the finesse to bargain economically. Nevertheless, in reality, pittance get to the victim, as substantial part of the money must have been hijacked by community elite (Aghalino, 2000:11-20).

In the case of the Regulations 23 of the Petroleum (Drilling and Production Regulation) it is obvious that victims of oil pollution may not get compensation unless it is established that the operator exercises its rights "unreasonably". Being a highly technical industry, it may be difficult to prove cases like this beyond reasonable doubt by the poor, "illiterate" and obligate fishermen. In other words, in most cases, compensations are not just paid by oil firms even when there is overwhelming evidence. They reluctantly pay after protracted negotiations and expensive law suits.

It should be expected that during this agonizing process of litigation, oil firms deploy intimidating number of lawyers and experts to ease their case. An example should suffice here. In *Ogiale and others versus Shell*, the plaintiff sued the defenders at the High Court Oleh, Delta State for well over \$23,000. This amount was for the general damages allegedly done to the plaintiff's farmland at Olomoro area of Isokoland (Delta State Law Report, 1996:64-110). The plaintiff called six witnesses, two of which were experts. The plaintiff also tendered expert report of estate valuers as exhibit. The defendant denied any damage to the land of the plaintiff calling one expert witness who tendered his report, which was admitted as exhibit. The trial judge dismissed the plaintiff's claims on the ground that the conclusion reached was not supported by rigorous scientific analysis that involved, chemical analysis and soil test.

There is also the problem of delays in giving judgement due in part, to court congestion and what the people claim to be unnecessary adjournment solicited for by lawyers to the oil firms to wear out litigants. While this claim is difficult to substantiate, there is strong evidence to suggest that there is semblance of delay tactics to frustrate oil pollution victims. For example, on a damage caused in 1979, there was consequent writ of summon in 1984. This case was heard for the first time in 1987. Subsequently the case was appealed in 1989 and heard in the Supreme Court in 1994 (Nigeria's Weekly Law Report, 1994:689). Thus in this instance, this case dragged on for a period of sixteen years with its attendant waste of time and money. How else does one equate this protracted procedure in the court especially when it is viewed against the backdrop of justice delayed is justice denied? Understandably, it is reasonable to suggest that the legal bottleneck, encountered by the people must be a contributory factor to the spate of sabotage of oil installations in the Niger Delta (Human Rights Watch, 1999: 58).

The Land Use Act needs some commentary. As it were, for oil production to take place, land is acquired for the construction and installation of oil facilities. In Nigeria, the principal law governing land ownership is the 1978 Land Use Act. The Act provides that:

all land composed in the territory of each state in the Federation are (sic) hereby vested in the Governor of that State and such land shall be held in trust and administered for the

use and common benefit of all Nigerians'. (see Section 1, Decree No.6 of 1978, Cap 202, Laws of the Federation of Nigeria).

In spite of this general proclamation, if land is required for mining purpose, the Land Use Act provides that the occupier is entitled to compensation as is also applicable in the Petroleum Act.

In contrast to the Land Use Act, the Petroleum Act, however, makes no provision for compensation to be paid for land acquired. Section 1 of the Act vests the entire ownership and control of all petroleum in, under or upon any land within the country or beneath its waters in the state. By extension therefore, because oil is a federal property, land occupiers are entitled to no royalty for oil extracted from their land (Human Right Watch 1999:75-77). In view of this, the Federal Government collects mining rents, and petroleum profit tax, conceding a meagerly 13 per cent derivation fund to the oil bearing states. This is in sharp contrast to what is obtainable in the Ghanaian Diamond Industry where landowners were paid royalties, which were in proportion to the net profit accruing from mining concessions (Greenhalgh, 1988:86-113).

Victims of oil spillage and environmental damage can also lean on the Common Law to seek for compensation. In this instance, they rely on negligence and the rule in Ryland and Fletcher (Uzodike 1987:66). The rule in Ryland and Fletcher is a fall out of an English law case of 1866, which held that anyone bringing onto land, in the course of a non-natural use of land something likely to do mischief if it escape... is prima facie answerable for all the damage which is the natural consequence of its escape (Ekpu, 990:23-284). How successful victims of oil pollution have exploited this alternative is still a matter of conjecture. What to emphasize is that in the case of negligence, the claimant must convince the court that: (1) the operator owed him a duty of care, (2) the breach of the duty, (3) a causal link between the breach and the injury suffered (Ibid). There is no doubt that these are serious legal bottlenecks. More often than not, the people of the Niger have failed to scale through these barricades to obtain fair and adequate compensation for damage done to their environment.

There are rules of international law, which could be exploited by victims of oil spillage. These rules impinge on the subject of oil pollution and compensation. Ekpu has shown that Nigeria is a party to the 1969 International Convention on Civil Liability for oil pollution damage. Nigeria is also a signatory to the 1971 convention on the establishment of an International Fund for Compensation for Oil Pollution (Fekumo, 1990:231). The purpose of this is to provide uniform International rules. This as it were, would enhance the procedure for determining questions of liability and providing adequate compensation for person who suffers damage caused by discharge of oil from ships. These conventions have little bearings on local issues mostly when it is noted that there is absence of local equivalent legislation to make the provisions of the convention enforceable locally.

It is difficult to discuss the issue of compensation in the oil industry without a cursory reference to the issue of sabotage. The Petroleum Production and Distribution (Anti-Sabotage) Act of 1975 defined an offense of "sabotage" thus: any person who does any of the following things, that is to say:

- (a) willfully does anything with intent to obstruct or prevent the production or distribution of petroleum product in any part of Nigeria or;
- (b) willfully does anything with intent to obstruct or prevent the procurement of petroleum products for distribution in any part of Nigeria.

There are very strong indications that the oil firms use claims of sabotage to avoid compensation payment to the local communities (Frynas, 1998:457-478). This point was succinctly expressed by the Niger Delta Environmental Survey when it opined that many operators have hidden under the cloak of sabotage to avoid payment of compensation in cases of oil and discharges (Akpezi, 1996:62). The oil industry catch on sabotage because in accordance with Nigerian laws, they do not pay compensation on the ground that it may create incentive to damage oil installations and harm the environment (Human Rights Watch, 1999:83). Nevertheless, oil firms are under obligation to clean the environment. Thus in each case, the oil firms can as well claim that spillages are caused by sabotage in order to avoid payment of compensation. Indeed so much mileage has been made about sabotage because there seem to be an economic incentive to it.

Since oil companies are in themselves responsible for the provision of spill data to the Department of Petroleum Resources, there is little to prevent them from reporting incidents such as equipment failure as sabotage. This position seems more apposite when it is viewed against current events in the oil industry in Nigeria. For example, Shell has been accused of inflating her oil reserve base in Nigeria- a situation which culminated in the sacking of top management staff in the company (Economic Update. Volume 1, No.5,

May 2004:9). In any case there are a lot of sharp practices in the oil industry and it would appear that the issue of sabotage is a veritable framework for milking the people out of their genuine demand for compensation. This is fulcrum of the criticism of the then Governor of Rivers State, Melford Okilo when he queried that:

Rupture of petroleum pipelines due to deterioration is presented by oil companies as sabotage. What if pollution happen in America, it is not done(sic) by the people, but in Rivers State, local people are blamed (Daily Times 14 July 1981).

Evidence available suggests that the issue of sabotage is controversial, a position which Claude Ake described as 'irresponsible propaganda' (GreenPeace,1994:52). It would appear that the illegal act of sabotage of oil installation shows a conviction among the people of the complexity of seeking redress through negotiation and litigation in the law court (Aghalino, 1999:225). The point to emphasize is that while the government is not in a hurry to implement its own environmental laws in the oil industry, it is contented with religiously implementing laws such as 'the anti-sabotage' law to the detriment of her people. Ordinarily, it is expected that government would avails itself the opportunity of tackling the root cause of the issue of sabotage rather than its symptom.

Payment of Compensation by Oil Firms

The point should be made that the payment of compensation by oil firms is procedural. In an event of oil spill resulting in damage to property, the first approach by the concerned department of the oil firm is to initiate assessment or evaluation of the extent of damage. Land officers, estate officials and surveyors do this assessment. In the process, property destroyed are identified, assessed and recorded. A major principle comes into play in this regard. This has to do with the use of 'before' and 'after' value of the impacted property. This, as it were, must be quantified. With this, the valuers will deduct the value of the property before the incident (Uduehi, 1986:51).

It is observed that this method is full of ambiguities. For example, the owner of the impacted or impaired property is never consulted in the so-called scientific evaluation to ascertain how much he had invested on the farm, pond or land as the case may be. Agents of the oil companies assess damages within their whims and caprices paying little attention to market and farm gate prices of the impacted properties. To be sure, in most cases this so-called assessment is done in collaboration with local elite who capitalizes on the ignorance of victims to fleece their own people in return for a part of compensation money. More than anything else, most victims do not have extant documentation to fall back on to guide them in preparing their claims.

It could be seen that victims are helpless in the process of pursuing claims. They are caught between disinterested state officials, greedy company agents and local elite who are shylocks. From this permutation claimants are between the devil and the deep blue sea. Faced with Hobson's choice, they make do with the pittance that trickles down to them in the final analysis. In any case, there is ample evidence to show that up to the 1980s, the value of money paid for land acquisition for the construction of facilities for oil operation had been generally low. For example, Orubu,(2001:107) has shown, that ELF paid twenty eight thousand, four hundred naira, for 1.4 hectares of land acquired at Obodogwu 4 Location in Ndokwa East Local Government Area of Delta State.

Shell on its own seems to have paid comparatively smaller amount. It paid seventy-seven thousand and twenty six as compensation for 23 hectares of land for Okpokuwu 1 Location for all economic crops huts, shrines, animals and loss of fishing rights. As stated earlier, due to the colonial origin of the oil industry with its attendant template of laws that undermined the interest of the local people, the oil firms failed to see payment of adequate compensation as part of their corporate social responsibility (Aghalino, 2004: 16).

The point to note however, is that rates for compensation have been evolving. For example in 1976, the baseline rate for Cocoa was three naira and forty three kobo, while the revised rate for 1993 and 1997 were fifty naira and one thousand naira respectively (Oremade, 1986:67). The wave of anti- oil protests in the Niger Delta spearheaded by the Movement for the Survival of Ogoni People (MOSOP) must have added impetus to agitation for compensation. The series of protest in the region must have also influenced the oil firms to revise their rates paid for compensation. It is arguable if the revision is as a result of the pro-active administrative style of the oil firms. There is strong evidence to suggest that these are responses to the truculence and restiveness of youths in the region.

Anyhow, in fairness to oil firms, they pay higher rates than the officially established rates. For example, in 1997 the Oil Producers Trade Section of the Lagos Chambers of Commerce (OPTS) recommended five thousand, eight hundred and sixty naira per hectare of land while the 1995 official rate was one thousand three hundred and seventy five naira (Frynas1998: 460). It is evident that there is deliberate attempt by the state to impoverish her people. This is understandable because the people of Niger Delta are minorities in the power calculus in Nigeria. In most cases their opinion is never sought when decisions that affect their lives are made. Interestingly, the oil firms are aware of the rent-seeking nature of the Nigerian State hence they pride themselves as doing more than what is corporately required. But the bogus claim of the oil firms as to paying adequate compensation is easily exploded in the face of reality. In point of fact, the World Bank has shown that, based on annual rent of five thousand naira the Bank concluded that amount of compensation for land should at least be fifty thousand naira per hectare (World Bank, 1995). In comparison to other countries in terms of compensation payment, the Nigerian situation is appalling. In Tanzania, compensation for one hectare of mangrove ecosystem in 1991 ranged from \$300-600, while in Trinidad and Tobago in 1974, it was \$500 (Orubu 2001:107).

Akpezi, (1996:45) has shown that there are various irregularities in the payment of compensation. This includes paltry sum forced down the throat of hapless victims who do not have the wherewithal to engage in litigation to challenge their oppression. Furthermore, many victims go without any form of compensation. Available evidence shows that for a five-year period, one oil company received 1,081 claims for compensation. It settled only 124 while 24 claims went to court (Omobolaji, 1985:45). More than anything else, the attitude of Nigerian judges to issue of compensation leaves much to be desired. This contrasts sharply, with the disposition of American Courts towards awarding punitive damage (Ekpu: 1990:258). For example, in the case of Exxon Valdez spill; the trial court awarded \$5 billion as punitive damage in favour of the plaintiff. Apart from the attitude of judges in Nigeria, claimants of compensation also face a number of obstacles. These, according to Orubu and Odiase are (1) lack of adoption of a holistic approach in the valuation of resources for compensation by oil companies and (2) obnoxious role of compensation agents and consultants. Other obstacles are in form of unprotective legal system, untimely intervention of oil companies and corrupt oil industry officials who connive with local 'princes' to undermine the interest of victims of oil pollution.

In its entire ramification, the increase in the tempo of crisis in the oil producing communities would suggest that the hype by the government and the oil industry of paying adequate compensation is a ruse. The crisis in the region is predicated on the volume, value and quantum of revenue that is generated from the area in contrast to what they get in return as compensation from the havoc wrecked on their environment. This ill feeling has resulted in most cases in bloody encounter with the state and the oil firms.

The question may be raised as to why the oil-bearing communities would not tailor their grievances to the government who is the largest recipient of oil revenue. The point is, the oil firms are more in direct and physical contact with the communities and their expropriated inhabitants. The deprived peasants can easily reach out to the oil companies than to the distant, obscure and often inaccessible Nigerian government (Scot, 1999:14). This situation is akin to what Eteng, (1997::21) referred to as 'internal colonialism'. The highly exploitative pattern of compensation payment in the region must be a contributory factor to the clamour for resource ownership, control and management by the inhabitants of the oil-bearing enclave of the Niger Delta.

Conclusion

The issue of payment of compensation to victims of oil pollution and other forms of environmental modification is a subject of heated debate. It has taken the dimension it is today possibly because of the colonial origin of the oil industry and the predatory attitude of leaders in post colonial Nigeria. This probably explains why the history of the oil industry is the history of imperialism.

To be sure, because of the nature of colonialism as it was geared toward expropriation of surpluses from colonies to the metropolis, template of laws was put in place to check local aggression to the extraction of mineral resources. Thus, in Nigeria all mineral resources were vested in the Crown. The Colonial State dispensed with Nigerian oil wealth, as it deemed fit without paying compensation to the owners of the oil. Recipient of power in post colonial Nigeria failed to filter the laws they inherited to be in tune with the reality of independence. Rather they accepted and complicated colonial mode of property

rights as the watchword. Thus oil mineral was retained in Nigerian Statute as federal property. This was done just like the colonial period without seeking the opinions of the people in the oil - producing areas.

Possibly because the people in the region saw the only positive sides of having oil in their region and the dozen barrel of promises made to them, they failed to take the issue of compensation seriously early enough. But with the clear manifestation of the negative externalities from the industry, they began to agitate for fair compensation. There are basic legal regimes for the payment of compensation in Nigeria. But a careful reading and analysis of these legal frameworks has shown that they are faced with a number of problems. In spite of this, the oil firms have attempted to pay some compensation to victims of oil pollution. In comparative terms, the rates paid by the oil firms are higher than those set out by the government, yet they do not meet international standard, as they do not reflect current market value. In any case before payments are made there is always the agonizing process of negotiation and litigation. Thus legislative bottleneck and the lack of transparency in the payment of compensation as well as the paternalistic attitude of the judiciary are impediments to the actualization of fair and adequate compensation in the oil industry.

Management of Global Warming through Rig-Veda and Justification through the Indian Constitution

*Dheeraj Kumar Shringi, Department of Philosophy, Mohanlal Sukhadia University, India
Kuchata Ram, Department of Law, Mohanlal Sukhadia University, India*

Abstract

The present paper entitled "Management of Global Warming through Rig-Veda and Justification through Indian Constitution" is an attempt to control and manage the problem of global warming through Rig-Vedic model of cosmic management. This model is justified in the light of Indian constitution. The problem of global warming is prevalent today. Regarding global warming, 'Stockholm Conference'¹ 'Kyoto Protocol'² and 'COP-15 & 16'³ are widely recognized to eliminate and decrease the problem of global warming but these have not been successful. Many attempts have been made by the knowledgeable persons of this field to control and manage the global warming but these attempts are not enough to control the problem of global warming. The problem is rising day by day.⁴ Global warming is basically caused by three factors viz. greenhouse gases, pollution and deforestation.⁵ Greenhouse gases are the main source for global warming after deforestation and pollution. There is a need to control the global warming so that a person can live happily, merrily and prosperously without stress. This paper presents a model for controlling & managing this problem through Rig-Veda. Rig-Veda is the oldest book of knowledge in India. It contains the knowledge which is eternal & universal. According to F. Max Muller 'Rig-Veda have so many remedies for the problems of philosophy, science, art religion, cosmology, ethics and poetry.'⁶ It is also considered as a holy book in Hinduism. By the Hinduism it is regarded as a book of divinity. It is regarded as revealed by the Brahma. According to some scholars, it is said to be merely a book of poetry. Rig-Veda contains ten-mandates to controlling global warming.

Introduction of Global Warming

Global warming refers to 'climate change that causes an increase in the average temperature of the lower atmosphere.'⁷ Global warming can have many different causes, but it is most commonly associated with human interference, specifically the release of excessive amounts of greenhouse gases, pollution and deforestation. It is used to describe 'a gradual increase in the average temperature of the earth's atmosphere and its oceans, a change that is believed to be permanently changing the Earth's climate forever.'⁸ According to Encyclopedia of American History 'gases created through human, industrial and agricultural practice primarily carbon dioxide from burning fossil fuels and wood, as well as methane, nitrous oxide and chlorofluorocarbons increase the heat-reflecting potential at the atmosphere, thereby raising the planet's average temperature.'⁹ 'Global warming is the observed increase in the world's temperature of the Earth's atmosphere'¹⁰ Greenhouse gases and greenhouse effect was discovered by Joseph Fourier in 1824 and was first investigated quantitatively by Svante Arrhenius in (1896). It is a process by which absorption and emission of infrared radiation by atmospheric gases warm a planet's lower atmosphere and surface.¹¹

Causes of Global warming

Causes of global warming are greenhouse gases, deforestation and pollution. These are the major factors of global warming. The problem of global warming began with the Industrial Revolution in the 1850's and accelerated after that, the human consumption of fossil fuels has elevated CO₂ levels from a concentration of ~280 PPM to more than 380 PPM today. These increases are projected to reach more than 560 PPM before the end of the 21st century. It is known that carbon-dioxide levels are substantially higher now than at any time in the last 750,000 years.¹² Along with rising methane levels, these changes are anticipated to cause an increase of 1.4 - 5.6°C between 1990 and 2100.

The major causes of global warming are the emission of greenhouse gases like carbon-dioxide, methane, nitrous oxide into the atmosphere. The major source of carbon dioxide is the power plants. These power plants emit

large amounts of carbon dioxide produced from burning of fossil fuels for the purpose at electricity generation. About twenty per cent of carbon dioxide emitted in the atmosphere comes from burning of gasoline in the engines of the vehicles.¹³ This is true for most of the developed countries. Buildings, both commercial and residential represent a larger source of global warming pollution than cars and trucks.

Building of industrial structures requires a lot of fuel to be burnt which emits a large amount of carbon-dioxide in the atmosphere. Methane is more than 20 times as effected as CO₂ at entrapping heat in the atmosphere. Methane is obtained from resources such as rice paddies, bovine, flatulence, bacteria in bogs and fossil fuel manufacture. When fields are flooded, an aerobic situation build up and the organic matter in the soil delays, releasing methane to the atmosphere. The main source of nitrous oxide include nylon and nitric acid production, cars with catalytic converters, the use of fertilizers in agriculture and the burning of organic matter. Another cause of global warming is deforestation that is caused by cutting and burning of forests for the purpose of residence and industrialization.

Rig-Vedic Model

Rig-Veda is one of the oldest Veda written about 1500-1000 B.C. It is also known as Rig-Veda Samhita. Vedas means Knowledge.¹⁴ Etymologically, originated from the two Sanskrit terms 'Ric' means praise and 'Vid' corresponding to the English words 'wit' and 'wisdom.'¹⁵ According to Prof. H. Zimmer 'the vedic hymns are the oldest extant literary and religious monument of the so called Indo-European family of languages.'¹⁶ 'The Vedas give us abundant information, respecting all that is more interesting in the contemplation of antiquity.'¹⁷ 'Vedic hymns not only present us with a universal standard of morality represented by Rta they also lay down certain duties as the concrete manifestation of Rta.'¹⁸

In the Rig-Veda Rta means Dharma both the terms are used in the same sense. 'Ritam represents the basic truth, harmony, system or eternal moral order of the entire universe. That which is universally true is ritam and that which is the opposite or false is termed Anritam.'¹⁹ Rta means the course of things. It shows an order in objects of universe. The Principle underlying the cosmos is termed as Rta by the Vedic seers. Rta is antecedent to all the objects of the universe and the external universe is its manifestation. Rta is unchangeable and eternal. Rta denoted the fixed course of the universe. Heaven and Hell owe their present existence to it.²⁰ In this way, Rig-Veda presents the concept of Rta which is a representation of cosmic management in the universe.

In the further part of Rig-Veda connotation of Rta becomes more comprehensive and it was taken to signify the ethical course of Gods and Persons. The world follows the course of Rta.²¹ The whole universe depends on Rta and moves with it.²² The concept of Rta propounds the existence of an intelligent basic principle that regulated the cosmos as well as the life of Individuals. As E.W. Hopkins says about Rta that 'it is the order instituted by the wise spirit as regulator of world.'²³

Further Rta as a natural law gradually developed into a moral principle. It is the summum bonum of the individual and society. Without Rta there is no goodness in human life but in the universe. In this way, universe is teleological. Vedic Gods⁺ also follow the Rta, an eternal law. In reference of Gods it is metaphysical and in case of persons⁺⁺ it is moral. Through the moral order person follow the path of Gods.

Rig-Veda believes in the existence of Karma⁺, Samsara⁺⁺ and Dharma⁺⁺⁺. Rig-Vedic concept of Rta presents the concept of cosmic management. Cosmic management means "everything is managed through cosmic laws and order."²⁴ Sometimes it is said that when everything is managed by the cosmic law then what are the rights and duties of a person. It means one should follow only the path which is prescribed to him by his own capacities and capabilities. It means every person is free to do whatever he like or not. It is a form which forms the part of morality. It presupposes the personality, conscience (rationality) and freedom to will.

Cosmic management is referred as Rta in the Rig-Veda. Rta denotes the moral law towards the well-being of each person. When one acts accordingly to cosmic management then there will not be a problem. A problem is a problem only and only when because it has a solution. A problem which has no solution is a riddle or mystery. To control the behaviour of a person some prescribed code of conduct is referred to each person. As Purusha-Sukta* maintains that the "Brahmin originated from the mouth, Kshatriya originated from arms and Vaishya from

thighsand Shudra from the Legs.”²⁵ This notion is misinterpreted by the most of the scholars as B.R. Ambedkar** maintains that this part of Rig-Veda is added to Rig-Veda in 4th or 5th century A.D. This view is not right. In the Purusha-Sukta Brahmins represents the knowledge, Kshatriya represents the courage and bravery, Vaishya denotes the ability to deal and Shudra denote the servicing. These are only the symbolic representation of Brahmin, Kshatriya, Vaishya and Shudra. This classification present the choice for each person to live accordingly and fulfill the duties associated with these varna.

Later, this view was fully elaborated by Rama Krishna Paramhans ***. He says “I am a Brahmin, Kshatriya, Vaishya as well as Shudra too.”²⁶ This view is also supported by M. K. Gandhi. ⁵ This reference is made only to denote that every person has some distinct qualities and capabilities. These capabilities can be improved through training and development of a person. This notion also characterizes the four-fold classification regarding their quality. The Varna-Vyavasthaahas never been on birth but on the desire to do something which one likes. It is based on action.

Every person is a participant in this framework of cosmic management. It leads to the ultimate and highest good (Purusartha). # In Indian tradition, there are so many ultimate goals have been mentioned by the different schools of thought. According to Vatasayana,⁵⁵ Kama~~~ and Artha~~ are the main goals for which every person should pursue.²⁷ According to Hinduism (Sanatana belief), Dharma~, Artha, Kama & Moksha~~~~ are the goals for a person.²⁸ According to Chaitanya⁵⁵⁵, who propounded the school of Vaishnavism, Love is the ultimate goal after attainment of these four goals.²⁹ Chaitanya literally means consciousness in English. Love is the fifth goal for a person.

When a person acts according to these attainable goals then a person at micro level and society at the macro level will enjoy the serenity of body as well as of mind. These goals are a combination of truth, right and beauty.³⁰ Each person should act in a way in which he himself as well as others may get the human-ideals. It doesn't mean that a person should exploit the nature and environment. When a person participates against cosmic management it leads to stress, pain and so many life-threatening diseases. So, it is the duty of each person to act rightly in regards of cosmic management. One should follow the moral codes of cosmic management. When this moral code is pursued by a person then he becomes knowledgeable as well as wise. Knowledge leads to intelligence. Intelligence is of four type viz. rational intelligence, moral intelligence, emotional intelligence, spiritual intelligence. When one's actions are directed to ultimate good then one can actively participate in the cosmic management. It is a moral pressure that leads to do the right actions in the light of the highest good. A good may contain so many right actions according to the capacity, capability and aptitude of a person. The right which does not fall under the category of good, that right is wrongly right. Here it can be concluded from the above discussion that an action should be directed towards the highest goal which is love. According to Narada#, love has five characteristics. These are, viz. love is devoid of any characteristics, it is free from desire, it increases with time, it is subtle than subtlest and it is based on experience.³¹ experience According to Swami Vivekananda##, love has three characteristics viz. it knows no bargaining, it knows no fear and it knows no rival. ^{31(a)} According to Vaishnavism### love has six characteristics viz. respect, whatever one like give it to the loved one, subject accepts whatever object give, express the secret before the object, ask for the secrets of the loved ones and offering foods to object. ^{31(b)}

Vedic Justifications

To control the global warming, Rig-Veda presents so many insights. First of all, Global warming is caused by the polluted water and air. Regarding this it is said in the Rigveda that Varuna is the deity of water.³² Water is supposed to be a deity namely Varuna. Water is mentioned as a divine entity. Its lord is Varuna.³³ It is mentioned in the Mahabharata that thirty-three Crore deities resides in the water. It is said in the Rigveda that ‘Earth is the mother and I am her son.’ The deity of air is Maruta. In Gita, Nature is termed as ‘Aasthaa-Koni.’³⁴ In the VarahaPurana it is mentioned “preserving the trees is a pious work.”³⁵ The environment is metaphorically compared to deities to control the behaviour of Individuals towards the preservation of water, tree and greenery. These examples mention that when one treat the environment in this way then the problem of global warming can be controlled. In, sum total it can be said that nature and environment is worshipped by the person. Nature is regarded as mother and no one

exploit the mother. Trees are described as the manifestation of Supreme Power. So, one should not cut the trees and should not impure the air and water because they are the gods and leads to the fulfillment of desires of person.

Justification through Indian Constitution

Global warming is a problem that is raised in the last century. It is believed that it is caused by the gases, pollution and deforestation as well as the other reasons also mentioned by the different scholars and the knowledgeable persons of this field. It affects human as well as humanity at the micro and the macro level, respectively. Recently, Tsunami at Japan may be referred as an effect of Global Warming. So, it is duty of every human being to save the world. It is the duty of each person to protect the environment and to control the pollution as well to reproduce the natural resources.³⁶ Indian constitution also attempts to proceed with the concept of Rta (Dharma). It took some notions from the Rig-Veda to the constitution. It provides significant importance to the morality into legal codes. Major cause of global warming is greenhouse gases. Regarding this Indian constitution under article 21(a) maintains that “a company should be banned if it deals with harmful gases.”³⁷ It is the duty of every person in most of the constitutions to use the filters in their companies so that the greenhouse gases may be firstly filtered and then come into the contact of environment. It will eliminate the global warming. Second cause of global warming is deforestation. Regarding deforestation article 48(a) and 51(a) clause seven maintain that each person will preserve the nature and environment.³⁸ As well as one will help in increasing the plants in the community as well as will endeavor to improve the conditions of plants. There are three types of pollution, noise pollution, air pollution, water pollution. These pollutions are generally made by the individuals. Third cause of global warming is pollution. Regarding pollution control Indian Constitution maintains that clean water and fresh air will be provided to every person. It is mentioned in article 21 which is of right to live. One may writ public interest litigation under article 32.³⁹ This notion maintains that one will get the fresh air and water.

Conclusions

The problem of global warming can be eliminated or decreased through the Rig-Vedic model. This model treats the air and water as a Deity which fulfills the human desires and provide him good health and wealth. It doesn't mean that one person should exploit or harm them. These are my personal opinion as well as sanctioned by the different scholars in the world, when these are practiced by a layperson then the problem of global warming will not be a problem. Further. It can be said that Morality is easy to follow because it is based on individual's free will on the other hand Law enforce the behavior of a person. These are very helpful guideline to control the behavior of human-being. Industries and companies are governed by the human-beings. If they follow the above mentioned suggestions, then our forthcoming generations will respect their fathers and will live happily (Aananda).[#] Otherwise, there will not be any human-being to live on this beautiful earth due to global warming. By the way, the world will have the children without full biological parts in their body. As we follow the Vedic Management in our daily life, the problem of global warming will not be a problem on which we have to worry. This is an idealistic model to control the global warming through the cosmic management. Here it must be noted that ideals are for the attainment. When humans have those ideals which are far from the achievement, then they are not the ideal. They are merely the imagination and phantasy. I believe, when we think about water, air, earth, nature in this way then the earth will be a better place to live happily and merrily without stress. (in the state of Aananda And Shiva)^{##}

End Notes

- ¹+Vedic Gods means Deities mentioned in the Rig-Veda Like Indra, Agni, etc. for further details refer to the Hindu Mythology: Vedic and Puranic’ Wilkins, W. J. Rupa and Cmpny, Delhi. 2006
- ²++ For the further details regarding who is a person refer to the “Joseph Fletcher “Indication of Humanhoof : A Tentative Profile of Man” Bioethics Edited by Thomas A. Shannon. NewyorkPaulist Press 1970 PP. 320-324
- ³+Karma literally means action. It is believed that everyone is responsible for his actions.
- ⁴++Samsara literally means the external or physical world.
- ⁵+++Dharma literally means Sanatana Dharma which is eternal. It refers to the Hinduistic belief
- ⁶* Purusha-Sukta is the hymn 10:90 of Rig-Ved. It is dedicated to purusha the cosmic being. One version contains 16 verses, while other version contains 24 verses.
- ⁷** B.R. Ambedkar is the first law minister of independent India.
- ⁸***Rama Krishna Paramhans is a saint, philosopher as well as an enlightened person. He is Guru of Swami Vivekananda
- ⁹\$ Mohandas Karamchand Gandhi is the father of India.
- ¹⁰\$\$ Vatsayana is the name of a Hindu Philosopher in the Vedic tradition. It is believed he lived in 4th to 6th century.
- ¹¹He is credited for writing the ‘Kama-Stram’ a book on art & science of love making.
- ¹²\$\$\$ Chaitanya is a Hindu saint and social reformer in the 16th century. He is believed by the GaudiyaVaishnavism the full incarnation of Lord Krishna.
- ¹³# Purusartha means which is sought by man. It is the human purpose, aim and goal of a person. The four-fold Purusartha
- ¹⁴~Dharma literally means which upholds the world. Literally it means the duty and responsibility.
- ¹⁵~~Artha, it represents the material prosperity and the purchasing power, owing the relations is also a part of artha.
- ¹⁶~~~Kama means dreams and desires. Literally it means purpose in Hindi. In other meaning it is the sexual demand as well as desire to unite or union.
- ¹⁷~~~~Moksha is the liberation or freedom from the worldly stress, sorrows and pain.
- ¹⁸# Narada is the Divine sage from the Vaisahnava tradition. He propounded the Philosophy of love. Philosophy of Love is termed as ‘Saptam-Darsana’ (Seventh Philosophy)
- ¹⁹## Swami Vivekananda is a enlightened person. He is known for his practical vedantic approach.
- ²⁰### Vaishnavism. It is a thought of school in Hinduism.

²¹# Aananda is the state of highest bliss. It is not the happiness. It is the mental happiness.

²²## Shiva is the state of dance, music and intoxication. In the Saktism (it is a branch of Hinduism) Shiva supposed to be the Supreme Lord. Symbolically, Shiva is being represented in the word 'Om' in the Rig-Vedic tradition. It literally means Love. It is believed that there are four character in the 'Om.' These three characters represents the three types of love. On the character one emphasizes gets that type of love from the lord Shiva.

Green Energy and Sustainability: Reality and Potential

*Harbans Singh, PhD.
Singhh@mail.montclair.edu
Montclair State University, United States*

Abstract

Expansion of Green Energy is central to the achievement of sustainable economic growth and to the maintenance of a healthy and supportive environment. Fossil fuels, the current dominant suppliers of energy, are associated with air pollution, harm to human health as well as climate change and global warming. These effects have the potential to severely reduce the life sustaining capacity of earth. Fossil fuels are finite resources. Therefore, their use in the longer run is unsustainable. Their shortages and resulting high prices (especially of petroleum) have the potential to jeopardize economic prosperity in the developed countries and stagnate the economies of poor countries into perpetual poverty. The development of green energies requires research and development in new technologies. Large capital investments are needed in this new and vital sector. As yet, no nation is dominant in this sector. The nation that brings green energy technology to the market may become a world leader and a dominant power in the 21st century. The analysis shows that the fossil fuels will remain the major sources of energy for a long time. Among the renewables, wind energy will grow in importance. Nuclear energy will remain a component of the clean energy mix.

Key words: fossil fuels, Renewable Energy, Energy Consumption USA, China, India, OECD, Brazil, Japan

Introduction

Inexpensive and accessible fossil fuels created unprecedented economic growth and prosperity and gave rise to the highly developed economies of Western Europe, USA, Canada and Japan. During the last two to three decades, emerging economies, first in China and later in India, with each having more than one billion people, have successfully achieved high economic growth and a rising standard of living. Instant communication and global internet connections have raised aspirations to an improved standard of living. A related big factor in this equation is the world population which reaches seven billion in mid 2011. The global population in just four decades is projected to grow to more than 9 billion people by 2050. Another far-reaching demographic development is the urbanization of the global population. In 2011, more than half of the world population lives in urban centers. The share of urban population will most likely continue to grow. Concurrent with urbanization is the increase in the number of mega cities of more than 10 million. Almost all of this demographic growth will happen in the less developed countries (PRB 2010). These demographic factors suggest that there are at present 7 billion consumers and we will add 2 billion more during the next four decades. More and more energy resources will be required to meet their universal expectations of an improved standard of living and improved functioning of the ever enlarging urban centers and their economies.

Expansion of energy from the fossil fuels – coal, crude oil, natural gas – is problematic (IPEC 2007). Emissions from fossil fuels are the primary cause of global warming which has disruptive effects on the economy, society and ecosystems. Ecosystems provide myriad vital and free services that hugely contribute to human well-being and a high standard of living. (Daly1997. Constanza et al. 1997). Air pollution from the emission of fossil fuels consumption adversely affects human health and a significant portion of the cost of health care. Also, fossil fuels by nature are non-renewable. Overtime, they will become harder to find and costlier to extract. As a result, the price of fossil fuels would rise and stagnate the economies and frustrate human aspirations, especially, in the less developed countries.

From the policy perspective green energies, solar, wind and others, are ideal sustainable alternatives without the shortcomings of the fossil fuels. Will these green energies develop fast enough to emerge as an alternative to the fossil fuels? What is the time frame for this to materialize? What are the types of obstacles green

energy faces? What are the policy tools that encourage growth of green energy? What is the impact of clean energy on the green energy? These and other related questions are the central focus of this paper.

The Context

Mass media provide a measure of the importance of the availability of energy to the economy as well as to the overall well-being of the society. During the last six months, from mid-August 2010 to mid-February 2011, sixty major reports and op-ed pieces appeared in major national newspapers. The New York Times carried 29, Financial Times had 16 and The Wall Street Journal carried 15. Each of these newspapers published a special report on energy coinciding with the 2010 Cancun conference on climate change. The journal Science in the 13 August 2010 issue published a special section on “Scaling up the Alternative Energy”. The issue provides an in-depth status of all renewable energy resources written by experts.. In the United States, the energy policy has become a contentious issue .

The shift from fossil fuels to renewable green sources of energy is described as the equivalent of a great transition of the 21st century. The smooth transition will enable the continuation of the process of global economic growth. At the same time the transition will spare the societies from the adverse effects of global warming and climate change.

The projections about the green energies replacing fossil fuels are polar opposites. Scientific American in its November 2009 issue offered “A Plan for a Sustainable Future-How to Get all Energy from Wind, Water and Solar Power by 2030” (Jacobson and Delucci, 2009). This comprehensive analysis shows a promising path to renewable and environmentally friendly energy transition. The International Energy Agency, a Paris-based organization that advises industrialized countries on energy, reached its assessment that oil, natural gas, and coal will remain the primary fuels till 2035 and beyond. The New York Times in its special section on Energy on November 17, 2010 provided a similar assessment as to the continuous role of fossil fuels especially from new oil and natural gas sources. These new sources, we are told, will provide power for decades at reasonable prices. The Wall Street Journal in its special report on “Energy” on February 22, 2010 had a front page headline “The Long Road to an Alternative Energy Future”. This report discussed in detail the developments in various renewable, such as, wind and solar, as well as clean energy developments in new nuclear reactors, algae biofuels, electric cars and lithium batteries. The conclusion of the report is that it is going to take many years before the new energy technologies contribute a significant amount to the total energy output. The report sites three reasons for this slow development. Lag in the development of new energy technology is the first reason. The second is the lag in the development of new infrastructure that is required to accommodate new sources of energy. The third reason is the absence of a US National Energy Policy. (See also Bryce 2010). Within this broad overall context, the status of green energy is analyzed.

Data and Methodology

The International Energy Agency (IEA) and the US Energy Information Administration (EIA) are respected organizations that collect data on energy and make it available to the public. The International Energy Agency (IEA) is a Paris based organization that advises industrialized countries about all aspects of energy. Their website is www.iea.org. Another source of data is the United States Department of Energy. Within this department, the U.S. Energy Information Administration collects data on all aspects of energy. The report “Annual Energy Outlook “ is an important publication that contains data for the United States. Their website is “www.eia.gov”. The U.S. Energy Information Administration combines its own database with the database of IEA and publishes the “International Energy Outlook”. It is updated every year. This report projects data to 2035. The 2010 report is the primary source of data for this paper. Since January 2010, energy related articles and op-ed pieces from the New York Times, The Wall Street Journal and Financial Times are incorporated into the analysis. The content analysis of newspaper articles is essential to get a nuanced as well as an in-depth understanding of the debate on energy policy.

Analysis

Clear patterns of energy consumption emerge from the analysis. The fossil fuels will remain the dominant supplier of energy. Nuclear will remain a smaller but important sector. Among the renewables, hydropower is overwhelmingly the largest component. Wind energy will grow in importance but will remain a smaller player, Solar and geothermal will remain much smaller than the wind. Increases in energy efficiency, measured in terms of production of the gross domestic product (GDP) per unit of energy, is a worldwide trend.

Globally in 2010, fossil fuels accounted for 84 percent of the energy demand. Nuclear provided 5.3 percent. Renewables, which include hydropower, supplied 10.4 percent. Hydro dominates the renewable energy sector. For example in 2007 hydro accounts for 86.6 percent of the electricity produced by renewables. In comparison, wind produced 4.8 percent, geothermal 1.6 percent, solar 0.29 percent and others (waste, wood, etc) 6.7 percent. By 2035, hydro's share will still be 68%, wind's share among renewables will increase to 17 percent, a substantial growth. Solar and geothermal will be 2 percent each. Others will be 11 percent. Fossil fuels will remain a dominant supplier of energy and will account for 80 percent of total supply of energy for the world in 2035.

A comparison of Table 1 and Table 2 is instructive for the understanding of energy demand. Table 1 shows the amount of energy use by Type in Quadrillion BTU for different years. Table 2 shows the same data converted to percentages. Percentages shows relative share of each type of energy for a year and masks the actual amount. During this period 2010 to 2035, the energy from liquid sources will increase by 29.3 percent, natural gas by 38 percent, coal by 58 percent, nuclear by 77 percent and renewables, including hydropower, by 92 percent. Renewables as a percentage of the total energy consumption were 10.4 percent in 2010 and their share will slightly increase to 13.5 percent in 2035. Excluding hydropower, other renewable green energies (wind, solar, geothermal, wood, waste, etc.) will be minor contributors of energy during the next quarter century.

TABLE 1: WORLD ENERGY USE BY TYPE 2005 TO 2035. (QUADRILLION BTU)

Year	Liquids	Natural Gas	Coal	Nuclear	Renewables	Total
2005	170.4	106.3	122.3	27.5	46.2	472.7
2010	172.9	117.3	130.3	26.6	52.1	499.2
2015	179.3	129.1	139.1	32.2	63.8	543.5
2020	186.1	141.2	152.4	37.4	73.4	590.5
2025	197.2	150.2	167.8	41.1	82.4	638.7
2030	210	155.8	185.7	43.9	91.2	686.5
2035	223.6	162.1	206.3	47.1	99.8	738.7
% Increase 2010-2035	29.3	38.1	58.3	76.7	91.7	48

OECD-Europe and Non OECD

These two groups of countries illustrate developed and less developed or developing countries respectively. Energy consumption in these two groups shows current and future energy trends. European countries of the OECD are developed mature economies with stable population and a track record of promoting green energy and taking seriously the threat of global warming. They have ratified the Kyoto Protocol which requires reduction in carbon dioxide emissions – a primary source of global warming. The Non-OECD countries with rising population and urbanization will accommodate the additional two billion people by 2050. The changes in energy consumption of this group will have the most impact.

OECD-Europe energy consumption is on a green trajectory. The renewable energies which were 7.1 percent of the total energy consumption in 2007 will rise to 15% in 2035. Nuclear and natural gas, which are considered clean energies, also show a relative growth during this period. Liquid fuels and coal are declining as a source of energy. In spite of these desirable trends, fossil fuels accounted for 78.5 percent of the total energy in 2007 and this percentage will decline but remain substantially high, 70.2 percent by 2035 (Table 3).

Among the renewables, wind energy has a greater momentum in Europe. Solar is far behind. Nuclear also plays a dominant role as a generator of electricity. Non-OECD countries will consume more of every type of energy (Table 4). The energy consumption will increase at an average annual rate of 2.2 percent between 2007-2035. In comparison, OECD-Europe projects only 0.2 percent average annual increase in the same period. Every type of energy consumption in the Non-OECD group shows a substantial increase from 2007 to 2035. Fossil fuels supplied 87.3 percent of the energy in 2007. By 2035 the fossil fuel will continue to supply an overwhelming 82.3 percent of total energy consumption. Renewables will increase from 8.5 percent in 2007 to 13.4 percent in 2035. This high renewable share is attributed to hydroelectric.

Five Major Economies

Next, the analysis focuses on the consumption pattern of energy of the five major economies of the world. Their energy use will show the progress of green and clean energy or lack of it. This will have far-reaching ramifications on climate change and the development of green and clean energy technologies.

United States

The U.S. has the largest economy in the world. Between 2007-2035, US population of 300 million will grow to 391 million. Its economy in constant dollars 2005 will grow from \$13 trillion to \$25.3 trillion during the same period. Average annual growth rate between 2007-2035 is 0.9 percent for population, 2.4% for economy and 0.4 percent for energy.

Fossil fuels account for 87 percent of the energy consumption in 2007. Its share will slightly decrease to 81 percent by 2035. Renewables between 2007-2035 will grow from 6.1 percent of the total energy consumption to 10.8 percent (Table 5). At present hydro is the dominant component of the renewables. Hydro electric potentials are fully developed. As a result, future growth will be small. Wind, solar and others will be contributors to renewable in the coming years.

The United States Senate did not ratify the Kyoto Treaty of 1997 which required nations to commit to a reduction in emission of greenhouse gases that cause global warming and climate change. The Senate voiced its concern as to the high cost of the shift to green energy which will result in higher energy prices and stifle economic growth and employment. The other reason was that the emerging economies of China, India and other developing countries were exempt from the carbon dioxide reduction mandates. In the meantime, China has emerged as the biggest emitter of carbon dioxide. Coal, which generates nearly half of U.S. electricity, has deep political support in the U.S. Congress. Also some politicians in high positions do not believe that the burning of fossil fuels causes global warming or that climate change has the potential to disrupt societies.

TABLE 5: TOTAL ENERGY CONSUMPTION IN THE UNITED STATES 2007 TO 2035. (QUADRILLIONS BTU)

Fuel Type	2007	2015	2020	2025	2030	2035	%Average Annual Change
Liquids	40.6	38.8	39.4	40.0	41.1	42.0	0.1

Total	101.7	101.6	105	108.3	111.2	114.5	0.4

Source: International Energy Outlook 2010. Office of Integrated Analysis and Fore casting, US Department of Energy, Washington DC 20585. Web: www.eia.gov/oiaf/index.html.

There are compelling reasons for the United States to promote renewable energy. Such a policy will ameliorate global warming, create new 21st-century jobs, promote energy independence and national security (NYT 2010). The U.S. Department of Energy plans to set up eight innovative hubs in universities, industries and private research labs to solve the eight biggest energy problems. They are mini Manhattan projects in eight areas that will produce breakthrough technologies in the energy sector. These eight focuses of research are, smart grid, solar electricity, carbon dioxide capture and storage, extreme materials, batteries and energy storage, energy efficient buildings, nuclear energy and fuels from sunlight (Friedman 2010).

Clean energy with little or no carbon footprint is located in the middle as the transition from fossil fuels to green energy is expected to take place. Natural gas is a relatively clean fuel. Nuclear power has no carbon footprint and is considered clean in this respect. But it raises other serious concerns (Pfeifer 2010). With new technology, the United States has untapped huge reserves of natural gas from shale which can provide energy for decades (McNulty 2010). The new technology is called hydraulic fracturing. This process requires injecting water, sand and chemicals deep into the shale to crack open gas-bearing shale and allowing the gas to flow to the surface. There are environmental concerns about contamination of groundwater. Water used for deep injection becomes toxic and, if released in the streams, can contaminate the surface water.(WSJ 2010).

China

China is a manufacturing powerhouse and emerging as the second biggest economy after the United States. China's manufacturing output has caught up with the United States, the first ranking country for a century. China's GDP is projected to grow at an annual average rate of 5.8 percent and China's energy consumption will grow at 3.1 percent

up to 2035. In comparison the United State’s energy consumption during the same period will grow by 0.4 percent annual rate. China’s rapidly expanding economy has a voracious demand for energy (Rosenthal 2010, Oster 2010).

TABLE 6: TOTAL ENERGY CONSUMPTION IN CHINA 2007 TO 2035. (QUADRILLIONS BTU)

Fuel Type	2007	2015	2020	2025	2030	2035	% Average
							Annual Change
Liquids	15.5	20.4	23.7	27.7	31.4	34.6	2.9

In China, fossil fuels accounted for 93.5 percent of the energy consumption in 2007. Their share will slightly decrease and will be 86.1 percent by 2035. Coal, among the fossil fuels, is overwhelmingly the largest supplier of energy. Coal provided 70.3 percent of the total energy consumption of China in 2007 and in 2035 it will still be a very high 62 percent (Table 6). From the perspective of electricity, coal is the preferred energy source. Coal generated 80 percent of the electricity in 2007 and will be generating 74 percent in 2035 (Krauss 2010).

Among China’s renewables, hydropower is the largest component accounting for 430 billion KWH electricity or 14% of the total electricity. Hydropower will triple in amount to 1262 billion KWH but its share in total electricity mix will be slightly less, 12 percent. Wind power, which was insignificant, will account for 3.5 percent of total electricity by 2035. Solar’s share is small 0.2 percent of total electricity by 2035. China also has an expanding nuclear electricity program and its contribution to the total electricity mix was 2.1 percent in 2007 and by 2035 it will be 5.7 percent. Between 2005 and 2010, China has emerged as the dominant manufacturer of solar panels and wind turbines mostly for export (Harvey 2010). China subsidized new industries with low interest loans with no interest in the initial years and land at a low cost. These arrangements are carried out mostly at the municipal level but with tacit approval from the center. Local content requirement for foreign manufactures located in China is another mechanism to acquire new technology. Local content requirement is up to 75 percent. The way it works is that the foreign company has to buy 75% of the content from Chinese manufacturers.

Foreign companies have to provide technology to local companies. But the local companies are free to sell to others and export. Most foreign competitors lost the market share not only in China but also in other markets due to exports from China. Because of subsidies, solar panels and wind turbines exported by Chinese manufacturers are much cheaper and are increasing their market share all over the globe (Barkley 2010). This practice of local content and subsidies to manufacturers are forbidden under World Trade Organization (WTO) rules. They achieved the desired objective of making China a powerhouse for renewable energy manufacturing (Fiona 2010. Bradsher 2010). Competitors who have manufacturing in China did not complain of WTO rule violations because of fear being shut out from the Chinese market (Bradshaw 2010).

India

TABLE 7: TOTAL ENERGY CONSUMPTION IN INDIA 2007 TO 2035. (QUADRILLIONS BTU)

Fuel Type	2007	2015	2020	2025	2030	2035	% Average Annual Change
Liquids	5.9	6.6	7.4	8.1	8.8	9.6	1.8

Nuclear	0.2	0.7	1.3	1.7	1.9	2.1	9.0
Renewables	2.5	3.2	4.0	4.5	5.1	5.8	3.0
Total	20.3	24.3	28.2	31.1	34.1	37.6	2.2

Source: International Energy outlook 2010. Office of Integrated Analysis and Forecasting, US Department of Energy, Washington DC 20585. Web: www.eia.gov/oiaf/index.html.

India and China are grouped together as emerging economies. India and China both have more than one billion people but by 2035, India's population of 1.5 billion will be slightly larger than China. Economic growth in both countries will be high, 5.0 percent a year in India and 5.8 percent in China. But there is a wide gap in terms of total GDP and total energy consumption. In 2007, China's economy was three times larger than the Indian economy and by 2035 the gap will further increase. China's economy will be 3.6 times larger. Total energy consumption of China was 3.8 times larger than that of India in 2007. The gap will widen to 4.8 times by 2035 (Table 7).

In India, fossil fuels account for 87 percent of total energy. Coal is dominant among the fossil fuels. All sources of energy are expected to grow at a healthy rate. Nuclear, though small, will grow faster at 9 percent annual rate. According to the World Nuclear Association, India has at present 20 nuclear reactors and an additional 23 are in progress or planned. In comparison, China has 13 existing reactors and 77 are in progress or planned. All nations are anxiously watching the situation at Fukushima Daiichi nuclear plant that was damaged by the massive earthquake of 9.0 Richter magnitude and tsunami of March 11, 2011.

India's renewables, including hydro, provide 12.3 percent of total energy in 2007. By 2035 they will account for 15.4 percent of the total energy. Coal remains an important energy source. Coal generated 71 percent of electricity in 2007 but will decrease in relative importance and contribute 51% of the electricity by 2035. Hydro generated 16 percent electricity in 2007 and its share will increase to 18.7 percent by 2035. Among the renewables, electricity from wind power shows promise. Wind contributed 1.4 percent of the total electricity in 2007 and is expected to contribute 2.7 percent by 2035.

Brazil

TABLE 8: TOTAL ENERGY CONSUMPTION IN BRAZIL 2007 TO 2035. (QUADRILLIONS BTU)

Fuel Type	2007	2015	2020	2025	2030	2035	% Average Annual Change

Liquids	4.8	5.8	6.2	6.7	7.5	8.1	1.9

Brazil, with its 200 million people in 2010, is the largest country in Central and South America both in terms of area and population. Its energy resources reflect its natural endowment and contrast with other major economies of the world. Hydroelectric and ethanol from sugarcane are the primary energy sources (Table 8). Brazilian Coal, which is of very low grade, never became a dominant energy source as it has been in all other major economies. In Brazil, 76 percent of the electricity comes from hydro. Two hydro electric projects, Turcurui and Itaipu provide one third of Brazil's electricity. Hydro power potentials are immense (Sternberg 2011). In 2010, Brazil announced the discovery of vast offshore petroleum reserves. These reserves can be tapped through deep water drilling techniques. Once these reserves come on line, Brazil will become a major exporter of oil. This will boost the Brazilian economy.

In Brazil, coal only provided 4 percent of the total energy consumption in 2007. In 2035, Coal's share will be 5 percent. One third of Brazilian energy will come from ethanol. Hydro will continue to provide one half of the total energy needs of Brazil. Nuclear is very small. Brazil is one of the nations which can truly be said to be on a clean, sustainable energy path.

Japan

TABLE 9: TOTAL ENERGY CONSUMPTION IN JAPAN 2007 TO 2035. (QUADRILLIONS BTU)

Fuel Type	2007	2015	2020	2025	2030	2035	%average Annual Change
Liquids	10.1	8.4	8.7	8.6	8.4	8.2	-0.7

Renewables	1.3	1.3	1.5	1.6	1.6	1.7	0.8

Source: International Energy Outlook 2010. Office of Integrated Analysis and Fore casting, US Department of Energy, Washington DC 20585. Web: www.eia.gov/oiaf/index.html.

Japan was the second biggest economy in the world after United States. In 2010, China surpassed Japan in terms of total GDP. Liquid fuels are the largest component in Japan. Natural gas and coal are equal in amount but coal use is expected to decline. Only nuclear will grow at an annual rate of 1.9 percent between 2007-2035. Renewables will grow at an annual rate of 0.8 percent during the same period (Table 9).

In Japan fossil fuels accounted for 83 percent of total consumption of energy in 2007. Their contribution will be 73 percent in 2035. Over time nuclear will grow in importance. Japan has 55 nuclear power reactors. An additional 15 are in progress or planned. Japan gets 24 percent of its electricity from nuclear. By 2035, nuclear will account for 34% of the electricity. Natural gas provides one quarter of the energy. Its share will remain the same.

Coal provided 31% of electricity in 2007. It will only account for 23 percent in 2035. Hydro will provide 7-8% of the electricity. Wind and solar will provide 1 percent of electricity by 2035. The future of atomic energy depends upon what happens to the Fukushima Daiichi atomic plant which suffered structural damage from the earthquake of March 11, 2011. A meltdown or extensive radioactive release from the plant may dampen interest in nuclear energy. If the damage is controlled, even then the safety issues will remain of utmost importance.

Policy Perspective

Research and development in green and clean energy, reduction in greenhouse gases emission and devising incentives that promote the above two programs are essential building blocks of a successful energy policy. Fossil fuels will remain the dominant source of energy by 2035 and even beyond. They are relatively cheap and abundant. Infrastructure to deliver them to the consumers is already in place. Even though there is a lot of excitement about wind and solar energy, they account for a small share of total energy. Along with conservation, they will increase in importance. Wind energy output is significantly higher than solar. Wind and solar are also costlier. Without subsidy they are not competitive. The wind energy is coming under attack because the residents near the wind turbines complain about the noise (Carr 2010, Bryce 2010). Threat to wildlife is another concern. Because wind is intermittent and variable in nature, utilities will have to keep the backup plant running or ramp up or down depending upon the wind. Coal and gas fired plants run efficiently when they run continuously. It is akin to stop and go car driving which lowers efficiency and creates more emissions. Wind energy has this drawback and may not bring reduction in carbon dioxide emissions (Bryce 2010).

Research and development is of utmost importance to develop clean and green energy. On the model of Defense Advanced Projects Research Agency a similar agency is set up in the US DOE for energy. Some projects on wind, solar and electricity storage, after the initial research with seed money, have attracted private funding. There are a lot of innovative developments in solar cells, hydrogen, carbon capturing at the thermal plant with sea water and converting into limestone as a building material, small modular nuclear plants, small nuclear plants that use nuclear waste as a fuel and hosts of other developments. The green technology which will emerge as the winner is not settled. It will take much more innovation and research to make clean energy competitive. Clean energy should be viable enough for the poor as well as the rich. Lowering the price of clean energy should be the priority of energy policy. For this to happen, research support is crucial.

Global warming is the combined effect of two groups of gases and their emissions. One is the well known carbon dioxide which has a longer life and remains in the atmosphere for a century. The other group of gases are short-lived and stay in the atmosphere for a few days to a few years. Their global warming impact is 80 percent of carbon dioxide's. These gases are methane, some hydrofluorocarbons and lower atmospheric ozone. In addition, dark soot particles also act as global warming agents. Controlling the amount of these short lived pollutants is attainable. In comparison, carbon dioxide produced by fossil fuels which are currently the basis of economic development is harder to control. Trillions of dollars of new investment are needed to convert the economy from fossil fuels to clean energy.

Methane a short lived but potent global warming gas is 25 times more powerful than carbon dioxide. Methane is released to the atmosphere from coal mines, landfills, rice paddies and livestock. Methane is the main component of natural gas and leaks from pipelines also contribute to its emission. By controlling natural gas line leaks, controlling water in rice cultivation, capturing landfills and manure releases, methane amounts can be easily reduced by half. The already existing frame work of the Montreal Protocol of 1989 can bring about cuts in hydrofluorocarbons(HFC). The warming effect of HFC is 1000 times that of carbon dioxide. Therefore, a reduction in HFC can have a greater impact on the reduction in global warming. Similarly soot can be controlled through existing air pollution control programs. Reducing these short lived pollutants will not solve global warming. It will buy time (Ramanathan and Victor 2010).

Retiring old diesel and coal fired plants and replacing them with clean natural gas fired electric generating plants in the United States is a feasible way to reduce global warming emissions. The abundance of natural gas at a low price is a window of opportunity to reduce emission of global warming gases and a step towards clean energy.

Incentive

What is the right way to promote clean energy? A carbon tax is considered desirable. A tax will be an incentive to further innovation in new technologies in a competitive environment. New technologies will emerge in the market place which will be cost competitive. A graduated carbon tax is proposed with a zero rate in the first two years of the program. Starting with \$8 per ton in 2013. The carbon tax will rise to \$200 a ton by 2040 (Blinder 2011).

A bottom up approach is another way whereby states require green component as a fixed proportion in its electric supplies from utilities. Many states in the United States have such programs. Europe has feed-in tariffs for solar energy whereby a consumer who installs solar panels is paid for the electric generation which is consumed at the site and an extra payment for the surplus electricity sold to the grid. Such programs are being scaled back due to the aftermath of the financial crisis of 2008.

Subsidies are a short term measure. In the longer run, new energies have to be cost competitive. The transformation from fossil fuels to green energy must include clean energy resources with little or no carbon footprint. The stock of nuclear as a clean energy source was rising. The tragic earthquake in Japan on March 11, 2011 and the damage to the Fukushima Daiichi atomic plant and radioactive release has reminded the world of the dangers of nuclear power.

An Agricultural Management System Designed To Determine the Farmland Capability for Sustainable Land Use Planning In the Mekong Delta, Vietnam

*Nguyen Hong Tin, nhtin@ctu.edu.vn
Ngan Collins
David Fraser
RMIT University, Australia.*

Abstract

Agricultural production is a key contributor to the Vietnam GDP. Recently, it leads Vietnam to become one of leading growth economies in the Asian Pacific and the world third largest rice exporter. This sector, however, is facing challenges generated by global issues as well as such as climate change, financial crisis and merging with the WTO. On top of this there are other internal challenges that the country has faced since the economic reform began. Further, intensive and indiscriminate development of farming systems has resulted in environmental degradation, including water and soil pollution, soil/land degradation and desertification. While the Vietnamese government's objectives are to move Vietnam in general and the Mekong Delta in particular toward sustainable development. This sustainability is secured by the balance of three main goals, environmental health, economic profitability, and socio-economic equity. This paper presents a theoretical model of agricultural management system that designed to determine the farmland capability and the viability of farming practices for sustainable land use planning in the Mekong Delta, Vietnam. Many disciplines relating to natural, bio-physical, human, socio-economic, policy, and institutional factors are integrated into a spatial model and the relationships within and between the factors are analysed and examined. The study hopes to develop a new model to fill the current gap in knowledge relating to the current management of farmland capability and agricultural production in the Mekong Delta. The study outcomes will be useful for farmland users, agricultural/land managers, and agricultural policy makers in the Mekong Delta, Vietnam.

Keyword: Vietnam, Farmland capability/practices, sustainable land use planning, Mekong Delta.

Introduction

Currently, there are approximately 2.6 billion people worldwide living on less than \$2 per day (World Bank, 2007). Most live in the rural areas and depend directly or indirectly on the agricultural sector for their livelihoods (Nancy et al., 2003; WRI, 2008; World Bank, 2008). Taking a long-term perspective, agriculture undoubtedly will continue to play a key role for sustainable development and poverty reduction, because it stimulates economic growth, particularly for the agriculture-based countries. This makes less vulnerable to climate change, generates raw materials, and creates more livelihood opportunities for rural inhabitants, and provides more environmental services as well (World Bank, 2008).

To illustrate this, agriculture feeds approximately three-quarters of the population in developing countries, and offers new job opportunities for around one hundred- million rural poor allowing them to move out of their poverty situation. Moreover, it still makes up about 13 percent of the economy, and employs 57 percent of the labour force (World Bank, 2008).

However, aspects of agriculture and the agricultural system are vast, varied and always changing rapidly (Shoup, 2004). Today world agriculture in general, and agricultural land use in particular, are facing many emerging problems such as climate change, sea level increase, floods, land degradation, soil erosion, water and soil pollution, land desertification, and exhaustion of natural resources, (Tilman et al., 2002; Wassmann et al., 2004; Oosterberg et al., 2005).

In other words, besides positive impacts on social development as already recognised, agriculture also impacts negatively on the environment, ecological systems, bio-diversity and other natural resources. The “Green Revolutionⁱ” in Asia between 1970 and 1995, and intensively agricultural systems later have led to the excessive and inappropriate applications of agro-chemicals (fertilizers, insecticides, herbicides) are testimony to this. Such excess creates water pollution, water scarcity, and frequent droughts and flooding, poisons people, upsets ecosystems, and degrades agricultural land as well as creating health problems (Pioram, 1997; UNEP, 2000; Malkina-Pykh et al., 2003; World Bank, 2008).

In other fields, humanity is currently facing global challenges of population increase, industrialisation, and urbanisation. World population, increased from about 2.5 billion in 1950 to 6.8 billion in 2009, and will pass 7 billion in 2011 or 2012 (Population Reference Bureau, 2008; 2009). As a result, a higher competition in terms of housing, manufacturing, planting and other social services is created (Vandermeulen et al., 2009). This means natural land areas in general, and farmland in particular, are reduced in area and extent.

As in where else agricultural land is one of the most important components of the land and, is defined as land under arable use and permanent crops in Vietnam. It has an area of 4,931,862,000 hectares and occupies approximately 37.8% of the world land area (Table 1.1).

TABLE 1.1: THE LAND AREA BY REGIONS AND KINDS OF USE (UNIT: 1000HA)

Regions	Land areas	Agricultural areas	Arable land and permanent crops	Arable land
Vietnam	31,007	10,072	9,430	6,350
South – Eastern Asia	434,093	117,660	100,596	66,171
Asia	3,093,949	1,662,869	573,284	504,537
World	13,009,115	4,931,862	1,553,689	1,411,117

Source: FAO, 2009, Compiled by the Author. Data are of year 2007, and subject to rounding.

Data in Table 1.1 show that agricultural land area in Asian, South-Eastern Asian, and Vietnam (research site) dominates a range of 30-40% of their total natural land area. This confirms that agricultural land plays an important role for socio-economic development in Asian, South-Eastern Asian, and Vietnam.

There have been several solutions proposed by researchers; but one of the shortest and most effective approaches for sustainable agricultural development suited to the present era, could be reasonable agricultural land use planning (ALUP). ALUP allows the integration of goals, including environmental health, economic profitability, and social and economic equity. The conflicting interests of industry, urban areas and land degradation can partly solved through ALUP to generate the balance in responsibility and profitability for actors in the production system including farmers, laborers, policy makers, researchers, retailers and consumers (Sands & Podmore, 2000; Gold, 2009).

A range of approaches for land use planning is available, the main ones are the Land Use Planning guidelines by FAO (FAO, 1993), the Participatory Land Use Planning (PLUP) methodology (FAO, 1991; Jones and Sysomvang, 2005; Beall and Zeoli, 2008), the Land Use Planning and Analysis System (LUPAS) (Van Ittersum et al., 2004 and Rotter et al., 2005), the Conversion of Land Use and its Effects (Veldkamp and Fresco, 1996; De La Rosa et. al., 2009). Among them, advantages and disadvantages of FAO, PLUP and LUPAS have been compared by a case study in the Mekong Delta, Vietnam (Trung, 2006). The most important activity in the land use planning procedure is selecting land use alternatives based on land evaluation. Land evaluation can be summarised as the process of matching land requirements with land characteristics in terms of land quality to assess the suitability of land use (FAO, 1976; FAO, 1985; FAO, 1993; Laborte et al., 1999; Liu et al., 2007; Ritung et al., 2007).

Similarly, farmland suitability evaluation (land use requirements) is an extremely important activity in the agricultural land use planning procedure (FAO, 1985). It provides guidance for agricultural land managers and users on how to exploit land resources in a way that heads to sustainable agriculture. Land and farmland suitability evaluation are studied, applied and described by FAO (FAO, 1976; FAO, 1985; FAO,

1993), Indonesian Soil Research Institute and World Agroforestry Centre (Ritung et al., 2007), Jaruntorn Boonyanuphap et al. (2004), Lingjun et al.(2008) and Mongkolsawat et al. (1997).

Land suitability is a statement of the adaptability of a given area for a specific kind of land use (e.g. rice-fish or rice-soybean farming system) rather than the performance of the inherent capacity of the land at a given level for a general use (FAO, 1976; FAO, 1993; Rowe et al., 1981). Nevertheless, so far, there has been no study on determining the capability of farmland through an agricultural management system (AMS) (technical, bio-physical, socio-economic and human resources) designed to integrate sub-components in the AMS, and explore interactions between those variables which relate to the prosperity of farms. And therefore, this research titled “An Agricultural Management System designed to determine the capability of farmland at District, Commune, Hamlet, and Household level in the An Giang Province, Viet Nam” has been undertaken.

Context of the research

Recently, Vietnam has emerged as one of the most striking economic successes (FAO in Vietnam, 2008). From a country with quite a high rate of hunger in the 1980s, Vietnam quickly recovered from poverty, to become the second largest rice exporter in the 1990s, based on the “Doi Moi-innovation” policies. However, its economy has relied heavily on agro-forestry and fishery sector such as rice production, aquaculture, and forestry exploitation (GSO, 2006). In general, these sectors have employed more than 55% of the labor force, distributed nearly 27% of the GDP and contributed 25% of the export value to the nation (GSO, 2007).

In general, Vietnam is an agricultural country in Southeast Asia. Its economic growth and export values still based on agricultural and aquaculture sectors. Rice, fruits, and fishery are typical products for exporting. However, recently high crop intensification and quick industrialization in aquaculture are threatening to the capability of agricultural lands. So far, Vietnam has no national program or project to evaluate the farmland capability. Selecting Vietnam as the study area to test the theoretical model of agricultural management system designed to determine the capability of farmland is very significant and reasonable. By this, local agricultural land managers in Vietnam will have references to plan and utilize sustainably their land resources.

The Mekong Delta

The Mekong Delta starts at *Kongpong Cham* in Cambodia, covers an area of 5.9 million ha, of which about 4 million ha are in the south of Vietnam. The Mekong Delta is a relative young land, which was formed not more than 10,000 years ago.

Of the eight agro-ecological zones of the nation, the Mekong Delta is a strategic zone for national food security. It plays the most important role for Vietnam agricultural development in particular and for Vietnam economic development in general. Also, it is the most downstream part of the Mekong River Basin with 17 million inhabitants living in 12 provinces and one central Can Tho city (GSO, 2006). In fact, the MD accounts for more than 27% of Vietnam’s GDP and contributes over 50% of the total aquatic volume, 80% of the total rice export value (US\$ 3,246,000 per year) and 75-80% of the total cultivated area (GSO, 2006).

Nevertheless, the MD has been facing physical constraints that affect socio-economic development, especially related to agricultural production (Nam, 2007; Loc, 2007). Especially, it has an area of 1.2 to 1.9 million hectares under annual floods (Minh, 2002) and the complexity, degree and frequency of the floods are increasing. Over the past 40 years, floods had occurred in the study area, in the years: 1961, 1978, 1991 and 2000. This is one of the first, and largest, concerns of policy makers, agricultural managers and local inhabitants in the region because floods are recognized as both the “enemy” and a “friend” of the local farmers. Floods can devastate crops, and result in reduction in their productivity, and yet floods also bring much benefit to

farmers such as natural fish resources, alluvium deposition as natural fertilizers for fields and the flushing of toxicity from acid sulphate soil: flood water has been utilized to improve the quality of acid sulphate soils by taking away toxicity released from the soils.

Overall, the most serious constraints to agricultural production, and land use, in the Mekong Delta currently are recognised as (1). the status of fresh water shortage and the deterioration of water quality through the transformation of the cultivation structure accompanied by acidification due to sulphate soils in the dry season and, (2). most land areas are flooded several months in the annual wet season, this damages agricultural and aquaculture production, threatens infrastructure in general and the agricultural irrigation system in particular. (3). the movement of young labour force in the rural to the cities and (4). the lack of farmers' accessing opportunities (new technology, capital resources for production, production skills and market information) and the lack of supporting policies for farmers, and the limitation of the rural vocational training as well. Those reveal that farmland capability evaluation by an integration of components in the agricultural production system, including socio-economic factors, technical and biophysical factors is essential. This capability evaluation will provide a tool to assist with meeting the goal of sustainable agricultural development in the Mekong Delta.

Research aim and objectives

The aim of this research is to develop a geographically referenced agricultural management system that is designed to determine the viability of farming practices in order to recommend technical solutions and management for the optimisation of agricultural land potential. The discipline areas to be integrated into this research are farm management, financial management, land capability, socio-economic management, environmental impact assessment, Geographic Information System development and spatial-temporal data management.

This research involves the integration and analysis of geographically referenced socio-economic and physical attributes relating to the farms in the An Giang Province, Mekong Delta, Vietnam as a case study. This integration allows the relationships within and between the datasets to be analysed, which reveals factors that impact upon the agricultural production and the prosperity of farms.

The research uses existing and proposed agricultural data sets, such as farm practices, economic factors, and environmental control factors, physical characteristics, stored in a geographically based information system. The management system allows the production capability of the farming in the Province to be determined.

Additionally, an investigation has been conducted in two communes of the An Giang Province as a case study. Specifically, the study is guided by the following objectives:

Objective 1: To develop the theoretical model for an agricultural management system.

Objective 2: To gather environmental and agricultural data sets relating to the agricultural land use in the An Giang Province, Mekong Delta, Vietnam.

Objective 3: To manipulate the data sets to align them to a geographical coordinate system which allows geographical relationships between the data sets to be analysed?

Objective 4: To merge the farm attributes data sets and analyse the data using statistical techniques.

Objective 5: To determine suitable geographical analysis techniques which, when applied to the data sets, allows new information products to be created as an aid to decision making in agricultural policies.

Objective 6: To develop an agricultural land capability management system, suitable for capability analysis at five administrative levels: Province, District, Commune, Hamlet, and Farm for use in determining the effectiveness of existing farming practices.

A holistic approach to the agricultural land capability management system development involves geospatial modelling of the relationships between the different characteristics of the farms in the Province based on land data, crop data, the application of chemicals, on-farm and off-farm income, demographic data and agricultural production.

The research uncovers existing datasets which are incorporated into a new capability model designed to determine the viability of the farming based on a five level capability rating from very low viability through to very high viability.

An agricultural management system, designed to determine the capability of farm land at the province, district, commune, hamlet and farm level, provides available tools for agricultural policy makers and producers in the development of global sustainable agriculture. The creation of Agricultural Management System also supports an objective in the convention of collaboration and sustainable development for the Mekong River Basin of Vietnam National Mekong Committee (Decision N^o 860 of Vietnamese Prime Minister, 1995). Moreover, the research will produce invaluable data sets for further research in the Mekong Delta.

Hypotheses of the study

In this study, the following hypotheses are tested:

1. The major sub-components required for an effective agricultural management system that relate to the capability of farmland can be identified.
2. The relationships and interactions between major sub-components in the system can be determined.
4. The key factors impacting upon the economic viability and prosperity of farms can be isolated.
5. GIS can be used effectively as a tool to map and monitor agricultural production.
6. A GIS based agricultural management system can be developed to effectively measure and monitor the capability of farmland

Expected outcomes

First, the research results in the production of a GIS-based agricultural management system, underpinned by a sound theoretical and logical structure. The application of computer based land use modelling tools and geographical analysis tools help in the understanding of the factors influencing the viability of agricultural land.

Second, the study will develop a procedure for analysing the viability of the agricultural production using selected spatial and temporal datasets stored in a Geographic Information System. Spatial data relating to characteristics of the agricultural land and the physical environment will be acquired in a suitable form for spatial modelling.

Third, the study will develop techniques and procedures for spatial analysis and multi-variety analysis based on datasets relating to soil, demographics, agricultural production, land cover and crop cycles; these techniques and procedures will be integrated into the agricultural land capability system being developed

Final, the study will provide the theoretical and

empirical evidence relating to agricultural land capability use by policy makers and rural development planners as a basis for program development and policy formulation.

Hence, this research titled “An Agricultural Management System designed to determine the capability of farmland at District, commune, hamlet and household level in An Giang province, Vietnam” has been undertaken.

The research attempts to answer the following questions:

1. What are the major sub-components required for an effective agricultural management system that distribute to farm land capability?
2. What are the relationships and interactions between those major components in the agricultural management system?
3. What are the key factors that impact upon the economic viability and the prosperity of farms?
4. How do the key factors relating to agricultural production impact upon the economic viability of farmland?
5. Can a Geographic Information System (GIS) be used effectively to map and monitor agricultural production in the An Giang Province?
6. Can a GIS based agricultural management system be developed to effectively measure the capability of farmland in the An Giang Province?

Research methodology and case study

This chapter presents two most important phases of the research: (I). the first is the fundamental steps and methods that were applied to design a theoretical model for an agricultural management system (AMS) to determine the farmland capability. The main contents include theoretical framework of the research; conceptual framework of the research; and development of a theoretical model of the AMS for farmland capability determination. The key expected output is that components and factors in the AMS that impact upon the capability of farmland were explored and designed; and a system for farmland capability classification was developed and described. (II). the second phase is the case study, its purpose was to test the developed model. First, the proposed farming systems for farmland capability determination were identified; based on that, the theoretically developed model was adjusted to suit the local conditions; then land characteristics in the adjusted model were considered and weighted with respect to the capability of farmland. After that, a farmland investigation was conducted according to farmland characteristics adjusted in the model. Ultimately, farmland capability in the research site was analysed, determined, and presented through matching and modelling found farmland characteristics with modelled farmland use requirements. The case study research area of Viet Nam, the Mekong Delta, and the An Giang Province that are introduced in a late section.

Developing a theoretical model

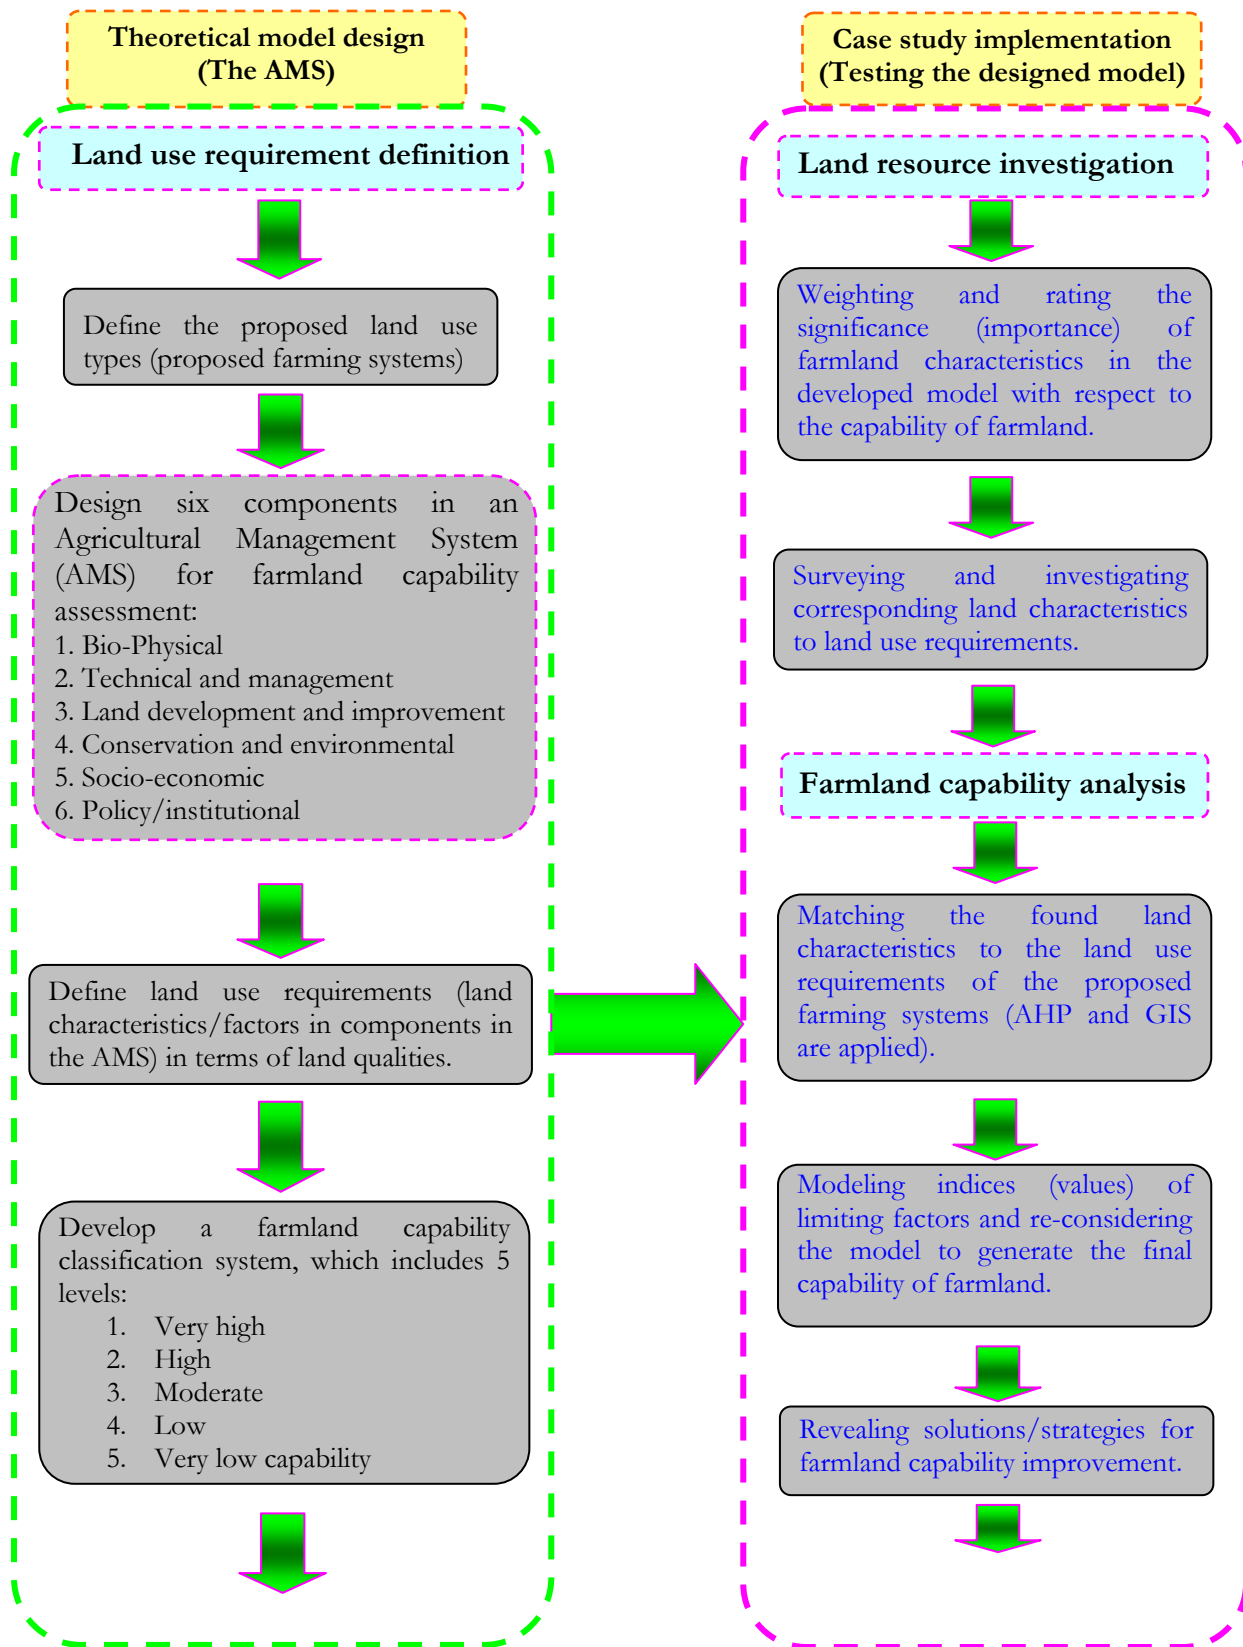

The process and important steps in conducting the study include three interrelated activities: land use requirement definition, land survey and investigation, and land capability analysis (Figure 3.3). These activities were integrated and grouped into two main phases, developing a theoretical model of the AMS for farmland capability assessment, and testing the developed model by conducting a case study.

First, a theoretical model was structured and developed based on a literature review with possible application in many parts of the world. This model design could also be adjusted and modified to be used for different specific situations.

The following steps are involved in the development phase of a theoretical model (theoretical model development phase):

- (1). Defining the proposed farming systems for farmland capability assessment
- (2). Designing key components in the AMS for farmland capability assessment
- (3). Identifying class-determining factors (required land characteristics) of each component in the AMS
- (4). Developing a farmland capability classification system for proposed farming systems
- (5). Determining the capability of farmland for proposed farming systems

Then, the model design would be tested through conducting a case study (practical testing phase), which is presented in the next parts.

A theoretical model of the agricultural management system for determining the capability of farmland was designed

Results of the final farmland capability for prioritized uses;
Feasible solutions for sustainable conservation and farmland improvement;
Recommendations/suggestions.

FIGURE 1.1: THE CONCEPTUAL FLOWCHART OF THE RESEARCH APPROACH

Case study execution

The case study was conducted in the Vietnam, Mekong Delta region, An Giang Province, Cho Moi District, where agricultural land use and farming systems have been continuously changing. The case study involves six main tasks (Figure 1.2):

- (1). identifying suitable farming systems for farmland capability determination;
- (2). modifying/adjusting the theoretical model and standardizing the capability classes
- (3). revealing the factors which impact upon the farmland capability
- (4). conducting farmland surveys;
- (5). undertaking farmland capability analysis; and
- (6). modeling the value of capability factors to improve and increase the capability of farmland. Detail of these tasks was presented below

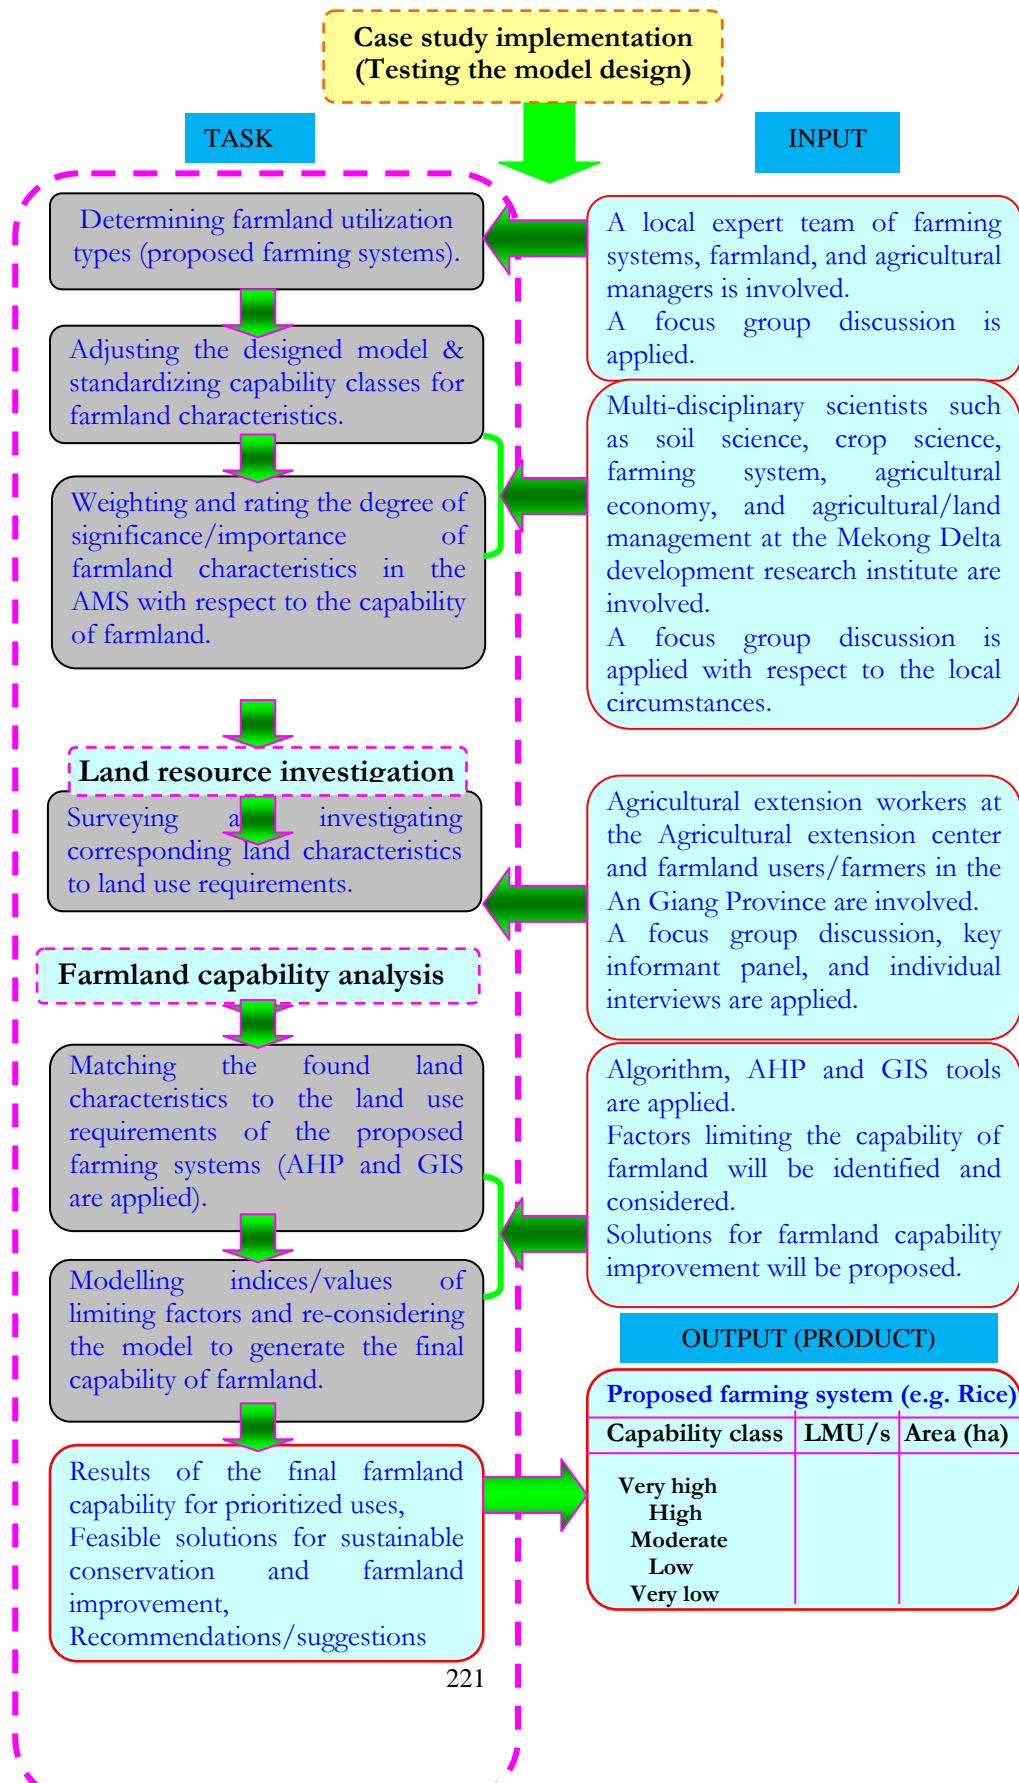

Figure 1.2: The conceptual flowchart of the case study approach

Significance of the research

In the twenty-first century, food and fiber production systems will need to meet three major requirements: (1) adequately supply safe, nutritious, and sufficient food for the world's growing population, (2) significantly reduce rural poverty by sustaining the farming-derived component of rural household incomes, and (3) reduce and reverse natural resource degradation, especially that of land (World Bank, 2006, p.2). While, land use in general, and agricultural land use in particular, are facing many emerging challenges of climate change, intensification of agricultural production, floods, drought, land degradation, soil erosion, water and soil pollution, land desertification, and exhaustion of natural resources (Tilman et al., 2002; Wassmann et al., 2004; Oosterberg et al., 2005). These above stated-issues give human a foreseen challenge in exploring ways for sustainable utilisation and exploitation of the natural resources, particularly the land resource. Land capability assessment is an extremely important component of land evaluation for sustainable use of the land resource, where the capability of the land is determined. There are many studies regarding to land capability/suitability evaluation (please refer to "A framework for land capability assessment" section in the literature review chapter of this thesis) conducted in many parts of the world, and with different approaches. De La Rosa et al. (2004, 2009) have reviewed a number of case studies in English and Spanish, Rowe et al. (1981) and Hanson et al. (2001) described their studies in Australian, Christof Walter & Hartmut Stützel (2009a, 2009b) introduced a new method for assessing the sustainability of land-use systems in Germany. While, many other authors defined and developed a framework or guidelines for land evaluation, land capability assessment, as well as conducted case studies on land evaluation (FAO, 1976; 1985; 1991; 1993; 2007; Karlen et al., 1997; USDA, 2001; Smith et al., 2004; Murphy et al., 2004; The State Planning Commission, 1989; EPA, 2003; Peter, 1996; MAF and ME, 1983; The ACT Parliamentary Counsel, 1999; Ritung et al., 2007; Jaruntorn Boonyanuphap et al., 2004; USDA, 2009).

This study applies the holistic approach and refers to previous studies, as well as literature review to develop a theoretical model that, integrates land characteristics in terms of land quality to determine the capability of farmland. The study takes theoretical perspectives from systems theory by FAO (1993; Haaf, 2002; Pidwirny, 2006a; 2006b) that (1) an agricultural management system (AMS) will be structured, formed, and developed; (2) sub-components in the AMS, which contribute to the capability of farmland and the prosperity of farms will be explored and defined, including biophysical, technical and management, land improvement or development, conservation and environmental, policy and institutional, and socio-economic factors; (3) roles and functions of every factor in the AMS will be determined and analyzed; (4) functional interactions and relationships within and between sub-components in the AMS will be considered and evaluated; (5) modelling optimal expected scenarios of the capability of farmland and the prosperity of farms; (6) the capability of farmland and the prosperity of farms (processed outputs of the ASM) will be revealed. Hence, the broad significance of this study is that the theoretical model for farmland capability assessment was designed and introduced. This model can be applied widely in many regions in the world. Depending on specific circumstances, the model will be adjusted and modified to adapt to local conditions. The model allows evaluate

multidisciplinary capabilities of farmland, and during the evaluation, interrelationships and interactions between land characteristics will be considered. This helps the capability of farmland is determined objectively and appropriately. More importantly, in regions where land uses changes are occurring the model can determine and predict potential capability of farmland, as well as introduce solutions for farmland improvement. It is the fundamental requirements for land evaluation, sustainable land use and planning.

For Vietnam's context, in the period 1975-1985 (after Vietnam's independence), agricultural land use in the whole Vietnam depended on a five-year centrally planned economy decreed and approved by the party congress (Trung, 2006). Agricultural land use was planned by local and provincial authorities, guided by the Ministry of Planning and supported by the National Institute for Agricultural Planning and Projection (Governors). Land use planning was viewed as a top-down process rather than where land use decisions are made by land users and farmers. Therefore the use of farmland was imposed by a master plan of the nation; in many cases this lead to an incorrect evaluation of the genuine capability of farmland.

In 1986, economic liberalization was executed through the "Doi moi-innovation" policy of the Vietnamese government. Hereby, farmers negotiated with the local authorities on long term lease contracts for land use rights and were free to decide on land use by themselves. The role of local authorities and governors was to act as overall land managers and advisors. Recently, FAO framework for Land Evaluation has been used most widely as a methodology for land use advice in Vietnam. Also, scheme such as Participatory Land Use Planning and, a Land Use Planning and Analysis System, and others, are also applied. However, the land evaluation activity for most approaches is only land suitability evaluation by matching land use requirements and land characteristics in terms of land quality. Therefore, relations and interactions between factors (sub-components) in a farming system (land use type) are not fully utilised.

The an agricultural management system design proposed in this thesis has extremely important significance in finding a satisfactory approach for the determination of the capability of farmland by analysing technical, socio-economic and bio-physical data. Relations and interactions between factors in the system, as well as management techniques and limitations to land use, are considered carefully. This provides benefits not only for agricultural officers and managers; it also has a great potential for improving the livelihoods, and increasing the income, of the local inhabitants and farmers.

The study determines the key factors that impact upon the prosperity and viability of farmland, and the relationships and interactions between those key factors. This allows farmers to exploit and optimise the use of their land resources. The results of the study provide theoretical and empirical evidence for policy makers and rural development planners as a basis for program development and policy formulation as it relate to agriculture.

The research presents limitations associated with land characteristics and provides guidance on necessary management techniques to improve farmland capability.

Finally, the most important outcome of the study is that it builds and develops a theoretical model to be use as a system and framework for farmland capability determination. This is done by integrating the results of the evaluation and analysis of related sub-components in an agricultural management system.

Scope and limitation of the study

The study provides important baseline information on socio-economic and bio-physical characteristics for input to an agricultural management system that is designed to determine the capability of farmland. The case study is confined to the two communes in the An Giang Province. The study uses both primary and

secondary data through household interviews, key informant panels, participatory rural appraisal and existing data available at the Mekong Delta Development Institute, Can Tho University, Viet Nam and the An Giang Agricultural Extension Centre. The study focuses on the capability of farmland based only on distributions of key factors stored in the agricultural management system.

Socially Sustainable Business: Generating Economic Sustainability and Social Impact Core Projects & Technologies Ltd. (CPTL)-A Case Study

*Ashish Singh, ashish.singh15@gmail.com,
Core projects and Technologies Ltd., India*

Abstract

Social Business is a business venture that operates primarily for meeting social objectives. The primary aim of investors in such businesses is generation of not only profit but also for social good. As a pioneer, CORE Projects and Technologies Limited(CPTL), India's largest global education company has been instrumental in enabling the creation of a better future across the globe by imparting best in the class technology, school management ,teachers training ,public policy enhancement consulting ,quality in education and vocational training solution worldwide. The case intends to present "Socially Sustainable Business: Generating Economic Sustainability and Social Impact, CPTL –A Case study". The research methodology adopted is a case study which helps in building analytic bridges between theory and practice (Case Method: Cases in Management, 2005). The focus, in my research has been to recount objectively and meticulously as possible real events and problems in adopting Socially Sustainable Business as a strategy not only for profit but also for creating social equity, so that it opens doors for further research. This case study would help in understanding not only what Socially Sustainable Business means for CPTL, but also throw light on how Social Business adoption by young entrepreneur can create a social ,economical sustainability. The findings reflect CPTL initiative towards social business, and strategic move to achieve its vision and becoming a benchmark for the Global Business.

Introduction

Social Sustainable Business is a business venture that operates primarily for meeting social objectives in sustainable manner. The primary aim of investors in such businesses is generation of social value and secondary of generating profits for future business sustainability.

In general society consists of two halves (Bill Drayton article): (a) business, and (b) social. The business half has made phenomenal progress because it has benefited from application of entrepreneurial energy in free market, competitive economies. Currently the social half are either drives by government policies,schemes and Corporate social responsibility (CSR) initiatives of big business houses running as Nonprofit making units (NMU) which are funded by current profit making units but sustainability of these social initiatives are a challenge as CSR are on the willingness of business houses and most of the government schemes are either suffering from corruption or with implementation challenges.

Some of entrepreneurial energies are gradually showing interest in the social sector. Their intervention is needed, not only because they can inject financial resources into the social sector, but also because they can provide sophisticated technologies and creative solutions for this sector which will be sustainable in nature. As an example, the 'e-choupal' initiative of ITC Ltd. is generating large social impact in several rural areas and overcoming poverty.

The social development challenges like provision of water and sanitation, health, education and power for the weaker sections of society can be best addressed if there are collaborative arrangements involving Government, business and citizen sectors.

CPTL entrepreneurial values and methods are playing significant role in successful accomplishment of such collaborative missions where CPTL is working with Governments & citizen sector for creating sustainable business which create the social value and same time provide the profits to their investor .

Social sustainability Perspective

Sustainability is about protecting the natural environment and delivering on social and ethical responsibilities whilst maintaining profitability. Sustainability is about resolving complex challenges and reconciling diverse demands. But overall, sustainability is about innovation and the creation of value: social, environmental and economic.

Most specifically, social sustainability refers to the personal and societal assets, rules and processes that empower individuals and communities to participate in the long term and fair achievement of adequate and economically achievable standards of life based on self-expressed needs and aspirations within the physical boundaries of places and the planet as a whole.

At a more practical level, social sustainability stems from improvements in thematic areas of the social realm of individuals and societies, ranging from capacity building and skills development to environmental and spatial inequalities blend traditional social objectives and policy areas such as equity and health with issues concerning participation, needs, social capital, the economy, the environment, and more recently, with the notions of happiness, well being and quality of life. More specifically Social sustainability perspective covers the development that meets the needs of the present without compromising the ability of future generations to meet their own needs and also continually generating fuel for its own growth.

TABLE-1: KEY THEMES OF SOCIAL SUSTAINABLE

Dimension	Key theme area
Social	Education, Gender Equality ,Health, Justice and Leadership, Poverty Eradication, Security and Crime ,Skill Development ,Social Diversity and Multiculturalism
Socio-Institutional	Capacity Building ,Participation and Empowerment
Socioeconomic	Economic Security, Employment, Informal Activities/Economy

Socially Sustainable Business – Overview

“Only the individuals can think and create new values for society – nay, even set up new moral standards to which the life of community conforms. Without creative, independently thinking and judging personalities, the upward development of society is as unthinkable as the development of individual personality without the nourishing soil of community”

-- Albert Einstein

These words of Albert Einstein beautifully express the importance of socially creative individuals in the process of social development. Unfortunately, societies in many parts of world often discourage and even turn hostile to these creative and independently thinking individuals if they start working for changes in the existing social set-up. Despite the opposition and hostility from certain elements in society, change agents have existed in India as elsewhere in all ages. The gap between one’s values and dreams on one side and social realities on other side leads to creative tensions, and drives individuals to work for social changes. While some of these change agents have impacted society through their personal examples, advocacy and practical grass root activities for social progress; others took to political, legal or religious and spiritual routes for uplifting the society; and some even adopted violent means to fight against tyrannical social values and practices.

In the context of social change agents during the 20th century, Mahatma Gandhi deserves a special mention. He was able to inspire and lead a large number of people to work for social harmony and development. Although the social values and constructive social programs of Mahatma Gandhi and his followers have created significant impact on the contemporary social life in India, an assessment of his speeches and writings shows that many of his dreams and hopes were unrealistic. Gandhi dreamt of a free India where the quality of social life of its people will be one of the best in the world in a short span of time. While elaborating his constructive programs in 1941 (i.e. about 6years before India’s independence), he declared, “ The contrast between the palaces of New Delhi and the miserable hovels of the poor labor class nearby cannot last one day in free India in which the poor will enjoy the same power as the richest in the land.” We know the reality of what happened after India got freedom in 1947. People around the world have seen the visual images of level of poverty, misery, homelessness, hunger, inequity and exploitation of weaker sections in free India through media reports. Today about 300 million Indians are not able to

meet even their basic subsistence needs. The alarming rate of environmental degradation is another cause of serious concern. A report published by UNDP places India at 127th rank in terms of Human Development Index (HDI) in a list of 177 countries. Since the social realities in India are often daunting, we need more of poetic vision and entrepreneurial energy in our development endeavors.

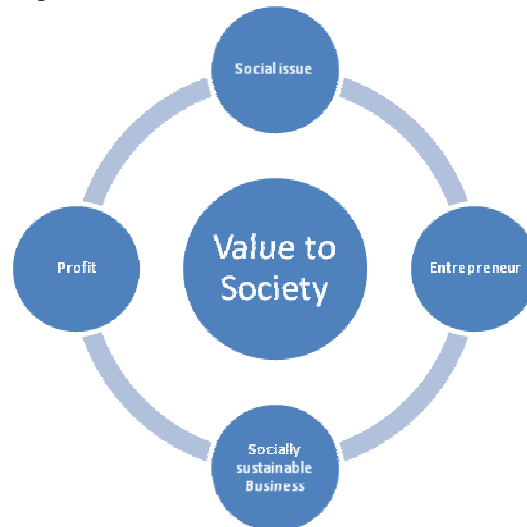

FIG.1: SOCIALLY SUSTAINABLE BUSINESS

Entrepreneur who can create socially sustainable businesses can play an important role in addressing India’s problems. These entrepreneurial strategies and activity plans usually include elements of positive, life building, socially and ecologically enriching values, attitudes and behaviors for the target population.

Stages of Indian Economy

India has started economic reforms from 1991 due to the winds of change in the international economic scenario. The need for a policy shift had become evident earlier, as many countries in East Asia achieved high growth and poverty reduction through policies, which emphasized greater export orientation and encouragement of the private sector. India had taken some steps in this direction in the 1980s, but it was only in 1991 that the paradigm shift occurred. Policies signaled a more open economy with greater reliance on market forces, a larger role for the private sector, including foreign investment. On the face of it, the figures are compelling. India's real GDP grew by 9.2% in the year (2006) to last (2005) September. Over the past four years it has clocked up an average annual pace of more than 8%, compared with around 6% in the 1980s and 1990s—and a meager 3.5% during last three decades. India seems to be reaping the rewards of reforms that were made in the early 1990s. These lowered barriers to trade and liberalized capital markets. As a result, total trade in goods and services has leapt to 45% of GDP, from 17% in 1990.

Overview of Indian Education System

Education in India is mainly provided by the public sector, with control and funding coming from three levels: federal, state, and local. Child education is compulsory. The Nalanda University was the oldest university-system of education in the world. Western education became ingrained into Indian society with the establishment of the British Raj.

Education in India falls under the control of both the Union Government and the states, with some responsibilities lying with the Union and the states having autonomy for others. The various articles of the Indian

Constitution provide for education as a fundamental right. Most universities in India are Union or State Government controlled.

India has made progress in terms of increasing primary education enrolment rate and expanding literacy to approximately two thirds of the population. India's improved education system is often cited as one of the main contributors to the economic rise of India. Much of the progress specially in Higher education, Scientific research has been credited to various public institutions. The private education market in India is merely 5% although in terms of value is estimated to be worth \$40 billion in 2008 and will increase to \$68 billion by 2012.

However, India continues to face stern challenges. Despite growing investment in education, 35% of its population is still illiterate; only 15% of Indian students reach high school, and just 7% graduate. As of now, India's post-secondary high schools offer only enough seats for 7% of India's college-age population, 25% of teaching positions nationwide are vacant, and 57% of college professors lack either a master's or PhD degree.

There are more than 1522 degree-granting engineering colleges in India with an annual student intake of 582,000, plus 1,244 polytechnics (aprox.) with an annual intake of 265,000. However, these institutions face shortage of faculty and concerns have been raised over the quality of education.

Genesis of CPTL

Mr. Sanjeev Mansotra the founder-Chairman & Global CEO admits, the company started operations seven years ago “without a vision to where it was heading”. The initial business plan was to acquire IT companies in the US with on-shore delivery capabilities and move their services to offshore delivery centres in India. Typically, these companies were owner-driven and had revenues in the range of \$5-20 million. “We acquired three companies and one company was by default also into the education space,” says Mr. Mansotra. What started off as a default soon became a grand design. **The defining moment came with a front page story in a national daily that spoke about how most of India’s expenditure in education was being misused — a news clipping that Mr. Mansotra still retains.**

This was the time when with the strong vision and commitment ‘creating social value’ Mr. Sanjeev Mansotra made CPTL to enter into Education domain and created a model which can create socially sustainable business in education domain .Since 2003-04, CPTL has evolved to emerge as an integrated education company and increase its presence in more than 3 continents. CPTL is focused on providing technology enabled education solutions, ICT education, Vocational Education, Teachers training to government bodies, schools and students. Today CPTL’s education customer base is spread across the USA, UK, Africa, Sri Lanka, Bahamas, Caribbean and India.

Mr. Mansotra is an example of a new form of entrepreneur whose motivation is not profit but to do “Social Good,” a motivation that is leading to profit-maximization with “sustainable social values.”

CPTL has been awarded many prestigious contract under the “Education for All” program (Sarva Shiksha Abhiyan) and is looking at strengthening its socially sustainable business in India backed by its International education experience for not only creating the social value but same time provide the profits to its investors .

CPTL- Generating Economic Sustainability and Social Impact

Sustainable Enterprise – an approach to business in which some of the world’s most challenging issues, such as environmental degradation and social inequality, are recast as profitable opportunities for the Private Sector- is generating considerable interest in the corporate, academic and policy spheres. A central focus of this emerging field is the role global business which may play in alleviating poverty through considering the four billion plus people living at the ‘bottom of the social and economic pyramid’ as an untapped, under-served market.

Proponents of this approach argue that innovative technology and new business models should be developed by the private sector to actively engage ‘the poor’ in the global market-place. It is hoped that this approach of ‘business as unusual’, in which social value creation is a central operational premise in previously invisible markets, will generate a more inclusive and economical sustainability and form of global capitalism.

Long-term economic sustainability is directly tied to educational excellence. Tomorrow's jobs will primarily be high tech jobs, and the success of the India or any country will be dependent upon consistent, uniform and challenging educational standards and dedicated R&D programs. We know that the old industries have left and will not return and that new industries based on new technologies will be the backbone of tomorrow's economy.

New technologies do not develop in a vacuum, nor do they appear out of thin air in some miraculous way. Technological innovations arise from excellence, creativity and innovation in current Education system - from knowledge - not from a course in underwater basket weaving. Educational excellence is therefore the principle basis of any real sustainable economic policy for India, or any country for that matter. Those countries that pursue educational excellence will be tomorrow's economic leaders.

With the focus on Generating Indian Economic sustainability and social impact CPTL started socially sustainable business in education space with operations in the US, the UK, the Caribbean, Africa and India. CORE's offerings cover compliance, assessment, ICT, content, teacher training, vocational training, examination management system, language skills and has globally impacted more than 76,000 schools, 28 million students and trained over 100,000 teachers. Twenty state Governments in USA including California, Maine, Michigan, North Carolina, Texas and over 40 Local Educational Authorities in UK work with CPTL for education projects and consultancy services. CPTL is currently working with Haryana Government, Gujarat, Maharashtra, Nagaland, (States of India) for giving Information and communication technology (ICT) education, Computer Added Education system, Development of learning tool kit for enhancing the education standard and experience in high end technology infrastructure for primary, secondary and higher secondary government schools. All projects are based on public private partnership model.

FIG.2: BUSENESS MODEL

CPTL has made the concerted effort to remove all obstacles and eliminate all hurdles of creativity and innovation in education space for creating social impact in economically sustainable way and created a socially sustainable business which is not only creating social value at centre but also increasing economic sustainability.

Four Pillars of Socially Sustainable Business at CPTL

The definitions of “learning”, “education”, and “schooling” are useful to review here. “Learning” is a lifelong process in which the individual acquires different kinds of knowledge, skills, manners, values, and so forth. “Education” involves deliberate intentions of both teaching and learning, and thus involves social roles of the

“teacher” and the “learner”. In “schooling”, teachers do not only teach, but also rank the students based on certain criteria. Schooling also produces those who are “schooled” and “not schooled”.

Although school education extends only a limited period of time in the lifelong process of socialization of a person, it occupies a relatively large psychological space in human lives today because school education is seen as a crucial determining factor for the later lives of people. It is important to re-confirm that school education is very important part of the lifelong process of socialization and human development, and that socialization is the process that is crucial for social sustainability and growth of society.

Many issues plaguing the School education system in India, lack of a robust and functioning education system at the primary level, a high-dropout rate from schools, especially seen in rural/semi-urban areas, has resulted in a large number of people entering the workforce straight after school, without any skill work result lower wages and increase in poverty.

To address solution of all above issues CPTL has made the its four strong pillars which are the strong base of CPTL business .These pillars not only provide the enhance school education but a educational which focus on 'context for learning'.

India is slated to be the third largest economy in the world — its population of 1.2 billion people, two-thirds of which lives in rural areas, needs to be suitably educated in order to be productive members of the workforce. CPTL constant innovation in education with strong four pillars, is the key to brand profitability in India.

CPTL’s four pillars are based on the above needs and a solid base for socially sustainable business. CORE socially sustainable business focus on giving world class school in affordable way to the children of India by using advance technology, effective teaching methodology by trained teachers and further giving them employable higher education and vocational education in order to be productive members of the Global Economy and catalyst of growth.

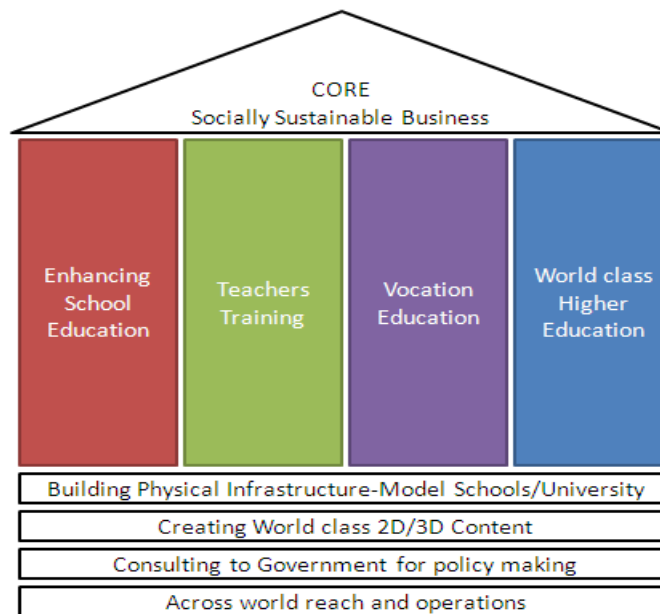

FIG.3: PILLERS OF CORE SOCIALLY SUSTAINABLE BUSINESS

CPTL- Socially sustainable Business cycle

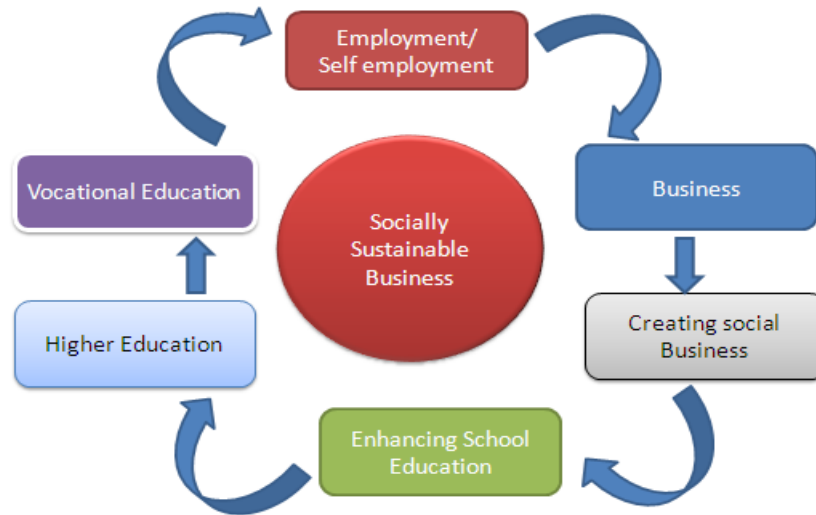

FIGURE-4: SOCIALLY SUSTAINABLE BUSINESS CYCLE

Key Enablers for Social sustainability at CPTL

- CPTL business represents a new private-sector approach to achieving the goals of sustainable development – by creating profitable enterprises that simultaneously raise the quality of life for the world’s millions of students which will help in the growth of society & country.
- CPTL employs profitable strategies that approach social and environmental challenges as business opportunities and minimize harmful social and environmental impacts. Sustainable enterprises measure success in terms of a “triple bottom line”: -financial profitability – ecological integrity – social equity.
- Strategic innovation is a central component of CPTL, as both a means and an end of adopting socially sustainability business strategies
- CPTL sustainability is about delivering on social and ethical responsibilities whilst maintaining profitability so that continues social values can be created.

Results of CPTL Socially sustainable business

- Covered more than 76,000 schools across world
- Touch lives of 76 million plus students
- Trained over 100,000 teachers
- Working with 20 States of the US
- Working with 40+ Institutions in UK
- 8 African & 3 Caribbean Nations

- Currently working with more than 9 states of India
- Included in Forbes 200 Asia's Best Under Billion Company for 2010
- Fastest growing company in Maharashtra (Government of India) which has main focus on IT into Education
- Ranked 20th in Deloitte Technology Fast 500 Company List, Asia Pacific 2007
- Special jury award by the Ministry of HRD (Government of India)

Conclusion

Research indicate that business must now focus its attention on both increasing its bottom line and creating a Social Good. In this scenario, keeping abreast of global trends and remaining committed to financial obligations to deliver both private and public benefits are forcing organizations to reshape their frameworks, rules, and business models.

Business should not be only profit targeted , Profit for the shareholders is important but unless entrepreneurs have a larger purpose and business that change lives of millions of people, a socially sustainable business cannot be created which is a need of the hour.

To understand and enhance current efforts, the organizations like CPTL is creating a socially sustainable business and continue to revise their short- and long-term agendas, to stay ahead of rapidly changing challenges.

This research paper aims at opening new vistas in the field of social business .Questions, which need to be addressed in the coming years for organizations to excel, in spite of good strategies and Knowledge base would be:

- How socially sustainable model of business can be implemented across industry?
- How social business will be encouraged by Government policies in developing countries like India?
- How social business will reduce poverty and migration from rural to urban area?

Abstract

Corporate social responsibility (CSR) has become a key issue in management strategy. The most extended tool for CSR communication are sustainability reports (SR). Previous research has looked at the level of trust provided by assurance statements (AS) issued by auditors and consultants, and have analyzed their importance and characteristics. This study looks at the perception of quality of AS using advanced accounting students in two countries as proxy for users of CSR reports. We base our analysis on a measure of quality developed by Fernandez-Feijoo, Romero & Ruiz (2011) as well as variables defined in other studies to test if the aforementioned measure is in accordance with the perceptions of users of CS reports.

Introduction

Corporate social responsibility (CSR) has become a key issue in management strategy. The most extended tool for CSR communication are sustainability reports (SR). The growth in the number of companies publishing SR is increasing continually. Their objective is to voluntarily disclose information about their economic, environmental, and social performance. As in other reporting process, accuracy and reliability are necessary values to offer guaranties to the final beneficiaries of SR, the stakeholders.

During the last decade, debate, proposal and development of standards for sustainability reports have increased significantly. This discussion produced as output a worldwide recognition of the SR as the basic tool to communicate CSR, even though without a full agreement on formats. Contrary to the reporting standards in sustainability, there is no generally accepted tool to assure sustainability information. However, international institutions, academic researchers and other organizations are conscious that this is the path to the future. Wallage (2000) highlights the need to research in, at that moment, the emerging service of SR assurance, concluding that there is an absence of criteria and verification standards.

In the AS standardization field, the most important initiatives are: 1. SA8000, by Social Accountability International, with two versions (SAI, 2001) and (SAI, 2008); 2. AA1000AS by AccountAbility - Institute of Social and Ethical Accountability, with two documents as well (ISEA, 2003) and (ISEA, 2008); and 3. ISAE3000, in 2004 by International Auditing and Assurance Standard Board (IFAC, 2008, 922-941).

The importance of reliable AS has been addressed in previous studies (Hodge, Subramaniam, & Stewart (2009); O'Dwyer (2010); O'Dwyer, Owen, & Unerman (2011) and Roebuck, Simnett, & Ho (2000)). These studies are focused on the level of trust provided by AS issued by auditors and consultants, and have analyzed their importance and characteristics, but not many of them look at measures of quality of AS to allow comparison of different reports.

Kolk & Perego (2010) propose that “future research should examine the quality of sustainability assurance statements rather than merely their adoption”. Our paper fills this gap by looking at the perception of quality of AS, using advanced accounting students in two countries as proxy for users of CSR reports. Through questionnaires with students in the United States and Spain, this paper tries to find agreement into the development of a measure of quality of AS, using variables defined in previous studies. We base our analysis on a measure of quality developed by Fernandez-Feijoo, Romero & Ruiz (2011) as well as variables defined in other studies (Fonseca, 2010), to test if the aforementioned measure is in accordance with the perceptions of users of SR and AS.

Literature Review

Main standards in AS have been being published during the last decade and have contributed to enhance the debate with an international scope. Kuruppu & Milne (2009:47) give a clear opinion about the importance of AS:

There are compelling arguments to suggest the importance of assurance, both to companies and to external stakeholders. Despite these arguments, initial results from the field suggest if in fact assurance does add credibility to sustainability reports, not all or perhaps even most stakeholders can perceive it. This is no argument against the practice of independent assurance. Rather it is an argument in favour of a clearer and better articulated programme of communication that informs stakeholders about the practices, outcomes and benefits of independent assurance.

Wallage (2000) highlighted the need of research in, at that moment, the emerging service of SR assurance, due to the absence of criteria and verification standards. Once the main standards were issued, the lack of homogeneity in both the assurance process and the AS, was emphasized in literature. Hasan, Roebuck & Simnett (2003) analyzed the different AS types based on the level of assurance defined in the engagement, and the consequent perception of the addressers. Oelschlaegel (2004) posits that there is no systematic procedure to assess for assurance practitioners' competence. O'Dwyer & Owen (2005), working on a sample of the year 2002 with data from UK and Europe, conclude that there are differences among the reports issued by auditors and those issued by consultants. They draw attention to the managers' control of the AS process, evidenced by the frequent reference of managers as addressees of the AS. With a similar scope, Deegan, Cooper & Shelly (2006), using a sample of UK and European reports from 2000 to 2002, conclude on the variability and ambiguity of the ASs.

The relationship between AS quality and assurance provider has been also approached by Perego (2009). He concludes that big-4 auditors provide a higher quality in format and procedure aspects, and less in recommendations and opinion questions. He also finds that companies operating in countries with weaker legal systems are more predisposed to choose one of the big auditing firms. Turker (2008) presents a scale to measure CSR in terms of expectation of stakeholders based on data gathered from business professionals in Turkey. His measure identifies the items that are considered of higher importance by users of SR, finding for example that information about employees is the highest rated. However, this paper does not consider the quality of the reports or provides any measure to compare different AS or SR.

Cahyandito et al. (2005) look at the communication processes between companies and their stakeholders using a two sided/reciprocal model (corporation and stakeholder). For the corporation group, they interview managers of two German companies (Weleda and Deutsche Telekom). For the stakeholder group, they asked the interviewed managers for a list of stakeholders from which they chose the interviewees. Their objective is threefold:

- discuss how much the managers understand SR and their stakeholders (pre-communication stage),
- the motives and goals of SR (communication stage), and
- the view of the stakeholders' acceptance of the content of the report and their perception of the corporate image (post-communication stage).

The findings of the paper are that the perception of communication in those two parties is different, and based on their knowledge of the environment, their competence, and their interests and ideals.

In the AS literature, Manetti and Becatti (2009) report the need of specific guidelines for assurance providers to increase effectiveness and reliability of assurance services. They do not compare the differences in the reports when produced by auditors or consultants, and they do not measure its quality as well. However, Hodge, Subramaniam & Stewart (2009) find weak support for the auditors having more credibility than other providers. They also find that the AS adds credibility to the SR, but they find no relationship between users' confidence and perceived credibility of the SR.

Focusing on AS quality measure, Simnett, Vanstrelan & Chua (2009) use the type of provider to measure the quality of the AS and assign higher ranking if the AS is issued by an auditor. With an industrial view, Fonseca (2010) measures the quality of a sample of AS of mining companies, based on compliance with requirements set out in current standards. The author applies a qualitative evaluation of a set of ten variables, establishing for each one the level of contents to classify them as "high quality" or "low quality". The ten variables analyzed are: Scope of engagement; Addressee; Responsibilities of reporter and assurator; Competency of assurator and respective team; Independence of assurator; Level of assurance; Assurance standards used; Methods and criteria used to assess

evidence and reach conclusions; Conclusion/Opinion; and Recommendations or additional comments and observations. The sample of ASs was selected from the websites of companies belonging to the ICMMⁱ and from other open databases of SR between November and December 2007. Fonseca concludes that procedure requirements increases trust on external assurance although “Trust is a concept whose meaning and implications may vary substantially among stakeholders, nations, and cultures” (364). Fernandez-Feijoo, Romero & Ruiz (2011) design a model to evaluate the quality of the SR and AS, based on a set of items disclosed, proposing a measure of its quality. They also analyze the characteristics of the companies that present high quality reports. The proposed model is supported by Spanish company data. This paper concludes that auditors issue higher quality AS than consultants, and that measures indicating size (size, listed companies, Big4 auditor) are associated with the quality of AS reports. Another finding of the paper is that those variables related to the industry of the company (sector, size, leverage) are associated with the quality of the SR report.

Methodology

The approach followed in the paper is descriptive and intended to understand how users of AS evaluate its quality. Since this “perception” is qualitative, it is measured in qualitative terms.

Our study was conducted in different moments and with different populations both in the United States and Spain, described as follows:

- Group 1 (November 25th 2010). 12 Spanish Master in accounting students. These students have an undergraduate degree in economics or business but in general, they have no previous knowledge of CSR. The study was conducted after they were lectured about GRI SR and AS standards. We call this group GAS1.
- Group 2 (November 12th 2010). 14 Spanish advanced accounting students. These are accounting and auditing students in the fifth and last year of their career. Due to the Spanish university systemⁱⁱ, these students can be considered as master-level students since they do not receive an undergraduate degree (bachelor) but a diploma accreditation. They have introductory level skills in CSR. We call this group GAS2.
- Group 3 (December 14th 2010). 23 US advanced accounting students. These are accounting undergraduate students in their last year with no formal training in CSR. We call this group GAS3.

The same questionnaire was used in the different sessions to evaluate AS quality perception. The questionnaire was divided in three parts. The first one refers to identification data, to define the students’ profile; meanwhile the second collects the importance given by the students to a set of variables, in a 7 point Likert scale. The variables tested are the ones proposed by Fernandez-Feijoo, Romero & Ruiz (2011) (FRR hereinafter) to measure AS quality. After completing the second part of the questionnaire, the students were asked to review and evaluate a set of AS, and to provide their opinion about the worst and the best of them.

Results

Descriptive Statistics

Table 1 presents the descriptive statistics of the participating groups. Group 1 includes 12 Spanish students in a Master in accounting program. 5 of them are younger than 26 (41.67%), 4 are between 26 and 35 (33.33%), and 3 are between 36 and 45 years old (25%). There are 7 female (58.33%) and 5 male (41.67%) students. The 83.33% of the students (10) have an average of 5.1 years of work experience in accounting, financial or commercial tasks, in all grouped sectors except Mining. Group 2 includes 14 Spaniards in the last year of a 5 years program BS/MS students. 12 of them (85.71%) are under 26, and 2 (14.29%) are between 26 and 35 years old. There are 9 female (64.29%) and 5 male (36.71%) students. 7 of the students (50 %) have an average of 2.14 years of work experience in accounting and financial tasks, in all grouped sectors except Mining. Group 3 includes 23 advanced accounting students, the majority under 26 (82.61%) and 13 women representing 56.52% of the total students. The 86.96% of them, (20 students), have work experience (5.4 years in average) and only 6 of them (26.09%) reveal not much previous knowledge about CSR.

TABLE 1. DESCRIPTION OF THE SAMPLE

	Number	Age		Gender		Work experience		Previous knowledge of CSR	
		≤25	>25	F	M	No	Yes	Not many	More
GAS1	12	41.67%	58.33%	58.33%	41.67%	16.67%	83.33%	66.67%	33.33%
GAS2	14	84.62%	15.38%	69.23%	30.77%	53.85%	46.15%	61.54%	38.46%
GAS3	23	82.61%	17.39%	56.52%	43.48%	13.04%	86.96%	26.09%	73.91%
Total	48	72.92%	27.08%	60.42%	39.58%	25.00%	75.00%	45.83%	54.17%

Findings

The analysis is structured around the main issue of the paper, AS quality perception, as follows:

- ✓ Analysis of GAS1 plus GAS2 plus GAS3 answers to the closed questions, to evaluate their opinion on the importance of the different criteria proposed, and to test if there are significant differences among the three groups or between the two countries (GAS2 vs. GAS2 vs. GAS3).
- ✓ Analysis of the answers of the groups to the measures proposed by Fernandez-Feijoo, Romero & Ruiz (2011) (Reliability of the FRR model).
- ✓ Relationship between student’s perceptions of quality and the result of the FRR model to measure AS quality, applied to the same companies (Validity of the FRR model according to the student’s assessment of AS quality).

GAS1 vs. GAS2 vs. GAS3

The FRR model is based on the contents and the structure of the assurance report. Taking into account that there are professional assurance standards dealing with those elements, the quality indicator is defined in terms of objective and formal components. To validate the measure developed in the mentioned paper, we collected the students’ evaluation of each one of the formal variables described by the standards (defined in Table 2), to infer their perception of the importance given to these variables. As stated before, all variables were measured in a 7 point Likert scale.

TABLE 2 VARIABLE DESCRIPTIONS

Variable	Value assigned to quality if the AS has
Formal aspects	
Name, signature, place & date	the name and signature of the auditor and the place and date of the auditing
Title	title of the document
Addressees	the reference to whom is addressed
Subject matter	the explanation of the assurance subject matter
Entity responsibility	the identification and responsibility of the entity whose SR are assured
Auditor responsibility	the identification of the auditor and his/her responsibility
Independence	the clear specification of auditor's independence
Verification	
Work performed	information about procedures and work performed
Assurance standards	information about the assurance standards used
No Limitations to the scope	limitations to the scope
Level of assurance	information about the level of assurance
Conclusions	conclusions
Recommendations	recommendations
Availability	
On-line access	an easy and clear access (on-line access)

The results of the participants’ assessment are resumed in table 3. An ANOVA test of the differences between groups deals no significant difference between them. The three groups of students assigned the lowest value to the existence of a clear identification of the addressee in the report. These values represent 81% (GAS1), 71.4%

(GAS2) and 73.4% (GAS3) of the maximum value of 7 for each variable. It seems that the participants in the study are not concerned about independence, quality and AS addressed to the managers. O'Dwyer and Owen (2005) question the independence of the assurance and the degree of management control, evidenced among other factors by the AS addressed to the managers.

TABLE 3. IMPORTANCE OF QUALITY AS CRITERIA

	GAS1 (n=12)		GAS2 (n=14)		GAS3 (n=23)

Table 4 presents the items with the lowest and the highest ranking. There is some agreement among groups in the less-valued items, but a great dispersion on the more-valued items. Master students rated all the variables over 6, except the one measuring the availability of the addressee of the report. They assign more value to aspects related to verification like the level of assurance and the existence of conclusions as well. This behaviour might be related to the maturity of the participants. A similar effect of age is found in the measurement of the availability of the reports. Younger students, especially American, assigned less value to the possibility of getting the report easily on line. Cultural country characteristics can explain this evaluation.

TABLE 4. LOWEST AND HIGHEST RANKING OF COMPONENTS OF AS QUALITY MEASURE

Reliability of the FRR model

To estimate the reliability of the measure of AS quality included in the FRR model, the Cronbach Alpha coefficient is calculated. The variables linked to formal aspects have a coefficient of .738, while the variables linked to verification have a coefficient of .821. Although there is no general agreement on what is a perfect coefficient, a value higher than .70 is considered a good measure (Peterson (1994), found a mean coefficient value of .77 among 4286 Alpha coefficients); therefore, we can argue that the FRR measure is reliable based on the scores of the participants in the study.

A principal component analysis of the student’s responses deals five components (Table 5). The first of them includes five of the measures linked to verification. Those variables define the technical scope of the assurance. The last component includes on-line access only, and is included in the model as a measure of availability of the report. Regarding format, component 3 relates to auditor characteristics (identification, independence and giving recommendations), component 2 relates to determinants of responsibility (existence of statements of responsibility of entity and assurance, and disclosure of the subject matter). Finally, component 4 includes the existence of title and identification of the addressee, formal variables that define an identification of the AS, and that were ranked in the lowest level by all the groups.

TABLE 5. PRINCIPAL COMPONENT ANALYSIS OF THE AS QUALITY CRITERIA

Variable	Verification technique	Formal responsibility	Formal auditor identification	Formal AS identification	Availability
Formal aspects					
Name, signature, place & date			.814		
Title				.692	
Addresses				.771	
Subject matter		.724			
Entity responsibility		.715			
Auditor responsibility		.828			
Independence			.685		
Verification					
Work performed	.808				
Assurance standards	.672				
No Limitations to the scope	.769				
Level of assurance	.745				
Conclusions	.577				
Recommendations			.481		
Availability					
On-line access					.897

The less weighted variable “Recommendations” is the only one not perfectly adjusted to the item structure. However, analyzing its valuesⁱⁱⁱ, it can be considered as a neutral variable for nearly all components.

Validity of FRR model according to student’s assessment of AS quality

At the end of the study, students were asked to evaluate at least two AS (some of them evaluated three). They were asked to measure in a 7 point Likert scale the level of satisfaction of the ASs with the variables defined in the FRR model, and to judge which AS was the best and which one the worst. 37 of the 46 students (80%) who evaluated the quality of the AS gave higher average rankings to the best than to the worst company assessed according to the FRR model, which indicates an agreement between both assessments.

A pair comparison of each student’s assessment and the related FRR model value shows that the means are not different ($p < .0217$) (Table 6).

TABLE 6 – PAIRED SAMPLE COMPARISON BETWEEN STUDENT’S ASSESSMENT AND FRR MODEL

	Mean	StdDev	N	t	sig.
Student valuation	.695	.328	104		
Value FRR	.655	.211	104		
Paired sample test	.040	.330		1.243	.217

Table 7 presents the mean of the students' assessment and the FRR model value. Both variables are highly correlated (Pearson Correlation = .768 at .001 level).

Cajasol	0.51	0.40	ENUSA	0.68	0.70
SegurCaixa Holding	0.84	0.90	BBK	0.64	0.40
TERSA	0.55	0.50	Abbey Nat. Plc	0.75	0.80
Antena 3 Group	0.62	0.40	Reynolds	0.76	0.75
Repsol YPF	0.85	0.90	Amec	0.71	0.40
Lavola	0.69	0.50	Ferrovial-grupo	0.68	0.90

A comparison was made between the agreement in the judgment according to the students and the model. For that purpose, a variable PICKBEST was defined, with a value of 1 if the student picked the best company according to the model, and 0 if the judgment disagreed. There is agreement in 67% of the cases, but with differences between groups. There is a higher disagreement in the US undergraduate students than in the other two groups (Spanish). A chi square test shows that the differences are significant (Table 8). This difference can be related to the previous knowledge of the students since the undergraduates had not had any course related to CSR, while the other two groups had had at least some introduction to the topic of AS for sustainability reports. It could also be related to cultural differences between countries.

TABLE 8 – SELECTION OF THE BEST COMPANY ACCORDING TO THE FRR MODEL

		Group			Total
		GAS1	GAS2	GAS3	
Pickbest	0	0	1	13	14
	1	12	10	6	28
	Total	12	11	19	42

Chi-square test Asymp. Sig (2 sided) 0.000

Finally, we run a regression to understand which of the variables affected the selection of the best and worst AS. The independent variables are the differences in the ranking of the format, verification and access between the best and the worst companies, while the dependent variable is the PICKBEST variable defined before. The demographic variables age, group, work experience, previous knowledge of CSR, experience reading AS, and importance assigned to the AS are introduced in the model. The results show that previous knowledge of CSR, as well as verification and format differences affect the selection of the best company. Another significant difference is group, where the cultural factors may be present, since the previous knowledge of CSR was accounted for in another variable (Table 9).

TABLE 9. COEFFICIENTS LINEAR REGRESSION
(dependent variable: PICKBEST)

	St. Coeff. Beta	t	Sig.
(Constant)		3.83421	0.001
group	-0.59791	-3.81291	0.001
age	-0.21724	-1.43591	0.162
gender	-0.16048	-1.48731	0.148
workexp	0.06109	0.57795	0.568
csrknow	0.27070	2.22781	0.034
readas	0.01983	0.17223	0.864
importanceas	-0.08470	-0.66406	0.512

diffverif	0.46837	4.37953	0.000
diffacc	-0.03130	-0.27095	0.788
R Square		0.772	
Adj R Square		0.693	

Group has a value of 1 if GAS3, 0 if GAS2, -1 if GAS1. Age is divided in ranks where 1 is the youngest group, and 4 the oldest. Work experience has a value of 1 if they worked, 0 otherwise. Gender is 1 if male, 0 if female, Csrkow is 1 if they have training in CSR, 0 otherwise. ReadAS is 1 if they ever read AS, 0 otherwise. ImportanceAS has a value from 1 to 7, where 1 is having no importance and 7 is extremely important. Diffformat, differif, diffacc is the difference between the individual assessment of the components of the best and worst companies.

Discussion, Conclusions and directions for future research

This paper reports the results of a study developed to evaluate if the users' perception of AS quality is in agreement with the model developed by Fernandez-Feijoo, Romero & Ruiz (2011). 49 accounting students participated as proxy for users of ASs, both in Spain and in the United States. The FRR measure has three components, formal, verification and accessibility. Each of them is described by different variables. All the variables included in the model were ranked by the participants as having high importance in the assessment of quality of AS. The lowest mean value, 5 in a scale of 7, was assigned by the Masters students, to the identification of the addressee in the report. The other groups agreed on the lower ranking for this measure, compared with the others. We found differences in the assessments of the groups, although they are not significant. Masters students, on one hand, gave less value to factors related to presentation formats, like the report having a title or identification of the addressee. They assigned more value to aspects related to verification like the level of assurance and the existence of conclusions as well. This behaviour might be related to the maturity of the participants. A similar effect of age is found in the measurement of the availability of the reports. Younger students, especially American, assigned less value to the possibility of getting the report easily on line. The usability of the Internet in the USA, which has levels of 77% according to www.internetworldstats.com, may reduce the assessed value of this variable because access is given for granted.

The values assigned by the participants to the components of the measures are highly correlated, which adds reliability to the measure. In this sense, the variable "formal aspects" has a Cronbach Alpha coefficient of .738, while the variable "verification" has a coefficient of .821. This variable, verification, was found affecting significantly the evaluation of quality of AS.

In evaluating the quality and picking the best and worst ASs among 2 or 3 that the participants had to evaluate, there was an agreement between the assessment and the model in 67% of the cases. The students with more disagreement were the ones in the undergraduate program that had not had any in class training on CSR. This result is significantly different according to the Chi-Square test performed. Besides the students being undergraduates, they were students in a US university. We need to stress here that CSR is not fully adopted in the USA. According to Kaye (2011) American companies lag behind other countries in the development of CSR, since 45% of the companies using the GRI reporting model are European and only 12% of them are American. By being part of a culture that does not place value in the AS of the SR, they may not be prepared to evaluate them. Students in Spain had formal training on CSR, and by knowing what it means, are more able to evaluate its quality. Although AS is an instance of assurance, like financial statement auditing, it is not mandatory, this has different implications for users' evaluation of trust.

This study has limitations due to the inclusion of participants of only two regions. We found differences that could be related to cultural components. Two of the participating pools are from Spain, a country that has had an important increase in their CSR reporting strategies during the last years. A KPMG survey places Spain second in the world with around 70% of the SR assured (KPMG, 2008, 57). The third pool is from the US, which has only 14% of their SR assured. Although half of the participants are undergraduate students, they are seniors, and familiar with analysis of corporate information. Future research requires the extension of the study to larger samples, preferably of MBA students. It is also needed research with participants in different countries, to look for the possibility of other cultural differences. It is also necessary to develop and test measures of quality for SR as a complementary task to the evaluation of AS quality.

Environment Related Reporting in Indian Cement Companies-a sustainability study

*M. D.SaiBaba,
Padma Srinivasan ,BPadmaSrinivasan@yahoo.co.in
Manipal University, Bangalore Campus*

Abstract

Environmental issues have become major business factors due to the negative externalities inflicting higher external costs on to the society. Besides, allocative efficiency is impaired, particularly in the areas of non-renewable assets. Thus increased awareness of social responsibility and environmental concern is now a challenge facing the corporate world. This study is intended to construct an index, based on the environmental issues related information in annual reports and find its relationship with firm values. The data is based on the listed cement companies whose market values are available in the Annual Reports for the year 2008-09. The findings reveal that board size and compositions has a significant relationship with environmental reporting.

Introduction

Progressive cement companies, of late are slowly realizing that to remain competitive in the future, they must combine sound financial performance with a commitment to social responsibility and environmental stewardship. These three dimensions are referred to as the “triple bottom line” of sustainable development. This translates into a fundamental goal of meeting the needs of the present without compromising the ability of future generations to meet their own needs. To achieve this there is a need for a paradigm shift in redefining the objectives of the company into economic growth, ecological balance, and social progress instead of straight jacketed focus on enhancing shareholder’s wealth.

The purpose of this research paper is to develop an index, (Environmental impact score-EIS) based on the data available in the annual reports on the lines of sustainability and correlate it with performance. The construction of the index is on the premise of factors concerning stakeholders outside the industry and boards, (who are primarily responsible for such implementation) as internal governance mechanisms.

Accordingly the chapter is organized as follows. Section 2 deals with literature review. Section 3 deals with the methodology, section 4 deals with analysis of data and section 5 deals with conclusion.

Literature review

In the developed countries there have been numerous studies on corporate social reporting and environmental reporting (Gray *et al.* 1995; Deegan and Gordon, 1996; Hackston and Milne, 1996; Adams, 2002; Cormier and Magnan, 2003, 2007). There is a similar growing trend in the developing countries as well (Cho and Patten, 2007; Zauwiyah *et al.*, 2003; Nik Nazli and Maliah, 2004; Romlah and Sharifah, 2004; Sumiani *et al.*, 2006; Amran and Devi, 2008).

The idea of this study is to link company’s internal processes to the environmental information contained in the annual reports. The premise of this idea is rooted in the concept of Adams (2000), who says that there are three factors that can influence corporate social reporting, namely, corporate characteristics, general contextual factors and the internal context.

According to Cho and Patten (2007), the companies disclose environmental aspects in financial reports. This ensures that the firms' activities are perceived to be legitimate in the eyes of the stakeholders thereby enhancing the firm's reputation.

Following the 1997 Asian financial crisis and 2002 ENRON collapse, regulators have focused on corporate governance legislations aimed at protecting the shareholders, primarily the minority ones. However there are no specific regulatory measures except state enforcing discipline mechanisms related to the environmental issues. The focus was on accounting transparency, disclosure and accountability and not beyond. In this context, voluntary reporting on environmental issues and CSR improves the social visibility of the firm.

Scandals of high profile as Enron, WorldCom, Tyco and some other firms in the U.S, have raised the question of the effectiveness of monitoring mechanisms in organizations (Raphaelson and Wahlen, 2004). As per Kolk (2006) the focus is shifting towards the internal mechanisms and in this context, corporate governance and sustainability reporting has emerged. This is on voluntary basis concerning the societal issues. Disclosure on environmental issues has the potential to increase shareholder's wealth and can be regarded as one of the elements of good corporate governance (SIO, 2006).

Theoretical aspects of environmental issues

The most frequently cited theory in social and environmental reporting studies is the *legitimacy theory* (Gray et. al., 1995). The theory is based on the notion of 'social contract', which limits the activities of an organization within the boundaries set by the society (Gray et. al., 1996).

In essence, the organization will gain support from the stakeholders and continue in existence in so far as its activities give benefits, or at least are not harmful to society. 'Legitimacy' is said to exist as there is congruence between the activities of the organization and societal expectations. Otherwise, the organization has to deal with the 'legitimacy gap' by improving its actual performance, changing the societal expectation, or the perception of its performance, or deviating away the public attention from the issue under scrutiny (Lindblom, 1994).

Another useful theory to explain the environmental reporting practice is the *stakeholder theory*. This theory stems into two other theories: the *normative stakeholder theory* and *empirical stakeholder theory* (Gray et. al., 1996). The *Normative stakeholder theory*, the more relevant of the two, posits that an organization (this would mean any party interested in the corporate environmental performance including NGOs, government and the public at large) will report on the environment simply because the 'environment' is one of its many stakeholders and its information needs must be fulfilled. Thus, in the absence of any mandatory reporting, a company should report on the environment voluntarily to discharge its environmental accountability to the public.

Methodology

Cement companies cause huge external costs, both in production and in supply chain process.

We have considered awards and other practices (global reporting initiative etc) as the criteria for developing the index because it is a bottom up process. Mandatory practices such as complying with ISO900 are considered as threshold levels of compliance and hence they are considered as a top down process. Accordingly issues like earning carbon credits, Global reporting initiative figure in our index (Environmental impact score-EIS)

For board composition and meetings; the source of data is from the annual reports.

Financial data is from the CIME data base which all researchers use in India (Balasubramanian, 2008; Palepu, 2006).

Analysis of Data

Table 1 shows the results of the regression with Tobin's Q is the dependent variable and other control variables[. reg tobinsq eis brdind brdsiz brdmtg]

	Coef.	Std. Err.	t	P>t
EIS	0 .163054	0.0564293	2.89	0.008
Board ind	0.0373064	0.0646075	0.58	0.568
Board size	-0.0383191	0.0473516	-0.81	0.425
Board meeting	0.0427117	0.0725676	0.59	0.561
_cons	0.8399022	0.4957785	1.69	0.102
Source	SS	df	MS	Number of obs = 32
Model	1.07794	4	.26948517	F(4, 27) = 2.18
Residual	3.3390	27	.123667904	Prob > F = 0.0983
Total	4.41697411	31	.142483036	R-squared = 0.2440
				Adj R-squared = 0.1321
				Root MSE = .35166

The value of EIS is positive and significant at 1% levels; other positive factors being board independence and meetings which is consonance with other research findings.

TABLE 2

EIS	.1521399	.0570202	2.67	0.013	.0349331	.2693466
tobinsq	Coef.	Std. Err	t	P>t	[95% Conf. Interval]	
_cons	.6374236	.525847	1.21	0.236	-.4434704	1.718318
Dual CEO	.178105	.1596202	1.12	0.275	-.149999	.506209
Board size	-.0410379	.0472011	-0.87	0.393	-.1380611	.0559854
Board ind	.0375112	.0643166	0.58	0.565	-.0946935	.1697159
Board meetg	.0618239	.0742434	0.83	0.413	-.0907857	.2144335
Source	SS	df	MS	Root MSE = .35008		
Total	4.41697411	31	.142483			
Residual	3.18644905	26	.1225557	Adj R-squared = 0.1399		
Model	1.23052506	5	.2461050	R-squared = 0.2786		
Prob > F = 0.1108				F(5, 26) = 2.01		

The second set of table comprises of regressions with additional control variables .While there is change in the coefficients the values are positive and significant showing consistency in EIS values.

Conclusion

The purpose of the current study is to examine the level of environmental reporting among Indian cement companies and its association with corporate governance mechanisms such as board structures. On the whole, this study concludes that environmental reporting practices are not very clear. This finding provides limited evidence on the application of the stakeholder theory where ‘environment’ is considered as one of the important stakeholders. Additionally, findings on the corporate governance variables suggest that only the *board independence and meetings are* positively related.

The findings of the study should be interpreted in light of several limitations. First, only one year of data was considered in the current study. Hence, it would be interesting to conduct a longitudinal study on a yearly basis as it may help to trace the trend of environmental disclosure and the impact of corporate governance on environmental reporting practices. Second, the study focuses merely on examining the existence of environmental reporting in annual reports. Future research may adopt content analysis to examine the quantity, quality and nature of the reporting.

The findings might have altered if these variables had been applied and, therefore, would be able to explain environmental reporting behaviors. Additionally, the result will possibly have important implications on our understanding of the motive and consequences of environmental disclosure.

Sustainability Collaboration: Integrated multiple stakeholder contracts

*Sudhi Seshadri, sudhi@smu.edu.sg
Singapore Management University, Singapore*

*Michael Ehret, michael.ehret@ntu.ac.uk
Nottingham Trent University, UK*

Abstract

We develop the concept of Sustainability Collaboration in B2B marketing to be consistent with the Resource Based View (RBV) and the often cited UN Committee (convened in 1983) conceptualization of Sustainable Development. We propose that a contractual approach is central to Sustainability Collaboration (SC). The usual three dimensions of externalities in sustainability can be reflected in contractual SC agreements provided a multiple stakeholder perspective of business is taken. SC and the contractual approach is then applied to typical multiple stakeholder configurations employing appropriate contractual instruments. We illustrate the concept with examples. The paper contributes to understanding why and how multiple stakeholder contracts find their nexus in a firm's Sustainability Collaboration performance.

Introduction

Sustainability efforts are by essence collaborative. There are two main reasons. One is that successful results affect all stakeholders and are in the common domain. For instance, a major metric of success in anthropogenic global warming is tons of CO₂-equivalent emissions. Regardless of the specific effort, green house gas (GHG) output is homogenous and immediately mixed into the planet's atmospheric layer. Therefore trading of the results of GHG reduction efforts can be commoditized in carbon markets, even for the most location-specific effort. Other sustainability collaborations may not have such universal logic, but usually there are many beneficiaries. A second reason is that the effort is long term, risky and involves substantial financial burdens, and therefore requires alliances between different specializations in the entire supply chain. For instance, replacing petroleum based fuels by biofuels require innovative technologies, R&D, biomass sources, logistics, blenders, brokers, fleet managers and ultimately consumers to align their expectations and business models. Similarly, renewable energy for the grid is generated by a variety of start-up businesses that need to collaborate on building an infrastructure of high voltage direct-current transmission, which does not exist today, to deliver power to major utilities located thousands of miles away. Collaboration is beneficial to multiple partners.

Sustainability Collaboration is a performance outcome that demonstrates the firm has overcome these barriers and found solutions to negative externalities generated by traditional business models. Sustainability Collaboration is strategic since performance can advantageously orient businesses to superior future financial performance outcomes. While collaboration in general may be voluntary and arise from mutual self interest, there are many reasons why formal contracts should be attempted where possible. We argue that Sustainability Collaboration arises as a superior performance outcome only when it harnesses contractual agreements.

Modern business models require managers to clearly identify strategic resources that enable them to develop advantages in competitive marketplaces. Their firm's financial and non-financial performance outcomes depend on their ability to employ resources that are unique, and hard to imitate or surpass. The link between firm resources and firm level performance is a focus of the Resource Based View of the firm (Wernerfelt 1984; Barney 1991). Collaboration among businesses is widely studied in the literature, and its importance to innovation cannot be overstated. However, collaboration among multiple stakeholders, some of whom are not businesses, is necessary for business level performance outcomes in a sustainable world. How may we conceptualize performance? This paper addresses the central question of a "collaboration for sustainability" concept. It argues that a Sustainability Collaboration stems from and is safeguarded by contracts. A sound understanding of contractual approaches is central to performance.

The firm that does not seek to develop its business along sustainable lines may come out ahead for a short period, but is courting collective disaster in the long run. As all businesses survive in a collective business environment, the wisdom of Sustainability Collaboration among all stakeholders should translate to enlightened self-interest. Regulators argue that as enlightened self-interest is not always voluntary it may have to be mandated and compliance may have to be enforced. But evidence from Green Clubs (such as RGGI, the mid-Atlantic US based Regional Greenhouse Gas Initiative) shows that firms embrace enlightened self interest quite often, even when not stimulated by the possibility of imminent regulation. Firms voluntarily enter into contracts with a variety of stakeholders. Often these contracts are bilateral and therefore self-enforcing. Contracts are designed to reduce business risks and provide incentives in the supply chain for improved performance.

Broadly, externality risks and therefore all sustainability performance outcomes stem from environmental, social and economic sources. While these mutually reinforce in some ways, they may also be in conflict if sustainability business solutions are not well designed. Sustainability success metrics are determined along these three dimensions. They are closely related to pre-existing KPIs from various established business frameworks that were considered independent in pre-sustainability business models. Therefore, Sustainability Collaboration retains many features of business solutions already in place. Guinipero et al (2006) argue that supply chain managers must develop specific skills and apply them entrepreneurially in the future. However, to the best of our knowledge the literature has not explicitly proposed Sustainability Collaboration as performance outcome. The role of contracting in Sustainability Collaboration is an additional contribution of this paper.

The next section of the paper briefly reviews the literature relevant to the construct of Sustainability Collaboration (SC). The next sections propose agency-theoretic contractual instruments that SC can build upon. We next outline an illustrative example of the consequences of SC failure, and conclude with future research directions.

Literature Review

The relevant literature for a framework on Sustainability Collaboration links sustainability, resource based views, collaboration and contracts.

Sustainability: In the course of producing goods and services in modern economies, firms emit various types of pollutants, wastes, and emissions. Many products such as waste packaging have a post-consumer life that contributes even further to environmental degradation. These environmentally degrading consequences impose an unwanted and unintended social cost, and traditional business models seek to relegate them to external costs by avoiding their impact on the bottom line or on prices. A true cost to society that does not show up in a firm's profit and loss statement is termed an external cost or externality. One major class of external costs is due to environmental degradation in the production of goods and services. The producer and the recipient of the externality may be different parties, as in an upstream paper mill and a downstream water supply system, or the same party as in global green house gas emissions (Field & Field 2009: p. 74). The economic impact then becomes an externality. The problem is broader than economic externalities as was recognized in the economics literature many years earlier. A telling quote is: "But it is, of course, desirable that the choice between different social arrangements for the solution of economic problems should be carried out in broader terms than this and that the total effect of these arrangements in all spheres of life should be taken into account. ... problems of welfare economics must ultimately dissolve into a study of aesthetics and morals (Coase 1960: p. 43).

Traditional business models generate externalities such as toxic pollution, climate change and depleted natural resource. These are all damaging to mankind's ecological environment. The Stern Review Report on The Economics of Climate Change (2007) has pointed out the wide ranging market failure associated with emission. Over five years ago, the UN sponsored MEA (Millenium Ecosystem Assessment 2005) found that approximately 60 percent of the ecosystems services that supported life on earth were being used unsustainably. A measure of the economic value of such services is GBP 30 trillion in 1996. The costs of stabilization would be about 1 percent of GDP by 2050, according to the Stern Review, although it is a considerably higher percentage at this time. What if stabilization is ignored? The Stern review estimates the direct and indirect costs to consumption, environmental services and health 11-14 percent of GDP. The obvious conclusion is that a small cost to the GDP could prevent ten

times as much in lost value. Not many investments in the “business-as-usual” approach can boast of such returns (May 2008).

Other externalities are economic and social, and damage long run business environments and community systems. Negative externalities by definition are difficult to deal with by voluntary actions, as they arise as mutual best responses to tragedy of the commons or prisoner dilemma situations. These “best” responses are individually rational actions which aggregate to collectively inferior outcomes. Almost three decades ago sustainable development was defined by a UN Commission that grappled with these externalities on a global scale. The often cited definition is consistent with a performance outcomes orientation inherent to Sustainability Collaboration.ⁱ

Resource Based View: A major paradigm in management strategy research is that of the resource based view (RBV: Barney 1991; Wernerfelt 1984;) of the firm. In the RBV, the firm’s performance is explained by its resources. Resources can be material, financial, organizational, technological or human capabilities. Barney (1991) includes as resources all organizational processes that “enable the firm to conceive of and implement strategies that improve its efficiency and effectiveness.”(p.101). Firm resources are hard to imitate, unique and are developed over long periods of time. From a strategy perspective, Resource Based Theory (RBT) postulates the most basic conflict in market economies is in the competition between processes for resources. RBV is proposed as an approach naturally compatible with sustainability research as natural resources should be nurtured over time, ecological advantages can provide economic advantages (Connelly et al 2011).

Crook et al (2008) conduct a meta-analysis of RBV research to examine the links between strategic resources and performance, and find that human and intangible resources are more effective than tangible resources. They argue that RBV studies should develop performance measures that are unaffected by financial reporting norms. Functional level performance measures, such as corporate social responsibility (CSR), are preferable to organizational measures in RBV studies as the latter may be confounded by financial accounting adjustments.

CSR, an aspect of sustainability, leads to improved corporate social performance. Research has demonstrated that corporate social performance has a positive effect on financial performance (Orlitzky et al 2003); Luo & Bhattacharya 2009). Epstein (2008) finds that corporate sustainability performance leads to superior financial performance. Recent research indicates that more specific pathways to financial success. Greater expenditure on mitigation efforts significantly enhances Tobin’s Q, and that the market is beginning to penalize large emitters, while at the same time rewarding firms that undertake concrete mitigation efforts (Aggarwal & Dow 2010).

Collaboration: A business-to-business view of collaboration is usual in the literature. An early investigation into collaboration uses the RBV to argue unique joint competencies emerge from heterogeneity of capabilities (Jap 2001). Many authors closely link collaboration performance with financial performance (for instance, Spekman and Carraway 2006; Paulraj, Lado and Chen 2008; Nyaga, Whipple and Lynch 2010; Claro and Claro 2010).

Even earlier work links collaboration performance to innovation and new product success (Lehmann and O’Shaughnessey 1974, 1982; Sivadas and Dwyer 2000). Meta analysis shows that there is a sales growth advantage with innovation and inter-organizational networking (Bahadir, Bharadwaj and Parzen 2009). Collaboration is well established as a concern at introduction stages, including new product design and development. Jean, Synkovics and Kim (2010) link relationship learning to collaboration performance in a cross border context. Their indicators use technology and product information sharing, and adjustments in common understanding of trends in technology. Collaboration in new product development and commercialization needs involvement in specification development processes (Min, Mentzer and Ladd (2007). A primary route to more rapid innovation is supplier collaboration (Piercy (2009). Dabhilkar *et al* (2009) measure collaboration as active adaptation of production processes for both companies, and early supplier participation in the development of new products (see also Seshadri 2011).

La Forme et al (2007) differentiates between structural and procedural models of collaboration. The authors stress the importance of collaboration, and related processes such as coordination and cooperation, to facilitate responsiveness, competitor satisfaction and competitiveness. Hallikas *et al* (2005) discusses single and double loop learning in the context of collaborative strategic planning.

Crittenden et al (2011) note that many companies treat sustainability as a single level rather than an end-to-end supply chain issue. They argue for a proposition (P4a: p. 77) that “a sustainability strategy will be associated with a collaboration culture among supply chain members.”

Contracts: Contracts between a principal and one or many agents can be designed as mechanisms that help resolve divergent interests of the parties. The theory that underlies this approach to understanding contracts is Agency Theory. The strategic use of information asymmetries and the costs of monitoring and verifying costly effort underlie agency costs. Jensen and Meckling (1976) proposed the theory, and the business and economics literature finds many applications of agency theory to contract mechanism design. A recent survey of possible theoretical approaches to sustainability research identified the potential of agency approaches (Connelly et al 2011). From a collaboration perspective, it may be more appropriate to focus on bilateral contracts. Agency Theory helps identify bilateral contractual elements that shift the financial burden of risk between parties, and thereby provide incentives for aligning interests between a principal and its agents. The level of risk is greatly increased due to externalities. Contracts allocate and shift the balance of risks and obligations in the supply chain. Information asymmetries introduce agency problems in the design of contracts. Sustainability Collaboration results in highly uncertain performance outcomes. Effort from various parties can improve outcomes, but not deterministically. Therefore, if risk is apportioned mainly to a single party, other parties in the supply chain have an incentive to shirk effort and save costs. A departure from cost-plus contracts is therefore necessary to *deliberately include some risk* for suppliers and other parties. The interaction of externality and agency needs to be addressed in contracts for Sustainability Collaboration. As both moral hazard and signaling (varieties of agency costs) are similar to externalities, there is a natural fit with mechanisms such as contracts to reduce moral hazard and signaling costs. Many contractual designs are directed toward these ends. Therefore, contractual approaches to reducing externalities may be fruitfully explored.

Neoclassical contracts use instruments such as royalties, fees, expense sharing, profit sharing, penalties, damages, and the like to share risks and provide incentives. They are typified by the Uniform Commercial Code and the Second Restatement of Contracts. Relational contracts, on the other hand, subjugate short term self interest to long term or enlightened self interest (Feinman 2000; Macneil 2000). Learning, commitment, and reputation are processes that link the two. Transaction costs can be very high in markets with high contingency situations, as when externalities are involved, and relationships help mediate neoclassical contracts (Nordberg et al 1996).

Sustainability Collaboration: A definition

We offer a definition that draws on RBV, sustainable development, collaboration between multiple stakeholders and the pivotal role of contracts. *Sustainability Collaboration is the firm's strategic performance in sustainably governing multiple stakeholder interests through practices based on mutually reinforcing contractual agreements.*

The more general construct of Collaboration has been defined in early work as the degree to which partners are able to work together in a joint fashion toward their respective goals (Frazier 1983). Another early definition of Collaboration is “two or more independent companies work jointly to plan and execute supply chain operations with greater success than when acting in isolation (Simatupang and Sridharan 2002, p. 19).” Our definition of *Sustainability Collaboration (SC)* differs as it includes RBV, multiple stakeholders, contractual approaches and the goal of sustainability. Like definitions of other forms of collaboration, SC is a desirable outcome for the firm in and of itself.

Epstein (2008) discusses collaboration between firms and NGOs for sustainability, and devotes several pages (P. 97-102) to this important process. He explains Sustainability Performance with nine principles: Ethics, Governance, Transparency, Business relationships, Financial return, Community involvement / economic development, Value of products and services, Employment practices, and Protection of the environment, and provides over five dozen metrics for the construct (p. 172-3). Our definition is complementary, in that we identify Sustainability Collaboration as a performance outcome in the RBV, and the three dimensions of sustainability. However, the emphasis is on contractual collaborations rather than the relational partnerships that the Corporate Sustainability Model proposes.

It is useful to examine definitions of Sustainability that may include aspects of collaboration. An excellent summary of definitions of sustainability and its principles of its assessment is in Gibson *et al* (2005). Global cooperation and inter-country assistance is listed repeatedly as core objectives of Sustainability in declarations such

as from The Stockholm Conference of 1972; UNEP, WWF, IUCN declarations of 1980; and the Brundtland Commission of WCED in 1987. Other definitions include democratic self-determination and distributive justice. Several include loyalty of adherents through economic equity, special mechanisms, public involvement, and ability to participate creatively and self-directly. Community participation and shared knowledge are recurrent dimensions in regional, and country level declarations. Stronger versions are community control, provision of social structures, pluralism and participation of civil society. Other assessment approaches require municipal councils to have multi-sector stakeholder group and community consultation, including formal public consultations and public hearings of draft regional growth strategies. Effective and negotiated conflict resolution and deliberations with related stakeholders and authorities are basic. Stewardship Councils require multi-stakeholders in a consultative process and specifically lists environmental and social organizations, sector bodies and corporations, community groups, indigenous peoples' organizations, and certification bodies.ⁱⁱ

Governance of Sustainability Collaboration

A useful definition of governance in sustainability contexts is provided in Francesch-Huidobro (2008: p. 11): "Patterns of *interaction* between the state and civil society and the various processes of *coordination and collaboration* between government and NGOs for policy making, as well as the *participation* of non-state actors in the policy process [emphases in the original]." The multi-stakeholder perspective and the collaborative nature of sustainability efforts is evident in this view of governance. The plurality of forms is less explicit, but reference is made to interaction, coordination, collaboration and participation processes. Plural forms of governance are likely to provide greater flexibility in safeguarding inter-firm exchanges (Cannon et al 2000). These options, the authors note, should be viewed as building blocks for complex governance structures and not as either/or alternatives. Multiple stakeholder involvement creates a higher imperative for plural form governance.

Relationships are complex exchange governance mechanisms, in which efforts at relationship continuity are necessary. There is no pre-set duration, and recourse to third parties is not enforcing, although they may be bilateral or multilateral, and may often reveal leadership roles. Relationships as exchanges therefore have a spectrum of interactive behaviors. They range from arms length, one time transactions to close, repeated collaborations (Day 2000). The market-contract and transaction-collaboration relationship interdependencies are a useful way to think of exchange governance mechanisms for sustainability, from emission allowances to clean technology R&D.

Markets are exchange governance mechanisms, usually based on spot prices, or small spreads between bid and ask prices. There are large numbers of buyers and sellers, many exchanges, and a commonly acceptable mechanism for registering the trades and transacting payments, thereby transferring ownership of the tradable offering. In sustainability markets the tradable offerings could be physical products such as biofuels, basic certificates and allowances such as emission permits, or more complex derivative products such as futures and options on those permits. Trading schemes for emission allowances are voluntary or mandatory. In mandatory markets the allowances are allocated by regulatory authority to specific sources of emissions that are required to participate in emissions allowance program. Over-the-counter trades directly match buyers and sellers without moving them through a centralized exchange (Bataller et al 2008).

It is well recognized that market forces alone are inadequate. Sachs (2008) explains four macro-reasons why market forces fail. Profitability may not be attractive enough for R&D investment; adoption and diffusion of innovations may be too slow; cause and effect may actually be reversed and markets may be the outcome of larger forces like population distributions that are harmful; and not all people have access to markets. With negative externalities social costs remain unaccounted for, and the market price mechanism for coordination of business decisions has failed. The logic of contractual interventions for sustainability could be the lowest cost alternative, and we note that the organization in society that is best placed to design and engage in contractual behavior is the firm.

Contracts are departures from markets in two ways. One is the period from inception to liquidation of the contract is finite and not necessary immediate. The duration may be long. The second is that parties to the contract are restricted and do not include all buyers and sellers. Usually the restriction is severe and may have only two parties. Contracts are often self-enforcing but third parties may also be involved, such as courts or arbitrators. The

terms and conditions further qualify the offer and exchange and make it a one-off exchange. Contracts are characterized by a principal and one or more agents; and contractual rules are largely determined by the principal. In contracts, the effort is long term, risky and substantial; and therefore requires collaboration between different specializations in the entire supply chain. For instance, energy from renewable sources is generated by a variety of start-up businesses that need to collaborate on building an infrastructure of high voltage direct-current transmission, which does not exist today, to major utilities located thousands of miles away. Some OTC trades are contractual in nature, although the contract may be simple and standard.

Markets, Contracts and Relationships are complementary mechanisms. Better contractual agreements, where they can be drafted, support deeper and more complex relations (Seshadri and Mishra 2004). An industry's ability to rapidly accelerate sustainability innovation is critically dependent on better governance mechanisms for exchange. Sustainability efforts are governed by, for example, cap-and-trade (markets); vendor-purchaser agreements that specify emission targets (contracts); and associations and relationships between firms in many sectors (transactional and collaborative relationships).

Businesses often use all three governance mechanisms simultaneously to improve exchanges. Markets provide a baseline for self-enforcing contracts, and parties to a contract usually write future-looking contracts to improve on what they can clearly achieve or offer at the current time with markets. Contracts provide a fall back basis for building relationships, and can limit perceived risk from violations of trust. Relationship complexity and continuity can improve in incomplete contracting situations, when such fall-back simpler contracts exist. The remainder of the paper focuses on the pivotal role of contracts in Sustainability Collaborations.

Sustainability Collaboration and Contractual Instruments

Externalities are difficult to deal with since self interest drives consumption in the supply chain, but that self-interest is the source of collective disasters. Consumption of natural resources and technological capacity to meet present and future needs through the market mechanism cannot be curtailed without adequate incentives (Salzman 1997). Specific contracts provide a framework of incentives that could be used to support Sustainability Collaboration.

Principal-Agent Contracts: Two parties may develop bilateral contractual agreements in order to govern their exchange in a manner that does not require recourse to courts or arbitrators. The contracts usually are self-enforcing and specify what penalties will occur if terms are breached. Bilateral contracts recognize that complexities of modern business render third parties incapable of understanding the relevant details and the best parties to govern exchanges are the concerned parties themselves. The parties are either two businesses, or a business and a regulatory authority. Contracts that are not self enforcing need a third party to enforce the contract, and perhaps adjudicate and penalize breach of contract. The third party is usually the presiding court, relevant government body such as a Pollution Control Board, or industry association. Instruments in Sustainability Collaboration third part contracts are introduced by law, such as the Clean Air Act, or a Clean Water Act. They may also be Association Certification requirements, such as the MARPOL Annex VI, *Prevention of Air Pollution from Ships* of the International Maritime Organization, IMO (Moffat 2010). Instruments of bilateral contracts may typically be:

1. **Quotas:** Resources are rationed based on the ability of natural processes to regenerate. Forestry and fisheries have long been subject to such quota limitations. Longer term quotas provide R&D targets, as in fuel efficiency and car exhaust emissions. Energy supplied over the grid has positive quotas for renewable sources that must be exceeded.
2. **Linear Incentives:** A target level of pollution is established and under-runs or over-runs are rewarded or penalized in accordance with a formula agreed upon between the supplier and the buyer in the contract. This removes the need to verify polluter effort when supplier specific uncertainties on cleanness of technology exist.
3. **Equity Investments:** Supply chains may internally finance investments in clean technology with loans and equity shares between buyer and seller. Financial benefits can accrue to the supply chain by lowering the cost of working capital and ensuring investments go to mutually beneficial clean technologies.
4. **Mandates:** Laws against using specific chemicals (chlorofluorocarbons in refrigeration equipment) or production processes (child labor) changes products and services offered at the point of sale or consumption.

5. Taxes: Pollution is taxed directly where possible, and output from dirty technologies is taxed at a higher rate than clean technologies which may even receive a subsidy. This modifies consumption of technological processes and reduces pollution.

Multiple Stakeholder Contracts: Battacharya et al (2009) emphasize the need to include all stakeholders for value creation, and to avoid a single stakeholder perspective. Sheth et al (2011) argue that sustainability must necessarily reflect the stakeholder view. They note that the customer embodies multiple stakeholder identities.ⁱⁱⁱ Contractual agreements in value chains between multiple stakeholders could have beneficially addressed externalities. Performance management requires recognition of all stakeholders and the necessity of securing their collaboration (Donaldson and Preston 1995; Crittenden et al 2011). Criteria for improvement of incentives depend on appeal to multiple stakeholders.^{iv} A variety of instruments, such as those listed below, govern exchanges with multiple stakeholders.

1. Branding: Certifications that impact customer perceptions of environmental friendliness help modify demand for branded products and services. The ISO 14000 certification is one, but several sector specific awards exist.

2. Yardstick incentives: Contests and tournaments between suppliers for business rewards are useful when common uncertainties and unverifiable effort are involved. These instruments allow the principal to use multiple agents as their own yardstick for performance. Pollution abatement can become an effective learning race between agents.^v

3. Bidding and reverse auctions: Hidden information on supplier competencies and types are revealed by special price discovery mechanisms. These help in creating a market for sustainability outcomes and setting reference prices for contractual agreements.

4. Markets – Permits and Credits: A system of allocating permits is introduced, with the possibility of a permit trading market. Cap-and-trade is the best example of this. Permits of units of pollution are quantified and businesses are allocated or have to buy amounts of pollution permits. Exceeding pollution without commensurate permits is steeply penalized. Subsequently a market of bid or brokered exchange allows buying and selling (and donations) of permits.^{vi} Unutilized capacity which reduces dirty output can also yield excess permits to the seller that earns it an income. A price discovery mechanism follows from this process for pollution permits.

5. Labeling: Information is provided to the customer at the point of purchase that influences purchase and use behavior. The usual labels for sustainability are carbon footprints, and Green Marks.

6. Lifecycle Assessments: Extended Producer Responsibility (EPR) laws, such as EPR take backs, require the producer to assume responsibility for post-consumer disposal of waste. The principle of “least cost avoider” applies and the stakeholder with the lowest cost of dealing with the externality is assigned the task (Wiersema 2008). EPR can also extend upstream to an expanded boundary for emissions disclosure (Vandenbergh and Cohen 2010).

7. Consortia: Global consortia such as Global Reporting Initiative (GRI) have influenced CSR reporting initiatives (Nikolaeva & Bicho 2011)

Parties to Contracts: Social choices by multiple stakeholders will lead to conflicts of interest between specific parties, and systemic conflicts will need to be resolved through specific arrangements. Coase (1960) concludes his famous essay : “ ... in choosing between social arrangements within the context of which individual decisions are made, we have to bear in mind that a change in the existing system which will lead to an improvement in some decisions may well lead to a worsening of others. Furthermore we have to take into account the costs involved in operating the various social arrangements (whether it be the working of a market or of a government department), as well as the costs involved in moving to a new system. In devising and choosing between social arrangements we should have regard for the total effect. This, above all, is the change in approach which I am advocating (p. 44).” Adopting the Coasian approach requires businesses to devise new approaches. Contractual agreements between stakeholder dyads in an industry are not hard to visualize. As the NKH example (Appendix 1) and others illustrate, these may typically be:

1. Pollution Board – Pollution processing plants . Pollution processing plants (like CETP in the example) have a critical part to play. At NKH a moving target based on current state-of-the-art technology rather than a zero liquid discharge mandate would have encouraged development.

2. Pollution processing plants –Polluter Units: Incentive contracts from polluters that rewarded CETPs for advancements in treatment standards.
3. Banks – Pollution processing plants: International transfers of funds under Clean Development Mechanisms and other supply chain financial arrangements will be necessary. In TKH, larger loan amounts for effluent treatment using advanced cascade technologies and for R&D into “clean tech” with subsidies. Employer-Worker: Unionized agreements for planned community benefits and provident funds, retraining and community development.
4. Global Brands- Value Added Resellers/Suppliers: ISO 14000 certification requirements and Green Mark auditing from suppliers. Carbon disclosure agreements in the broadened boundary of supply chains across developed and developing countries is one proposal that furthers the involvement of global brands with VARs. emissions reduction incentives can extend to offshore suppliers. Wal-Mart is a well researched example of a global retailer that enforces sustainability standards domestically in the US as well as in emerging economies such as China.^{vii} The Supply Chain Leadership Collaboration (SCLC) furthers this agenda with a standardized process for supply chain reporting of carbon emissions (Vandenbergh & Cohen 2010).
5. Value Added Resellers/Suppliers – Polluter Units: Supplier financing for clean tech investments and mandatory certification. Reverse Marketing franchise agreements for unit development. ComEd, a unit of Exelon, purchases electricity generated from landfill methane gas at 22 sites, and wind energy from two additional projects. More than 50 photovoltaic systems by end 2004 came from several universities, single family homes, and a court house. In another instance, the German engineering firm Siemens has annulled its contract with Areva on the Finland nuclear reactor project due to delays over 42 months and cost escalations of 90 percent. This has entangled Areva and the Finnish operator in litigation (Bidwai 2011).
6. Pollution processing units – R&D Institutions: Consortium contracts for technical solution to effluent evaporation, involving multiple Institutes of Technology and CETPs. For instance, DuPont leads the Integrated Corn-Based BioRefinery (ICBR) project – a US Department of Energy funded research program. As part of the ICBR, DuPont, the National Renewable Energy Laboratory, and other companies will develop the world’s first integrated pilot-scale “bio-refinery” – with multiple products (Hoffman 2007: p. 133). Cummins joined the US Government and other industry partners in the Twenty-First Century Truck Initiative, with the goal of developing commercially viable truck and propulsion system technologies, that will dramatically improve current solutions (ibid: p. 152).
7. Associations/ Coalitions - Global Brands: Global Brands would require these cross-border associations to certify adherence to common standards. TEA (India) in the apparels sector could form affiliations with similar associations in China, and SE Asia for mandated standards that augment TÜV SÜD PSB standards for dyers. DuPont in another relationship is partnering with BP to develop “biobutanol” that offers significant advantages over biofuels currently on the market (Hoffman 2007: p.134).
8. NGOs – Pollution Control Board/National Regulators: Standard setting and MVR (monitoring, verification and reporting) agreements between non-governmental organizations (NGOs) and Pollution Control Boards.^{viii} Environmentalists lament the disrespect for civil rights in advancing developmental projects in emerging economies.^{ix}
9. Pollution Control Board (State Government) – Dept of Environment (Central Government): National and state policies are often aligned, and often at odds. National manufacturing policy is cited for infrastructure facilities development such as financial subsidies, import of machinery, containerization and railheads. National environmental acts need to be locally applicable to plug disparities in environmental law.
10. Polluters- Customers & community: *Interface* purchases a range of carbon offsets to support its Cool Carpet™ program, enabling its customers to purchase “climate neutral” flooring products. It is also a member of CCX. AEP is a founding member of the Chicago Climate Exchange (CCX), a group of organizations that includes the City of Chicago and Mexico City. Through CCX, AEP has made legally binding commitments to reduce its GHG emissions by 4 percent below the average of its 1998 to 2001 baseline in 5 years (Hoffman 2007:p. 161).

SC Propositions: The construct of *Sustainability Collaboration* (or SC) is associated with other useful concepts for strategic business management. Based on the previous development of the SC concepts we may propose the following set of associations.

- P1: SC is positively associated with other collaboration performance measures.
- P2: SC is positively associated with organizational performance measures.
- P3: SC is positively associated with policy performance.
- P4: SC is positively associated with firm sustainability assessments.
- P5: SC is positively associated with contractual performance.
- P6: SC is positively associated with relationship performance.
- P7: SC is positively associated with market success.
- P8: SC is positively associated with brand image.

The next section concludes with future research directions.

Conclusion

The paper argues for a construct *Sustainability Collaboration* that is complementary to but distinct from previous constructs of Collaboration or Sustainability Performance. One of the first authors to call for an examination of practices that underlie collaborative and inclusive approaches to sustainability may well have been Coase (1960): "... it is possible to conceive of better worlds than the one in which we live. But the problem is to devise practical arrangements which will correct defects in one part of the system without causing more serious harm in other parts. (p. 34)." Leading management theorists have recently recast even the most durable frameworks as collaborative shared value. Michael Porter says: "A growing number of companies known for their hard-nosed approach to business—such as GE, Google, IBM, Intel, Johnson & Johnson, Nestlé, Unilever, and Wal-Mart—have already embarked on important efforts to create shared value by re-conceiving the intersection between society and corporate performance. Yet our recognition of the transformative power of shared value is still in its genesis. Realizing it will require leaders and managers to develop new skills and knowledge—such as a far deeper appreciation of societal needs, a greater understanding of the true bases of company productivity, and the ability to *collaborate across profit/nonprofit boundaries* [emphasis added]. And government must learn how to regulate in ways that enable shared value rather than work against it." (Porter and Kramer 2011). With its focus on contractual collaborations with multiple stakeholders this paper provides a departure from previous approaches to sustainability that is more closely aligned with this concept of shared value.

Sustainability Collaboration is a firm level performance construct. It positions the firm advantageously in comparison to its competitors. Its long term positive impact on firm financial performance may be direct, or indirect through a collective improvement for the industry. Sustainable Collaboration development requires businesses to accelerate a variety of efforts. Many of these efforts may not be undertaken without closer attention to the pivotal role of multiple stakeholder contractual agreements.

We envisage future theoretical and empirical research to further deepen and develop the Sustainability Collaboration construct and to operationalize its measurement. A suitably validated scale should be linked to other performance measures that may be based on organizational and financial data. The propositions suggested in the paper are possible starting points for such an investigation. RBV approaches will suggest models of competencies that have direct and indirect causal effects on Sustainability Collaboration. Specific contractual arrangements that leverage markets and relationships may be explored, as Sustainability Collaboration expands the number of concerned parties to multiple stakeholders. The contractual processes between firms in the formation of syndicates and consortiums could impact their access to and pricing discovery in tradable emission permits. This direction of research would assist in understanding alternate practices and social arrangements.

End Note

ⁱ The Brundtland Commission, formally the World Commission on Environment and Development (WCED), known by the name of its Chair Gro Harlem Brundtland, was convened by the United Nations in 1983. The commission was created to address growing concern "about the accelerating deterioration of the human environment and natural resources and the consequences of that deterioration for economic and social development." In establishing the commission, the UN General Assembly recognized that environmental problems were global in nature and determined that it was in the common interest of all nations to establish policies for sustainable development. Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs. It contains within it two key concepts: (1) the concept of 'needs', in particular the essential needs of the world's poor, to which overriding priority should be given; and (2) the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs."

ⁱⁱ See Gibson et al (2005: p.206-234) for references, other elements, and several definitions of sustainability that do not include collaboration.

ⁱⁱⁱ Smith (2010, p.4) calls the customer a "citizen, a parent, an employee, a community member, or a member of the global village with a long term stake in the future of the planet."

^{iv} For example, carbon disclosure helps multiple stakeholders with information. Some decision makers who are enabled are customers, NGOs, investors, employees, managers. Decisions improve when stakeholders are able to understand, compare, and act. Financial stakeholders are individual investors, public pension funds, and socially responsible investment (SRI) funds (Vandenbergh and Cohen 2010).

^v "Significantly, the Agreement also allowed for a form of adaptive management. The 1987 Agreement committed to develop, adopt, and begin implementation of, by July 1988, "a basin-wide strategy to equitably achieve by the year 2000 at least a 40 percent reduction of nitrogen and phosphorus entering the main stem of the Chesapeake Bay." 175 Yet it also provided for reevaluation of this 40 percent reduction target by December 1991, "based on the results of modeling, research, monitoring and other information available at that time." Over the next thirteen years, the Chesapeake Bay Program re-evaluated its target and expanded its protection to the Bay's many tributary" Wiersema 2008.

^{vi} DuPont has been active with others in pilot emission trading schemes, through bi-lateral agreements and on the emerging carbon exchanges [using therefore relationships and markets]. DuPont is a member of the Chicago Climate Exchange and the International Emissions Trading Association. The Winter Olympics of 2002 could be declared "climate neutral" due to DuPont's donation of 120,000 metric tons of CO₂ e emission credits (Hoffman/Pew Center 2007).

^{vii} A firm uses supply chain contracts and screening to act as a "private regulator of its supply chain, imposing requirements on suppliers that are typically the concern of governments, not private firms. ... The pressure for emissions reductions will arise from numerous acts by private parties in response to public and private disclosure requirements, not by demands for emissions reductions from national governments "(Vandenbergh & Cohen 2001).

^{viii} "Bargaining occurs not only over legally constructed entitlements, but also socially-constructed entitlements, and it occurs not only at the local level, but also at the global level." (Vandenbergh & Cohen 2010)

^{ix} France, where an EPR design nuclear reactor is set up in Flamanville, and India have instances of civil protests against EPR design nuclear reactors. In India, the Department of Atomic Energy plans to locate six (1,650 MW each) nuclear reactors designed by Areva in Maharashtra's Ratnagiri district in India. Almost all the 2,375 families in the area who have lost land have refused compensation. The democratically elected local governing bodies have passed resolutions opposing the project.

Symbiotic linkage of Sustainability, Development and Differentiation

Abstract

Care for environment with growth necessitates symbiotic linkage of sustainability, development and differentiation. The framework addresses intensity of innovation to woo consumers' need for novelty with ecology benign development mandated by climate change concerns. Such adoptions are cost add-on that lacks competitive advantage. Differentiation creates grassroots distinctiveness to development that transforms sustainability into opportunity. This cost to benefit gap is bridged through the symbiotic chain of sustainability, development and differentiation. The competitiveness coupled with environmentally benign technology can be sustained when the customers' preference for products and services satisfy their quality of life needs. This paper uses logit analysis to estimate the symbiotic index of a local, regional or globally scalable habitat. The output indicates the significance (0.037 at 95 percent confidence level) of the constant term representing 'quality of life need for novelty' justifying symbiotic linkage of sustainability, development and differentiation and need for further research with primary data.

Keywords: sustainability, differentiation, symbiosis, logit, innovation intensity, quality of life need for novelty

Introduction:

Why Sustainable Differentiation

Care for environment with growth necessitates symbiotic linkage of sustainability, development and differentiation. The ongoing debate on issues of sustainability, emissions reduction post Cancun (Climate Change conference, 2011) poses the challenge mitigation commitments, policy approaches and incentives to organizations for the technological adoption of eco-efficiency. The path of sustainable development needs to have symbiotic and cooperative sector specific as well as cross-sectoral interrelationships. The technology mechanism transition to low carbon development for developed as well as developing countries need enhanced climate financing along with innovation. This also puts to focus the need to secure an enduring relationship satisfying the quality of life need for novelty aspirations of the customers and stakeholders. This is addressed as sustainable differentiation. The symbiosis of sustainability, development and differentiation promises to fuel the momentum of the virtuous sustainability trajectory. Sustainability, development and differentiation in synchronous linkage provide innovative growth paths that are holistic and resilient and allow creative maneuvering to meet the changing consumer needs evolving due to health, food and lifestyle adaptations in response to climate change. Consumers and grassroots community faces consequences of global warming and are responsive towards the environment. Sustainable differentiation creates mutually symbiotic opportunity that serves produces and service providers with resurgent demand for sustainability products and services as well as collaborative partnerships customers and stakeholders. When people consume they do so with some rational as well as for empathy or emotional fulfillment. Sustainable development evolves to sustainable differentiation when there is a rational as well as an emotive linkage. Incessant rise in damages caused by climate change triggered disasters and the viewpoint of organizations that sustainability investments are more like a cost than a benefit has led to a search beyond sustainable development. This research gap is addressed here. The emotive linkage is usually excluded from sustainable development models for lack of a metric.

This paper explores sustainable development (SD) literature based on four parameters that unfurls or enables sustainable differentiation (SDf) in terms of interpretation, interactions of relevant parameters, comparison of coefficients and measures of the two levels of sustainability, SD and SDf. The concept of value gear is introduced as a model that unfurls innovation.

Organizational strategy is usually driven by the investors and stockholders who look for returns. This is literally the 'push' factor for organizations. This 'push' generated by embedding sustainable development could be

strengthened with innovation driven 'pull' to maintain the value derived from sustainability. This is sustainable differentiation. Uncertainty, change and volatility pervade global markets (Elliot, 2011). Dynamic and complex economic events such as debt crisis, global currency imbalances, quantitative easing policy are influencing the foreign direct investors. Additionally, it is mandatory to offer rapid yet sustainable response to climate change triggered events impacting the sustainable growth of institutions (Sachs, 2008). The lingering effect of the recession slows growth. The care for environment coupled with economic growth poses a challenging balancing task.

Literature Review:

Conceptual basis for Sustainable development to Sustainable differentiation

Usually markets reflect an organization's economic performance. This fails to reflect the full costs of the processing including natural resource inputs like water and climate sensitive outputs like waste. These are not factored in the calculations. Integration of environmental footprint into economic calculations determines sustainable developmental efficiency or eco-efficiency (Nikolova, 2008). However the challenge is to incorporate into the entrepreneurial mindset the fact that green growth adds value economically and ecologically (MCED, 2005). The reality is that the cycle of economic productivity is not synchronized with that of the ecological efficiency. This poses as a research gap that is addressed here with the concept of sustainable differentiation model. Sustainable differentiation not only puts in step the environmental costs along with the process costs, but also adds a competitive durable pitch by engaging the customer and the community at the emotive plane. Consumers and community usually look for originality in the products and services and adheres long term with such organizations who unfurl innovation in an ongoing manner. The organization stands out as it is sustainably differentiated from the competitors.

Sustainable development tends to be embedded with limited scope to generate appeal of novelty through differentiation of networks in action (Zuscovitchf, 1994). Innovation is the key factor for Sustainable Differentiation (SDf) in organizations including small and medium-sized enterprises (SMEs) based on the sustainability intensity required to mitigate and adapt to climate change while retaining growth. The contemporary literature identifies the relevant policy tools that guide to develop this conceptual framework. It tracks the sustainable development pathway driven by technology which unfurls into sustainable differentiation powered by innovation. The framework dynamically integrates technology with the need to innovate that combines reason with empathy. This justifies the need to incorporate sustainability practice onto development (Lacy, 2007). Sustainable differentiation adds a competitive durable pitch over sustainable development that engages organizations to unfurl innovation to woo consumers who look for novelty. This innovation need necessitates the incorporation of green growth vision in order to shape a more balanced economic, social and ecological order (Chung, 2008). Sustainable differentiation creates grassroots distinctiveness through innovation while sustainable development adopts environmentally friendly technology based common platform. The stakeholders (Freeman, 1982) and consumers were conditioned to respond to the 'marketing mix' emanated creative communication cues. With the world population doubling from 5.5 billion to 11 billion by 2030, sustainability issues such as loss of biodiversity, waste, deforestation necessitate technology for nature swaps. This would lead to the intensity to innovate in ecologically efficient competitive strategies for sustainable differentiation (Shrivastava, 1995).

Development that is designed with sustainable infrastructure principles provides the sense of emotional novelty that is imperative to community adherence to sustainability habits. The sustainability oriented quality of life need to be reoriented in terms of seeking novelty in consumption. Such control can manifest through measures like adopting green tax, eco efficiency, environmentally benign processes of extraction of natural resources in areas where sustainable development can influence, such as, housing, transport, energy, water, waste and sanitation services (Sachs, 2007).

Limits to absorb pollution and provide natural resources, Sustainable development builds on clean technology and enterprise. Sustainable Differentiation forges enduring and competitive growth through innovation (McKee, 2008). Growth becomes ingrained with differentiation leading over sustainable development by adopting delineation that etches a lasting and sustainable appeal on the users' empathy and emotions. Sustainable development is more norm based and policy driven. This leaves limited maneuvering space among competing organizations to woo and retain consumers.

Conceptual model:

The need to innovate

Ecological sustainability practices to harness climate change are inadequate at current practices of consumption intensive, need for novelty triggered quality of life aspirations. This gap is addressed in the conceptual model (figure 1) of the Innovation Value Gear relating Sustainable development to Sustainable differentiation by the emotive parameter of quality of life need for novelty (Viotti, 2002, Rungpry, 2007). The network is driven by the need to innovate and connected with bidirectional flow of the required intensity of eco-efficient technology, competitiveness related sustainable intensity and climate change related innovation intensity.

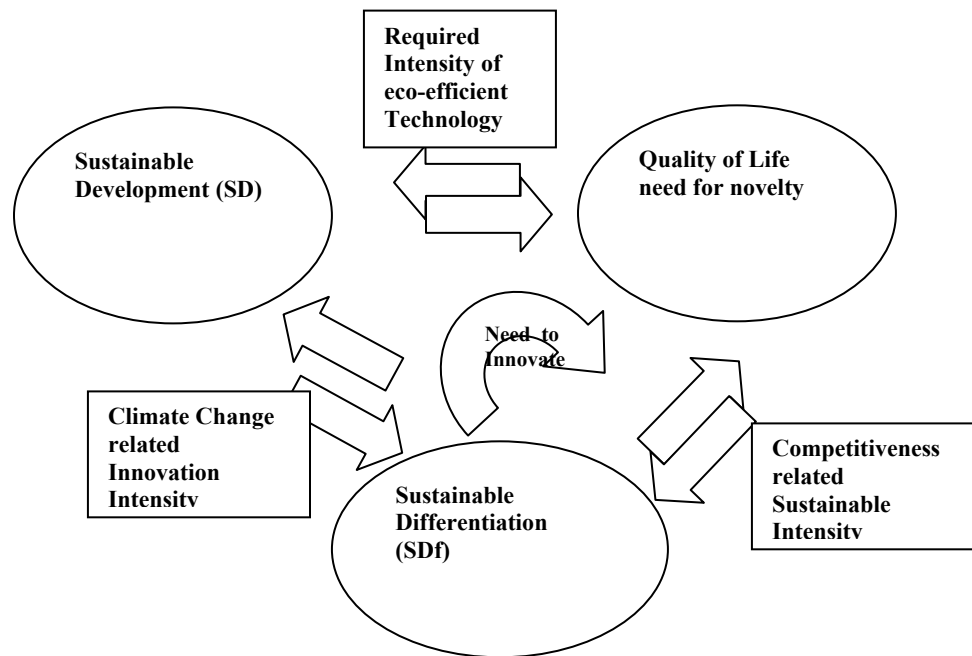

FIGURE 1: SUSTAINABILITY SYMBIOSIS

In the pursuit of climate change mitigation and adaptation, policy makers urge organizations to shift to environmentally friendly technology in their quest for sustainable development. Such adoption is often viewed as a cost add-on that affects competitive advantage. This Innovation Value Gear model (figure 1) is driven by need to innovate to scale the stages of sustainable development with the increase in intensity of eco-efficient technology transfer and adoption. The environmentally benign technology *push* drives the value gear. The competitive pressures from the customers' preference for differentiated and distinctive products and services create a *pull* for features that go beyond the mere appeal for sustainable development. This need is manifested by the quality of life need for novelty by the consumers and community. This intensifies the need to innovate, as firms compete to stay emotionally connected to the consumers and stakeholders. The momentum in the value gear is *picked up* by the innovators and entrepreneurs.

Organizations create a niche, and competitors need to be differentiated to generate sustained appeal from the consumers and community who may be potential users. Sustainable development focuses on underlying

processes such as eco-efficient transfer of technology that soon get standardized. This creates a gap in the empathy space in the minds of the users who look for novelty to fulfill their quality of life aspirations. Often investors and corporate service providers feel the cost of investing in sustainable development technology without receiving commensurate hike in consumer generated revenues. Sustainable differentiation provides the opportunity to apply sustainable technology as well as the emotive and differentiated appeal for consumers and community. Organizations may innovatively reposition themselves in the evoked mind-set of consumers, stakeholders and people through sustainable differentiation.

Research framework:

sustaining the sustainable development through sustainable differentiation

The research question proposed here is whether sustainable differentiation can better embed the balance of the demand from natural resources with quality of life needs for novelty than sustainable development. Assessing the efficacy of sustainable development drivers need the dynamic envelopment of innovation elements such as intensity of eco-efficient technology, competitiveness related sustainable intensity and climate change related innovation intensity.

FIGURE 2: THE SUSTAINABILITY ARRAY:
SYMBIOTIC LINKAGE OF INNOVATION, DEVELOPMENT, DIFFERENTIATION

The value gear transform provides the Sustainable differentiation scorecard that would benefit policy makers to assess options of growth while integrating the sustainable development inputs (figure 2) of intensity of eco-efficient technology, competitiveness and climate change with sustainable differentiation outputs of sustaining quality of life, satisfying ones’ need for novelty and creating a sustainable emotive collaboration with the organization.

Methodology

The research problem needs integration of issues that is best practiced by the use of mixed methods research methodology (Given, 2008). In this value gear, the dependent variable, Sustainable Differentiation may become an indicator variable that may assume binary form. Here the policy makers are interested to assess whether a selected region is a good prospect for unfurling sustainable differentiation from its position of sustainable development. This can be envisaged as:

$$SD_f = \begin{cases} 1 & \text{for Sustainable Differentiation} \\ 0 & \text{for Sustainable Development,} \end{cases}$$

This represents the logistic regression function (Hoetker, 2007) and is represented by equations 1a and 1b and the value gear as equation 2:

$$y_i = \alpha x_i + \varepsilon_i \quad (1a) \qquad SDf_i = \alpha SD_i + QoLnovl_i \quad (1b)$$

where, y_i = Propensity for symbiosis between sustainability, development and differentiation (SDf_i)

i = applicable area under consideration, e.g, ASEAN

x_i = Observable variable, e.g, Sustainable development (SD_i)

ε_i = other not directly observable factors, Quality of Life need for novelty (QoLnovl_i)

As the propensity for symbiosis between sustainability, development and differentiation represented by Sustainable Differentiation is not observable and is a paradigm or category. Representative of logit models, the limiting values are assigned as one when there is full propensity for Sustainable Differentiation and zero when there is Sustainable Development, without Quality of life need for novelty.

This leads to the hypothesis: Intensity of innovation makes it possible to sustain the sustainable development through sustainable differentiation.

wherein, $y_i = 1, \quad SDF_i = 1$ for Sustainable Differentiation (2)

and $y_i = 0, \quad SDF_i = 0$ for Sustainable Development

The logit model (Boulanger & Brechet, 2005; Iram, 2008; Hair et al, 2006) methodology provide good indicators to predict direction and magnitude of the symbiosis towards differentiation aligned with sustainable development. The statistical significance of each of the estimated coefficients can be an indicator of the possibility of interaction and need for alignment of the interrelatedness between the vector variables of sustainable development and sustainable differentiation. The vectors variables (conceptual model, figure 1) are the intensity of eco-efficient technology (Iecotech_i), competitiveness related sustainable intensity (Icomp_i) and climate change related innovation intensity (IclimCh_i). These are driven by the need to innovate.

Equations 3 describe the expected value of y_i given x_i . This estimates the probability that y_i will equal 1, given the value of x_i . It indicates the propensity for going beyond sustainable development represented by sustainable differentiation, expressed as probability of $y_i = 1$ (SDF_i) subject to x_i (given the scenario that there is Sustainable Development, SD_i) is expressed as represented graphically (figure 2):

$$P(y_i = 1 | x_i) = \frac{\text{exponential}(x_i \beta)}{1 + \text{exponential}(x_i \beta)} \quad \text{for Logit} \quad (3)$$

where $\beta =$ vector of the coefficients being estimated

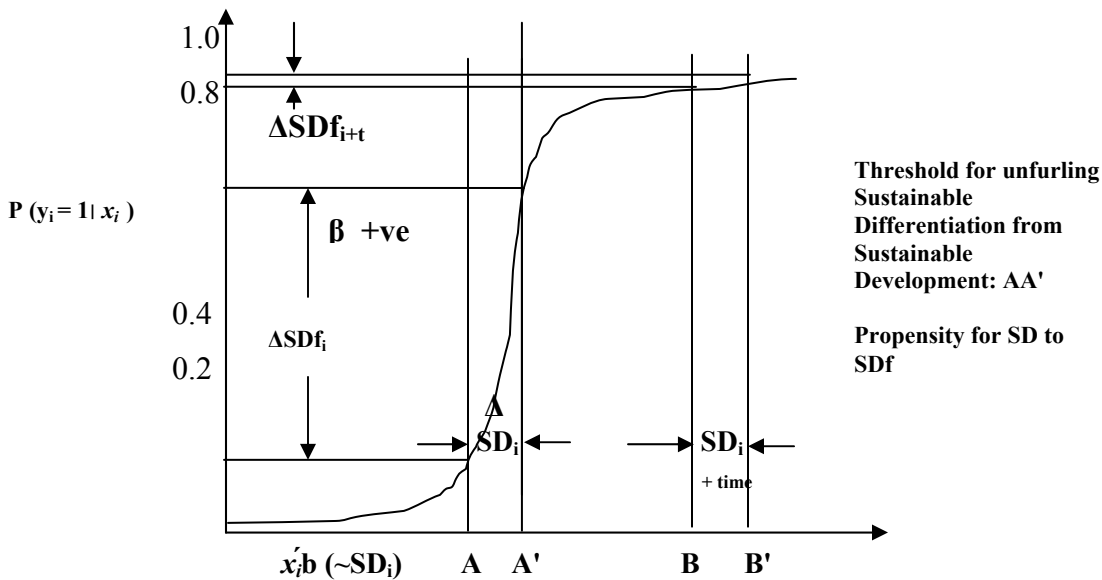

FIGURE 2: LOGISTIC DISTRIBUTION THRESHOLD FOR SUSTAINABILITY, DEVELOPMENT AND DIFFERENTIATION

Sustainability, Development & Differentiation Symbiotic analysis and interpretation of logistic regression

Secondary data analysis (adapted from Wackernagel, 2005; Tubiana, 2010; UNFCCC Climate Change Conference, 2011) was performed for key ASEAN and Asia Pacific countries including Thailand, Malaysia, Indonesia, China, India, DPR Korea, Republic of Korea, Japan extrapolated over the period 2008 quarter one to 2010 quarter four. Growth in the Asia Pacific region were factored on population, GDP and ecological footprint and used as a indicators of sustainable development, viz, intensity of competitiveness, intensity of eco-efficient technology, intensity of climate change and those of sustainable differentiation, viz, sustaining need for novelty, sustaining quality of life, sustaining empathy (table 1). The dependent variable Sustainable Differentiation index is a categorical, non-metric variable, while the independent variables are metric variables. The propensity for symbiosis between differentiation while adhering to sustainable development is represented by the dichotomous value of SD_f .

Table 1 is a representative part of the secondary data is used for the pilot logistic regression application for symbiosis between sustainability, development and differentiation indicated by direction and magnitude of logit dependent variable SD_f :

TABLE 1: PILOT DATA FOR LOGISTIC REGRESSION

	Sustainable Development			Sustainable Differentiation		
	Intensity of Eco-efficient technology GDP (Logistic Regression input)	Intensity of Competitiveness Population (Logistic Regression input)	Intensity of Climate change Ecological Footprint (Logistic Regression input)	Sustaining Need for Novelty(Logistic Regression input)	Sustaining Quality of Life(Logistic Regression input)	Sustaining Empathy (Logistic Regression input)
Thailand	46% (2)	12% (4)	16% (4)	70% (3.5)	70% (3.5)	82% (4.1)
Malaysia	47% (2)	13% (4)	22% (3)	90% (4.5)	74% (3.7)	44% (2.2)
China	158% (5)	10% (4)	23% (3)	50% (2.5)	54% (2.7)	70% (3.5)
India	78% (4)	20% (1)	18% (4)	50% (2.5)	46% (2.3)	84% (4.2)
Indonesia	44% (2)	16% (3)	15% (4)	40% (2.0)	42% (2.1)	78% (3.9)
Japan	12% (1)	3% (5)	7% (5)	100% (5.0)	84% (4.2)	80% (4.0)
Korea, DPR	n.a. (1)	11% (4)	-25% (5)	10% (1.0)	24% (1.2)	28% (1.4)
Korea, Rep.	71% (3)	9% (5)	37% (1)	80% (4.0)	78% (3.9)	50% (2.5)
Philippines	40% (2)	23% (1)	40% (1)	50% (2.5)	40% (2.0)	68% (3.4)
World	32% (1)	15% (3)	13% (5)	40% (2.0)	48% (2.4)	60% (3.0)

Sources: Adapted from Wackernagel, 2006, Tubiana 2010, Climate Change Conference 2011

Goodness of fit from the initial stepwise estimation provides a reliability of alpha 0.5617, Wald statistic 0.93establishes the significance of the three variables of GDP (representing intensity of eco-efficient technology), population (standing for intensity of competitiveness) and sustaining empathy (in response to climate change). Their statistical significance indicates the propensity to differentiation given sustainable development would substantively improve the overall construct (tables 2a, 2b).

TABLE 2a: SIGNIFICANCE OF SUSTAINABILITY INDEX (COEFFICIENT IN LOGISTIC REGRESSION)

	Logistic Coefficient	S.E.	Wald	df	Sig.	Exp(B)
Sustain. Constant	.062	.203	.093	1	.037	1.064

TABLE 2b: SIGNIFICANCE OF SUSTAINABLE DEVELOPMENT CATEGORY WITH SUSTAINABLE DIFFERENTIATION

			Score	df	Sig.
Variables:	Eco-Eff Tech.	GDP	27.489	1	.000
Sust Develop.	Competitive.	Population	3.781	1	.052
	Intensity of CC	Ecology Fprt	1.311	1	.252
Sust Differen.	NewProd&Ser	NeedForNovel	.297	1	.586

	P-P-CommuP.	Empathy	15.936	1	.000
	Overall Statistics		68.242	6	.000

The chi-square value is small (134.378) and measures the change from the base likelihood model indicates a better model fit designated as symbiotic fit of sustainability, development and differentiation. The Cox & Snell R square (0.750) and Nagelkerke R square (0.867) being over 0.5 indicates that the logistic regression model accounts for at least one half of the variation conforming to the SDF_i equals to 1 for Sustainable Differentiation and SDF_i equals 0 for Sustainable Development logistic conditionality.

Learning outcomes & Limitations

The output of the Logistic regression (Table 3a) provides learning outcomes that underscores the validity and significance of the emotive parameter of 'quality of life need for novelty' (QoLnovl) in the overarching metric of sustainable development. The value gear framework advances knowledge base of assessment, prediction, and scenario building for sustaining the sustainable development through sustainable differentiation. The output indicates the significance (0.037 at 95 percent confidence level) of the constant term representing Quality of Life Need for Novelty (QoLnovl). Output justifies further research with primary data. Among the coefficients, sustained need for novelty is significant. The limitation is the extensive variation of the parameters and the divergent notions on sustainable differentiation that exists across the sample. In order to unfurl sustainable differentiation strategy, firms need uniqueness. More attributes needs to be significant (Table 3b). The findings underscore the vital need to innovate, and reinforces the need to sustain customer empathy that ensures loyalty while being responsible to the ecological needs. This criterion is applicable across firms. Hence, the distinctiveness is provided by sustainable differentiation.

TABLE 3a: INTENSITY OF ECO-EFFICIENT TECHNOLOGY, COMPETIVENESS, CLIMATE CHANGE (approximated by GDP, Population, Ecological Footprint impacts across key countries, regions, Globe)

	B	S.E.	Wald	df	Sig.	Exp(B)

Variable(s) entered on this Logit step 1: GDP, Population, EcoFootprint, NeedForNovelty, QltyOfLife, Empathy.

Conclusion and Recommendation Future Scope:

This approach benefits policy makers to estimate the propensity to adopt sustainable development path or the sustainable differentiation route. This Sustainable differentiation metric harnesses a dormant, yet fundamental key to the success of sustainable development, the emotive linkage. This explanatory variable adds robustness to sustainable development models by way of etching a long-term memory trace for the sustainability practices of the organization as well as innovation efforts to differentiate long term providing an essence of competitiveness.

Strategic Leadership: Innovation as a Strategy for Competitive Advantage in Banking

Rajeshwari Narendran,, rajeshwari18@yahoo.com
Ranjith Nayar, ranjith.nayar@gmail.com
Mohanlal Sukhadia Univ, India

Abstract

As cost pressures mount in a bad economy, financial institutions (FI) challenge internal non-core competencies to rethink their value-proposition or be outsourced. Yet, 50% of outsourcing fails, partly because the existent problem is cost, not quality, while outsourcing brings questions of quality. Competitive advantages must, therefore, come from a differentiating strategy – contributing better value – than from technology costs reduction. Innovation, coupled with organizational streamlining and governance, is the solution. This paper recommends how to drive innovation, with evidence of best practices in FI.

Our data shows two primary drivers for driving innovation: Prevalence of a ‘Culture of Innovation’, and an organization to sustain this culture. With IT budget-to-revenue ratio at 7.5% for FIs (compared to 1.1% for construction firms), the challenge is bigger in the financial sector. An innovation for the currency remittance industry in Singapore was done by the authors and proposed for implementation to Singapore Telecom to enter the financial sector as a strategy to derive competitive advantage.

Introduction

The Global Innovation Survey, 2010, mentioned clearly that “The Innovation Roadmap should be driven jointly by the IT department as well as various ‘Lines of Business’. The Lines of Business tend to have more input into the Innovation Strategy and the Execution Strategy, while the IT department tends to have more input into the Innovation and Technology Enablers”

What differentiates a successful bank from another? Given that the fundamental product is the same (repository of money, source of loans, basic products like bonds), banks were once distinct from each other only by the financial backing they had (solidity of reputation, stolidity of backing), and management styles. There was little to distinguish one bank from the other. Hence, older banks sought to convey solidity by employing symbols of stolidity (such as big buildings, Greek columns etc. and pictures of eminent well-suited Board members). The strategy, thus, was to convey an impression of safety and risk aversion.

Innovation As Strategy

In time, regulation from national monetary authorities enhanced further indistinctness between banks. But, with advent of deregulation from the 1980s came innovation of financial products offered by banks which led to an ability to offer differentiated services (service differentiation). Scaling – capitalizing on economies of scale and geographical reach (the ability to project resources across geographies) – enabled financial institutions to offer even larger base and hence ability to project security. This security in turn helped them leverage even higher and consequently, a larger and riskier product range.

Thus, with the advent of globalization and consequent reach of banks to audiences across traditional national boundaries, the significant – if not the primary – driver of competitive advantage changed from stolidity to product range to innovation of products offered. Banks changed from being traditional repositories of money to lender of first resort, to growth vehicles for personal funds.

Forward looking banks are now focusing on several types of innovation – limited only by imagination:

- Business Model Innovation: Zopa, Prosper, Grameen Bank, ING Direct

- Product Innovation: Capital One's Identity Theft Service. (this product was a finalist at the 2008 financial innovation awards and is differentiating Capital One from other credit cards in UK).
- Operations Innovation: Washington Trust Company
- Business Function Innovation
- Services Innovation: Citibank Philippines' mobile banking; Banco do Brasil partnering with VISA
- Strategy Innovation: Zecco.com
- Marketing Innovation: Washington Mutual (WaMu)'s "WaMu Kid Area"; Credit Suisse's provides gay financial advisors to clients who are themselves openly gay.

To harness the power of imagination, it is recognized by corporate leaders that innovation is an intangible resource which, like any other internal resource, needs to be managed and channelized if we are to reap the most benefit from it. According to March 2005 McKinsey Quarterly survey of 9,345 global executives, "CXOs recognize innovation as the most important capability for competitive differentiation and growth Source". One of the critical challenges is that innovation is instinctively resisted down the ranks since it is intrusive (interferes in the day to day set pattern of doing things), is everywhere (impacts several layers in the organization), and is disruptive (impedes the 'normal'). The key to overcoming this challenge is to stress on the fundamental principle of change management – that the organization's need for the change be aligned to the individual's self-goals. While it is instinctive to resist change, it is also instinctive to want to improve oneself and one's own environment, by emphasizing and harvesting enlightened self interest, we will be able to overcome the instinctive resistance to change.

Industry analysis – supported by my peer survey and surveys from INSEAD etc. – shows two primary drivers for boosting or encouraging innovation in any organization:

1. The prevalence of a 'Culture of Innovation', and
2. An organisation to organise, measure and sustain this culture of innovation.

My survey shows that respondents felt the need for autonomy and clarity on many skills (63% of IT respondents, 80% of non-IT). Thus, innovation is desired by most people but needs to be managed; i.e. Innovation "management".

The First Driver: Creating an Innovation culture. In the words of McKinsey Consulting, "Organizing the innovation process from beginning to end is a critical element of IM. Lack of formal organization is a common problem. Execution is the biggest challenge. Fundamentally, the biggest challenge is organisation". There are two ways to start the innovation journey in any organization:

- a. **Big-bang** method of becoming a partner in achieving the strategic KPI of the business. It is a blue-ocean strategy since it is a new area, the equivalent of building an Eiffel Tower, of venture.
- b. **Systematic developing of the culture** – the equivalent of building a city. We start the innovation journey by developing an innovation culture within each Service Function of the FI. Setting up an Innovation Management organisation to guide and lead the introduction of the culture, and setting up a consultancy organisation within each Service Function for Fast Innovation

Innovation Management is a pyramid. Successful innovation management is a multi-layered pyramid of 3-sides: managing (a) the **competencies of the team**, (b) the **external influences**, and (c) the **management platform**. Implementing Innovation in an organization boils down to implementing a good Innovation Management (IM) system.

Within each of these 'sides' (columns in table below) we have the different component layers. We will now examine these layers.

TEAM CORE -COMPETENCIES	EXTERNAL INFLUENCES	MANAGEMENT PLATFORM
<u>Idea Management</u>	<u>Internal to Company</u>	<u>Culture</u>
<u>User Management</u>	<u>Industry Level</u>	<u>Strategy</u>
<u>Projects portfolio management</u>	<u>Socio-Technical Level</u>	<u>Tools & processes</u>
<u>Platform Management</u>		<u>Metrics</u>
<u>Project Management</u>		

All sides of the IM Pyramid are equally important, without anyone of them the effort will not succeed. As a business function, IM requires specific expertise and tools. The proposed Centre of Innovation Management will manage these three cornerstones.

INSEAD's survey⁴ indicates a number of areas like 'Idea Generation', 'Structured Processes', 'Leadership' and 'Skilled Workers', 'Promoting Industry Clusters', 'Improving the Environment for Innovation', and 'Boosting Company Payback on Innovation' as key areas to work on, to drive innovation. (This

is supported by my own survey. Of these, Structured Processes, Improving the Environment, Promoting Clusters (or collaborations) need an organisation to be driven by.

Consultancy group, McKinsey, reports a survey⁵ where "the responses indicate that a lack of formal organization is a common problem: more executives chose the absence of a formal process to align the necessary internal resources as the top commercialization challenge, although those at companies with a formal process for commercialization – 23 percent of all respondents – say execution is the biggest challenge"... "Fundamentally, the biggest challenge is organization: 42 percent of respondents say improvement in this area alone would make the most profound difference in innovation performance (And) is closely followed in importance by developing a climate that fosters innovation; commercializing new businesses, products, or services; and selecting the right ideas and managing a portfolio." Accountability is also seen as critical, "... notably, even among respondents at early-growth companies, where innovation is likely to be a particularly high priority, only 34 percent say their business leaders are effectively held accountable."

What these terms cover and what they encompass is explained in some detail below.

1. CORE COMPETENCIES is the entire gamut of skills set of the organisation – from technical skills to the ideation process, and everything in between such as ideas, project management, execution skills, etc. – the 'essential capabilities' that we need to manage.

Idea Management: We need to understand, absorb, validate and categorise innovative ideas. We need to foster the climate of innovation (as mentioned in earlier sections of this paper). Next, we need to create an atmosphere and capability to collaborate with others such as technology experts, colleagues and outside experts if possible such as universities and competitors where possible. Next, we need to use known innovation techniques like technology scanning/evaluation, collaboration, and boundary spanning. To encourage ideation, we need also a good rewards scheme, with performance measurement criteria quite different from the traditional.

Customer/Users Management: Look for opportunities and prioritise according to greatest value to users and to FI. What is different here is to classify the information into categories of usability.

Projects portfolio management: Focus on the right set of projects in line with KPI increase (dovetailing into the strategic partnership role that is needed to be played as opposed to executor/service delivery role) as well as projects that provide differentiation.

Platform management: Setup the platform strategy, reference architectures. Examine new platforms that could produce differentiation, e.g. applications (apps) development for the mobile smart-phone paradigm to enable e-remittances, which is \$450 billion market worldwide by World Bank estimates (in 2009)

Project Management: provide project management and development capacity guidance for all innovation projects including major projects for Operations.

2. ENVIRONMENTAL INFLUENCES – Environment includes the IT skills that we don't have, or don't yet have but are available in either our competitors or in the market, the threats that exist to our business and to our skills –sets, including the ability of competitors to poach our resources. (For the ease of discussion, the IT function is taken as representative of all the non-financial or non-core competencies, below):

Internal: IT is part of the Corporation, both as a service provider today or as a strategic partner in the future as proposed in this paper. Therefore, we are influenced by the environment that surrounds us. Innovation Management involves setting up channels of communication to enable collaboration within the FI as well with the players we work with such as suppliers, competitors where required and experts on the topic, setting up a conducive environment to encourage open communication on ideas and problems resolution.

Industry Level: CoIM will need to identify industry trends and benchmark our practices, tools, processes and metrics.

Socio-Technical Level: CoIM will follow trends in academia and industry and study their probable impact these trends could have on our internal IM tools and processes. A good example is the trends towards cloud computing or toward computing on hand-held devices, mentioned in the appendix as well as in section 9.3. It will also participate in various Innovation Management forums that prevail in the business, both within the semiconductor industry and other businesses.

3. MANAGEMENT PLATFORM – primarily is the set of actions that IT managers / management must take in order to foster a culture of innovation that we talked of extensively in Sections earlier. These cover five dimensions: culture, strategy, tools & processes and measurement criteria.

Culture: This determines IT capability to encourage, sustain and gain from innovation. We need to assess our skills and strategy to cover those skills that are currently lacking in the team. Further, we need to define the values we wish to encourage. This includes freedom to take risks, measurement of processes rather than successes (in order to avoid risk-aversion), seeing all employees as Innovators (with the caveat that those with a higher propensity to invent and innovate will be full-time innovators and valued equally with those who innovate as well as are involved in operational aspects.), encourage empowerment (which is already a value strongly promoted in the FI) and participation.

Strategy: Strategy determines success. Therefore, we need to define the metrics we use for strategy development and enhancement. Further, IT products and services define the value proposition and relationships with the Business. Therefore we need to ensure alignment between strategy and the Business.

Tools & processes: Management must define the tools to encourage collaboration, project management, simulation/forecasting, scorecards, etc., and ensure the widespread dissemination of these tools and techniques. Collaboration tools include widespread use of virtual meeting-rooms. Processes include metrics used for measuring not only projects but also the innovation parameters and the rewards scheme that sharing of best practices across the corporation should be encouraged.

Metrics: These are simply the KPIs of the innovation strategy of the organisation. It is essential that the rewards models should be tied both with the strategic intent, proficiency of innovation as well as the propensity to innovate.

SUMMARY OF FIRST DRIVER: In summary, FIs need an Innovation Management organisation at top management level to create, and coordinate the Core competencies, Management platform and the Environmental factors. The proposed organization, CoIM, will need to have the sponsorship of the office of the CIO, and report into it.

Nine Steps for Successful Innovation:

1. Innovation management is not about ideas; it is about the successful implementation of ideas. It is said, “Generating ideas is fun – execution is hard work.”
2. Innovation comes naturally from motivation. And motivation comes from reward and clarity on the rewards pattern. In fact, lack of reward will kill motivation.
3. Everyone can innovate – yet, someone needs to take care of operations too. Depending on the skills, some people in the team will be more innovative / innovation oriented – they need to be more ‘full-time’ innovating. Meanwhile others have to do operations as well as some innovation. Yet, someone needs to take care of operations. Both innovators (fulltime ones and ones that share operations workload) are equal.
4. Titles are important. Dedicated innovators may not fit into traditional titles because their roles are different. Find new titles for them.
5. Spatial considerations: keeping the full-time innovators separate from the operations avoids temptation of “putting-all-hands-to-the-deck-to put-out-the-fire” syndrome.
6. Look for external staffing also when setting up innovation teams.
7. Have clearly defined roles and skills within the team. While the atmosphere should promote an ability to suggest across skill sets, overlapping roles lead to problems.
8. The original plan is not sacrosanct – make sure that it can be modified along the way as and when necessary, without the innovation team feeling let down.
9. Embrace the uncomfortable; accept that teams will go from enthusiasm to resistance from time to time. What is important is not to lose sight of the big picture.

The Second Driver – Organization to Drive Innovation Process

Fostering a Culture of Innovation

Innovation is a strategy to improve the competitive advantage. To manage the culture of innovation is an implementation of that strategy, and requires a focused and continues effort. This requires an organization to manage it at the corporate level. We propose an organization (to be named the Centre of Innovation Management or CoIM) as part of the Strategy Organization within the Office of the CIO, for this.

Gartner studies (Feb 2009; see their chart below) indicate that the biggest IT value is achieved through encouraging of Innovation and through business restructuring. Bringing efficiencies into the IT function follows the four steps for bring efficiencies into the IT function.

Source: Gartner (February 2009)

The least value accrued comes from negotiating pricing for IT purchases, since all competitors are likely to get similar negotiated price, the competitive advantages from this is not significant. Highest efficiency is achieved by identifying internal opportunities to reduce IT costs and implementing cost-saving through BITa-like processes (“implement process improvement, business restructuring and innovation”).

FIs have been moving up this value / difficulty chain for the last few years and currently are looking at the possibilities that could accrue from innovation and business restructuring.

An organisation structure for the proposed CoIM is shown below. CoIM should be embedded within the existing Strategy organization. The Centres of Excellence (dotted line reporting into the CoIM, but otherwise embedded within each of the Solutions group) will make innovation management more effective, since they will enable **collaboration** – a key requirement for innovation – by ensuring a ‘pull’ from the functional IT as well as business group it serves, rather than being ‘pushed’ by the CoIM from above.

Responsibility distribution between the corporate (CoIM) and the embedded Centres of Excellence is as follows:

CoIM	Centres of Excellence / Teams of Experts
Defining the metrics	<u>WORKING WITH FUNCTIONAL SOLUTIONS-GROUPS:</u>
Managing the ideas life-cycle	- to provide timely help, advice, suggestion
Definition of clear goals	- acting as repository of all sites' experience
Correct alignment of actions to goals	<u>WORKING WITH BUSINESS ANALYSTS:</u>
Ensuring high participation in teams	- clarify technical requirements for sites
Constant monitoring of results	Managing ideas life-cycle (with CoIM)
Improve communication, access to information	

Managing the Transition: Although the basic elements of traditional management are planning, organizing, controlling and motivating, managing change requires a different skills-set and approach, innovation and management seem counter-intuitive. Hence, traditional managers think of innovation as a loss of power (control). In reality though, leadership is critical in orchestrating change – seeding the team with ideas, building a team that goes beyond power play and acceptance of the risks involved in change that sees the individuals' goals being satisfied by the team goals.

Creating the Culture of Innovation: Creating an innovative business is not a straightforward question of implementing an innovation strategy overnight. First, the senior leaders must show staff that they are champions of innovation. Second, the organisation must have an “innovative climate” – i.e. all managers appreciate and understand the complexity of the innovation process and the risks involved. Every manager should be trained to understand the theoretical and practical approaches to innovation, and taught that innovation can mean introducing new or improved products, services or processes, and therefore, the following traits and behaviours need to be inculcated: analyse the market, Identify opportunities for innovation, overhaul the services delivery processes, assess whether team ideas have profit potential – and encourage innovation.

Sustaining the Culture: Methods & Practices The organisation should pay undivided attention to creating and sustaining the presence of Enabling Processes, Ownership, Career track, Hiring, Inspire colleagues to be more innovative, etc.

Defining The Problem

As cost pressures mount, top managements challenge organizations to rethink their value-proposition to the Corporation. Every challenge is either a tipping point or an opportunity in disguise. The current economic downturn has led to costs-model being challenged; this is, in fact, an opportunity for FIs to move further up the value chain by introducing Innovation into their operations.

- In order to remain in-house and relevant, non-core competencies will need to
- Increase their cost effectiveness: How to find cost savings? Can they themselves generate revenue?
 - And prove its value to the business as a partner who can contribute to the process, and not just as a provider of commoditized services that can be outsourced.

While this is a challenge, Financial Institutions recognizes that the streamlining of financial practices they undertook and the adherence to the governance structure which have now been put in place, points to innovation as the next logical step forward and the ideal methodology in order to achieve the new costs-model that FI Managements have challenged it to achieve to avoid obsolescence.

At the base of the challenge is the awareness of the fact that any organisation could pursue one of the following business models: As-is: Remain an OEM, designing and develop its own products, with in-house non-core competencies, or outsource its non-core competencies. Competitive advantages will determine which

model will be adopted, and will at least partially depend on the cost-effectiveness. Challenges & Key Priorities are set accordingly.

Why innovate? To avoid obsolescence and to contribute real value to the business, it needs to transform itself to become more cost effective and to re-invent itself as a strategic partner. Why is it important? IT and org decentralization together increase productivity by 5%.

Why not outsource? Surprisingly, there is evidence of a direct correlation between IT, organizational transformation and organisation's performance. Firms that are more decentralized than the median firm have, on average, a 13% greater IT elasticity and 10% greater investment in IT than the median firm (*Journal of Economic Perspectives*). The graph below shows that economic value of firms is significant for firms that are simultaneous high users of IT and are highly decentralized.

- The weight of the firm-level evidence shows that a combination of investment in technology and changes in organizations and work practices facilitated by these technologies contributes to firms' productivity growth and market value.

But, why innovate? With increasing competition from the Eastern world, falling prices and huge market opportunities, financial institutions need to innovate to adapt to the new world of globalised purchasing power and reach out to a customer base that is vastly spread out compared to what they were in earlier decades. The world is becoming richer – farther and faster. With ever increasing globalization – and with emergent economies now driving globalization and innovation – demand curves are shifting towards a de-aggregation.

- United Nations' World Investment Report calculates that there are now around 21,500 multinationals based in the emerging world. This leads to **far greater competition for existing companies.**

But the opportunities are equally extraordinary. The potential market is huge: populations are already much bigger than in the developed world and growing much faster (see chart).

What is known about this problem? The problem is not quality, it is cost. FIs needs to build a differentiating strategy. Innovation is the solution to both the above. It is known, that the problem is not quality, it is cost. Non-core competencies are expensive, and is easier managed through outsourcing.

The purchase of IT and development of an I.S. are seen as sources of increasing cost and concern to management (*Heo and Han, 2003; Legris et al., 2003*). According to the World Information Technology and

Services Alliance (WITSA) (2005) report, Global IT spending is expected to be nearly \$3.7 trillion in 2008 (with a compound growth rate of 7.7%). With technology cost continuing to fall, it is no longer efficient for management to try and reduce direct infrastructure costs alone.

To secure a bigger share of the market, organisations tend to invest substantial sums of moneys on IT investments. Yet, the costs of IT infrastructure continues to fall (Hamm et al., 2004), exerting more pressure on organisations to find new areas of cost reduction beside the direct costs related to hardware and software.

Companies want to see value and ROI; thus, the expectation of the Business is for non-core competencies to demonstrate explicit value addition. To remain relevant, FI's need to redefine core strategies by building a differentiating strategy so as to move down the experience curve faster and contribute better value, as well as to avoid the risk of being outsourced.

Innovation, organisational streamlining and governance are the solutions to both the above problems. The examples cited in this report show how Innovation can be used by FIs to change their value proposition by generating a new revenue stream, as well as help improve processes and ICT products.

Innovation Strategy: Since innovation is clearly not 'creativity', we need to have a clear innovation strategy. However, creating an innovative business is not a straightforward question of defining and implementing an innovation strategy. The truly innovative firm has several ingredients.

- First, the senior leaders must show staff that they are champions of innovation.
- Second, FIs must have an "innovative climate", and all managers must understand the complexity of the innovation process and the risks involved.

The real catalyst behind these two factors is management development which accelerates and guides firms on the path of becoming more innovative, what is called the "innovation journey". It is difficult to quantify the benefits of generalized innovative proposals. Much of it depends on specifics of the organisation that implements the idea, its environment and its topicality – i.e. the point of time that it was deployed.

Business is beginning to see non-core competency both as an enabler and a strategic partner. Indeed, "increasingly, business leaders are demanding that IT play the role of a business partner and a strategic enabler" (Agarwal, Ferratt & Roepke, 2000). My survey also shows that 90% IT practitioners are favourably inclined towards strategic partnerships. Business colleagues feel a less capability (66%), but agree in principle.

Methodology

1. An industry survey will help benchmarking, especially with regard to resultant benefits. Innovation Management techniques are developed using literature survey and case studies.
2. Suggestions for Innovation are established through the Quality Circle method, largely brainstorming.
3. Finally, a survey of IT professionals and other corporate professionals will help validate theoretically established needs perceived by the actual practitioners of the IT function in business enterprises, and specifically to understand whether a strategic role (as opposed to service provider role) is desired by them.

Thus, in seeking to improve innovation, we target to:

1. Achieve strategic **partnership** with Business ensuring value-add for the non-core competencies like IT. IT is a very important player. Hence incorporating a culture of innovation in IT will showcase IT to the rest of the organisation and enhance ICT's nascent role as a strategic partner in the business. In fact, this process has already been started with the B-ITa – the Business-IT Alignment.
2. Achieve strategic **leadership**: Make a break-through improvement in role, potentially helping the FI achieve leadership in the industry by helping make a critical change.
3. Inculcate and diffuse a culture of innovation in the whole organization.
4. Last, and certainly not the least, improve the quality of solutions deployed.

Social Entrepreneurship: Opportunities And Challenges In East Africa

*Edward D. Bewayo,
bewayoe@mail.montclair.edu
Montclair State University, USA*

Abstract

Social entrepreneurship is the creation of social value through innovative entrepreneurial business models (Seelos and Mair, 2004). Social value is about satisfying basic humanitarian needs such as abject poverty, needs which typical business entrepreneurship cannot or doesn't satisfy. Situations such as this are growing everywhere, even in countries such as the U.S. Consequently, social entrepreneurship is a growing sub-field within the entrepreneurship field. In response to this trend, the United States Association for Small Business and Entrepreneurship (USASBE) just recently added social entrepreneurship to its list of membership interests. Universities, for example Oxford and Harvard, have set up research centers that focus on social entrepreneurship. There is also an expanding number of corporate and philanthropic foundations devoted exclusively to social entrepreneurship. The Skoll Foundation is one of the leaders. Recently, the Nobel Prize for Peace has gone to social entrepreneurs, such as Muhammad Yunus, the founder of the Grameen Bank. Social entrepreneurship is extremely important in developing countries such as Kenya in East Africa. But how does one succeed as a social entrepreneur, especially in East Africa? This paper examines existing literature to provide some answer. It studies four successful social enterprises, including the Grameen Bank in Bangladesh and the Green Belt Movement in Kenya.

Introduction

Social entrepreneurship is the creation of social value through innovative entrepreneurial business models (Seelos and Mair, 2004). Social value is about satisfying basic humanitarian needs such as abject poverty, needs which typical business entrepreneurship cannot or doesn't satisfy. For example, people may be too poor to buy goods and services produced by traditional entrepreneurs. Situations such as this are growing everywhere, especially in developing countries. Consequently, social entrepreneurship is a growing sub-field within the entrepreneurship field. In response to this trend, the United States Association for Small Business and Entrepreneurship (USASBE) just recently added social entrepreneurship to its list of membership interests. American and European universities are beginning to set up research centers and chairs that focus on social entrepreneurship (Urban, 2008). Three such centers are at The Skoll Centre for Social Entrepreneurship at Oxford University, The Hauser Center for Non-profit Organizations at Harvard University and the Center for Economic Self-Reliance at Brigham Young University. There is also an expanding number of corporate and philanthropic foundations devoted exclusively to social entrepreneurship. Probably the most famous of these is the Skoll Foundation, which also sponsors the Skoll Awards for Social Entrepreneurship. Others include the Ashoka Foundation which appoints Ashoka Fellows, and the Cisco/Kellogg-sponsored Acumen Fund, which is New York-based but specializes in supporting social enterprise to eradicate poverty in developing countries (Credit Suisse, 2010). Additionally, in the last 10 years the judges for the Nobel Prize as well as the Right Livelihood Award have recognized the contributions of leading social entrepreneurs and awarded three of them these honors. One recipient is Muhammad Yunus of the Grameen Bank.

Deficits in political, economic and social development in East Africa create social problems that attract social entrepreneurs. Take the recent political upheaval in Kenya (East Africa) following the 2007 elections. Social entrepreneurs found an opportunity to help Kenyans who had been left homeless, hungry and jobless.

The opportunities for social entrepreneurship in East Africa are abundant, given the political, economic and social environment in the region. But so are the challenges. Like commercial entrepreneurship, social entrepreneurship requires an appropriate "context". The absence of political stability and legal transparency, which are commonly known, can thwart the chances of a successful social enterprise just as it does a traditional, commercial enterprise. For example, a social entrepreneurial venture undertaken by the Swedish International

Development Agency (SIDA) to promote organic exports from East Africa highly succeeded in Uganda although it appears to have succeeded only slightly in Tanzania (SIDA 2008). Why did this happen? As Boris Urban (2008) states, it is time to ask such questions about social entrepreneurship in Africa. This paper attempts to identify and examines patterns of successful social entrepreneurial ventures in East Africa.

The paper focuses on three cases of successful social entrepreneurship in East Africa: The Green Belt Movement in Kenya, ApproTEC, also known as KickStart, in Kenya and Tanzania, and Yefu Microfinance in Kenya. The paper also examines Grameen Bank, mostly because of its growing influence on the thinking about how to design business models with a prominent concern for social value. In order to examine these cases the paper extensively relies on a framework developed by Alvord, Brown, and Letts (2002) in which they identified common patterns in internationally well-known social enterprises. Furthermore, the paper relies on existing literature in terms of reports by social entrepreneurs and published research papers.

Social Entrepreneurship: What is it any way?

Even though there is a growing interest about social entrepreneurship, there doesn't appear to exist a common definition of this concept. Nevertheless, social entrepreneurship is a form of entrepreneurship. It is entrepreneurship that focuses on social problems. Morse and Dudley (2002) stated that social entrepreneurs and social entrepreneurship combine a spirit of enterprise and a spirit of community in order to bring about community improvement. This concept of social entrepreneurship is complicated by the fact that nearly all legitimate enterprises, i.e., socially and legally sanctioned enterprises, are connected with a certain degree of community spirit, to the extent that any enterprise satisfies a community need. Traditional enterprises provide employment opportunities and pay taxes. Other things being equal, traditional entrepreneurship and the market system can take care of all people's needs. Also, again other things being equal, the government can use tax revenues to finance and provide purely public goods, goods that are consumed collectively, such as police protection.

Now, there is no country where all things are equal for traditional entrepreneurship and government to produce and cater for all social needs. This is particularly true in poor developing countries. First, there aren't enough traditional entrepreneurs (Seelos, Mair, 2004). This is a problem many governments try to address. Where government programs aren't working fast enough to create new entrepreneurs, there is a need for social entrepreneurs. Essentially, social entrepreneurship addresses failures in market and public sectors.

Social entrepreneurship is not the only way humanitarian needs such as lack of healthcare, education and food can be addressed. Food, medical services and other afflictions of the poor can be directly met through donations of money and materials. Enlightened philanthropy, corporate social responsibility and civil society organizations have been making donations towards the alleviation of human miseries for years. All these arrangements are humanitarian needs-oriented. But they aren't necessarily socially entrepreneurial. Social entrepreneurial initiatives create social value; they bring about lasting improvements in the well-being of those afflicted by poverty, disease, and hunger.

Patterns In Well-Known Social Entrepreneurship Ventures

S. Alvord, D. Brown and C. Letts (2002), all associated with the Hauser Center for Non Profit Organizations at Harvard University, did a study in which they identified four key patterns in highly successful and well-known social entrepreneurial ventures. They based their study on seven cases. Two of these cases operate in Africa, and one specifically in East Africa (The Green Belt Movement in Kenya). The cases also include the now world-famous Grameen Bank in Bangladesh. With the exception of one case, the Highlander Research and Education Center, operating in the Appalachian region of the United States, all seven cases relate to developing countries. Furthermore, with the possible exception of the Green Belt Movement, which also focuses on sustaining the environment, all seven cases are centered on the eradication of poverty.

The seven cases are not only means to fight against poverty, but their approaches are highly entrepreneurial in the sense that they all embrace very innovative components. Innovation is considered by Schumpeter and many other observers to be the foundation of entrepreneurship. These social entrepreneurial ventures attack poverty, and

do so in an innovative way. For example the Grameen Bank identified the demand for very small loans among poor people and created a mechanism for delivering such loans. The key innovation of the Green Belt Movement in Kenya, was building local capacity. Poor people, at grass roots level, were organized to plant trees to protect the environment and to improve their own well being.

All seven cases had leaders who were able to create bridges across diverse and often antagonistic groups. In the case of the Grameen Bank, Mohammad Yunus, its founder, was able to build lasting relations with business leaders, both in Bangladesh and abroad, government officials at different levels, donors, and academicians. Most importantly, Yunus was trusted by poor villagers and he trusted them. In the case of the Green Belt Movement, Wangari Maathai, was an activist within women groups in Kenya. She was also highly respected internationally for her long-standing commitment to environmental causes. To launch the Green Belt Movement Wangari Maathai needed and was able to get support from many stakeholders.

The establishment of sound organizational structure was also critical in all seven cases. There was a critical mass of passionate and capable staff. The staff on the payroll was critical, but so was the presence of volunteers. Grameen Bank had a large staff because they distribute loans to poor villagers. The Green Belt Movement relied on a small cadre of highly passionate staff who worked directly with local groups.

In all seven cases the founders had a long term vision for their social enterprises. But also they had to find ways for scaling up the social impact of those enterprises. Grameen Bank hired more staff, while the Green Belt Movement involved more external actors. Additionally, both social entrepreneurs developed new products. In the following section we discuss how these patterns contributed to the success of four social enterprises, including Grameen Bank and the Green Belt Movement.

Grameen Bank, Green Belt Movement, ApproTEC, Yehu Microfinance

According to Alvord, Brown, and Letts (2002) the following four broad patterns run through the seven highly successful social ventures they had studied and analyzed: a true innovation that made the venture truly entrepreneurial, leaders with long term vision and capacity to build bridges across different stakeholders, organizational structures that matched chosen innovations, and well-articulated ways to scale up the social impact of the initiative. As indicated earlier, the Grameen Bank in Bangladesh and the Green Belt Movement in Kenya were included in the seven well-known and highly successful social entrepreneurial ventures that were studied by Alvord and his colleagues. In this section we discuss more extensively the factors that made them successful. To see how these same factors have led to success in a few other social entrepreneurial ventures in East Africa, we also discuss ApproTEC (Kenya, Tanzania and Mali) and Yehu Microfinance (Kenya and Uganda). For clarity, we discuss these factors separately. Table 1 below provides a summary of the four patterns in terms of Grameen Bank, the Green Belt Movement, ApproTEK and Yehu Microfinance.

Innovations to Eradicate Poverty

The innovation to eradicate poverty is by far the greatest distinction about the social entrepreneurial ventures being discussed here. It is abject poverty that attracted the attention of the founders of each of the four initiatives.

Grameen Bank started out as a deliberate effort to find a way for helping poor people in Bangladesh. Muhammad Yunus, a Nobel Prize laureate, the founder, was head of the Rural Economic Development program at a university in Bangladesh. In a research project seeking ways to reduce poverty, he found out that group lending could rescue poor people from exploitative money lenders. The groups could get small loans without offering collateral. There was no need for the traditional collateral because group members put enough social pressure on one another to repay the loan.

Yehu Microfinance, which started in Kenya, but now operates in Tanzania and Uganda, was inspired by and modeled after the Grameen Bank in Bangladesh. Yehu Microfinance was founded by Louis Pope, an industrialist and CEO in the United States. Concerned about poverty in developing countries, Pope had joined and became a Board member of CHOICE Humanitarian, a charity non-governmental organization (NGO). This

organization sent volunteers to Kenya, among other countries, to work on development projects such as constructing school facilities. This is the modes operand for most development NGOs. Pope felt that this approach, while commendable, provided no lasting solution to poverty. Helping poor people to help themselves was a better approach. He persuaded CHOICE Humanitarian to initiate a microfinance project. Relying on personal resources, Pope decided to operate the microfinance project independently from CHOICE Humanitarian, mostly because he wanted to concentrate on the extremely poor people in Kenya’s Coast Province, areas that were not being served by urban-based microcredit organizations. Many NGOs have been criticized for not being able to reach those who deserve their benefits most (Bars,Fafchamps & Owens 2005). He was able to capitalize on the “Harrabee” (Self Help) movement being promoted by the political elite in Kenya at that time to organize groups of poor women who would be able to borrow small loans without collateral.

The Green Belt Movement was founded by Wangari Maathai. She was a longtime activist in two movements, the environment movement and the women movement. She was able to combine these two interests to organize groups of poor people to begin planting trees to both protect the environment and to create a source of income for themselves. Wangari’s innovation was to use tree planting to build local capacity for self help. Poor people can come and work together to improve their well being.

TABLE 1: PATTERNS IN FOUR SUCCESSFUL SOCIAL ENTREPRENEURIAL INITIATIVES

	Innovations	Leadership	Organization	Scaling Up
Grameen Bank (M Yunus, Bang’desh Nobel Laurete)	-Group lending for poor people without collateral. -Bank staff help villagers form groups	-Well-educated founder - had contacts in NGOs, government and academia and poor villages	-Large staff to deliver services to borrowers	-Created new microcredit packages -Expanded staff to reach more clients
Green B’t Movem’nt (Wangari Maathai Kenya, Nobel Laurete)	-Grassroots mobilization -Leadership development through environment alactivities	-Well-educated founder had leadership roles in academia, government and women groups	-Small staff that worked closely with village representatives	-Developed new programs for skill building in village groups
ApproTEC/ KickStart (N Moon and M. Fisher Kenya, Tanzania, Uganda)	-Developed and promoted inexpensive and easy to fix farm tools for poor people to buy and use to grow four crops a year instead of one	-Founders former volunteers for international NGO -Had contacts in Bangladesh and East Africa to develop manufacture & produce inexpensive farm tools	-Small staff to design farm tools, train manufacturing personnel and monitor farm tools usage	-Developed even cheaper farm tools -Small profit made on farm tools used to expand production to reach more poor farms
Yehu Microfinanc e Trust (L. Pope Kenya, Tanzania, Uganda)	-Group lending to poor people without collateral. - Focused on rural poor people not served by urban-based microfinance organizations. -loan insurance	-Founder was a successful CEO with great leadership skills. Also member and Board of Trustees of Choice Humanitarian -Set up Foundation to raise funds.	-Minimal staff, mostly family and volunteers from his alma matter (BYU) -Lately recruited Kenyan CEO with local contacts	-incorporated client reps on advisory board -new loan programs (e.g) meat goat loans -Attracted Unitus .

ApproTEC's founders, Nick Moon and Martin Fisher, launched their organization after recognizing the limitation of traditional practices in development NGOs. The two men were volunteers for ACTIONAID, a British charity NGO. ACTIONAID manufactured farm equipment and donated it or sold it at heavily subsidized prices to poor farmers. The founders felt that ACTIONAID's approach was not providing a long lasting solution to the poverty problem. "We were creating dependency and all too often left things no better off" (Rangan 2003). ApproTEC's innovation introduced three incremental changes: their farm tools were easier to fix and maintain, the tools were not given away for free, and ApproTEC's staff regularly visited poor farmers to provide advice on how to use the tools. ApproTEC's innovation led to improved incomes because poor farmers were now able to grow four crops per year instead of one.

Transformational Leadership in the Service of the Poor

Passion about a social concern and garnering support from diverse and often antagonistic stakeholders are critical for launching a social enterprise towards alleviating that concern.

Grameen Bank reflected Mohammad Yunus's passion about doing something for the rural poor in Bangladesh. Even though he belonged to the professional elite, and was highly educated in the West, he empathized with the poor. He used his university position to research the root causes of poverty and look for a solution. He began to trust rural community groups and the latter did the same. To launch and develop the microcredit project for the rural poor, Yunus needed the support of many stakeholders. The list included the academic community, himself being a leader at a university. But he also garnered the support of government officials. Grants from governments, domestic and foreign, along with those from international NGOs, such as the Ford Foundation, ultimately led to the formation and expansion of the Grameen Bank. Yunus was able to positively influence an assortment of stakeholders, exhibiting a great degree of "bridging capacity" (Alvord, Brown and Letts, 2002).

Yehu Microfinance was founded by Louis Pope. He was already a CEO of a major corporation in the U.S. Pope had joined CHOICE Humanitarian, a charity NGO, to help with poverty eradication in Africa. The development projects sponsored by CHOICE Humanitarian in Kenya led Pope to think about microfinance as a better approach to the eradication of poverty. Although Pope incubated the microfinance project while still connected with CHOICE Humanitarian, Yehu Microfinance developed as a separate organization (NGO), outside CHOICE Humanitarian. Pope wanted Yehu Microfinance to concentrate on the extremely poor people in Kenya's Coast Province. As Yunus in Bangladesh, he began to work with local community/village groups to help the very poor. In return the village groups began to understand him. In order to launch Yehu Microfinance Pope had to rely on personal resources. Family and friends chipped in. He relied extensively on volunteers.

The Green Belt Movement In Kenya was founded by Wangari Maathai. She was already a charismatic leader and activist within women groups in Kenya. She was also highly respected internationally for her long-standing commitment to environmental causes. Before launching the Green Belt Movement, Maathai was a professor and department head at the university of Nairobi. She had also been a member of parliament and government minister in Kenya. Her good political and leadership skills played a critical role in galvanizing government and community support for her organization in the highly contentious political and social environment of Kenya. This is in spite of the fact that Maathai is a Kikuyu, easily the most dominant ethnic group in Kenya. Although recognized as one of most successful social entrepreneurship initiatives in the world, Alvord, Brown and Letts (2002) found that the impact of the Green Belt Movement has been markedly compromised by tribal frictions in Kenya. This forced her to rely more on international support, especially support from environment and women organizations.

ApproTEC was founded by two volunteers of the Britain-based charity NGO, ACTIONAID, which had development projects in the slums of Nairobi, Kenya. One of the founders, Nick Moon, had already owned and operated his own company in the U.K. He left the company to volunteer on development projects, first in Togo and later in Kenya. The other founder, Martin Fisher, initially went to Kenya on a Fulbright scholarship to study how development agencies apply technology to solving poverty problems in developing countries. Fisher and Moon met at ACTIONAID and passion to eradicate poverty brought the two together. Disillusionment at ACTIONAID, because of this NGO's "development philosophy" (Rangan, 2003) forced the two men to launch ApproTEC.

However, they persuaded ACTIONAID to support their new organization with a \$500,000 grant. Close contacts with other international development agencies, such as the USAID, brought them more funding. To develop and promote their low-cost, low-maintenance and easy-to-use farm tools, ApproTEC worked and continues to work with external actors. Some of their tools, for example, the irrigation pump, were adapted from the one used in Bangladesh.

Organizational Structures Designed To Match Core Innovations

Any innovation to eradicate poverty can only be implemented when there is staff and other organizational arrangements. In each of the four social entrepreneurial initiatives being discussed here there was a critical mass of capable staff. Within the staff, passion about the social cause of eradicating poverty was important. The staff on the payroll was critical, but so was the presence of volunteers. Few social enterprises succeed without support from volunteers and philanthropists (Dees, 2007)

Grameen Bank always had a large staff, now over 20,000 (Grameen-info.org, 2010), because its core innovation is to package small loans and to widely promote them to groups of poor people throughout the rural areas of Bangladesh. Unlike a traditional bank, borrowers and savers don't come to the bank. Bank staff meet the poor at whatever convenient place the village groups can find within their villages. The bank's approach also includes closely working with the villagers on the deployment of the loaned funds. The "misuse" of loan funds has been one of the major problems that microfinance organizations in Africa have faced (Sigalla & Carney 2009). To minimize this problem Grameen Bank provides extensive staff training. This is what makes the loan program to experience minimal default rates.

Yehu Microfinance, which is registered as an NGO in Kenya, operates in very much the same way as the Grameen Bank does. But the organization started much more slowly and relied a lot more on volunteers, especially from the founder's family in the U.S. and his alum-mata, Brigham Young University. It still had only 40 paid employees by 2007, serving 13,000 clients. That number had risen to 20,000 clients at the end of 2010. Yehu Microfinance has its main office at Mombasa in mostly rural Coast province. But its clientele is the rural poor outside of Mombasa. There are ten branch offices and numerous sub-branches located in villages 1 to 2 hours from the main office. This enables the organization to "offer friendly and accessible customer service" (Yehu.org 2010).

The Green Belt Movement has a small staff and has relied a great deal on volunteers, enthusiasts of both the women and environment movements, with which Wangari Maathai, the founder, has long been associated. The core staff employed by the organization largely operates through representative of local groups, for example a local church, to promote tree planting skills. Because the scope of the Green Belt Movement is tree planting in villages and urban parks, working closely with government agencies, such as the police, sanitation, and zoning, has been critical for the Green Belt Movement. It was pointed out earlier that this has not been always easy because of political, religious and especially tribal divisions in Kenya.

ApproTEC's organizational structure has, what can be described as a "network organizational structure" (Anand & Daft, 2007). The founders, Nick Moon and Martin Fisher, rely a great deal on outside actors in their approach to the eradication of poverty. To design some of the farm tools they are known for, such as the inexpensive irrigation pump, they consulted with local machine shops and farm equipment designers in Bangladesh. While they help train the machinists to manufacture the tools, the machine shops where the tools are manufactured are independently owned. ApproTEC's core innovation calls for inexpensive farm tools being made available to poor farmers, but not without charge. The founders believe that poor people aren't motivated enough to use tools that they get for free. So, the tools are sold. They are sold in independently-run retail stores. As a result, many of the core activities in ApproTEC's innovation strategy are carried out by outside actors. So, the organization maintains a small staff, mostly for training outside groups. They train employees for equipment manufacturers. More importantly, they train the purchasers of the farm tools in how to use the tools.

Poverty Eradication Has No Quick Fixes: Scaling Up The Social Impact

Social Entrepreneurship is entrepreneurship in the first place. Joseph Schumpeter (1947) and many others define successful entrepreneurship in terms of venture growth. In the case of social entrepreneurship, expanding the

social impact of the venture is the most visible sign of success. Obviously they are different ways a social enterprise can scale up its social impact. Alvord, Brown and Letts (2002) have identified three patterns in scaling up social impacts in social ventures: expanding coverage to provide services to more people, expanding the range of services/products to the initial group or groups targeted by the venture, and activities that change the behavior of other actors who directly or indirectly influence a given social problem.

Grameen Bank started in a single village. It now operates in over 81,000 villages throughout Bangladesh. First and foremost, it has expanded by increasing staff, which now stands at over 20,000. Secondly, the bank has introduced many additional loan packages, e.g., housing loans and education loans.

Yehu Microfinance now serves nearly 20,000 members, up from about 5000 in 2000. This has been accomplished in two basic ways: expansion of staff to reach more poor villages and creating new products. The organization has opened more sub branches, especially in recent years after the appointment a Kenyan CEO, in 2006, with very local roots. They also have created new loan packages, the most important of which is the “meat goat loan”.

ApproTEC’s founders proudly say that their organization has moved over 500,000 people out of poverty, 400,000 in east Africa. They farther say that over \$100 million of new income has been generated (Kickstart.org). The organization has achieved these impressive results through reaching more poor people by expanding staff and especially by introducing new farm tools. For example, they came up with a cheaper irrigation pump which sold for half the price of the older version. An additional important contributing factor to the success of ApproTEC has been operational efficiency. They outsource most production and promotion activities. Also the founders have been able to maintain good relations with the international donor community. They state that a \$1 dollar donated creates \$15 in profit that goes back into their campaign to eradicate poverty.

The Green Belt Movement has grown so much as to divide into two: “Green Belt Movement KENYA” and “Green Belt Movement INTERNATIONAL”. Founded by Wangari Maathai, this organization has been responsible for planting 45 million trees in Kenya, since its inception in the early 1980s. It now operates in 9 districts in Kenya, especially in Central, Western and Rift Valley provinces. Rooted in two social movements, women and environment, the Green Belt Movement appeals to a wide cross section of the population, both in Kenya and outside. Its beginnings required a large number of volunteers. Volunteering is even enshrined in its mission. Clearly, its expansion is hugely related to the constant flow of volunteers. The donor list to the organization reads like who is who of philanthropists, government agencies, churches and other organizations.

Summary and Conclusions

Social entrepreneurship is more complicated than traditional entrepreneurship. It is also more complicated in East Africa than it is in developed countries such as the United States. In the U.S. a major source of funding comes from government sources. There is also funding from private foundations. The social enterprise can even tap donations from individuals. In African countries nearly all funding for social enterprises come from international sources. First, African governments face immense problems financing basic government obligations such as roads. Second, the newness of these nations remains a source of all sorts of division. We referred to how tribalism has compromised the success of the Green Belt Movement in Kenya. Winning the support of government for a social venture often is difficult, especially if the social entrepreneur doesn’t belong to the same ethnic group as the one’s own. The founders of ApproTEC in Kenya complained that government didn’t show interest in their organization (Rangan, 2003). They were not even Kenyan.

The funding for social ventures in East Africa comes from international sources. But international organizations often find it to evaluate the need for funding. Fighting poverty is often the basis of the request. But an international organization faces difficulties determining how much of the granted funding goes towards fighting poverty and how much is put into huge salaries (Aldashev & Verdier, 2009) To address this problem, at least partly some major social entrepreneurship foundations operate branch offices in East Africa. One such organization is the Ecumen Fund. Even more promising are a few homegrown foundations. These include the Zain Foundation set up by Sudanese Mo Ibrahim and the Africa Grantsmakers Network, founded in Ghana and Kenya. The founders of the Network aim to “change the narrative of Africa as helpless and hapless...tilt the balance of stories” (Credit Suisse,

2010)

Funding for a social enterprise is essential, but even more essential is human capital. East Africa needs more Wangari Maathai, the founder of the Green Belt Movement. She was challenged by tribal forces but persisted. She even uses her organization to fight poverty and other social ills, because misery has no tribal boundaries. In response to the post-2007 elections tribal war bloodshed, her organization set up “Peace Tent Initiative”, to bring the warring groups together. Wangari Maathai belongs to the elite class in East Africa, just as Muhammad Yunus belongs to the elite class in Bangladesh. They share the passion towards reducing others’ misery, which is probably the most commonly shared trait among highly successful social entrepreneurs. ApproTEC has been hugely successful, removing 500,000 poor people out of poverty (KickStart 2010) The founders are professionals from the West. There is a need to develop avenues for attracting more people of this caliber. International NGOs, such as ACTIONAID, through which these men were introduced to East Africa should be commended and requested to do more of the same.

Abstract

The purpose of this study is to understand the factors influencing outsourcing decision in the manufacturing industry. Existing literature reveals that manufacturing industry face with challenges in the competitive environment with expectation to produce products at the lowest cost possible yet meet customer specification without affecting the quality and delivery schedules. Thus, outsourcing has become one of the alternative opportunities among the manufacturing firms. The theoretical framework is developed to understand two components namely operating cost and internal resources and technology. The questionnaire was distributed to 150 firms in Northern region of Malaysia with a response rate of 45%. The data was analyzed using regression to test the hypotheses. The findings showed that capital investment, latest technology and high efficiency becomes the key determinants for outsourcing decision among the manufacturing firms. It poses some implications for managers and policy makers.

Introduction

Outsourcing means engage outsiders to handle some business functions that reduce the company's expenditure and save money. It is not a new phenomenon. For decades, jobs have been migrated from other part of the countries namely, American and European countries as well as other countries worldwide, to global service providers, primarily India, China, Singapore and Malaysia, due to lower operating cost. The recent wave of outsourcing affected a different mix of jobs, at different wage levels. It has confined only to a small industry but cut across all industrial sections in new geographic area rapidly. Not many companies fully understand the benefits of outsourcing. It is true that outsourcing can save money, but that is not the only (or even the most important) reason to do it. As many companies discovered during the outsourcing "mania" of the early 1990s, outsourcing brought mix results to companies that choose outsourcing. However, outsourcing can provide a number of long terms benefits: lower operating cost, improve competitiveness, reduce in capital investment, shift resources to focus on core functions, generate demand for new growth and market segment, access to world class capability, sharing risks and make capital funds available for core business investment. In Malaysia, there were many companies looking into outsourcing opportunity to reduce cost, to overcome internal limitations and achieve lower cost of operation especially in the current economic recession. In view of this, the objective of this research is to understand the factors influencing companies in Malaysia in the outsourcing decision.

Review of Literature and Hypothesis Development

What is Outsourcing?

The term 'outsourcing' from literature has different interpretations recent years. Therefore, it will be good to review the various views on the meaning of outsourcing. Most authors agree that outsourcing means exploring business activities outside the firm. Thus, we can classify the definitions into three types: (a) the outsourcing entails a stable, long-term collaboration agreement in which the supplier becomes a strategic partner and where there are exchange relations with independent firms (Mol, Van Tulder & Beije, 2005; Quelin & Duhamel, 2003), (b) the type of activity or service that can be outsourced, i.e. activities and services that are non-strategic for the firm (Quinn &

Hilmer, 1994) and (c) outsourcing is an action that transfers planning, responsibility, knowledge and administration of activities through contacts (McCarthy & Anagnostou, 2004).

This definition has three important characteristics. Firstly, it states that outsourcing has to be a strategic decision that forms part of the firm's strategy and aimed at the pursuit and maintenance of competitive advantage. Secondly, it considers the firm must be able to identify which activities or business processes are candidates for outsourcing and developed by suppliers whose capabilities and skills are superior to those of firm. That means outsourcing decisions are relate to the firm's resources and capabilities. Thirdly, it includes the concept of business processes, whereby resources can only be a source of competitive advantage if they exploited through it (Ray, Barney & Muhanna, 2004). Therefore, outsourcing is a strategic decision that entails the external contracting of determined non-strategic activities or business processes necessary for the manufacture of goods and services by means of agreements with higher capability firms to undertake those activities, with the aim of improving competitive advantage.

Propensity to Outsource and Performance

The literature review suggests dividing the discussions into two categories according to the objectives: firstly, study the propensity to outsource and secondly study the relationship between the decision to outsource and organizational performance. The first analysis analyze the level of outsourcing according to moderating variables such as the type of resource, the environment, strategic orientation, the suppliers' capabilities (Argyres, 1996; Aubert, 2004; Leiblein & Miller, 2003; Quinn & Hilmer, 1994). In a conceptual-type work, Quinn & Hilmer (1994) see the suitability of developing internally the activities that comprise the core activities, and in every case advise that their outsourcing been undertaken in a framework of strategic alliances with the aim of reducing the vulnerability of the organization. Argyres (1996) shows that organizations tend to outsource when the suppliers have superior capability, and the organization does not accept the short-term cost of in house development with the aim of developing the necessary capabilities internally. Leiblein & Miller (2003) conclude that specific assets and uncertain demand increase the danger of exchange and so decrease the probability of outsourcing activities.

The second analysis reveals the use of specific assets and other variables to determine the relationship between outsourcing and the performance of the activity and/or organization (Gilley & Rasheed, 2000; Klaas, 2003; Murray et al., 1995; Poppo & Zenger, 1998; Teng, Cheon & Grover, 1995). Teng et al. (1995) conclude that the discrepancies in the perception of the outcomes (i.e. cost, the quality of the activities and financial performance) are positively relating to the propensity to outsource. Murray et al. (1995) identifies a negative relationship between outsourcing and organizational performance as the asset specifically and innovations in products and processes increase. However, there is also negative relationship between outsourcing and organizational performance when the bargaining power of supplier increase. Apart from these two groups of works, the contribution of McIvor (2000) has also been included because he analyzed outsourcing in the perspective of core competency, resources and capabilities. McIvor proposes a theoretical framework that integrates the elements of value chain, the concept of core competences and the selection of suppliers, which are key aspects that should guide the outsourcing decision.

Outsourcing in the Manufacturing Industry

In Malaysia, the demand for outsourcing was not only from global multi-national companies but also from local companies. Among the local companies, Bumiputra-Commerce Bank (BCB) was the first bank to outsource its IT function in late 2002 to Electronic Data System Corp. Subsequently, Maybank follows the footstep in outsourcing its IT function in 2003 to Computer Sciences Corporation group. SMT Industries also outsource its IT function to Sun Network and Human Resource Management to Human Resource Consultancy in Penang. The demand of the outsourcing has driven by the fact that companies could access a more reliable infrastructure that could ensure smooth core business operations at lower costs and flexibility. As Malaysia ranked the third (3) most attractive outsourcing locations in the world, Penang and Kulim Hi-Tech Park could be an advantage of this fact by attracting quality operators to the state. In addition, the government decision in constructing the second bridge connecting the island and the mainland to improve the efficient and effective way of transportation to the locals would also help Penang as a strategic location for outsourcing niche businesses. The competitive tax regimes and customized incentive would also be a pull factor for foreign outsourcing investors.

Decision Factors

This study would assess the relationship between the factors (as independent variables) and the outsourcing decision (as dependent variables). The conventional approach to the creation of resources has centered on the lack of firm resources and capabilities. He believes that the firm has to decide between developing resources internally and acquiring them externally. Therefore, in order to exploit the combination of resources and capabilities existing in the firm and to develop a strategy leading to competitive advantages, it may be necessary for the firm to acquire complementary resources from outside, and therefore an organization must not be limited to exploiting its own stock of resources and capabilities (Teng et al, 1995). Generally any lack of resources can be made up by purchases or strategic alliances, and outsourcing is one way of complementing the firm's resources and capabilities by helping to improve the firm's strategy to make better use of its capabilities when faced with external opportunities. Whilst, Schroder (1989) focused on high performance competency, which was a relatively stable set of behaviors that, produces significantly superior workgroup performance in more complex organizational environment.

Reduce In Operating Cost

Williamson (1974) used *operating cost* as a starting assumption from traditional economic theory but not explicitly measured in most transaction cost economics (TCE) based study of outsourcing. Therefore, instead of confounding scale economies with other factors, we consider the cost advantage or cost saving from outsourcing a project versus produce internally. Cost advantage has defined as the expected overall cost saving gained from outsourcing a project instead of pursuing it internally. This conceptualization allows us to examine the cost advantage or reduce in operating cost by outsourcing. There are three areas being measure would be the capital investment, overhead and fixed cost as well as space. How would the outsourcing help in reducing the capital investment such as equipments, building and land used in operating activities? Outsourcing the non-core operation functions would save some portion of the capital investment and used the investment into the core business that can generate more revenues to the companies. The saved fund could also used on researching and generating new market segment development (Williamson, 1974). This lead to the first hypothesis:

H1a – Reducing in capital investment positively determines outsourcing decision

The current economy recession has forced many people out of work. Outsourcing the non-core business function to external provider would reduced the number of headcounts or employees, and shift the core employees to focus on the core functions. In addition, utility cost also could reduce due to less consumption. Overall, the greater the perceived reduce in overhead and fixed cost by outsourcing a project, the higher the likelihood the companies in northern region of Malaysia will choose to outsource the project. This lead to the second hypothesis:

H1b – Reducing in overhead and fixed cost positively determine outsourcing decision

Space was a measure of the extent on how outsourcing would help to reduce space consumption, flexibility for core business use, capacity expansion to generate new revenues or cash infusion to reduce operating cost. As project complexity increase, it will lead the companies in northern region of Malaysia will be more likely to outsource the process. This lead to the third hypothesis:

H1c – Space constraint positively determines outsourcing decision

Unavailability of Internal Resources and Technology

Knowledge as a key resource that guides in managerial decision making. According to the theoretical perspective, firms viewed as distributed repositories of tacit and explicit knowledge whose heterogeneous knowledge bases are they key determinants of sustained competitive advantages. Therefore, outsourcing arrangement serves as a vehicle for utilizing vendors' complementary skills and expertise. Firstly, focus on whether the company has the necessary technical knowledge for successfully accomplishing a project; the second on whether the company has the latest and sophisticated technology during the new product development process. The final focuses on whether the company has the intensity to growth in term of space and capacity.

The organization will retain in-house the operations for which it has a higher capability, with the result of efficient production (Argyres, 1996). The operations for which a firm does not have a higher capability or technical expertise would be outsourced. As Argyres (1996) states that organizations outsource what they do not know how to do and develop in house on what they do better than the suppliers do. Therefore, lack of internal technical expertise and infrastructure will lead the company in northern region of Malaysia to outsource his project to external provider. This also leads to the next hypothesis:

H2a – Lack of technical expert and support infrastructure positively determine outsourcing decision

Outsourcing has implication for strategic management. In particular, it poses challenges to the company to explore and expose to the latest and high technology equipments at the vendor’s premises. Old and low efficiency technology equipments make the company more difficult to perform a high quality product, unable to access to the new product development and hard to fulfill the customer’s upward demand in sudden. Therefore, the lower the client’s technical equipments in house, the higher the chances of the company to outsource to the external provider. This lead to the next hypotheses:

H2b – Latest and high efficiency technology positively determine outsourcing decision

Intensity to growth is one of the objectives of any company to success in their business platform. Unfortunately, production and space limitation would be a major constraint for any expansion. Outsourcing non-core business activities would create space and capacity flexibility to support the core business function or customer’s upside demand. If the company’s outsource the non-core business in bulk volume, it could help the company in cost saving by negotiating for lower operating cost. Such exercise could benefit for both companies. This lead to the next hypothesis:

H2c – Company’s intensity to growth positively determines outsourcing decision

Research Model

Based on the above discussion, the research model for this paper depicted in Figure 1.

FIG. 1: RESEARCH FRAMEWORK

Methodology

This study is a quantitative research and questionnaire used to collect data for statistical research analysis. A hundred (100) questionnaires had distributed to Managing Director, Procurement Manager, Operation Manager, Engineer and Buyer of the companies in northern region of Malaysia. Data collection from respondents was used SPSS (Statistical Package for Social Science) software to evaluate the factors that influencing outsourcing decision in manufacturing industry of northern region Malaysia. Questionnaire survey form was send by the researcher to few companies as a pilot study, which required the respondents to feedback on their understanding to the questions. The objective of the pilot study is to understand the relevancy of the questions, difficulty to answer the questions, to understand the quality of the questions and the question appropriateness. In view of the time constraint, the respondents are required to return within three (3) days from the date of delivery.

Population and Sampling

The source of getting the population was from FMM directory, labor department, friends and internet. The population is all the various manufacturing industries in northern region of Malaysia and the researcher only selected a hundred (100) respondents targeted were the working adults from multinational company (MNC) such as Motorola, Intel, Daewoo, Celestica, Flextronics, Toshiba, Matsushita, Hitachi, Yamaha and few SME companies. A hundred questionnaires have distributed to the selected respondents via electronic mail (e-mail) and hard-carry. This non-probability sampling has selected due to (1) cheap, (2) greater speed of data collection, (3) flexibility, and (4) availability of population elements. Cost and time considerations influence decision about the size, type of sample and data collection method. Almost all studies have some budgetary constraint, and this is the reason encourage the researcher to choose a non-probability sample. The analysis of the independent factors that lead the manufacturing industry in northern region of Malaysia has likelihood to choose “outsourcing” as a strategic tool to solve their problems. Therefore, a candidate selected to serve as respondent to represent each company.

Findings

This result has made up of 70% response rate. The sample population of demographic data shows that the data quite evenly distributed to the manufacturing industry, with different segment of duration of company established and size of the organization. Table 1 shows the results of the linear regression analysis. From the results of the regression analysis, the R square of the model of this study is 0.264. This indicates that this model can explain only 26.4% of the outsourcing decision variability. The R is 0.514, which indicates a high level of linearity within the model, which fit to the key assumption of the linear regression analysis. The Durbin-Watson is 2.077 indicating no auto correlation problem in the data.

TABLE 1: LINEAR REGRESSION ANALYSIS

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig	Sig. F Change
	B	Std. Error	Beta			
1 (Constant)	2.437	0.926		2.632	0.011	0.022
Capital investment	0.682	0.297	0.364	2.297	0.025	
Overhead & fixed cost	0.184	0.272	0.115	0.678	0.500	
Space constraint	-0.414	0.437	-0.187	-0.948	0.347	
Lack of technical expert & support infrastructure	-0.013	0.235	-0.006	-0.055	0.956	
Latest technology & high efficiency	-0.712	0.263	-0.331	-2.707	0.009	
Intensity to growth	-0.479	0.252	-0.226	-1.899	0.062	

The analysis result shown that H1b and H1c have no significant impact to the outsourcing decision because the sig. t higher than 0.05 significant effect level. However, reducing in capital investment (H1a) positively influence in outsourcing decision because the significant effect of 0.025, which was below the 5% significant level. Thus, the hypotheses H1a has accepted. The H2a and H2c predictors had found no significant impact on outsourcing decision based on the result of analysis because sig. t was higher than 0.05 significant effect level. Thus, the hypotheses of H3a and H3c had rejected. Conversely, H2b has found to have significant effect on the outsourcing decision, which at the 5% significant level. Therefore, the hypotheses H2b has accepted.

Discussion

The results have three important practical implications for both clients and vendors. First, outsourcing decisions are not driven predominantly by relative cost advantage of doing so. Clients must therefore better understand the best practice element of an internal cost structure before outsource a project to vendors, to avoid any unnecessary significant amounts of hidden costs occurred during outsourcing. Second, technology knowledge, skills and attitudes differences influence outsourcing decisions. For vendors, this suggests the need to convince and demonstrate how their technical expertise exceeds that of prospective client. Finally, in projects of high strategic importance, client's willingness to outsource is influence by their ability to specify requirements and to keep them stable over the course of a project. Vendors with well-developed capabilities for requirement analysis and management might therefore enjoy an advantage in attracting contract for strategic applications development projects.

The respondents are from the selected manufacturing industry in northern region of Malaysia. Total 70 companies been selected to collect the quantitative response and sampling data. There were several limitations to this research study as the following. Cost and time might influence about the size, type of sampling and data collection method. The budgetary constraint will lead the researcher to choose a non-probability sample in this study. The interpretations of the questionnaires are subject to the understanding of the respondents, the different manufacturing experience and exposure might influence the respondents on answering the questions. The survey was conducted based on different market segment in the manufacturing industry and various levels of employees as the respondents. It may not be accurate and good representing of support the factors influencing the outsourcing decision. The constraints on how many attributes could simultaneously be included in this analysis limited us to just twelve predictors from reducing operating cost, new product development, unavailability of internal resource and technology as well as management competency. This also constrained the breadth of some measures such as lack of coordination and control cost, which was measured on the somewhat simplistically as the absence of the client-vendor trust and teamwork.

Based upon the limitations, the researcher would like to provide some suggestions for future research into outsourcing decision in relation to capital investment as a factor of influencing outsourcing decision. First, studies on capital investment as a factor should cover a large sample in Malaysia not only northern region of Malaysia to evaluate the consistency of the responses across the country. With the sufficient capital investment, the research may conduct better sampling method and interview the respondents personally. This would help to obtain more data, which would lead to applicable and accurate results. Secondly, Questionnaires design has to be well defined and restructured to ensure the respondents understand the questions in order to provide accurate feedback. Third, the researcher would suggest that survey has conducted based on similar business market segment in the manufacturing industry and limit to management level as the respondents. Feedback on the similar manufacturing industry will produce better analysis results.

Lastly, lack of coordination and control cost can mitigated through a variety of features of the outsourcing contracts. Similarly, a shared identity and culture can also help create shared understanding and build a good business partnership beside the requirements. Future work should examine such less salient variables identified by these theories that have not considered in our analysis. Future research should also incorporate and analyze other variable such as sharing risks, accelerating re-engineering and cash infusion due to outsourcing. It would be interesting also to include the moderator for the future research such as top management support.

Conclusion

This research was motivated by the scarcity of a systematic comparison of the various theoretical perspectives that have been invoked to examine the principal findings of research on outsourcing, four independent variables such as reduce operating cost, focus on new product development, unavailability of internal resource and technology as well as management competency. Our primary objectives were therefore to understand whether there is a cost implication after the outsourcing decision, and to analyze the relationship of the above-mentioned factors that influencing in considering the outsourcing decision. We also explored how these four independent variables complement and contradict in their predictors for some factors.

We tested the model using regression analysis and the results showed only two out of twelve predictors supported the hypotheses and have positive as well as significant influence in outsourcing decision. This study has given some insight views and usefulness of the research data to the manufacturing industries that cost is not the only and main factor to determine outsourcing decision. It is necessary to validate the conceptual framework to the outsourcing decision in different economic sectors and geographical zone that helps to forecast the types of activities that need to outsourcing and in demand by the companies. In order to consider outsourcing as one management strategy to keep the business running, managers need to study carefully for better understanding the position of manufacturing firms in dealing with outsourcing. The government agencies should understand the realities in Malaysia before making any policies, which will be impact the profit of manufacturing firms.

Key Nation Branding Drivers in Emerging Economies: A Strategic Perspective for India

Mercy S. Samuel, mercems1@yahoo.co.in

CEPT University, Ahmedabad, Gujarat, India.

Pallavi Mittal, pallavisingh@yahoo.com

St. Kabir Institute of Professional Studies, Gujarat, India

Abstract

Nation branding is all about positioning a particular nation state in the minds of consumers. The consumers might be voters or citizens of other countries, potential tourists, potential investors. There are a number of different segments that a typical nation branding strategy could potentially target, but the idea is to put the best image forward and make clear to each target segment what the special qualities, attributes and benefits are, vis-à-vis the many other nations in the world. Emerging economies are the ones who are in a larger space competing for the attention of investors, tourists, and citizens. **An emerging economy can be defined as a country that satisfies two criteria: a rapid pace of economic development, and government policies favoring economic liberalization and the adoption of a free-market system (Arnold & Quelch, 1998).**

Introduction

Marketing a country is not entirely new; in fact, numerous countries have traditionally promoted their image for tourism. However, the current process of globalization has underlined the need for countries to brand themselves on four different dimensions (public diplomacy, tourism, exports, foreign direct investment) and in an integrated manner. As we are over with a decade in the new millennium, three things are clear: i) state branding is no longer a choice but a necessity; ii) it is no longer conceived as a function to be performed individually by the state, associations or individual private companies, but as an integrative and concerted effort by all interested stakeholders; iii) if done effectively, state branding can provide 'soft power to create preference in terms of choice both for consumers and investors. Many cities, regions and countries are now actively marketing themselves using techniques normally associated with the creation of classical product brands. This phenomenon has manifested itself in several ways with varying degrees of success.. Governments are turning to branding techniques to differentiate their country on the global stage in order to establish a competitive edge over rival countries in the belief that a strong country brand can contribute to the country's sustainable development (Jaffe and Nebenzahl, 2001; Kleppe and Mossberg, 2006). American Marketing Association has defined a brand as a name, term, design, symbol, or any other feature that identifies one seller's good or service as distinct from those of other sellers. Branding a country is rather a very complex task and it involves multiple dimensions to be analyzed. But at the same time in the current era of competitiveness branding a country is very important to generate a cognizable position in the world market. Consumers and investors continue to rely heavily on images of places to make their economic decisions. Brands or images have become a shortcut to a purchasing decision. Effective state branding not only serves to reinforce positives images but also helps to fight negative ones by shaping new images and associations. Equally important, branding has become a central tool of state competitiveness because having a bad reputation or none at all seriously affects a states' ability to compete. Dinnie (2008) has stated that country branding is an exciting and complex but controversial phenomenon; it is exciting because there is currently little theory but a significant amount of real-

world activity. It is complex because it encompasses multiple levels, dimensions, and disciplines beyond conventional branding. And, as a highly politicized activity that generates conflicting viewpoints and opinions, it can be controversial. A country brand can also be influenced in the short- or long term by major events. Egypt's country brand, for example, was deeply affected this year by the public outrage and the environment of political instability prevailing over the country. (Papadopoulos and Heslop, 2002) have investigated the influence of major events on the country image.

Literature Background & Research Gap

Research on state branding is not new. For the past 40 years, numerous studies have been carried out on the so-called 'country of origin effect': the effect of national image on products. During the 90s, Philip Kotler dealt with the topic of place branding and marketing in four books: *The Marketing of Nations*, *Marketing Places Europe* (on how to attract investments, industries, residents and visitors to cities, communities, regions and nations in Europe), *Marketing Asian Places*, and *Marketing for Hospitality and Tourism*. Another significant contribution to the field is *National Image and Competitive Advantage* by Eugene D. Jaffe and Israel D. Nebenzhal. In addition to reviewing the theoretical underpinning of country image for products, they provide useful insight as to how it can be managed by countries, industries and firms. One of their central points is that country image is product specific. What's much more recent, however, is the coining of the term "brand state" or "state branding." The September 2001 publication in *Foreign Affairs* of the article "The Rise of the Brand State" by Peter Van Ham was a turning point, attracting a great deal of attention both from the academic community and the world of practitioners, and bringing about further research on the multidimensional nature of state branding. In April 2002 *The Journal of Brand Management* devoted a special issue to the topic of "Branding the Nation" bringing together contributions from the leading experts in the field, including scholars (Kotler, Papadopoulos), consultants (Anholt, Ollins) and practitioners. Simon Anholt, one of the leading international marketing thinkers, has written about state branding in the collective work *Destination Branding*. Despite an increasing number of articles dedicated to the topic, there is still no common definition of country brand. Fan (2006, p. 8) makes an early attempt at defining it as "a country's whole image, covering political, economic, historical and cultural dimensions. The concept is at the national level, multidimensional and context dependent." Dinnie (2008, p. 15) defines country brand as "the unique, multi-dimensional blend of elements that provide the nation with culturally grounded differentiation and relevance for all of its target audiences." Aronczyk (2008, p. 42) states that a country brand should "attract the 'right' kinds of investment, tourism, trade, and talent." Kotler et al. (1993) as well as Rawson (2007) argue that governments should create, promote, protect, and supervise a country's brand. According to Fetscherin (2009) it entails the collective involvement of the many stakeholders it must appeal to. It concerns a country's whole image, covering political, economic, social, environmental, historical, and cultural aspects. The main objectives of country branding are to stimulate exports, attract tourism, investments, and immigration, and create positive international perceptions and attitudes. Anholt in his book *Brand New Justice* argues that developing countries can increase their competitiveness and therefore reduce economic disparity through effective branding. Similarly Wally Ollins in his book *Trading Identities* establishes a linkage between state branding and companies going global. The International Marketing Council of South Africa (IMC) has put together a number of case studies of how countries around the world (of India, Britain, Brazil, Thailand, Spain, Germany and others) have approached the promotion of their national image.

FIG. 1 NATION BRAND HEXAGON, SIMON ANHOLT 2002

Thus the related research reflects how India from a developing nation' just two decades back, India, today, has emerged as one of the decisive nations shaping the contours of the world economy consistently charting a growth path over the last few years. As people and companies decide where to plop down their roots and cash, just like with any other buying decision they need to feel the emotional connection to their needs and the earned trust to reduce their fears. Our literature review reveals that, there is a gap in terms of identifying the dimensions of country branding for an emerging economy like India. Anholt (2002) stated that the nation brand is the sum of people's perceptions of a country across six areas of national competence. Together, these areas make the Nation Brand. They are defined by the hexagon above in fig1.

Based on the above literature review it has been identified that not much of work has been done in studying and defining branding drivers and strategies for emerging economies individually. This paper contributes to assess the branding drives for an emerging economy like India. The paper provides organizations and governments with a tool to measure the strengths of India as a brand, and then revise the country brand strategy, to achieve a significant position on the world map.

Objective

The objectives are framed with the reference of India as an emerging economy

1. To assess the current country image of India as an emerging economy in the world map
2. To identify the impactful dimensions of country branding for an emerging economy like India
3. To suggest a suitable branding strategy for an emerging economy

Hypotheses

1. There is a linear relationship between business environment of an emerging economy and the investments made in the economy
2. Governance of a country has a direct impact on country image
3. Exports of a country has a direct impact on country image

Research Instrument

A structured questionnaire was administered on the sample. The questionnaire was divided into three sections. Section I dealt with the profiling information. Section II focused on aspects of country brand image and perceptions regarding image building. Section III used the Anholt GfK Roper Nation Brand Index as the basis for identifying attitudinal responses regarding five parameters viz; Exports, Governance, Culture, Tourism, Immigrations and Investment.

Sample

The sample size was 60 respondents selected through convenience sampling from India and residing in India as well as in foreign nations. The criterion for selecting the respondents was that they should have visited any foreign destination in the past 6 months or are residing in a foreign location for the past 6 months.

Hypothesis Testing

There is a linear relationship between perceptions regarding business environment of an emerging economy and the investments made in the economy

TABLE 1 RELATIONSHIP BETWEEN BUSINESS ENVIRONMENT AND INVESTMENT

Model	Unstandardized Coefficients		Standardized Coefficients	T	Sig.
	B	Std. Error	Beta		
1 (Constant)	.303	1.879		.161	.873
i1	.629	.284	.310	2.217	.032
i2	.137	.287	.062	.478	.635
i3	-.110	.339	-.046	-.325	.746
i4	1.152	.454	.345	2.538	.015

This hypothesis was tested using regression analysis. Regression analysis is a powerful and flexible procedure for analyzing associated relationships between a metric dependent variable and one or more independent variable. In the above hypothesis Business Environment was taken as independent variable and country image for emerging economies was taken as dependant variable. An attempt has been made to understand that the variation in country image be explained in terms of perceptions regarding business environment. *The result of the analysis is as follows.*

The above table indicates that the critical value of t with 58 degrees of freedom and alpha= .05 is 1.67. As the calculated value of t for i1*and i4*is larger than the critical value the null hypothesis is rejected and the above is

accepted for i1 and i4 and rejected for i2 and i3. Hence it shows that there is significant linear relationship between perceptions regarding business environment and investment opportunities in India and the liberal policies for business set up. An open business environment will always position the country in a better framework than otherwise. This indicates emerging economies should concentrate on creating better business environment and attracting foreign direct investments from the better part of the world. However people don't link quality of life and quality education programs with the overall business environment as proved by the above analysis.

Governance factors will have a positive impact on country image

TABLE2: GOVERNANCE PERCEPTIONS AND BRAND IMAGE

Model	Unstandardized Coefficients		Standardized Coefficients	T	Sig.
	B	Std. Error	Beta		
1 (Constant)	1.043	.335		3.118	.003
g1	-.020	.041	-.058	-.475	.637
g2	.116	.066	.250	1.776	.082
g3	-.092	.058	-.229	-1.583	.120
g4	-.144	.064	-.273	-2.237	.030
g5	-.145	.049	-.398	-2.946	.005
g6	.070	.062	.190	1.134	.262
g7	.341	.077	.697	4.439	.000

The above hypothesis is tested using regression analysis. This hypothesis was tested using regression analysis. The above table indicates that the critical value of t with 58 degrees of freedom and alpha = .05 is 1.67. The above hypothesis is accepted for parameters g2 and g7. These state that India is competently and honestly governed and secularism is actually practiced in India. The Indian citizen with exposure to foreign countries stated that the brand image of a developing economy is impacted by the ideology and competence of governance. Hence it can be established that emerging economies need to concentrate on these two parameters of governance along with the others included in the governance sector.

Exports of a country has a direct impact on country image

The above hypothesis is tested using regression analysis. The table indicates that the critical value of t with 58 degrees of freedom and alpha = .05 is 1.67. The above hypothesis is accepted on the e4 parameter which states that Indian products are considered trustworthy in foreign nations. This further establishes that brand image has an impact on reducing country of origin effect, thus rendering more trust on the brands of the country which has a better brand value in the foreign nations.

Note: Perception parameters are defined in appendix 1.

TABLE 3 EXPORT PERCEPTION AND BRAND IMAGE

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
1 (Constant)	1.344	.241		5.585	.000
e1	-.171	.069	-.299	-2.484	.016
e2	.044	.086	.089	.506	.615
e3	-.138	.078	-.311	-1.773	.082
e4	.257	.060	.505	4.252	.000

The above hypothesis is tested using regression analysis. The above table indicates that the critical value of t with 58 degrees of freedom and alpha = .05 is 1.67. The above hypothesis is accepted on the e4 parameter which states that Indian products are considered trustworthy in foreign nations. This further establishes that brand image has an impact on reducing country of origin effect, thus rendering more trust on the brands of the country which has a better brand value in the foreign nations.

Findings

1. The respondents were asked to rank India on parameters such as infrastructure, law and order, business opportunities, government Support, Business Environment, Taxation policies, growth potential, quality of life for a common man. The analysis reveals that respondents feel India is ranked high in the world in terms

of growth potential and the world recognizes the potential of India to make a significant presence on the world map. The second aspect on which India was rated high was quality of life for a common man. Approximately 20% of the respondents view that an India can be ranked high on this parameter. However business opportunities and infrastructure hold very low scores and the other features like government support, law and order and taxation policies feature nowhere in the preference criteria. Hence the government has to take these into consideration for further enhancing the brand value of India in the world.

\TABLE 4 RANKINGS OF INDIA

2. Respondents were also asked to identify the most impactful dimension in designing a brand image for India. The responses show that heritage sites along with growth potential, skilled manpower and cheap power can be used to create an effective brand message.

TABLE 5: IMPACTFUL PARAMETERS IN DESIGNING BRAND MESSAGE FOR INDIA

- 3 The respondents were also asked to rank the parameters which contribute to spoiling the image of brand India. The results show that the infrastructure sector is the one contributes the most towards spoiling the brand image of India. This is also supported by the fact that the majority (approx. 75%) of the respondents who were unhappy with the image of India found infrastructure as the major reason for their dissatisfaction.
- 4 The results also display a very strong association of brand India with Mahatma Gandhi. This reveals that brand India is perceived as a mature, humble, ethical and visionary with immense amount of tolerance.
- 5 The citizens of India feel that an open business environment will always position the country in a better framework than otherwise. They believe that India should concentrate on creating better business environment and attracting foreign direct investments from the better part of the world. However people don't link quality of life and quality education programs with the overall business environment as proved by the above analysis. As shown by the analysis in Table 1. Significantly high scores for the statements [i1 & I4] show that the citizens view a better business environment can be linked to higher returns on investment and will attract the best resources from around the world.
- 6 The Indian citizen with exposure to foreign countries stated that the brand image of a developing economy is impacted by the ideology and competence of governance. Hence it can be established that emerging economies need to concentrate on these two parameters of governance along with the others included in the governance sector.
- 7 The Indian citizen who are not happy with the image of brand India believe that the brand image of a developing economy is impacted by the ideology and competence of governance. (Ref; Table 2)
- 8 The brand image associations of brand India is directly linked to the parameter (Ref. Table 3) which states that Indian products are considered trustworthy in foreign nations. Hence reflecting that this aspect of trust and belief can be further emphasized in designing a branding strategy for India.
- 9 The 5 parameters identified for measuring brand perceptions were charted on a pentagon.

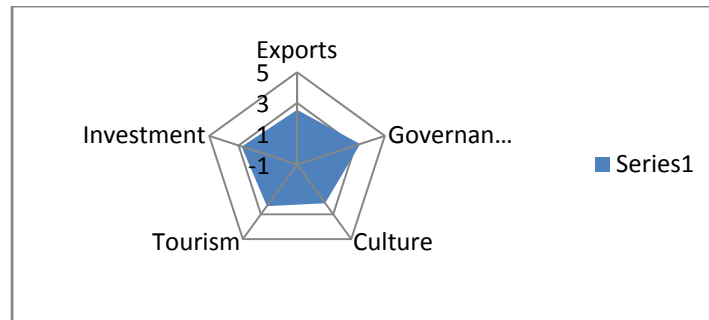

FIG2. NATION BRAND PENTAGON

The above chart depicts that governance is a major factor contributing towards creating positive perceptions of nation's brand. Governance is closely followed by the investment parameter. However tourism and exports are at par. Culture does not have a major impact in creating positive brand perceptions as far as India as an emerging economy is concerned.

Conclusion

The above paper highlights that India can utilize dimensions like Governance and infrastructure to strengthen its brand image. The brand message should essentially project India as a land of immense growth potential for business opportunities and availability of skilled labor at competitive compensation add on to the business facilitation. Hence emerging economies should work on creating better value for business in their nation and creating business facilitations for attracting more FDI's through better governance and infrastructure. An emerging economy predominantly focused on culture like the case in India where India is positioning itself as Incredible India has to be revisited and a new communication message incorporating the above values of superior governance and infrastructure need to be planned.

Further scope of research

The paper has incorporated all the five dimensions and a combined analysis had been done. However a sectoral approach can be followed and each parameter of probed in deeper to Exports, Governance, Culture, Tourism, Immigrations and Investment so that specific dimension based brand strategy can be identified. This can be further used for customized targeting depending type of audience and venture. Further this

paper has taken a case study of India which can be expanded and other BRIC economies can also be compared so as to create a differentiation for brand India amongst the BRIC economies

Sustainable Global Business in Emerging Economies- Multinationals from Asia-Pacific

SumitMitra Msumit2011@aol.com

India

G Arun Kumar, ArunKumar@ait.ac.th

Asian Institute of Technology, Thailand

Abstract

Multinationals are struggling to balance their viability from a market economy and competition perspective with their social viability from an environment sustainability perspective. Under the market economy driven profit maximization model, western multinationals extending their business to developing countries, face challenges of preserving ecosystem and social system health including natural wealth and bio-diversity. If instead of preserving living systems ability for self-renewal multinationals try to circumvent the problem by delinking consumers from producers and consumers from polluters in their attempt to globalize operations across continents, this attempt is labeled as ‘environmental apartheid’ calling for opposition to global operation of such multinationals. According to a model developed in this paper, long term sustainable business depends on a wider stakeholder influence of MNC vision/mission by reflecting changing social and ecological morality in recognition of intergenerational and interspecies equity, going beyond concepts of their mutual interdependencies. Use of this model to evaluate MNCs from emerging economies in the Asia-Pacific region reveals that firms dealing transparently with a wider stakeholder base are better positioned on a long term sustainable business path than those that merely react to environmental legislation and or unilaterally perform CSR activities, limitedly involving the local community.

1.0 Introduction:

Multinationals are struggling to balance their viability from a market economy and competition perspective with their social viability from an environment sustainability perspective. Under the market economy driven profit maximization model, western multinationals extending their business to developing countries, face challenges of preserving ecosystem and social system health including natural wealth and bio-diversity. If instead of preserving living systems ability for self-renewal multinationals try to circumvent the problem by delinking consumers from producers and consumers from polluters in their attempt to globalize operations across continents, this attempt is labelled as ‘environmental apartheid’ calling for oppositional to global operation of such multinationals. Whether it is Exxon-Mobil or Union Carbide or more recently BP, environmental stigmas have seen MNCs lose intrinsic value besides their image and business competitiveness. This paper tries to develop a model for successful sustainable global business, identify medium to long-term benefits of such business models for MNCs and then discuss the progress of some Asian/ Indian MNCs using this model. In conclusion, the paper attempts to predict the long-term benefits achievable for MNCs from progression along this path.

2.0 What traditional business is or is not?

Traditionally business pays no attention to non-human nature and therefore is absent from Strategic Management, Stakeholder theories and limitedly in Business Ethics- there is no reference to biophysical world in Management theory i.e. no reference to physical world including fresh water, fertile soil, food chain,

biochemistry and nutrient cycle. Business, by focusing on competitive advantage, leverages on technology for profit and efficiency achieving human development. Is this development sustainable?

3.0 What is Sustainable Development?

According to the Brundtland Commission, development that meets the needs of the present without compromising the ability of future generations to meet their own needs- a normative abstraction widely accepted, is sustainable development. Thus, sustainable development is more complex inclusive human development than accepted in business thus far, embracing economic, social and ecological interdependence. In the argument is included a critical aspect of intergenerational, intra-generational and interspecies equity. Thus the challenges of sustainable global business are in maintaining traditional profit and efficiency priorities of business while operating within an essential sustainable development frame.

To meet the above challenges of business priority, sustainable business development needs the inclusion of a unique set of stakeholders in governing business, which includes:

- Citizens
- Policy makers
- Health experts and
- Environmental experts

Overall, sustainable development of business must recognize fundamental socio-economic and environmental truths like

- World is relatively full than empty
- Regenerative and absorptive capacity of the natural environment is limited
- Wealth distribution from the poor to the rich and from the future to the present is not just irreversible but detrimental and unsustainable in the long run.

One other concept considered a sub-set of sustainability is Corporate Social Responsibility (CSR). It is a means used to measure and quantify sustainability in terms of global reporting initiative, ISO 14000, often referred to as social reporting, citizenship report or triple bottom line reporting (Goetz, 2010; Trabucchie and Lee, 2007)

3.1 Challenges of including sustainability in business:

Sustainable business needs to include some of the above priorities that may be in opposition to the conventional focus of business- maximization of profits and returns to the owners. Traditional models of global business which is called 'market induced globalization' allows through its breakup of production, consumption and waste disposal in different parts of the developed and developing world, a mystification of the producer-consumer-polluter link (Rist, 1999). As a result, migration of wastes from pollution of north/developed countries to south/developing countries and wealth, knowledge from south to north is interpreted as 'environmental apartheid' under neo-liberal globalization (Shiva, 2001). With risk of 'environmental apartheid', how responsive is business to sustainability issues may critically depend on how permanent and forceful is the change.

As identified by John Naisbitt, business and organizations have responded to megatrends in the past, whether they be rise of information society or hierarchical organizations giving way to networked ones (Lubin and Esty, 2010). These megatrends capture incipient societal and economic shifts. The common thread across such megatrends is that they present inescapable strategic imperatives for business leaders. How sustainability is the latest megatrend is captured in the following discussion of Lubin and Esty (2010):

Why do we think sustainability qualifies as an emerging megatrend? Over the past 10 years, environmental issues have steadily encroached on businesses' capacity to create value for customers, shareholders, and other stakeholders. Globalized workforces and supply chains have created environmental pressures and attendant business liabilities. The rise of new world powers, notably China and India, has intensified competition for natural resources (especially oil) and added a geopolitical dimension to sustainability. "Externalities" such as carbon dioxide emissions and water use are fast becoming material—meaning that investors consider them central to a firm's performance and stakeholders expect companies to share information about them. These forces are magnified by escalating public and governmental concern about climate change, industrial pollution, food safety, and natural resource depletion, among other issues. Consumers in many countries are seeking out sustainable products and services or leaning on companies to improve the sustainability of traditional ones. Governments are interceding with unprecedented levels of new regulation—from the recent SEC ruling that climate risk is material to investors to the EPA's mandate that greenhouse gases be regulated as a pollutant. Further fueling this megatrend, thousands of companies are placing strategic bets on innovation in energy efficiency, renewable power, resource productivity, and pollution control. What this all adds up to is that managers can no longer afford to ignore sustainability as a central factor in their companies' long-term competitiveness.

These megatrends took firm hold of business only when they became an integral part of society and individuals, for example, IT became an integral part of business when it entered into the personal life of workers and customers alike through desktop computing. Changes come through innovations in strategy and entirely new sources of value in business models. Experiences from earlier megatrends indicate businesses succeeding in a sustainable way need to incorporate innovations in their strategy in the evolutionary stages. Some of these may be

Stage 1: Do old things in new ways.

Firms focus on outperforming competitors on regulatory compliance and environment-related cost and risk management. In doing so, they develop proof cases for the value of eco-efficiency. At its inception 30 years ago, 3M's Pollution Prevention Pays (PPP) was just this kind of initiative. As of 2005, PPP had reduced 3M pollutants by more than 2.6 billion pounds and saved the company more than \$1 billion.

Stage 2: Do new things in new ways

Firms engage in widespread redesign of products, processes, and whole systems to optimize natural resource efficiencies and risk management across their value chains. DuPont's "zerowaste" commitment, for instance, increased the company's prioritization of eco-efficiency across their operations.

Stage 3: Transform core business.

As the vision expands further, sustainability innovations become the source of new revenues and growth. Dow's sweeping 2015 Sustainability Goals, designed to drive innovation across its many lines of business, yielded new products or technology breakthroughs in areas from solar roof shingles to hybrid batteries.

In line with the idea that Environmental Burden (EB) depends primarily on Technology (T) given that Population (P) and Affluence (A) are beyond corporate control and matters of national policy (Gladwin et al., 1995), investment in clean technology by corporations that touched about USD 9 billion in 2008 was expected to rise to USD 200 billion in future with G20 countries earmarking USD 400 billion of its USD 2 trillion stimulus fund for clean technology and sustainability.

Given that resources earmarked for sustainable business, it is important to identify if 'incentives' as opposed to 'dies-incentives' are more effective in motivating sustainable business. For a 'command and control' government and environmental agency, predominant approach to sustainability has been the route of coercion or disincentives for non-compliance; incentives reward change but disincentives punish failure to change (Tools of Change, 2009). Since governments and individuals comply with a law for fear of punishment under disincentives, there is constant need of government vigil for violators (Iannuzzi, 2002). While incentives may not change mindsets in the beginning and only behaviour, peer pressure and success from these changes,

customer preference and business gains can over time induce a mindset of sustainable business for all time in future.

Including sustainability into business will spread accountability beyond immediate business to net in wider stakeholders as Kanter (2010) illustrates

Selling a simple cup of coffee, for example, already requires much more knowledge than how to brew and serve it. Where was the coffee grown, under what labor conditions, and with what pesticides? Is the cup made from recycled paper, and how many trees were cut down and how much water was used to manufacture it? Does the plastic lid leak toxins, and does it snap shut well enough to prevent burns from spills?

Obsolete systems of sequential processes, in which each group performed just one step, with no responsibility for what happened before or after, have given way to more integrated, simultaneous planning and management, with every group, including suppliers and distributors, bearing a share of responsibility for the end product and not just for a specialty. Circles of influence, business fortresses are replacing chains of command by collaborative business ecosystems. A vital difference of this stakeholder model from the traditional agency model includes pre-empting stakeholder demands from the perspective of sustainable business, which, as mentioned before, needs building different forms of sustainability criteria into strategy formulation of business and highlighted in the three stages before.

4.0 Stakeholder approach to sustainability:

Unlike the shareholder model of business, the wealth distribution priorities of stakeholder model are different, particularly if there is a fixed pie of profits (Parmar et al., 2010). In the stakeholder model the focus is on process and procedural justice; on just distribution of resources and new sources of value creation; a higher acceptability of a process of all this that is fair. Unlike as claimed by some it does not lead to higher managerial opportunism (Jensen, 2000; Sternberg, 2000) although some claim stakeholder theory requires change in current law for this (Hendry, 2001). Maren and Wicks (1999) show that business judgement rules allows use of stakeholder theory without running afoul of law. It is also not a social policy enforced by the state but a system of voluntary exchanges of individuals (Phillips et al, 2003).

Stakeholder theory is a comprehensive moral document (Orts and Studler, 2002) but while John Rawls (2003) claims that it can answer a full array of moral questions, Philips and colleagues (2003) claim that stakeholder theory cannot answer many of the moral questions related to business. This may well refer to some of the moral questions arising out of the environmental sustainability of business included in such business ethics questions of 'what is the purpose of existence of the firm?' and 'to whom does management have an obligation?' (Parmar et al., 2010)

5.0 Sustainability Model:

Based on the discussion so far, a model for sustainable business is developed (see figure-1).

6.0 Methodology:

For this study, four firms located in emerging economies are chosen based on their annual report and sustainability report available online. The sampling is a convenience sampling in this case. These firms are in

diverse business from power generation to banking and have international presence qualifying as Multinational Corporations (MNC). A content analysis methodology adopted to identify and segregate the activities of these firms, primarily into those that are firm internal initiatives addressing CSR, sustainable business issues and those that involve the wider community but aimed at serving the same objective of sustainability of business. The concept of 'sustainability' used here pertains to preservation of natural environment in the course of business, preservation of intergenerational and interspecies equity as highlighted in the model and broadly recognizing interdependencies of society, ecology and economic activities of MNCs.

The firms are:

- China Light and Power (CLP): Operates in power generation with operations in emerging economies like China and India besides Australia- its origins.
- INDORAMA: It is a company of Indian origin and registered in Indonesia in the business of PET (plastic bottle) resins and products. It has operations in different parts of the world.
- PTT Thailand: A leading Thai MNC operating in energy business with oil and gas assets and operations in different countries.
- HSBC China: It is a banking entity, regional subsidiary of the global banking entity HSBC Plc.

7.0 What firms are doing:

7.1 China Light and Power (CLP):

CLP delivers value through its triple bottom line reporting using its sustainability report along with its annual report. It adopted a climate strategy framework, as part of which is climate vision-2050 reducing CO2 emission, non-carbon generation and renewable energy in power generation of at least 5% by 2010. Under its community partnership, CLP wants to involve more than 4500 students of HK, china and India in its Young Power Program together with tree plantation involving local communities besides model power generation facilities in HK, China and India for communities to see.

Online education on home energy consumption with carbon footprint calculation is available at TRUenergy website in Australia with options of purchasing green electricity and carbon offsets. Suppliers are involved and educated to encourage green purchasing and supply where viable. CLP continued to promote energy efficiency through the provision of advisory services to residential and commercial customers and supporting public education in the Pearl Delta Belt and Guangdong province helping 150 users including hotels, factories, office buildings, residents.

In developing countries like China and India, construction sites are still the highest risk areas and CLP face particular challenges at Jhajjar in India and Jiangbian in China. They cannot completely eliminate risks but strive hard to raise safety standards substantially above the local prevailing norms. Jiangbian has been recognised as a model site in Sichuan and Jhajjar has just achieved 3 million man-hours without a lost time injury. However, CLP are well aware that significant risks remain due to working at height and with rock bursts.

CLP provided funds, infrastructure and even human resources as volunteers from its employees and their families to set up two primary schools in the earthquake hit Sichuan area of China providing education to 570 local students in 2008. As part of its organization structure to implement sustainability, CLP's Sustainability Committee is a Board level function, which oversees CLP's position and practices on sustainability issues that affect shareholders and other key stakeholders. Appointed by the CLP Holdings Board of Directors, the

Committee comprises of Executive Directors and Independent Non-executive Directors of the Board, Group Director – Carbon Ventures, and Director– Group Environmental Affairs. The Committee reflects the Board’s increased focus on managing the social, environmental and ethical risks and opportunities that CLP faces. Its key function is to ensure that these risks and opportunities are properly identified, and steps taken to address them. Recommendations from the Committee are available for the Board’s consideration in setting the overall direction of the company.

In attempting to link its sustainability effort to its values and strategy the following statement of the top management is significant

Our values, abilities and strategy must adapt to, ideally anticipate, changes in technology, markets and societies’ means, needs and expectations – changes which appear to be occurring with increasing frequency. In recent years, we have developed a formal Value Framework which sets out the values which govern ourselves, our business and our relationship with our stakeholders. Our abilities have increased and become more attuned to the importance of excellence in the management of the environmental implications of our business – in recent years, we have acquired experience and expertise in a wide range of clean energy technology, including nuclear, hydro, wind and solar energy. Our strategy specifically addresses the issue of global climate change through our ‘Climate Vision 2050’ issued in December 2007, which commits CLP to massive reductions in the carbon intensity of our generating portfolio from 2007 through to the middle of this century.

7.2 INDORAMA

This is a company focused on its people, products and customers together with a social responsibility that enhances environment around and corporate governance focused on transparency, accountability and ethics. While Indorama attributes its business risk to cyclical nature of PET business, supplier problems, increasing cost and market problems besides operational risks, it nevertheless recognizes imposition of eco-taxes and fees besides product stewardship that are being introduced in USA. Consumer concern for solid wastes and its recyclability has seen reduction in demand for PET resins. Indorama has to face both central and local regulations of business whose non-compliance may result in fines and penalties.

Indorama Ventures PCL (IVL) believes in striking a balance between economic and social goals by executing high standards of Corporate Governance and always strives to implement the Corporate Governance principles set by the Stock Exchange of Thailand. The Company firmly believes in transparency, accountability and ethical conduct in pursuit of its mission and acts in accordance with its framework for sound corporate governance to enhance Company’s competitiveness and best serve the interests of its many stakeholders – and business. IVL has in place a written Corporate Governance Policy and the Policy follows the guidelines set out by SET. The Board and management are strongly committed to the implementation and practice of the Corporate Governance principles and this reflects allegiance to doing what is fair, right and legal. Indorama has been awarded a “blue” rating by the Ministry of Environment Performance Rating Program for consistent good compliance from 2002-09; the textile products tested for harmful substances by the international association for research and testing in textile ecology. They were awarded the prestigious OEKO-Tex standard 100 for several consecutive years. PlantBottle packaging is a PET plastic package made with up to 30% of its material derived from plant material. As a significant step towards recyclable bottles, the PET resin for the PlantBottle is made from molasses, which is a by-product in refining sugar from sugar cane. It is estimated that the production of this PlantBottle could reduce the amount of petroleum product use annually by 2045 KL.

However, the priority here is in maintaining the legal requirements of governance relating to board member appointment, remuneration, dividend payment and internal information. IVL and its subsidiaries cares about safety of its society, environment, and quality of life of people associated with all its operations and strives to comply with applicable laws and regulations. IVL and its subsidiaries try to participate in all activities that support and care for environment and society and promote the cultures in which the companies operate. IVL and its subsidiaries treat and dispose of waste in a manner that will have least impact on society, environment and people. No specific activities aimed at achieving these outcomes or organizational structure and system to implement such efforts are however discussed in IVL annual report. While most tree planting and health check up activities involved employees and IVL community, some involved other community stakeholders as well.

Among the community activities IVL participates in are:

- Scholarships for primary education of children
- Sponsor sports team
- Support for a public health centre
- Green program for planting trees
- Support and organize cultural activities and events
- Participating in various local festivals, such as National Children's Day, Songkran, Loy Krathong and Makhabucha Day.

IVL focus is also to reduce and reuse natural resources

A Boat Race conducted on Oct 5th, 2009 at Bangkham River, Koksalod Village located at the backside of Indorama Polymers, PCL, Lopburi. This is a traditional function for conservation of water source at Bangkham River. Activity training on HIV AIDS by Thailand Business Coalition was conducted at Lopburi (IRP) on Sept 28th, 2009. Indorama Polyester Industries PCL-Nakhonpathom's employees co-operated to donate blood with Department of Transfusion Medicine, the Faculty of Medicine Siriraj Hospital, Mahidol University on September 21st, 2009.

In other activities around the world where Indorama operated:

*At OGPET Lithuania the following activities are conducted

- Meeting with Klaipeda Environment organization Žvejonė like Green Peace organization
- Annual presentation of Environmental Monitoring for society (villagers, city administration, Environment Department).
- Also conducted was the Fire prevention training with Klaipėda Fire and Rescue Department
- Annual Football Charity Cup at FEZ

*At Alphapet, USA, the following activities took place:

- Relay For Life- American Cancer Society
- Charity Golf Tournament at The Pilot Club of Decatur
- Annual Membership Industrial Emergency Association
- Scholarship Funding Decatur General Foundation
- Hindu Cultural Centre of North Alabama
- Avon Breast Cancer Foundation
- Student Leadership Scholarship DECATUR

*In 2009 the following external projects were executed at Indorama Polymers/Holdings Rotterdam B.V:

- Donated redundant computers to a charity organization in the Netherlands
- Participated in the program "feel the chemistry". This program initiated by the VNCI (Association of Chemical Industry). The objective is to let children, from primary school, visit chemical plants and see what

chemistry is all about. Approximately 35 school kids visited our site in June. Presentation about Indorama and their products was given. The children were invited to execute chemical proofs by making hair gel and shampoo.

- Indorama participates in the Process College Mainport Rotterdam. Promoting the schools for process operator and maintenance technician is one of the major tasks. The need for more students following a technical education is a priority. By inviting students from secondary schools to Indorama site, giving presentations, explaining about the job should help students to make a decision about their next step in education. During the week of the process industry in January, various groups of students visited the plant site.
- A number of trainees from the Process College are offered an internship within the company. For some of them it resulted in employment with Indorama.

*Indorama Petrochem Plant in Rayong undertook the following activities during the year

- Coordinated with IEAT and Ban Chang District local community leaders during Jun-Dec 09 on smell impact reduction plan to nearby communities.
- Regular visit to local communities every month during Jan-Dec 09.
- Organized “School Safety Project” activities at Prachummit Bumrung School (basic fire fighting training for school children and teachers) on 4/9/09.
- Donating items, luncheon, and organizing sports activities for orphans at Huay Pong Youth Care Center, Rayong, on 26/12/09.
- Joined MPR (Map Ta Phut Public Relations Club) activity of “Happy Healthy Youth Camp with MPR” during 28-29/5/09 at PTT Herb Garden, Rayong.
- Supported gifts and presents to young children during 2009 National Children Day.
- Donated to support 2009 Rayong Red Cross Fair organized by Rayong Province.
- Donated to support Songkran Festival organized by Prachummit community and Chak Look Ya community.
- Donated to support 2009 Chinese temple charity at Payoon Chinese Temple

It may be worthwhile to try and link these sustainability and CSR activities of Indorama to its stated mission, objectives and strategy to find the impact of one on the other.

Vision:

To be one of the leading global producers with key focus on people and processes thus making INDORAMA one of the most admired companies in the world.

Mission:

Continuously improve quality of product and services through people involvement and world-class processes to attain customer delight thus becoming a preferred supplier and institutionalize people learning as a key factor for business growth

Values:

1. Social Responsibility: We believe in being responsible and caring for society; maintaining as well as enhancing the environment around us.

2. Corporate Governance: We believe in transparency, accountability and ethics. We aim to achieve highest degree of governance in accordance with best practices.

7.3 PTT Thailand

PTT is determined to be a good Thai business entity with a vision of being a Thai Premier Multinational Energy Company, using local strength for competing in the international arena. The company is committed to a mission that stresses responsibility to all stakeholders – the nation, society, communities, shareholders, business

partners, customers, and employees. The company has in place a clear guideline for sustainable development by keeping a good balance between Corporate Social Responsibility (CSR), Corporate Governance (CG), and High Performance Organization (HPO) in order to lay a strong foundation for the long-term development of the organization.

In addition to taking part in sustainable development networks, which has strengthened the policy, principles, and knowledge within the company, PTT applies guidelines and standards for managing quality, safety, occupational health, the environment, and society. To exert control over air pollution and alleviate impacts on the environment and communities around PTT's business operations, PTT stressed air pollution through managing pollution reduction at sources and controlling pollutant levels at operating sites of oil storage and distribution. The key is to ensure that the pollutant levels are within legal standards.

As a national energy company, PTT has recognized climate change issues. Therefore, the company has investigated its impact and consistently monitored public policies and control measures. A carbon footprint for PTT is established since 2006, through activity analyses, source identification, and calculation of Green House Gas (GHG) emission. Process steam recycling reduced 650,000 MMBtu of gas consumption, equivalent to 38,152.9 tons of carbon dioxide emission. PTT recognizes its responsibility for global climate change by promoting natural gas as a replacement for fuel oil; preferred transport of products by pipeline or by rail, which resulted in lower Green House Gas emission than transport by truck; a switch from 38-watt (T8) fluorescent light bulbs to 28-watt (T5) ones at all operating sites; and restoration of natural balance by promoting stewardship activities and rehabilitation of natural resources in a sustainable way – including a complete reforestation project and the implementation of forest stewardship projects. The land use for reforestation absorbs about 4 million tons/year of carbon dioxide.

In addition, PTT conducted R&D of biofuels; biomass-to-liquids synthesis; waste-to-energy; leveraging hydrogen derived from natural gas in fuel cells (through cogeneration); nuclear energy; solar energy; and wind energy. The company also investigates ethanol production from grassy plants, reducing ethanol production costs; joint R&D of diesel from vegetable oil (the so-called bio-hydrogenated diesel (BHD)) through assorted raw materials, including jatropha and algae; and the construction of a pilot biodiesel plant.

To ensure that PTT's sourcing of water supply does not create significant impacts on natural water bodies while continually sourcing additional water supply for its activities, it buys water from the Provincial Water Authority and East Water Plc., but continually reuses water in its processes and also reduced water consumption. This reduction has been 17,500 cubic meters per year.

Much of PTT's business operation is in areas outside protected or biodiversity areas. One gas transmission pipeline route, however, lies in the forest area of Amphoe Thong PhaPhum, Kanchanaburi. About 44 km of the total 50 km of the route is in an area that contains deserted mines and ore transport roads, and the other 6 km is in a deciduous forest. PTT joined the Biodiversity Research and Training Program (BRT), an independent organization attached to the Ministry of Science and Technology, in conducting biodiversity research under the West Thong PhaPhum Project in forests around TambonHuaiKhayeng, Amphoe Thong PhaPhum, Kanchanaburi. This endeavor, an area based research development under Thailand's first multidisciplinary research project management, focused on linking knowledge from assorted fields to form a new body of knowledge. It is expected that the research findings from this endeavor, numbering 61 and covering plant species, animal species, valuable biological resources, and culture and folk wisdom, will prove practical knowledge, particularly at the local community level in various forms. This includes local product manufacturing, ecotourism, and the joint creation of local curricula and learning processes among academicians and the community to bolster their long-term stewardship of natural resources.

Apart from these, PTT and BRT launched a project on biological resource management from the shore to the peak around Khanom Beach and Khao Nan of Nakhon Si Thammarat, to conduct holistic ecological research from the shore to the mountain peak for the first time in Thailand, and to investigate the interdependence of local communities and local biological resources. This research fell into two subprojects, namely (1) the biological resource management for Khanom shore, focusing on community engagement in studying local

wisdom, their marine-bound livelihood, and utilization of marine resources, and (2) the Khao Nan research project, Nakhon Si Thammarat mountain range, focusing on biodiversity and the cloud forest ecology, which is rare in Thailand and a major source of streams.

7.4 HSBC China:

HSBC China has CSR as an essential part of its Corporate Sustainability Strategy with responsibility to contribute to the society and community in which it operates. In 2009, environment protection and education remained the focus of HSBC China's CSR priority. This includes efforts like the Eco-Schools Climate initiative and the Green Roof Project where HSBC staff as 'climate champions' attended a training programme on climate change and another 400 volunteered to participate in the Eco-Schools project. HSBC China follows four corporate sustainability objectives including:

- Commercially viable projects that impact environment and society positively.
- Promoting carbon neutrality and reducing environmental footprints by reducing use of energy and water as also waste and carbon dioxide emission.
- Community investment for sustainable social development.
- Minimizing business risk particularly reputational risk.

A Corporate Sustainability Committee set up under the Group Board of Directors is responsible for HSBC's sustainability strategy. In regions like Asia-Pacific, Latin America, N.America and Middle-East Corporate Sustainability Committees implement the Group sustainability strategy. Mainland china and 19 other countries come in the Asia-Pacific region.

As the first bank to become carbon neutral in 2005, HSBC tries to reduce carbon emission in its activities, purchase 'green electricity' wherever possible and tries to offset carbon emission. As part of its 'carbon footprint management', it tries to reduce consumption and waste of both energy and water. This includes installing video conferencing at its HQ and regions to reduce need to travel, printing on both sides of paper and recycling of used paper including newspaper and magazines. These efforts in China are estimated to have saved 541 tonnes of CO₂ emission in 2009 itself. Replacement of all incandescent bulbs with energy saving bulbs is estimated to have saved 650,000 KWHr per year equivalent to reducing carbon emission of 429 tonnes per year. Besides considerable savings in energy is achieved through purchase and use of energy from renewable sources. HSBC China invests in projects with some environmental and social risks like forestland and fresh water infrastructures.

8.0 Discussion:

As per the model developed from literature, sustainable business crucially depends on market viability as also ecological viability. Sustainable business impacts in redefining the future organization from that of its present which carries with it the burden of its past as well. To find a balance between market and ecological focus, organizations need to not only acknowledge interdependencies of ecological, social and economic sustainability but given environment's exhaustible resources, limited carrying and regenerative capacity need to be cognizant of inter and intra-generational equity as also inter-species equity. While existing mission and vision of MNCs define their strategies from which flow actionable organization roles, these may only take care of ecological, societal and economic interdependencies. However it is the futuristic morality of society, ecology and economics that defines the long-term direction of MNCs by influencing their mission/ vision for the future via their many and diverse stakeholders. The framework argues that the long-term sustainability of business critically depends on organization action that goes beyond implementing present strategies on sustainability to influence future societal, ecological and economic morality and its influence on future mission/vision of the organization through a broad based stakeholder representation, not just shareholders as in representatives of owner's interest in an agency model.

CLP maintains transparency of activities through sustainability reporting and a climate strategy framework as part of climate vision-2050 for long-term objective and target setting. It also has societal commitment through

student involvement in its 'Young Power Program' and model generation plants such that future generations are aware of not only the corporation's operational plans but also moral stand over the long term. This helps define not only the corporation's morality but also societal morality by achieving intergenerational equity.

Supplier involvement and green purchasing together with advisory services to residential /commercial customers online on energy usage helps in progressively shifting from 'hierarchy of commands' to 'circle of influence' involving different stakeholders leading to long term sustainability of business. Concerns of risk from working in developing countries like China and India positively influence morality of MNCs like CLP through its social consciousness.

Structurally CLP has provisioned through its 'Sustainability Committee' to incorporate its Board's vision of sustainable business and environment. Its activities discussed before help in creating the actionable strategy born out of the vision with its advisory role maintaining communication and transparency with different stakeholders.

While focusing on transparency, accountability, Indorama's focus seems to be less on the moral side of societal and ecological sustainability and more on the operational side of legal imposition of environment taxes as captured in 'doing what is fair, right and legal'. Accordingly, Indorama targets government awards as recognition focusing more on the disincentives of non-compliance to rules and policy than on voluntarily and proactively influencing environment policy. There is no mention of specific structural aspects aimed at implementing sustainable business strategy. Most of the activities of Indorama have societal impact of the CSR category that need not necessarily address sustainability aspects of business. These include primary education, health centers, and HIV AIDS awareness. Process training for students at Indorama's Rotterdam facility equips them to seek employment in Indorama but desirable levels of stress on sustainability of PET business may be lacking when the same need be stressed through the PlantPETorPlantBottle technology using molasses from sugar replacing extensive use of petroleum products for PET and promising recyclability of PET bottles. Indorama's focus on disincentives for failure to comply, that necessitates government vigilance (see discussion earlier) is likely to prioritize compliance by value chain/ supply chain partners under a 'vertical hierarchy' of authority and not so much under a voluntary 'circle of influence' stakeholder approach. With inadequate stress on societal and ecological morality, Indorama may be operating as a business under an 'agency' model and not 'stakeholder' model with managers acting as agents of owners trying to maximize profits for them at cost of long-term sustainability. The mission and vision of Indorama while stressing on people and processes does not explicitly capture sustainability priorities.

PTT, the oil and gas MNC from Thailand claims to focus on sustainability guidelines with stress on CSR and high performance. Its efforts to meet legal limits of air pollution control, monitoring emission, use of natural gas, saving on light energy use, recycling of water and reduced transportation related pollution while highlighting organizational role in implementing a sustainable business strategy and even PTT's corporate moral stand does not focus on societal and ecological morality. Increased societal involvement in PTT's outreach programs like reforestation effort, R&D to generate bio-hydrogen fuel from plant base like Jatropha and algae may help strengthen societal and ecological morality besides economic. PTT's biodiversity research project adds to societal knowledge and involves diverse stakeholders' increasing focus on sustainable business besides organization role of PTT. Its project on biological resource management not only defines PTT's willingness to invest resources as part of sustainable business strategy but can over time shift morality of society and corporation who through their expanded stakeholder role can influence long term vision/ mission of MNCs like PTT.

HSBC, the global bank with operations in China has CSR as part of sustainability strategy. HSBC China's 'Eco-School' and 'Green Roof' projects highlight its willingness to invest valuable resources into ecological projects and involve the society in its sustainability effort. Structurally senior management at Group level Board oversees sustainability of business and has a Corporate Sustainability Committee implementing group sustainability strategy. Continuously improving sustainability focus in business comes from stakeholder impact on corporate vision and mission- arising out of shifting corporate, societal and ecological morality. At corporate HSBC China level, morality is captured in the focus on carbon neutrality from reduced travelling, use of energy saving light, renewable energy whereas societal and ecological morality can be understood from community linked projects like forestation and fresh water infrastructure.

9.0 Conclusion:

CLP has a long-term vision of climate and ecology. It can also have societal morality influenced by programs like Young Power Program where the youth become conscious of inter-generational equity issues. Including suppliers, customers in ecological sustainability widens the base of stakeholders such that their changing morality can influence future mission/vision of CLP. Structural arrangement exists for implementing strategy and making changes in the same in line with changing mission/vision.

Indorama's organizational role in implementing sustainability strategy focuses on safeguarding legal requirements that need to be reactive to rules and policy needs than proactive, thereby acknowledging ecological, societal and economic interdependencies but failing to identify morality issues arising out of intergenerational equity as in case of CLP. In the absence of a wider stakeholder base, technological sustainability examples of PlantBottle or non-petroleum PET resins may fail to highlight intergenerational or interspecies equity issues that influence future vision/mission of Indorama.

PTT like Indorama focuses on CSR issues of pollution control, lower energy use, recycling of water but also creates a wide and diverse stakeholder base through reforestation, biodiversity research projects that generates and disseminates new knowledge to a wide base locally and internationally. This may result in the wide stakeholder base influencing future vision/mission of PTT because of shifting morality with regards society and ecology similar to CLP.

HSBC China, a service firm (bank) undertakes CSR efforts to implement sustainable strategies but also involves the larger community through its Eco-School and Green Roof projects. These efforts expand stakeholder base, whose morality if influenced can effect change in the future mission/vision of HSBC china. Like CLP, young generations are made conscious of intergenerational equity and existing structural arrangements support sustainable business from the very top that also monitors any shift in organization mission/vision.

In using the given framework to understand sustainable business efforts of MNCs from emerging economies, the possibility of a wide stakeholder base of these MNCs influencing their vision/mission for the future plays a critical role. The four MNCs discussed in this paper seem to be in different stages of evolution from present or currently sustainable business to future sustainability of their business. While firms like Indorama seem to be in the early stages of sustainable business, the others are in a more advanced stage. This is explained by the fact that while organizational effort of MNCs to implement sustainable strategies may only acknowledge issues of societal, economic and ecological interdependencies, for stakeholders to influence future mission/ vision of MNCs and thereby their long-term sustainable strategies, an understanding of shift in morality at societal, economic and ecological levels is required. This is captured through the involvement of a wider stakeholder base of MNC that can foresee issues of intergenerational and interspecies equity. The paper also identifies that for this to happen MNCs need to not only undertake CSR practices but also involve their local society, bring transparency of their intentions to this society and in turn incorporate the views of the larger society as stakeholders in their vision/mission. It also identifies that those firms that have long-term sustainable business, also have structural arrangements to incorporate the changing vision/mission and strategy into the organization role. The limitations of this study lie in using secondary information on only four firms from emerging economies to draw conclusions. The scope of the study has to be widened to include MNCs from diverse industries and geographical locations.

ABSTRACT

Pakistan has a large number of trading partners but still bulk of its exports are concentrated in few countries including USA, UK, Germany, Japan, Hong Kong, Dubai and Saudi Arabia which account for nearly half of its exports. In this paper the composition of Pakistan's exports of three major sectors i.e. Agriculture, manufacturing and minerals & oil sectors have been presented. Oil and manufacturing sector is contributing most towards trade deficit of Pakistan. An extended Gravity model of trade has been used to test the impact of economy sizes (of countries), their relative distance from Pakistan on its bilateral trade with them. Using a panel data analysis, the results show that in general the model has good explanatory power. Almost all the coefficients of the basic Gravity equation are statistically significant and have expected signs. The most seemingly interesting result is in terms of common border but this result is comprehensible in terms of Pakistan. Among OECD member countries Pakistan's exports are more with those members with whom it shares common official language viz. Australia, Canada, New Zealand, UK and USA.

Keywords: Pakistan; Exports; Gravity Analysis; OECD; Panel data.

I. Introduction

International trade is crucial to maintain and augment the pace of economic growth for a country like Pakistan which is bestowed with huge amount of natural resources. Exports are significant to boost any economy and even more important in the context of Pakistan due to its early openness in the international market as compared to other economies in the region. Pakistan is famous for the exports of rice, cotton, fiber, marble, textile, leather goods, sports goods, surgical instruments, electrical appliances, wheat, sea food and vegetables. Its exports reach all over the world but almost 70% of its exports go to United States, United Kingdom, Japan, United Arab Emirates, Afghanistan and China. The export earnings from raw cotton, textile goods, rice, leather and surgical products are very less because these items get awfully little price in international market. Moreover, natural hazards can drastically reduce export earnings of these commodities. On the contrary expenses on import of machinery, industrial raw material, petrol and electronic goods are more because of ever increasing prices of these items in the international market¹. To compound problems for Pakistan it has to import several agricultural products despite being an agricultural economy itself thus significantly steeping its import bill. These supply and demand side constraints (exports and imports) are the major causes of the slow pace of Pakistan's economic growth. In order to overcome these constraints some urgent steps are crucial to be taken such as good macroeconomic management, development of high-value added export industries, "export promotion" policies, investment on research and development and increase in the non-agricultural sector total factor productivity to sustain its cost advantage

(Mahmood, 2004). Hence, there is lack of empirical evidence to support demand and supply side constraints for the economic growth of Pakistan through export's growth. It's quite relevant and beneficial now to describe the export composition of Pakistan and to explore the determinants of Pakistan's exports and their distribution across countries. In this paper an extended Gravity equation of trade has been used to accomplish this objective. In order to incorporate the qualitative factors as control variables four highly important dummy variables have been introduced in the standard Gravity equation. More recently, partial theoretical foundations for the Gravity equation have been provided by (Anderson, 1979), (Helpman and Krugman, 1985), (Deardorff , 1997), but there is an extreme lack of the implications of Gravity equation for the economy of Pakistan. This paper is an attempt to fill this gap.

II. Trade Composition

On the basis of the 1 digit-level of Standard International Trade Classification Revision one (SITC Rev.1) the composition of Pakistan's export and import is structured on three main sectors:

TABLE 1: TRADE COMPOSITION: 1962-2008

SITC Rev.1 1-digit	
Code	Description
0	Food and Live animals
1	Beverages and tobacco
2	Crude materials, inedible, except fuels
3	Mineral fuels, lubricants and related materials
4	Animal and vegetable oils and fats
5	Chemicals
6	Manufact goods classified chiefly by material
7	Machinery and transport equipment
8	Miscellaneous manufactured articles
9	Commod. & transacts. Not class. Accord. To kind
NOTE	code 0, 1, 4 & 5 = Agriculture Sector code 6 - 7 = Manufacture Sector Code 2 & 3 = Minerals & oil

Source: Source: United Nations Commodity Trade Statistics

Export composition of Pakistan has changed significantly over last five decades. The noteworthy changes were observed in the percentage shares of manufacturing (increasing on average) and in minerals & oil sectors (decreasing on average). Agricultural products showed almost an unpredictable trend over the whole study period (Fig.1).

From the perspective of imports composition, Pakistan's economy experienced almost halved in the imports of manufacturing products over five decades starting from 64% in 1962 to 34% in 2008. The minerals & oil sectors showed uneven trend. The same sort of trend was observed in agriculture sector starting from 22% during sixties and a sharp rise in later decades i.e. 41% in nineties and finally 25% in 2000s (Fig.2).

FIG.1: EXPORTS COMPOSITION OF 3 SECTORS OF PAKISTAN

FIG.2: IMPORTS COMPOSITION OF 3 SECTORS OF PAKISTAN

Throughout the history of Pakistan balance of trade has not usually been in favor of Pakistanⁱⁱ (Fig.3). However, from Fig.1 and Fig. 2 it's evident that overall out of the three major sectors trade surplusⁱⁱⁱ is very much sustainable in manufacturing sector from last four decades, unstable in agriculture sector and the major sector contributing towards trade deficit is oil and manufacturing sector.

I. Model Specification

Gravity Equation of trade is used by many economists since its invention by the first Nobel Prize winner in Economics (Tinbergen, 1962). He proposed that trade between any two geographic entities is very similar to Newton's Gravitation Law except that instead of the masses of the two objects in Gravity Equation of trade we use the GDPs of two countries and instead of predicting the force of Gravitation; we estimate the volume of trade between the concerned geographic entities. The Gravity Equation of trade is given by equation (1).

$$Trade = B \frac{GDP_i GDP_j}{D_{ij}^n} \quad (1)$$

Where trade is the volume of trade (can be measured by either imports, exports or their average) between two countries, GDP_i and GDP_j are the gross domestic products of the trading countries i and j respectively and Dⁿ is the distance between them. We use exponent n for distance because we are not sure of the precise relationship between distance and trade. The term B, explains the effects of all factors (other than size and distance) that can influence the amount of trade between two countries e.g. tariffs, sharing a common currency etc. The bilateral trade between any two geographic entities is positively related to the size of their economies and negatively related to the trade cost (proxy of distance) between them (Head, 2000). Countries with larger economies trade more, this is because they

produce more as a consequence they tend to export more and they tend to import more as their demand for commodities tend to be higher. The geographic distance is an impediment in trade between different trading economies because of factors such as transport expense, shipment time, synchronization & communication expense, transaction expense and cultural dissimilarity etc (Feenstra, 2003). Owing to the multiplicative nature of the Gravity equation natural logs can be taken to obtain a linear relationship between logged trade flows and the logged economy sizes and distances. Hence, the linear form of standard Gravity equation will be as given equation (2),

$$\log Trade = \log GDP_i + \log GDP_j - \log D_{ij} + e_{ij} \quad (2)$$

Gravity equations are very efficient at explaining trade with just the size of the economies and their distances. However they are unable to explain a huge amount of variation in trade. In this connection (Aitkin, 1973) introduced a dummy variable (DV) in Gravity equation of trade. When dummy variables are used with a logged dependent variable, the coefficient of the DV has a percentage interpretation. The augmented Gravity Equation used in this paper is given in equation (3),

$$\begin{aligned} \log X_{ijt} = & \alpha + \beta_1 \log(GDP_{it}) + \beta_2 \log(GDP_{jt}) + \\ & \beta_3 \log(D_{ij}) + \beta_4 \log(CB) + \beta_5 \log(CL) + \\ & \beta_6 \log(CC) + \beta_7 \log(CR) + e_{ijt} \end{aligned} \quad (3)$$

The variables are defined as,

X _{ijt}	The bilateral export flows between country i and j in time t.	CL	Common official language. This dummy variable takes value of 1 if the two countries share the common language and 0 otherwise.
GDP _{it}	Gross Domestic Product of Country i in time t (Supply of goods).	CC	Common Colonizer. This dummy variable takes value of 1 if the two countries have been a British colony at some time during history and 0 otherwise.
GDP _{jt}	Gross Domestic Product of Country j in time t (Demand of goods).	CR	Common Religion. This dummy variable takes value of 1 if the two countries share the common religion and 0 otherwise.
D _{ij}	Distance between country i and j.	E _{ijt}	The normally distributed error term. Where E(e _{ij}) = 0.

CB Common border. This dummy variable takes value of 1 if the two countries share the common border and 0 otherwise.

To estimate equation (3) STATA software has been used by applying panel^{iv} Time Series Cross Sectional (TSCS) regression approach on complete data set as well as on OECD & non OECD countries.

II. Data Sources

In the current study the data set comprises on 173 trade partner^v countries of Pakistan. The primary sources of data for this paper are the United Nations Commodity Trade Statistics Database (UN Comtrade database)^{vi} and the Institute for Research on the International Economy Database (CEPII)^{vii}. The time period used in this study is from 1962 to 2008 (47 years). Total export (US dollar) is calculated by adding exports and re-exports for 47 years. The Export data is obtained from online database UN-Comtrade. The 1 digit-level of Standard International Trade Classification Revision one (SITC Rev.1) has been used to estimate Gravity equation of trade for Pakistan's exports at aggregate level. The data on GDP (current million US dollar) are collected from the UN Comtrade and World Bank^{viii} databases. The weighted distances (kilometer) data have been collected from CEPII database. Finally, the information about Dummy Variables (common border, common colonial history, common language and common religion) is taken from CIA^{ix} – the word Fact book.

III. Results and Discussion

Due to log-linear structure of the Gravity Equation of trade, the coefficients of the Gravity Equation are in terms of elasticities or ratios of percentage changes (Bergstrand, 1985). The structure of economic data used in this study for estimation is panel data. A panel data may have group effects, time effects or the both, which are analyzed in this paper by constant coefficients models and One-Way Fixed Effect Models. In constant coefficients model, both intercepts and slopes are assumed to be constant. In this model we can pool all of the data and run an ordinary least squares regression model having robust standard errors^x. This model is sometimes called the pooled TSCS (Time Series Cross Sectional) regression model. There are several strategies for estimating Fixed Effect Models (Balestra, 1995). In this paper we have used two types of One-Way Fixed Effect Model^{xi} i.e. Least Square Dummy Variable (LSDV) Model and Within Effect Model. The LSDV models have constant slopes but intercepts differ according to the cross-sectional (group) unit i.e. country in our case. Although there are no significant temporal effects, there are significant differences among countries in this type of model. The LSDV regression is ordinary least squares (OLS) with dummy variables. A Within Group Effect Model does not need dummy variables, but it uses deviations from group means. Within Effect Model check time variant variables effect such as countries in our case and it transforms variables using group means to avoid dummies (i.e. dummies dropped as they are time invariant variables).

Pooled TSCS Regression (Complete Data Set)

In Table.2 Pooled TSCS Regression results of complete data have been presented. In general, the model has good explanatory power with coefficient of determination (R^2) 0.61 which indicates that 61% of the variations in the exports are explained by the explanatory variables used in the model. All the coefficients of the basic Gravity equation variables are highly statistically significant at 1% level with expected signs. The obtained coefficients of GDPs could be interpreted as income elasticity^{xii} of Pakistan's exports (Lgdpi: supply side) and income elasticity of partner countries imports (Lgdpij: demand side).

TABLE.2: POOLED TSCS REGRESSION
(COMPLETE DATA SET)

Dependent Variable: Log X		
In depended Variables	Coefficients	Estimated Coefficient
Constant	α	13.471 (24.91)**
Lgdpi	β_1	0.328 (11.84)**
Lgdpij	β_2	0.891 (78.06)**
Ld	β_3	-1.279 (25.27)**
1: if common border	β_4	-0.408
1: if common off-language	β_5	(2.47)* 0.578
1: if common colony	β_6	(9.04)** 0.599
1: if common religion	β_7	(8.61)** 0.580
	R^2	(8.79)** 0.61

Robust t statistics in parentheses * significant at 5%, ** significant at 1%

From the supply side, the pooled TSCS regression shows that the log estimate of gross domestic product (gdpi) of the exporting country is 0.328; indicates a 1% rise in income will cause a 0.328% rise in supply of the good, it means if elasticity is less than one; larger countries have less trade as a share of its GDP. Likewise from the demand side, the coefficient for GDPj shows that as income of country j increases, exports of country i to country j increase (Mathyas, 1998). The log estimate of GDPj is 0.891, for 1% increase in income there will be 0.89% increase (almost proportional increase) in the demand of the goods by trade partners of Pakistan, hence larger the partner country, the more it imports from Pakistan.

The home country GDP coefficient is smaller than the partner country GDP coefficient in pooled TSCS regression. This shows large economies tend to spend large amounts of their incomes on imports because they have large incomes. At the same time they also tend to attract large shares of other countries' spending because they produce a wide range of products (Feenstra, 2001). The distance variable is significant with negative sign i.e. the larger the distance of a country from Pakistan the lower will be the exports of Pakistan towards that country, but here the log estimate of distance is greater than what we usually expect. It is -1.279 which means if the distance between Pakistan and any other country increase by 1% the exports decrease by 1.28% (more than proportional decrease) indicating distance variable is highly elastic. The coefficient for the Common land border dummy in pooled TSCS is -0.408 which is highly significant with negative sign. The negative sign is quite unusual but in case of Pakistan it is quite comprehensible. The main causes of Pakistan's low trade (as indicated by negative sign of common border coefficient) with most of its shared border countries can be explained considering its historical relationship with common border countries. There are long-standing territorial and religious differences between Pakistan and India that have existed since 1947. Afghanistan is a least developed country. Similarly a variety of agricultural and non-agricultural commodities are traded illegally at Pak-Iran borders (Sharif and Bashir, 2000). Lately, China became 4th biggest trade partner of Pakistan in 2009 and the main cause behind it is the China-Pakistan FTA which achieved

good results for both countries^{xiii}. Hence, out of four common border countries Pakistan does extensive trade only with one country that is China. The common language dummy variable has a positive coefficient 0.578, significant at the 1 percent level in pooled TSCS indicating exports are about 57% larger between Pakistan and other partner countries using the same language, *ceteris paribus*. This is true as most of Pakistan's exports are with USA and UK. The estimated coefficient of common colony and common religion are also very significant and positive demonstrating Pakistan usually like to trade with countries that belong to British empire and it trades more with Muslim countries. In Table. 3 the One-Way Fixed Effect Models (LSDV model and Within Effect Model) are estimated accounting complete dataset. Here again basic Gravity equation variables are statistically significant at 1% level. Whereas all dummies have expected signs but they are no more significant under LSDV Model and they dropped under Within Effect Model because all dummies are time invariant variables.

TABLE.3: ONE-WAY FIXED EFFECT MODELS
(COMPLETE DATA SET)

Pooled TSCS Regression: OECD & non-OECD Countries

The historical trade direction of Pakistan indicates that it trades more^{xiv} with those countries that are the members of OECD countries i.e. USA, UK and Japan. Hence it is a good idea to figure out the impact of OECD and non-OECD countries on Pakistan's exports. Table 4 provides the results of re-estimating the Gravity equation only for OECD and non-OECD countries instead of complete data set using pooled TSCS regression method. The pooled TSCS results for OECD and non-OECD countries are almost similar except GDP coefficients in case of OECD countries i.e. there is wide difference in the estimated coefficient values of GDP_i and GDP_j. Pakistan has almost zero (0.09) GDP_i effect as an exporter which means Pakistan exports to OECD countries just as much as it exports to any small country being a large country. Whereas, the GDP_j of OECD countries is very high (1.056), indicating a 1% rise in income of OECD countries will cause 1.05 % rise in their imports demand from Pakistan.

TABLE.4: POOLED TSCS REGRESSION
(OECD & NON-OECD COUNTRIES)

Dependent Variable: Log X			
		OECD Countries	Non-OECD Countries
In depended Variables	Coefficients	Estimated Coefficient	
Constant	α	14.172 (10.01)**	12.629 (20.82)**

	R2	0.75	0.54

Robust t statistics in parentheses * significant at 5%; ** significant at 1%

The distance parameter is the same for both set of countries and it's highly significant. The coefficient of common border towards non-OECD countries is positive though it's not significant but there is a future need to investigate this result. The common border dummy has been dropped in case of OECD countries because there is no OECD country that shares border with Pakistan; same is with common colony dummy in case of OECD countries. The official language dummy is very high and highly significant at 1% level indicating Pakistan trade more with those OECD members that share common official language with Pakistan e.g. Australia, Canada, New Zealand, UK and USA. The common religion dummy for OECD countries shows negative sign though only Turkey shares common religion with Pakistan out of all OECD member countries and on top of that Turkey has become OECD member quite recently when Turkey is dropped from the list of OECD countries to check its effect on results, It has been found that the common religion dummy dropped as well. All variables of Gravity equation and dummies are highly significant in case of non-OECD countries except common border that shows expected sign but it's not significant. Moreover, the common colonizer dummy is highly significant for non-OECD countries. Table 5 and 6 presents One-

way Fixed Effect Models (LSDV Model and Within Effect Model) for OECD and non OECD countries. All the gravity equation variables are statistically significant. The dummy of common religion with OECD countries is no more significant in LSDV model estimation. Whereas only common colony and common religion dummies among non-OECD countries remain significant in LSDV model as shown in Table. 6.

IV. Conclusion

The main purpose of this paper is to describe trade composition of Pakistan, to analyze the determinants of Pakistan's bilateral trade and to explicate distribution of Pakistan's trade across its trade partners using 1-Digit Level SITC Rev.1 Classification covering 47 years (1962-2008). The composition of Pakistan's trade indicate trade deficit during the entire period of analysis. However, the major contributor towards trade deficit in recent years is Minerals & Oil sector of Pakistan. For determining bilateral trade and its distribution across countries an augmented Gravity equation of trade is used; we run Panel TSCS regressions on entire countries data, OECD and non-OECD countries. The Gravity equation works well and yields satisfactory results complying with the theoretical background of the model. The basic variables of Gravity equation are significant most of the time. Apparently most unexpected results are from the estimated coefficients of the common border.

Abstract

A crucial aspect of strategic competitive advantage is the interest in the emerging markets as the trend of the past and future decades. Nowadays, the internationalization process models clearly specify the way to be involved in exporting products and establishing the firms in the domestic market prior to developing international strategies. The term 'born global firms' is according to many researches useful tool how to change the thinking of the firm owners and to proceed in the internationalization process as the result of emerging economies. The aim of this article is to define the ways of the successful internationalization process and to highlight the relationship of internationalization and entrepreneurial activity of SMEs in Slovakia. All begins in choosing the perfect partner and target country. Indeed, the different cultures, changing economies and personal involvement, among others the contradictory visions of the managers are the serious barriers of the internationalization.

Introduction

Internationalization takes a place in the area of the world economy mainly as effect of international economic interdependence - hence its dependence between individual parts and ultimately between national economies. Economic activity of one country with the outside world is reflected in the status and activities of other economies and it itself is influenced by what happens beyond its borders. It is clear that internationalized, interdependent and globalization processes are closely linked and mutually reinforced. On the one hand globalization and international economic interdependency are the effects of the internationalization, on the other hand a prerequisite. Companies whether with "local" or "regional" activities must continuously monitor the situation on the market by adapting their activities to the environment. The subject of the scientific contribution is the issue of business internationalization.

The article aims to highlight the relationship of internationalization and entrepreneurial activity of SMEs, to examine factors of internationalization which knowledge is inevitably to manage subjects successfully in the business environment of the EU. Some internationalization models are described to view the ways of spreading international activities to the global world. Emerging economies as the trend of the globalization force even small enterprises to act global, not excluding Slovak firms.

In the article at first we would like to describe the theoretical background of internationalization with focus on Small and Medium Enterprises (SMEs), distinguish principles and expressions and strategies used in internationalization. In our research we examine specifics of internationalization of SMEs in Slovakia, their motives, barriers and process of internationalization. In the end we would like to mention the cultural differences that are very important to comprehend in internationalization process.

Internationalization

Internationalization of SMEs

In a globalizing economy, regions and firms are competing on an international level. The contribution of the internationalization process is unquestionable - economic development of nations, development of national industries, improvement of productivity and creating employment. Small and medium sized enterprises (SMEs) play an important role in this process. Nowadays, internationalization affects all firms large and small which are confronted with international competition.

This internationalization can take many forms, such as import, export, foreign direct investment (FDI) and international collaboration. An important motive for going abroad is the access to know-how or technology. According to recent studies internationalization is often accompanied by improved performance and competitiveness of SMEs. (Flanders DC Study)

Nowadays, small firms find it difficult to overcome the barriers of internationalization, although they have been reduced in the past two decades. Moreover, internationalization is indirectly linked with increasing risk and uncertainty, and not all entrepreneurs are willing to take this risk. On the other hand, the entrepreneurs cope often with limited information about conditions in foreign markets. To overcome these obstacles, small firms often rely on the international experience of their network and progressive communication.

There is still huge difference between small and large firms in the strategic concept. SMEs and their limited sources cause difficulties in strategic decisions. While large firms can choose to internalize certain activities, SMEs often have insufficient resources to do so.

The decision to access foreign market is then a rational decision motivated by external factors. The decision can often be a result of the internal factors such as the vision of the strategic leader or organizational dynamics. Thus the SMEs start to be involved in international operations. „The process of increasing involvement in international operations“ is one of the most useful definitions of internationalization of SME's provided by Gibb. (Gibb and Scott, 1985)

Gibb identifies *the key aspects of SME's internationalization as follows:*

1. They move from being completely domestically oriented firms to having an awareness of international influences. At this stage no more than a simple tracing of events or a defensive response to overseas competition may be relevant,
2. The movement from being a purely domestic firm to undertake some upstream or downstream international activity (either beginning to source from abroad or selling to a foreign market would be included in this, the development of informal international linkages or collaborative ventures),
3. The decision to contact, maintain or expand the existing level of international activities in the case of the firm which is already operating at international level.

Born Global Firms

To become a “born global” firm, a firm can benefit from an accelerated process of accessing competitive advantages across national borders. Quick and early internationalizing of firm value chain activities can provide firms with business models that allow them to be as efficient, effective and competitive as possible right from the start. In this context and in the international terminology there are several expressions to distinguish (TABLE 1).

TABLE 1: TERMINOLOGY OF GLOBAL FIRMS

Born globals	SMEs that started exporting within five years, to at least five countries, including one outside the EU
Born internationals	SMEs that started exporting within five years, to fewer than five countries
Traditional internationalizers	SMEs that started exporting after more than five years, to less than five countries
Born-again globals	SMEs that started exporting after more than five years, to at least five countries, including one outside the EU

Any country considered “developing” is not necessarily an emerging market. Some stand out as having advanced more quickly and made many of the necessary structural changes to ensure economic growth. For the Born Global entrepreneur, these countries potentially offer the greatest opportunity for this type of firm. Broadly, the factors that make these countries attractive are their large populations, large resource bases, large markets and the fact that all of them are regionally powerful with strong geopolitical significance. These countries are actively seeking participation globally, both politically and economically, and acquiring the latest technologies in order to advance their global competitiveness. Not every country can be considered as Born Global. In this case several tips and steps how to become a world leader has been established.

A Study by London Business School (London Business Studies) offers a few- step process for businesses wishing to reach the world level:

- Enterprise should establish a *new fashion technology* very judiciously. Simple copying what others are doing is not enough. The aim is to come up with new ideas on how to beat the competition. Success usually makes the adaptation of the best ideas from the external environment to specific local conditions.
- A crucial role in bringing about change is the highest representative of the company. The highest representative of the company must be able to motivate people in his neighborhood so that the ideas are understood and implemented well.
- *Financial criteria* are misleading regarding the strategic "health" of the company. Warning signals of fundamental problems (arising within three or four years) are non-financial indicators such as customer satisfaction, staff morale and quality.
- *Setting ambitious goals*. It is not enough only to strive for survival. The company will not survive if it does not follow what other businesses do and does not try to be better from them.
- Most companies put *emphasis on performance* - reducing costs, increasing the utilization rate of resources... Ambitious companies try to combine efficiency with effectiveness – by improving skills and abilities necessary to improve the competitive position.
- The core is *strategic innovation*. The only sustainable competitive advantage today is the company's ability to achieve continuous improvement. This means promoting innovation and creative thinking at all levels, especially at middle management level.
- Achieving world class level requires *improvement of skills*. It is necessary to establish long-term, medium- and short- term goals, to find the skills for achieving the goals and then to create a strategy leading to their adoption or developing.
- Good management is the process of finding a *balance and permanent solutions* to a dilemma: achieving effectiveness and efficiency, differentiation and low cost, long-term financial goals and vision, consistency and flexibility.

In order to achieve world class level, an analysis of internationalization potential is needed. This analysis captures the business factors that affect its external activities. Its aim is to determine what the business opportunities are and what strengths the company has to operate on foreign markets.

This internationalization potential consists of following factors:

- *Internationalization business know-how* - includes knowledge of foreign activities and experience with foreign activities. This includes mainly the essential knowledge concerning international issues, for example: contracting, financing foreign activities, issues of transport, customs clearance...
- *Business resources* - includes all the factors which are available for business activities. This may be the physical resources (hardware, personnel and financial resources) and intangible resources which the most essential is know-how (technical, technological, managerial, marketing and internationalization, already mentioned).
- *Business potential* - can be defined by various functional areas such as scientific research, manufacturing, marketing, financial, personnel and others. The company must have a competitive advantage not only to the currently processed markets, but also to potential markets. In general, we can define the following advantages: product, technology, experience, management, raw materials and other resources (capital, money), advantages derived from the domestic market, placing business, capacity utilization.

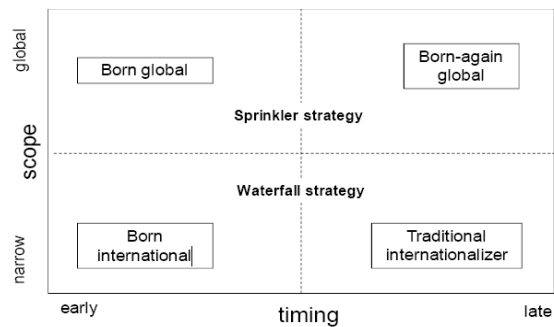

This set of mentioned advantages is not final. For the enterprise, it is important to know which features are relevant to a special area.

Firms that are born global are set up to exploit international market opportunities in almost any sector. These firms destroy the classical forms of entering the international market and they adopt a global approach to the business from the beginning. Born global firms are becoming the driving power of radical innovations in the new economy. They create new markets for new products. Using the business resources and potential may help to become a born global firm.

Internationalization Strategies

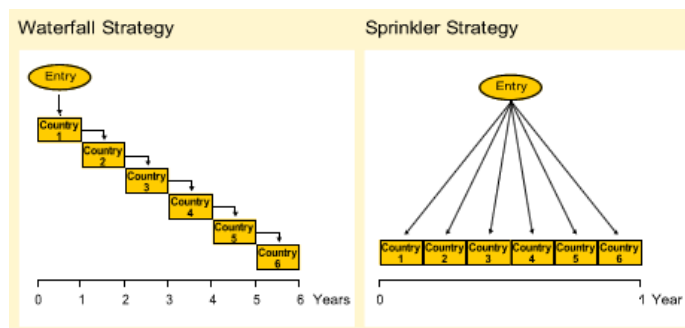

SMEs can also opt for early or late internationalization in their life cycle and use a waterfall or sprinkler strategy. As a result, four types of internationalization strategies can be identified: new firms that start exporting soon after inception (international new ventures) and incumbent firms that start exporting after a substantial number of years of purely domestic growth (late internationalizers), both opting for either simultaneous entry in multiple markets (sprinkler strategy) or entering a single market and consecutively spreading activities over different markets in time (waterfall strategy). Combining scope and timing of internationalization, the typology of internationalization strategies is proposed and presented in FIG. 1. (Kalish and Mahajan and Muller, 1995)

FIG. 1: TYPOLOGY OF INTERNATIONALIZATION STRATEGIES

- *Waterfall model* – model slowly cascading from one country to the next. This model is suitable for entry into countries with different administrative and market structures and different consumption patterns. The advantages of this strategy include better processing market and a stronger focus on the requirements and specificities of individual countries. The disadvantages include the long duration of the procedure and the risk of errors through transforming experience for subsequent processing market.
- *Sprinkler model* - based on the existence of targeting multiple countries at once. It is suitable for products with short life cycles and higher costs for research and development. Important determinant is small and low cost barriers to market entry. Benefits are rapid market penetration of more countries acquiring international image, the potential use of standardization. The disadvantage is often lower intensity processing based on the limited resources at the beginning of a rule, only a weak position in individual markets and often insufficient consideration of market peculiarities.
- *Combined model* - based on existence of similar target groups in the respective markets countries. It takes into account technological and socio-cultural factors, as well as diversification of market structures across countries. Its determinants are different barriers to entry and the various costs of entry.

FIG. 2: TWO MAIN TYPES OF INTERNATIONALIZATION STRATEGIES

Especially for starting SMEs, a global approach is often not an option. SMEs are more likely to gradually move from a successful domestic launch towards entering more advanced countries and in a later stage to less developed economies. Using a sprinkler strategy, firms can maximize revenues by exploiting economies of scale in R&D and manufacturing. Moreover, a sprinkler strategy may pre-empt competitive moves in some countries, thus maximizing sales and market share. Entering markets before competitors do may result in substantial first mover advantages. From the interpretation of the comparative statics and dynamics of the model, Kalish et al. (1995) found the following market conditions to favor waterfall strategies: (Kalish and Mahajan and Muller, 1995)

- Very long life cycle of the product
- Small foreign markets
- Slow growth in the foreign markets
- Low innovativeness in the foreign market
- High fixed cost of entry into the foreign market
- Weak or no competitors in the foreign markets
- Co-operative behavior among competitors

Moreover, possible benefits of delayed internationalization are improved learning by doing resulting in higher productivity and a stronger competitive position. There is substantial evidence that only the more productive firms export and survive in export markets, i.e. those firms that have reached a certain productivity level necessary to compete in international markets (Bernard, Jensen and Schott, 1999).

From the considerations above it follows that choosing a sprinkler or a waterfall strategy involves a strong tradeoff between sales maximization and risk minimization. Although a sprinkler strategy may be more appropriate in many cases, managers might favor a waterfall strategy as a way to limit the risk of failure.

Method

In the article the theoretical background of internationalization was described according to the summarized facts and analyzed theory. The focus is on the models used in decision-making processes in SMEs. In our research we examine specifics of internationalization of SMEs in Slovakia, their motives, barriers and process of internationalization. Some internationalization models are analyzed to view the ways of spreading international activities of domestic enterprises to the global world.

To solve a defined problem a method of analysis of the theory was implemented in the plane of current theory and current approaches to the internationalization. Several “modern” expressions were explained in order to understand the situation in the markets. Synthesis method allows summarizing current knowledge of the internationally active companies. Several surveys concerning the issue of internationalization of Slovak SMEs were studied and with help of researches we gathered useful information about Slovak perception of the global world.

International journals, domestic researches, professional articles have helped to complete and fulfill the aim of this article, as following surveys, researches, reports and agencies:

- Enterprise Europe Network
- Hofstede G. Culture’s Consequences
- NADSME: National Agency for Development of Small and Medium Enterprises
- SARIO: The Slovak Investment and Trade Development Agency
- Several reports on business environment in Slovakia

Results and Discussion

In this part we would like to describe internationalization of SMEs in Slovakia. We primarily focus on three areas:

- Specifics of internationalization of SMEs in Slovakia
- Internationalization process
- Intercultural management

Specifics of internationalization of SMEs in Slovakia

The importance of the involvement of Slovak companies to foreign trade relations is undeniable. In addition to economic profit, internationalization may also bring social profit to strengthen its position on the domestic market and thus increase to consolidate or increase their competitive advantage.

Internationalization of firms by entry to the foreign market is a process which precedes responsible preparation in the form of a range of activities and activities associated with the determination of this entry. Increased demands on the internationalization process resulting from the geographical distance of foreign market, language barriers, cultural and social differences, or from not knowing the market.

In Slovakia, exporting is considered a traditional way of internationalization however in recent decades, internationalization has become much more differentiated business activities: foreign partnership, foreign investment and cross clustering represent viable ways to facilitate the exchange of knowledge and technology and to strengthen the internationalization strategies.

According to the recent research about internationalism of small and medium-sized enterprises (Enterprise Europe Network) the most common form of internationalization is the relationship consists of aid from abroad, which represented 30% of SMEs. The second is the predominant form of internationalization export represented 18% of SMEs. The other three percent rated SMEs are relations of cooperation, primarily with foreign SMEs and another 3% have set up subordinate company or branch abroad.

Motives of internationalization are variable, firms are looking for access to know-how or new technology, for new capital, for new approach of work, for additional production capacity, for ways how to lower high production costs on the domestic market, to access to new and larger markets for goods / services, to have less strict laws and regulations as on the domestic market. To obtain the "know-how" and / or new technology is the most common motive to go abroad.

Generally small countries with small domestic markets are more internationalized. Size of the domestic market is very strong factor for internationalization. SMEs with specialized production or high volume production in a small country then soon realize that the needs of the domestic market for its business do not comply. Tendency to increase specialization global mean snagging more SMEs in international trade. Medium-sized enterprises are more interested in international activities than small and micro enterprises. Only 17% of micro-exports, while the medium-sized enterprises export 51%.

A study by Enterprise Europe Network reported prominent findings that there is a direct relationship between internationalization and increasing performance of SMEs - international activities drive growth, enhance competitiveness and promote long-term sustainability of companies. The study highlighted two key points, to increase economic prosperity through international activities of SMEs and public support for playing a vital role in promoting greater internationalization.

Several Slovak firms pointed out the internal or external barriers of internationalization. The most common internal barrier to appear "high cost of internationalization" (setting up a business abroad - 24%). Nevertheless, over a third of firms indicated that knows no internal barriers. Some point to lack of internal management planning in relation to the internationalization process. External barriers also occur too often. The most common external barrier to the internationalization of the "existing legislation and regulation" cited by 29% of SMEs with subsidiaries abroad.

There is a strong need for policies with a holistic approach aimed at individual SMEs. EU countries generally have a wide range of policy measures to support the internationalization of SMEs, especially in exports and foreign direct investment. Include the basic information services to the company specifically targeted (personalized advice to support exports).

TABLE 2: MATRIX OF STRATEGY RECOMMENDATION BY SOLBERG

Level of international experiences	Level of market globalization		
	Local Market	Globalizing Market	Global Market
Adult Company	Enter into new industry	Prepare yourself for globalization	Strengthen your global position
Adolescent Company	Strengthen your position in export market	Consider expansion on international market	Look for global alliances
Immature Company	Stay at home	Look for market gaps on international markets	Get ready for merger

Application of the Solberg Matrix (TABLE 2) to Slovak SMEs can be concluded that in terms of experiencing the international level companies can be classified as immature or adolescent. Solberg matrix indicates that companies in Slovakia will have to (in order of their development and existence) internationalize its business, actively penetrate international markets, or cooperate with others in the international environment

Internationalization Process

The SMEs in Slovakia have two ways how to deal with the process of internationalization:

- to monitor all aspects of internationalization and modify steadily its strategy and behavior,
- actively join in internationalization process.

The first approach has a character of passive confirmation to internationalization’s trends. This way is chosen mostly by small firms in Slovakia which want to produce for local markets or firms that do not have enough money, qualified staff or essential know-how to enter international markets. The second approach assumes active joining in internationalization process. This strategy does not see internationalization as a threat of its entrepreneurial activities but perceives it as an opportunity. This approach is as a rule connected with a change from a national to a multinational company. Competitiveness of small and medium sized enterprises in Slovakia is an effect of a number of economic, social and even cultural factors. The SMEs potential is a resultant both of the behavior of entrepreneurs themselves and the state, as well as the so-called external conditions.

There are several problems (Lesáková, 2001) that Slovak firms have to cope with, among them external factors such as:

- instability of the legal system and ineffective enforcement of the law,
- high financial burdens imposed by the state like taxes and social security contributions,
- lack of capital and as a consequence - limited investment possibilities,
- expensive loans, complicated credit procedures,
- red tape burdens.

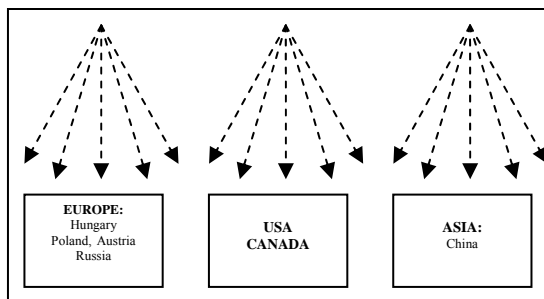

FIG.3: SPRINKLER MODEL ADAPTED TO SLOVAKIA

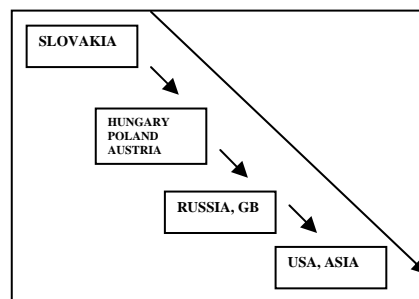

FIG.4: WATERFALL MODEL ADAPTED TO SLOVAKIA

The Slovak SMEs are more likely to move step by step from the domestic country (where they have strong position) to the foreign markets with the aspect of the geographical distance. Differentiated business activities as foreign partnership, foreign investment and cross clustering may help to strengthen the internationalization strategies across the borders. From this point of view the waterfall strategy (FIG. 4) is the most common way for Slovak enterprises how to reach the international level. Essential success factor of SMEs to penetrate foreign markets is the right timing for entering this market. Among additional key success factors of internationalization of Slovak SMEs were some others included: improving management skills, systematic and purposeful planning, strategic use of appropriate intermediaries and foreign partners, improving technical capabilities and skills, increasing the company's ability to quickly identify changes and to respond to them. From the perspective of internationally active company managerial skills and international orientation are crucial influences. And all the mentioned factors need to be improved in order to move Slovak firms from the domestic markets to the international.

Multicultural management

The growing internationalization of business brings important question of coping with intercultural differences. First it is necessary to clarifying the terms "multicultural" and "intercultural". In practice, but also in literature it is often consider as a synonyms, mutual substitution.

According to the Oxford Dictionary, the word "multicultural" refers to the creation and existence of several of cultural or ethnic groups within a society and the word "intercultural" refers to taking place between cultures, or derived from different cultures. The term "intercultural" has become particularly more fashionable in scientific circles over the last years.

Multicultural approach is not only about creating attitudes towards members of other nations but especially in the use of knowledge, acceptance and tolerance of other cultures to degrade barriers to increasing the economic efficiency costs of people

Number of international researches (the best-known is G. Hofstede's research), shows the existence of significant cultural differences across countries. Knowledge and respect of cultural differences will also have a significant impact on the success of managerial work mainly in companies operating in the international environment and international work teams. From this perspective, understanding allows them to avoid some narrow places and problems arising from cultural ignorance and cultural blindness.

Geert Hofstede's research gives us insights into other cultures and their specifics in five dimensions:

- Power Distance
- Individualism
- Masculinity
- Uncertainty Avoidance
- Long-Term Orientation

Slovak culture has some specifics that need to be mention. According to Hofstede studies and observation we need to point out, that especially in two dimension (masculinity, power distance) Slovakia has very strong results in comparison to other selected countries (GRAPH 1, GRAPH 2).

GRAPH 1: HIGH MASCULINITY

GRAPH 2: HIGH POWER DISTANCE

These results should me not only interested to Slovak firms; understanding of culture specifics should reduce level of frustration, anxiety, and concern in any case.

Cultural influences are reflected in many ways, in choice of organizational cultures, in degree of emphasis on the individual management functions, in leadership style, in communication, in method of decision, in ways of motivating people in order to achieve common goals.

In Slovakia, the number of international teams has expanded proportionally with foreign investors (Začková, in Trend). Foreign investors used to almost always bring not only their managers, but also standards of corporate culture, which they proved in the parent company or other foreign locations.

Standards management styles are relatively well-defined formal framework, this solid content structures is often lacking. Workers in foreign company that establishes itself on the Slovak market, usually fairly quickly accepted as the style of dress formality or internal communication. But it lacks content. People do not understand the structures presented a rather pretend that they are all clear. Some foreign firms prefer sterile relationships, in working practices is missing the creation of open relations, taking into account the features of people, including emotions and ways of survival situations typical for them.

Therefore specialists and consultants in intercultural management recommend to managers of multinational companies, first to invest in mutual understanding of individuals, work teams across the company. This is the only way to avoid communication problems. They recommend preparation of international partnership. There are many possibilities of preparation like informal meetings, joint work on the mini-project, visiting the parent company abroad, social events or training activities where both sides need to speak openly about their expectations, differences, similarities and boundaries of tolerance. Claims for understanding, acceptance of tradition, rituals and values must be on both sides.

Conclusion

As confirmed by the results of the empirical research, the companies (before entering the new target market) analyze the market and the decision about entering the market is made on the basis of pre-defined criteria. The most important selection criteria are the economic status and situation in the country. The respondents reported as other criteria the geographical distance and effective conditions for market operation. The fact that geographic distance is an important factor in choosing a market is supported by the reality that geographically close countries are major commercial importers of Slovakia (Germany, Czech Republic, Austria). Among major trading partners in terms of export volume, are countries like Ukraine and Russia, countries geographically close but economically less stable with heavier convenience of operation conditions in these markets. According to the survey results, these factors (economic stability, favorable conditions for market operation) were perceived as very important, may be the reason why Slovak business activities have not yet been directed to these territories. Interesting fact is that socio-cultural proximity of the respondents is not considered as significant factor when deciding which market to enter. This may mean that Slovak companies operating in foreign markets are relatively well marketing and personnel equipped, with facilities capable enough to analyze the external environmental conditions (external market), which also include socio-cultural cognition of the country's conditions.

Several options about operating in a foreign market are defined. Decision-making process of firms, therefore, also includes deciding on the form of exposure to foreign market. Clearly the most common form of business activity in foreign markets, according to findings is systematic export activity. Other Slovak firms prefer to operate in foreign market in the form of irregular, sporadic exports.

The researches have shown that motives of internationalization are varying. The most common motive to go abroad is to obtain specific know-how and new technology. Different factors could be searching for new capital, for new approach of work, for ways how to lower high production costs on the domestic market, to access to new and larger markets for goods / services, to have less strict laws and regulations as on the domestic market.

To sum up, Slovak companies have gradually started to open international markets in a globalized economic world and irregular export started to change to purposeful action in a foreign market through export business methods. Internationalization is much more than exporting and importing. Activities such as cross-border cooperation, communication and networking are still important. This tendency is seen as a basic structural feature and is therefore expected to be strong in the long run. Substantial amount of SMEs use the internationalization in order to gain access to know-how, technology or work. Internet and new means for rapid and easy communication and cooperation have become key factors in facilitating complex partnerships.

The contribution of local governments to create business advantage. The case of Puerto Vallarta, Jalisco.

*Pablo Pineda-Ortega, ppinedao@yahoo.com.mx
Universidad de Guadalajara, Mexico.*

Abstract

The purpose of this essay is to show that despite the institutional weaknesses that characterize local governments in Latin America, in the area of promoting economic development do exist interesting experiences with a reasonable level of success, such as those discussed referring to a Mexican state of Jalisco. Also stresses that they face structural problems that prevent cutting to full advantage.

The approach of the study farm in certain indicators for the area of local economic promotion which have been defined in a scheme called local public policy from the Local Agenda. The study takes a comparative approach. The greatest value of the test is based on a scheme proposed little studied to assess local public policies, and that despite their novelty, and has important sources of information on their indicators.

1. Introduction.

With a very rich history in the process of institutional reform of the public system, Mexico is now undergoing a consolidation phase of its decentralization policy, through which they seek to strengthen the powers of local government bodies.

With this strategy, beginning with a group of constitutional reforms in 1982 which gives greater powers to the municipality, the governing body of more direct connections with citizens, laid the groundwork to reverse a process of concentration of national public life, which wine brewing since the triumph of the revolution that the country suffered in the second decade of last century.

As is known, the centralization of political life in Mexico was mainly due to the claim of the new governments of the Revolution to assert and consolidate its power over local chiefdoms created under the boxes of political control and military generals who settled in local plazas exercised the triumph of the revolution. In that vein, national political history in the postrevolutionary period, at least in its early decades, can be characterized as a process of concentration of political power at the expense of local power-spaces with very different degrees of legitimacy; often went beyond the formal powers that the Constitution gave the central government.

In this context, such reforms of 1982 marked a process of redistribution of public powers, against the public life of previous decades, sought to recognize the dynamism and initiatives of local political and economic actors. This atmosphere also helped, of course, a renewed wave of stagnant political system, wave led by prominent democratic figures, both from within the ruling party and outside it.

Without doubt, one of the most egregious levels of this new atmosphere of dynamism of local areas has to do with the actions of local governments in promoting economic. These actions, however, remain inadequate, and in this essay analyzes the main reasons. In that vein, the next section reviews very briefly the legal-political structure of the country and relate their instruments of public planning to study in the third section, the Economic Development proposals set out in development plans of municipalities selected media the state of Jalisco. Finally, the fourth section reviews the federal strategy for coordination of public programs, the call from the Local Agenda, noting, for the municipality of Puerto Vallarta, how this mechanism aims to increase the effectiveness of economic promotion programs offered by different levels of government.

2. Legal structure policy, planning tools and relevant axes.

There is a wide discussion about the benefits of both centralized systems like the Federalists, although the literature and contemporary institutional political practices show a general trend whereby national governments are competent defense responsibilities, trade and, more generally, foreign affairs, regulation of migration processes and industrial development as well as communications and transport. For its part, the interim government under them-often on a shared basis, among other responsibilities, the agriculture, forestry, regional infrastructure, and environmental protection, and finally to local areas they are responsible for police and fire, sanitation and transport and utilities infrastructure, among others (Cabrera, 2004: 347).

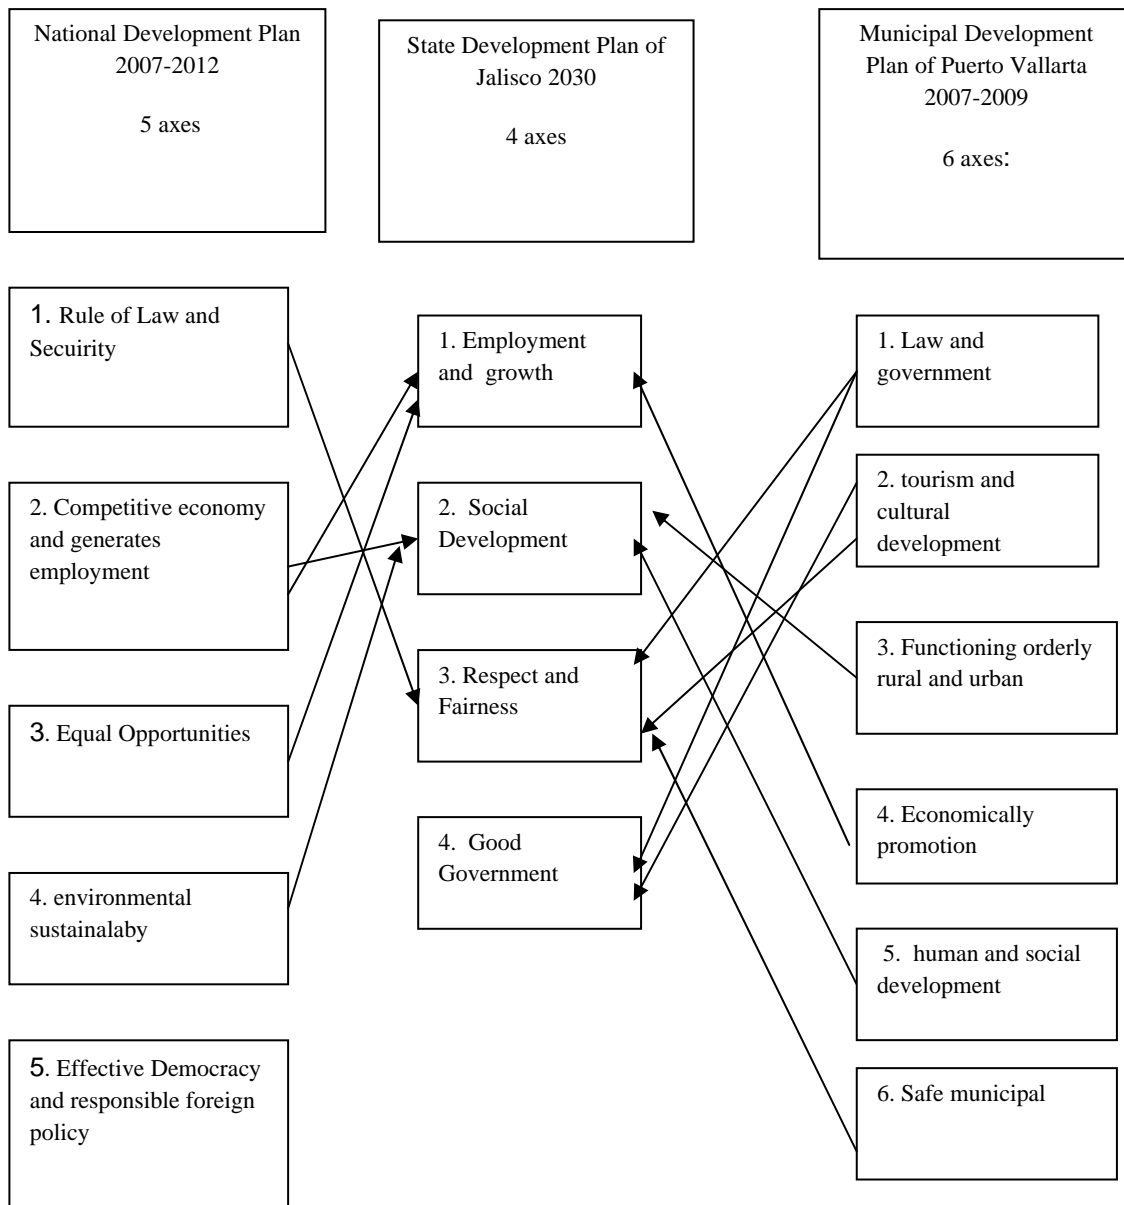

In this general trend is part of Mexico, whose constitution defines the country's political legal structure as a representative republic, democratic, consisting of free and sovereign States in all matters concerning their internal government, but united in a federation, for what will states, the Constitution says they "adopt for their internal system, the republican form of government, representative, popular, based on territorial division and its political and administrative organization the Free City." Finally, the second section of Article 115 of the Constitution confers on them legal status and powers of municipalities to manage their assets according to law.

In this context, a growing number of municipalities in Mexico, just under 2,500 in total, have been expanding their range of actions beyond those traditionally undertaken, relating to public services (water supply, street lighting, clean ...) and engaging in activities to promote economic and social development mainly in the recent past had been the responsibility of other levels of government. They have also developed environmental sustainability policies and actions to improve the efficiency and effectiveness of its governance policies and strengthen transparency.

The fact that since the eighties there an institutional process of development planning and involving the three levels of government (called National Democratic Planning System) provides the definition of public priorities and aligning them between the three levels of government. Such a system provides the definition of a Development Plan for each of the three levels of government, same as, in theory, enable the coordination of policy actions. Needless to say, however, that planning exercises in Mexico have seen a maturation process with ups and downs and have not been exempt from detours and disruptions, and even of today's small towns continue to operate without its plan due to limitations financial resources and qualified personnel. Notwithstanding the foregoing, it should be noted that the law makes it obligatory public programs that adhere to the provisions of the development plans of their respective levels of government that, to varying degrees, has helped reduce the spread and inconsistencies the actions of the various levels of government.

Figure 1 presents the alignment of priorities, or backbones-established policy in the planning of the three branches of government in Mexico for the period 2007-2009 (or 2012, whichever is applicable), and where the municipal level is taken as concerning our study municipality, Puerto Vallarta, one of the five boroughs means considered in this essay. The federal government and the state last in office for 6 years while only three municipalities, which is why the current management of the municipalities of study corresponds only to the first half of the management of the other two branches of government.

FIGURE 1. ALIGNMENT OF PLANNING IN THE THREE BRANCHES OF GOVERNMENT. PUERTO VALLARTA.

As shown in the graph, the axes are relevant to this study, the national plan, the competitive economy of Employment, State Plan, the Employment and Corporate Governance, and the municipal plan, the Economic Development. In short, the axis federal (national) states:

Achieving greater competitiveness and generate more and better jobs is central to sustainable human development. This requires macroeconomic stability, increase investment rates, an efficient structure of property rights and a clear delineation of state involvement in the economy.

For its part, the state axis arises:

Making Jalisco families achieve a greater purchasing power through the state's economic development, creation and strengthening value chains, generating more higher-paying jobs and opportunities for growth for all.

Finally, the municipal axis is proposed:

Support Economic Development of the Industry, trade and services, encourage domestic and foreign tourism in the municipality and strengthen the agricultural potential of the municipality. The truth is that while federal level each of the broad lines of the National Plan are systematically divided into programs that address the different ministries that make up the Federal Executive statewide this year is less systematic and level of implementation varies each of the 31 states that divide the country. As is the lowest order of government, municipal, here the level of systematization and implementation of the plan through specific programs is even more scattered and uneven, and uneven are the dimensions and capacities of the municipalities themselves. Suffice it to say that while the municipalities of the largest municipalities, mainly but not only the capital cities of states have significant budgets and qualified personnel in key areas, smaller municipalities, mostly rural with very limited capacities, have budgets do not allow minimally meet the basic needs of its population. See Table 1, the large spread between the towns of Mexico.

TABLE 1. POPULATION AND MUNICIPALITIES IN MEXICO BY RANGES.

Ranges of population	total population, 2000	%	Municipalities in the range of population	%
0-14,999	8'286,687	8.50	1,407	57.55
15,000-49,999	18'748,413	19.23	684	27.98
50,000-99,999	12'729,139	13.06	187	7.65
100,000-499,999	29'424,500	30.18	135	5.52
500,000-999,999	13'465,410	14.12	21	0.86
1,000,000 y más	14'527,286	14.90	11	0.45

Source: Arroyo, 2007: 106, taken from Censo General de Población y Vivienda, 2000.

In any case, the amplitude of the objectives of each of the broad lines of the various development plans, its scope needs a variety of instruments and, most desirably, a reasonable level of coordination in the actions of the three levels of government . Already said there are legal instruments for that purpose, however, its functionality and effectiveness vary greatly in each state experience, and even within each state coordination can also be uneven.

3. Jalisco Municipalities and media promotion of their economic development plans.

The state of Jalisco, one of the 31 policies that divides Mexico, is among the lowest states of marginalization and their population size and GDP exceeded only by the State of Mexico and the capital country, although in per capita terms, there are other states, additional to those that are above Jalisco. that the country has a megalopolis in the central region consists of 8 metropolitan areas of different size, where more than 23 million people, there are also six cities of more than one million people with just over 11 million people, 18 cities average between 500 thousand and a million inhabitants and 37 cities conurbations not mean, of between 100 thousand and 500 thousand inhabitants. With a population of 110 million inhabitants, therefore, Mexico is a predominantly urban, but with a rural sector of some importance.

As nationally, also inside the state has a strong centralization of economic life, to the extent that the majority of its population is concentrated in the capital city, Guadalajara and its suburbs, which covers 6 municipalities. Nonetheless, among the 125 municipalities of the state has a small number of them that are considered urban average, same as have about 100 000 inhabitants or more and, therefore, offer an interesting

example and representative of what The medium-sized municipalities can offer to society in terms of economic promotion.

Table 2 shows the basic data of these municipalities in terms of population levels of marginalization and suffering, as is known, the marginality index measures the level of deprivation of basic services to a population, especially-but not exclusively, on health, housing and literacy. As seen in him the degree of deprivation in these municipalities is extremely worrying, but within them there are areas with very high poverty rates because they all have a heterogeneous spatial structure.

TABLE 2. BASIC SOCIAL INDICATORS. SELECTED MUNICIPALITIES OF JALISCO.

Municipality	2005 Total Population*	% Population entitled to health services	% Population 15 years and more illiterate	Average grade of schooling% occupied private dwellings that have	% occupied private dwellings that have piped water to the public network	% Occupied private dwellings that have drainage	% Occupied private dwellings that have power	Degree of marginalization
Tepatitlán de Morelos	128,924	51.43	8.28	6.89	90.36	94.86	96.72	Very low
Lagos Moreno	142,633	43.9	9.69	6.98	87.02	85.87	95.66	low
Puerto Vallarta	240,019	59.11	3.6	8.82	91.05	93.44	94	Very low
Zapotlán Grande El	99,966	57.87	5.79	8.9	95.69	96.67	96.74	Very low
Ocotlán	91,818	61.26	6.06	7.94	88.71	96.40	97.59	Very low

Note: Data for 2008 estimated by COEP.

Source: Based on data from the Marginalization Index, 2005 and II CONAPO Census of Population and Housing, 2005 INEGI Source: Second Report of the Government of the State of Jalisco, 2009.

The brief characterization of the municipalities of study showing the picture can understand the need for targeted public actions to its economic development since the end of the day, the creation and preservation of jobs associated with it results in the lowering of rates marginalization and therefore, in raising social welfare.

Already said that Mexico's law in the three branches of government requires the start of each design management plan of government, and in this sense, Table 3 specifies which of the municipalities covered by this study which type of plan action for economic advancement. The table includes in its second column a figure that refers to the "Book from Local" on which we will later.

As is the town of Tepatitlán, economic promotion measures are under Axis Economic Development, and Lagos for the route in question is called Lagos de Moreno competitive, globalized and Equity, on the other hand, if Puerto Vallarta these actions are covered by two of its axes, the Tourism and Cultural Development and the Municipal Economic Development. Finally, to Ocotlán the most relevant actions are included in both the center Employment Promotion and prevent migration and in that of encouraging public investment.

TABLE 3. ECONOMIC DEVELOPMENT AREAS CONSIDERED

<i>Municipio</i>	<i>A. L.</i>	<i>Tepatitlán</i>	<i>Lagos</i>	<i>Vallarta</i>	<i>Ocotlán</i>
Area					
Promoting MSMEs	2.1, 2.8				&
Training and technical assistance	2.4, 2.1		&	&	
Production infrastructure and services	2.6	&	&	&	&
Strategic business information	2.1, 2.2, 2.8		&	&	&
Information and channels of interaction in the labor market	2.4, 2.7	&			
Attracting investment schemes	2.1, 2.6	&	&	&	&
Administrative Simplification	1.1, 1.10				
External sector growth	2.1, 2.8		&		
Promotion of business and / or local products	2.8	&	&		&
Promotion of tourism	2.5	&		&	&
Agricultural support	2.7	&	&	&	&

For Tepatitlán relevant strategies proposed for the reference axis are as follows: 4.1 To support the economic development of the Industry, Commerce and Services, 4.2 Encourage domestic and foreign tourism; 4.3 Strengthen the Agricultural Potential, 4.4 Source Generation Employment for citizenship and 4.5 Safeguarding Fair Wage.

The Lagos Plan includes programs with varying degrees of relevance for the economic advancement on three broad themes, namely: the Productivity and Competitiveness in the Field of Population and Labour Market and eventually into the Infrastructure and Services Municipal Basic. The first axis relevant programs are: Program 1 (page 1) Technological Development, with 5 strategies; P.2 Enterprise Development and Strengthening, with 4 strategies; P. 3 Calls a Business Business Missions with 3 strategies, and finally, P. 4 Improvement of Agricultural Policies in the municipality with 15 strategies. In the workplace relevant programs are: P.1 Training and Placement of Unemployed Labour, with 4 strategies. Finally, the relevant program of municipal infrastructure and services field is the Mobility and Transportation Routes.

Of the two relevant axes of Puerto Vallarta and plan due to its known tourist vocation, you're totally focused on this sector, and it highlights the following strategies: Negotiating for tourism development, strengthening

organizational capacity and Valuation of assets. For his part, said other axis, more generally, includes among other lines of work: promoting the competitiveness of economic activities, best business practices and promote innovation.

With respect to Ocotlan, each of the five areas that make up your Plan (two of which have a marked relevance to our topic and are listed above) are broken down in the same sections each. The first one is called the Economic Development and it's where you get the relevant information.

As shown in Table 3, the efforts of municipalities in Jalisco media to support and promote micro, small and medium enterprises, and whose experience can reasonably be generalized to other such municipalities in the country, is reduced, which is explained in large part because national policy exists for such an ad hoc way, the SME Fund, due to which local governments prefer to use this support to undertake their own initiatives. Such is indeed the case study of our town, Puerto Vallarta, on whose plan does not contemplate actions of this nature.

Municipal actions concerning technical assistance and training are especially limited, reflecting the relatively high technical level that they need for institutional capacity that have municipalities. It also seems that there is no interest by local governments to undertake this task because the SME and operates the Global Fund activities in this field. Notwithstanding the foregoing, Puerto Vallarta is one of only two municipalities which does provide for this initiative.

The creation of infrastructure for production and service itself is a widespread practice among municipalities means, but its presence is explained largely because investment spending in general, transverse effects in other public policies, and that gives greater weight the political sensitivity of the population, and therefore the demand for such actions. In general, municipalities in Mexico means allocated to investment spending just under 30 percent of its total budget, and the bulk of the costs of investment in its territory from state initiatives. As shown in the respective line, Puerto Vallarta also includes activities in this area.

The development of an area of strategic information for business is a public service in the municipalities still nascent media, and it seems that so far only been developed systematically municipalities with a very clear economic vocation, as happens in Puerto Vallarta tourism area. Undoubtedly, the recent efforts of strategic planning (with very mixed success) requires the relevant legislation, are contributing to these issues to be considered further by local governments.

Local management in the workplace, such as the establishment of institutional spaces for more efficient and fluid information in labor markets, as shown in the table are not very handy, and certainly are not in Puerto Vallarta. Again, this can be explained because there are actions in the matter of some success in other levels of government. On this, see the relevant item in Table 5.

As shown in the table of analysis, virtually all considered municipal development plans provide for promotion of investment, local or foreign, a fact which accounts for local government recognition of the important role they play in the field. Suffice it to say that the Mexican Institute for Competitiveness has been established that there are ten major variables affecting the attraction of investment, and of these 5 are variables in which municipalities have an impact. Showing high levels Puerto Vallarta in this sector, mostly but not exclusively in the field of tourism, due in part to this promotion.

The issue of administrative simplification is another displayed little analysis plans, and not in the Puerto Vallarta, if it occurs in all the generic reference to improve government performance. Here there are a systematic federal government mainly on administrative deregulation, which has been undertaken through a program that includes affiliation to it, if you are interested, the municipal governments. The program in question is called Rapid Business Opening.

What actions have called External Sector Growth concerns that whole set of initiatives aimed at the promotion abroad of local production (in both goods and services) and unlike other similar items, such as investment promotion and promotion and business and / or local products, targeted actions here refer exclusively to international markets. As seen in this plane the actions of municipal governments are almost nonexistent, and there is none in the planning of Puerto Vallarta, even though the index of economic openness in the country is the highest in the continent. This means that actions in this area are mostly undertaken in the other two levels of government, and especially at the federal level.

In the promotion of business and / or local products, as seen, most of the municipalities considering taking action in this area, with the important exception of Puerto Vallarta. The truth is that in this field, the local public actions are increasing, and often, they are coordinated with those developed at other levels of government. As with other policies, here also in the corresponding area there is a window that undertakes both activities promoted by local government and serves as an intermediate instance of programs of other levels of government.

The last two planes, Tourism Promotion and Support to the Agricultural Sector, have been for some time, areas where local governments play a very visible effort. In particular, as is understandable, the first actions are more systematic in municipalities such as Puerto Vallarta, have a vocation known in the industry, but gradually the media in the country towns have been recognizing the benefits of strengthening this sector . Moreover, agriculture has been an area of special interest because in this sector is a significant percentage of the population of those municipalities.

4. As a conclusion, the Agenda from the Local and municipal economic promotion in Jalisco.

The previous section discussed which areas of economic promotion undertaken by the municipalities of study, as reported in their respective Municipal Development Plan, and Table 3 presents this information in a more agile as it looks, this table includes a first column for the call from the Local Agenda.

The above Agenda is a federal government strategy whereby it seeks to strengthen the response capacity of local governments to specific problems that they themselves selected. As a noun, it establishes a coordination between the three levels of government through which they reached agreement on what issues in particular are facing. In that vein the first column states which area of the Agenda is for the policy action contemplated in the municipal plan.

For its part, Table 4 presents the economic theme of the Agenda and the breakdown of it in specific areas, as seen it also need some federal programs to address identified each of the areas in which decomposes the economic field, programs that are envisioned in the strategies defined in the framework of the Agenda.

The very fact that municipalities have full autonomy to define their policies, and means that in practice this happens, they are free to take action in a coordinated, independent, complementary and even counter to the proposals in the other two levels of government. The test shows that this freedom is expressed in effect on the definition of economic promotion measures do not always coincide and that some of the actions they are absent because there are already fairly consolidated programs in the other two branches of government. In particular, one of the best examples is the so-called federal government's Small Business Fund, whose coverage and diversification has led municipalities to take up such a program instead of offering shares in this field.

This does not mean, however, that coordination between the three levels of government is not efficient and that there can be significant improvements in it. Although from the Local Agenda offers the soundest strategy coordination, their jobs are still young (it dates from 2004) and the municipalities they enjoy full freedom to join or not to her.

In any case, the paucity of local public resources, the ban on immediate reelection of the incumbent president (which prevents giving continuity to policy), the generally low professional level of municipal officials, and inadequate capacity-derived of the above, to define and implement appropriate measures for economic promotion, make this an area of local public policies in Mexico are totally inadequate development. From another point of view, however, this presents an important window of opportunity for municipal public affairs and diversity policies under development plans realize the interest in advancing the field.

Finally, even if you said the law gives a mandatory plans, to the extent that the programming of expenditure should outline how it corresponds with the relevant development plan prevails in practice-wide latitude to define and budget year that allows us to understand that there is no full consistency between the plan and formulated specific policies that are exercised in each budget year.

TABLE 4. THE ECONOMIC FIELD OF AGENDA FROM THE LOCAL AND FEDERAL PROGRAMS FOR IT.

2.1 Innovative economic alternatives	National Support Fund for Solidarity companies, Productive Options Program, etc
2.2 Promoter productive vocations	Care Program Agricultural Workers, etc.
2.3 Responsibility for promoting the supply of basic commodities	Rural Supply Program, Program Tortilla Microrregiones Program: Supply and Collection, etc.
2.4 Promoter of local job training program for the Support of Training	Employment Support Program, etc.
2.5 Promoting tourism	Magical Towns Programme, etc
2.6 communicate internally and externally	Roads Program, Roads and Bridges, etc
2.7 Promoter of the agricultural sector	Human Development Program Opportunities, etc.
2.8 Promoter of industry, commerce and services	Support Programme for Competitiveness for industries, etc.

Two decades of transformation in Central and Eastern European countries

Koloman Ivanicka, Slovak University of Technology in Bratislava, Slovak Republic, koloman.ivanicka@stuba.sk

Danes Brzica, Slovak Academy of Sciences, Slovak Republic, danes.brzica@savba.sk

Abstract

The transition of the CEEC (Central European countries) in last decade was first marked by high growth, large foreign direct investment and improvement of the quality of life of the population. The economic crises, however, have shown much vulnerability of the countries in the region. These vulnerabilities are partly the consequence of the socialist system heritage. Some researchers, however, had expressed the opinion, that the economic model following the Washington consensus caused also the deep economic problems during the crises.

The present paper shows the basic economic differences among the countries in the region. Although the countries have the common socialist heritage, now some of them are the members of European Union, while others have only some bilateral agreement with EU. Paper also discusses the alternative economic viewpoints on the transition in the light of the recent economic crises and tries to outline the major tendencies for future.

Introduction

Extensive literature exists on transformation in Central and Eastern Europe since the time it begun in early 1990s. Initial papers had stressed more some specific issues either thematically or regionally. Most of the papers written on the topic analyzed privatization as a crucial transformation step important both from political and economic perspectives. Two decades of transformation in countries of Central Europe (CEECs) have had an enormous impact on socio-economic development in these countries. Naturally, the results differ substantially. Some countries have been able to harmonize political will with interest of main political and economic actors; some others have been less successful. Nevertheless, the general view of reforms and transformation is positive.

The basic principles of transformation were stated by Washington consensus (Loréal 2010) that was the set of recommendation developed by Williamson specifically for the needs of Latin American economies. The principles included: fiscal policy discipline, redirection of the public spending, tax reform, determination of the interest rates by market, competitive exchange rates, trade liberalization, liberalization of inward foreign direct investment, privatization of state enterprises, deregulation – abolition of regulations that impede market entry or restrict competition, legal security for property rights. The practical application of these recommendations enabled to transform relatively quickly the CEECs, however they also brought unexpected negative phenomena.

This paper aims to look at transformation process in CEECs from two perspectives: (1) it tries to cover briefly main transformation issues in the region in the period 1990-2000, and (2) it aims to provide insight into more recent transformation events emerging during the period 2001-2010.

Part 1: The first decade of reforms

The CEE countries have mostly emerged after the former Soviet bloc was dissolved, except of the countries that that were established after the disintegration of Western Balkan, where Yugoslavia had somewhat specific position pursuing the more independent policy before 1990. During the period of Communism, the situation in the region differed because of the historical reasons, in spite of prevailing politic and economic doctrine derived from Marxism-Leninism. While the Visegrad countries (Slovakia, Czech Republic, Hungary, Poland) and the Baltic States were the democracies and the market economies before the World War II; most of the Balkan countries were semi-feudal while the Eastern European countries, such as Russia, Belarus and Ukraine were under the Communist dictatorship. Cultural traditions entrepreneurial capacities, institutional structures, and

geographic position, were also to some extent different. Thus, the pace of the reforms and their outcomes differed through the region.

The basic transformation of CEE countries was realized during the first decade of the transformation that is in Nineties. The structural adjustment of the economies have brought substantial hardships for the population, the decline of GDP, high level of the inflation, but in spite of high social cost it was successful. This first decade had been characterized, in “radical reform countries”, by a focus on speed and critical mass of changes. “Gradual reform countries” had tried to balance different groups of actors, stabilize conditions and gradually and partially privatize their state assets.

Political parties that were responsible for economic changes were composed from people that understood very well that the prolongation of the communist economic practices would lead to further reduction of the competitiveness of the national economies, to overall poverty and the decline. On the other hand, these parties were composed from the former opposition, that have during the communism era only limited possibilities to develop the new economic and political system because of the persecution. This led of course to many decisions that were not very fortunate and had to be corrected later. Nevertheless the crucial reforms had been done which has had a substantial impact on the further reform processes.

The most crucial problems during the first phase of the transformation were: (1) different views how to privatize; (2) how to guarantee irreversibility of economic (and political) reforms; (3) how to guarantee transparency of the process, equal access to most citizens and how to avoid criminal and corruptive behavior in the process.

Reforming countries, socialistic ones before 1989, had very concentrated ownership structure with a dominant role of the state. State or public ownership represented in most countries more than 90 percent of business assets. More details are in Table 1 below.

TABLE 1: INITIAL LEVELS OF STATE SECTOR IN SELECTED CEECS

Country	Year	Share of state sector (in %)
Bulgaria	1970	99.7
Cuba	1988	95.9
Czechoslovakia	1988	99.3
East Germany	1988	96.4
Hungary	1988	92.9
Poland	1988	81.2
Romania	1980	95.5

Source: Kornai, J. (1992)

Since the beginning of reforms, positive effects of privatization have been expected. It was expected that new owners, resulting higher competitiveness, restructuring and de-monopolization as well as improved access to new markets would invest new capital to privatized firms. It was believed that new owners would develop more efficient corporate governance. In the short term these expectation were not always achieved, although in the longer term the evaluation of the situation is more positive. The local privatizers were often the people with insufficient knowledge and social responsibility, but closely linked to political parties, which enabled them the easy access to credits in the banks that were public and only later privatized. The property of these incompetent owners had to be later restructured and taxpayers often repaid the losses from bad bank credits.

Corporate governance and institutions become crucial problem on the way towards market-based economic system. The following problems were typical for CEECs: (1) weak regulatory institutions; (2) weak financial market institutions; (3) inexperienced banking sector, and (4) weak corporate culture.

Part 2: The second decade of reforms

Whereas the first decade of reforms presented window of opportunities for many post-socialist countries, during the second decade it was possible to identify those countries, which are less or more successful in their

reform effort. In addition, certain countries decided to formulate their own specific ways adequate to their political strength and economic power (Russia or Ukraine) or different political preferences (Belarus). Therefore, in this part we focus more on the central European core of reformers.

Policies and institutions

The second decade the basic legislation necessary for functioning market economy has been implemented. The second decade of the reforms was mostly targeted on stabilization and “fine-tuning” of the progress made during the first decade. Moreover, the CEEC countries became the candidate for EU membership and therefore they were obliged to implement set of legislative measures/institutions required by *acquis communautaire*, such as:

- measures for attracting foreign direct investments (FDI);
- policies supporting development of medium and highly innovative industries (MHII);
- further liberalization and privatization of national economies;
- support to formation of technological centers;
- still in operation were the policies supporting small and medium-sized enterprises (SMEs) and regional development (sometimes with elements eliminating regional disparities).

Events and processes

Various events and processes mark the second decade of reforms. Similar to the first decade, also in this second decade no uniformity in adoption of policies, institutions and measures had existed. Different political set ups, various industrial structures or even substantial different institutional arrangements, all that have created some specific national approaches to emerging problems and existing difficulties. One important event in this period was the EU membership of some of the CEECs. From the outset, there has been tough competition among transitive countries regarding which ones will become the first new members. As announced by the EU bodies, the intention at that time was to have several rounds of enlargement based on the preparedness of individual countries. This scenario later became reality. After the first enlargement, new EU members have become a model what barriers and opportunities EU membership will bring to other candidates. It was generally accepted, by most political countries within CEECs (except some post-communist or nationalist parties), that EU conditions for membership will serve as an institutional anchor for the future institutional building.

The second decade of reforms – consequences

The larger part of the second reform decade was successful for the CEEC countries. These countries attracted substantial FDI, generated new companies and they have also benefitted from substantial knowledge transfers and after 2004 from the EU membership. The global economic crisis (Spirkova, Zajacova 2010) that had affected these countries mostly in 2008, stopped the successful growth of these countries and their economic performance has profoundly deteriorated.

All reform steps have been translated into substantial differences in economic performance of individual countries. As expected, transformation has led to wide disparities among population in terms of income, wealth, or job opportunities. This represented a phenomenon not known in transitive countries before 1989. Such changes had had a negative consequence for citizens, as they had not been prepared for such abrupt changes. Social cohesion has been eroded by polarization of the society, traditional intra-societal values - such as confidence in institutions, elected representatives etc. – has been weakened as well. Improvement of corporate governance represents an important element in corporate restructuring. Our research (Brzica and Olsson, 2001) found relatively highly concentrated ownership as shown in the Table 1.

TABLE 1: VOTING POWER OF THE LARGEST AND SECOND LARGEST OWNER (AVERAGE AND MEDIAN, % ON VOTING RIGHTS) AND AN ESTIMATE OF CONCENTRATION FROM 2004 SURVEY IN SLOVAKIA

Country	Year	Biggest owner of voting rights			Second biggest owner of voting rights		
		No. of firms	Median	Average	No. of firms	Median	Average
CR	2001	57	52.6	61.1	43	25.3	26.1
SR	1999 – 2000	34	39.4	43.8	29	18.8	19.1
	2004 (*)	31	-	64.6	23	-	18.5
Estonia	1999 – 2000	21	52.6	53.2	18	12.6	14.5
Slovenia	2000	136	22.3	27.4	136	12.1	13.4
Hungary	2000	64	43.5	44.7	64	18.0	18.6

Note: (*) = In this survey, only ownership concentration was analyzed.

Seemingly easy ownership transformation in theory has been in fact difficult in reality. Tough competition over property and sources has brought many unethical and even criminal activities along with desired processes of privatization. Looking at results one can see that in general practically all CEECs have overcome similar initial problems and start process of catching-up of the old EU countries.

Territorial perspective Visegrad countries and Slovenia

Poland, Hungary, Czech Republic, Slovakia and Slovenia are the transition countries of Central and Eastern Europe with the highest GDP per capita, the smallest state share and the highest share of foreign investors both in the industrial and the banking sectors. They also have the highest degree of financial intermediation. Slovakia and Slovenia already joined the Euro zone. The banking sectors in these countries are mostly foreign owned except for Slovenia. Four out of five countries in the region has formed the group of V4 countries. Visegrad Group (hereafter referred to as V4)¹ is the unofficial name for the countries Czech Republic, Hungary, Poland and the Slovak Republic, which entered into close cooperation. Originally, there were only three Visegrad countries but since the split of Czechoslovakia there are four countries. After 1989, in V4 countries starts the rapid economic growth. Initially, the most successful country in the region V4 was Hungary, although its economic growth was financed largely by massive inflows of foreign investment and foreign debt of the country (public and private) has grown steadily. The V4 countries underwent the major structural reform. The share of the public expenditures declined in majority of these countries except for Hungary where the value of this indicator represented about 50%, maybe highest among the among the post-communist EU countries (see Figure 1).

FIG 1: GDP DEVELOPMENT IN CEECS

Source: Eurostat, Statistical Office of the Republic Slovenia

The Slovak Republic and Poland belonged to the ten fastest growing economies of the world in 2007 together with Latvia, Lithuania, and Russia. An important role in post-communist transformation of V4 countries as well as in the whole region was played by the foreign direct investment (FDI). Their inflow since the beginning of the transformation process gradually increased until 2003. At the beginning of the transformation, Hungary was most attractive to foreign investors. Later the FDI were growing substantially in other countries of the V4 region. The most significant inflow of FDI was directed mainly to the automotive industry, which represented a significant improvement in position of the V4 countries in 2006.

The impact of the crisis on V4 region was strong, but in comparison with some other CEECs much milder. The reason was the relatively good macroeconomic fundamentals characterized by not too large financial imbalances and their stable funding (although more problematic situation is in Hungary).

The Slovak Republic is the smallest and most open economy among V4 countries, which also means that it is quite vulnerable to crisis. The economy is open and due to the higher share of cyclical industries, it is in times of crisis thus more vulnerable. One of the key reasons of the slow restructuring of the Slovak economy in 2000 was very low FDI, which lagged behind neighboring countries. Economic reforms at the early 21st century made the country more attractive for the FDI. The year 2000 brought the substantial change. The FDI grew and were directed to the privatization projects in banking, utilities and industries, such as automotive and electrical, which enable also to reduce the unemployment level. The multinational companies raised their production in Slovakia with the substantial impact on the growth of export and GDP. The Slovak Republic also became very export dependent, which cause the economic troubles after the importing countries reduced the demand for Slovak production because of their economic problems. Nevertheless, the FDI helped to reindustrialize the country after its deindustrialization in 1990s and helped to develop the real economics producing the internationally competitive products. So even though the GDP decline represented 4.7 % in 2009, the growth of demand in Germany and France enabled to restart the growth in the 2Q 2010, when GDP grew by 4.3%. The good fiscal position before the crisis enabled the Slovak government to adopt two anti-crisis packages with 62

social taxation measures including several initiatives to help small and medium-sized enterprises (SMEs) and scrapping scheme, applied in coordination with eleven other EU countries

Before the crisis, the Czech Republic benefited from the improved fiscal performance, low inflation and interest rates, liquid and conservative banking sector. During the crisis, the economic position of Germany had deteriorated, and as the result of that, the Czech Republic has experienced substantial drop of the export to this main export partner. Foreign direct investment more than halved, but rising inflows of EU funds filled the gap. The Czech banking sector has anticipated the global financial turmoil relatively well. The Czech National Bank starts to ease the monetary policy in August 2008 in order to cushion the GDP decline. The crisis led to a sharp widening of the overall deficit in 2009, a rapid accumulation of debt, and an increase in interest rate spreads. It is the reason why the Czech government now plans to increase the indirect taxes, such as VAT, and to reorganize the public institutions in order to lower the public expenses.

The situation in Hungary was more complicated. The country needed the fiscal consolidation before the crisis and did not have sufficient capacity to prepare adequate anti-crisis measures. The economic growth slowed down gradually, while Hungary moved into stagnation in 2007, while the other European economies were still booming. Reduced economic growth affected the decline in household consumption and government spending as a result of administrative changes and fiscal measures implemented in 2006. Although such measures enabled to reduce slightly the unemployment level to 7.4%, the inflation rose to 7.9%. The price of goods and services grew substantially because of VAT increase from September 2006. The unsustainable management of public finances (with the partial impact of the global financial crisis) forced Hungary to seek the assistance of the IMF in autumn 2008. The impact of global recession on Hungary in 2009 was a slump in real GDP of 6.3%, the deepest among the V4 countries, confirming the trend of slowing economy from the previous year.

In the early 2000s, declining international interest rates had encouraged borrowing in foreign currencies where exchange rates were favorable. Nearly 90% of Hungarian mortgages are denominated in Swiss francs since 2006 and the total mass of loans in Swiss francs from Switzerland is estimated at 500 bn. EUR. Some 45% of the total market for home loans and 40% of all consumer loans of Hungary are expressed in Swiss francs rather than in the domestic forint, which has become a trap when interest rates on Swiss Francs and capital flight has caused the drop of the Hungarian forint. Such mortgages were originated also in Baltic states, Romania and Bulgaria, and to a lesser extent in Poland. In all of these countries, they are source of repayment troubles.

Poland and Albania were the only countries that had the positive GDP growth in whole Europe in 2009. Poland is unambiguously the CEE region's strongest economy (RSM International 2010) In the five years before 2008, Poland experienced rapid growth of more than 5% on average. This enabled in 2007 to reduce its budget deficit below two percent. Moreover, the Polish economy is more closed compared to CEE countries and so its economic results are less dependent on the global trade. The country's large domestic market with diversified economy is the guarantee of Poland's economic strength. Poland is not the member of the Euro zone and its currency Polish zloty is not pegged to Euro. Therefore, Poland could use the monetary policy as a tool to influence the economic activity. The depreciation of Polish zloty enabled to adjust Polish economy to external shocks very quickly by raising its competitiveness. Poland was also successful in utilization of the foreign and domestic investments, in spite of the underutilization of the production capacities. At the same time, the access to credit for unproductive investments was tightened. Fiscal support of the household enabled to maintain the private consumption. In addition, the Polish banks were not involved in the large extent in the high-risk speculation.

- With the outbreak of the crisis in 2009, the Slovenian government adopted several packages of short-term anti-crisis measures to cushion the shock experienced by the economy. These measures enabled the preservation of numerous jobs and prevented the growth of poverty, but in the long term, neither the economy nor the country can survive in this way. The latest crisis has exposed numerous weak points in existing systems, so the recovery of Slovenia requires radical structural changes. The changes have been already listed in the document Slovenian Exit Strategy 2010-2013 (Statistical Office of the Republic Slovenia 2010)

Slovenia and the Slovak Republic, both members of the Euro zone were insulated from turbulence in foreign exchange markets. However, this also denied them the possibility to devalue the currency, and to run the fiscal deficit, that are strong tool of the adjustment for stimulating the growth.

Baltic States

The three Baltic States, Latvia, Lithuania and Estonia have suffered a dramatic reversal of fortune in recent years. Latvia, the Europe's fastest growing economy in the mid-2000s, is posting 10-12% yearly growth rates. Estonia and Lithuania grew in the high single digits during the pre-crisis period. Latvia, Lithuania and Estonia declined to devalue their currencies in the face of the recession, which would help these countries to make the faster adjustment to crisis and raise the competitiveness. Instead, they cut wages and spending in austerity packages to achieve the same end. Latvia also had to take a 7.5 bn EUR bailout, lent by the International Monetary Fund and the European Commission. Estonia managed to keep its budget deficit low, in spite of the economic problems, with the goal of entry to euro zone next year. In Latvia, public wage bills have been cut by 23.7 %, pensions by 10 % and increase in the value added tax (VAT) rate was from 18 to 21 %. Latvian government had to accept these conditions in order to get the second part of the IMF package. In Estonia and Lithuania, a 20% cut in public wages and a reduction in social benefits was enforced. Large current account deficits combined with excessive credit growth and mounting housing bubbles had led to an economic crash. Estonia and Latvia were already registering negative GDP growth in 2008, and endured output falls of 14.0 and 18.0% respectively in 2009. (RSM International, 2010) The Lithuanian economy contracted by 18.5% in 2009, the steepest GDP decline of any European country and one of the biggest in the world. It is surprising how the Baltic States managed the crisis without major population upheavals. The austerity measures that were implemented in Baltic states were considered to be the economic disaster (Dunkley 2010). However at this moment such policies paid off and brought improvements in Baltic States' competitiveness that led to a strong rebound in industrial production and exports. Moreover, in spite of the serious economic difficulties Estonia managed to meet the stringent Maastricht criteria, and become the seventeenth member of the Euro zone from 1 January 2011.

South Eastern Europe (SEE)

South Eastern Europe includes two EU member states Romania and Bulgaria and one EU candidate country - Croatia. The other countries of the Western Balkans are Serbia, Macedonia, Montenegro, Bosnia and Herzegovina, Kosovo, and Albania. They have signed individual Stabilization and Association Agreements with the EU. This may lead to their membership in the European Union if legal and institutional reforms would be successfully implemented.

Romania and Bulgaria was dependent on foreign capital inflows to finance household consumption. Both countries were facing severe difficulties as capital flows dried up. Household debt became a drag on the economy in 2008. The issue was especially troublesome for Romania, where a large share of loans was taken in foreign currencies, exposing households to heavy risks of currency fluctuation increasing the real value of repayments.

All the Western Balkans countries were hit profoundly by the crisis. The impact of the crisis is well visible on the following Table, where the GDP from selected CEECs are compared with West Balkan countries. It is interesting to note that the impact of crisis was weaker on later group of the countries (Table 2).

TABLE 2: GDP GROWTH FOR SELECTED CEECS INCLUDING WESTERN BALKAN

	2009	2010
European Union	-4.2	1.8
<i>Estonia</i>	-14.7	2.4
Hungary	-6.0	0.8
<i>Latvia</i>	-17.9	1.8
<i>Lithuania</i>	-15.2	0.4
Slovenia	-7.5	1.0
<i>Bulgaria</i>	-4.8	0,3
Romania	-7.0	1.9
	<i>In 7 new EU member states output fall greater than in most WB</i>	<i>In 4 new EU member states output growth still not positive (contrary to WB)</i>
Western Balkans		
Albania	4.3	3.1
Bosnia & H.	-4.4	0.7
Croatia	-5.9	1.4
Macedonia	-1.2	1,3
Montenegro	-4.3	1.8
Serbia	-3.1	1.7

Source: Duvalic2010, and [The World Factbook](#) (2011)

As can be seen from the Table 1 the impact of the crisis on the Western Balkan (WB) countries was in general milder than on new European Union member states. Duvalic (Duvalic 2010) explains this situation by the following:

- Most WB countries are less integrated with the EU than the new EU member states, FDI are low;
- There are similarities of WB with new EU countries: Foreign banks in WB hold 78-98% of banking assets, lending policies of easy credit led to the credit boom, many loans were in foreign currency (60% in both Croatia and Serbia), the credit crunch in 2009 brought increasing credit defaults in 2009;
- Financial markets in WB are less integrated with EU, which also means a lower exposure to the effects of the global crisis. The increasing regional integration among WB countries has made the effects of the global crisis less severe.

Conclusions

The reforms in CEECs have been very complex and their results initially very uncertain. Unlike traditional views our conclusions stress high variety of transformative modes despite that some policies and measures adopted by one or few countries since the early 1990s have been later copied by some other governments. Some results can be mentioned as typical for CEECs, others were typical for some of those countries:

- Initially dispersed ownership has been gradually transformed into a more concentrated one.
- Highly concentrated ownership in the Slovak companies (Olsson and Alashayeva, 2001; Brzica, 2002) - the situation in the Slovak Republic was similar to that of the Czech Republic.
- Rapid change of large part of state ownership evidenced.
- Privatization of SOEs in early and mid-1990s represented a prerequisite of restructuring.
- Privatization together with FDI has lead to corporate restructuring and better governance.

The second decade of the reforms brought the impressive economic growth in the majority of CEE countries. The countries has benefited from the reforms based on Washington consensus and some of them from their entry to European Union. In the last decade the CEE countries relied on specific growth model based on (Deuber 2010):

- Low savings;
- High consumption smoothing based on potential positive economic effects from EU membership;
- High dependency on external funding (external savings);
- High foreign participation and EU anchor (openness towards the Western Europe).

The openness of the CEE economies, large share of the cyclical sectors, and their export orientation to old EU countries revealed the vulnerability of such model. It has shown that the possibilities of using such model in the future are limited and some more complex growth strategies will have to be developed. Moreover, new forms of the economic adjustment during the crisis have to be developed for those countries that are already members of the Euro zone. This is, however, rather more complex problem that is being solved at present on the EU level

Understanding Trade in “Personal” and “Impersonal” Services

P.M. Rao, PMRao@liu.edu
Long Island University/C.W. Post Campus, USA

Abstract

Consider the following statements that express growing concern or opportunity depending on which side of the argument one finds himself or herself:

- “there is no job in America that is America’s God-given right any more”(Carly Fiorina, former CEO of H-P).
- “everything you can send down a wire is up for grabs”(Nandan Nilekani, former CEO of India-based Infosys) .

The purpose of this paper is to examine, critically, the fear expressed by some very mainstream economists in the U.S—most notably, Alan Blinder (2006)—over very large potential negative impact on U.S. jobs resulting from imports of *impersonally-delivered* services from countries like India. Blinder estimates that as many as 40 million U.S jobs could be at risk of being offshored over the next two decades. Others like Jensen and Kletzer (2005) have argued that the U.S is a net exporter of services and likely to gain relatively high-wage, high-skill jobs through increased exports of services while importing low-wage, labor-intensive services from countries like India. The paper examines these issues with special reference to the pattern of trade *in personally-delivered and impersonally-delivered* services between U.S and India.

Introduction

Trade in services has been at the center of policy debates, at least since 1995, over the terms of the General Agreement on Trade in Services (GATS), and more recently over potential job losses in the developed world due to offshoring, which is the focus of this paper. However, the offshoring debate is fraught with confusing array of conceptual, definitional and measurement issues. The purpose of this paper is to shed light on these issues drawing upon Bhagwati, Panagaria and Srinivasan (2004), Blinder (2005), Lipsey (2006), Jensen and Kletzer (2005), and Moncarz, Wolf and Wright (2008) among others and provide better understanding on the impact of services offshoring.

We begin with the definition of certain key terms for purposes of this paper. *Offshoring* refers to shifting business activities or processes to a foreign country. When they are shifted to a foreign affiliate of the same company, it is called *captive offshoring*; and when they are shifted to a third party abroad, it is known as *offshore outsourcing*. The term *Outsourcing* refers to shifting operations or processes previously performed within the company to an unaffiliated third party at home or abroad. When offshoring is done to meet the company’s production needs or customer demand in the home country, it would have the effect of increasing imports. However, if offshoring represents business expansions abroad without any change in business activities at home, it would have no effect on imports into the home country while it could reduce current or future exports. (NAPA 2006)

We owe to Alan Blinder (2005) the terms “*personal*” or *personally-delivered services* and “*impersonal*” or *impersonally-delivered services*. Personal services (e.g., a waiter in a restaurant) involve a strong element of personal, face-to-face contact, which is either essential or highly desirable. By contrast, impersonal services are those that can be delivered electronically (e.g., online airline reservation) or through call centers located anywhere without degrading the quality of service. Most personal services are said to be either nontradable or tradable only to a limited extent. Impersonal services--that is, services that can be delivered electronically--have become highly tradable. Paradoxically, impersonal services have more in common with manufactured goods, at least in terms of tradability, than they do with personal services.

Measurement Issues in International Trade: Goods vs. Services

Robert Lipsey (2006) addressed many difficult and often intractable issues concerning measurement of cross border trade in services. Trade in goods has two measurements--one for compilation of trade statistics and the other for balance of payments (BOP). Trade statistics are compiled on the basis of geography according to the guide lines adopted by the United Nations Statistical Commission. That is, the basic principle for compilation of trade statistics involves crossing the border rather than change of ownership. On the other hand, the measurement of trade in goods for the balance of payments is based on ownership of goods between residents and non-residents of a country. For example, trade statistics include--because there is a change of location--and the BOP data exclude--because there is no change of ownership--goods purchased by travelers and brought home. Similarly, trade data include but BOP data exclude goods imported for projects by non-resident construction firms. Another source of serious measurement problem for services trade, according to Lipsey, is the growing use of low tax jurisdictions to place certain financial and intangible assets like patents and trademarks.

By contrast to trade in goods, trade in services has only one measurement--the BOP measure involving no information on quantity, origin, destination, invoice and the like. Moreover, trade in services often involves no crossing of international border by the service per se.

Bhagwati, Panagariya and Srinivasan (2004) suggest that the GATS categorizes four different ways in which services can be traded: 1). arm’s-length supply of services, with the supplier and buyer remaining in their respective locations (e.g., back office work performed electronically by an Indian firm located in Bangalore for a U.S. firm located in New York). Both individuals and firms can provide this service and it cannot easily and readily be subjected to customs inspections. 2). Services are provided by moving the service recipient to the location of the service provider (e.g., travel by foreign residents, education provided to foreign students and healthcare to foreign patients). 3). Service provider establishes a commercial presence in another country requiring an element of foreign direct investment (FDI). This often occurs in banking and insurance without involving full-scale FDI. 4). The service seller moves to a location of the service buyer involving temporary migration (e.g., consulting services and healthcare and educational services, which can also be provided by moving doctors and teachers to the location of patients and students, respectively). The authors suggest that the debate on offshore outsourcing should focus on the narrow definition of trade in services-- arm’s-length supply of services noted in (1) above.

Examining from, say, the U.S. perspective, potential impact on job losses from (1) is no different from the impact of any other import of good or service. However, the other categories are not so straight forward. For example, in category (2), the costs of foreign students’ education and living expenses (\$19.9 billion U.S. exports and \$5.6 billion imports in 2009) become a service export of the U.S., the host country, because they are treated as residents of the country they come from. Thus, as Lipsey (2006) notes, the definition of residents can turn what is essentially a domestic transaction into an international transaction. Service “exports” to foreign students’ home countries never leave the U.S.; and when those students become residents of U.S., as many of them do, no corresponding “re-import” is recorded in the BOP. Similar issues arise in category (4) involving temporary migration, which could transit into permanent migration. Category (3) presents its own measurement issues if FDI is more than a miniscule amount. Note that while many more impersonal services such as those in category (1) are likely to be offshored, many personal services--requiring service recipient or service provider to travel across borders-- such as those in (2) and (4) are likely to become tradable. Moreover, as information and communications

technology (ICT) improves (e.g., technologies used in providing “distance learning”), more and more personal services could fall into the impersonal services category. More important, even if the personal face-to-face service (e.g., a visit to doctor’s office) is not tradable in itself intermediate service inputs involving, say, medical records that can be electronically transmitted across borders are tradable.

The Size and Growth of World’s Services Trade

As Lipsey (2006) notes, it is difficult to ascertain, with high level of confidence, the size and growth of services trade because, unlike trade in goods, the number of countries measuring it and the number of categories covered have been increasing over time. According to the latest data reported by the World Trade Organization (WTO 2009), world’s service exports in 2008 (US\$2,765 billion) were 23 percent of the world’s exports of goods (US\$12,096 billion). Lipsey (2006), who examined similar data from the International Monetary Fund (IMF) over many different time periods, from 1972 to 2003, separately for 22 countries accounting for half of the world’s service exports and 30 countries accounting for two thirds of the world’s service exports concluded that “... there is fairly general agreement on a current ratio of service trade to goods trade of about one quarter” (Pg.4). What is more interesting, according to Lipsey’s research, is that there has not been any strong trend in the ratio of world service trade to goods trade over the last half century. However, this should not mask the fact that both growth in services trade and goods trade have outpaced growth in GDP in almost every country over the same period.

U.S. Trade in Services

As shown in Table 1, the ratio of services exports to the export of goods is much higher for the U.S than it is for the world. In 2010, exports of services--based on BOP definition--were \$561billion, 44 percent of goods exports; and imports of services were \$405billion, 21 percent of goods imports. Neither of the services to goods ratio is much different from what it was in 1992--42 percent of goods exports vs. 23 percent of goods imports. Assuming that price indexes for services and goods accurately reflect actual movement in their relative prices, this fact essentially holds even when one looks at the same ratios based on constant dollar data. Moreover, services exports and imports as a percent of goods exports and imports have not shown any trend either--24 percent in 1992; 21 percent in 2000; and 22 percent in 2010. The data also support the widely known fact that, *in the aggregate*, service exports and imports are much smaller than goods exports and imports relative to their respective outputs. Thus, in 2010, service exports and imports accounted for only 10 percent of service sector output with only slight increase since 1992--compared with a similar percent for the goods sector of 79 percent with a strong upward trend from 49 percent in 1992 and 65 percent in 2000. (BEA 2011)

In contrast to trade in goods, U.S. has been a net exporter of services and (\$156 billion in 2010). The favorable balance of trade in services U.S. enjoys extends to almost all major categories, especially travel, royalties and license fee and other private services including business, professional and technical services, financial services and education. There are only three sub categories--freight, insurance and computer and information services--in which U.S. had trade deficit (\$56 billion) which accounted for 12 percent of exports and 17 percent of imports of private services in 2009 (Table 4).

Services Trade by Affiliation

One of the issues in the analysis of trade data has to do with intra-multinational enterprise (MNE) trade. This is especially the case with the U.S. data because of the country’s dominant MNE presence abroad in terms of FDI and trade. Intra-MNE trade is quite different from arms-length trade because it goes to the heart of how an MNE leverages its global dispersion of tangible and intangible assets to create and sustain competitive advantage. Overall, in the Other Private Services category--the one that is at the center of many debates--comprising of Business, Professional and Technical Services (BPT), Financial Services, Insurance Services and others (which together

accounted for half of all private services exports as well as imports in 2009), about 40 percent of imports and a third of exports are transactions between MNE's and their affiliates abroad. Similar ratios for the BPT category in 2009 were much higher--50 percent of exports and 68 percent of imports--indicating perhaps greater MNE propensity for intra-MNE trade with respect to exchange of skills where ICT plays a greater role (BEA 2011). This is especially the case with R&D services.

Estimates of Job Losses

A Forrester Research study by McCarthy (2004) estimated that by 2015, some 3.3 million service sector jobs or about 300,000 per year will move offshore. A University of California at Berkeley study by Bardhan and Kroll (2004) estimated that about 11 percent of jobs in all U.S. occupations were *potentially* at risk of being offshored. Numerous estimates of this type were documented in a study by the National Academy of Public Administration (NAPA 2006) for the U.S. Congress and the Bureau of Economic Analysis. These estimates by themselves do not warrant an alarmist view of the service-sector offshoring.

However, Blinder (2005) suggests that the above estimates of job losses represent just tip of the iceberg. He estimates that "...the number of *current* (emphasis added) U.S. private service jobs that will be susceptible to offshoring in the electronic future is 2-3 times the total number of manufacturing jobs" (Pg. 18). Employment in manufacturing was 13 million in 2008. If one were to apply Blinder's "crude estimate" (his words) for 2004 to the more recent 2008 data, some 27 to 40 million service sector jobs will be at risk of being offshored; and somewhat *lower* in 2018--24 to 37 million-- because of the expected drop in manufacturing employment to 12.2 million (Table 3). Thus, some 18 to 28 percent of service sector jobs in 2018 would be at risk. According to Blinder, among the service sector jobs that would be at high risk are information services, professional and business services, college teaching, and some parts of healthcare. Sectors least vulnerable are leisure and hospitality services and government jobs in the public sector, the latter because politics won't allow these otherwise potentially offshorable services to be offshored.

Tradable vs. Nontradable Industries and Occupations

Jensen and Kletzer (2005) developed a new empirical approach to identify service industries and occupations that are at risk of being exposed to offshoring. Following the economic intuition, first suggested by Helpman and Krugman (1985), the authors postulate that services traded tend to be geographically concentrated, while services that are not traded tend to be more ubiquitously distributed. Using the 2000 Census data, the authors identify the level of geographic concentration (measured by the Gini coefficient) that enables them to classify an industry or occupation as tradable and nontradable.

As shown in Table 2, Jensen and Kletzer (2005) estimate that, in the aggregate, 39 percent of total employment is tradable and 61 percent is nontradable. Of the 39 percent tradable employment 59 percent is in private services and 32 percent in manufacturing. This is contrary to the traditional view of services as being largely nontradable.

By occupation, Jensen and Kletzer report that the groups with largest shares of tradable employment include computer and mathematical operations (100 percent); legal (96 percent); healthcare practitioners (86 percent); and life, physical and social sciences (83 percent). And the occupational groups with largest shares of nontradable employment include education and library (99 percent); healthcare support (97 percent); and food preparation/serving (96 percent).

Jensen and Kletzer also examined worker characteristics in tradable and nontradable industries and occupations. They found that workers in tradable service industries and occupations are higher skilled and have higher income than workers in the manufacturing sector and nontradable service activities. The authors found little evidence that tradable service industries or occupations have lower employment growth than nontradable industries and occupations. Negative employment growth at the low end of skill distribution is the exception. There is higher rate of job loss and hence greater job insecurity associated with tradable service activities. A Bureau of Labor Statistics study based on survey data conducted by Roncarz, Wolf and Wright (2008), came to similar conclusion with respect to skills of workers, income and job growth in 160 *offshorable occupations*.

Concluding Remarks

With well over three quarters of employment in the service-providing sectors and over a fifth of the trade in services, combined with a growing sense of economic insecurity, it is no surprise that fear of offshoring has taken center stage in the U.S. policy debates. The trouble with many of these debates is that they got themselves far ahead of basic understanding of the nature of services trade and even facts.

First, at the most basic level, potential impact of offshoring on the U.S. economy depends on how one defines offshoring. For example, should we consider intra-MNE cross border trade the same way as arms-length trade of the call-center type? The latter shifts relatively low-skilled low-wage jobs overseas and hence, driven by cost savings. On the other hand, trade between parents of the U.S. MNE's and their foreign affiliates increasingly involves high-end strategic activities such as product development and go to the heart of the way MNE leverages its global dispersion of tangible and intangible assets (Rao 2010). As such, if one looks at offshoring to foreign affiliates narrowly in terms of potential impact on home-country jobs, then one would be ignoring the many beneficial effects in terms of jobs created through subsequent exports, access to foreign markets and talent, which could more than offset the jobs "sent" to the affiliates. In short, such an argument based on a purely home-country perspective, would question the legitimacy of U.S. MNEs themselves.

Second, as Bhagwati, Panagaria and Srinivasan (2004) and Lipsey (2006) pointed out, because trade in services is more difficult to define and measure than trade in goods, its size and growth are subject to much wider margin of error. This is particularly the case with educational services, royalties and license fees, and financial services.

Third, estimates of service sector jobs at risk of being offshored generally do not go beyond direct employment impacts. Indirect positive employment effects resulting from well known complementary relationships between imports, exports and FDI would surely reduce the negative impacts from offshoring.

Fourth, while trade in services remains only a small fraction of the service sector's output (10 percent in 2010 with only a slight upward trend since 1992) Jensen and Kletzer (2005) estimate that about a quarter of *employment* in private services is tradable compared to about 12 percent in manufacturing. However, as the authors note, just because a job is in tradable service, does not mean it will move to a low-cost location. A tradable service is not necessarily an impersonal service. Nor does the distinction between personal and impersonal service jobs correspond to high-skilled and low-skilled work. To the extent U.S. comparative advantage is in tradable services that require higher skills than nontradable services, policy emphasis, so it is argued, should be on greater investments in education and training as well as removal of barriers to trade in services. However, even on this point experts differ. For example, research by Blinder and Kruger (2009) cited by Krugman (2011) suggests that high-wage jobs performed by highly educated workers are more "offshorable" than jobs performed by lower-paid, less-educated workers. This outcome is a result of the ICT revolution combined with competition from countries like India and China that are able to offer the services of highly educated workers at a fraction of the U.S. wage.

Finally, alarmist views in the U.S. policy debates about offshoring need to be placed in historical context. At the turn of the 20th century, well over 40 percent of the labor force was employed in agriculture (Bureau of the Census, 1975). Currently, agricultural employment is barely over 1 percent because of the dramatic increase in agricultural productivity over the past century. Manufacturing, followed by services, absorbed the movement of population out of agriculture on a rather large scale. A similar phenomenon has been occurring in the manufacturing

sector, especially since 1980, when the proportion of manufacturing employment began to drop from about 25 percent to its current level of under 10 percent. Here too dramatic increases in manufacturing productivity have played a significant role in moving the work force from manufacturing to the service sector. Of course, at the center of this vast structural change is technology. While we do not know what changes technology will bring in the next hundred years, we can be sure the change will be no less dramatic and services offshoring is likely to be a needle in the haystack.

Torn In Two: Competing Discourses Of Globalization and Localization In India's Informational City of Bangalore.

Kalpana Gopalan. kalpanag07@iimb.ernet.in
Indian Institute Of Management, Bangalore, INDIA

ABSTRACT

Bangalore city saw unprecedented growth in the 1980s and 90s, in size, population and global importance. This derived chiefly from its positioning as a centre for Information Technology and associated industries. Even as the world watched this amazing growth in wonder, Bangalore's own response was typically dichotomous. On the one hand, there was a throwback to a mythicized past, a longing for the pensioner's paradise and garden city of old; there was also an aspiration for a neoteric future, a Singapore in Bangalore.

This paper studies the phenomenon of Bangalore's growth through a kaleidoscopic lens. It asks the question: How has this growth affected and manifested in Bangalore's Economy, Society, Politics, Planning and Spatial characteristics? It points that the corporate led development imperative has resulted in, and is partly sustained by, a concomitant growth of a working class, and assorted migrant and poor groups. So Bangalore's divided response to growth is in fact an inability of this erstwhile middle class city to accept the plebian democracy that threatens notions of restraint and order. The paper positions itself in the literary terrain of studies on Bangalore, deriving from three streams of literature : Bangalore –specific studies; scholarship on Bangalore as a typical Indian city; and Bangalore in a global context.

The consequence of growth is a fragmented and polarized society, partly a legacy of a divided history. In the economic sphere, there the corporate neo-liberal ideology stands in contrast to small local economies of trade and textiles that are still major employers; socially, there is a nouveau elite who prefer to invisibilize the migrant and poor; politics and policy are handmaidens to either group, both of whom influence policy through very different political alliances and processes.

The paper leaves us with an open question: What is Bangalore's way forward? It solicits your opinion regarding the city's future agenda.

I. INTRODUCTION

In the 1980s, the city of Bangalore was shaken from a slumberous existence into a startled realization of its new-found destiny as a metropolis and 'the city of the future'. In the five decades since Independence, this small unremarkable town metamorphosed into an internationally known boom town, overtook Mysore as the *urbs prima* of the Karnataka region, and outdistanced its neighbours in Chennai and Hyderabad. No other contemporary Indian city allows us to track the passage from small town to metropolitan status within a few decades as well as Bangalore does (Nair J. , 2005) (Heitzman, 1999). Largely unprepared for this hurtling destiny, Bangalore's response was characteristically dichotomous. On the one hand, there was a throwback to a nostalgic past, a longing for the good old days of a 'garden city' and 'pensioner's paradise'. A mythicized past, placid and restrained, offered an ideological refuge from the bewildering and dismaying onslaught of modernity. Juxtaposed with this was a futuristic vision of a global city that conformed to international standards, a veritable Singapore in the making (Nair J. , 2005). There was reason for this. Between the yearning for a Bangalore of a bygone era and the hankering for futurity lies a complex history of a city whose rite of passage to metropolitan status was marked by regional, national and global forces. Unlike presidency cities such as Mumbai, Chennai or Kolkata, Bangalore was denied the advantages of gradual growth; its transformation was crowded into a short span of just over a decade. Its meteoric rise to a globally integrated location of software and service sectors created, and masked, profound changes in the metropolitan socio-economic map, creating aggravating disparities and a highly fragmented and polarised urban society. Even as a narrow upper stratum of affluent urban elite realized the benefits of growth, new pockets of urban migrants and marginalised poor swelled its ranks. The trend for information technology expansion in Bangalore

began with specialised self-contained IT Parks that were 'islands' of first world amenities. However, beyond these pockets of world class facilities, and partly because of them, the digital divide widened between the beneficiaries of the IT boom and those it hardly touched. The case of Bangalore poses the dilemma of whether developing the city, and by extension a region, space or nation, as an IT hub is the only dream worthy of pursuit; or should this yield to a balanced development plan benefiting a wider constituency (Ghosh, 2006) (Nair J. , 2005) (Yahya, 1-21) (Dittrich, 2007, p. 46).

II. SIGNIFICANCE OF PAPER

Different aspects of the new metropolitan experience, of which Bangalore is an exemplar, have been written about. This paper draws upon three different streams of urban literature. The first relates to specific studies on the city of Bangalore. Venkatarayappa (1957) and Gist (1986) made early attempts at defining the ecological zones of the city. R.L.Singh's (1964) monograph on Bangalore traced the city's geographic and economic systems; more ambitiously Prakasa Rao & Tewari (1979) used the sample survey method to relate Bangalore's social and economic structure to its spatial characteristics (Nair J. , 2005). These studies converged into more recent literature on Bangalore's rise as a metropolis. Its internationally acknowledged status as a hub of IT ,ITES and BT industries, attracted the attention of a range of scholars interested in the logic and potential of such growth (Heitzman, 1999) (Nair J. , 2005) (HEITZMAN, 2006) (Harikrishnan & Mahendra, 2008) (Sastry, 2008) (Nilekani, 2008) (Yahya, 1-21).A third group of literature places Bangalore in the context of global changes and their impact on the urban firmament. Many metropolitan cities in India are undergoing change; much of the change is driven by the needs of the internal economy. However, increasingly since the late 1990s, change has also been the result of a response to global markets. Hence the case of Bangalore has wider applicability to other developing cities in emergent economies. (Nair, 2005) (Benjamin, 2000) (Dittrich, 2007) (Ghosh, 2006) (Kamath, 2006) (Menon, 2005) (Shaw & Satish, 2007, p. 149).These three groups of literature coalesce to inform this paper and provide it with a nesting place. While most corporate and policy discourse on Bangalore's rise is undilutedly positive, this paper tempers this optimistic perspective with a more sceptical point of view, focusing on the risks and negative effects of globalisation on the metropolitan social map.

III. SEGMENTED HISTORY : A DIVIDED LEGACY

The asymmetrical development of Bangalore begs the question whether the city might have inherited the development process from its past experiences of development. So it is worth reviewing the process and pattern of historical development of the city of Bangalore (Nair, 2005) (Sastry, 2008, p. 2).The history of Bangalore is a tale of two cities, a western part or *pete* that dates back to atleast five centuries; and the eastern part or 'Cantonment' that is no more than two centuries old. In 1949, the twin municipalities of Bangalore City and Cantonment were united into the Bangalore City Corporation. Bangalore was wrenched out of its existence as a divided town to become a big city in the 1970s. Yet the integration of these two distinct linguistic, political and economic cultures and their spatial identities remains an unfulfilled task (Nair J. , 2005, p. 26). By the early twentieth century the two cities had developed as two distinct nodes, with their own central markets, railways stations, hospitals, and wholesale and retail areas. A swathe of parkland, the Cubbon Park, separated City from Cantonment, keeping the two areas and their respective cultures apart well into the twentieth century. The public life of the city was thus divided, between east and west, and not only in a spatial sense. The cantonment was peopled by those for whom British rule had spelt not just political certainty but unbridled economic opportunity. The traffic between the two areas was regulated as strictly as ideas between them. On the eve of Independence, then, the city of Bangalore retained its divided character, with the two halves only weakly joined in the social, political or economic spheres. In the immediate post-Independence years, the task of strengthening these bonds was left more or less entirely to administrative compulsions, with significant consequences for the contemporary design and social life of the city. History thus determined that Bangalore developed with dual characteristics since its foundation. As the city developed, the inter-

mix of two cultures was overlaid with footloose IT professionals and migrant labour who swarmed into the city of opportunity (Sastry, 2008, pp. 2-3).

IV. A CONTESTED TERRAIN: THE BATTLEGROUND OF BANGALORE

Nonetheless, Bangalore's divide is not just a function of history; it is part of the urban present. Change in modern metropolitan cities has made them arenas of complicated and conflicting politico-economic processes both local and global. Planning and governance are shaped by the congruence and confrontation of interest groups with conflicting interests which compete over limited resources. These resources are not just physical; they encompass intangibles such as state power and legitimacy (Nair J. , 2005). In its latest, metropolitan phase, therefore, Bangalore typifies a ground on which broadly two contending forces stake their claim: on the one hand are the newly renovated citizens, who are amply aided by a technocratic vision of change offered by the leaders of the new economy; on the other are those for whom democracy has come to have a different meaning in the urban setting: slum dwellers, unemployed young men, women's groups. Thus, not all changes occurring in Bangalore can be attributed to global forces/agency. There are significant local forces/agency, processes from below that have changed the city. The resulting conflicts are reflected in vigorous rivalries for access to prime land, to the best private colleges and to employment opportunities in the modern service sector. Because of this merciless competition, many of the lower middle-class families are doomed to economic failure, which leads to tendencies of political radicalisation. This trend of social fragmentation catalyses urban conflicts that find expression in an increasing number of crimes and communal clashes and in violent conflicts between the supporters and opponents of the globalisation project. During the last decade several anti-globalisation campaigns were fought in Bangalore, for example the campaign of the local farmer unions against the US-based multinational companies Cargill and Monsanto, the demolition of the Kentucky Fried Chicken branch, or the massive clashes during the Miss World campaign in the late 1990s. At the top end of the city's socioeconomic pyramid is a tiny but heterogeneous and competing urban elite. This mainly conservative core-elite traditionally holds many of the key positions in the politico-economic arena. But the newly established service elite, tied to foreign investors in a close coalition of interests, is attempting to achieve more influence and power resulting in aggravated conflicts over the utilisation of resources and power. Meanwhile, the well-off sections of society have lost any interest in tackling the problem of the appalling civic conditions of the urban poor. (Dittrich, 2007, p. 55) (Sastry, 2008, pp. 9-10). The discussion of these questions proceeds by analyzing specific elements of the cityscape of Bangalore where the divide manifests itself: economy, society, policy and politics and the designing of urban space.

V. THE CITY THAT BECKONS...

Bangalore is the fifth largest metropolis in India and forty-third in the world with a population of almost six million spread across five hundred and ninety-five square kilometres. It is a multifaceted city: at once the political capital of Karnataka state; a leading educational centre with scientific and research institutes; a hub for India's space research and aviation technology; the home of large public sector industries; and more recently the preferred destination of private electronic, infotech and garment industries. As one of the fastest growing cities of the world, with a population growth of 3.25 percent annually, (its population doubled during 198-2004) it is poised to become a mega city with population ten million by 2021 and an area of 1,000 square kilometres by 2015. With less than 0.5 percent of the area of Karnataka, metropolitan Bangalore supports thirty per cent of the state's urban population. With over 125 multinationals, 1150 software exporters 1,20,000 IT professionals, and software exports estimated at US\$ 2.5 billion in 2003, its sobriquet of 'Silicon Valley of India' is well deserved. It is also an internationally recognized gateway to styles of globalized consumption (Heitzman, 1999) (Nair J. , 2005) (Narayana, 2008) (Smitha & Sangita, 2008) (Harikrishnan & Mahendra, 2008). Major milestones dotted Bangalore's journey to become the IT hub of Asia. The Software Technology Park scheme was announced in 1985 with special rules and concessions for hundred percent export-oriented units. The Bangalore ITPL was launched in 2000 at a cost of US \$ 480 million, a joint venture between the Government of Karnataka, the Tata Corporation and of Singapore consortium, built to

international standards as a self contained facility with captive power supply and satellite links. It supports high-tech industries such as software development, electronics, communications, research and development and financial services. The ITPL remains the benchmark for IT parks in India with its world class infrastructure and has the highest number of occupants among Indian IT parks. Next came the Electronic City, also developed as an enclave to provide space for IT multinational and domestic companies such as Texas Instruments, Hewlett Packard, IBM, Infosys and Wipro. As the demand for associated services swelled, the sphere of the IT/ITES industry grew to nearly 3000 firms, including medical transcription, back office operations, and call centers. Emerging as a hot new tech city, a preferred location for high-technology industries and a globally integrated centre of high-technology research and production Bangalore absorbed about FDI US\$ 5 billion and the highest per capita income of any Indian city. Its software and service industries still grow at around 30% annually amazing compared to world standards. Out of the total software and services exports, almost sixty six percent were to the Americas (USA, Canada and Latin America), twenty four to Europe, and nine percent to the Asia-Pacific market. The USA continues to be Bangalore's largest export destination. For supporters of a deregulated and liberalised global economy, the city represents a positive showcase of the new opportunities for newly industrialising countries to benefit from recent trends in economic globalisation (Heitzman, 1999) (Dittrich,2003) (Nasscom, 2004) (Shaw & Satish, 2007, p. 153) (Harikrishnan & Mahendra, 2008). (Sastry, 2008, p. 13) (Yahya, 1-21).

VI. THE CHANGING SOCIO-ECONOMIC LANDSCAPE.

The growth phases that Bangalore passed through left their imprint on the, economic social and spatial landscape of the city.

■ **The New Economy.**

The transformation of Bangalore began in the sphere of economy and employment. It corresponded to changes in the significance of the state as the prime mobilizer and distributor of resources; as the increasing command of the market eclipsed the developmentalist state and its apparatus. Until the 1980s, private investment did not dim the presence of the state as the prime mover of industrial production in the city; only 2619 of over 3, 80,000 workers were employed in the hardware and software in 1991. Within a decade, this was to change drastically as IT/ITES accounted for 60,000 jobs distributed over 1400 firms by the late 1990s. Today, over 1,300 companies employ 170,000 people. Thus the phenomenal growth of the city initiated by governmental agencies and the public sector to was spurred on by a booming IT sector. This has implication for future trends. The large public sector industries and the private textile and garment production units still have an important impact on the city's economy. The formal sector with the largest impact on employment is still textiles; followed by the public sector giants and the institutions of central and state governments. Together with all their subcontracting units these two pillars of the formal economy are employing approximately 250,000 people. Though business and employment opportunities across sectors remain in the foreseeable future, it is doubtful that they will generate employment or subcontracting arrangements that will keep up with the rate of population increase in the Bangalore metropolitan region. The public sector heavy industries are undergoing reorganisation processes that have resulted in substantial staff cuts. The downsizing programme under implementation by the state government has cut hundreds of office jobs. The size and visibility of the public sector has been overshadowed by the private sector, with the ICT-sector by far the most dynamic part of the city's economy. The growth of the economy will depend on the dynamism of private sector enterprises with high-value outputs, minimal environmental impact, and the ability to generate direct employment as well as indirect growth of services. (Nair J. , 2005) (Dittrich, 2007, pp. 46-9).

■ **Growth of Middle Classes.**

The spectacular boom in software brought increasing visibility to Indian information technology professionals. The societal impact of this was significant in its relationship to popular demand-making. Even as employment prospects in all other sectors were shrinking, the granite, steel and tinted glass offices in Bangalore posed a stark contrast to ill-maintained factories facing falling orders and tighter credit. Youth from middle-class families, encouraged by anxious parents, saw the software sector as the only destination with good prospects in an otherwise dismal scenario.

Social circuits abounded with stories of high starting salaries and children who have been very successful abroad (Benjamin, 2000, p. 36). A promising new urban middle-class of the computer elite emerged in the city. This group, comprising about ten to fifteen percent of the urban population, profited from the new Bangalore, increasingly adopted westernised lifestyles and consumption habits and were now in the position to influence the city's political and development agenda.

▪ **Corporate Visions of Singapore.**

Urban efficiency was the mantra of the nouveau elite, who saw Bangalore in a race not just with Hyderabad and Chennai but with Manila and Kuala Lumpur to sustain the city's competitive advantage and investment flows (Harikrishnan & Mahendra, 2008) (Shaw & Satish, 2007, p. 160). When the new Congress Government was sworn to power in 1999, these aspirations received forceful articulation. The then Chief Minister declared his intention of turning Bangalore into another Singapore. This was a fresh attempt at moving to centre stage the economic and technological aspects of planning which may be at odds with social, community, and ecological uses of city land. At the Bangalore Summit, the corporates were in command; the elected corporators attended but remained spectators than genuine participants in the exercise (Nair J. , 2000) (Menon, 2005) (Kamath, 2006). For all its enthusiasm, this obsession of technocrats, media, and policymakers is an inadequate response to the very real problems of metropolitan planning. Rather than building up a meaningful planning mechanism that takes account of the diversity of city economies and respects the multiplicity of claims to the city, it takes refuge in an imaginative bankruptcy that finds it difficult to separate the global and the local, and simplistically borrows ideals from other cultures. For a while now, Bangalore has been talked of as an enclave, a hi-tech island that must conform to internationally acceptable standards. The government has eagerly sought opportunities to welcome private investment, domestic and foreign. Being a part of the world city network brings in many advantages for cities in developing countries and the largest Indian cities have started competing with each other to gain a foothold into this network (Taylor et al, 2002).

VII. THE 'OTHER' BANGALORE: WHOSE GROWTH IS IT ANYWAY?

Bangalore is the showpiece of the success of the new economy, defining the city as 'the site of a new and confident definition of urban space by capitalism' (Nair J. , 2005). Yet the shining city masks an unhealthy process of unplanned growth and development, and associated infrastructure and service deficiencies. Its integration into the highly competitive framework of inter-city linkages produced profound processes of urban restructuring creating new disparities and a highly fragmented and polarised urban society. While a relatively tiny stratum of affluent society benefits from the transformation, the living conditions of the majority of the urban population are subject to deterioration. The livelihoods of the most vulnerable groups are most exposed to risks and adverse future developments. The internationalisation of Bangalore has had mainly negative impacts on the urban poor. The transition from small town to metropolis is fitfully managed; the reforms undertaken since the 1990s, though resulting in a high economic growth, have also given rise to critical social and environmental concerns. These include unequal employment and income distribution, emergence of new forms of vulnerabilities, weakening state regulation, deteriorating governance, the paradoxical presence of poverty, imbalanced demographics and intra-city disparities (Nair, 2005) (Sood, 2007). Despite the concerns of the corporate sector, and the coverage in the media, substandard roads and traffic congestion are only one part of the infrastructure crisis facing the city. A study conducted by Solomon Benjamin reveals a startling picture of lopsided infrastructural development. Infrastructural investment in poor, working class slums in central, west and south Bangalore differs by a factor of 1: 40 when compared to Whitefield, an area with a concentration of software companies and large-residential layouts. With off-site investments such as dedicated expressways, the ratio becomes 1: 60. Benjamin says: "A key problem we witness today in globally connected cities such as Bangalore is that of unequal access to public investments for infrastructure and services. The vast majority of small firms and trades, despite providing almost 80 percent of the jobs, remain in 'shadow areas where residential and work environments lack even basic infrastructure and services. In contrast, the hi-tech areas have access to publicly provided and subsidized high-grade infrastructure, services and land. (Menon,

2005). Slums have a clandestine presence in planning documents, their dubious legal status sometimes inviting 'clearance' as an official response.

VIII. SMALL VERSUS BIG: A FRAGMENTED ECONOMY.

There are two distinct economies in Bangalore, the corporate global and the small local economy. The former comprises the enclaved high-income neighbourhoods, the corporate business centres of MG Road, and the exclusive urban design mega-projects. The latter comprises a much more diffused set of services and small-scale manufacturing- centred local economies providing a bulk of employment generation. The local economies provide most of the population particularly poor groups with their livelihoods. They mostly develop outside the master planned areas, with diverse and complex economies and land tenure forms within which poor groups find accommodation and work. Their links with government are through local government, the City Corporation and its councillors and lower level bureaucracy. The corporate economies include the information technology industries for which Bangalore is well-known. Most of their links with government are with state and national parastatal agencies that control most of Bangalore's development functions and have access to most government funding. But there is little local representation in these agencies. The institutions and processes of governance in these two economic settings are quite different; so are their political and economic affiliations. Notwithstanding, there is an important relationship between the two. The corporate economy provides sustenance for the local economies in terms of employment. Conversely, the informal economies subsidise the corporate ones because of low wages and missing protective labour legislation and are thus preserve the position of the corporate economies in the highly competitive world market environment. Most local economies are located in two main areas: the two city centres (housing the wholesale and retail markets) and the mid- and peripheral zones. These areas, serving as the city's employment nodes, are almost always non-master planned, which allows them to be of mixed use. The mid- and peripheral zones concentrate 70 percent of the industries, almost all in smaller privately created industrial estates or in mixed use residential areas. The peripheral areas, with basic levels of infrastructure and services, also serve as bedroom communities with residents travelling to the main city for employment. There is a startling scale and diversity of employment generation. The economies are constituted by small and tiny enterprises, distinctive in the range of products manufactured or traded. Enterprises cluster to share functional links. In contrast, higher end corporate economies locate in and around MG Road, Bangalore's corporate downtown, or within master planned enclaved neighbourhoods located mostly in the south and, more recently, in east Bangalore (Benjamin, 2000, pp. 38-40). As Dittrich comments "The selective internationalisation of Bangalore produces 'winners' and 'losers' of urban society. (Dittrich, 2007, p. 56).

IX. POLITICS, POLICY AND PLANNING

▪ The Politics of Infrastructure.

Understanding the divide in Bangalore requires an understanding of the governance processes through which different groups compete for public investments and support. The contestation of the groups is a highly politicized process. In considering the role of the state and political actors, it is important to note that (a) the role and priorities of the state have changed over the years keeping pace with Bangalore's transition (b) the state itself is not a unitary, homogenous entity. Even at the level of the sub-national state, it operates at the state government, local body and parastatal agency level, and each of these mediate with each other and in the lives of the citizenry with varying and differential impact. (Benjamin, 2000, pp. 54-6). Bangalore's transition to metropolitan status paralleled a shift in the character of the state. In the early phases of the city's economic history, the developmentalist role of the state was evident in the preponderance of the public sector, controls on consumption, and redistributive mechanisms. This began to change with state encouragement to private investment and the increasing influence of the private corporate sector in influencing state policy. Nair comments with intended irony that the state apparatus which restricted consumption in its redistributive role in the 1970s had sufficiently altered in 1996 as to put to use the police force to protect Kentucky Fried Chicken outlets from attacks of Kannada activists, thus 'protecting the rights of those who wished to consume branded chicken' (Nair J. , 2000). This change in state priorities mirrored a shift in the

construction of electoral constituencies. In the 1970s and 1980s, the electoral representation of core city constituencies was the stronghold of left-wing trade unionists; a trend which gave way to those who founded their careers in the real estate business, a group that directly benefited from Bangalore's growth (Nair J. , 2005). The entry of corporate actors into the public sphere was not through the conventional electoral route but by a more nebulous route of governance Home-grown Bangalore-based IT giants such as Infosys Technologies made their presence felt in the city's political environment. They became the driving force behind civic governance initiatives such as the Bangalore Agenda Task Force, which pressed for the implementation of a public private partnership model in areas of governance that were earlier under exclusive government control(Yahya, 1-21).

■ **The Clamour for Megaprojects.**

The concept of the information technology sector as a basis for modernization captured the imagination of Bangalore's political and bureaucratic elite. Slogans claimed that Bangalore would compete not with its neighbour Hyderabad but with the real Silicon Valley in California. These slogans translated into large public investments and fiscal policy. The main justification is to make Bangalore 'globally competitive'. Corporate information technology groups were quick to point out the deficiencies in infrastructure in Bangalore and to demand ever more dedicated investment by the state to promote growth; their views were amplified, nationally and internationally, by the corporate media. It was pointed out that the hidden costs of operating in Bangalore made it more difficult for multinational corporations to move into Bangalore. Infrastructure issues were the big headaches, including poor water, irregular power, potholed roads, and non-existent parking spaces. State government response focused on instituting dedicated investment for mega-projects (Heitzman, 1999, pp. PE-8). "Let us go back to the basics in this controversy. . . The three major IT belts, the Hosur Road corridor, the Whitefield Road corridor and the Peenya corridor, support 2.5 out of the seven million residents of Bangalore. Sixty per cent of the State's revenues come from Bangalore. Shouldn't it get a part of that for its own improvement?"(Chief Financial Officer, Infosys in an interview (Menon, 2005). The official response to the IT lobby's demand for better roads and infrastructure was quick and generous. The Infrastructure Policy 2007 was launched 'to provide a fair and transparent policy framework that helps facilitate the process of economic growth and encourage public-private partnership in upgrading, expanding and developing infrastructure in the state'. It emphasised dedicated investments for mega-projects such as: the billion rupee 'mega-city project' which focuses on modernising Bangalore by urban renewal and urban design; a new international airport at Devanahalli; flyovers, ring roads and other grade separators, provision of fibre-optic services in high value industrial areas; of the six-lane high-speed corridor expressway between Bangalore and Devanahalli; upgrading airports at Hubli, Belgaum, Mangalore and Mysore; Greenfield airports at Hassan, Gulbarga, Bijapur and Shimoga; the Bangalore-Mysore Infrastructure Corridor , a six-lane 111-km highway connecting Bangalore and Mysore; the 138.9 square kilometre IT corridor; a 109 km long eight lane Rs. 1100 crore peripheral ring road which will be the longest highway in the country and the high-tech city beyond Sarjapur. Land for these projects was mostly acquired by the KIADB at very low rates. Meanwhile, the publicly sponsored mega-projects do little to support the local economies; and may even serve to disrupt them (Benjamin, 2000, p. 35). In order to make way for the newly constructed elevated expressway, many of the specialized trades operating in the vicinity were moved out in order to de-congest the roads and increase traffic speeds. What used to be an intensive support system is rapidly becoming disbanded with serious consequences for the poor. The disruption in the local economy has also meant that remittances to rural areas have fallen. Walking around the pathways that have been disrupted by the construction and demolition, a common refrain from squatters: "most now realize that they are the dirt to be cleaned off" (Dittrich, 2007, p. 51) (Sharma, 2009) (Menon, 2005) (Benjamin, 2000, pp. 36,48-9,50-51.).he financial implications of mega-project funding on local bodies are severe. The future burden of maintaining what was constructed by these funds falls directly on local bodies. This would have consequences for funds meant for upgrading basic infrastructure like drinking water, sewage lines, drains and basic roads which would be reduced as a consequence. Meanwhile governmental investments in providing shelter and affordable housing to the urban poor have been substantially reduced and the protection of tenants gradually removed (Dittrich, 2007, p. 51) (Benjamin, 2000, p. 36).

■ **The Political Backlash.**

Notwithstanding the underpinnings of links between government and the new economy, the corporate-driven program of governance and infrastructure development experienced setbacks. The excessive attention the then

government paid to the urban sector, particularly the demands and requirements of the information technology industry, at a time when agriculture was going through a serious crisis, cost the Congress dearly in the 2004 elections. The State faced a severe drought in three out of the five years of Congress rule, but drought relief was inadequate and mismanaged. The government's attitude towards the phenomenon of farmers' suicides is seen as callous, particularly the delay in payment of compensation to the families of suicide victims. The extent of popular disenchantment with the government's performance found expression in the voting. The Janata Dal (S) carried the mantle of the 'third front' in Karnataka, and consolidated its position. The coalition political leadership that came to power did not intend to repeat the mistakes of surrendering policy-making to the corporate sector or diverting civic resources to build infrastructure (Menon, 2004) (Yahya, 1-21). As a former Deputy Chief Minister said: "We cannot have islands of prosperity in an ocean of poverty" (Menon, 2005). Still, the neoliberal outward oriented discourse of the corporate sector, and the counter-discourse from below, are recurrent, at times simultaneous phenomena in Bangalore's public domain.

- **Local Politics and Agency**

There is a close connection between the local economies and local politics. Conventional public policy perceives 'the poor' as passive recipients of good or bad legislation. But, as we have seen, poor groups operate in the same arena as wealthier groups; both attempt to shape economic settings and institutions to benefit themselves. Poor and rich groups equally evolve complex political alliances, and in doing so influence institutional structures and policy. Messy chaotic settings where small informal economies flourish generate employment for the poor, provide proximity to demand, markets and suppliers, and open up opportunities for financial and sub-contracting links. Social connections are built, enabling demand-making discourse; local society evolves apace with the local economy; which in turn, shapes local politics' (Benjamin, 2000, pp. 38-9). The political setting for such settings for local economies is provided by the municipal corporation, with councillors and lower level bureaucracy playing a key role. The conventional middle-class, as well as bureaucratic view, tends to dismiss local political processes as 'vote-bank' politics, centred on patron-client relationships, exploitative of poor groups by the local elite, non-transparent, corrupt, and feudalistic. But to a politically trained eye, the direct exchange between a slum dweller and her councillor or MLA (member of the state legislative assembly) is a give and take relationship, an instance of direct democracy at work. "It might be more productive to rethink the workings of democracy under conditions of extreme poverty and differences of wealth, where the democratic processes are decidedly different from the ones these observers are used to..." (Dewit in Benjamin, 2000). This is because of the representation system, and the ethnic and social connections that exist between the lower level bureaucracy, local polity and local economic interests.

- **The Role of Parastatals**

A second critical issue relates to the relationship between parastatal agencies and local bodies. Several scholars of public administration have written extensively on how local bodies are disempowered by parastatal agencies such as development authorities who take over prime development functions that were previously at the local level, leaving local bodies with maintenance functions. Parastatal agencies have a formative role in the shaping of corporate settings, and have little or no local representation. The Bangalore Development Authority and the Karnataka Industrial Area Development Board have practically no local level representation; their governing committees are constituted mostly of bureaucrats under the direct control and supervision of the state and national government. The political representatives are appointees of the state level party in power; and they do not necessarily represent the constituency under the jurisdiction of the development authority. Irrespective of political affiliations, various chief ministers have maintained a direct control over these key developmental agencies. One Chief Minister was quoted as saying that if it was not for the constitutional protection to local bodies, he seriously considered superseding the city's elected body, so as to get on with his job of modernizing the city. Along with this centralized control comes access by the elite to key decision making. Perceiving a major problem as one of 'political interference' from lower level political circuits there is an active effort to de-politicize urban management, alienating local society and distancing decision making from poorer groups, while opening a direct channel to corporate interests. For instance, as part of an effort to shape Bangalore into a Singapore and as a setting for a Silicon Valley, specific organizational interventions such as recruiting senior people from the IT industry to head a newly constituted committee called the

Bangalore Metropolitan Task Force to decide on infrastructure and other key city management issues; and emphasising e-governance to reduce corruption. An urban management structure centred on parastatals is most conducive to this effort (Benjamin, 2000, pp. 44-5).

X. URBAN SPATIAL ARCHITECTURE AND DESIGN.

In this section we examine the spatial aspect of Bangalore's transformation; how the socio-economic changes have impacted on the cityscape, thus making city architecture and land developments reflective of the changing profile of the city.

- **A high rise city**

Apartments recast the concept of the ideal home as a standalone house on a site. Developers from India's two wealthiest cities, Mumbai and Delhi entered Bangalore's real estate market to convert large plots with colonial bungalows into multi-storey apartment blocks. They emphasized the attractions of apartment-style living in terms of a centralized location and enhanced safety. Apartments were increasingly sought as an investment by many who saw Bangalore as a possible refuge from the pressures of metropolitan life elsewhere in the country, or sometimes as a second home. Bangalore's high-class residential neighbourhoods, rather than catering to elderly elite from the senior bureaucracy and manufacturing industry, housed much younger information technology couples. Every builder of upper middle class housing in Bangalore promoted the idea that what he is offering on sale is not mere housing but a 'lifestyle'. The conveniences and luxury services offered by builders evoke a variety of images that would appeal to the city elite. First, there is the invocation of a pastoral idyll in such names as 'Whispering Meadows', 'Whitefield Bougainvillea', 'Laughing Waters', or 'Nisarga'. Then there are images of lush green meadows, babbling brooks, and nature apart from toil in the city. Second, there is the invocation of European history, in such names as 'Belvedere', 'Windermere', or the classic 'Prestige Acropolis'. Finally, there is the evocation of sentiments of peace and tranquility (Nair, 2005).
- **Occupants of fear: gated communities**

Builders now offer privatized luxury and a satisfactory negotiation of scarce public goods in the city, such as power or water supply, while guaranteeing new standards of safety. Beneath the list that bundles several services and conveniences together are the unspoken advantages of paying up for these gated cities. They are an escape from the travails and sheer unpredictability of plebeian democracy, and provide for new modes of sociality centered on the clubhouse, gym, swimming pool, and shops where there is a guarantee of homogenous social class and undisturbed enjoyment of privilege. The image of the white middle-class person is conspicuous in the lavish real estate brochures, at once the ideal consumer of these living pleasures and a reminder of the ideal towards which successful housing must strive. What is therefore offered here is a further item of consumption, relieving the middle-class buyer from the tedium of seeking permissions, negotiating bribes, or securing licences. Banished from these locations are the footpath encroachments, the occasional intrusive noises of street festivals or protests, and the untidy life of the street corner. The 'archisemiotics of class war' Mike Davis says, keeps out the masses by a number of visual, legal, and physical signs. Protected by architecture of fear-high walled compounds, 24-hour security, and restricted single point access-occupants find a refuge from the hurly-burly of political or social life, and a retreat into uninterrupted consumption (Nair, 2005). Privilege in the city wears a guarded look, so that a new architecture of fear is materialized in the gated, high-security enclaves which guarantee its occupants of life safe from the disorders of the streets, 24-hour security systems, and high and impenetrable walls with only one point of entry, once more reducing the occupants encounters with the unexpected. It is a city of fear, not unlike Night Shyamalan's images of imagined terror in 'The Village' (Dittrich, 2007, p. 51) (Benjamin, 2000, p. 38). Robert Sommer's words are worth recalling in this context: 'the deterioration of dominance relationships within a social system leads to a greater reliance on territorial rights. A society compensates for blurred social distinctions by clear spatial ones-physical barriers, keep out signs and property restrictions'.

XI. CONCLUSION

Bangalore's unprecedented rise to metropolitan status fired the technocratic and political imaginations to dream of a brave new world. Yet, even as the city grew, it was evident that its growth needed much more than the English educated netizen to sustain it. The compulsions of development necessitated a concomitant growth of migrant working class to keep it going. This offshoot altered the previously strong middleclass homogenized profile of the city. These groups not only nurture small localized economies that are in contrast to the global corporate IT led economies; they also bring a whole new range of political practices, processes and discourse that are at variance with the neo-liberal agenda. In its new metropolitan phase, therefore, the city has become the ground on which broadly two contending forces stake their claim: on the one hand are the newly renovated citizens, who are amply aided by a technocratic vision of change offered by the leaders of the new economy. On the other hand are those, including citizens-in-the-making, for whom democracy has come to have a different meaning in the urban setting. There may perhaps be no decisive victory for either of these forces in the short run given the heterogeneous composition of power in the city, although the well planned, legally unambiguous and increasingly legible city will gain visibility in the decades to come.

Marginal Intra-Industry Trade and Adjustment Costs: The Australian Experience

Michael Thorpe, m.thorpe@curtin.edu.au

Curtin University, Australia.

Nuno Carlos Leitão, nunocarlosleitao@gmail.com

Évora University, Portugal

Abstract

The objective of this research is to investigate labour market adjustment associated with changes in Australia's trade pattern over the period 1992-2000. Specifically the focus is on the so-called smooth adjustment hypothesis (SAH) which posits that, compared with inter-industry trade, intra-industry trade (IIT) expansion is associated with relatively lower factor adjustment costs. A dynamic panel data approach (GMM-System) is employed. We find that there is a negative correlation between changes in employment and increased IIT. This result provides support for the SAH. Given the rise in IIT as a proportion of Australia's overall trade during the period under review, the adjustment in labour markets stemming from trade liberalisation at that time is likely to have been less than otherwise expected.

Key words: marginal intra-industry trade, labour market adjustment, dynamic panel data.

1. Introduction

Trade liberalisation and the resultant shifts in a country's trade patterns will be accompanied by significant resource reallocation effects. Transitional adjustment costs in factor markets will arise when markets fail to clear in response to changes in supply and demand conditions. More particularly, in labour markets there may be temporary unemployment and factor price disparity arising from price stickiness and the fact that resources are not freely mobile within an economy, at least in the short term. Balassa (1966) was the first to draw attention to the fact that the adjustment pressures stemming from trade liberalisation will depend on the extent to which the changes in trade which is engendered is inter-industry or intra-industry in nature. The widely held smooth adjustment hypothesis (SAH) proposes that a rising share of intra-industry trade (IIT) will be accompanied by lower factor adjustment costs, particularly in respect of labour market disruption (Brülhart, 2000). With intra-industry adjustment, workers move within rather than between industries,

While there has been increased focus in the literature on this issue of adjustment costs associated with IIT in recent years, it has tended to have very much a European focus. Very little work has addressed the Australian experience.

The results presented here tend to support the SAH which suggest that the impact of trade liberalisation policies over the 1980s and 1990s, which lead to a rising share of IIT for Australia, were relatively less disruptive of labour markets than might have been expected. This finding has implications for future policy considerations in this area.

The remainder of this paper is organised as follows. The next section addresses the theoretical issues related to adjustment and IIT. A review of recent developments in Australia's IIT trade is then given, followed by discussion of methodological issues associated with the measurement of IIT. Details of the dynamic panel data approach employed and the model specification are provided together with the empirical results and discussion.

2. Adjustment and Intra-industry Trade

It has been argued that the level of adjustment costs associated with trade liberalisation will depend on the extent to which any trade expansion is intra-industry rather than inter-industry in nature (Hamilton and Kniest, 1991; Greenaway et al., 1994; Brülhart and Elliott, 2002). Adjustment costs occur when markets are slow to respond to changing supply and demand conditions and in the context of a changing trade environment are likely to be particularly important in labour markets, with unemployment arising as a result of price rigidities and switching costs due to job search, re-location and retraining (Ferto and Soos, 2010).

Given that IIT tends to be characterised by reallocation of resources within industries while inter-industry trade is more reflective of a reallocation of resources between industries, Brülhart (1994) argued that increases in exports in a particular industry over a given period matched by increases in imports will not require significant movements of factors into or out of the domestic industry in question. To the extent that workers have accumulated human capital that allows for ease of portability between firms within the same industry, adjustment costs will be expected to be relatively less for matched changes in trade compared to a situation where labour is forced to move from a contracting importing industry to a different expanding exportable industry (Lovely and Nelson, 2000). Brülhart and Elliott (2002) provide a theoretical exposition drawing on the specific factors trade model which yields the so-called “smooth adjustment hypothesis” (SAH) inferring that trade expansion that is IIT in nature will be accompanied by relatively smooth resource reallocation. The theoretical literature, however, falls short of providing a clearly specified framework for empirical modelling.ⁱ

3. Policy Reform and Trade Patterns in Australia

Australia experienced significant reductions in trade protection for the manufacturing sector during the period of the mid to late 1970s and again from 1988 when a program of phased reductions in nominal tariffs was introduced. Revenue duties were also removed along with quotas for the manufacturing sector at this time. The average nominal rate of protection for Australian manufacturing had fallen from 13 per cent in the mid 1980s to 9.6 per cent in 1989-90 (Menon, 1994). By mid-2001 the rate was down to 4.4 per cent (WTO, 2002). The average rate of effective protection for manufacturing meanwhile, fell from 16 per cent in 1989-90 to 4.8 per cent in 2000-2001. The resulting increase in global competition resulted in significant increases in imports (and exports) of manufactured goods and was reflected in a sharp increase in Australia’s IIT from the mid-1980s through to 2000 (Sharma, 2004; Harjono, 2002). While Gaston (1998) has observed the adverse effect on manufacturing employment arising from trade reforms in Australia, to the extent that trade expansion over the period of the 1990s was more IIT in nature, then the labour market pressures would be relatively less than might be expected, assuming the SAH. Moreover, this would have implications for the efficacy of further trade liberalisation.ⁱⁱ

4. Measuring Marginal Intra-industry Trade

The Grubel and Lloyd (1975) index of IIT, or a variant, underpins much of the discussion of changing trade patterns in the literature. However, it is a static measure which captures the trading pattern at a point in time; changes in the index do not adequately reflect changes in the flow of goods traded over time (Hamilton and Kniest, 1991; Menon and Dixon, 1997). The measure also fails to address scale effects and therefore does not allow for comparisons across industries of different size. Given that adjustment costs are dynamic in nature a measure of marginal intra-industry trade (MIIT) is needed to capture changes in the structure of trade. Lovely and Nelson (2002) provide a useful survey of the various theoretical and empirical approaches that have been undertaken in this area. One particular “dynamic” measure of the share of IIT in new trade was proposed by Brülhart (1994) and is widely used in empirical work. If X and M denote exports and imports, respectively, of a particular industry grouping, then this index is given by:

$$MIIT = 1 - \frac{|\Delta X - \Delta M|}{|\Delta X| + |\Delta M|}$$

The Brülhart index is a transformation of the Grubel and Lloyd (1975) index and takes values between 0 and 1. A value of 0 indicates that the marginal trade in the industry is exclusively of the inter-industry trade and a value of 1 represents marginal trade that is entirely of the intra-industry type. The index relates to the share of IIT in trade changes over a designated time period and the approach employed in this study is to use this index based on annual changes.ⁱⁱⁱ

Empirical studies in this area have differed with respect to the measures of labour market adjustment that have been used. They encompass a range of proxies including changes in employment, output and numbers

of establishments, job turnover rates, unemployment duration and wage variability (Brülhart and Elliott, 2002; Lovely and Nelson, 2002).

5. Econometric Model

There is no formal theoretical model which dictates a particular econometric specification in investigating the labour market adjustment associated with trade liberalisation. There is no clear suggestion as to what control variables to include in any fully specified model. Methodological approaches in empirical work have varied, for the most part looking at simple correlations or looking to control for a small set of other factors in an OLS framework. A review of recent studies in the area by Erlat and Erlat (2006) finds mixed support for the SAH.

The current study applies a dynamic panel data approach. The GMM system (GMM-SYS) estimator which is used addresses the problems of serial correlation, heteroskedasticity and endogeneity among explanatory variables which can arise in static panel data models. A system of equations in both first-differences (with lagged levels as instruments) and levels (with lagged first differences of the series used as instruments) are combined. This system estimator was developed by Arellano and Bond (1991), Arellano and Bover (1995) and Blundell and Bond (1998, 2000). While an alternative first-differenced GMM (GMM-DIF) estimator has also been suggested by these authors, the GMM-SYS estimator is considered to exhibit superior finite sample properties where there are lagged effects (Bond, Hoeffler and Temple, 2001).

The good performance of the GMM-SYS estimator has led to its wide application in applied panel data studies where series are persistent and data are characterised by relatively small number of time periods (Bun and Windmeijer, 2007). Employment changes are a dynamic phenomenon with persistent, lagged effects likely. The use of a lagged dependent variable can provide information regarding short run and long run adjustment effects (Ferto, 2009) while the introduction of a lag structure for independent variables allows for an enhanced dynamic estimation process. Little use has been made of this approach in empirical work in the trade area to date.

Data

All data are obtained from World Bank Trade and Production database. The data includes the manufacturing sector and is at industry level as measured at the three-digit level of the International Standard Industry Classification in US dollars. The full sample contains 27 industries and covers the period 1993-2000.

Dependent Variable

Industry level employment changes are considered as an inverse proxy for adjustment costs.^{iv} Brülhart (2000) has suggested using the absolute value of employment changes in a particular industry ($\Delta EMPL$) since expected changes in total employment would be indeterminate in the specified model. According to the SAH it is expected that $\Delta EMPL$ will be negatively related to MIIT. The variable is defined as follows:

$$\Delta EMPL = 2 \times \frac{(EMPL_t - EMPL_{t-1})}{(EMPL_t + EMPL_{t-1})}$$

Explanatory Variables and Development of Hypothesis

Following the research literature we have proposed the the following hypotheses:

Hypothesis 1: A positive correlation between change in apparent consumption and change in employment is expected. The variable $\Delta CONS$ represents the change in domestic and external demand. It is the absolute value of the change in apparent consumption ($C = Q + M - X$) between t and $t - n$, where Q a measure of industry output and M and X are imports and exports respectively for that industry.

Fertö (2009) found employment changes to be positively related to consumption changes in a study of the Hungarian food industry. Brülhart and Thorpe (2000) also found a positive relationship looking at the manufacturing sector in Malaysia.

Hypothesis 2: There is an ambiguous sign between change in labour productivity and change in sector employment. An increase in productivity may lead to labour substitution or alternatively it may be an indicator of an expanding industry with growing employment.

The variable Δ PROD is the absolute value of the change in labour productivity at industry level. In a study of Turkey Erlat and Erlat (2006) found a negative relationship, while Fertö and Soós (2010) looking at Hungary and Poland and Brülhart and Thorpe (2000) in the case of Malaysia, found the opposite effect.

Hypothesis 3: The marginal intra-industry trade has the lower the adjustment cost.

MIIT is marginal intra-industry trade is measured by the index of Brülhart (1994). According to the SAH (Brülhart 2000) we hypothesise a negative relationship between marginal intra-industry trade and the changes in employment.

Hypothesis 4: Increased trade will induce enhanced competition and hence increased structural adjustment pressures on firms (Brülhart, 2000). Consequently a positive relationship is expected between trade openness and employment changes. The variable TRADE is the absolute value of the change in exports plus imports between t and $t - n$. Studies by Cabral and Silva (2006) and Fertö (2009) have found significant positive relationships.

Model Specification

Constrained by data on individual worker movement we follow Brülhart and Thorpe (2000) and Erlat and Erlat (2006) to study the relationship between marginal intra-industry trade and labour market adjustment:

$$\text{Log}|\Delta\text{EMPL}|_{it} = \beta_0 + \beta_1 \text{Log}|\Delta\text{EMPL}|_{it-1} + \beta_2 \text{Log}\Delta\text{CONS} + \beta_3 \text{Log}\Delta\text{PROD} + \beta_4 \text{LogMIIT} + \beta_5 \text{LogTRADE} + \eta_i + \varepsilon_{it}$$

All variables are in the logarithm form; η_i is the unobserved time-invariant specific effects; δ captures a common deterministic trend; ε_{it} is a random disturbance assumed to be normal, and identically distributed with $E(\varepsilon_{it})=0$; $\text{Var}(\varepsilon_{it})=\sigma^2 > 0$.

6. Empirical Results

Table 1 report on the GMM-System estimator. The Arellano and Bond test for Ar(2) indicates that the equation presents consistent estimates, with no evidence of second-order serial correlation and with the instruments not correlated with the residuals. The Sargan test shows that there are no problems with validity of the additional instruments used in the estimation. The Windmeijer (2005) finite sample correction is performed to address any issues due to the unbalanced panel.

The instruments in levels are $\text{Log}|\Delta\text{EMPL}|$ (3,7), $\text{Log}\Delta\text{CONS}$, $\text{Log}\Delta\text{PROD}$ (3,7), $\text{Log}\Delta\text{CONS}$ and LogTRADE (3,7) in the equations in first differences. For levels equations, the instruments are first differences, with all variables lagged t-2. As show in table 1, all explanatory variables are significant ($\text{Log}|\Delta\text{EMPL}|_{it-1}$, at 5%, $\text{Log}\Delta\text{CONS}$, at 1%, $\text{Log}\Delta\text{PROD}$ at 5%, LogMIIT at 1%, and LogTRADE at 5% significance level).

Lagged changes in employment ($\text{Log}|\Delta\text{EMPL}|_{it-1}$) are seen to have a significant and positive effect on changes over the current period, a result which is in accord with evidence reported by Fertö and Soós (2010) for Hungary and Poland. The coefficient of the absolute value of the change in apparent consumption ($\text{Log}\Delta\text{CONS}$) has the expected positive sign. There was no *a priori* expectation regarding the link between changes in productivity ($\text{Log}\Delta\text{PROD}$) and employment. The observed positive relationship is in line with results observed in some other studies (Brülhart and Thorpe, 2000; Fertö, 2009; Fertö and Soós, 2010).

The proxy LogTRADE which captures increased openness is seen to exhibit the expected positive relationship with employment changes. There is support for the SAH given that the coefficient for the index of marginal intra-industry trade (LogMIIT) has the predicted negative sign and is highly significant.

Table1: Employment Changes, Marginal Intra-industry Trade, and Adjustment Costs: GMM-System Estimator

Variables	GMM-SYS	Expected Sign
Log Δ EMPL $_{it-1}$	0,263 (2,15)**	(+)
Log Δ CONS	1,13 (4,61)***	(+)
Log Δ PROD	0,33 (2,40)**	(+/-)
Log Δ MIIT	-1,51 (-4,65)***	(-)
LogTRADE	0,59 (2,48)**	(+)
N	149	
Arellano-Bond test for Ar(2) (P-value)	0,223	
Sargan test (P-value)	1,000	

The null hypothesis that each coefficient is equal to zero is tested using one-step robust standard error. T-statistics (heteroskedasticity corrected) are in round brackets. P-values are in square brackets; ***/**-statistically significant at the 1%, and 5% levels. Ar(2) is tests for first-order and second-order serial correlation in the first-differenced residuals, asymptotically distributed as $N(0,1)$ under the null hypothesis of no serial correlation (based on the efficient two-step GMM estimator). The Sargan test addresses the over-identifying restrictions, asymptotically distributed X^2 under the null of the instruments' validity (with the two-step estimator).

7. Conclusion

This paper addresses the issue of labour market adjustment in the Australian manufacturing sector following a period of significant trade liberalisation which commenced in the late 1980s. Over the 1990s Australia experienced significant structural change in response to the shift in trade patterns engendered by the policy reforms. It has been noted that during this period the share of IIT in Australia's trade rose significantly. To the extent that the share of IIT in trade changes has been rising, then it is hypothesised that the adjustment pressures in labour markets will be relatively less than would otherwise be the case. This stems from the SAH which is predicated on the notion that trade expansion which is IIT in nature entails relatively smoother resource reallocation, occurring within industries as opposed to between different industries and as a result, there are expected to be lower transitional adjustment costs. There has been only limited investigation of the evidence for the SAH in the literature, particularly in the Australian context. This study goes directly to this issue as evidenced by recent adjustments that have occurred in Australia's manufacturing sector.

The results obtained do lend support to the SAH while controlling for other factors expected to be important influences on labour market outcomes. As expected, growth in consumption and productivity are seen to positively impact on employment changes. Increased trade also has an expected influence and is found to also be directly related to greater adjustment costs as measured. Changes in employment associated with trade liberalisation and trade expansion over the period of the study are found to be inversely related to increases which are IIT in nature. This outcome conforms to the prediction based on the SAH.

There are implications for policy makers in this outcome to the extent that the adjustment pressures accompanying further trade liberalisation in manufacturing will likely be lower than expected. The results presented here are indicative and further empirical investigation in this area is suggested. Studies involving IIT have sought to separate out this type of trade into vertical and horizontal components. The implication for studies of adjustment is that factors may be relatively less mobile within vertically differentiated industries compared to horizontal differentiated industries due to differences in skill requirements. Any analysis would benefit, therefore, from such disaggregation of IIT flows. The proxies which are required of necessity to measure adjustment in labour markets are also problematic. Data limitations have been a constraint on efforts to capture fully the nature of adjustments that can arise. Further comparative work, looking at other periods for Australia, as well as the experience in other countries, will also help understanding the adjustment impacts of policies directed towards greater trade liberalisation.

ⁱ Lovely and Nelson (2000; 2002) adopt a general equilibrium modeling approach which incorporates changes in domestic consumption as well as production resulting from trade liberalisation. They conclude that the relationship between MIIT and factor market adjustment suggested by theory is complex and not unambiguous in terms of net impacts.

ⁱⁱ Marks (2010) has noted that IIT changes in response to reduced protection in Australia has differed between the textile and clothing and footwear sector and the motor vehicle industry. While it is suggested there is a

correlation between changes in output and employment growth in these industries linked to the shift in trade patterns, the study stops short of developing a formal model.

ⁱⁱⁱ Brülhart (2000) favors the use of this index based on annual change data when used as a proxy although there is no a priori expectation as to any preferred interval.

^{iv} Measures of adjustment cost that are used in empirical work will be constrained by the availability of data (Greenaway et al, 2002). Brulhart and Elliott (2002), for example, have looked at unemployment duration and wage variability in a study which finds that adjustment costs associated with changing trade patterns in the UK reflect in large part the greater heterogeneity of labour between industries than within industries.

Research and Development (R&D) Cooperation: Economics Foundations of Business Strategy

Rand Geroges Yammine, gergesyammine@em-lyon.com

EMLYON Business School, France

Abstract

The purpose of this paper is to present a literature review on the topic of R&D specifically tackling cooperation versus competition amongst firms. Furthermore, the paper aims at suggesting a brief critique by linking the economical perspectives of R&D to other management fields in particular strategic management and organizational theory. In the first section, I will start by reviewing an eclectic set of celebrated journal articles in the aforementioned field.

Literature Review

According to Galbraith (1952), the era of cheap invention was over and Research and Development (R&D) could be only conducted by firms with considerable resources. Nevertheless, R&D requires substantial efforts and resources often not even held by large firms and thus the need for cooperation. The research stream of R&D and cooperation has attracted significant attention in the past few years. Two ways of modeling knowledge externalities have emerged, specifically the AJ and KMZ models.

One of the most influential papers in the area of R&D has been that of D'Aspremont and Jacquemin (1988) in which they introduced the AJ model. The authors contribute to the field by suggesting that firms could cooperate in conducting research but still compete aggressively in the market. To understand the different types of cooperative and competitive agreements among firms, they examine two-stages namely research and the subsequent production strategy. Consequently, the authors scrutinize three possible strategic games by employing the two-stage approach. In the first game, firm *i* and firm *j* decide not to cooperate in both stages thus neither in R&D nor in production (D'Aspremont & Jacquemin, 1988). This type of game has been later described as "Case N" standing for Nash (Amir, 2000). In the second stage, the two firms strategically cooperate at the first stage of R&D but opt to remain competitors in the production stage (D'Aspremont & Jacquemin, 1988). According to Amir (2000), this game could be referred to as "Case C" meaning R&D cartel. In comparison with the complete non-cooperative condition, this game displays an increase in R&D levels as well as an increase in the amount of production. In the last game, firm *i* and firm *j* cooperate in the form of a monopoly by cooperating at both stages (D'Aspremont & Jacquemin, 1988) and considered as the "Case CC" in Amir's (2000) terms. When contrasting with the non-cooperative game, the R&D level in full cooperation is dependent on the amount of spillover. In cases of large spillovers, R&D is higher in the fully cooperative game than in the non-cooperative one. In comparison with game two, we can notice that the level of R&D is higher although the actual quantity produced is lower (D'Aspremont & Jacquemin, 1988). The authors utilize several equations to represent the three games and conclude on the highest levels of social efficiency. The results show that game two increases R&D expenditure and production levels in the case of large spillovers. Given the aforementioned condition, production levels reach a social optimum. On the other hand, R&D levels touch the social optimum in the monopoly game when the spillover level is high. The paper illustrates that the best form of cooperation is that at both stages namely R&D and production especially when spillover effects are high enough (D'Aspremont & Jacquemin, 1988). An underlying assumption is that R&D spillovers represent the benefits transferred from firm *i* to firm *j* in which "leakages in technological know-how take place in final outcomes: Each firm's final cost reduction is the sum of its autonomously acquired part and a fraction of all other firms' parts" (Amir, 2000, p. 1014).

Kamien, Muller, and Zang (1992) introduced another influential model in the field of R&D known as the KMZ model and often considered as an extension of the AJ model. Similar to the AJ model, the authors separate the cooperation process into two stages namely R&D and production. Instead of three games as in the AJ model, the KMZ model suggests four scenarios. In the first scenario termed as "Case N", the firms compete on both stages. The firms make decisions separately on the R&D level of investment in stage one. In the second stage, the costs of production are reduced by the firm's R&D investment as well as spillovers from the competing firms (Kamien, Muller, & Zang, 1992). "Case N" could be considered as an equivalent to the first game in the AJ model

(D'Aspremont & Jacquemin, 1988). The second scenario of the KMZ model is R&D cartelization named as "Case C". Firms merely cooperate on the R&D stage but remain competitors in the second stage. As in the first scenario, the firms benefit from their own R&D cost endeavors and spillovers. Even though the firms coordinate their R&D decisions, they decide not to form a RJV. This scenario is comparable to the second game in the AJ model (D'Aspremont & Jacquemin, 1988). In the third scenario of RJV competition termed as "Case NJ", firms decide to form a research joint venture (RJV) although the R&D expenditures remain uncoordinated. Each firm aims at maximizing its profits independently of the rest of the competitors. Firms remain competitors in the second stage and spillover is increased to the maximum level (Kamien, Muller, & Zang, 1992). In the last scenario RJV cartelization named as "Case CJ", firms create an RJV and thus maximize combined profits by coordinating their R&D efforts and expenditures. In the production stage, firms are still competitors and the outcomes are similar to the third scenario. Based on the results, RJV competition proves to be inferior to the other three scenarios as it causes low levels of technological improvements as well as a high product price. Nevertheless, forming a research joint venture is not always associated with negative consequences. The results have shown that RJV cartelization leads to the highest profits benefiting all of the cooperating firms in addition to the lowest production prices. Firms that opt for cooperation as part of their R&D strategy should follow the RJV cartelization for optimal outcomes. The understanding of spillover differs from the AJ model where "each firm's final R&D investment is the sum of its own expenditure and a fixed fraction of the sum of other firms' expenditures (Amir, 2000, p.1014).

Economists have long employed the AJ and KMZ models interchangeably when modeling knowledge externalities. Amir (2000) presented a comparison of the two models with the aim of highlighting the differences and emphasizing the superiority of the KMZ model in generic situations. To do so, Amir (2000) scrutinizes the models from a quantitative and qualitative point of view. Furthermore, he evaluates the validity of the two models. Quantitatively, the paper manages to empirically prove that the AJ model systematically leads to higher levels of R&D as compared to the KMZ model in all of the different tackled scenarios or games. On the qualitative level, Amir (2000) finds conflicting discrepancies between the two models. For the KMZ, the summation of the firm's own R&D investments and spillovers from competing firms result in a decreased spillover rate. The results of the paper show that the above is not applicable for the AJ model (Amir, 2000). In the validity check, the author finds that the KMZ model is fully valid whilst the AJ model is not completely valid specifically in the case of high spillovers. In conclusion, the AJ model could be useful in particular situations for instance to explicate the emergence of technology parks. In contrast, the KMZ model is more appropriately employed as a generic model (Amir, 2000).

As we can notice from the above brief review, the role of cooperation in R&D has been acknowledged in previous literature. However, an important question remained unanswered at that stage regarding the level of expenditure in the different cooperation scenarios. In his empirical paper on German service firms, Kaiser (2002) aims at addressing whether cooperating firms spend less, the same or more than non-cooperating firms. In order to do so, the author first investigates the cooperation choices by tackling horizontal versus vertical cooperation. Horizontal encompasses cooperation with competitors whilst vertical includes cooperation with customers or suppliers. Additionally, firms could opt for a mixed type of cooperation involving both, horizontal and vertical. According to the results, RJVs are more prevalent in the latter form of cooperation. Furthermore, the results show that merely horizontal spillovers positively impact the likelihood to cooperate, although displaying a weak significance. Another significant result is that horizontal spillovers display a positive effect on innovation intensity specifically when goods are substitutes and spillovers are at a lower level. Research productivity has also been proved to have a positive effect on RJV formation and R&D expenditures. The more general the R&D approach employed by the firm, the higher the incentive for a firm to form an RJV. In a similar context, generality of the R&D approach and expenditure display an inverse U-shaped effect. Moreover, the results show that market demand fluctuations have no effect on RJV formation or R&D expenditures. Perhaps the main finding of the paper is that cooperating firms spend more on innovation and R&D as opposed to firms not involved in any joint research project (Kaiser, 2002).

Another area of interest in R&D research has been the relationship between R&D cooperation and spillovers. In their paper on spillovers, Cassiman and Veugelers(2002) differentiate amongst two types of spillovers namely incoming spillovers and appropriability. Incoming spillovers stand for the knowledge and information

incoming to the firm from external sources such as competing firms and suppliers, for instance. Conversely, appropriability portrays knowledge and information flowing from within the firm to the public. The results show that the distinction between the two types of spillovers determines the nature of the R&D cooperation between firms. For instance, firms with high incoming spillovers and well-managed appropriation are more likely to cooperate with their R&D efforts. Moreover, firms are more likely to cooperate with research institutes in the case of high incoming spillovers. On the other hand, firms tend to prefer to cooperate with customers or suppliers when appropriation is better. Nevertheless, those firms should be cautious in protecting their information when opting for agreements with customers or suppliers as such cooperative agreements reduce the efficacy of protection measures. The opposite results are observed for research institutes. The main underlying contribution of this paper is the fact that the two different spillover effects should impact the decision concerning the type of R&D cooperation between two firms (Cassiman & Veugelers, 2002).

In order to investigate the cost functions of R&D, Amir, Jin, and Torge (2008) scrutinize the relationship between additive spillovers and returns to scale in R&D. To explicate this relationship, the authors postulate a criterion stating that a joint research is capable of replicating and even being more efficient than the outcome of numerous independent labs with the condition of natural spillovers. Further, they manage to revisit the AJ model by altering the R&D cost function in order to match it with spillovers in the inventive output. Thus after applying the criterion, the authors modify the cost function by first introducing a positive initial marginal cost, adding a fixed cost to the cost function and finally enabling increasing returns to scale. The returns to scale depend on the level of activity, increasing at a low level and decreasing at a high level. Although the results of the study are not necessarily applicable to all industries, they still carry useful implications for R&D policies. For instance when spillover rates are high, the two cooperating firms could profit from economies of scale as a result of R&D endeavors (Amir, Jin, & Troege, 2008).

Literature Critique

After reviewing the literature, the following section aspires to connect the economic point of view of R&D to areas of strategic management and organization theory. The rationale is to link the diverse perspectives to tackle the field from different possible corners thus providing the reader with a fresh and broad impression.

To compete or to collaborate is probably one of the most critical decisions firms have to embark on in various situations ranging from production collaboration to R&D cartels to internationalization strategies (Anand & Delios, 2002). Economically, competing or collaborating is perhaps best elucidated from a game theory standpoint. Analogous with the eminent "Prisoner's Dilemma", firms might decide to fiercely compete on the R&D level despite the numerous incentives to cooperate hence representing perfect Nash equilibrium. In this case, individual profit maximization is the answer to competitors' strategies. Conversely, firms might opt for cooperation as a strategic option thus maximizing profits jointly. In relation to R&D, firms decide to symmetrically commit to cooperation (Suetens, 2005). We can notice that AJ and KMZ, the two most influential models in the area of R&D, are a reflection of game theory as they present several possible "collaboration versus competition" scenarios.

The significant influence of the two models has not stopped severe criticisms from emerging. For instance, Henriques (1990) and Amir (2000) argue that the AJ model is only valid in the case of high spillovers. Furthermore, the AJ model could be of use merely in an attempt to explicate the emergence of technology parks such as Silicon Valley (Amir, 2000). Although technology parks are not the most important source of innovation, recent studies have shown that location in fact is a crucial innovation engine. The old school of thought has often focused on the internal factors behind innovation such as the resources to innovate and commercialize new technological advances. Yet, recent ideologies have aimed at equating the magnitude of the internal force with that of external forces. This school of thought highlights the role of location as a crucial incubator of innovation. A favorable innovative environment could consist of linkages with educational and research institutes, high vertical and horizontal spillovers and a conglomerate of scientists and field experts. Recent studies have shown that countries with favorable innovation environments are much more likely to innovate than their counterparts. This carries implications for firms deciding on the optimal strategic game. Opting for an R&D location should be based on

advantages related to spillover rates and relationships with key stakeholders who facilitate information access and knowledge sharing. Again, this raises the issue of “compete versus collaborate”. Some might argue that such clusters or technology parks carry disadvantages linked to the loss of competitive advantage due to high spillover rates making it tricky to protect novel ideas from rivals. Yet, such clusters are usually characterized by a set of indirect competitors such as suppliers which are sources of complementary ideas that enforce the competitive advantage of individual firms in addition to that of the overall location (Porter & Stern, 2001). This is in line with Kaiser’s (2002) findings on the likelihood of RJV formation in the cases of vertical cooperation. If the future of R&D will be mainly driven by location, the criticism targeted towards the AJ model would be diluted. In this case, the applicability of the AJ model would be strengthened as most clusters are characterized by high spillover rates.

Another stream of criticism states that most of the literature on R&D assumes the symmetry of R&D endeavors (Salant & Shaffer, 1998, 1999). In the real world of R&D, this assumption does not apply. In a typical collaboration, one firm often places more efforts than its partner. Nowadays, the nature of the innovation process is changing. Instead of internal R&D teams, the current state is shifting towards global multifaceted networks of relationships bringing together anyone from academic institutions to the fiercest competitors. Due to this increasing complexity, firms have to acquire the dexterity to better manage collaborations. In order to do so, partnering firms could first decide on their contribution such as the added knowledge. To avoid free-riders, firms could divide an R&D project into several phases each underpinned by an IP agreement and exit plan. This way, each firm could decide on the quantity and nature of information to be shared (Collins, 2007). In line with Kamien, Muller, & Zang (1992), coordinated expenditure in the case of RJV cartelization leads to the highest profits and the lowest production prices for the collaborating firms. Furthermore, the above plan could be the answer to one of the most prevalent dilemmas in the area of R&D: IP. To protect their innovations, firms often spend immense amounts and thus minimize spillover rates (Collins, 2007). Yet, IP is not always the answer. As we have already acknowledged from the AJ and KMZ, well-managed collaboration in R&D could have superior results as opposed to alternative strategies.

An issue of concern could be the fact that the R&D literature fails to consider the asymmetry of size amongst different firms in both, competition and collaboration scenarios. From an organizational learning perspective, powerful organizations manage to create their own environments whilst weaker organizations imitate. Moreover, stronger firms are less capable of learning than their counterparts (Levitt & March, 1988). Another perspective highlighting the substantial role of size firm in relation to innovation is Schumpeter’s (1975) renowned article on “creative destruction”. According to Schumpeter (1975), small firms often replace their larger counterparts with disruptive innovations that alter the whole industry. Probably by not considering the natural asymmetry of firms, R&D literature fails to draw a realistic view on competition and collaboration. This brings us to the possible link between the economical perspective on R&D in relation with organizational theory, specifically organizational learning. According to literature, the main sources of learning are “own” and “other’s” experience. Learning from one’s own experience is advantageous as it produces unique outcomes. Nevertheless, this source of learning could incorporate high costs and in many cases, duplicated effort (Schultz, 2005). This is consistent with the literature review on R&D from an economical point of view. Furthermore, we can compare the organizational learning perspective on diffusion with the two types of spillovers namely incoming spillovers and appropriability as termed by Cassiman and Veugelers (2002). Diffusion of technologies for instance happens through several mechanisms such as imitation and pressure. Firms could benefit from the experience of others and thus gain profits through those forms of incoming spillovers. On the other hand, firms that are copied could lose their competitive advantage especially when technological efficiency is a success determinant (Levitt & March, 1988). Thus as already described in appropriability, firms have to learn how to properly manage the knowledge flowing to competitors and partners as to not lose their competitive advantage in the market (Cassiman & Veugelers, 2002). Nevertheless, firms that are copied could enjoy an advantage in other cases. In specific situations where gaining legitimacy is a crucial prerequisite for success, diffusion might place the mimicked firm at a superior position.

One more thought concerning the literature could be related to Coase’s (1937) article on the nature of the firm. Collaboration in R&D efforts might be in line with the underlying notion of transaction costs. With the purpose of saving transaction costs, firms coordinate their R&D endeavors with partners thus forming what could be compared to a monopolistic firm as described by the reviewed literature. Moreover, the results of the R&D literature

show that cooperating firms tend to spend more on innovation as opposed to those who do not (e.g. D'Aspremont & Jacquemin, 1988). This proposition is in line with the Schumpeterian proposition that monopolistic firms tend to innovate more as they have enough cash flow to invest in research activities (Schumpeter, 1934). Strategic management seems to be in line with this ideology. For instance, Turner, Mitchell, and Bettis (2010) suggest that a highly concentrated market places pressure on firms to innovate.

A last issue to be tackled in this section concerns the “free riding” problem mentioned in the article of Kamien, Muller, and Zang (1992). According to the authors, one of the common hazards of research joint ventures is free riding leading to disadvantages for cooperating firms such as a lowered level of research (Kamien, Muller, & Zang, 1992). The solution to this challenge could be underlying in the organizational theory’s perspective on networks. From the network point of view, building strong personal relations and strategically belonging to a social network generates trust thus discouraging malfeasance. Continuous economic relations bring expectations of trust from all the involved parties and minimize opportunism (Kilduff & Tsai, 2003). “Prisoner’s Dilemmas are nevertheless often obviated by the strength of personal relations, and this strength is a property not of the transactors but of their concrete relations” (Granovetter, 1985, p.491).

Conclusion

This paper presents a brief literature review on R&D competition and cooperation strategies. At the same time, it critiques the literature by linking the economical perspective with strategic management and organizational theory. In the literature review, several influential papers are reviewed namely the AJ model (D'Aspremont & Jacquemin, 1988), the KMZ model (Kamien, Muller, & Zang, 1992), a comparison of the two models (Amir, 2000), the level of expenditure in different cooperation scenarios (Kaiser, 2002), the relationship between R&D cooperation and spillovers (Cassiman & Veugelers, 2002), and a review of the AJ model cost functions (Amir, Jin, & Troege, 2008). In the critique section, the paper connects the dots between economics, strategic management and organizational theory. For instance, the first section of the critique builds on the criticism towards the AJ model regarding the high spillover levels in order to relate to the emergence of technological parks (Henriques, 1990; Amir, 2000). If the future of innovation will be driven by location clusters, the AJ model would gain applicability as it is mostly valid under the condition of high spillover rates. A second criticism of R&D literature is linked to symmetry of R&D efforts (Salant & Shaffer, 1998, 1999). The paper suggests ways to better control the asymmetric nature of those efforts by bringing the viewpoint of strategic management literature (Collins, 2007). A third criticism of R&D literature revolves around the assumption that firms are of symmetrical size, which is not the case in real scenarios. The critique thus introduces Schumpeter’s (1975) celebrated “creative destruction” highlighting the relationship between size and innovation levels. This paper then moves to the aspect of organizational learning in connection with R&D’s economical perspective. Diffusion of technologies (Levitt & March, 1988) is compared to incoming spillovers and appropriation (Cassiman & Veugelers, 2002). Organizational learning has proposed different conditions in which appropriation results in competitive disadvantages as well as advantages. After that, the critique relates Coase’s (1937) nature of the firm and the monopolistic perspective from a Schumpeterian (1934) and strategic management point of view (Turner, Mitchell, & Bettis, 2010) to the corresponding levels of innovation. Finally, the critique suggests how organizational theory’s network perspective could be utilized to solve “free-riding” problems in R&D collaborations. In conclusion, the paper has managed to bring together diverse perspectives from several areas of study. Fresh notions are usefully employed to critique, interpret and find possible solutions to the economical perspectives and fundamental topics in the area of R&D.

Strategic Alliances, Institutions, and Performance in Emerging Markets

Rand Gerges Yammine, gergesyammine@em-lyon.com
EMLYON Business School, France

Abstract

This study tackles two research questions. First, how do institutional contexts impact the decision of foreign firms to opt for strategic alliances as entry strategies in emerging markets? Second, are strategic alliances linked to superior performance in specific institutional contexts? Building on a network perspective, I investigate the relationships between strategic alliances as entry strategies, home and host countries' institutional contexts, and performance consequences. In particular, I argue that foreign firms are more likely to enter emerging markets with a strategic alliance to counteract market inefficiencies. However when the institutional context is similar, foreign firms prefer alternative entry strategies. I also argue that in a weak institutional context, strategic alliances are associated with superior performance in comparison with other entry strategies.

Introduction

When home markets mature, firms have to seek opportunities elsewhere. Recently, many emergent economies have received a massive inflow of FDI projects especially from foreign firms based in developed countries. Despite the growing attention, entering emerging markets remains a challenging endeavor due to the specific contextual hindrances (Chung and Beamish, 2005). One of the most problematic impediments to successful entry to emerging markets is the host country's institutional framework. Institutions are often referred to as 'rules of the game' as they play a crucial role in supporting the efficient functioning of market mechanisms. Foreign firms based in developed countries are typically accustomed to operate in properly-functioning institutional contexts where property rights are protected and contracts are respected (Meyer, Estrin, Bhaumik, and Peng, 2009). However, the institutional context differs greatly in emerging markets (McMillan, 2008). The weak institutional context often characterized by informal rules poses various difficulties for foreign firms such as corrupt business practices and limited access to information (Peng, 2003). Thus strategic entry decisions have to be tailored to the specificity of the institutional framework (Brouthers and Brouthers, 2000). Although entry strategies have been extensively scrutinized over the course of years particularly in terms of ownership and control (e.g., Agarwal and Ramaswani, 1992) and capabilities of the foreign firm (e.g., Anand and Delios, 2002), the institutional context of the host country remains unexplored (Meyer, 2001). Furthermore, very few studies address the interaction effect between the institutional context of the foreign firm's home country and that of the host country. Foreign firms are more likely to learn quickly and more efficiently if the new learning elements are similar to existing memory elements (Lee and Paruchuri, 2008). For instance, the foreign firm might be capable of dealing with the challenges of the host country if it is already familiar with a weak institutional context. Hence a marginal difference allows the foreign firm to comprehend and cope with rules of the game. Numerous studies have tackled the institutional context of the foreign firm's home country, although remarkably few consider the possible interaction effect (Meyer and Vo Nguyen, 2005). Institutions not only affect the entry mode decision of foreign firms, but also carry performance consequences. In the weak institutional framework of emerging markets, the asymmetry of information places the foreign firm at a disadvantaged position hence increasing the likelihood of market failure (Casson, 1997). Furthermore, the proliferation of informal norms creates an environment favoring local players (Meyer, 2001). Scrutinizing the consequences of the entry strategy on performance has been a relatively untapped field of research. For instance, minimal studies investigate strategic alliance performance (Saxton, 1997) in spite of escalating research calls (Gulati, 1998). Specifically to my knowledge, none of the previous research has tackled the relationship between entry strategies, institutional context, and performance in emerging markets.

Responding to the crucial role of institutions in determining the entry mode and performance results, I propose the following research questions: (1) How do institutional contexts impact the decision of foreign firms to

opt for strategic alliances as entry strategies in emerging markets? (2) Are strategic alliances linked to superior performance in specific institutional contexts?

The decision to scrutinize strategic alliances in the two research questions spurs from the underlying assumption that strategic alliances counteract the challenges imposed by weak institutional contexts (Meyer *et al.*, 2009). Strategic alliances provide access to crucial resources impacting survival and performance especially key networks (Gulati, 1998). Since the key resources offset weak institutions, I argue in the first hypothesis that foreign firms will opt for strategic alliances as an entry mode in a weak institutional context. Second, foreign firms initially operating in a developed country characterized by a weak institutional context are expected to cope better with the institutional context of emerging markets (Lee and Paruchuri, 2008). Thus, foreign firms originating from a weak institutional context tend to be accustomed to the conditions of emerging markets and are less in need of learning how to deal with informal rules such as corruption and contract violation. Consequently the rationale behind entering the new market with a strategic alliance is diluted. Based on this reasoning, I suggest a second hypothesis indicating that firms are less likely to opt for strategic alliances as an entry mode when the difference in the institutional context is minimal. Finally, a strategic alliance bestows the firm with networks that counteract the negative aspects of a weak institutional context resulting in a competitive advantage (Casson, 1997). In the third hypothesis, I propose that the decision to enter with a strategic alliance in a weak institutional context is expected to positively impact the alliance performance as opposed to alternative entry strategies.

To test the three proposed hypotheses, I am collecting archival data over two time spans namely 1995 and 2005. The main advantage is to capture venture performance via various measures hence augmenting internal validity (Lunnan and Haugland, 2008). In order to capture home and host countries' institutional variations, I opt for a cross-country dataset of multi-industry firms. I particularly examine firms originating from developed countries entering into emerging markets through a strategic alliance, acquisition and/or Greenfield entry mode. In spite of the recent growing interest in the impact of institutions on entry strategies (Meyer *et al.*, 2009), numerous gaps persist. The paper contributes to the field by applying the network perspective to link between entry strategies, home country *and* host country institutions, and performance consequences.

Theory and Hypotheses

Strategic alliances and networks

'Strategic alliances can occur as a result of a wide range of motives and goals, take a variety of forms, and occur across vertical and horizontal boundaries.' (Gulati, 1998:293). Firms decide to enter a strategic alliance due to formal governmental regulations in the host country as is the case in several Asian countries (Delios and Beamish, 1999). However, other motives might underpin the entry decision through this specific strategic mode such as minimizing transaction costs, enhancing market power, organizational learning and acquiring knowledge on the specific environmental context (Kogut, 1988). The aforementioned benefits are mainly achieved thanks to the access of key networks in the host country. Besides, social networks allow the firm to build relationships of trust which enable a larger exchange of information. All of the stated advantages impact performance positively giving the firm a competitive advantage over rivals (Burt, 1997). A network perspective is indispensable to comprehend the relationship between networks and performance. According to the open systems perspective, social networks are a crucial component of the firm's environment (Powell, Koput, and Smith-Doerr, 1996). A social network can be defined as the 'set of nodes (e.g., persons, organizations) linked by a set of social relationships (e.g., friendship, transfer of funds, overlapping membership) of a specified type' (Laumann, Galaskiewicz, and Marsden, 1978: 458). Embeddedness, one of the most referred to notions in the network perspective, is described as the structure of relationships constraining the actions available to the involved actors (Marsden, 1981). The degree of embeddedness can minimize uncertainty faced by the actors hence providing valuable information (Gulati, 1998). Social networks bestow firms with a social capital that is advantageous, especially in specific contexts.

Strategic alliances and institutions

The essence of well-functioning markets comes from the support of institutions (North, 1990) which could encompass property rights, legal frameworks, information systems, and regulatory procedures as well as other coordination mechanisms enabling markets to function properly (Meyer, 2001). In more developed countries, institutions that support the efficient market mechanism are nearly invisible despite their substantial underpinning role. Conversely, the striking majority of emerging countries suffer from weak institutions thus resulting in corrupt practices and inefficient markets (McMillan, 2008). Foreign firms aiming at entering emerging markets have to face challenges associated with the weak institutional context, often incurring massive transaction costs and various success barriers (Globerman and Shapiro, 1999). For instance, information asymmetry proves to be one of the main reasons behind market failures. Institutions act as information providers about business partners thus reducing asymmetries (Casson, 1997). Given the weak institutional framework of emerging countries, entering firms have to spend resources in order to compensate for the asymmetries and reduce risks associated with business partners (Meyer, 2001). Therefore, the costs of entry are vastly dependent on the institutional context of the host country (Heinsz, 2000). For this reason, the strategy choice of foreign firms entering emerging markets should be targeted at counteracting the aforementioned challenges. Specifically, strategic alliances such as joint ventures (JVs) bestow the firm with valuable resources that could offset the disadvantages related to the host country's weak institutional environment (Delios and Beamish, 1999). Strategic alliances provide the entering firm with access to local networks and relationships which could not be acquired by employing other strategies. These valuable resources enable the firm to enforce contracts that are often based on informal norms hence mitigating the risk of contract violation (Peng and Heath, 1996). In contrast with strategic alliances, other forms of entry do not bestow the firm with access to local networks and are hence less favorable in weak institutional contexts. Therefore,

Hypothesis 1: The weaker the institutional context of an emerging market, the more likely are foreign firms to opt for strategic alliances as entry strategy.

Institutional context of home country

Since institutions could act as facilitators or constrainers of economic exchange by providing valuable information, a large distance between home and host country implies that the foreign entrant has to invest in more resources to search for information regarding the unfamiliar institutional context. The more similar this knowledge is to the home country, the less likely is the foreign firm to face the 'liability of foreignness' (Zaheer, 1995). Besides, foreign firms based in developed countries characterized with a strong institutional context are not accustomed to deal with challenges associated with weak institutions such as corruption, embeddedness, and property rights violation (Mezias, 2002). Foreign firms also face the challenge of transferring organizational capabilities to a host country that is substantially different in the institutional context. In most cases, capabilities are specific to the context of the home country because the solutions tend to be particularly designed to solve problems related to that environment (Hannan, 1998) thus determining the strategic orientation of firms as they 'learn by encoding inferences from history into routines that guide behavior' (Levitt and March, 1988: 319). Routines are a result of experience and are retrieved when necessary in future situations as answers to possible complexities, hence directing strategic decisions. Therefore when the institutional context of the host country is considerably different from that of the home country, the foreign firm is less capable of leveraging previous knowledge and experience to formulate novel solutions which places the firm at a disadvantaged position in comparison to local firms (Szulanski, 1996). Strategic alliances assist firms to solve problems of institutional differences by counteracting information asymmetries and corruption through access to valuable networks (e.g., Delios and Beamish, 1999). When the institutional distance is large, firms are probably more reliant on a partner to help with the familiarization process in the alien context. On the contrary when the distance is small, the firm is more likely to approach the foreign market with other entry modes such as Greenfield which allows higher levels of control as well as transferability of knowledge and experience (e.g., Meyer and Vo Nguyen, 2005). Thus,

Hypothesis 2: The greater the similarity between the home institutional context and that of the emerging market, the less likely foreign firms are to opt for strategic alliances as entry strategy.

Strategic alliances and performance

One of the prevalent reasons behind market failure is linked to information asymmetries. Buyers have a limited capability to access information prior to the actual exchange and are faced with the challenge of deciding under ambiguous conditions (Arrow, 1971). Institutions act as the main providers of information thus facilitating the predictability of business partner behavior. Firms operating in a strong institutional context are not required to invest in additional resources in search for information to eliminate uncertainty (Tong, Reuer, and Peng, 2008). When institutions are weak, market mechanisms supporting efficiency severely malfunction. Foreign entrants targeting countries with weak institutions face difficulties accessing local resources and acquiring complete transparent information (Meyer *et al.*, 2009). In such contexts specifically prevalent in emerging countries, embedded resources held by the local firm particularly networks and relationships are indispensable (Delios and Beamish, 1999). Such environments are generally based on informal rules and idiosyncratic structures that tend to set an environment favoring local firms accustomed to 'rules of the game' (Meyer and Vo Nguyen, 2005). Foreign firms have to design strategies to accommodate to those rules. Contract enforcement and property rights protection come from networks and relationships with government authorities, business networks with other firms, and distribution channel agents (Peng and Heath, 1996). For foreign firms merely familiar with legalities, doing business without a local partner in such environments could prove tricky leading in many cases to brutal market failure. Strategic alliances provide the means to access such resources hence lowering transaction costs and partner risks (Buckley and Casson, 1998). The aforementioned context-specific resources enable firms to attain a competitive advantage over other foreign rivals in emerging countries (Delios and Beamish, 1999). Hence, the resources attainment could be positively linked to superior performance. The influencers of performance on alliances and the firms involved have been an underrepresented field of research, especially from a network perspective (Lunnan and Haugland, 2008). Lately, researchers have attempted to examine the relationship between embeddedness in social networks and firm performance (Gulati, 1998). According to structural sociologists, social networks are one of the most substantial aspects of an organization's environment as its actions are embedded in the social network of relationships (Laumann, Galaskiewicz, and Marsden, 1978). Firms with access to social networks can enjoy information and control advantages as compared to those with little or no access (Burt, 1992). As already stated, strategic alliances bestow firms with valuable social networks in the local market. Especially in a weak institutional context (Meyer *et al.*, 2009), the social capital obtained can become the source of competitive advantage and consequently, superior performance (Gulati, 1998). Furthermore, partnering firms have the benefit of trust which minimizes the risk of opportunistic behavior. Due to the weakness of institutionally supported mechanisms such as lack of property rights protection and contract violation, trust could be considered as one of the most critical assets a firm could own (Meyer and Vo Nguyen, 2005). Trust encourages the exchange of information amongst actors thus enforcing the flow of information bestowed through the mere access to networks. Additionally, trust facilitates the interaction between actors as they are not compelled to search for risk-minimizing information at each transaction. All of the mentioned conditions increase the likelihood of the superior performance of an FDI project (Gulati, 1998). Previous research supports the positive relationship between social network embeddedness and performance (e.g., Kogut, 1989). As social networks especially in a weak institutional context are linked to superior performance, the following hypothesis is proposed:

Hypothesis 3: In a weak institutional context of the host country, strategic alliances are expected to be linked to higher performance as compared to other entry strategies.

Research Method

Sample

In order to test the three hypotheses, I opt not to limit the sample to specific countries. I thus select a broad cross-country sample with the aim of highlighting the variation in the institutional context. The institutional variation is both across the foreign firms' home countries (developed countries) and the host countries (emerging countries). The variation allows me to scrutinize the institutional impact on the strategic alliance as an entry mode as well as the effect of institutional distance. The sample will include FDI randomly selected projects from diverse industries all representing foreign firms from developed countries entering into emerging markets. The rationale behind choosing several countries and industries is to capture the utmost institutional variation regardless of country or industry specificities.

I am currently collecting data on the same sample at two time periods, 1995 and 2005 due to several advantages. First, observing the sample at two time periods enables me to monitor FDI terminations and examine performance over the short-term and long-term. Second, the selected period is not too distant in time hence minimizing bias related to events too far in the past. At the same time, the dataset is not extremely recent which allows me to reflect on performance and termination.

Measures

Strategic alliance as entry mode

FDI project could be a strategic alliance, acquisition, or Greenfield (Meyer *et al.*, 2009).

Performance

Measuring alliance performance 'remains one of the most exciting and unexplored areas' of alliance research (Gulati, 1998: 306) This paper aspires to encapsulate a broader perspective by utilizing a multidimensional construct based on Lunnan and Haugland (2008). I operationalize performance using three measures: (1) short-term performance, (2) long-term performance, and (3) abrupt termination (Lunnan and Haugland, 2008).

Institutions

Based on my conception of the notion in this paper, institutions are deemed as strong or weak according to the extent to which they are supportive of a well-functioning market mechanism (Meyer *et al.*, 2009). In order to evaluate the strength or weakness of market-supporting institutions, I select the Heritage Foundation economic freedom index (Kane, Holmes, and O'Grady, 2007). The ten freedom categories reflect Adam Smith's theories on market efficiency and economic freedom.

Control variables encompass *foreign firm age*, *foreign firm size*, *cultural distance*, *GDP per capita*, and *prior experience*.

Contributions, limitations, and future research directions

This study is a theoretical and empirical contribution to the field of strategic management. Theoretically, I apply the network perspective from the field of organization theory to address entry strategies in emerging markets. The paper integrates strategic alliances, institutional context of the home and host country, and performance consequences. Empirically, the paper will contribute to the field on multiple aspects. In response to the call by Meyer *et al.* (2009), I work with a large set of countries to increase the institutional cross-country variations. The data will encompass FDI randomly selected multi-industry projects representative of firms from developed countries

entering into emerging markets. The data will also capture performance from a multidimensional perspective namely short-term, long-term, and termination of ventures (Lunnan and Haugland, 2008).

Although the paper carries interesting implications, I suggest a limitation and future research openings. The archival data on FDI project performance will be of a secondary nature. Secondary data does not entirely capture all aspects of performance, especially subjective facets. In order to strengthen the results, primary data is advisable in future endeavors. Moreover, network analysis offers possible future research opportunities. For instance, research could tackle whether centrality in a network in specific institutional contexts impacts performance.

Conclusion

Despite the crucial role of institutions in the determination of entry strategies and performance consequences for foreign firms, several gaps persist. When entering emerging markets, firms have to tailor the entry mode to counteract the weak institutional context of the host country (Brouthers and Brouthers, 2000). The difference between the institutions of home country and host country also influence the entry strategy (Lee and Paruchuri, 2008). Nevertheless, the impact of institutions on entry modes has been underrepresented. The paper answers the aforementioned research gaps by asking ‘how do institutional contexts impact the decision of foreign firms to opt for strategic alliances as entry strategies in emerging markets?’ Another research gap relates to the consequences of entry strategies in specific institutional contexts on performance (Saxton, 1997). The paper taps this gap by attempting to answer the following question: ‘Are strategic alliances linked to superior performance in specific institutional contexts?’ The paper employs a network perspective to theoretically support the relationship between strategic alliances, institutions, and performance. The results will be based on a sample of multi-industry and cross-country FDI projects. The paper is a contribution to the international strategic management field.

Strategic Options for Vietnam in the East Asian and Global Economy

Guy Schulders, synergies.2010@yahoo.fr

Abstract

Since the *Doi Moi* re-orientation of 1986, Vietnam has experienced substantial economic expansion, with GDP growth unfolding at rates between six and nine percent per year. While Vietnam was able to crown this growth with accession to the WTO in 2006, it now faces serious constraints, only some of which reflect the current global recession..

Our analysis of Vietnam's constraints focuses on monetary policy and institutional governance. Excessive monetary growth has fueled rising inflation. In turn, corruption in various sectors has undermined the efficiency of foreign direct investment flows, particular in the state enterprise sector.

In terms of strategic options, we find that the reform measures of 1986 now require more fundamental reforms of domestic financial institutions, improved budgetary management, and a sustained effort to reduce historic rates of inflation. We are confident that structural reforms along these lines can once again bring sustained economic growth in Vietnam at rates similar to its export-driven Asian neighbors.

1. Introduction: Vietnam at the heart of a turbulent world

It is increasingly clear that no country has mastered the skills and policies for successful integration in the global economy. Since Asia has been the focus of much efforts to track globalization, it is of some interest to examine how countries other than China, Japan, and South Korea have proceeded.

Vietnam, a country with a current population of 88 million, provides an interesting case study. In particular, we choose to examine the strategic options adopted by Vietnamese leaders. In so doing, we take up the paths that Vietnam has adopted in terms of internal reform as well as examine how these policies have helped to shape Vietnam's response to external economic challenges and opportunities. We do so in the context of the recent global recession, the backdrop of seismic events in Japan, and in consideration of the scale and depth of social upheaval taking place in the Middle East.

Vietnam's economic future depends very much on how the above external environment unfolds. At the same time, it also depends on Vietnam's internal governance, in particular, the capacity and willingness of the current leadership to tackle financial austerity as well as reform of its public enterprise sector. We look first at Vietnam's internal reforms.

2. From the *Doi Moi* to the WTO

Vietnam's present challenges can be traced to the initial reforms adopted by the country following re-unification in 1976. From 1976 to 1986, Vietnam leaders extended Communist party rule over the former Republic of Vietnam in the south. This process placed the economy largely on a path of economic autarky and an elimination of any effective political opposition. During this period, Vietnam's economy did not experience much notable growth. Vietnamese leaders recognized that continued party control would require something in exchange for the continuation of the regime. In this sense, Vietnam was not unlike China under Deng Tsiao Ping, who put forth a post-Maoist doctrine of financial and economic reform that could help stimulate economic growth while at the same time providing a basis for political legitimacy under Communist party rule¹.

As with Deng's reforms, Vietnam began to open its economy to international trade and a shift in governance toward a market economy. The *Doi Moi* reforms were based on several key factors affecting the Vietnamese economy.

First, as other socialist economies had done, Vietnam had imposed collectivization of agriculture that, as with the former Soviet Union and elsewhere, had failed to lift production sufficient to feed a rapidly growing population. Privatizing agriculture was one key element in the *Doi Moi* reforms.

Second, public enterprises created and operated by the Communist party under a system of centralized planning had failed to meet both production targets, but also internationally competitive quality standards. Domestic enterprise and financial reform was a necessary step to bring Vietnam into the global economy.

Doi Moi thus can be viewed as a comprehensive shift in emphasis away from an historical socialist planned economy toward a market-driven economy. The *Doi Moi* reforms did indeed revive the Vietnamese economy, bringing sustained annual growth rates of between 6 and 9 percent that affected in mutually reinforcing patterns both agriculture and industry. In so doing, the *Doi Moi* reforms paved the way for Vietnam's re-entry in the global market, and which was crowned by Vietnam's admission to the WTO in 2006.

FIG. 1

Evidence of Vietnam's success can be seen in Figure 1. While starting from a relatively small base, Vietnam's growth in per capita income has placed it on a par with the kind of growth rates seen in China and South Korea, even if Vietnam's per capita GDP is not about to equal or exceed levels in those countries for several years.

As agricultural and industrial reforms proceeded under *Doi Moi*, Vietnam also became increasingly attractive to foreign investment. This meant that under gradual privatization of public enterprises, Vietnamese firms began to develop partnerships with external investors, thus facilitating technology transfer and augmenting Vietnam's domestic savings rate. The most telling measure of this engagement is in terms of Foreign Direct Investment.

FIG. 2

Figure 2 shows comparative rates of Foreign Direct Investment (FDI) to GDP ratios for selected countries in East Asia. Vietnam's rate exceeded others in the region, in part because its base level of per capita GDP was relatively low, and in part because, like China in the early post-Mao years, it was looking to accelerate investment and technological innovation in the shift toward a more market-driven economy.

3. Vietnam since 2007 – An Overheated Economy under Weak Governance

Despite the impressive revival of economic growth and newly acquired membership in the WTO, Vietnam's economy began to show the limits of its reforms in achieving sustained economic growth. The rosy projections of per capita GDP in Figure 1 assume that growth could continue without any additional reforms. Such has not been the case. Instead, even as foreign investors looked to Vietnam's membership in the WTO as a sign of approval, growth has generated both inflation and rising corruption that threaten to undermine the economy.

3.a Excessive Monetary Expansion

How has inflation arisen in the Vietnam economy? Coupled with rising foreign direct investment, Vietnamese authorities have used an expansionary monetary policy to sustain rising rates of economic growth. As this has taken place, inflation rates have increased. Local institutions, ranging from banks to state enterprises that make up some 40 percent of GDP, have been weak in responding to changing market opportunities, with corruption as a key measure of the costs of doing business. Inflation and corruption together have threatened to bring Vietnam's growth to a halt, even if it were not confronted with the impact of the recent global recession.

Figure 3 illustrates the growth of the M2 money supply in Vietnam and in other East Asian regions. Starting from a low base, monetary growth in Vietnam began surpass that of South Korea, and at the pre-recession rate, would soon surpass that of China and East Asian economies as a whole.

FIG. 3

Monetary growth can achieve sustainable growth as long as an economy's productive capacity is expanding at some proportional rate. Unfortunately, the weak structure of governance in Vietnam has meant that even as monetary growth rates expanded, productive capacity did not, with the result that inflation rates began to rise.

Figure 4 illustrates consumer inflation rates for Vietnam, China, South Korea and East Asian economies as a whole. While inflation rates in China have been a concern to international economic stability, Vietnam's much smaller economy has had rates that have surpassed those in China and East Asia as a whole. As in any economy, rising inflation creates economic uncertainty, and investment tends to shift from more productive areas to those that serve simply as an inflationary hedge.

FIG. 4

In the presence of inflationary pressure, monetary velocity also increases, further undermining the ability to manage economic expansion through monetary policy alone. We can state this relationship in terms of the basic equation of exchange across the respective monetary aggregates:

$$(1.1) \quad MM = (M_1)(V_1) + (M_2)(V_2) + (M_3)(V_3) = \sum M_i(V_i) = (P)(Q)$$

where: M_i = the corresponding measure of the supply of money,
 V_i = the corresponding velocity of circulation,
 P = the general level of prices,
 Q = the aggregate quantity of output, or real GDP.

In equilibrium, the value of the money supply, or base, which combines both domestic and foreign direct investment, is equal to the value of production for the domestic and international market. In a non-inflationary environment, changes in the supply of money can lead to an increase in real output. However, if real output is constrained by an imperfect set of incentives, then an increase in the supply of money will lead essentially to an increase in the price level alone, i.e.:

$$(1.2) \quad \sum MM > \sum Q \rightarrow \sum P > 1$$

in which some increase in real GDP is dominated by the rising level of pricesⁱⁱ. For Vietnam at least, the absence of significant institutional reform beyond the *Doi Moi* framework meant that inflation would ensue, with attendant effects on the balance of payments, fiscal deficits, as well as in rising national debt.

3.b Weak Economic Governance

Membership in the WTO soon revealed the weakness of Vietnam's underlying governance institutions. In the 2007-2009 period, credit expansion went largely unsupervised, with too-big-to-fail conglomerates taking the lion's share of borrowingⁱⁱⁱ. One reason why these state enterprises were able to take on such levels of borrowing is that they had the implicit backing of the Vietnamese government. But when faced with the slightest degree of financial stress, the Vietnamese government adopted a hands-off policy, insisting on a strict separation of government debt proper and state enterprise debt, effectively repudiating any implicit government guarantees to honor public enterprise debt obligations. Once this happened, even diaspora Vietnamese, the *Viet kieu*s, stepped back from continued lending, thus helping to precipitate a liquidity crisis in the Vietnamese economy.

Faced with falling investor confidence, the Vietnamese government chose to fill the financing gap not by accounting and institutional governance reforms but by monetary expansion. Because easy credit meant an increase in non-performing loans, the interaction of bank loans, nepotism, and corruption, monetary policy became increasingly ineffective, thus leading to a wave of currency devaluations. *Vinashin*, Vietnam's principal shipbuilding state enterprise, faced charges of nepotism and corruption in 2010, following revelations that it had over \$U.S. 5 billion in losses, which represented approximately 4.5 percent of Vietnam's overall GDP^{iv}.

3.c Serial Currency Devaluations

In the presence of imperfect information, investors are prone to asset bubble behavior. As elsewhere, Vietnamese investors took note of the high flows of credit and weak performance to hedge their risks through real estate and stock market speculation. By 2008, Vietnam's annual inflation rate exceeded 25 percent. Export prices rose accordingly, leading to a rising external deficit that currently is in excess of \$U.S. 12.5 billion.

In response to rising inflation and falling exports, the Vietnamese began a series of successive currency devaluations: three times in 2008, twice in 2009, twice in 2010, and the latest in February 2011. With each successive devaluation, imports became more expensive. Rising import

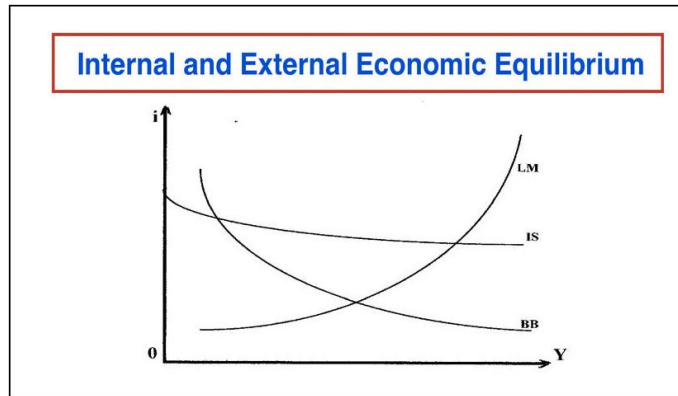

prices increased consumer prices, thereby placing pressure on the Vietnamese central bank to increase interest rates and reduce the rate of expansion in the money supply.

FIG. 5

A very steep currency devaluation can create an electric shock to an economy that can either produce a positive adjustment or cause a general loss of investor confidence. Figure 5 illustrates the combined impact of currency devaluations and credit tightening on Vietnam’s consumer inflation rate.

FIG. 6

For Vietnam, the challenge is to set an interest and exchange rate that could lead to a non-inflationary steady-state economic equilibrium. Figure 6 illustrates the dis-equilibrium that arose from excessive monetary growth and an external imbalance. An initial IS-LM intersection on the right would generate a macroeconomic equilibrium that is non-sustainable, leading to an increase in the central bank’s discount rate and a lower level of GDP. But the fiscal balance (BB) may still be an unstable equilibrium point as IS no longer intersects LM at that point. Clearly, Vietnamese authorities had to seek an interest and exchange rate that would simultaneously enable them to reach non-inflationary output with an internal fiscal and external balance at the same time. And none of this would be possible in the presence of excessive credit growth and corruption distorting effects of investment in the economy.

Table 1

Vietnam Trade Balance and GDP						
	2006	2007	2008	2009	2010	2011*

Source: The World Bank, and authors' estimates

Per capita real GDP, on a \$2005 purchasing power parity (PPP) basis, depends on the economy's rate of savings and on its export share of GDP. In turn, these variables depend negatively on the level of government consumption, negatively on the level of corruption, and positively on the ratio of FDI to GDP. When forecast values of the gross domestic savings rate (GDSR) and the ratio of exports to GDP (EXPGDP Ratio) are used along with the ratio of tax revenue to GDP to explain economic growth, it is clear that government intervention has worked adversely on the level of PPP Per Capita GDP. While we have not included estimates of monetary policy here, we also note that monetary policy alone does not explain a significant degree of per capita growth, for reasons we have summarized in this paper.

4. The Outlook for Vietnam in 2011

Given Vietnam's rising inflation rate wrought by successive currency devaluations noted above, prospects for continued economic growth will depend on establishing a set of institutional reforms along with monetary and fiscal restraint. We focus on several key steps that are most likely to make a difference in Vietnam's current outlook.

Vietnamese authorities need to act without delay in implementing a credible plan of adjustment, starting with large public sector enterprises on the scale of the naval construction conglomerate, *Vinashin*. What drives the need for reform is the impact of downgrades by S&P and Moody's on Vietnam's local financial institutions, three of which at BB- are close to junk bond status^v. These downgrades reflect the rising level of risk exposure on loans to Vietnam's public sector enterprises. The cumulative effect is to reduce foreign direct investment and the ability of the Vietnamese government to secure external credit for overall government capital projects.

Meeting in a party Congress in January of 2011, Vietnamese authorities have set out a series of goals for the next ten years^{vi}. In summary fashion, they are:

1. GDP growth of between 7 and 8 percent per year, reaching \$3,000 per capita in 2020
2. Limit inflation to a maximum annual rate of 7 percent by increasing the central bank commercial discount rate to 12.5 percent, for a real rate of 5.5 percent.
3. Reduce the government deficit to 4.5 percent of GDP and create 8 million new jobs.

Reaching these goals will not be easy. While they are comparable to macro-economic standards adopted by many countries, for them to succeed will require additional measures, which we identify below.

4. Essential Steps in Vietnam's Economic Reform

While Vietnamese authorities have put in place a program of monetary and fiscal austerity, restoring both investor confidence and creating sustainable economic growth will require additional measures. We view the following steps as essential building blocks for this to occur.

1. Public enterprise must undertake major reforms, including a systematic effort to reduce corruption, the elimination of nepotism, and an end to tax shelter legislation that has given these firms the illusion of competitive institutions. In short, Vietnamese public firms must adopt practices now applied to private sector firms if they are to be able to compete in the global market.
2. Consider a short-term plan to use wage and price controls to break the inflationary psychology now unraveling the economy. We view this only as a short-term measure, with a long term view to restoring product and factor markets to competitive conditions.
3. Adopt a flexible exchange rate that would avoid the cascading set of artificial rates and place the economy more in line with internationally competitive standards.
4. Increase banking real interest rates to levels that would generate more sustainable investment decisions, whether in the public or private sector.
5. Adopt internationally competitive auditing standards for Vietnamese firms, and which would apply equally to both public and private firms, to enable greater transparency in the performance of firms and in helping to set prudential levels of investment, consistent with more obviously measured levels of risk.

These measures are essential if Vietnam is to increase the effectiveness of investment flows in the economy, and to achieve the kinds of goals outlined in the National Congress of 2011. While they may be politically unpopular in some quarters, one needs to keep in mind what is likely to happen if these measures are not adopted, namely, a further weakening of Vietnam's economy, even as neighboring Asian economies move to adjust to the difficult challenges ahead.

ⁱ It should be noted that Deng’s reforms were inspired to some extent by a recognition not just of China’s lack of economic growth, but that its former partner, the Soviet Union, was on the verge of economic collapse, even though the formality of that collapse did not become obvious until the fall of the Berlin Wall in 1989, and the end of the Soviet Union in 1991. Much of this comparative observation has been presented in detail in Philippe Delalande, “*La politique économique vietnamienne, ses étapes de 1975 à 2009*”, Franco-Vietnam Friendship Association conference, February 5, 2009.

ⁱⁱ This illustration illustrates a classic division in economic theory, namely the relevance of monetary versus fiscal policy in achieving a sustainable level of full employment growth. The quantity theory of money, which has a long pedigree dating back to Jean Bodin (1596), has been resuscitated against a once dominant Keynesian emphasis on fiscal policy by Milton Friedman, in particular in terms of his *Essays on the Quantity Theory of Money* (1956), in which he took issue with Keynes’ elaboration of the liquidity trap in his *General Theory of Employment, Interest, and Money* (1936). For our purposes, suffice to say that excessive monetary inflation can undermine economic growth, which has clearly been the case with Vietnam.

ⁱⁱⁱ Large borrowers included Vinarubber, Petrovietnam, VNPT (Vietnam Posts and Telecommunications), Vinatex (Vietnam Textile Corporation), and EVN (Electricity of Vietnam).

^{iv} Pham Thanh Binh, CEO of *Vinashin*, was suspended from office on July 20, 2010, and charged with mis-management, including the ill-considered use of \$U.S. 750 million that provided key management positions to his son and his brother.

Corporate Governance in a Globalized Environment

Competencies Based Development in Emerging Market: Case Study of Toshiba Thailand

*Phallapa Petison, cmphallapa@mahidol.ac.th
College of Management, Mahidol University, Thailand*

*Chailert Nithi-ubati, chailert07@yahoo.com
GDIC, King Mongkut's Institute of Technology Thonburi, Thailand*

Abstract

From a 180 degree view, this study explores the competencies necessary for a foreman by comparing perspectives of foremen and their supervisors. We utilize both qualitative and quantitative research methods, critical incident interviews, and surveys. Toshiba Thailand Co. Ltd. is selected since all production lines have been moved from Japan to Thailand; therefore, competency development, particularly at the level of the foreman, is crucial to the company to produce global standard products. By adopting Spencer and Spencer's competency model as the basic framework seven more competencies are added according to interview results with top management. The survey results reflect that foreman and supervisor perceptions on the importance of competency for the foreman position are quite similar. Although the finding reveals that functional competencies are important, it is interesting that ethics, which is not mentioned in Spencer and Spencer, is perceived by both foreman and supervisor as an important competency.

Introduction

Human resource is regarded as an organization's best source of competitive advantage (Hay, 2004). Human resources with the right competencies and commitment allow an organization to achieve its goals and achieve success in business (Slocum, Jackson, and Hellriegel, 2008). Low competencies lead to poor jobs and consequently poor performance of the organization (Thai-Ngam, 2005). Therefore, many organizations determine required human resource competencies that allow the organization to implement strategies according to the organization's goals (Spencer and Spencer, 1993). Competencies-based development (CBD) is widely adopted and is mentioned as the best way to manage people in their jobs (Carretta, 1992). Accordingly, CBD is a popular framework in human resource development both in developed and developing countries (Serpell and Ferrada, 2007). Similar to the practical world, research focusing on CBD is gradually increasing in the academic world, with a few addressing emerging countries. Further, among those studies, CBD focuses mostly on the management level, not the operational level. This leads to a knowledge gap. To compete with rapid competition, a company in an emerging country needs more than the manager-level CBD but also operational-level CBD including employees, particularly at the foreman level. Walker and Bierema (2008) point out that in a new competition paradigm, the foreman as a man of the process is crucial. More focus on developing the role of the foreman is needed to ground the strong employee-based resource in the further development of the company.

In the case of Thailand, CBD has taken its first step in implementation, mainly in multinational companies (Tantiwong and Thanatiwakul, 2005), particularly in American subsidiaries. It is interesting to note that CBD is rarely found in the case of Japanese companies in Thailand even though they are major foreign investors and play important roles in driving the major leading Thai industry. This study attempts to fill the knowledge gap. By raising country level competitiveness and focusing more on human resource development, particularly in the level of operation in the manufacturing sector, which is considered an important contributing factor to the prosperity of the country. Among the subsectors in the manufacturing sector, electronics and electric home appliances are considered the leading subsector (BOI, 2010; Viboonchart, 2011). Thai government encourages industry development, at first as an attempt to substitute imports and now to raise its competitiveness as a hub of exports. Currently the country is reported as the ASEAN's largest production base for home appliances with its leading products of air conditioners and refrigerators (BOI, 2010). Toshiba Group Thailand is selected as a case study to explore since the Toshiba

Corporation has decided to move all of its product lines from Japan to Thailand, supporting its aim to use Thailand as its production hub. To supply global standard products, it is necessary for the company to have competent local employees to ensure the effective and efficient use of human resources talent to accomplish business goals. The HR department attempts to develop competencies, particularly at the foreman level, which is crucial for the company to produce global standard products.

Literature review

“Competency” originates from the Latin word meaning “suitable” (Bueno and Tubbs, 2004). In academia world, the concept of competency is first introduced in the work of McClelland in 1973. His work reflects that competency is a determination of work success rather than IQ. Excellent working employees are not those who have good academic records but ones who are capable of applying knowledge to benefit their work. For the last thirty years, competency has changed from being specialized to being a widely adopted technique and a key factor in HR (Vathanophas and Thai-ngam, 2007).

Along the way, various scholars provide a wide range of competency terminology, including

- *skills* (McClelland, 1973; Boyatzis, 1982; Kolb, 1984; Morgan, 1988; Nordhaug, 1993; Sandberg, 2000, etc.),
- *knowledge* (McClelland, 1973; Boyatzis, 1982; Sandberg, 2000, etc.), *motives* (McClelland, 1973; Mitrani et. al. 1992; Spencer and Spencer, 1993),
- *self concept* (McClelland, 1973; Mitrani et. al. 1992; Spencer and Spencer, 1993),
- *attitude* (Slocum, Jackson, and Hellriegel, 2008; Athey and Orth, 1999),
- *self image* (Ieamvijarn, 2005),
- *attributes* (Sandberg, 2000; Rassamettummachot, 2005, UNIDO, 2002),
- *abilities* (Simpson, 2002), *social role* (Ieamvijarn, 2005),
- *traits* (McClelland, 1973; Mitrani et. al. 1992; Simpson, 2002), and
- *behavior* (Slocum, Jackson, and Hellriegel, 2008; Woodruff, 1992).

Although various scholars term competency in various ways, after a detailed review of those terminologies, the definitions of some terms are actually the same. In sum, competency includes a person’s skills, knowledge, motives, self concept, and traits. Competency is the inner drive that leads to unique characteristics of that person. Spencer and Spencer (1993) further note that competency relates to work effectiveness and efficiency. Competency is measurable and can help differentiate between effective from ineffective employees; therefore, competency allows one to outperform than others (Pornnutwittikul, 2000; Saenthong, 2004).

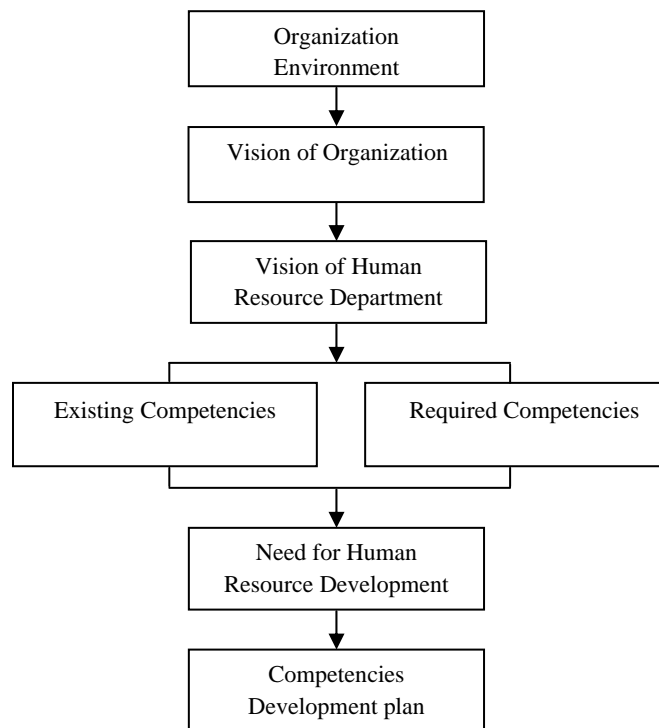

Every organization should encourage competency based development as it benefits both individuals and the organization (Rao, 2000; Rodrigues and Chincholkar, 2005). The challenge in CBD is that some competencies such as skill and knowledge are visible and easy to develop through technical training whereas self concepts, traits, and

motive are the invisible, embedded inner layer of a person and are more difficult to notice, measure, and develop. However, with the systematic competencies based development, these inner competencies can be developed (Tantiwong and Thanatiwakul, 2005; Thai-ngam, 2005).

Competency based at the labor level

Competency is generally classified based on managerial tasks. However, different levels of HR need different competency focuses. Unlike other studies, Serpell and Ferrada (2007) address the different competencies at the labor level. According to their works, competency is divided into three groups: (1) basic competency, which includes a person’s knowledge, ability, and attitude; (2) organization competency, which includes competencies related to the value and culture of an organization; and (3) labor function competency, which includes a mix of knowledge, ability, and psycho-social behavior that cover both technical and generic competencies.

Fig. 1: THE PROCESS OF A HUMAN RESOURCE DEVELOPMENT PLAN

Source: Adapted from Serpell and Ferrada (2007) and OCSC (2004)

To identify competency requirements and gaps as an integrative part of the organizational environment, an appropriate competencies model with proper research data collection such as interview, questionnaire, and focus group with key stakeholders (OCSC, 2004) can be used. This research adopts the above process as the framework for this study.

Research methodology

This research utilizes both qualitative and quantitative research methods aimed to explore the competencies necessary for a foreman to identify competency gaps by comparing perspectives of the foreman and supervisor. First, an in-depth interview with the CEO of the Toshiba group was conducted in order to understand the strategic vision of the company, the direction of the company, and the perception toward the necessity and expected competency of the foreman position, particularly after Toshiba established set its Thailand production center as an export hub.

Secondly, interviews with seven top managers, including general managers, senior managers, and other managers, from five companies under Toshiba (Thailand) group. The companies include Toshiba consumer products (Thailand) Co. Ltd., Toshiba carrier (Thailand) Co. Ltd., Toshiba lighting Co. Ltd., Thai Toshiba electric industries Co. Ltd., and Toshiba Hokuto electronic devices (Thailand) Co. Ltd) were conducted. Critical incident interview techniques are used because this technique is regarded as an appropriate method for indentifying competency (Klemper and McClelland, 1986; Spencer and Spencer, 1993). Interviews focused on current and expected competency levels of the foreman and the competency development plan. Narrative data from interviews were transcribed and analyzed to find out the competencies of the foreman.

Thirdly, by adopting Spencer and Spencer's competency model as the basic framework, competencies that were obtained from the interview in the second stage are compiled to prepare a list of competencies for a survey questionnaire. The Spencer and Spencer model is selected because this model is regarded as one of the most popular models that measures underlying intent competencies while also covering all common competencies of any position (Thai-ngam, 2005; Mansfield, 2000; Chyung et al., 2006). Spencer and Spencer (1993) developed the competency dictionary that represents 20 common competencies for all types of jobs. The common competencies are: (1) Achievement orientation-ACH, (2) Concern for order-CO, (3) Initiative-INV, (4) Information seeking-INFO, (5) Interpersonal understanding-IU, (6) Customer service orientation-CSO, (7) Impact and influence-IMP, (8) Organizational awareness-OA, (9) Relationship building-RB, (10) Developing others-DEV, (11) Directive-DIR, (12) Teamwork and cooperation-TW, (13) Team leadership-TL, (14) Analytical thinking-AT, (15) Conceptual thinking-CT, (16) Technical/expertise-EXP, (17) Self control-SCT, (18) Self confidence-SCF, (19) Flexibility-FLX, and (20) Organizational commitment-OC.

After comparing the competencies obtained from interviews in Stage 2, seven more competencies are identified – ethic, foresight, positive thinking, self development, problem solving and decision making, writing communication, and presentation skill. A few competencies from the competencies dictionary are omitted: customer service, concern for order, self control, and organization awareness. The most common reason pointed out by top level managers is that according to the job description and expected role of the foreman, these competencies seem to receive less focus. A few top managers point out that these competencies are expected from the supervisor rather than of the foreman.

Fourthly, a survey questionnaire is prepared and piloted by 30 people to ensure the reliability of the questions. A short description of each competency is provided to ensure clarity. The same questionnaire, which asks about the importance of competencies for the foreman position, is used to survey 93 supervisors and 146 foremen. The survey uses a five-point scale, asking survey participants to rate their perceptions of how important each competency is for the foreman position. The sample numbers for supervisor and foreman are presented in Table 1. The return rate is 100 percent with all useable questionnaires returned, mostly because support was provided if participants did not clearly understand the questionnaire.

TABLE 1: TOTAL SAMPLE SIZE FOR SIZE FOR SUPERVISOR AND FOREMAN POPULATIONS

Company	Supervisors	Sample	Foreman	Sample
Toshiba consumer production (Thailand) Co. Ltd.	48	37	84	52
Toshiba carrier (Thailand) Co. Ltd.	21	16	56	35
Toshiba Hokuto electronic devices (Thailand) Co. Ltd.	9	7	22	14

Toshiba lighting component (Thailand) Co. Ltd.	9	7	4	3
Thai Toshiba electric industries Co. Ltd.	24	18	40	25
Thai Toshiba lighting Co. Ltd.	4	3	14	9
Thai Toshiba fluorescent lamp Co. Ltd.	6	5	6	4
Control component Co. Ltd.	-	-	7	4
Total	121	93	233	146

Findings and Discussions

From the interview with the CEO, competition in home appliances has been increasing severely. Key success factors of Toshiba Thailand Co. Ltd. are the ability to produce home appliance products at competitive costs, global standard quality products, modern product design, and excellent after sale service. As a hub, it is very important for the company to pay a great deal of attention to the development of human resources. Considering for manufacturing process, the foreman plays an important role since he works most closely with the line workers. A highly competent foreman allows Toshiba Thailand to operate more efficiently and effectively production so the company can deliver home appliance products on time. Furthermore, this can help the company gain advantage by having the first products launching to the market. This is a unique advantage to triumph over competitors in the market.

It is interesting to find out from interview results with top-level managers that there are more competencies to be added to the Spencer and Spencer's competency model. The seven new competencies are ethic, self development, foresight, positive thinking, problem solving and decision making, writing communication, and presentation skill.

As described by top management, the production line is operating 24 hours per day and if any problem occurs, the foreman has to make precise and timely decisions to solve problems. Thus, problem solving and decision making is very crucial to ensure a smooth production process that prevents bottleneck problems, those that stop the production line resulting in a production delay or those that can impact production quality. Reflecting on the importance of "problem solving and decision making," one interviewee said:

"....We have big gap between supervisor and foreman, our foreman pays too much attention on day to day operation. To survive in business, our foreman has to be able to make a quick decision. Faster accessible to root cause of the problem is a must. ..."

"Foresight" is another competency that the top management team believes is important for future growth and performance. One general manager pointed out that:

"....as our competition will not limited only to Thailand, we compete with India, China, and most important is Vietnam. We cannot win with low cost production anymore. Our foreman needs effective communication skills both in verbal and written to help generate better knowledge management for the company. ..."

Furthermore, top management reveals that if the foremen have positive attitudes and attempt to continue developing themselves, it helps raise the competitive advantage of Toshiba over its competitors. Furthermore, changing from shift to shift, the foreman has to pass information regarding production progress, problems, and solutions to the foreman and supervisor of the following shift.

Opposite, a few competencies such as concern for order, customer service orientation, self control and organization awareness are omitted due to the common comments of top level managers that these competencies are expected at the supervisor level not the foreman.

From survey results, in term of demographics, there are 62 male and 6 female supervisors, and 118 male and 25 female foremen as survey respondents.

From the perspective of supervisor, considering mean scores and standard deviations for each competency, 19 out of 23 competencies are regarded as very important competencies for the foreman while four competencies (self development, positive thinking, analytical thinking, and perspective) are regarded as important. The

competencies that received the highest mean score of 4.66 are “team leadership” and “technical/expertise.” The lowest competencies are “analytical thinking” and “foresight” with mean scores of 4.12.

From the perspective of the foreman, the mean scores and standard deviation for each of the following seven competencies are regarded as very important: technical/expertise, team leadership, teamwork and cooperation, impact and influence, ethic, problem solving and decision making, and self development. Among these, “technical/expertise” is perceived as the most important competency with 4.43 mean score. The lowest competency is “foresight” with 3.23 mean score. The rest are regarded as important.

In this paper, the five most important competencies are highlighted. While Spencer and Spencer propose a long list of competencies, they suggest focusing on the five to nine most important competencies. Hence, the top five most important competencies, ranked by both supervisors and foremen, are presented in Table 2.

TABLE 2: SUPERVISOR AND FOREMAN PERCEPTIONS ON THE IMPORTANCE OF COMPETENCY FOR THE FOREMAN POSITION

Competency	Importance of Competency					
	Supervisor			Foreman		
	Means	S.D.	Ranking	Means	S.D.	Ranking
Team leadership	4.66	0.536	1	4.41	0.695	2
Technical/expertise-	4.66	0.536	1	4.43	0.645	1
Teamwork and cooperation	4.63	0.544	2	4.40	0.595	3
Organizational commitment	4.57	0.633	3	4.18	0.646	8
Impact and influence	4.54	0.609	4	4.36	0.644	4
Problem solving and decision making	4.50	0.586	5	4.22	0.652	6
Ethic	4.28	0.542	13	4.25	0.655	5

The finding of the top five important competencies for the foreman position in this study is different from what noted in Spencer and Spencer’s model. Spencer and Spencer (1993) pointed out that top five important competencies for technician job are achievement orientation, impact and influence, conceptual thinking, analytical thinking, and initiative.

The survey results reflect that foreman and supervisor perceptions are quite similar. A focus group of supervisors and foremen was arranged to discuss the results. Supervisors comment that with organizational commitment, the foreman will give priority to achieve organizational needs. With strong commitment, the foreman will be willing help line works and other colleagues complete their tasks. Furthermore, a few foremen who have worked with the company may be inactive. With organizational commitment, supervisors believe that a foreman who has been with the company for a long time is a great asset for the company. On the foreman side, they think commitment is important but not very important.

As for the ethic issue, supervisors comment that it may be difficult to analyze because currently the foreman ethic level is appropriate so they do not give high score to ethics. However, during a focus group, foremen pointed out that when problems occur in the production line, having an ethical foreman is very crucial because transparency information will be shared and reported so the problem can be solved correctly and on time.

Prior to writing this article, the HR department of Toshiba is interested in learning how the results of this study can be used to benefit Toshiba Group. One HR manager shares that previously at Toshiba, where human resources development is mainly conducted through on the job training, offered training focused on rules, regulations, and quality control -- perhaps due to the Japanese cultural influence. There are two new training modules offered to the foreman: leadership development and industrial engineering for foremen. With academic research results, two new training modules on leadership development and industrial engineering for foremen are provided.

Conclusions and Suggestions

In the case of a manufacturing focused company, unlike other types of business, competent human resources in the position of foreman is very crucial. With the new management paradigm, development of foreman competency should be aligned with business vision and mission. The perception of important competencies in a position can be different from different perspectives; from one who performs the job and one in another position who has more understanding on the company's strategic direction.

To adopt competencies based on human resource development, Spencer and Spencer's competency model provides a guideline for examining competencies, which is a good place to start. However, with different organizational environment, unique organizational needs and unique characteristics of the job, searching for information from relevant stakeholders provides a better picture of competencies study.

Besides, to develop competencies for human resource development, not only functional competencies like skill and knowledge, which are easy to notice as important, but also invisible competencies like value, believe, and attitude should not be ignored.

University of Guadalajara, Mexico*

Abstract

The purpose of this paper is to identify the relationship between a set of variables and determine their level of participation in the development of restaurant industry's Competitiveness. For this research we proposed a quantitative approach, based on regression models. 250 questionnaires based on 31 questions and 163 reagents were applied to managers of the Restaurant Industry in Guadalajara, Mexico.

Activities associated with corporate social responsibility and Customer Relationship Management can be taken into account as an approach to develop strategies for this industry in order to guarantee their surviving, development and consequently to support company's competitive goals.

The results were analysed using factor analysis, Cronbach's alpha and subsequently regression models, which indicated that implementation of social responsibilities and CRM actions linked with Knowledge Management, provide appropriated conditions for organizations to develop competitive advantages, benefits and future revenues.

Keywords: Competitiveness, Corporate Social Responsibility, Customer Relationship Management, Knowledge Management.

Paper type – Academic Research Paper

Corporate Social Responsibility

Recently, corporate social responsibility has been taking more importance in the agenda of companies, this mainly as a result of two factors. The first is the recognition of governments to be partially unable to meet the basic needs of its inhabitants optimally, sufficient and general. In this sense, there is great demand from society for the improvement in their conditions of life, which cannot be covered by authorities and as a consequence are cover by private initiatives to satisfy the needs of the population.

The second one is related to the globalization phenomenon, where pressure from international organizations and governments has positively influenced the conduct of companies to behave ethically and to have a positive impact on those regions where they are established. Similarly, companies are collaborating through the imposition of limitations by governments and as well, demanding actions to generate positive impacts in the society.

Corporate Social Responsibility, also known as "corporate social responsibility", "corporate citizenship", "corporate accountability" or "corporate responsibility" is defined as the financial, legal, ethical and altruistic responsibility, which is assumed by a company through the development and implementation of strategies to work with a social cause, (Kelly, 2001; Werhane, 2007; Kima & Reber, 2008) also, it seeks to reduce the negative effects of everyday's activities of enterprises (Dahlsrud, 2008). In this sense, Bronn & Vrioni (2001) agree that CSR is an expression of ethical standards of a company, a reflection of the values that govern the behavior derived from socially responsible and legal systems and an entrepreneurial culture which aims to ensure compliance with social needs. In this regard, Van Der Putten & Dubbink (2009) states that society is also responsible for issuing the principles on which the company will have to act responsibly by attending regulations.

CSR can be classified into two main groups: one group comprises the multidimensional aspect that companies must carry out through social responsibility activities as a part of observing the rules and regulations imposed by the state. While in the second group, the company takes action for the welfare of their clients and society in general, also known as social marketing (Kotler, 1991).

There are different definitions of CSR, however, all authors converge on the idea that its main purpose is to improve the quality of life of society and at the same time it seeks to increase the financial benefits of the company. Hence, a socially responsible company is one profitable company with a CSR agenda equated in importance to other vital activities and also it is aware of the positive or negative impacts on the environment (Dahlsrud, 2008).

Benefits of Implementing CSR

In recent years, there has been a notable increase of aware and better customers whose purchasing decisions are supported by a cost-benefit analysis of the offering products for companies. Another factor that greatly affects the decision-making is a positive image projected through the CSR, which can be translated into a powerful competitive advantage that can differentiate the companies from their competitors thus obtaining the preference of customers (Vrioni & Bronn, 2001). Hence, consumers are benefited from CSR since they obtain higher added value originated from the positive impact on social, health and environment; therefore the customer can reward companies that act ethically by conditioning their purchase (Mohr, Webb, & Harris, 2001; Molteni, 2006)

Finally, it must be mentioned that the costs of development, implementation and maintenance of CSR programs are very expensive and therefore are subject to the financial capacity that the company has (Estallo, Giner, De-la Fuentes & Griful-Miquela, 2007). Similarly, the duration and effectiveness will depend on a correct and consistent administration (Heal, 2005), otherwise, it could origin negative effects to his image and income (Gugler and Shi, 2009; Molteni, 2006).

Competitiveness

Competitiveness is described as the capacity of companies, regions and countries to create higher wealth and generate satisfactory levels of sustainable employment striving to benefit their shareholders and population at the time that they are participating in an international competition (OECD, 1996).

As well, competitiveness is a multidimensional concept divided into distinct stages as mentioned previously: nations, industries and corporations (Ambastha & Momaya, 2004). Porter (1998) considers that international competitiveness is explained from a macroeconomic examination of particular aspects like accessible and reasonably priced employment, abundant raw materials, healthy financial statements, reasonable exchange and interest rates, high-quality administration practices; and through other advantages resultant from a positive trade balance, and an elevate and rising industry productivity. Furthermore, Mohammed (2008) indicates that competitiveness involves the capabilities of a nation to create an environment that endorses the continuous and increasing international trade while improves the quality of life of its population, especially in terms of earnings. Flanagan (2005), also, argues that the most important purpose resulting from competitiveness at the national level must be the human development and enhance the quality of life of its inhabitants.

On the other hand, the second perspective of competitiveness is placed at the industry level, that is defines as the extent of a business sector to satisfy the needs of clients by offering an appropriate mix ratio of goods and services based on attributes and characteristics such as cost, utility and originality. Returning attractive revenues to investors must be a distinctive from a competitive industry, besides the achievement of objectives related with customer's satisfaction (Flanagan, 2005).

At the firm's level, competitiveness is directly related to the performance of the market, where high efficiency is considered the key to success. Once companies have guaranteed their survival, competitiveness depends on the creation and development of new products and services with added value for customers and superior value's return for its Shareholders (Schuller, & Lidbom, 2009). According to the perspective of John Kay (1993), competitiveness is described in four components: capacity for innovation, internal and external strategic relationships, corporate image and strategic assets. In this context, the structure of competition has been extended to tangible and intangible resources that provide an advantage over their competitors (Hamel & Prahalad, 1989)

Moreover, competitiveness also comprises entrepreneurial attitudes such as adaptability, flexibility, superiority, etc., and it is necessary to understand the competitiveness not only as merely productivity but also as a

strength that includes the level of skills developed by an organization, institution or person to participate at equal or superior in the market (Vilanova, et al., 2009).

Several authors have suggested quantitative indicators to measure and analyze the competitiveness, considering factors such as financial; however, other authors also consider important to add intangibles elements (Martin & Stiefelmeyer, 2001). Additionally, Porter suggests that productivity as a good indicator of competitiveness at the firm's level.

Customer Relationship Management (CRM)

Nowadays, enhanced products and services are not enough to compete, it is also necessary to improve and develop relations with the consumer, especially now that their expectations have increased (Puschmann, T., Alt, R., 2001). And despite the academic literature has argued at length the positive effects of managing customer relationships, it has not been until recent years that the CRM has become a need for companies (Pan, SL, Lee, JN, 2003).

For Wright and Ashill (1996), the available market information in a company should increase, considering that the market becomes more or less predictable. Therefore, it can be determined that the Marketing Knowledge will be very useful for business at the time to understand customers and economic environments, allowing firms to make smart decisions, following successful actions and thus maintain a competitive pattern (Kjell, 2002).

In competitive markets, companies invest substantially in the implementation and development of customer relationships (Bohling, Bowman, Lavalle, Mittal, Narayandas, Ramani et al., 2006). Parvatiyar and Sheth (2001) attributed the development of CRM to recent technological changes, especially in innovative interfaces related to customer information, and the philosophy of total quality associated with cost reduction efforts. The authors explain that the main purpose of CRM is to increase the productivity of marketing and increase the value of relationships between consumers and business. It was understood that the CRM is focused on developing and maintaining long-term relationships for mutual and significant benefits for both companies and customers (Buttle, 2001).

While the customer relationship management (CRM) has been defined in different ways (Grönroos, 1995, Morgan & Hunt, 1994; Rigby, Reicheld, & Schefter, 2002, Payne and Frow, 2005, Winer, RS, 2001), common characteristics can be found in all concepts: Using technology to create a dialog that allow companies identify their products and services to attract, develop and retain consumers. Currently there are modern CRM packages that include applications that store information such as finance, inventory and resource planning.

Other researchers, such as Srivastava et al. (1999) proposed the CRM as a management process that identifies the needs of consumers in order to create awareness, build customer relationships and acquire information about the perception of the organization and its products. It can also be said that even in smaller organizations, CRM is characterized by the integration of customer information from various sources through technological resources (Clark, McDonald, and Smith 2002).

In general, CRM focuses on acquiring customers, know them, provide them with services and anticipate their needs (Goodhue, DL, Wixom, BH, Watson, HJ, 2002), but it is also considered as the result of the continuing evolution and integration of marketing ideas, technology and information (Boulding et al., 2005).

It stressed that the integration of CRM requires a strategy or model, an analysis of organizational capacities and the company's willingness to adopt and implement this model. The CRM will require a functional and cross integration of processes, people, operations and marketing skills through information, technology and enterprise applications (Kendrick & Fletcher, 2002, Payne 2001, Payne & Frow, 2005).

In addition, companies need to reorganize their operations and contemplate the customer as the center of all processes and strategic decisions, before acquiring a platform for CRM. Therefore, only when a structure and customer-oriented philosophy has been introduced, the company is ready to implement this system (Petrisans, 1999 and Buttle, 2000; Bona, 2003 and Herschel 2004). The authors Payne and Frow (2006) argue that successful implementation of CRM depends on four factors: organizational changes aimed at CRM, employee commitment, the pre-deployment assessment and management of projects related to CRM.

On the other hand, the CRM might not be successful. Among the main reasons for failure is the lack of strategic planning before implementation (Day, 2000), technology implementation problems and lack of

organizational integration and customer orientation (Maselli , 2001). Moreover, Kale (2004) states that there are seven sins that cause no or negative results of CRM: (1) viewing the CRM Initiative as a Technology Initiative, (2) Lack of customer-centric vision, (3) Insufficient Appreciation of customer lifetime value, (4) INADEQUATE support from top management, (5) underestimating the Importance of change management, (6) failing to re-engineer business processes; and (7) underestimating the Difficulties Involved in data mining and data integration.

Handled effectively, CRM will then be a reaction chain generated based on new strategic initiatives to communicate with customers. It has documented positive effects of its implementation, such as more effective marketing and sooner introductions of products and services to the market (Grant & Schlesinger, 1995; Hill, 1998; Ruediger, Grant-Thompson, Harrington, & Singer, 1997; Dick Lee, 2000). Customers are satisfied because CRM helps companies to differentiate their offerings and companies can improve customer experiences by effectively managing their information and their relationships through various stages (Mithas et al., 2005)

Hypothesis

H1. To higher levels of Corporate Social responsibility, the greater the level of competitiveness.

H2. To higher the implementation of CRM systems, the greater the level of competitiveness

Analysis of Results

The corresponding analysis were realized separately in order to determine the impact of each group of independent variables related with the development and application of CRM activities on the dependent variable “Competitiveness”. The first model, analyzed how company’s competitiveness can be enhanced trough the improvement of products and services taking into account the necessities and customer’s characteristics as a result of CRM system’s implementation. However, for the second model it was necessary to make some changes in order to compare dependent variables, therefore variable competitiveness focuses on the company’s level of sales as an indicator of it. The results are shown below.

Table 1 shows that the reliability obtained by the Cronbach Alpha has a level of 0,707 which indicates that the selected variables are interrelated by 70.7%. As a result, it can be considered that these variables are highly eligible to make statistical studies are presented below.

TABLE 1: RELIABILITY STATISTICS

Cronbach's Alpha	N of Items
.707	8

Source: Own Elaboration

In Table 2 it is described the ability to explain the total variance regarding the dependent variable "Competitiveness". In this case the value of R for the first model, it was demonstrated that the variance of the dependent variable is predicted by the independent variables (CRI2, MPP8 and MPP9). Consequently, the linear relationship between the criterion variable and predictor variables is fairly significant. On the other hand, for model 2 the competitiveness variable predicted by the independent variables (RSG1, RSG4, RSB4) represents low levels of both R and R2, as a consequence the level of error is highly significant proving that there is no close association between selected variables.

TABLE 2: MODEL SUMMARY^B

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.685 ^a	.470	.462	.651
2	.312 ^a	.097	.085	.931

Model 1 a. Predictors: (Constant), CRI2, MPP8, MPP9 b. Dependent Variable: CRI1

Model 2 a. Predictors: (Constant), RSG1, RSG4, RSB4 b. Dependent Variable: FP2

Source: Own Elaboration

At last, Table 3 shows that the ANOVA p-value associated with the value of (F) for model 1 has a uniform level; therefore it is considered statistically significant. As well, it is determined that this case the null hypothesis is rejected. However for the model, the results do not evidence significance; consequently, the null hypothesis is accepted.

TABLE 3: ANOVA^b

Model	Sum of Squares	Df	Mean Square	F	Sig.
1 Regression	19.661	3	6.554	7.5	.000 ^a

Conclusions

According to the results obtained from this research it can be noted that in the case of the restaurant industry in Guadalajara, there is a fairly significant relationship between CRM activities and competitiveness, which enhances the creation of a competitive advantage through the correct supply of products and services as a result of the investigation of customer needs, characteristics and preferences.

Concerning corporate social responsibility, its implementation leads to a slight increase in the level of competitiveness of companies that integrate the local restaurant industry. However, it also was possible to demonstrate that such activities are carried out without continuity and consistency and, as well, companies do not have a properly structured program. Therefore, it can be interpreted that CSR at the restaurant industry in Guadalajara is an activity not equated in importance to other functional activities of the companies and due to the current economic situation implementing it only represents an expense that does not return profits.

Finally, it is important to remark that CRM and corporate social responsibility represent an essential role in the competitiveness of enterprises, as a consequence managers and entrepreneurs will have to incorporate them into their business strategies, align to their core activities and designate them higher investment in order to make use of potential the advantages.

Finally, to lessen limitations, it has been suggested that additional research using samples from other industries or countries in view of the fact that research focuses only on the restaurant industry in Guadalajara,

Jalisco. Moreover, as quantitative data rather than qualitative data were collected, the research does not illustrate the particular work conditions of participants.

Does Changing Corporate Governance Alone Result in Better Firm Performance?

Abstract

An important public policy issue actively debated in the financial economics literature is whether firms can increase their value solely by changing one or more corporate governance mechanisms. In this paper, we develop and implement a new approach to examine whether firms choose their governance structure optimally and the effect of governance changes on firm performance. Specifically, we analyze the impact of large governance changes on future firm performance using a differences-in-differences approach. We sort firms based on changes in their governance structure for thirteen different governance measures, focusing on firms that make large governance changes to enhance the power of our tests. We find no significant difference in future performance between firms that have a large increase in governance measures and firms that have a large decrease in governance measures. We conclude that firms choose their governance structures in equilibrium, and changing governance alone does not result in better future performance. These findings are robust to many different specifications, definitions of large governance changes, samples, and definitions of firm performance.

I. Introduction

There has been considerable discussion in the academic literature of managerial agency problems that arise from the separation of ownership and control (see for example, Jensen and Meckling 1976 and Amihud and Lev 1981). A number of corporate governance mechanisms have been proposed to ameliorate this agency problem between managers and their shareholders (see Morck, Shleifer, and Vishny 1988, Jensen and Murphy 1990, among many others). Such studies have found a positive *contemporaneous* correlation between firm performance and various governance measures, which has led to numerous attempts to reform governance by institutional investors, stock exchanges and the Congress. For example, the NYSE and the Nasdaq require board committees to be mostly comprised of independent directors; activist institutional investors have lobbied firms for compensation reform; and the 2002 Sarbanes-Oxley Act vastly increased director accountability. There is, however, little evidence has been provided on whether changing a firm's governance structure in a particular direction can lead to subsequent better firm performance for the general firms and important questions remain on whether firms can improve their performance as expected by simply following the governance prescriptions. Making a causal argument that governance changes in a particular direction can deliver value-increasing effects for all the firms is "jumping the gun," or at the very least, incomplete. As Prendergast (1999, page 19) aptly argues (emphasis added) "... many of the factors relevant for choosing the level of compensation are *unobserved* ... As a result it is difficult to determine whether compensation schemes are *set optimally*, or to claim that the relationship between pay and performance is too low or too high." There is also no consensus on whether even the *observable* factors constitute value-increasing or value-decreasing governance practices.¹ There are few guidelines for empirical specifications because of the absence of formal theoretical models that link firm performance to a firm's governance structure. The issue becomes even more complex when considering the full array of governance mechanisms that firms can jointly and/or independently choose. Results from examining one governance mechanism cannot be extrapolated to the set of other governance mechanisms. While the firm might make seemingly suboptimal choices along one dimension, the governance structure as a whole may be optimal.

However, proposals for governance changes, in many cases based on the significant linear relationship between various governance measures and performance from the literature, are almost always targeted towards

specific governance measure(s) and are imposed on all firms. But as shown by Benmelech and Moskowitz (2010), Hermalin and Weisbach (2006), and Chidambaram and Prabhala (2009), firms and individuals can frequently offset the impact of external regulation by making other changes. Further, the regulations and the offsetting behavior can impose substantial dead weight costs. It is therefore important to evaluate whether changes in one or more governance measures are sufficient to deliver higher firm performance. Our empirical approach is as follows. Based on the simple economic argument that governance proposals implies, we ask whether firms that *change* their governance structure in one direction consistently outperform those that change their governance structure in the opposite direction. Sorting firms based on the governance change alone and examining the future performance of each sample will reveal whether such governance changes alone, without considering other observable and non-observable firm characteristic, results in value increases, as the governance proposals suggest. By contrasting the future performance differences between the samples of firms that change governance in the opposite directions allows us to examine the impact of governance changes controlling for the endogeneity of governance and firm characteristics. Essentially, our approach represents a *differences-in-differences* methodology and helps mitigate endogeneity concerns (Bertrand, Duflo, Mullaiathan 2004). Given that there is no complete model of corporate governance and firm value that helps us understand which variables are exogenous and endogenous, our empirical approach avoids the twin Herculean tasks of finding instrumental variables for each corporate governance mechanism and finding an unexpected exogenous event.

We first determine the governance changes in firms for thirteen different governance measures, three measures based on the board of directors, five measures of pay-performance sensitivity, two measures of shareholder rights, institutional ownership, and CEO turnover. We then sort the firms into those that have experienced a large increase in the governance measure, and those that experience a large decrease in the governance measure. In constructing these samples, we control for abnormal prior performance to control for the problem of reverse causality. We also control for significant corporate events in the firm such as asset sales and mergers to control for governance changes driven by these corporate events.

Our differences-in-differences methodology compares performance between the sub-sample of firms with a large increase in governance measures and the sub-sample of firms with a large decrease in governance measures. We find that governance changes in both directions lead to statistically significant performance changes. However, comparing the performance between the two sub-samples of firms with the opposite directions in governance changes, we find that there is no statistical difference in the percentage of firms with positive future performance, nor is there a statistical difference in the mean and median of future industry-adjusted stock returns in the two sub-samples. The only exceptions seem to be the samples in which firms have large increases in the amount of cash bonus paid to the CEO and the sample in which firms have a large increase in the percentage of shares held by institutions. We find the latter result to be due to “timing” of trades by rather than an incentive to generate better performance.

We interpret our results to imply that firms optimize on a Coasian envelope across various governance measures. Our results are also consistent with prior work that has found each governance mechanism to be endogenously related to firm characteristics (see, for example, Demsetz and Lehn 1985, Smith and Watts 1992, and Himmelberg, Hubbard, and Palia 1999). But different from the literature, our findings *directly* show that simply prescribing a particular change in any governance measure cannot generate expected value-increasing effects for all the firms. Our results also offer evidence in favor of firms being in equilibrium with respect to their governance structure. In addition, we note that our study is over an 11-year period (1992-2002) that is significantly larger than most previous studies. Further, we have concurrently examined a broad set of governance measures rather than focusing on just one or two governance measures as in the prior literature.

One reasonable argument that is often made is that a firm’s prior performance characteristic may influence the impact of governance changes. For example, governance changes can be expected to have a significant positive impact on performance in the sample of firms that experience large performance declines. Or, during good times some firms may use the opportunity to reduce the quality of their governance while others might seek to reinforce good performance by improving governance. We expand our study to examine these arguments by constructing two additional samples of firms. We create an *Abnormally Bad Performance* sample that consists of firms that have experienced large performance declines and an *Abnormally Good Performance* sample that consists of firms that

have experienced large performance increases. Unlike the samples of firms in our main empirical tests, the set of firms in the *Abnormally Bad Performance* and the *Abnormally Good Performance* samples do not vary as a function of the governance measure analyzed. In these samples therefore, we are able to construct a compound *Aggregate Governance Change* measure for each firm. In addition to examining the effect of changes in each of the thirteen governance measures, we also examine the impact of the *Aggregate Governance Change* for each firm in the abnormal performance samples. Once again, we find no statistical difference in the performance of the firms with increases in governance measures and the firms with decreases in governance measures.

We take several additional steps in order to ensure the robustness of our results (results available on request from the authors). We repeat our analysis on all samples (no prior abnormal performance, and abnormally good and bad performance samples) with firm performance defined as industry-adjusted Return-on-Assets, the Fama-French-Carhart four-factor asset-pricing model, and Tobin's Q. Our results hold for each of these alternative performance measures. We also changed the various cutoff points for defining a large governance change, different non-monotonic functional forms on the value-insider ownership functional forms and find no significant changes in our results.

As an alternative to our future performance tests, we conducted event studies to examine the impact of governance changes. Details on a firm's compensation and the board of directors are revealed in the firm's proxy statement. We therefore use the proxy filing date as the event date and examine returns around the proxy filing date. Consistent with our results, we do not find significant abnormal returns around the proxy filing date.

2. Methodology and Data

In this section we describe the data sources, the construction of our samples of firms with large increases in various governance measures and firms with large decreases in various governance measures, and provide summary statistics of the data.

2.1. Research Design

We begin by determining the governance changes in firms for thirteen different governance measures, three measures based on the board of directors, five measures of pay-performance sensitivity, two measures of shareholder rights, institutional ownership, and CEO turnover. In constructing our sample, we control for abnormal prior performance to control for the problem of reverse causality. In our base case analysis, our sample excludes firms that experience extremely good or extremely bad performance changes in order to control for reverse causality. We also exclude firms that undergo a merger, an acquisition, or a CEO change in the two years before and after the current fiscal year (except when examining CEO Turnover) as firms undergoing changes in control experience natural changes in their governance (see Lehn and Zhao 2006).² In parallel empirical tests, we also separately examine firms that have experienced abnormally large performance declines or abnormally large performance increases.

We sort the firms into those that experience a large increase in the governance measure, and those that experience a large decrease in the governance measure, and study the future performance effects in each of these sub-samples. Our classification of the governance changes in the opposite directions is based on the significant linear relationship between various governance measures and performance that the literature has reported. For example, the literature has shown that board independence, pay-for-performance sensitivity, or shareholder rights are positively related to firm performance.

For each sub-sample, namely the sample with a large increase in governance measures and the sample with a large decrease in governance measures, we determine the future industry-adjusted performance and test if the performance is statistically significant. We then test for differences in performance between the sub-samples of firms with the opposite directions in governance changes. If one restricts the analysis to only increases in governance measures or only decreases in governance measures, one might incorrectly conclude that governance changes leads to performance changes. In performing these tests, our hypothesis is that governance changes in a specific direction can have value-increasing effects and deliver better performance than the opposite direction.

While we classify the governance changes in the opposite directions in determining our two large governance change samples, these ex-ante directions are not crucial to our differences-in-differences approach. By comparing the performance of firms that change governance in one direction to the performance of firms that change governance in the opposite direction, we will also be able to identify any other consistent governance impact. In our robustness tests, we also consider other ways to sort firms based on their governance changes and firm characteristics, e.g. we use several different cutoffs for defining a large governance change, examine subsamples of firms with high and low R&D expenses, and differentiate between transient and dedicated institutional investors.

2.2. *Sample Construction*

We use data from CRSP and COMPUSTAT to construct fiscal-year industry-adjusted stock returns. We exclude ADRs and firms that have total assets less than \$100 million. We do not exclude financial firms and utilities to be consistent with earlier research (e.g. Gompers, Ishii, Metrick, 2003). Further, to be included in our sample firms should not fall in the top quartile of industry-adjusted stock returns in the identification year and have industry-adjusted stock returns in the bottom quartile in each of the prior two years, nor should firms fall in the bottom quartile of industry-adjusted stock returns in the identification year and have industry-adjusted stock returns in the top quartile in each of the prior two years (to control for reverse causality).

We use data from ExecuComp, IRRG, The Corporate Library, CD Compact Disclosure and CDA Spectrum to create our governance measures as described in the previous section. Using a random sample of firms we first verify that there are no any coding errors from the firm's Proxy Statements for each previously described governance measure. For each governance variable, we determine the changes in the governance measures from the previous year to the current year for each firm that satisfy the conditions above and for which we have available data. We then select the sample of firms with the changes in each governance measure sorted into the top or bottom 5%,³ i.e., the sample of firms with the largest increases or with the largest decreases in each of the governance measures. We perform these steps separately for each of the governance measures, which results in thirteen different sample pairs consisting of firms with the largest changes in each of the governance measures with the opposite directions.

Table 1 reports the mean and median for each of the governance measures for the sub-sample of firms with a large increase in governance measures and for the sub-sample of firms with a large decrease in governance measures. Note that the governance changes are significant between each pair of the sub-samples with the opposite directions in governance changes in terms of each governance measure. For example, the median increase (decrease) in *Shares* is 1.6% (-2.7%), the median increase (decrease) in *G-Index* is 2(-2), the median increase (decrease) in *Instshares* is 40.8% (-40.8%), and the median increase (decrease) in *Bsize* is 2(-3). The number of firms with CEO turnover is 12.53%, which is in line with the base level of turnover rate of 11.19% in ExecuComp firms (we estimate this as the ratio of the number of total CEO changes to the number of firm-years in ExecuComp).

TABLE 1: SAMPLE GOVERNANCE CHARACTERISTICS

This table shows the mean (median) level of governance characteristics for our sample of firms. Firms are classified based on whether they have an increased governance measure or a decreased governance measure. The table reports the number of firms, the average level of the governance measure in the identification year ($Year_0$), and the governance change from the previous year ($Year_{-1} - Year_0$), for firms with increased governance measures and for firms with decreased governance measures. The sample period is 1992-2002. Median values are shown in parentheses. The superscripts ***, **, and * denote statistical significance at the 1%, 5%, and 10% levels respectively.

	Increased Governance Measures			Decreased Negative Governance Measures		
	# Firms	Level $Year_0$	Change $Year_{-1} - Year_0$	# Firms	Level $Year_0$	Change $Year_{-1} - Year_0$
<i>Pay-Performance Sensitivity:</i>						
Bonus	304	\$3600 (\$2000)	\$1949 ^{***} (\$1177) ^{***}	304	\$715 (\$98)	-\$1425 ^{***} (-\$917) ^{***}
Options	295	3.64% (2.85%)	1.61% ^{***} (1.16%) ^{***}	303	1.95% (1.41%)	-1.39% ^{***} (-0.98%) ^{***}
Ppswealth	290	14.74% (10.22%)	3.79% ^{***} (2.21%) ^{***}	299	13.53% (10.78%)	-5.22% ^{***} (-3.28%) ^{***}
Newoptions	294	1.37% (1.01%)	1.20% ^{***} (0.91%) ^{***}	293	0.20% (0)	-1.47% ^{***} (-1.06%) ^{***}

Turnover	755	-	-	4610	-	-

3. Future Firm Performance

We examine the impact of governance changes by examining the industry-adjusted stock returns over the two-year period subsequent to the year the firm experiences a large governance change (i.e., from $Year_{+1}$ to $Year_{+2}$).

We also compare the industry-adjusted stock returns of the sub-samples over a three-year period that includes the current year and the subsequent two-year period (i.e., from Year₀ to Year₊₂). The three-year performance measure explicitly control for the price impact of the governance change in Year₀; if a governance change occurs in the middle of the year and the firm's stock price moved at the time of the event, it would be reflected in the three-year performance measure.

Table 2 shows the subsequent industry-adjusted stock returns for the sub-samples of firms with an increase and with a decrease in each of the thirteen governance measures. We report results for each governance measure separately. The data shows that firms with decreased governance measures have significant negative mean and median performance in the subsequent two-year period for some of the governance measures we examine. For example, the median two-year industry-adjusted stock returns following a decrease in *Ppswealth*, *Shares*, and *Insiders* are -6.91%, -6.91% and -10.48% respectively, all of which are significantly different from zero. However, firms with increased governance measures also show similar negative performance in the subsequent two-year period, although this effect is not significant. For example, the median two-year industry-adjusted stock returns following an increase in *Ppswealth*, *Shares*, and *Insiders* are -3.27%, -2.46%, and -6.57% respectively, although the effect is not significantly different from zero for *Shares*. Further, the percentage of the firms with positive industry-adjusted stock returns is the same for the sample with an increased governance measure and the sample with a decreased governance measure, except for *Bonus* and the *Instshares* measures for which firms with an increase in these measures have a significantly higher percentage of firms with positive industry-adjusted stock returns.

When we compare the performance of the firms with large increases in governance measures with that of large decreases in governance measures,⁴ we find that the performance of the firms is not significantly different within each pair of samples for all the governance measures. These results hold for both mean and median values. For example, the mean (median) two-year industry-adjusted stock returns following a decrease in *Ppswealth* is -3.02% (-6.91%), which is not significantly different from -1.66% (-3.27%) of mean (median) two-year industry-adjusted stock returns following an increase in *Ppswealth*. Further, the results are robust to performance measured over the three-year period rather than the two-year period, except for the mean and median *Bonus* measure and the median *Instshares*, where firms with an increase in these measures have significantly better three-year period (Year₀-Year₊₂) performance, compared to the firms with a decrease in these measures. With respect to *Ppswealth*, *Shares*, and *Bmeeting*, there is also a significant difference for the three-year performance measure. We note however, that firms in the sample that is designated as having decreased these governance measures seem to perform better, which runs counter to those proposed in the literature.

For the performance differences between an increase and a decrease in *Instshares* measure, there is a reversal in sign between the performance differences measured over the three-year window (Year₀, Year₊₂), which is positive with the average return difference of 12.55%, and performance differences measured over the two-year window (Year₊₁, Year₊₂), which is negative with the average return difference of -36.75%. This implies that the performance measure in Year₀ is highly positive for the firms with an increase in *Instshares* (median increase of 40.77%) compared to firms with a decrease in *Instshares* (median decrease of -40.78%). There can be two potential explanations for the association between increased institutional shareholdings and performance. An increase in institutional shareholdings can result in better performance because institutions provide value increasing monitoring services. Alternatively, institutions may have superior information by virtue of being large shareholders and could be "timing" an increase (decrease) in their shareholdings when they know that share prices are likely to increase (decrease). We study this further by examining the change in institutional ownership separately for institutional shareholders that are classified as *Dedicated* institutions (those that hold shares and are likely to monitor) and those that are classified as *Transient* (those that trade in reaction to firm performance) as defined by Bushee (1998). We find that the differences in industry-adjusted stock returns exist only when we examine changes in *Instshares* for the sample of *Transient* institutional shareholders. This result makes it more likely that the difference in firm performance over the three-year window (Year₂-Year₀) for our *Instshares* measure is because of timing by institutional shareholders.

TABLE 2: SAMPLE PERFORMANCE CHARACTERISTICS

This table shows the mean and median of the industry-adjusted stock returns (%) for the sample of firms classified by their governance changes. For each governance measure, firms are classified as having adopted an increased governance measure and a decreased governance measure. Data reported are the average industry-adjusted stock return over the two year period, (Year₊₁ - Year₊₂), and the average industry-adjusted stock return over the three period (Year₀ - Year₊₂), following the identification year. The sample period is from 1992-2002. The table reports the *p-values* for tests of the performance difference between increased vs. decreased governance measures: *t*-test of the difference in the means, the *Wilcoxon* rank-sum test for the difference in the medians, and the χ^2 -test for the difference in the percentage of firms with positive performance. The superscripts ***, **, and * denote statistical significance at the 1%, 5%, and 10% levels respectively.

For the *Bonus* measure, the performance difference measured over the three-year window ($Year_0$, $Year_{+2}$) is positive, and performance difference measured over the two-year window ($Year_{+1}$, $Year_{+2}$) is not significant. This implies that the performance measure in $Year_0$ is highly positive for firms with an increase in *Bonus* (median increase of \$1177) compared to firms with a decrease in *Bonus* (median decrease of -\$917). An increase in bonus paid to executives can result in better performance because the prospect of bonus gives executives the incentives to expend effort and increase firm value. However, since we do not observe the ex-ante bonus commitment made by firms, it could also be possible that we only observe cases where firms have experienced better performance and therefore paid higher *Bonus* and do not observe cases where there was an ex-ante commitment to pay a higher bonus, but firms did not do so because the firm's performance was poor. We also separately examined the $Year_0$ performance alone for each of the sub-samples and the results (available from the authors) are similar to the results using the 3-year performance measure.

Our results are independent of assumptions that a governance change in any particular direction is good and a governance change in the opposite direction is bad, although the literature and the governance change proposals can suggest so. What we note is that governance changes in either direction seem to generate similar performance effects and moving in one direction is not better than moving in the opposite direction.

Our empirical methodology tests the impact of a sort on a single dimension, specifically a sort on a particular governance measure, and we do not control for other firm characteristics in analyzing the performance of the two samples of firms. Our findings imply governance changes alone do not capture the impact of governance on firm performance and have important implications for public policy with respect to governance reform in firms. Governance reform is not amenable to simple prescriptions that require cosmetic changes in any particular governance measure. We call for a nuanced view that recognizes the endogeneity of governance and that what constitutes good governance can vary across firms.

4. Abnormal Performance Sub-Samples

One reasonable argument that is often made is that a firm's prior performance characteristic may influence the impact of governance changes. For example, governance changes can be expected to have a significant positive impact on performance in the sample of firms that experience large performance declines. Or, during good times some firms may use the opportunity to reduce the quality of their governance while others might seek to reinforce good performance by improving governance. We expand our study to examine these arguments by constructing two additional samples of firms. Accordingly, we construct an *Abnormally Bad Performance* sample that consists of firms that have experienced large performance declines and an *Abnormally Good Performance* sample that consists of firms that have experienced large performance increases.

Our results for the Abnormal Performance Samples are summarized as follows. Similar as our original sample of firms, we do not find significantly different firm performance between the firms that have increased governance measures and the firms that have decreased governance measures, except for isolated instances. We also find, as before, governance changes in both directions lead to significant performance changes for both the *Abnormally Bad Performance* and *Abnormally Good Performance* samples. Since we use the same sample of firms for all the governance measures in each of these two samples, we can also examine the range of the governance changes that firms implement. We observe that governance changes often go in different directions after extreme performance changes, which suggests that firms change their governance in complex ways. Our results for the main sample and the two *Abnormal Performance* samples present strong evidence against the hypothesis that governance changes in a specific direction can have value-increasing effects and deliver better performance than the opposite direction. Note that these results do not imply that that governance is irrelevant but rather that that firms are endogenously optimizing their governance structure in response to observable and unobservable firm characteristics. Our results are consistent with the strand of the literature that has shown that firms are in equilibrium and that governance changes represent the envelope of value maximizing choices made by firms (see, for example, Demstev and Lehn 1985, Lehn, Patro, and Zhao 2003, Smith and Watts 1992, Coles, Lemmon, and Meschke 2006, Himmelberg, Hubbard and Palia 1999, and Palia 2001). But different from the literature, our findings *directly* show

that simply prescribing a particular change in any governance measure cannot generate expected value-increasing effects for all the firms.

5. Robustness Checks

We perform several additional tests as robustness checks of the results presented in the paper. In this section we discuss these additional tests and their results.

In our research design, we have defined performance as the industry-adjusted stock returns. In our robustness tests, we use three alternative definitions of performance and repeat our analysis. First, we use the industry-adjusted return-on-assets, where industry performance is calculated at the three-digit SIC level including all the firms on COMPUSTAT. Second, we use the intercept from Fama-French-Carhart regressions (Alpha). The Fama-French-Carhart regressions are run using monthly returns and factors obtained from the author's website. Third, we use the industry-adjusted Tobin's Q, where industry Tobin's Q is calculated at the three-digit SIC level including all the firms on COMPUSTAT. We find that our basic results hold when using these alternative measures of performance as well.

We replicate our performance tests by including the year of the governance change in the period over which we measure future performance. Incorporating the year of the governance change allows us to test whether our results arise because the stock market reacts quickly to the potential beneficial effect of governance changes. Including the year of the governance change does not change our results. We find similar results using both industry-adjusted stock returns and industry-adjusted ROA, which makes it unlikely that our results are driven by the possibility that the stock market reacts quickly in anticipation of future increases in accounting performance.

We have also considered alternative ways to construct a sample of firms with large governance changes. First, we have considered governance changes in firms that meet some criteria, e.g. low R&D vs. high R&D firms, and defined large governance increases and large governance decreases in these sub-samples. This addresses the concern whether governance changes in firms with high R&D and in firms with low R&D can be different, perhaps because of differences in their complexity. Second, we have replicated our study using a two-year window to measure governance changes for the case when we use the industry-adjusted stock-returns as the performance measure. We note however that changes over a two-year governance window require us to overlap years over which we measure governance changes and performance changes or incur a substantial time lag between governance changes and performance changes. Third, we have considered other cut-offs of up to 25% in defining what constitutes a large governance change in developing samples of firms with large governance changes. In the case of the G-Index and E-Index, we consider all changes in the index, i.e. we compare the performance of firms with an increase in the G-Index (E-Index) with the performance of firms with a decrease in the G-Index (E-Index). Our results are similar to those reported when we consider these alternative definitions of governance changes.

We have also performed event studies around the proxy filing date for the firms in our samples and do not find significant abnormal returns. It is difficult to find announcement dates for many of the governance measures that we examine and firms potentially disclose a plethora of information on various aspects of governance, compensation, and corporate events, on the proxy filing date, which makes it difficult to interpret the findings of these event studies.

6. Conclusions

Can any particular governance changes alone deliver value-increasing effects for the general firms, as the governance proposals suggest? The absence of formal models for corporate governance incorporating the many different governance choices of firms makes it difficult to test whether governance is optimally chosen. Furthermore, many observable and unobservable factors are likely to be important in determining the choices firms make and empirical tests that link governance levels to performance are subject to the critique that governance changes are thus endogenous. In this paper we develop a differences-in-differences approach to infer the optimality

of a firm's governance choices by using data on governance changes instituted by firms. If firms are not choosing their governance structure optimally, then firms can *change* their governance structure toward "value-increasing practice." In other words, firms that change their governance structure in a particular direction should consistently outperform those that change their governance structure in the opposite direction.

Our findings suggest that the interplay between governance, observable and unobservable firm characteristics, and firm performance, is not amenable to a simple sort on any single governance measure or firm characteristic. Our study is a large sample study based on a broad sample of firms across eleven years and speaks to the average impact of governance on firm performance. It is possible that for some firms, governance changes in a particular direction do lead to better performance. Future research is required to ex-ante identify a sample of the firms and their characteristics, in which such value-increasing effects can deliver.

Our study suggests that there is no simple formulaic approach to governance reform consistent with the arguments made by Brown, Goetzmann, Liang, and Schwarz (2009), Romano (2004) and the Interim Committee on Capital Market Regulation (2006). Very dissimilar changes in governance can lead to similar performance results, suggesting that unobservable firm characteristics such as corporate culture and management philosophy play a role in determining the impact of governance reform. While these results indicate that firms should, and do, try to optimize their governance structure, it is best perhaps to encourage firms to audit their governance choices rather than use externally imposed mandates that can prove to be costly.

End Notes

¹For example, CEOs who receive a disproportionately large percentage of the compensation to top five executives can reflect entrenchment (Bebchuk, Cremers, and Peyer 2007) or tournament incentives (Kale, Reis, and Venkateswaran 2009). Founder CEOs can decrease firm value reflecting entrenchment as noted by Anderson, Duru and Reeb (2009) and Morck, Shleifer, and Vishny (1988) or can increase firm value. Similarly, there is a debate whether perquisites consumption, such as corporate private jets, reflect agency problems (Yermack 2006) or reflect efficient management (Rajan and Wulf 2006).

² For robustness, we replicate our tests and check all our results for samples without this exclusion of firms with a merger or CEO turnover and find no changes in the general results.

³ Because every firm experiences changes in institutional ownership from year to year and the variance of the changes is high, we define large changes in the *Instshares* measure as the highest and lowest one-percent change in institutional ownership.

⁴ For the *Turnover* measure, we compare firms with CEO turnover and those without CEO turnover.

Theoretical Interfaces for a Coherent Picture of MNCs' role in Global Environmental Governance

Maarit Laihonen, *maarit.laihonen@aalto.fi*
Aalto University School of Economics, Finland

Abstract

The mainstream international business research (IB) has not tackled the question of politics as an important factor influencing MNC operating environment except in a very disunited way. It is understandable, as political environment is only one part of the macro environment where MNCs are operating. Nonetheless, the political questions, especially environmental ones, are becoming more meaningful due to for example climate change and the consequent near future regulation that firms have to confront and find solutions to manage the situation. Corporate social responsibility and business ethics are fields very close to IB but for some reason IB has not been able to draw from these for building coherent picture of the meaning of politics for MNCs. Also political sciences (global political economy and political philosophy) have started to recognize corporations as important actors in environmental policymaking. This paper plots these fields to find possibilities to fill gaps in IB research.

Introduction

Today the global socio-political environment in which companies operate is substantially shaped by increasing understanding of depth of environmental problems. The situation is tried to be governed through national and global environmental politics. In this situation multinational corporations (MNCs) 'drift' into participating in creating and executing environmental politics. The perspective of corporations' power in international environmental policymaking should more strongly take into account that corporations have become part of civil society and not being separate from it. This growing role is widely questioned in various fields. In the time of trends towards wider political collaboration, how does the global society see MNCs' role in it? Business research (here more precisely international business research, IB) has not taken standing, at least not a clear one, in this discussion. However, there are discussions that could be used to advance the research also in field of IB.

This paper concentrates on exposing how other selected fields of research have theoretically conceptualized this novel role of companies and how those approaches could advantage IB. Thus, this paper is by nature theoretical, finding relevant new perspectives from political sciences, especially fields of *global political economy* and *political philosophy*. Research in global political economy have concentrated to the question by studying corporations as political actors among others (e.g. Clapp, 2005; Newell, 2008a; Kelleher 2006; Pattberg and Stripple, 2008; Auer 2000). Political philosophy discusses the wider background with stress on e.g. justice and authorities (e.g. Parker and Pearson, 2005; Wijnberg, 2000 Singh and Carasco, 1996). In societal environmental decision-making model of democracy requires extension that discusses institutional roles, legitimacy, power relations, representativeness and participation justification of decision-making and especially MNCs' role in it. To this the discussed fields have more or less answered, albeit in very different ways that are able to deepen our understanding of MNCs in socio-political environment.

Thus, this paper explores theoretical interfaces of these different fields interested in corporations as political actors in order to clarify how the position of MNCs is today understood on academic discussions and what could be gained with drawing elements from other fields' theorizings to IB. This discussion paper is, by nature, a combined literature review and thus, a search for research gaps and untapped possibilities to fill them. First, I make a short review on 'mainstream' IB research and the lack of its political emphasis. After that, I discuss how corporate political activity (CPA, most commonly used term in business research considering the meaning of political environment and corporations in it) has been discussed in research and which are the main subthemes or upper

topics that raise questions of CPA. As a result, I outline the possibilities of IB research for learning from other fields and utilizing the existing research especially for IB purposes especially theoretically but also for new empirical approaches. The paper does not suggest that CPA even should be in the centre of IB research but that its meaning is today minimal and does indeed earn more attention in order not to lose important discussions totally to other fields of research. Multidisciplinary approaches and novel research problems could be one refreshing answer for IB research that is struggling to keep its position in business research that today has to understand the corporate-society relations more profoundly.

IB Research and the Political Dimension

Traditional IB Research and Its Gaps

At the present moment the ongoing discussion on the meaning of IB research has led into a situation where IB research is trying to find and establish its core competences, that is, own focus. The discussion has revealed the fact how IB research is fractured in various theory traditions and polarized in two very distant main subfields: to cross-cultural studies and to strategic and economics based studies. The research on macro-environment is not non-existent in IB research. It is in fact the focus of institutional analysis. Institutional approaches however are a mixed bunch of subjects and focuses. When discussed on general level of IB research, the institutional approach is often discussed very superficially as it is difficult to be situated in only standing among the wide field of IB research. (Brannen and Doz, 2010; Buckley and Lessard, 2005.) These facts complicate the search for IB's contribution to corporate political activity (CPA) research which has not been able to take clear standing for example in its relation to institutional approaches which, however, are crucially important when studying the political environment.

The mainstream IB research has somewhat established fields that dominate the research. Internationalization processes, networks and strategies connected to them still have major role in answering the crucial IB questions. These fields are also stigmatized strongly by positivist and quantitative characteristics. In this kind of research political aspects appear as studying the national political contexts of target countries and sometimes home countries. (Cf. Andersen, 1993; Johanson and Vahlne, 2009; Fletcher, 2008; Andersson et al., 2002.) So does this fairly narrow understanding in mainstream IB research give an extensive picture of all political aspects of MNCs' operations and especially on global level? Supposedly, the meaning of political aspects is understood, as it arises every now and then also in the mainstream research. The political dimension belongs in research to somewhere in crossroads of multidisciplinary research agenda that cannot be in the centre of IB research especially if 'the big question in IB research' is formulated as Peng (2004) does: 'What determines the international success and failure of firms?' Obviously, politics is not the main target when considering this question.

For the reasons mentioned above, IB research has not been able to capture the complexity of political operational environment. This crosses both economics and cross-cultural perspectives understanding the political context mostly in ways that can be easily measured, directly causally explained and in the separated in home country – target countries sectors. The 'A' journals tyranny and weak traditions of critical or alternative research in IB fields certainly have not encouraged new scholars diverging from those established perspectives and fields. (Cf. Brannen and Doz, 2010.)

Peng (2004) argues that globalization is not in the core of IB research. If this is accepted, the lack of incorporating global politics in IB research is understandable. Global politics seem to belong to one of those research topics that is shared by various social sciences but is not in the core of any. However, this approach can give much to IB research as it strengthens the multidisciplinary of IB research by bringing in fields such as global social sciences and other fields of business research (see e.g. Newell, 2008a). Bringing other disciplines into IB research does not weaken the core but instead can offer interesting approaches to more and more complex questions in IB as the world globalizes and environmental problems are becoming more acute.

A foothold for political analysis of MNCs' actions could be found in the fact that IB theories have received critique of their inability of handling the contexts. Politics is an essential part of history, culture and societal emergence of institutions and thus define both explicitly and implicitly operational environment of firms on global

and national level. The societal level analysis of for example formal and informal institutions becomes even more important in the age of globalization as these factors can have significant effect on strategic choices of a firm (lobbying activities, interest group relations etc.). It must be also noticed that in fact institutions are the basis of all economic activities through existing business systems. In practice society influences business systems by government or state dominance in shaping economic environment and regulatory systems. (See e.g. Redding, 2005.)

New Openings

Political aspects in IB are background or context factor in various fields inside the research but not explicit or even clearly defined when discussed. However, various other fields have brought the question more openly into discussion and opened it through themes such as business ethics, corporate responsibility and environmental questions.

The research on MNCs and their political activities and especially actual political outcomes seem to be in significant amount in other hands than those of IB researchers. The role of CPA questions has grown due to corporate responsibility (CR) discussion which is closely tied to interest group and network discussions. Also political sciences have tackled it through globalization, power relations and democracy aspects. CPA also appears strongly in strategy research which could be one of the important links to IB research. Unfortunately in IB strategy research political questions often are just analysed through for example political risk analysis. (Wilts, 2006; Keillor et al., 1997; Jakobsen, 2010; Niebling and Shubik, 1982; Alon and Herbert, 2009.)

Accordingly, it appears that discussion of CPA is growing on other fields of research and of course in public debate and even in half-scientific literature (Matten, 2009). Is it that other fields have been able to bring the questions of socio-political environment explicitly out where IB research has had to hide them in order to be able to focus on 'more relevant' questions concerning MNCs? Has this interesting question about MNCs been hijacked by other disciplines such as management and organization studies and political sciences? At least partly but it does not count out the possibilities of grasping the question in future. (Hadjikhani, 2000.)

Detomasi (2008) argues that corporate responsibility initiatives and its development have been strongly influenced by political institutional structures and effects of globalization. In the age of globalization firms cannot enter the global world without carrying some conceptions, ways of actions and values with them when acting internationally or globally. The effects of globalization are often positive for firms but when for example global environmental problems have to be solved the multinationals must take a new standing because of their significant economic and also political power. (See e.g. Parker and Pearson, 2005; Clapp, 2005; Singh and Carasco 1996.) This is one important link that IB has partly consciously delimited outside its scope.

The major problem of identifying CPA as a wider and more crucial question in IB or also other business research is the large fragmentation of perspectives among countless different fields. For example Getz (1997) identifies already nine basic social science theories discussing the question. According to her, the research has centred to answering questions who, why and how but the scope of time and space have been much less examined. For example these theories could give a wider picture of CPA but as they are rarely utilized together the picture given by CPA research is often only partial. Another relevant option would be to concentrate on much deeper analysis of certain cases even without trying to draw a bigger picture.

CPA research literature however is multiform, rich and numerous. Still for example the analysis of actual political outcomes and long-term effects has been in 'offside'. (Hillman et al., 2004.) This is one of those things why for example corporate responsibility discussion seems to have taken over in crucial parts of CPA. On the other hand, Hadjikhani (2000) claims that the political behaviour of firms has not gained notable attention. He might mean exactly the fact that the political actions are often understood very narrowly or analysed in their full scope (i.e. e.g. the actual socio-political outcomes). Mantere et al. (2007) also notice that misdirected CPA research is unable to identify the moral questions of firms' political activities. This can be also a practical problem if the understanding of political actions and corporate responsibility do not confront. This is strongly due to the fact that CPA research is often driven by a demand from business practitioners.

For example Newell and Levy (2006) are alleging that corporate political power must be analyzed through combining analysis of prevailing material conditions, organizational forms, and discursive practices and give up

concentrating to only state-centric thinking in creating global environmental governance (Newell & Levy 2006: 174–177). But are power relations somehow too delicate issue for IB researchers to touch even when many other fields have been able to produce even very critical research on firms in societies? Do business research and especially IB research leave the whole field of corporations' influence on surrounding societies to other fields? (E.g. Schuler, 2008; Barley, 2010.)

Process for Learning from Other Fields

The idea of finding new directions for a research field from other fields is not exactly original. However, business research, especially IB research has not been able to systematically learn from fields that could have much to give in order to build more coherent understanding of MNCs in a complex global political environment. Thus, I propose a systematic search for overlaps in themes from fields that I have identified as most fruitful sources of new theoretical and also empirical perspectives for business studies. In Fig. 1 is presented the idea in a very simplified form. I propose that the process could simply start from the already identified gaps in corporate political activity research. My focus in this paper is environmental politics because of its significantly global nature and complexity in dimensions. It is also good example as it has been one of the pathbreaking areas where corporations have had to explicitly participate in policymaking in national and global level through their own corporate responsibility programs but also by participating in negotiations and agreements which shape their operational future (e.g. McCormick, 2006; Charkiewicz, 2005; Bernhagen, 2008; Vormedal, 2008; Bled, 2009).

The above presented critique leads easily to the notion of deficiency of business research to understand the context it operates with comprehensively. Political science, to be exact global political economy and the research on international relations, offers keys to this lack. (See e.g. Hillman et al., 2004.) Further, to analyse the whole picture more profoundly to be able to contribute to popular discussions on business ethics and corporate responsibility, the analysis can continue by drawing from ethical perspectives, namely philosophy of politics and ethics. By this process, the paper suggest that IB could better analyse the operational network and multiple-way effects of corporate political activities in its own networks of stakeholders.

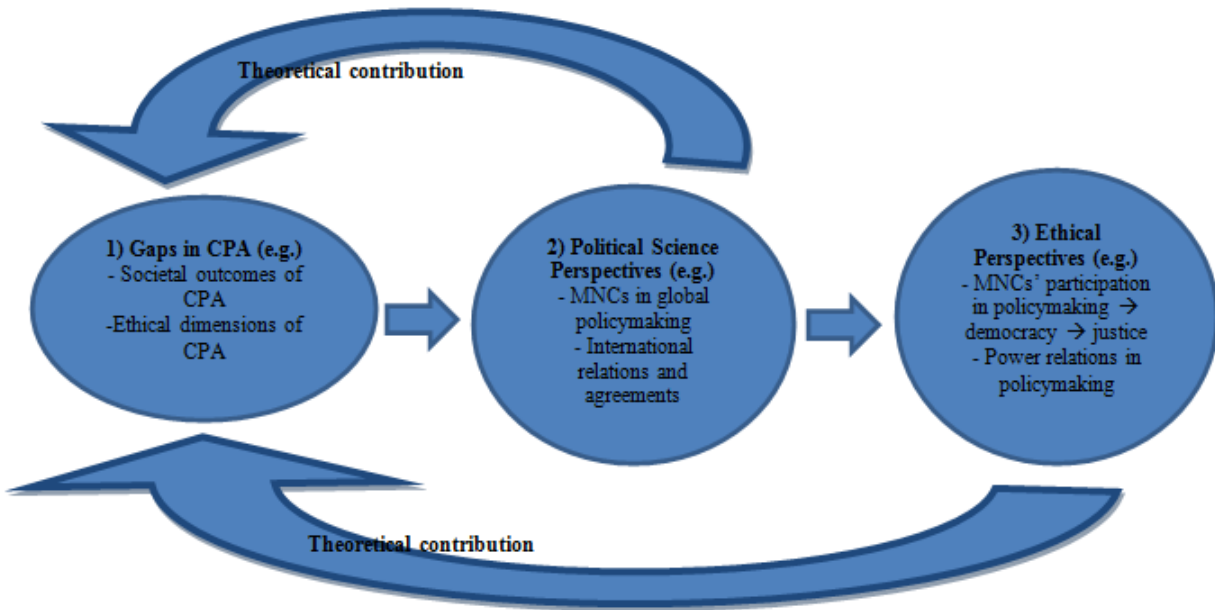

FIG. 1: SIMPLIFIED DESCRIPTION OF PROCESS OF LEARNING FROM OTHER FIELDS

Political Sciences Meets Business Research

In this section I present some perspectives from recent discussions in political sciences. These perspectives have obvious linkages to the interests of IB research and thus, could offer new insights for studying the relations of corporations and politics especially in the area of environmental questions. My focus is in aspects that have not been in the centre of IB research but could give fruitful new dimensions to study the nature of MNC: Ethical aspects of CPA, societal and institutional outcomes of CPA.

In their article, Mantere et al. (2007) claim for bringing in an ethical perspective in studying CPA. Business ethics and corporate responsibility discussions have long traditions in examining corporations as morally responsible actors in societies. They can be considered as relatively critical approaches in business studies but not anymore in a long time as really marginal. Thus, it is surprising how little IB has drawn from these widely discussed perspectives. Analysis of morales behind CPA and its meaning to liberal democratic societies have already been explicitly raised up in for example corporate citizenship discussion. This discussion has been able to combine political analysis to business studies and as the main representative of global business research, IB should certainly take its standing there. (See also Moriarty, 2008; Bazin, 2009.)

The traditional and most straightforward view of MNCs' relation to politics is tied to the ambiguous concept of 'lobbying'. Through lobbying MNCs are not only trying to build a certain kind of reputation but also directly influence decision-making by offering information on issues under decision processes. Lobbying and lobbying strategies are connected to corporations' stakeholder and network relations. In environmental issues lobbying seems to be crucial for various societal actors, also others such as non-governmental organizations (NGOs), as different political interest groups have very diverse goals and values connected to the certain issue. Corporations may seem the situations as political risks for business. (Gullberg, 2008; Holtbrügge et al., 2007; Jakobsen, 2010.)

However, the institutional field of global politics is much more complex than above described picture. The international business networks for example are already by nature somewhat politically biased because of their cross-border relations. Actors in those networks are tied to dealing with different political environments. In addition within last one or two decades businesses have started to network more closely with also other than business actors. Thus, non-market actors are knowingly brought from 'stakeholder' role into the business networks. Example of this is co-operation with NGOs. (Falkner, 2003; Pattberg 2005; Welch and Wilkinson, 2004; Hadjikhani et al., 2007.) As in situation of for example lobbying from business network perspective in global politics seems quite straightforward strategically fairly simple process, then close co-operation with other actors complicate the situation. Systematic theoretical and empirical work is nearly absent in this area. Combining institutional views and network approaches with research on international relations and corporate responsibility approach could offer valuable prospects to the formation of institutional environment of businesses.

If business researchers, and most importantly businesses themselves, are willing to admit the political power and responsibility of market-oriented actors in global political arenas, there are also some fundamental questions to be asked. What is actually environmental politics, is it governing the nature or something else? Who are the accepted participants in decision-making and who are left outside or to uncertain position? And perhaps, most importantly from the perspective of IB, what kind of position are businesses ready to take when considering the relation of markets and natural environment? All these questions come down to the political role of multinational businesses. (Newell, 2008a, 2008b; Auer, 2000; Pattberg and Stripple, 2008.)

In changing and globalizing world multinational corporations are in position where they not only operate in markets but also in natural environment that is territory for also people living in it and enjoying or suffering of its good or bad state. Understanding this new position is the common denominator for perspectives I have suggested above. (E.g. Steurer et al., 2005; Englander and Kaufman, 2004; Rondinelli, 2007.) The societal and ethical analysis of global businesses is a rising theme in various research fields. IB would have a lot give to the discussion by combining the perspectives to more traditional approaches as MNCs are the core competence of it. Understanding this when designing the theoretical backgrounds in future studies but also taking new perspectives in empirical analysis of CPA, IB could gain much itself too.

Conclusions and Discussion

Corporate political activities are indeed not in the centre of IB research. They maybe even should not be but now the political aspects of multinational corporations' are in position where they are mentioned incidentally or pruned to a form where they are analysed only for example as a risk of entering new markets. However, I argue that the attention to the whole scale of CPA has not been identified by IB research but it should be more coherently understood and gain certain status.

When MNCs are facing new challenges in a globalizing world the international business research has amazingly little tackled these questions in the mainstream. Even when political questions would not be brought into the centre of IB research it could benefit from learning from other disciplines actively discussing the issue. There is already strong links to organizational theories and strategy research and thus, the leap would be easy to widen the perspectives that way.

The existing research on CPA can be situated in the following fields of research: strategy (especially political strategy), institutional theories (formal and informal institutions, here especially global institutions but also national ones) and stakeholder and network approaches. Concentrating on actual political outcomes and political relations' long-term meaning for MNCs are still almost non-existent. The offering of these fields was briefly discussed with an objective to concentrate especially to themes in those fields that are already in the area of IB or at least close to it.

The research gaps presented in this paper show the unfortunate shallowness of (IB) corporate political activity research. Considering the examined literature at least following issues have gained amazingly little attention: Studying the actual political outcomes of CPA, utilizing multiple approaches in order to create a more coherent picture of CPA, studying the ethical and responsibility issues of CPA and overall building a strong tradition

around the CPA discussion. These gaps are not impossible to be filled even in frameworks of mainstream IB research if the traditions just are willing to yield to 'unfamiliar' areas. We have already seen this shift happening partly but there are still strong counterforces based on the characteristics and traditions of IB research.

This paper has aimed at offering a systematic approach for opening the 'IB mind' to other fields of research and daringly setting the research questions in order to breaking the moulds should not be in general anything new in research. Also increasing the amount of case studies and comparative studies that are by nature multidisciplinary could reveal interesting new streams.

Abstract

This paper is focused on the relationships between large retailers and small-medium enterprises (SMEs) in the food sector. A supplier perspective was adopted in the analysis of the large retailers' role, by considering how CSR policies adopted by retailers affect manufacturers organization and strategies.

The analysis has been based on a quantitative empirical research focused on the food sector, as a sector in which traceability, supplier's coordination and control are critical to ensure the development of ethical supply chains. In the survey, a questionnaire was addressed to a sample of 89 Italian SME manufacturers to investigate the primary factors influencing retailer-supplier relationships in those cases in which CSR policies by large retailers are adopted.

A limited diffusion of systematic and structured systems for CSR emerged among firms that have not developed significant relationships with large retailers.

1. Introduction

In the last two decades, economic development has increased firms' opportunities to achieve their economic goals, without respect to ethical and social values. As a result, in most countries, an increasing independence of products, capital and labor markets has been permitted to maximize profits, in turn, weakening the introduction of an internationally accepted rules system.

In Europe, this phenomenon has encouraged an endogenous response from society, with the emergence of new needs, for a more balanced process in creating value. Above all, more-educated and consciousness consumers are expressing their need for more transparency in production processes and supply chain operations. This issue has been investigated in many studies (Dagnoli, 1991; Shaw and Clarke, 1999; Shaw and Shui, 2001; Caselli, 2003; Maignan and Ferrel, 2004; Sciarelli, 2007).

Today, aware consumers are not only interested in new products, but they also require more information about manufacturers, labor conditions under which products are assembled, and how production systems impact the environment and economic growth of the local communities along the entire supply chain (Strong, 1996; Shaw and Clarke, 1998, Harrison *et al.*, 2005).

As consumers are becoming more responsive to ethical behaviors, they are also more aware of product evaluations (Macchiette and Roy, 1994; Hemingway and Maclagan, 2004) and their motivations are increasingly related to the need of personal and social benefits (Freestone and McGoldrick, 2008). Consequently, companies are becoming more ethical and socially responsible, by developing methodologies and tools linked to Corporate Social Responsibility (CSR) initiatives.

The literature illustrated a positive correlation between CSR policies and business performance (Balabanis *et al.*, 1998).

Recently, the importance of CSR has increased in all economic sectors, including retailing. In this sector, large international retailers are investing relevant resources to cope with consumers' ethical needs (Whysall, 2000; Pepe, 2003; Jones *et al.*, 2005). Key international retailers have begun to offer ethical products, and thereby, consolidate their approach to CSR through assortments related to sustainable development, fairness, and the distribution of value

among all subjects within the supply chain.

Consumers seem to be less critical of retailers, than they are of large manufacturers. In many cases, they perceive retailers as only partially responsible for the activities along the supply chain of products and tend to reserve more trust toward retailers' behaviors. Nevertheless, some retailers are becoming known as socially irresponsible companies, such as Wal-Mart (De Man, 2005; Wilson, 2005) and Benetton, with the latter being accused of child exploitation in Turkey in 1998 (Body *et al.*, 2005). At the same time, the low level of public awareness of CSR initiatives has illustrated the challenge that companies face in building a positive reputation. Companies that identify themselves as CSR leaders will enhance their reputation (De Man, 2005).

Retailers are often channel leaders and can control various activities in the supply chain. As a result, they appear more capable of adopting active roles in sustaining and leading international supply chains following a CSR approach. The most innovative retailers have capitalized on this opportunity and have managed their assortments and marketing policies by considering the extra-economic values in all the activities of supply chain partners.

This article offers an overview of the main drivers of CSR initiatives in which large retailers are leaders. A suppliers' perspective was adopted in the analysis of the large retailers' role, by considering the point of view of small-medium enterprises (SMEs) in the food sector. The primary objective of the analysis was to identify the key CSR issues along the large retailers-led supply chain.

Literature on key issues related to retailer-led channel relationships was considered (Baily, 1987; Davidson, Sweeney and Stampfl, 1988; Shuch, 1988; Packard, Winters and Axelrod, 1996; Musso, 1999). Afterwards, a quantitative survey was conducted, focusing on the grade of diffusion of CSR practices among SME manufacturers and the main factors influencing retailer-suppliers relationships within a retailer's CSR approach.

The quantitative survey regarded Italian small and medium sized manufacturers in the agro-food sector that were involved as suppliers in international supply chains led by large retailers. The choice of the food sector was due to the more sensitive ethical consumer issues. These issues require retailers to place priority in the adoption of CSR practices within such products.

2. The role of large retailers for CSR in international supply chains

CSR has recently become a new corporate buzzword, as well as an emerging field of competition among companies. CSR is an enlarged concept of responsibility, depending on a general evolution of "values" linked to the relationship between a business organization and its environment. For companies, this means responsibility to consumers, versus that of its shareholders, with the latter also related to the maximization of profit and assets.

In the literature, several studies have been concerned with corporate ethics and corporate responsibilities. Some of them investigated the importance of ethics in the purchasing and selling activities of industrial companies (Redelius and Bucholz, 1979; Dubinsky and Gwinn, 1981; Trawicket *et al.*, 1988; Wood, 1995). However, few studies have explored the importance of ethics in the buyer-seller relationships of retailer companies (Dickerson and Dalecki, 1991; Arbuthnot, 1997; Musso, 1999).

More recently, the boundaries of the classic concept of business ethics have enlarged, entering the wider realm of CSR and sustainable development. Indeed, the expression "sustainable development" synthesizes the three dimensions of the problem: *thesafeguarding of the environment, the respect for human rights, and the fairness in the redistribution of value among all subjects of the supply chain.*

Many authors have also focused on CSR within supply chains, primarily in relation to industrial, multinational corporations. Many of the corporations of interest were leaders of wide and complex supply chains (Carter, 2000; Park and Stoel, 2005; Mamic, 2005; Maloni and Brown, 2006; Amaeshiet *et al.*, 2008; Gonzalez-Padronet *et al.*, 2008). Some contributions have considered CSR in the national and international marketing activities of retail companies (Nicholls, 2002; Pepe, 2003; Jones *et al.*, 2005; Risso, 2007).

In regard to CSR, *the supply chain represents a focal point to adopt strategies related to the concept of responsibility and evaluate them.* Indeed, in those supply chains where it is necessary to manage all processes and relationships under the coordination of a channel leader, it is significant to understand the specific role of each

player and the general action conducted by all supply chain members. In particular, the retailer's role becomes relevant when its large dimension and its capability to influence consumer choices bring it to a position of a channel leader. Large retailers can play a predominant role in controlling the sustainability of both the production and distribution processes of their products. They frequently become guarantors of the entire value chains, particularly those of their own brand products that directly reflect their corporate image. As retailers are close to consumers and obtain information about them, they also have the ability to better understand the final demand and activate retail marketing tools based on local needs, as well as extra-economic needs. In this way, retailers are the first to face requests from consumers for more ethical and responsible approaches to managing products. At the same time, they are able to play an active role in influencing consumer behaviors toward ethical and social issues.

The increasing consumers' sensitiveness to the concept of sustainability has encouraged innovative retailers, particularly those from advanced countries within Europe (mostly in the United Kingdom), to adopt a CSR for managing their assortments (Freestone and McGoldrick, 2008). The retailers' involvement in ethical issues began in the 1990s, with organic products and Fair Trade food assortments. These CSR principles were then applied to beauty, personal care, handmade and clothing products (Balabanis, Phillips and Lyall, 1998; Harrison, Newholm and Shaw, 2005). In other sectors, operators also developed dedicated financial services (ethical and ecological funds) and eco-tourism initiatives.

By the adoption of CSR in managing assortments and related supply chains, retailers can more quickly and effectively, achieve the following goals:

- market differentiation (Piacentini *et al.*, 2000);
- enhanced word-of-mouth and the reduction of expensive marketing investments (Pepe, 2007);
- customer and worker loyalty (Pepe, 2003);
- eligibility for inclusion into a stock-market index that includes only those companies deemed to be socially responsible.

CSR policies have strategic and organizational implications within internal processes, but the CSR also requires paying attention to the behaviors of all partners involved in the product supply chain, especially those of the own brand products. Food-retailers insert CSR principles in the supply chain into the following ways:

- modifying and improving relationships with suppliers;
- exerting control, and in some cases, adopting vertical integration strategies;
- cooperating with existing CSR based supply chains (mainly for organic and Fair Trade products).

According to this approach that is recommended to be followed by retailers, *traceability*, means the ability to track any food, feed, food-producing animal or substance used for consumption through all stages of production, processing and distribution, becomes an important control tool.

Traceability is linked to a legal framework and is a way of facing potential risks that can arise in the food production and logistic processes to ensure that all food products in the European Union (EU) are safe (reg. UE 178/2002, D. CEE 2001/18, Dir. CEE 1760/2000, d.lgs. 155/97). In addition, traceability permits targeted withdrawals and the provision of accurate information to the public, thereby controlling each partner in the products supply chain. In particular, traceability systems are a technical tool to monitor each step of the supply chain, a managerial system to reduce costs, and an intervention system, in cases of non-compliance.

Traceability issues are more critical in international supply chains and relationships with SME suppliers. In international supply chains, there are two main reasons for this: the first is related to the need of warranties on the quality of products coming from countries with different legal frameworks, therefore focusing on product safety and the use of chemical components; the second concerns labor conditions that apply to employees in less-developed countries, the fair distribution of value among suppliers and the environmental impact of the production processes.

In regard to relationships with SME suppliers, there are some critical aspects to consider. In particular, it is very hard for SMEs to respect CSR policies. There are many reasons for this (Grayson and Dodd, 2007):

- the application of conduct codes can be excessively onerous (in reality, or as perceived by the firms);
- SMEs may have less of a direct advantage in CSR policies;
- SMEs have less time and fewer resources to invest in CSR processes, with more immediate business priorities;
- knowledge of CSR practices is limited and there are problems in training human resources;
- and
- external supports to firms are inadequate.

Recent studies have argued that for SMEs, CSR activity is more difficult, because entrepreneurs do not have the experience to help them to evaluate and manage key factors for CSR (Murillo and Lozano, 2006a; 2006b; Lepoutre and Heene, 2006; Williamson *et al.*, 2006). Despite such difficulties, large retailers are increasing their standards of safety, security, environmental sustainability and working conditions in the supply chains. In addition, SME suppliers must respect large corporation wishes to maintain relationships (Musso, 1999; Grayson and Dodd, 2007; Pepe, 2007; Pepe *et al.*, 2008).

3. Empirical research and methodology

To investigate the CSR approach within retailer-led supply chains, a quantitative research was conducted in 2008, in order to increase our understanding of SME manufacturers in their relationships with large retailers. The quantitative study focused on the food sector, as a sector in which traceability, supplier's coordination and suppliers control are critical to ensure the development of ethical supply chains.

A questionnaire was addressed to SME manufacturers to investigate the primary factors influencing retailer-supplier relationships in those cases in which CSR policies by large retailers are adopted. Data were collected through telephone interviews with 89 Italian SME manufacturers in the food sector (Tab. 1)¹.

The 89 interviewed SMEs were part of a panel used in an earlier study (Pepe *et al.*, 2008). Interviews were conducted with entrepreneurs, sales managers and marketing managers.

TAB 1 – FOOD SMES PANEL DESCRIPTION

	N. of firms interviewed
N. Food SMEs	89
Exporter	81
Suppliers of large retailers	89
- Italian retailers only	45
- International retailer only	3
- Both national and international retailer	41
Geographic area: North Italy	33
Center Italy	26
South Italy	30

The questionnaire focused on general issues related to supply relationships and specific issues with the CSR. General issues were divided in three main categories: market dynamics, export strategies and relationships with large retailers. The CSR section related to the awareness of CSR phenomena, CSR implications in business processes, CSR tools and instruments.

Among the 89 enterprises interviewed, 30 responded to the section regarding CSR. To extend the sample, in

2009, the relevant questions on CSR, were re-submitted to the 59 firms that did not answer the CSR section. 29 of them provided information on the policies they adopted, while 30 confirmed they did not adopt any CSR initiative. As a result, the total number of usable questionnaires for the CSR related issues analysis rose from 30 to 59.

The questionnaire was planned on the basis of three research questions that emerged from the literature review.

The first research question referred to the importance of the CSR in functional areas of the firm and in relationships with large suppliers:

RQ 1: What is the grade of diffusion of the CSR practices among SME manufacturers in the food sector.

The second research question was related to the aims of the CSR activities for firms. In particular, it comprised of: factors that stimulate firms to adopt CSR activities, requirements to manufacturers from large retailers, expected characteristics of CSR systems, and guidelines for CSR activities.

RQ 2: How spontaneous were choices to adopt CSR activities, and what subjects/needs did they address.

The third research question focused on the systems used to manage CSR activities (e.g., quality control and traceability of products, environmental rules, security, and ethical codes). In particular, it was directed to verify whether CSR activities were developed through formal practices or through an informal approach to ethical behaviors.

RQ 3: How formal/informal was the approach to CSR practices.

All research questions were analyzed together with some linked variables: firm dimension, weight of sales to large retailers on turnover, degree of internationalization, and age of the firm. The questionnaire was semi-structured with items referring to the previously mentioned research questions. A five-point Likert scale was used for the evaluation of single items (1 = low importance to 5= high importance). Responses to open ended questions were classified and a dichotomous scale of 0/1 (0 not relevant, 1 totally relevant) was used for each item. The measurement instrument was developed using a combination of existing scales. Data analysis was conducted by a SPSS statistical tool.

3. Results

Results from the quantitative study were analyzed with a cluster analysis to identify the specific categories of manufacturers inside the sample, as the results of the empirical study illustrated a prevalence of inhomogeneous behaviors. K-Mean methodology was applied, which allowed a minimized inertia within single groups and between clusters. The number of the singled-out cluster was 3 that resulted after a series of tests that revealed it to be the value that returns the clearest differences.

The variables used to divide the sample into more homogeneous groups included: overall turnover, export turnover, importance of national large retailers as customers of the manufacturer (as a % of turnover) and the importance of international large retailers as customers of the manufacturer (as a % of turnover). Tab. 2 illustrates the variables that contributed to defining the clusters within the sample. F-test revealed that turnover, the importance of national retailers in turnover, and the importance of international retailers in turnover were the more significant variables.

TAB. 2 – ANOVA ANALYSIS WITH DIFFERENT SIGNIFICANCE LEVELS

	Cluster	Error	F	Sig.
--	---------	-------	---	------

	Mean Square	df	Mean Square	Df		
Turnover	16,916	2	2,770	86	6,108	,003
Export turnover	4,275	2	1,807	76	2,366	,101
Importance of national large retailers	23797,128	2	208,918	74	113,906	,000
Importance of international large retailers	6682,549	2	73,808	67	90,539	,000

F-tests should only be used for descriptive purposes here, because the clusters were chosen to maximize the differences between the cases in the different clusters. The observed significance levels were not corrected for this, and thus, cannot be interpreted as tests of the hypothesis that the cluster means are equal.

Differences in the means between clusters were due to the variance in responses and to the different consistencies of the single clusters (Tab. 3).

TAB. 3- NUMBER OF UNITS PER CLUSTER

Cluster	Number of interviews	Number of answers received on the CSR section
1	24	16
2	51	29
3	14	14
Total interviews	89	59

Cluster 2 was more numerous, with 51 respondents that answered the questionnaire. Among them, 29 responded to the CSR section of the questionnaire. Cluster 1 had 24 units with 16 people that responded to the CSR section, while Cluster 3 had 14 units, where all people responded to CSR section. The respondents in Clusters 1 and 3 were more interested in responding to the CSR section. Indeed, 100% of the firms in Cluster 3 responded to the CSR section, with 2/3 of the respondents in Cluster 1 and 56,8% in Cluster 2.

Data on the importance of large retailers in turnover was not available from all the manufacturers. Considering their insignificant number, missing values were treated as with the option “exclude cases pairwise” that permits the assignment of single cases based on the distances from the variables without missing values.

In Cluster 1, turnovers revealed an average value between 10 and 20 million euros, export turnover had an average value between 5 and 10 million euros, sales to national large retailers had an average weight of 71,45% (Tab. 4), and sales to internationally large retailers had an average weight of 4,78%. In Cluster 2, average turnover was between 5 and 10 million euros, the same as export turnover; sales to national large retailers had an average weight of 15,51%, and sales to internationally large retailers had an average weight of 5,7%. Cluster 3 showed an average turnover between 21 and 40 million euros, an export turnover between 5 and 10 million euros, sales to national large retailers had an average weight of 27,25%, and sales to internationally large retailers had a weight of 35,2%.

The three clusters were differentiated from each other mainly by overall turnover and weight of large retailers (both national and international). Cluster 1 had a distinctively higher weight of national large retailers on turnover and a lower weight of international retailers. Manufacturers in Cluster 1 were mainly between 10 and 20 million in terms of overall turnover. Cluster 2 was characterized by fewer sales to large retailers and a smaller size of firms than Cluster 1 (mean of 5-10 million turnover). In Cluster 3, firm size was higher (mean of 20-40 million turnover) and large retailers were more important to turnover, particularly international retailers (35,2% on total turnover) as

compared to Italian ones (27,25%).

TAB. 4 – WEIGHT OF LARGE RETAILERS ON TURNOVER BY CLUSTER

Cluster	Weight national retailers %	Weight international retailers %
1	71,45	4,78
2	15,51	5,70
3	27,25	35,20

As far as RQ 1 was concerned (which is the grade of diffusion of CSR practices among SME manufacturers in the food sector), Tab. 5 illustrates the importance attributed to such factors by distinct firm areas. Evaluation on importance of CSR practices was asked in a Likert scale from 1 (low importance) to 5 (high importance). Means and standard deviations were calculated for each of the three clusters of firms. In Tab. 6, an indication on the initiatives conducted by the manufacturers in the same areas is illustrated. Rates vary from 0 (no activities) to 1 (activities conducted). Means and standard deviations were calculated for each cluster.

All enterprises considered quality products, traceability, labor conditions and bi-directional communication with consumers as fundamental issues. Less importance was given to support to the local community and to the development of practices for corruption contrasting. Comparing evaluations on the importance of CSR and the initiatives conducted, a consistent approach to CSR development emerged regarding all internal and external fields considered. Cluster 3 results revealed a more active support to the local community and to corruption contrasting activities compared to the other clusters. However, these two factors were considered less important than others.

TAB. 5 – MANUFACTURERS' EVALUATION ON IMPORTANCE OF CSR PRACTICES BY CLUSTERS OF BUSINESS ACTIVITIES AND RELATIONSHIPS

Cluster		Product quality and traceability	Labor conditions	Communication (bi-directional) to consumers	Environmental impact of production	Ethical standards	Regular and complete information on products	Support to local community development	Practices for corruption contrasting
1	Mean	4,38	4,25	4,31	4,06	4,25	3,69	3,25	2,38
	Std. Deviation	0,50	0,86	0,60	0,85	0,45	0,79	1,57	1,59
2	Mean	4,76	4,59	4,03	3,79	3,83	3,48	2,86	2,52
	Std. Deviation	0,58	0,68	1,35	1,26	1,36	1,27	1,19	1,33
3	Mean	4,93	4,57	4,64	4,86	4,43	4,29	4,36	4,00
	Std. Deviation	0,27	0,51	0,63	0,36	0,85	0,73	0,74	1,04
Total	Mean	4,69	4,49	4,25	4,12	4,08	3,73	3,32	2,83
	Std. Deviation	0,53	0,70	1,06	1,08	1,09	1,08	1,34	1,48

TAB. 6 – INITIATIVES CONDUCTED FOR CSR DEVELOPMENT BY CLUSTERS OF BUSINESS ACTIVITIES AND RELATIONSHIPS

Cluster		Product quality and traceability	Labor conditions	Communication (bi-directional) to consumers	Environmental impact of production	Ethical standards	Regular and complete information on products	Support to local community development	Practices for corruption contrasting
1	Mean	0,88	0,75	0,81	0,50	0,69	0,38	0,31	0,13
	Std. Deviation	0,34	0,45	0,40	0,52	0,48	0,50	0,48	0,34
2	Mean	0,76	0,72	0,66	0,55	0,41	0,28	0,21	0,00
	Std. Deviation	0,44	0,45	0,48	0,51	0,50	0,45	0,41	0,00
3	Mean	0,93	0,79	0,71	0,86	0,79	0,86	0,57	0,07
	Std. Deviation	0,27	0,43	0,47	0,36	0,43	0,36	0,51	0,27
Total	Mean	0,83	0,75	0,71	0,61	0,58	0,44	0,32	0,05
	Std. Deviation	0,38	0,44	0,46	0,49	0,50	0,50	0,47	0,22

Referring to RQ 2 (how choices to adopt CSR initiatives were spontaneous and what subjects/needs did they address), results revealed that firms aimed at protecting themselves from potentially negative effects (in terms of company image) that result from malfunctions in CSR related fields. In Tab. 7, rates were given on a dichotomic scale 0/1 (0 no influence, 1 influence). The CSR was developed by firms after requests from large retailers and consumers. In this way, product assortments can be perceived as more valuable. Less importance in terms of influencing factors was attributed to relationships with supply chain partners and to internal relationships.

As evidenced by Cluster 3, regarding larger-sized firms, more importance was given to reasons related to brand image construction and protection, as well as to the need to respond to consumers' requirements. On the opposite side, the response to large retailer requirements was indicated as no more a primary reason because relationships with large retailers are in most cases well developed by Cluster 3's firms. Hence, they don't need to increase CSR involvement as a tool to better develop relationships with large retailers.

TAB. 7 – REASONS THAT STIMULATE FIRMS TO ADOPT CSR INITIATIVES AND ACTIVITIES

Cluster		Brand image construction and protection	Requirements from large retailers	Requirements from consumers	Increasing product offer value – "Ethical value"	Equalization with supply chain partners	Internal relationships improvement
1	Mean	0,88	0,94	0,69	0,88	0,63	0,75
	Std. Deviation	0,34	0,25	0,48	0,34	0,50	0,45
2	Mean	0,82	0,86	0,82	0,75	0,71	0,54
	Std. Deviation	0,39	0,36	0,39	0,44	0,46	0,51
3	Mean	0,79	0,50	0,71	0,43	0,71	0,57
	Std. Deviation	0,43	0,52	0,47	0,51	0,47	0,51
Total	Mean	0,83	0,79	0,76	0,71	0,69	0,60
	Std. Deviation	0,38	0,41	0,43	0,46	0,47	0,49

Confirmation of this comes from Tab. 8, where firms' awareness regarding large retailers' requirements is analyzed in a Likert scale (1 = low, 5 = high) (all the 89 firms in the sample responded). Large retailers tend to require, at first, high levels of reliability from suppliers (total mean rate 4,59), as well as conformity to hygiene and security standards (4,57), and the quality levels of products and services offered (4,46). Price/value comes after such factors, with a rate of 4,31.

TAB. 8 – REQUIREMENTS TO MANUFACTURERS FROM LARGE RETAILERS*

Cluster	Quality levels of	Quality/price	Supplier	Conformity to	Reputation of	Level of human
---------	-------------------	---------------	----------	---------------	---------------	----------------

		products and services offered	(value) of product offer	reliability	hygiene and security standards	supplier	resources of supplier
1	Mean	4,42	4,29	4,67	4,63	3,92	3,79

	Std. Deviation	0,91	0,98	0,69	0,92	1,28	1,28

* Responses from 89 manufacturers.

Tab. 9 synthesizes the main points that should characterize a CSR system, according to the perspective of the firms. In a dichotomic scale 0/1 (0 not relevant to the presence in a CSR system, 1 necessary to a CSR system), all the firms of the sample indicated a necessity of the presence of measures for continuous improvement of environment sustainability; most (mean 0,98) indicated that voluntary character is necessary, as well as the presence of results measurement. High importance emerged also as regard to quality and reliability of all business processes (not only manufacturing), independence from stakeholders, as well as the presence of public and institutional support. All these points received a mean indication between 0,90 and 0,69. The character of cost saving was recognized as not necessary by almost all the manufacturers (mean rate 0,36).

Larger firms and those more related to international large retailers (Cluster 3), ascribed major relevance to the voluntary character of CSR systems, and considered the presence of results measurement systems to be less necessary. Such firms, with a more advanced approach to management and control of business processes, tend to consider such points as not characterizing, as they are regularly part of management criteria. At the same time, all of them considered a voluntary nature as a necessary characteristic of CSR systems.

TAB. 9 – EXPECTED CHARACTERS OF CSR SYSTEMS

Cluster		Continuous improvement of environment sustainability	Voluntary Nature	Presence of results measurement systems	Quality and reliability of all business processes	Independence from stakeholders	Public and institutional support	Notexpensive, cost saving
1	Mean	0,94	0,94	0,94	0,88	0,75	0,56	0,31
	Std. Deviation	0,25	0,25	0,25	0,34	0,45	0,51	0,48
2	Mean	1,00	0,89	0,96	0,75	0,79	0,75	0,36
	Std. Deviation	0,00	0,31	0,19	0,44	0,42	0,44	0,49
3	Mean	1,00	1,00	0,71	0,93	0,93	0,71	0,43
	Std. Deviation	0,00	0,00	0,47	0,27	0,27	0,47	0,51
Total	Mean	0,98	0,93	0,90	0,83	0,81	0,69	0,36
	Std. Deviation	0,13	0,26	0,31	0,38	0,40	0,47	0,48

CSR activities were mainly addressed to consumers and large retailers, as most of the sample indicated in a 0/1 dichotomic rate (Tab. 10). Consumers received a mean rate of 0,94, while retailers 0,88. In addition, other stakeholders were frequently considered as addressees of CSR activities. Among them, there were employees and suppliers (respectively 0,83 and 0,76 rate), stockholders (0,74), local communities (0,68) and institutional subjects (0,68). Less important were trade unions (0,57). Firms of Cluster 3 revealed more attention placed to all stakeholders, including trade unions. Firms whose relationships with large retailers were more developed (Cluster 1 and 3) paid more attention to local communities.

TAB. 10 – ADDRESSEES OF CSR ACTIVITIES

Cluster		Consumers	Large retailers	Employees	Suppliers	Stockholders	Local communities	Institutional subjects, Authorities	Trade Unions
1	Mean	0,81	0,81	0,81	0,75	0,63	0,81	0,31	0,56
	Std. Deviation	0,40	0,40	0,40	0,45	0,50	0,40	0,48	0,51
2	Mean	1,00	0,86	0,75	0,71	0,79	0,52	0,74	0,36
	Std. Deviation	0,00	0,36	0,44	0,46	0,42	0,51	0,45	0,49
3	Mean	1,00	1,00	1,00	0,86	0,79	0,86	1,00	1,00
	Std. Deviation	0,00	0,00	0,00	0,36	0,43	0,36	0,00	0,00
Total	Mean	0,94	0,88	0,83	0,76	0,74	0,68	0,68	0,57
	Std. Deviation	0,23	0,33	0,38	0,43	0,44	0,47	0,47	0,50

Items regarding RQ 3 (how formal/informal is the approach to CSR practices) emphasized a general orientation towards the limited formalization of processes related to CSR (Tab. 11). In particular, formal models were widely adopted for quality and traceability management and for safety inside manufacturing plants. In the first case, orientation to control quality and technical efficiency prevailed, in the second, the choice was less voluntary: in most cases, formal rules were adopted according to laws on safety and health.

In regard to social, ecological and ethical values, less involvement in process formalization was revealed. Moreover, the smaller the size of the firm, the more informal was the approach.

TAB. 11 – FORMALIZATION OF PROCESSES FOR CSR IMPROVEMENT

Cluster		Quality and traceability management	Safety management inside plants	Management of environmental impact	Social and ethical values management
1	Mean	1,00	0,94	0,50	0,50
	Std. Deviation	0,00	0,25	0,52	0,52
2	Mean	0,96	1,00	0,61	0,39
	Std. Deviation	0,19	0,00	0,50	0,50
3	Mean	1,00	1,00	0,64	0,86
	Std. Deviation	0,00	0,00	0,50	0,36
Total	Mean	0,98	0,98	0,59	0,53
	Std. Deviation	0,13	0,13	0,50	0,50

All the interviewed firms, except for some smaller ones that were part of Cluster 2, adopted quality control and traceability certification systems (Tab. 12) that were typical in the food sector. Less use of standards emerged for environmental impact controls and for safety control systems inside industrial plants, with a mean indication of adoption in a dichotomic scale 0/1 of, 0,68 and 0,43, respectively. Less use of certification standards was observed regarding social and ethical value management (mean 0,31), even if several firms with significant sales to large retailers, both national and international (Clusters 1 and 3), tended to adopt them more frequently.

TAB. 12 – CERTIFICATION SYSTEMS ADOPTED IN CSR AREAS

Cluster		Quality and traceability management	Management of environment impact	Safety management inside plants	Social and ethical values management
1	Mean	1,00	0,89	0,38	0,20
	Std. Deviation	0,00	0,33	0,50	0,42
2	Mean	0,92	0,50	0,42	0,07
	Std. Deviation	0,27	0,51	0,50	0,26

3	Mean	1,00	0,82	0,50	0,64
	Std. Deviation	0,00	0,40	0,52	0,50
Total	Mean	0,96	0,68	0,43	0,31
	Std. Deviation	0,19	0,47	0,50	0,47

5. Discussion

It is beyond a doubt that, for retailers, fair trade criteria application considerably affects supply chain relations. CSR practices can influence the entire structure of the buying network, as well as the quality of the relationships among partners and their behaviors.

For smaller suppliers, the level of cooperation is increasingly important, as it contributes to long term relationships. A large retailers' power is more often used, not to obtain better economic conditions (lower prices, longer payment terms), but more frequently to address smaller suppliers in improving their efficiency, innovation capability and organizational structure. What's more, a cultural change is stimulated and a systemic approach tends to be followed more frequently. This also happens at the international level with the involvement of a variety of subjects that contribute with their competencies (in terms of logistics, finance, and certification) to increase the level of integration among supply chain partners, and local and international institutions. Non-economic subjects were more frequently involved in supporting the introduction of socially responsible principles in international sourcing.

In some cases, the introduction of CSR-related standards was just a window dressing tool to improve company images of consumers and stakeholders. In most cases, however, there was an effective impact on all procurement processes. The introduction of products related to Fair Trade principles allowed for the enforcement of the level of responsibility along the entire supply chain, involving all the subjects at different stages towards a higher degree of transparency and efficiency. In particular, the following points come out:

- emphasizing cooperative issues (stimulated or, in most cases, necessarily required by larger retailers), supported by the commitment to share knowledge, capabilities, information and innovation;
- attenuation of the hierarchic perspective in buying relationships and the reduction of margin-compression effects for smaller suppliers as a consequence of power imbalances; at the same time, more support is provided by retailers to SME manufacturers to evolve toward more efficiency and higher quality levels;
- more space for shortening supply chains, more direct relationships between manufacturers, retailers, and consequently, more effectiveness within the network, cost savings, more rapid and adequate adjustments in the product offer by suppliers and in retailer assortments;
- more individually and socially respectful principles in all activities, including supply chain relationships, communication, logistics and service management;
- opportunities to pursue a relationship development model in which all involved subjects can benefit, including smaller partners inside the supply chains; among such partners there are, at the international level, farmers from developing countries.

As a consequence, all of these points support a virtuous circle that can be a stimulus for the strengthening of less unbalanced and more sustainable international supply chains, mostly where SME manufacturers are involved. The larger retailers' role in sustaining CSR principles (in all the related fields) along the supply chain is fundamental. A wide awareness of CSR among SME manufacturers was observed. All CSR related activities were more frequently adopted by smaller manufacturers, wherein larger retailers placed a significant weight in their sales and when the retailer acted as a channel leader. In this case, retailers' requirements for the adoption of CSR were a primary stimulus for structuring CSR activities and adopting specific standards.

In cases where large retailers were less relevant as customers for manufacturers, or where large retailers were less advanced (such is the observed case of national retailers for Italian manufacturers), CSR-related activities began to be adopted as well, but more informally and with less use of standards, formalized processes and certification systems (excluding those related to quality control and traceability, which are widely used in the food sector). For

other SME manufacturers and those less involved in relationships with large retailers, CSR was not seen as necessary, as it is considered a possible field for the differentiation of market positioning.

In general, it is possible to state that a large retailers' approach to CSR focuses on:

- developing traceability systems along the supply chain to gain accurate information and control at every stage. The objective is product quality and safety improvements on the one side, and a transparent responsibility of all the supply chain partners on the other side. This result is consistent with previous literature in this field (Pepe, 2007);
- increasing the number of products bought from smaller suppliers at the national and international levels and developing stable relationships with them to make relationship specific investments possible;
- following a more CSR-sensitive perspective in all marketing activities to: enforce brand-mix identity with socially-ethical responsible characteristics; apply social, ethical and ecological principles to all key activities of retail business; and improve the company's image in the consumers' perceptions. Similar results emerged from recent studies (Risso, 2007; Gupta and Prirsch, 2008);
- expanding interaction areas, both at the national and international level, with local actors (both public and private) that could support the company in developing activities related to social, environmental and ethical issues.

6. Conclusions and implications for future research

The increasing diffusion of CSR principles among large retailers, particularly in the food sector, is stimulating a progressive change in the entire supply chains and their members, including smaller manufacturers and intermediaries. In the case of Fair Trade products, a typical area developing CSR, retailers supply chains were strongly influenced by retailer-led CSR initiatives. Such involvement of retailers increases with their own brand products, in which a retailers' brand image was more directly associated to product characteristics in the consumer perception. This is a field in which global retailers are now basing a renewal of their image, acting in contrast with a negative reputation coming from their excessive power along their supply chains. In several cases, such power has been seen by consumers and stakeholders as a potential danger for more weak suppliers, such as those from Southern hemisphere and for the environment. Fair trade assortments, as well as organic products and "green" packaging, can be used by retailers as tools to enrich and diversify their offerings, propose new values and, at the same time, maintain power and control within the supply chain.

Consumer perceptions allow retailers to assume a central role as a guarantee for control over the safety, equality and ethically correct practices along the supply chain. The more consumers are aware of ethical and sustainability issues, the more retailers can play a coordinating role to ensure a transparent supply chain in which the value produced is equally distributed among all participating subjects. International retailers are quickly responding to this change, promoting initiatives as a result of increasing public demand for more sustainability in economic activities and trade. Small Italian manufacturers in the food sector have responded to such changes by adapting to the requirements of retailers. As the study emphasized, those more involved in relationships with large retailers have reached a higher level of consciousness in CSR relevance and, above all, are more capable of managing CSR activities by adopting standards and certification systems. Those with a lighter weight of large retailers in sales (they are also smaller) revealed a delay in adopting more advanced criteria for CSR management.

The analysis has pointed to some areas of research that can be further developed. A limited diffusion of systematic and structured systems for CSR emerged among firms that had not developed significant relationships with large retailers. Since retailers' role is critical to stimulate a diffusion of CSR practices and culture among manufacturers, it is important to analyze these firms in more depth. Further research should deepen the motivations for retailers to develop CSR systems and to extend them to smaller suppliers in the supply chain, focusing on the expected advantages and disadvantages. Moreover, a comparative analysis should be conducted with the manufacturers of other EU countries to verify the similarities and differences, also considering the specific characteristics of the industrial structure of each country.

¹The panel was composed of 46% firms with overall turnover of less than 5 million euro, 18% with turnover between 5 and 10 million, 9% from 10 to 20 million, 10,1% from 20 to 40 million, 5,6% from 40 to 60 million, and 11,2% over 60 million. 87,6% of firms in the panel were exporters, among them, 71% had an export turnover of less than 5 million. 59,9% of the panel had less than 30 employees, 15,7% from 30 to 50 employees, 10,1% from 51 to 100, and 14,6% had over 100 employees.

Corporate Governance and Audit Function: An Indian Perspective

*Suveera Gill, gillsuveera@yahoo.com
Punjab University, India*

Abstract

A major part of the debate on corporate governance centers on the pivotal role played by auditors in ensuring financial propriety. If auditors' report plays a significant role in corporate governance mechanism, engaging independent statutory auditors would certainly strengthen accountability. The present paper is motivated by such a viewpoint, as it develops a model to explain audit qualifications for select listed Indian companies. It also explores the oversight role of audit committees in enhancing audit quality. The findings provide evidence that the occurrence of audit qualifications is associated with return on assets and audit fees. The type of audit firm and accounting committee diligence do not affect auditors' propensity to qualify their opinions. The paper provides practitioners and researchers valuable insight into the extent to which a qualification could be expected based on publicly available data. It concludes by proposing a case for reforms in realm of reporting and auditing procedures.

Introduction

Lately, the issues and concerns relating to audit as well as the role of external auditors as endorsers of company systems, procedures, controls and records has been called into question. The auditors' report plays a significant role in corporate governance mechanism as it minimizes information asymmetry risk by attesting to the reliability of a company's published financial information, thereby safeguarding the interests of investors and other stakeholders (Peel & Clatworthy, 2001). If auditors are unable to endorse a financial statement wholeheartedly, they must qualify their opinion, or state that they are unable to express an opinion, or express an adverse opinion. The audit committee, further, has a particularly important function in monitoring the quality of disclosures made by auditors independent of their audit clients (Turley & Zaman, 2004). They approve the accounting practices adopted by the company and monitor their reliability as well as compliance with the required regulation.

As a consequence of the financial crisis and ongoing concerns about quality of accounting information, the auditing profession has been at the center of the policy debate and focus of considerable academic research. Against this milieu of changing priorities and perceptions, understanding the role of auditors' opinion as it pertains to reporting efficacy is an important aspect within the larger context of governance for two reasons. First, the occurrence of audit qualifications in published corporate audit reports is directly related to the concept of audit quality (DeAngelo, 1981; Carcello, Hermanson, & McGrath, 1992; Dye, 1993). Secondly, corporate financial reporting and auditing has been under the spotlight of regulators as there has been an increasing demand for greater transparency and quality in corporate financial communications (Dopouch, Holthausen, & Leftwich, 1987; Bell & Tabor, 1991; Laitinen & Laitinen, 1998; Ireland, 2003).

Until very recently, studies in auditing and audit committees were almost exclusively associated with the western part of the globe. Yet, their role in transitional and emerging economies is possibly equally important (Healy & Palepu, 2001). Recent events in India too have put the spotlight on reporting and governance practices of the Indian companies. The paucity of knowledge about the role of auditors in specific and corporate governance in general for a country trying to achieve double digit economic growth is a cause of concern. The present paper attempts to discern the extent to which combinations of financial information with non-financial variables influence auditors' opinion on the company's financial statements. Through an analysis of selected companies, this paper attempts to shed light on the question of whether that audit report contributes significantly towards 'effective governance of modern corporations'. It aims to contribute to the existing literature in two ways. First, to the best of my knowledge, this question has not been empirically tested using both financial and non-financial measures in India. Second, the paper goes beyond merely documenting the reporting efficacy by presenting the nature of audit qualifications raised by statutory auditors. The findings of the study will hopefully provide practitioners and

researchers valuable insight into the extent to which a qualification could be expected based on publicly available data in the context of Indian business.

Literature Review

The literature found to be relevant to the present paper includes accounting and governance studies examining the auditors' opinion decision and demand for audit quality.

Auditors' Opinion Decision

A wealth of auditing and accounting literature tries to explain that both financial and non-financial factors affect the audit opinion decision. Dopouch, Holthausen, & Leftwich (1987) developed a probit model to prove that the most significant variables in predicting qualifications were the current year loss, industry rate of return, and change in the ratio of total liabilities to total assets. Keasey, Watson, & Wynarczyk (1988) showed that the likelihood that a company receives a qualified audit report increases with large audit firm, small number of directors, leverage, and lag between the financial year-end and audit report date. Krishnan & Krishnan (1996) considered audit opinion models by incorporating economic trade-offs that arise in the auditor's litigation risk, the extent of outsider ownership, the relative importance of the client in the auditor's portfolio of clients, and future growth as important factors in the audit opinion decision. In modeling the auditor's opinion decision for financially distressed companies, Mutchler, Hopwood, & McKeown (1997) concluded that qualitative variables involving good and bad news items had no incremental explanatory power relative to financial variables. Laitinen & Laitinen (1998) showed that the likelihood of receiving a qualified audit report is higher with low growth rate, low equity to total assets ratio, and small number of employees. In another study, Spathis et al. (2003) suggested that receivables to sales, net profit to total assets, sales to total assets and working capital to total assets are useful predictors of audit qualifications. Similarly, Caramanis & Spathis (2006) showed that the occurrence of audit qualifications was associated with only financial metrics such as operating margin to total assets and the current ratio.

Prior studies have also found that auditor's going-concern assessments are related to company's financial condition, company size, dividend payout, default status, audit firm choice, and audit fees (Arnold et al., 2001; Lenard et al., 2001; Reynolds & Francis, 2001; Ireland, 2003; Spathis, 2003). According to Casterella, Lewis, & Walker (2000) auditors are less likely to issue a modified opinion when the financial prospects of the company are ambiguous and when auditors are faced with incentives to delay or avoid issuing a modified opinion.

Audit Quality

Governance theory and empirical evidence suggests that there is a greater demand for audit quality when agency costs are high (Bar-Yosef & Livnat, 1984; DeFond, 1992). Some authors take the perspective that an auditor should evaluate the corporate governance structure of its clients and incorporate such evaluation in their audit planning and in the associated risk. The reasoning is that an inappropriate governance structure might be a risk factor for the auditor and even sometimes a reason for refusing a particular risky client (Cohen & Hanno, 2000; Cohen, Krishnamoorthy, & Wright, 2002; Bédard & Johnstone, 2004).

Extant research also provides evidence that stronger audit committees may demand a higher quality audit and be willing to ratify higher audit fees (Abbott et al., 2003, 2003a, 2003b; Carcello & Neal, 2003b; Raghunandan & Rama, 2003). Further, the audit committee independence, financial expertise, diligence, meeting frequency affected audit committee members' propensity to support the auditor's position (DeZoort, 1998; DeZoort & Salterio, 2001; Carcello & Neal, 2000, 2003a; Abbott et al., 2002; DeZoort, Hermanson, & Houston, 2003; Ng & Tan, 2003; Agrawal & Chadha, 2005; Carcello et al., 2006; Goodwin-Stewart & Kent, 2006; Bronson, Carcello, & Hollingsworth, 2009). Additional analyses reveal that independent and diligent audit committees were more likely to engage an industry-specialist auditor (Abbott, Park, & Parker, 2000; Beasley & Petroni, 2001). Through a survey of 300 finance directors and 307 audit engagement parties, Beattie, Fearnley, & Brandt (2000) revealed that audit

committees generally reduce the level of negotiation between auditors and finance directors, and in majority of cases the same leads to changes in financial statements.

There are some preliminary evidence on increasing importance of the auditor and audit committee independence in the governance of companies in India (Sarkar&Sarkar, 2010). The results of a survey of Indian listed companies show that formation of the audit committee is slow and their composition lacks independence (Al-Mudhaki& Joshi, 2004). Simon, Ramanan, &Dugar (1986) tested an audit fee model to establish that audit fee was responsive to auditee size, complexity, risk profile, and auditor size. A few studies have also compared audit fee models in India with Pakistan (Hossain& Taylor, 2000; Ahmed &Goyal, 2005) as well as Bangladesh (Hossain& Taylor, 2000) to indicate some consistency across markets in respect of generic variables identified as core determinants of the level of audit fees. In general, discerning underlying factors differentiating companies receiving audit qualifications from the ones that do not is of paramount importance. However, the lack of knowledge about how audit profession provides a check on the information aspects of the governance system constitutes a real problem. The results presented in this paper has addressed this gap in literature and extended understanding on two fronts- develops a model to explain audit qualifications for a select listed Indian companies as well as evaluates the role audit committees can play in enhancing audit quality.

Propositions

Extensive review of the extant literature has resulted in the formulation of two propositions.

P1. Corporate financial and non-financial information can be used to predict audit opinion.

P2. Audit quality can be enhanced through effective oversight function of the audit committee.

Research Design

Sample Selection and Data Sources

From the 100 companies comprising the BSE 100 Index¹ as of March 31, 2010 a sample was selected comprising 59 companies. Following common practice in previous literature, 17 companies from the financial sector were excluded from the sample. Another 13 companies were not included as they belonged to the public sector and their performance is influenced by a large number of social obligations which might have been difficult to justify. Data for another 10 companies were not used since their financial accounting years ended other than March 31, 2010. Finally, one company was not used for data availability problems. From the 59 companies in the sample, 29 have received a qualified and 30 a clean audit report. The term audit qualification refers to ‘qualified opinion’, ‘adverse opinion’, ‘disclaimer of opinion’ and ‘critical observations’ in the present study. Further, audit quality is defined as the probability that the auditor will both discover and report a breach in the client’s accounting system.

The data sources were the annual reports of the companies, corporate database (PROWESS) maintained by the Center for Monitoring the Indian Economy (CMIE), and the reports filed by companies with the BSE (<http://www.bseindia.com>) as part of the listing requirements.

Variable Selection and Description

The variables used in this study were derived through a review of prior literature.² From the review of the literature a set of 18 financial and non-financial variables were initially identified. The exploratory principal component analysis with varimax rotation was conducted to identify fewer yet meaningful variables. The analysis resulted in extraction of seven variables - four financial metrics, one audit committee attribute and two audit engagement measures - which provide meaningful and non-overlapping information.³

The financial soundness of a company is represented in its financial statement variables. Several researchers have used financial metrics to formulate audit opinion expectations.⁴ Aspects of corporate financial performance were measured through return on assets (ROA) defined as operating margin to total assets. Solvency of the company

has been assessed both for short-term (receivables to sales or RECTURN) and long-term (leverage or LEV). Leverage was calculated as long-term debt to total assets. Furthermore, liquidity (LIQ) has been measured as the ratio of current assets divided by current liabilities. The proxies for governance include two categories, each incorporating individual variable(s) depicting specific attributes pertaining to audit committee (audit committee diligence) and audit engagement (audit fees and audit firm type). Audit committee diligence (ACDIL) connotes the attendance of independent non-executive directors in audit committee meetings in the year. Audit fees (AFEES) consists of all fees necessary to perform the audit or review in accordance with the Auditing and Assurance Standards (AAS). Lastly, the audit firm type (AFIRMTYPE) is a dummy variable that equals one when auditors are the Big four audit firms i.e., Deloitte Haskins & Sells, Ernst & Young, KMPG, and PricewaterhouseCoopers.

Framework of Analysis

Multivariate analyses were used to test whether there is an association between predictor variables and the auditor opinion decision. First, logistic regression analysis was applied to test the ability of various combinations of the variables to correctly predict the audit opinion. Second, the OLS regression analysis was used to find whether there is a relationship between the predictor variables and the number of qualifications in audit reports. The probability of a qualified opinion conditioned on predictor variables using a logistic regression approach on the sample was estimated using the following model:

$$\text{Prob}(\text{QUALIF}_i) = b_0 + b_1\text{LIQ}_i + b_2\text{RECTURN}_i + b_3\text{LEV}_i + b_4\text{ROA}_i + b_5\text{ACDIL}_i + b_6\text{AFEES}_i + b_7\text{AFIRMTYPE}_i + e_i \quad (1)$$

Prob(QUALIF_{*i*}) takes on the value of 1 if company_{*i*} receives a qualified audit opinion, and zero otherwise. The coefficients b₀, b₁, b_{*j*} are the parameters to be estimated, and e_{*i*} is a disturbance term. The coefficients on dummy variable AFIRMTYPE_{*i*} were expected to be positive. For the coefficients on LIQ_{*i*}, ROA_{*i*}, and ACDIL_{*i*} and AFEES_{*i*} it is expected that they would be negative and as for RECTURN_{*i*} as well as LEV_{*i*} to be positive.

The OLS regression approach was used to explain the magnitude of the number of qualifications (TQUALIF_{*i*}) as a function of predictor variables. The average number of qualifications (TQUALIF_{*i*}) was 0.81 with minimum 0 and maximum 3. The linear model as shown below uses the outcome variable in the number of qualifications in an audit report (TQUALIF_{*i*}) and the predictor variables were the same as in logistic regression.

$$\text{TQUALIF}_i = b_0 + b_1\text{LIQ}_i + b_2\text{RECTURN}_i + b_3\text{LEV}_i + b_4\text{ROA}_i + b_5\text{ACDIL}_i + b_6\text{AFEES}_i + b_7\text{AFIRMTYPE}_i + e_i \quad (2)$$

Further, to gauge the financial reporting quality of reported accounts of companies, Auditors' Report on Financial Statements was examined. As per the provision, auditors are required in their report to answer any of the statutory affirmations in the negative or with a qualification.⁵ Auditors also need to give reasons for any qualification in their report.⁶ This gives an additional insight into the books of accounts of the sample companies. Further, to determine whether companies responded to audit qualifications, an analysis was made of the previous year (financial year ending March 31, 2009) auditors' report of the companies. To identify companies complying with the corporate governance norms as stipulated under Clause 49 of the Listing Agreement, the Certificate of Corporate Governance Compliance as issued by the statutory auditors of the company were also scanned for the financial year 2009-10.

Descriptive Statistics

Table 1, presents three panels of descriptive information for the sample companies. Panel A provides means, medians, standard deviations, and maximum and minimum values for the key variables. The average company had liquidity of 2.84 times. There were companies with zero to leverage as high as 99.72 percent. The average company had a receivables turnover of 0.32 times. In terms of performance, the mean return on assets was 15.73 percent with

a maximum value of 60.74 percent and a minimum value of -2.58 percent. In terms of audit committee functionality, the average attendance of the independent non-executive directors in the audit committee meetings was 84 percent. The external auditors were paid on an average Rs. 2.09 million as audit fees. Panel B shows the results of difference of means tests between companies with qualified and non-qualified report. Companies with qualified audit report represent 49.0 percent of the sample. The average shareholding, in general, by insiders (i.e., promoter and promoter group) was higher for companies with non-qualified *re* qualified opinion hitherto not significant. On the other hand, the institutional and non-institutional investors have marginally higher shareholding in companies that received auditors' qualifications. On an average, companies with qualified *vis-à-vis* non-qualified audit report were older yet smaller both in terms of assets and sales. Companies with qualified audit reports show lower liquidity, receivables turnover and profitability (net profit margin and ROA) though not significant. The qualified groups of companies have higher values for leverage and risk. As regards the audit committee characteristics it is evident, albeit insignificant, that the number of independent directors on the audit committee of qualified groups was higher, while the attendance per year lower. The *t*-tests show statistical differences at the 0.05 levels between two groups of companies on both audit and non-audit fees. Companies with auditors' qualification were paying substantial higher fees than ones without qualifications. Panel C provides a simple correlation matrix for the variables in the sample. There is a negative correlation between total qualifications and liquidity, receivables turnover, ROA and audit committee diligence, while a positive correlation exists with leverage and audit fees. The association between total qualifications and audit fees is significant at the 0.05 levels.

TABLE 1: DESCRIPTIVE DATA FOR COMPANIES WITH QUALIFIED AND NON-QUALIFIED AUDITORS' REPORT

<i>Panel A: Summary Statistics for the Full Sample(n = 59)</i>						
	Mean	Median	Std. Deviation	Maximum	Minimum	
Liquidity (times)	2.84	2.11	2.40	13.53	0.46

Generally, bigger audit firms (e.g., Big 8, Big 6, and Big 5) have been identified in the literature as higher quality auditors due to their technical expertise in detecting earnings management and further have shown a higher probability of reporting errors and/or irregularities once detected. Panel A and B of Table 2 show the number of client companies for both the Big four and non-Big four audit firms. Additionally, Panel C shows that 20 of the 35 companies audited with Big four audit firms received a qualified audit report ($\chi^2 = 2.198$, $p < 0.138$). The χ^2 statistics indicate that the type of the audit firms (Big four vs. Non-Big four) does not affect the association for a qualified audit report.

Results and Discussion

Factors influencing Auditors’ Opinion

In order to test for any interaction effects between the predictor variables, multivariate analyses were performed. The objective was to develop a model(s) using the metrics identified as predictor variables. As discussed earlier, two models were developed, one for logistic regression and one for linear regression. Table 3 reports the results for the logistic regression model. According to the results, the overall percent of correct classification is 80 percent. The relationship between the outcome and the predictor variables is significant ($\chi^2 = 14.535, df=7, p < 0.05$). The $R_L^2 = 29.1$ percent (pseudo R^2), indicates a medium strong relationship between outcome and the predictor variables. The results indicate that only two variables with significant coefficients were included in the model. The ROA has an increased probability of being classified with firms with a qualified report ($\beta = -11.195; p < 0.05$) and this ratio has a negative effect. This implies that firms with low ROA have an increased probability of being classified with firms with a qualified report. The AFEES has an increased probability of being classified with firms with a qualified report ($\beta = 0.731; p < 0.05$) and this ratio has a positive effect. It implies that there is a higher probability of firms with a high AFEES receiving a qualified audit report.

TABLE 3: LOGISTIC REGRESSION ANALYSIS OF QUALIFIED AND NON-QUALIFIED AUDIT REPORTS

Variable	β	SE	p
LIQ	0.090	0.145	0.509
RECTURN	-2.801	1.486	0.060
LEV	-0.316	1.3021	0.808
ROA	-11.195	5.714	0.048
ACDIL	-1.516	2.746	0.581
AFEES	0.731	0.337	0.030
AFIRMTYPE	-0.086	0.658	0.898
Constant	2.342	2.945	0.426
Model χ^2	14.535		0.042
Pseudo R^2 (percent)	29.1		
Classification accuracy (percent)	80.0		

The impact of financial metrics, audit committee attribute and audit engagement measures on the number of qualifications (TQUALIF) was tested using OLS regression analysis (Table 4). The model is significant, $F(7,51) = 2.227, p < 0.05$, and explains 23 percent of the variation in the number of qualifications (Adjusted $R^2 = 0.234$). The

two variables with significant coefficients are ROA and AFEES. Companies receiving higher numbers of qualifications tend to have lower ROA ($B = -3.294$, $p < 0.05$), and higher AFEES ($B = 0.345$, $p < 0.01$). The results suggest that the number of qualifications is dependent upon profitability and the amount of audit fees.

TABLE 4: OLS REGRESSION ANALYSIS OF TOTAL NUMBER OF QUALIFICATIONS

Variable	B	SEB	β	ρ
LIQ	0.010	0.055	0.024	0.860
RECTURN	-0.588	0.493	-0.186	0.238
LEV	0.220	0.469	0.068	0.641
ROA	-3.294	1.536	-0.348	0.037
ACDIL	-1.348	1.104	-0.153	0.227
AFEES	0.345	0.123	0.392	0.007
AFIRMTYPE	-0.098	0.275	-0.049	0.724
Constant	1.789	1.094		0.108
Adjusted R^2 (percent)	23.4			
F Statistics	2.227			0.047

Overall, results of both the logistic and OLS regression analysis clearly indicate that ROA and AFEES are the major factors distinguishing the two groups of companies. The evidence from the remaining variables is mixed and not significant. The results support the widely accepted conjecture that companies having declining earnings were more likely to receive an audit qualification than other companies (Dopouch, Holthausen, & Leftwich, 1987; Sundgren, 1998). However, the results refute the findings that no significant association exists between auditors' opinion and audit fees (Craswell, Stokes, & Laughton, 2002; De Fond, Raghunandan, & Dubramanyam, 2002; Caramanis & Spathis, 2006) but support the 'quality differential argument' to audit quality (Palmrose, 1986).

Reasons for Auditors' Qualification

An examination of the audit reports reveals that auditors seldom qualify or comment negatively on the accounts. There are only a few instances where without qualifying the auditor mentions sections of accounts where its view is in divergence with that of the company. It is customary for the qualifications to be made by using certain expressions such as 'subject to' or 'except that'. As evident from Table 5, an audit qualification may vary from using inappropriate accounting methods to inadequate disclosure and scope limitation. The analysis of the previous year (2008-2009) auditors' report revealed that same/similar qualifications appeared in 52 percent of the cases. It seems that past qualifications were as yet not resolved due to some reason(s). Such findings put a serious doubt on the efficacy of audit committees as a mechanism of internal governance. A strong audit committee should have stimulated improvements in financial reporting and strengthened the credibility of corporate reports. Thus, as documented by Cohen, Krishnamoorthy, & Wright (2002), the potential for audit committees to enhance the quality of the financial reporting process has still not been fully realized. Further, the Auditor's Certificate on Corporate Governance was qualified for four sample companies, three out of which had also received qualifications on financial statements implying poor governance practices as well.

TABLE 5: NATURE OF AUDITORS' OPINION ON FINANCIAL STATEMENTS

Nature of Audit Opinion	Number of Companies (%)
Non-compliance with Accounting Standards	
<i>AS-9 on Revenue Recognition</i>	2 (3.39)
<i>AS-22 on Accounting for Taxes on Income</i>	1 (1.69)
<i>AS-30 on Financial Instruments: Recognition and Measurement</i>	1 (1.69)
Inappropriate use of funds	7 (11.86)
Default in payment of loan/interest to debenture holders, banks and/or financial institutions	3 (5.08)
Directors paid remuneration in excess of the limits specified in the Companies Act, 1956	1 (1.69)

Interest on loans granted to companies covered in the register maintained under Section 301 of the Companies Act, 1956 overdue	4 (6.78)
Regularity of principal payment unascertainable due to the grant of interest-free loans to companies covered in the register maintained under Section 301 of the Companies Act, 1956	2 (3.39)
Inadequate internal control systems	1 (1.69)
Certain fixed assets records not updated	1 (1.69)
Adequacy of certain purchases in excess of Rs. 5 lakh not established	4 (6.78)
Credit for a claim on a contract taken while not accounting for liquidating damages	1 (1.69)
Amounts withheld by customers carried forward as recoverable in books	1 (1.69)
Non-provision of proportionate premium on redemption of Foreign Currency Convertible Bonds since considered as a contingent liability	1 (1.69)
Claim for benefit in respect of which no provision was made by transfer from the Special Reserve Account, as the tax relief was withdrawn with retrospective effect	1 (1.69)
No tax liability recognized in the reduction-cum-arrangement scheme between MCX-SX and its shareholders	1 (1.69)
Provision for diminution in investments due to continuing losses made by certain subsidiaries as well as joint ventures	1 (1.69)
Delay in depositing statutory dues with authorities ^a	8 (13.56)
Commit or an attempt to commit fraud/theft	8 (13.56)

Note: ^aIncluding provident fund, or employees' state insurance, sales-tax, wealth-tax, income-tax, customs duty, excise duty, cess and others.

Conclusions and Implications

A major part of the debate on corporate governance centers on the pivotal role played by auditors in ensuring financial propriety. If audit report contributes significantly towards effective governance of modern corporations, engaging independent statutory auditors would certainly strengthen accountability. The present paper is motivated by such a viewpoint, as it endeavors to unravel the underlying factors that differentiate companies with qualified *re* non-qualified opinion in the context of Indian business. It also explores the oversight role of audit committees in enhancing audit quality.

The findings provide evidence that the occurrence of audit qualifications is associated with return on assets and audit fees. The type of audit firm (Big four vs. non-Big four) and accounting committee diligence (governance proxy) do not affect auditors' propensity to qualify their opinions. An examination of the audit reports reveals that auditors seldom qualify the accounts reiterating the fact that audit committees' oversight role is about non-operational. Moreover, companies with corporate governance qualifications were also found deficient on financial reporting and disclosures.

Results of the present study should be interpreted with caution due to certain limitations. First, the sample constitutes the shares of top hundred companies being traded on the BSE with an acceptable track record. Second, the data has been collected from databases like Prowess. The validity of the results drawn primarily depends on the nature of the database. Further, the information relating to audit committee characteristics were as mentioned in the corporate governance reports which are a part of the annual reports. It was assumed that the companies are reporting fairly to the regulators and the stock exchanges. Finally, a longitudinal research design would have allowed for a more rigorous analysis. Notwithstanding these limitations, the study is timely and relevant given the renewed interest in the relationship between auditors and audit committees. The present study contributes to accounting and governance research by examining variables that can best differentiate cases of audit opinion. The proposed methodological framework could be of assistance to practitioners for assessing the likelihood of qualified audit reports for businesses in India.

The findings undoubtedly steer a case for reforms in the audit system and process in India. A pan-industry reporting and auditing procedures involving a series of action steps is thus advocated. First, the registration, empanelment as well as audit assignments for all listed companies should be handled by a systemic regulator. Second, independence of the statutory auditors could be ensured by appointing joint auditors, rotating the auditors

after a specific term, and also prohibition of certain non-audit assignments. Lastly, an integrated accounting and taxation administration platform would foster better oversight and enforcement. Correct accounting information endorsed by credible statutory auditors would certainly serve as a critical governance constraint limiting management's ability to manipulate accounts.

Whereas, the present paper focused exclusively on the reporting quality of selected sample companies, future research could extend the study over a longer time span and to a larger sample. Another prospective area for research could be of a qualitative kind that takes into account the auditor's skills and abilities, the social contract and the auditors/auditee contract. Finally, alternative methods for identification of audit opinion decision can be used, such as discriminate analysis, multicriteria analysis, and neural networks. These extensions may aid in identifying those criteria that can best discriminate cases of audit opinion

Endnotes

¹ BSE-100 was launched in January 03, 1989 and was previously known as the BSE National index. The base year for this index is 1983-84 with base index value fixed at 100 points. The index has 100 companies with varying weightages and balanced industry representation.

² See for e.g., DeAngelo (1981); Mutchler (1985, 1986); Keasey & Watson (1987); Keasey, Watson, & Wynarczyk (1988); Hopwood, McKeown, & Mutchler (1989); Koh & Killough (1990); Hirst (1994); Krishnan & Krishnan (1996); Laitinen & Laitinen (1998); Sundgren (1998); Kleinman & Anandarajan (1999); Casterella, Lewis, & Walker (2000); Reynolds & Francis (2001); Craswell, Stokes, & Laughton (2002); DeFond, Raghunandan, & Dubramanyam (2002); Ireland (2003); Spathis (2003); Spathis, Doumpos, & Zopounidis (2003); Caramanis & Spathis (2006).

- ³ All the eigen values were positive i.e., the correlation matrix was of full rank. Further, the predictor variables under investigation did not suffer from serious degree of multicollinearity.
- ⁴ See for e.g., Kida (1980); Dopouch, Holthausen, &Leftwich (1987); Krishnan & Krishnan (1996); Mutchler, Hopwood &McKeown(1997); Laitinen&Laitinen(1998); Sundgren(1998); Francis & Krishnan (1999); Reynolds & Francis (2001); Lennox (2000, 2005); Craswell, Stokes, & Laughton (2002); Spathis(2003); Spathis, Doumpos, &Zopounidis(2003); Caramanis&Spathis (2006).
- ⁵ According to Para 20 of the AAS 28, '*The Auditor's Report on Financial Statements*' issued by the Council of the Institute of Chartered Accountants of India (ICAI), the opinion paragraph of the auditors' report should clearly indicate the financial reporting framework used to prepare the financial statements and state the auditors' opinion as to whether the financial statements give a true and fair view in accordance with that financial reporting framework and, where appropriate, whether the financial statements comply with the statutory requirements.
- ⁶ Para 29 of AAS 28 cites that an 'unqualified opinion' should be expressed when the auditor concludes that the financial statements give a true and fair view. An auditors' report is considered to be modified when it includes (a) matters that do not affect the auditors' opinion and (b) matters that do affect the auditors' opinion including 'qualified opinion', 'disclaimer of opinion', as well as 'adverse opinion' as put down under Para 31.

The cooperatives between economic and social excellence

Elisa Chiaf, chiaf@eco.unibs.it
Davide Giacomini, giacomini@eco.unibs.it
Mario Mazzoleni, mazzoleni@eco.unibs.it
University of Brescia

Abstract

The cooperatives should face two aims: the respect of the cooperative principles of democracy, mutualityⁱ and solidarity and their pursuit in line with the economic effectiveness principle. In order to represent efficaciously the social and the economic impact of the cooperatives actions, the evaluations of the outcome produced should bear in mind both dimensions above-mentioned. The aim of the paper is to hypothesize a comprehensive evaluation model that allows to estimate the cooperative excellence (Mazzoleni, 1994).

The methodologies adopted are the case study (Yin, 1981, Eisenhardt, 1989) and the triangulation of the informations – collected by a questionnaire - within every single case (Jick, 1979). The emerging model will be made up of two parts representing the social and the economic excellence in turn divided in “internal” and “external” variables depending on the stakeholder considered. In the second part of the paper the model will be tested on four Italian cooperatives.

Introduction

In order to fully understand the link between social and economic excellence in the cooperatives the idea of excellence here considered must be remembered. Furthermore, it seems opportune to mention some business economics principles to better determine the position of the cooperative in the economic world and to highlight their distinguishing marks.

People pursue various aims; the orientation to these aims generates needs. People, in order to satisfy needs, develop economic activity of economic goods production and consumption (Airoldi et al., 2005). Therefore, the economic activity carried out by people to people, has as ultimate aim, the satisfaction of heterogeneous and changeable needs. To completely fulfill these needs a long-time perspective is fundamental.

The pursuance of that activity is realized within human societies, in particular inside institutes as family, companies, public administration and not for profit organizations (Airoldi et al., 2005). Human societies, juridically and substantially divided but referable to the whole human society, pursue the common good of their members. The “common good” is a good functionally for all, a product of the cooperation; it is the collective answer to singular and plural demands.

Every company presents features shared by all institutes, common features between the companies and “personal” features. Among these the strategic view has a prominent role. The strategic view is defined by Vittorio Coda as “the deep identity, the hidden and invisible part of the strategic paint, it stays behind the concrete choices” (Coda, 1995). The strategic view is the variable determining the strategic development and it heavily influences, frequently implicitly, the whole corporate behavior. Looking toward the strategic view and its centrality in the corporate life, it is possible to understand the importance of the cooperative values in a long-term perspective (durability).

One of the strategic view key points is the role assigned to the profit. The cooperative world puts people before profit but it does not forget that the profit creation is infeasible in a durability view. Hence, unlikely a cooperative will fall in the exaltation of the profit trap and in the consequent focusing on the short-term view. The motivations on the basis of the cooperative movement, the overlapping between shareholders and stakeholders and the legislation that oblige a limited profit distribution avoid the risk that profit is considered as the primary and only aim of the company.

In the co-operative organizations, the risk that Vittorio Coda defines as “declassing of the profit role” can appear more realistic, (Coda, 1995) therefore, in front of social primary importance such as mutual aims, reaching

suitable levels of profit can be considered residual. A company without an adequate remuneration for capital and work compromises its autonomy and the real possibility to pursue the institutional goals it was firmly founded on.

The lack of economic stability, interconnected by not synchronous to the institutional stability (Airoldi et al., 2005), inevitably leads to one of the following solutions:

- The organization ceases to exist;
- Another institute absorbs the unstable organization;
- One or more subjects settle the losses regularly and the original organization remains formally active, but the subject of the organization changes substantially and the initial autonomy is definitely compromised. (Airoldi et al., 2005).

In light of what is illustrated, it is clear that one of the unavoidable elements to accomplish institutional goals is adopting a long-term view, but it is just as clear that a company cannot solely direct itself to a simple profit maximization. This, cannot appear as an objective able to insure the survival of the company, (Mazzoleni, 1996). Although the institute has prevailing economic business, the company is the centre where the expectations of different subjects flow and it is so represented by an organism where three dimensions (economy, society, politics) overlap with each other indissolubly. (Mazzoleni, 1996).

Therefore, to evaluate a co-operative company, it is relevant to take into consideration the moral values context at the base, the basic strategic direction and the ability to last during changing times and by the presence of an ideal of excellence that is pervasive in the entire organization. (Mazzoleni, 1996).

It can be useful to illustrate the variables of economic, social and competitive order that bring to company success in order to highlight how reaching company goals requires a circular procedure and necessarily inclusive of the different expectations that flow into the company. Therefore, the social dimension should be considered as a strategic variable inescapable in the long-term.

Institutional goals cannot be taken back to only one model with simple generalization and they cannot even be hammered out to the exclusive maximization of profit but they have to translate into “*a sort of economic deferred utility since it generates conditions of legitimacy in action and it brings consensus of its activity to the community*” (Matacena, 1990).

The close connection between economic goals and social ones assumes even more importance in the co-operative businesses as it is part of the motivation of the foundation of the movement itself. Co-operatives are born from the wish of a group of people to jointly satisfy the common needs of every component of the same group: work, purchases or distribution of goods at the best condition in the market, etc. It is clear how the typical objectives of one cooperative, declined in the three so called pillars: mutuality, solidarity and participation are not antithetic to the production of long-term gains. The co-operative tries to obtain a profit on the market since as a company, it has to pursue an objective of economic self-sufficiency (the ability to reach a financial income and monetary stability) (Mazzoleni, 1996).

The interweaving and overlapping of elements that compose the economic situation of the co-operative, just reinforce the concept of unitary tendency of the economic situation defined by Carlo Masini as *the whole of individuals for the interest of which the institute exists and is governed: these individuals, who are the holders of the economic and institutional interests, are part of the economic organisations* (Mazzoleni, 1996). The unitary result of the company, in its complex can satisfy interests of different people; consequently even the economic subject is bound to be unitary. *The unity and the uniqueness of the economic subject allow the company to carry out general management unity and general command unity*, thus allowing the prerogatives of an economic government.

The coincidence between capital givers and workers, that characterizes production co-operatives and work, reinforces the unity of the economic organization and poses the base for profit pursuit as a long-lasting element not conditioned by the typical short-term investor purpose. The same reasoning can be made for other types of mutualistic co-operatives taken in consideration.

The great strength that elapses between economic, social and environmental dimension has become object of study mostly starting from the end of the nineties when the theory of Corporal Social Responsibility (CSR) was being affirmed. Many companies started recognizing the value that was being created pursuing economic and social objectives at the same time (Mazzoleni, 2005)ⁱⁱ.

At the light of what is written, we can clearly see some indissoluble but not exclusive topics coming that tie the co-operative system; effectiveness, efficiency, long-term orientation and corporal social responsibilityⁱⁱⁱ. The moral values context at the base of the cooperative system imposes a long-term direction, there is, only one option for the completed satisfaction of the requirements brought by the members. It naturally directs the company to look for a continuous dialogue with its own stakeholder, first of all the partners who can be workers, clients and suppliers at the same time.

Therefore, this research wants to evaluate if and how cooperative of different sectors can combine economic performance reaching excellent results in a long-term perspective. Even the concept of excellence, just like the concept of CSR, cannot be ascribable to just one widely shared definition. It is therefore necessary to clarify which will be the definition used as a point of reference. A company can consider itself to be excellent when it pursues two orders of objectives at the same time: economic and social (Mazzoleni, 2005). As already mentioned, the concept where the social dimension is “one of survival” is a shared opinion. It is clear how the present idea of excellence has to necessarily be characterised as a bi-dimensional concept. (Mazzoleni, 2005). Using other definitions of excellence, more directed on the topic of economic performance, (Stadler, 2007) does not appear suitable to supply a holistic evaluation of the cooperative phenomenon.

With specific regards to the cooperative system, it is worthwhile separating the concept of social excellence into three “pillars” that summarise the main cooperatives sanctioned by ICA^{iv} in 1995: participation, mutuality and solidarity. These three characteristics should be recognizable in every cooperative founded on management democracy, on the limitations of objective gain, on the satisfaction of member needs and on the extension of the impact to subjects not part of social companies. A “good” co-operative needs to be able to combine such management rules with the permanence in the market and with financial and management autonomy.

At this point, it is necessary to investigate further a joint agreement among the “pillars” of the cooperation and the elements that determine the importance. Only through a clear representation of institutional references that characterize strategic orientations and the way the cooperative companies operate, is it possible to understand the base on which research, for the inclination for excellence, can lean on, in these types of businesses.

We can say that the DNA of the cooperation comes directly from the principles whereby these companies abide to, in order to be defined co-operatives. The guiding lines to direct how business works, come directly, even if mediated in time, from principle statements established by Rochdale’s “equitable pioneers” (Mazzoleni, 1996; Desroche, 1979).

These principles are updated by International Co-operative Alliance (ICA) and today they define the behaviour laws and the criteria for all the co-operative organizations.

There are seven reference principles which approximately describe the characteristics of every co-operative, as follows:

- voluntary and open membership;
- democratic members' control;
- members' economic participation;
- autonomy and independence;
- education, training and information;
- co-operation among co-operatives;
- concern for community.

In this paper we will not evaluate every single principle in-depth, however, it is useful to highlight how the references which the cooperation must adhere to, if interpreted at system level, appear to be as orientations that can influence management directly (limited interest on capital, residue distribution) as well as operative procedures with evident outcomes on how the co-operative organizations work. This means that the co-operative principles direct the companies that institutionally adhere to the co-operative movement by bringing them to move and giving them natural importance to particular interests such as collective ones and adapting management, organizational and communication systems etc. able to “democratically” involve their own members and generating collaboration among companies with the same institutional characteristics.

The “pillars” are the direct result of the principles.

- Democracy, carried out through free compliance and member economic and decision-making participation;
- Mutuality which offers members economic and extra-economic conditions useful to satisfy needs;

- Solidarity that is revealed through participation and initiatives directed toward the common good and the reference territory and even outside of the direct reference context.

The co-operative principles justly find citizenship with reference to the Stakeholder theory (Freeman, 1984) when the need of the co-operative company to satisfy the interest of vast categories is highlighted.

This is firstly true for the members that are on the same level in virtue of the appearance of the business and without any differences of rights tied to conditions of proprietary nature. At the same time, the reminder of solidarity found in the co-operative principles open the way to behaviour that tend to satisfy social instances, and even if not explicitly, ecological or environmental ones broadly speaking.

The strategic address that brought the co-operative system to cover an important place in the supply of products and services comes from a declared will on the part of these companies and of the entire co-operative movement to take on an active role in the economic social system.

The cooperative movement has confirmed its will to be trained by businesses that satisfy needs not by the normal procedures of supply managed by the market or according to departments institutionally delegated to the public administration.

The “social” mission that the cooperative system has ended up asserting and protecting is wanting the companies to adhere to this institutional system and to affirm the principle of leadership of the co-operative system which puts at the centre the needs of the people and tries to satisfy them through “alternative” ways, different from the standard classical economic models.

According to this interpretation key, it seems evident that for co-operative organizations the aims to reach are meant to explicitly satisfy objectives both of economic and social nature, defining profit as a durability point and placing attention to the interests referable to all stakeholders. By trying to connect the “pillars” of cooperation with those classically referable to the companies, we can highlight those that can be defined as excellence factors as reference, for cooperative companies, that see the coexistence of economic and social drives. This leads us to define the elements useful to create a “cooperative excellence matrix”.

The matrix of co-operative excellence can be represented to identify the elements that constitute the base for the excellence economic dimension, that, in synthesis, can be defined by highlighting the parameters able to synthetically picture the degree of economic-financial performance obtained by the co-operative.

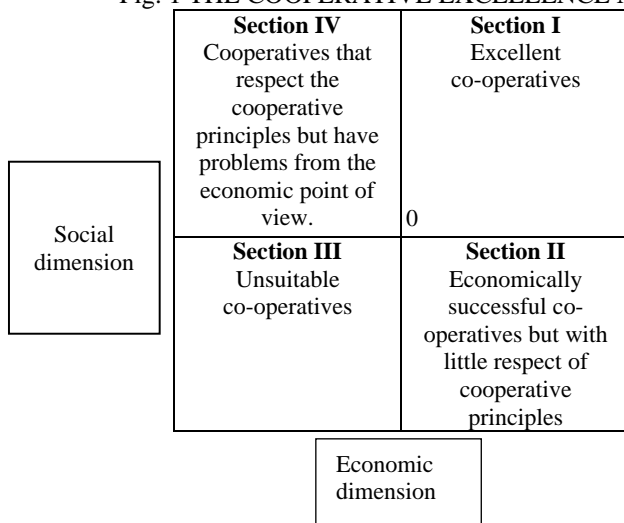

These indicators are referred to the ratios of profitability, solidity, liquidity and development whose aim is to clarify the ability of the company to reach goals on the economic and financial front. The possibility to express efficient evaluations through these indexes has to go through the ability to compare results obtained with other companies presenting the same institutional form and, later, with companies operating in the same contexts and sectors. In the case of co-operative organizations, the consideration of the analysis and comparison phase comes from the need to proceed with reference to the sectors belonging to the investigated companies, as well as with respect to the effects that the institutional form determines on the analysed indexes.

The construction of the excellence matrix then goes through the analysis of the “social” performance of the business - that is - what we can define as the social dimension of excellence. The reference parameters to create indicators suitable to represent this aspect in the life of the cooperative go back to the “pillars” above defined.

This way the social dimension is investigated through indexes able to explain the ability of the company to offer conditions of life, members' personal satisfaction, to begin to realize interventions able to satisfy the needs and demands of the local community and the environment or in general directed to satisfying the collective needs (of the community without direct reference to ones territory). Finally, the social dimension can be investigated through the ability to clarify how member involvement and participation takes place in the life of the cooperative, of the members, of the workers. It means defining political strategies, operative choices, setting objectives and research through which the company can aim to pursue its own results.

The so-defined matrix puts the single co-operatives in sections and can follow their evolution in time. In detail, and synthetically, it is possible to see the typical situations where to position co-operatives with reference to the figure below where the first section shows in ordinate the ability of the co-operative organization to move according to the movement leading principles, an in abscissa the levels of management performance obtained.

Fig. 1 THE COOPERATIVE EXCELLENCE MATRIX

The excellence section is the first where you can find companies showing a high inclination toward respecting co-operative norms in presence of very positive economic-financial indicators. (this, of course happens by keeping in mind what was said above, concerning the different assessments to adopt on the indicators with reference to the industry where the co-operatives operate). At the extreme opposite – III Sector - we have the companies that can be associated to a non-coherent behavior with regards to what is required by the co-operative system added to the inability to reach adequate management results.

In the other two sections, the prevalence of the behavior can “reward” the adhesion to the pillars of the cooperation without associating sufficient economic-financial performance, or, vice versa, the achievement of good management results accompanied by the inability (or scarce will) to stay within the guiding lines traced by the international co-operative alliance.

Placing the co-operative organizations within the four sections allows to highlight where the single companies required more investments between the social and the economic ones, and, if studied in time, they can highlight the effects and the outcomes that strategic, management and economic interventions, etc. have determined, by varying the positioning of the different co-operative organizations.

The representation of the results achieved and their variability in time highlights the effect that is determined for the cooperative following the different choices tied to the direct protection of the co-operative rules, but mostly it shows where the company needs to insure its possibility to last in time autonomously and safeguarding the company vocation of economy.

It turns out to be fundamental that these considerations should be accompanied by careful analysis not only qualitatively but mostly in relationship to the influences applied by the department where the co-operatives operate; in relation to the company mission, besides the normal limitations/opportunities that need to be highlighted with reference to the markets, the economic and social environment of reference.

Methodology

The methodology adopted in the development of this paper is the analysis of case studies belonging to different co-operative sectors. Often, the case study methodology is considered a younger brother in the family of research methods relative to social sciences (Miles, 1979), however, different authors, that support the opposite, consider case studies as a totally reliable method in the field of all social sciences, therefore including business economics.

An in-depth examination through the case study is the most appropriate choice *when the object of investigation are interrogatives such as “how” and “when”, when researchers have little control on investigative elements and when the phenomenon, object of investigation is strictly interrelated with some contexts of real life (Yin, 2002).*

In this work the focus is directly correlated to “whether” the cooperatives are able to reach excellence at the same time in both the economic and social field and therefore the methodology of case study particularly appears to be suitable. The sample analyzed is random, in order not to previously influence the analysis results. The only discriminating factor is belonging to different co-operative sectors.

The analysis will benefit from the use of quantitative and qualitative data, and the combination of the results of these two types of data typologies. In effect it seems to be the most suitable one to supply a detailed picture of the realities taken under examination and it does not conflict in any way with the methodology of the case study as established by Yin (1981).

As far as the analysis of the businesses singled out as heterogeneous both at the industry level and dimensional, the instrument used was a questionnaire that requires both qualitative and quantitative information to be filled out.

Once the data is collected, some re-elaboration has been carried out finalized for the evaluation of the two dimensions, object of the present study: effectiveness-efficiency and sociality. The score assigned to the economic dimension was extracted from the budget data presented and relative mostly to the last three year period; the quantification inherent to the social dimensions comes from the combination of data gathered relatively to the ones defined as “pillars of cooperation”: democracy, mutuality and solidarity. As foreseen by the illustrated matrix, the social and economic dimensions have the same weight and, within the sociality, democracy, mutuality and solidarity, they contribute respectively by a third.

As far as the economic dimension is concerned, the total score is given by five elements and equally weighted:

- capitalization rate (three year period 2007-2009);
- difference between Production Value and Production Costs (three-year period 2007-2009);
- social capital (ten year period 2000-2009);
- reserves (ten year period 2000-2009);
- earnings (ten year period 2000-2009).

The score relative to participation is composed by evaluations inherent to the participation and to the quantitative and qualitative characteristics of the members' group. Most of the weight was attributed to the quantitative items relative to the number of members and to the presence in the meetings, both evaluated in a three-year perspective.

Other points considered have been the presence of women and citizens migrating in the social companies and in the board of directors and discretionary evaluation on the part of the researchers, of the training activities in order to improve the assessing and decision-making abilities.

Mutuality, making up one third of the score relative to the social dimension, is evaluated by considering eight items. Firstly the distribution of the returns in the last three fiscal years (2007, 2008, 2009) is evaluated positively and it demonstrated at a quantitative monetary level which are the advantages for the members of the cooperative. Such a parameter is attributed a value equal to half of all the score relative to mutuality; the other seven points analysed are the benefits different from the returns and weight about 7.40% each.

The last variable composing the social dimension, is solidarity: in this case the score is attributed to equal to 12.5% for every item with the exception of the percentage relative to the donations toward the community that has a total weight equal to 37.5% and it is evaluated on a three-month basis. As a significant threshold of donations, 0.45% of the donations on the gains was adopted, that is, the average value of the donations of the private companies as registered by the Observatory of Private Donations in 2005.

Result analysis^v

Caseificio Alfa – Farmers cooperative^{vi}

The co-operative was founded in 1978 in the province of Piacenza to guarantee the process of milk transformation supplied by the farmers members. The co-operative strong point is the “Grana Padano cheese” produced from transformation of the milk provided by the 24 members of the Piacenza area.

The co-operative is constantly growing. In 1979, the year of the official beginning, 20 thousand quintals of milk were being made and by the end of the year 2000 that amount reached to 124 thousand quintals. High attention is placed on quality, since “Grana Padano cheese” is a certified product and has to respond to certain requirements that guarantee quality, goodness and safety. There are ten employees and workers in the cooperative in all. Presently the main activity is making “Grana Padano cheese”, but the organization is taking into consideration the hypothesis to get organized with other co-operatives to reach the great distribution.

As for the Alfa cooperative, there are good results from the economic point of view, considering the difficulty to operate in the dairy and cheese sector, while from the point of view of sociality; it is opportune to carry out some evaluations. About 90% of the business farming members participate to the assemblies during the year. However, the co-operative does not offer other initiatives to increase or support participation, nor does it evaluate the degree or level of participation. The members however, are “external” subjects to the co-operative (mostly if we compare it to a co-operative of Production and Work). There is no business training or co-operative courses offered. From the self-help point of view, the dairy does not distribute rebates, nor does it offer particular benefits to the members. From the external solidarity point of view, the cooperative makes donations and it sponsors other organizations, and besides this, very little is done from the point of view of collaboration with other cooperatives, training and information.

Alfa is positioned in Section II, registering an economic result of 62,2 point and a negative social result of -62,81 point.

Beta – Cooperative of Production and Work

The Beta co-operative, operating in the province of Brescia, has a long tradition in the field of machinery making. For years it has been the reference make in the sector of farming towing machines, modifying its production in the past 15 years towards compactors and recycling containers. The birth of the cooperative goes back to the ‘80s when the former private company was taken over by the same employees following a crisis of two year strikes and a strong involvement on the part of the territory.

This story, the important role played by the founding members, by their initial participation of the community to the life of the company, made it possible for the co-operative to take root in the territory and stimulate active participation among members.

Presently, the members' group of the co-operative is composed of 36 people. From the economic point of view, in spite of the turnover and the production value, we have registered slight increases in the four year period (+0,81% e +6,41%), the operating income decreased slightly (- 592,76%), and this is due mainly to the market crisis that reflects an increase of costs not equivalent to an increase of sales. In spite of this, thanks to the funds put aside that took place in the preceding years and to the basic philosophy that guides the company, the co-operative managed to avoid laying off its employees guaranteeing them a work place.

From the point of view of the respect of the co-operative principles, Beta is particularly careful to the growth of its own members, and offers a range of training and information courses well accepted by the members' group. There is a high number of meetings per year (4/5), way above the level required by the norms. The mutuality is guaranteed mostly by offering a safe work environment; the only criticisms can be made for the fact that this is also addressed to the non-members, making it hard to notice the real health care benefits. The principle of solidarity can be interpreted as a “collaboration among co-operatives” since Beta has chosen co-operative financial partners therefore supporting the system.

In the matrix, the co-operative can be positioned in Section I, with a good sociality (+26,71 points) and with a scarce cheapness. (+2,2 points). Its position is very low from the economic point of view, even if positive, it has shown a negative trend in the past few years.

Gamma – Cooperative Bank (Banca di Credito Cooperativo – BCC)

The Banca di Credito Cooperativo Gamma was founded 115 years ago and operates in the province of Brescia. It is the result of many mergers that starting from 1970. The Cooperative Credit Banks – originally called Rural Credit Bank – were founded between the end of 1800 and the beginning of 1900 with the aim to allow little loans among the rural population, in particular farmers and artisans to gain access to credit. This was inspired by the Church. After about a century they still have their distinctive identity of cooperative and local banks. Presently, the BCC Gamma operates with 30 branches and counts over 7.000 members in its social company.

As far as research is concerned, BCC had a downturn in the past four year period with a decreasing capitalization and profit rate. Nevertheless, the social capital, the number of members and the reserves are increasing constantly. The economic situation is strongly influenced by the crisis that hit the entire market, the companies and savers. From the social point of view, BCC guarantees great results from the self help point of view as well as solidarity, offering profitable conditions for its own members and significant participation in its territory. The topic of participation is a bit more critical, the average participation to the assemblies is quite low. BCC falls into Section I, with a effectiveness and efficiency score of (+60) and sociality (+47,4) positive.

Delta – Consumer cooperative

Delta was founded in 1973 with the objective to supply oil products to farming companies and to all other consumers for their business, in an area comprising 4 provinces: Brescia, Mantova, Cremona, Bergamo and Lodi. During the years, the cooperative passed from a simple group made up of farmers to a company counting 2.200 members in the entire region. Besides its member farming companies, it supplies industries and haulers, and it has the objective to safeguard consumers of oil products. Its commitment guarantees quantity and quality of fuels, assuring continuous supply protecting from speculation even in periods of product crisis and shortage, economic savings coming from competitive prices and profits to members. The cooperative guarantees technical assistance, supplied by experts, to optimize the use of fuels and lubricants.

From the economic point of view, the cooperative registers excellent results, guaranteeing a positive trend in years. From the sociality point of view, the cooperative has good results in terms of mutuality (distribution of profits and conditions that are really advantageous on the market for the members). It operates on the territory as market price controller and has some collaborations with non-profit companies, while the participation of the members is medium-low. In the matrix, Delta cooperative falls in Table I, with an economic result of 68,87 points and a social result of di 31,13points.

Below is the matrix with the positioning of the four case study analyzed.

Fig. 2: CASE STUDIES POSITION IN THE COOPERATIVE EXCELLENCE MATRIX

The best cooperative positioning is of Delta and Gamma, where the consumer cooperative excels particularly as far as economic results and BCC for the social results. The Work&Production cooperative, Beta cooperative, even if under Section I risks to go to Section IV with those who respect the cooperative principles but have economic difficulties. Alfa, the farm cooperative, in spite of good economic results, should apply some opportune strategies to improve sociality and respect for cooperative principles.

Conclusions and future developments

Evaluation of results is one of the most relevant points faced by business economics. When analyzing value on types of businesses that combine economic and social requirements, the topic becomes even more complex to treat and develop empirically. With the present study the researchers have presented an evaluation instrument usable for different types of cooperatives that combine their business with being company with moral issues typical of the cooperative system. This first-time model, subject to future improvements, has demonstrated a high level of applicability. It is worthwhile pointing out that the paper would like to demonstrate and try this instrument, and having chosen four cooperative cases completely different as far as their activity, market, dimensions and history. There was no specific comparative aim in reading the results and the matrix.

The positioning of each company, in addition, can be partially motivated according to the typology considered: it is almost natural to register a higher participation in Work & Production cooperative where the members are workers who live the business daily; with respect to co-operative farms or consumption cooperatives where the members automatically carry out their business and interact with the cooperative more for instrumental aims. The use of the matrix can be very useful to compare one's own positioning in time or with respect to similar companies as far as business and dimensions. Finally, the matrix itself has to be functional to consistent strategies, that allow the cooperative to evaluate actions of repositioning in the matrix's table to reach Section I, represented by economic and social excellence.

END NOTES

ⁱ In the paper the word “mutuality” refers to the specific feature of co-operative firms that operate in order to satisfy the needs of their members.

ⁱⁱ CSR, according to the following text “Promoting a European framework for Corporate Social Responsibility” Green Paper presented by European Commission), is “*going beyond compliance and investing “more ” into human capital, the environment and the relations with stakeholders*”.

ⁱⁱⁱ Not all literature agrees with that it is a competitive benefit to identify innovation and continuous search as basic elements to create a company that is able to last autonomously in time. For example see Stadler, C., Four Principles of Enduring Success, *Harvard Business Review*, July-August 2007. The contribution of the four key principles of long-lasting success are identified thusly: exploiting instead of exploring; diversifying the activity; learn from mistakes; careful attitude toward change.

The cooperatives between economic and social excellence

Corporate governance structure and the impact on the generation of competences in human resource management and financial performance

*Jorge Pelayo-Maciel, jorge.pelayo@acedemico.udg.mx
University of Guadalajara, Mexico*

Abstract

In the present paper we study the impact of corporate governance structure in human resource management and financial performance in the Colombian context. For this purpose, it will analyze the concept of corporative governance. Later, we will be discussed two streams that study both the structure of corporate governance as the behavior of managers, the agency theory and stewardship theory.

We find that the structure of corporate governance and distinctive capabilities of human resource are positively related to company performance, but this not explained the attitude steward of the CEO and collaboration systems.

1. Introduction

In the present paper is a first step of a comparative study that includes Mexico and Colombia. In this first approach addresses the issue of corporate governance structure and its impact on human resource management and financial performance in Colombia, which starts playing the theme of the corporate governance in Colombia, and then study the theories that have studied the corporate governance; the agency theory and stewardship theory and then analyze the research that has been done on these theories and their relationship with the variables already mentioned above. For after studying data from a survey of 40 Colombian companies that are listed as the 5.000 most important companies of the country by the *Revista Dinero* in 2008.

1.1. Colombian Context

The corporate governance in Colombia is based on analyzing the codes of conduct established in this country and being supported by the assumption that the corporate governance activities are inherent in financial reporting to allow society, the state, and shareholders to ensure their confidence in the management of companies (Cano, 2002).

As for the structure of corporate governance in the Latinamerican context in wish predominate the family business and therefore have different governance systems of the them used in Anglo Saxon countries, for example, the separation of ownership and control by the American companies will not occur in our context, given the high influence of shareholders on the board of directors and the president (Cano, 2002). The reasons for this concentration of ownership may be because the external monitoring institutions aimed at monitoring the agency are just beginning to be established (Khanna and Palepu, 1999). Another reason for what companies' concentrate ownership is for reason the culture of a society, that is, the set of shared beliefs that determine the behavior of individuals (Smircich, 1983). These cultural elements are socially created and therefore we can not be assumed that the structure of corporate governance is entirely a product of rationality and the explicit design of the individual. For Hernandez (2005), resistance to sell or transfer ownership beyond the family is deeply accepted Colombian business

culture. According to *Revista Dinero* (1999, cited by Hernandez: 146) in 1999 nearly 80% of large companies were family businesses that had been adjusted to the new modern management environment

2. Theoretical Framework

This section will discuss the theories that underpin this research, first discussed the concept of corporate governance, understood as a system by which business corporations are directed and controlled through the distribution of rights and responsibilities different participants in the corporation such as the board of directors, managers, shareholders and stakeholders. Later the two streams will be discussed studying both the structure of corporate governance as the behavior of managers, the agency theory and stewardship theory. In the first study of agency problems that arise when the director of the company has superior information and acts as a selfish trader can exploit the resources of the company for its own benefit, which would otherwise be the owner (principal) of the company who would. Agency costs can be low, if there is a close alignment between the interests or identity of the owners and directors. Stewardship theory is another perspective, which shows the advantages and disadvantages of the form of control of the company. This theory proposes that leaders and business executives aspire to high goals in their jobs given by high levels of self-motivation, responsibility and achievement, as well as protecting the organization through a collectivist behavior. Under this theory, managers are not simply selfish economic agents, act selflessly for the benefit of the organization and stakeholders (Miller, Le Breton - Miller, 2006).

2.1. Concept of Corporate Governance

The Organization for Economic Cooperation and Development defines corporate governance as (OECD 1999, cited in Clarke, 2004): The system by which business corporations are directed and controlled. The corporate governance structure specifies the distribution of rights and responsibilities among different participants in the corporation, as the board of directors, managers, shareholders and other stakeholders, explaining the rules and procedures for corporate decision making, and provide the structure and foundation of the establishment of objectives, the means to achieve and ways to monitor their implementation.

One of the key concepts of corporate governance is of the stakeholders which refers to the study of all stakeholders, whether internal or external, that are positively or negatively affected by the operations of the company, from a human point of view, ethical or social, without losing sight of the goal of maximizing the benefits to the organization.

For Freeman (1984) stakeholders are individuals or groups who can affect or be affected by the purposes and business success, however, several scholars have suggested that this definition is too broad, because the final analysis all social players are directly or indirectly affected by the actions of the company. What has given rise to different classifications of stakeholders, has suggested that there are primary and secondary, according to the degree of impact on the organization in terms of achieving its mission and objectives of the company (Clarkson, 1995, cited by Mitchell et al., 1997). Others have suggested that the stakeholders are all parts that are positively or negatively affected by the operations of the company those involve risks and therefore gain or lose by the results of corporate activities (The Clarkson Centre for Business Ethics School Joseph Rotman Management, University of Toronto, 1999, in Principles of Stakeholder Management, 2002).

For Mitchell et. al. (1997), are classified as voluntary or involuntary the first are those with a degree of risk, whether they have invested large sums of money, personnel, technology or other resources in the enterprise. The second are those who are interested in the business because their actions affect them, although it had no intention of doing so.

The relationship between the company and internal stakeholders (employees, managers and owners) is defined by formal and informal rules developed through history. While shareholders may fund managers, they rely on employees to create strategies. External stakeholders are equally important and are related to: consumers, suppliers, competitors and special interest groups are also considered for formal and informal rules. Finally, local

governments and communities together the formal and informal rules that businesses have to operate (Freeman, 1994; Post et al., 2003, cited by Clarke, 2004).

2.2. Agency Theory

The agency theory says that ownership in large companies is diversified across multiple shareholders who transfer authority in making decisions to CEO in order to achieve optimum business performance. The fact that shareholders have a small equity stake results in a difficult access to information on actions taken by its managers (Berle and Means, 1932, cited by Davis et. al., 1997, Jensen and Meckling, 1976), control is costly and information is costly to obtain, especially for a person.

For this reason there is the possibility that CEOs pursue their own goals even to the detriment of the interests of shareholders. The separation of ownership and control is the main problem to avoid possible opportunistic behavior of CEOs that could affect security on the investment return of shareholders (Jensen and Meckling, 1976). Williamson (1985) defines opportunism as an effort to make profits through the dishonesty in transactions. This can take two forms: the strategic concealment of information (which gives the agent a benefit) and the inability to obtain a commitment of responsible behavior during execution.

The agency problem arises when the welfare of a person depends on another: the agent is the person who acts and the principal is the person that affects the action. One major problem for investors is that CEOs can pursue their own goals, even at the expense of obtaining lower profits for owners. In any negotiation between two parties establishing a relationship of agent and principal, which is characterized by the existence of a hierarchical relationship, which can be established through a formal or informal. One party has possession of an asset or senior administrative role, the principal, the other party manages the assets of a company, which is called "agent" The key feature of this relationship is the asymmetry of information, the agent has more information about the daily operation of the organization and the primary has only generic information, thus incurring high costs to monitor the actions of the agent (Jensen and Meckling, 1976).

This is given by the absence of contracts made in full, therefore, identifies some actions that the principal can do to narrow differences to their interests, which are based on systems and incentive to incur costs monitoring to limit the aberrant activities opportunistic agent.

In particular, this model promotes the use of independent power structure is, that does not match one person in the position of CEO and chairman of the board of directors of a company, in order to avoid opportunistic behavior of managers (Jensen and Meckling, 1976).

Moreover, the agency problem has been widely criticized, as it faces a problem between managers and owners only and the shareholders are not the only ones affected by the activities of the company but also find all the stakeholders (groups interest), which are also affected by the organization, therefore arise stewardship theories such as described below.

2.3. Stewardship Theory

Stewardship theory is a model opposite to that established by the agency theory; the model holds that the interests of CEOs are aligned with the interests of the principal, in contrast to the selfish motivations that supports the agency theory. According to this theory, the CEOs seek to balance the interests of shareholders and interest groups, stakeholders, and therefore try to make decisions in benefit all of them.

Davis, et. al. (1997), determine the characteristics of behavior that should have the perspective managers stewards who are motivated to act proactively and to be collectivism, which has a high value compared to an individualistic and selfish actions. Due to the high need for growth and achievement, psychological motivations, the manager appreciates the value of collaboration using their initiative to promote success, establishing bonds of trust with them. This has a positive attitude towards group harmony by avoiding conflict or confrontation.

For all the above we can say that with a stewardship structure, internal stakeholders such as managers and the employees develop a high identification with the company while generating value and commitment to the

organization, and both the manager and investors (shareholders) have a motivation to self-realization, that thanks to general manager looking for the involvement of all members of the organization of your employees, managers and investors seek to generate investment and ensuring long-term yields at the cost of short yields term.

3. Literature Review

In this section we develop the assumptions underlying each hypothesis, will start with stating that the separation of ownership and control results in better performance, then analyze how the attitude of the CEO (steward type) can build capacity distinctive human resource management and employee collaboration.

3.1 The structure of Corporate Governance, Stewardship and Company Performance

As already mentioned, the agency theory assumes that the separation of owners (principal) and CEOs (agents) increases the attitude of the latter to take actions that do not maximize shareholder wealth (Jensen and Meckling, 1976). However, to Fama and Jensen (1983), the separation of ownership and control within the firm reduces agency costs and thus leads to high performance, which implies that the chairman of the board is different from the CEO.

In stewardship theory, The CEOs are inherently trustworthy and not prone to divert company resources (Donaldson and Davis, 1991). It is believed that CEOs are good stewards for the primary and will be effective in setting strategies to increase shareholder wealth. The duality between ownership and control encourages flexibility in the workplace and reduce conflicts between the board and management, which lead to high levels of returns to shareholders (Davis, 1997).

Both theories of agency and stewardship reflect two types of leadership in any organization. According to Said, Yaacob, and Ismail Awang (2009), one of the strongest debates about corporate governance is the question of whether the general manager of the company should also be the chairman of the board of directors. The general manager who heads the organization's decisions while the president of the board is responsible for working for the council, ensuring that all essential matters on the agenda, the council monitor and supervise the rectification of strategic initiatives director of the company and oversee the hiring, firing, evaluation and compensation of the CEO of the company.

Therefore there must be evidence that the duality of corporate governance brings better returns for the firm (Finkelstein and D'Aveni, 1994; Martinez, 2004), but there is also research that shows otherwise (Daily and Dalton, 1994; Judge, Naoumova and Koutzevol, 2003) and others that the results are mixed and inconclusive (Chowdhury and Geringer, 2001) so we feel the need to further analyze these structures using best practices. From this follows the first premise:

Premise 1: In companies with duality in the control generate better business performance.

With this premise the following hypotheses emerge:

H1: Companies with dual control structures generate behaviors steward of the director general.

H2: Companies with dual control structures generate good financial performance.

3.2. Stewardship and the Effects on Human Resource Management and Firm Performance

The evolution of governance models, presented by stakeholder theory and stewardship theory, extends the company's obligations beyond shareholders, this based on the assumption that the company has responsibilities to society and a variety of ethical and moral obligation (Caldwell, Karri and Vollmar, 2006).

The role of leadership in human resource steward type in the governance of the organizations has received increased attention in the post-Enron era (Caldwell et. al., 2007, Hernández, 2008). Caldwell et. al. (2010) describes the stewards CEOs, as leaders who have a complex set of obligations to stakeholders. These obligations achieve long-term wealth to achieve the benefits of all stakeholders and highlight the obligations of the company with society.

The success of the strategic management of human resources involves the design and implementation of a set of policies and practices that ensure that employees share knowledge, skills and abilities that contribute to achieving the objectives of the organization (Huselid, Jackson and Schuler, 1997).

Becker and Huselid (2006: 902) note that the intangibility of human resources is essential to achieve a sustainable competitive advantage, which depends on whether the leader of a company understands how to integrate people into the achievement of organizational goals. Supangco (2006), mentions that successful human resource practices in organizational capacity building help the organization to adapt to changes in a global environment, these practices provide the necessary infrastructure to enable the organization to create value in the market.

If we consider human capital as part of unique and valuable knowledge of the employees, they will be relevant features to generate a sustainable competitive advantage. The value of knowledge reflects the power to improve efficiency and effectiveness of the firm, exploiting market opportunities and / or neutralize potential threats, while the unique knowledge helps to differentiate from competitors

As Barney and Wright (1998) suggest, a resource creates value by lowering costs or differentiating the product/service in a way that the company can charge a high price, then a valuable knowledge will generate high returns in growth markets with rate benefit to consumers on their associated costs. For López Cabrales et. al. (2009) define the value to the extent that human capital provides low cost or an increase in the characteristics of the goods or services that matter to consumers.

However, some authors note that the resources of a company should not only be valuable and unique, to provide superior performance, it is also necessary to have an appropriate organizational structure to achieve an advantage of these resources (Barney and Wright, 1998, López Cabrales et. al., 2009). Goffee and Jones (2001, cited by Caldwell, 2006) mention that leaders must build relationships with employees to develop a sense of commitment in a competitive global market. This brings systems management practices of human resources, called collaborative or partnership/alliance (Lepak and Snell, 1999; López Cabrales, et. Al., 2009; Martinez Lucio and Stuart, 2005). The literature also emphasizes the importance of working in groups or teams to raise awareness of the unique and valuable members of the organization (Nonaka and Tekeuchi, 1995, Lepak and Snell, 1999, cited by López Cabrales, et. al., 2009). In the collaborative system, the ability to work as a team are necessary to move any selection process and these skills are the focus of training initiatives. In sum, the evaluation process and compensation provided complete with a criterion group (Helleloid and Simonin, 1994; Lepak and Snell, 1999). Therefore, the design teamwork is to generate a competitive advantage in the organization.

As we can see there is a paucity of empirical studies on the relationship between human resource management and corporate governance, which creates an opportunity for research to define the type of relationship. So you can give the following premise.

Premise 2: In companies with CEOs steward attitudes generate collaborative and distinctive capabilities in human resource management.

From this premise, our next hypotheses emerge

H3: Attitude steward of the CEO generates distinctive capabilities.

H4: Attitude steward of the CEO generates collaboration with employees.

H5: The employee collaboration creates distinctive capabilities.

H6: The distinctive capabilities produce good financial performance.

4. Methodology

In the present study will be used simultaneous equations models, using single equation methods that are most used because they may be less sensitive to specification errors. To make the sequence analysis, it must be the dependent variables are: distinctive capabilities (CD) and financial performance (DF). On the other hand, the independent variables: duality in the control (DC), stewardship attitude (ST) and collaboration (C).

To measure the relationships are presented in the following model equations:

$$CD = \alpha_1 + \alpha_2 ST + \alpha_3 C + \varepsilon_1 \quad (1)$$

$$DF = b_1 + b_2 DC + b_3 CD + \varepsilon_2 \quad (2)$$

$$ST = \gamma_1 + \gamma_2 DC + \varepsilon_3 \quad (3)$$

$$C = \alpha_1 + \alpha_2 ST + \varepsilon_4$$

(4)

As control variables we take the company size, family background (in case of family businesses) and the structure of the board.

We use the recursive OLS model equations taking as an assumption that the errors (ε) are not correlated with the dependent variables, in other words to the equation (1) has only independent variables on the right side of the equation and so therefore uncorrelated with the error term ε_1 , therefore this equation meets the basic criteria MCO. In equation (2), which contains a dependent variable (CD), as an explanatory variable along with other non-stochastic independent variable, you can also apply OLS as CD and ε_2 are uncorrelated, which is the same case of Equation (4).

For the conduct of the investigation we developed a questionnaire with items derived from the hypothesis, appropriate for a Likert scale (1932; in Hayes, 1999), often called grading method combined. This scale is also a widely accepted technique with which the participant indicates the amount of agreement or disagreement you have with a variety of statements about a particular attitude object. For this survey takes the instruments developed by López Cabrales, et. al. (2009) and Rodrigo and Arenas (2008). To measure the financial performance variables take the sales, assets, ROA, available at the National University of Colombia (see Annex).

For variables distinctive competencies, attitudes stewardship and collaboration is making a set of items to measure them. It is part of a population where it operates a set of variables and it tries to find several factors that could reveal the deep structure of that reality. For this, all the variables that form a factor must be correlated and yet be relatively independent of the rest. To validate the study used the Cronbach alpha resulting in 0.98, so one can assume that the factors have a good level of reliability.

5. Analysis of results

When estimating the equation $CD = \alpha_1 + \alpha_2 ST + \alpha_3 C + \varepsilon_1$ (Table 1). We can see that both α_2 and α_3 of model 1 are not significant, it has a very low R^2 , but we estimate the F-test and accepting the model achieved an overall significance level of 85%, so that reject the null hypothesis that the coefficients are zero, in other words, the whole stewardship and collaboration variable explained the distinctive capabilities of employees, and that has a positive relationship with both variables. By running the model with only the control variables firm size (Model 2) had an explanatory power of almost 90% the other control variables did not have significance level, so can be concluded that when the company have high levels of collaboration within it will develop distinctive capabilities in the employees, we can also conclude that larger companies will have higher levels of distinctive capabilities of employees and they can explain the generate plans for collaboration. Also applied the White test to verify that there is not heteroskedasticity, for the models 1 and 2, and we conclude which is rejected, because exist up to 50% and 75% critical value respectively. This is done to test the hypothesis 5, but considering that it has low levels of significance, is achieved partially test the hypothesis 3, given the non significance of the coefficient and globally acceptable levels.

Table 1: Estimated equation $CD = \alpha_1 + \alpha_2ST + \alpha_3C + \varepsilon_1$

	Constant	ST	C	R ²	F	Control variables
Model 1	-1.101836 ee = (0.502148) t = (-2.194246) p - value (0.0346)	0.195312 (0.173111) (1.128247) (0.2665)	0.275810 (0.197888) (1.393769) (0.1717)	0.085785	1.735942 Prob(0.190280)	
Model 2	-1.401058 ee = (0.527276) t = (-2.657164) p - value (0.0117)	0.223229 (0.170606) (1.308449) (0.1990)	0.337805 (0.197893) (1.707005) (0.0964)	0.145282	2.039712 Prob (0.125622)	Company size
Model 3	-0.805218 ee = (0.698706) t = (-1.152441) p - value (0.2567)	0.185189 (0.175352) (1.056102) (0.2980)	0.284848 (0.200106) (1.423484) (0.1632)	0.095326	1.264446 Prob (0.301135)	Structure of the board of shareholders
Model 4	-0.816571 ee = (0.948659) t = (-0.860763) p - value (0.3987)	0.223847 (0.202513) (1.105346) (0.2810)	0.424866 (0.334194) (1.271316) (0.2169)	0.103928	0.850531 Prob (0.481192)	Family background

In Table 2, we can see that the equation $DF = b_1 + b_2DC + b_3CD + \varepsilon_2$, in model 1 the coefficient b_2 does not have an acceptable level of significance, but it has a b_3 90% confidence, and with the F-test and accepting the model achieved an overall significance level of almost 90%, there is a relationship in the distinctive capabilities of the employees of the company, so we can say that in companies where further develop these skills, they will have better financial performance. By running the equation with variable structure control of the board of shareholders (Model 3), we can see that the model remains overall significance nearly 90%, and the same relation of signs, but not so with the other control variables as the models 2 and 4, which lowered its overall significance to 85 %, but still b_3 has a significance level of 90% with of these two models. Thus we can say that the capabilities of employees explain up to 90% the performance of the company, but the control dual structure and distinctive capabilities explain the performance of the company, but the variable structure of dual control individually does not explain the financial performance, based on this information we can accept hypothesis 6 and in part the hypothesis 2.

We applied the White test to verify that there is no heteroskedasticity, we found that heteroscedasticity is rejected in Model 1 to 25% of critical value in Model 2 is that there is heteroskedasticity, 3 and 4 we can conclude that no exists a critical level of 5%. For equations $ST = \gamma_1 + \gamma_2DC + \varepsilon_3$ and $C = \square_1 + \square_2ST + \varepsilon_4$ not managed to find statistically significant so poor that fail scenarios 1 and 4. Therefore, we can not accept the assumptions 1 and 4 (Table 3 and 4).

Table 2: Estimated equation $DF = b_1 + b_2DC + b_3CD + \varepsilon_2$

Conclusions

Based on empirical and theoretical studies are reviewed argue that the structure of corporate governance can positively affect the functioning of the company itself is generating capabilities to improve its financial performance. By contrast the agency theory and stewardship of six hypotheses were raised which could accept only proposals (1) and (2), of which explain the hypotheses 2, 3, 5 and 6, although with reservations since the coefficients (α_2 , b_2 ,) have no significance but the overall significance F test fails to pass the significance level for models 1 and 2 of equation (1) and equation (2) must be in all the models have acceptable levels of significance between 85% and almost 90%. We can also conclude that there is a positive relationship between attitude steward of CEO and collaboration in the generation of distinctive capabilities of human resources.

Rejection of equations (3) and (4) and therefore the hypothesis 1 and 4, given the low explanatory power of the equations, so there is no relationship whatsoever between the duality of the overall direction and attitude steward of the CEO and this in turn has no relation to employee collaboration. These results should be viewed with caution since it is a small sample of one of the main limitations of the study also to apply a perception survey of risk managers to evaluate only positive things about the organization so that suggests future research to other types of study as may be case studies in depth interviews with a group of companies of this sample.

Therefore we can conclude that in the Colombian context of corporate governance structure does not explain the behavior of the CEO, and neither collaboration systems existing within the company, but one can say that the attitude steward and collaboration have a positive impact in the generation of capabilities in the human resource and lead to better financial performance.

Sale, assets, ROA, Relationship ebitda/sales

Corporate governance structure

1. Is this a family-owned company?

- a. Yes
- b. No

If your answer to the previous question was "Yes" go to the next question. If you answered "No" go to question 2.

1.1. The current CEO is the founder?

- a. Yes
- b. No

1.2. How did he do founded it?

- a. Its own assets.
- b. With a state loan agency.
- c. With a bank loan.
- d. Through angel investors.

1.3. If it is a family business, is there separation between capital and the family patrimony?

- a. Yes
- b. No.

2. Is there a board?

- a. Yes
- b. No

2.1. The shareholders are mainly family members?

- a. Yes
- b. No

2.2. Is the company's general director the chairman of the board?

- a. Yes
 - b. No
-

Factor 1. Attitude Stewardship (López - Gamero et. al., 2008)

S1. The top management's behavior inspired continuous improvement un all members of the organization

S2. Te CEO ensures that workers continually develop skills in line with projection of the organization.

S3. There is a positive attitude of the CEO to provide strategies and activities for that the people in addition to contributing their time they'll generate their best effort

S4. Decision making is rational, technical and participatory

S5. Decision making is articulated in strategic business units.

S6. The administrative controls are applied consistently and regularly reviewed in their design.

S7. The CEO looks that HR practices are aligned with corporate culture.

S8. The company creates an environment where people have the opportunity to learn, grow and develop.

S9. The CEO ensures that workers continually develop skills in line with the projection of the organization.

S10. In the company there exist mechanisms for feedback.

S11. In the company there is a basic attitude concerning the possibility of growth and diversification.

S12. In the company there is a positive attitude towards the possibility of strategic alliances.

Factor 2 Distinctive capabilities in the human resources (Lepak and Snell, 2002)

DC1. All members of the organization know mission and share the objectives of the company

DC2. Employees have skills that contribute to the development of new products, services and/or opportunities.

DC3. Employees have the ability to create innovations.

DC4. Employees have the skills necessary to maintain high quality of products and/or services.

DC5. Employees have skills that are able to provide exceptional customer value.

DC6. The employees have skills that are developed through work experience.

DC7. Employees have skills that are difficult to imitate or replicate by competitors.

DC8. Employees have skills that are not available to our competitors.

Factor 3. Collaboration (Lepak y Snell, 2002).

C1. It generate cross-functional teams and networking within the company

C2. Training activities focus on building interpersonal relationships.

C3. There are performance evaluation methods that assess teamwork.

C4. The methods of performance evaluation are focus on the skills of employees to work with others.

C5. In the selection process assesses the ability to collaborate and work together.

Building Capabilities for Sustainability of Foreign Multinational Enterprises in China

Maria Lai-Ling Lammlam@malone.edu
Malone University, China

Abstract

This study is about the perceptions of thirty Chinese executives who are working for twenty foreign multinational enterprises in China through five years of field work in China, Japan and the U.S. Only three out of twenty corporations became really committed to building a “holistic and integrative” sustainable development programs in China because of the moral consciousness of their leaders. The recommended strategies for building capabilities of sustainability of foreign multinational enterprises in China include: increase innovation and localization, change the poor consumers to be producers, enhance the capacity of selected local suppliers, develop collaborative capacity with internal employees and external stakeholders, use a public-private platform to lobby the Chinese government, deepen organization learning process, and develop an internal culture of human flourishing based on sustainability concept.

Introduction

Chinese government and Chinese entrepreneurs since 2005 are more open to practices than can generate good capital through protecting the local environment and labor and expecting foreign multinational enterprises to exemplify these practices (China Entrepreneurs Survey System, 2007; Synato, 2010). Under the Chinese government’s principle of sustainable development, corporations are expected to approach economic growth, social progress, and environmental protection in a “holistic and integrated manner” (National Development and Reform Commission of China, 2009). However, many studies have showed that some foreign multinational corporations used their “corporate social responsibility (CSR)” activities or their “sustainable development programs” to mask their labor and environmental abusive programs in developing countries, including China (Abdul-Gafaru, 2009; Gugler & Shi, 2008; Harney, 2008; Murdoch & Gould, 2004; Lam, 2007, 2009a, 2001c; Lee, 2006; Lund-Thomsen, 2008; Philipp, 2009; Rondinelli, 2006; Rosoff, 2004; Sum & Ngai, 2005; Stiglitz, 2006; Yu, 2006). The recent suicide of twenty young Chinese workers and numerous workers’ strikes in 2010 show that many foreign multinational enterprises (MNEs) do not implement their industries’ code of conduct well.

Since China is one of the few countries that can be resilient to the recent international financial crisis, will the increasing power of the Chinese government push foreign corporations to adopt more “holistic” corporate social responsible programs (CSR)? This paper will assess whether foreign corporations’ corporate social responsibility programs contribute to sustainability (i.e., manage social progress, environmental protection, and economic development in a “holistic and integrated manner”). This paper recommends some strategies for building capabilities of sustainability of foreign MNEs based on the reflections of three major cases (A, B, C) in China.

Research Methodology

This article is based on the author’s extensive literature review, five years’ field work in China, Japan, and the U.S., and personal *reflections*. She uses the process model of organizational sensemaking explaining how Chinese managers, who are working for foreign multinational enterprises in China think, discuss, and act with their key stakeholders and the world (Basu and Palazzo, 2008). During her five years of field work in China, she interviewed thirty Chinese executives from twenty different foreign multinational enterprises which are classified as global corporate citizens (Logdson & Wood, 2005). Research was conducted in Beijing (2006, 2008, 2009, 2010); Shanghai (2006, 2010); Hangzhou (2010, 2007), and Chongqing (2006, 2007, 2009). The data for the perception of the corporate social responsibility practices of foreign multinational enterprises in China by Chinese executives were

collected through semi-structured, in-depth personal interviews during 2006—2010. Several interviewees were interviewed twice during these five year periods.

Each interview was conducted in the interviewee's native tongue and lasted from one to three hours. The data was interpreted and validated by the interviewee's corporate reports, their American and Japanese headquarters' interviews, published Chinese documents, articles, and Chinese students' dissertations about corporate social responsibility and multinational enterprises (Huberman & Miles, 1984; Glaser & Strauss, 1967). In addition, the author's field work in various cities in China during the last five years afforded her an opportunity to see the changing power relationships between the Chinese government and foreign multinational enterprises before and after financial crisis.

During April and May of 2008, the author also validated some findings of Japanese MNEs' environmental policies in China by interviewing seven Japanese executives in their headquarters in Japan. She also sought to validate her findings about American corporations' green supply chain practices by talking with more than twenty American executives in international professional conferences such as Academy of Management, International Center for Corporate Accountability, Corporate Responsibility Officers during 2007 and 2010.

Findings

Three out of twenty companies approached a commitment to building a "holistic and integrative" sustainable development programs in China after they learned how to mobilize their global corporate resources to restore a community in the Sichun earthquake area. Their headquarters' leaders were committed to improve the well-being of the workers in China. Seventeen companies just used corporate social responsibility programs to develop good relationships with their key stakeholder, the Chinese government. They did not face much pressure from the local non-government organizations. Their CSR programs were mainly for corporate reputations.

During the 2010 field work in China, the researcher found the working conditions of corporate social responsibility officers of foreign multinational enterprises were more restraint than before the financial crisis occurred. Many Chinese expatriates with CSR titles had been replaced by local Chinese for the purpose of the lowering costs of operation. Two Chinese expatriates, without knowing Chinese language, had to strengthen their positions by helping their companies to reduce their risks of brand names in China. Their key responsibilities were to deal with stakeholders coming from the headquarters. The hiring of local Chinese as CSR officers to deal with the local media, which is highly controlled by the Chinese government officers, also increases the role of CSR activities as political tools. Indeed, many foreign companies tended to use their corporate social responsibility programs (CSR) to please the Chinese government without incorporating these programs seriously in their core business and strategic plans because the Chinese government held excessive power over local stakeholders. Many foreign companies relied on the local government to protect their economic interest and disregarded any negative criticism from the local non-government organizations (Lam, Lam, Lam, 2010).

The power of the Chinese government is increasing after the international financial crisis. The Chinese media and the state-funded corporate social responsibility centers tend to attribute the corruption problems to the foreign corporations and ask foreign corporations to take more responsibility. On the other hand, faced with increasing pricing pressure and increasing scrutiny from international non-government organizations in the international market, foreign corporations must find many alternatives to cut costs and document their practices in China to fulfill international corporate social responsibility standards. In this study, the common practice was to compartmentalize the activities of corporate social responsibility and make the CSR officers not to be responsible for the conditions of local manufacturing or supply-chain management. The CSR officers were marginalized and treated as mere public relations functions. Some CSR officers who kept their jobs by focusing on reducing the operational costs inside their companies and working with the colleagues for internal operational efficiency. Many did not like to develop practical collaboration work with local non-government organizations for the interest of communities as this caused more distrust from their existing employers in China.

In summation, many corporate social responsibility (CSR) programs are mainly used for political legitimacy and operational efficiency. The CSR practices are not always integrated into the Chinese subsidiaries' organizations' structure and system. The idea of economic aspect of sustainability is to create sustainable reports

without the involvement of many internal employees in the daily operations. The present international financial crisis pushed many MNEs' CSR activities to be more politically oriented and cost efficient. The chasm between the CSR practice reported in the international media and the local media in China is increasing as all practices in China are handled by the local media that is highly controlled by the Chinese government.

Three Major Cases

The following three foreign MNEs have developed their capabilities for sustainability that integrates social, environment and economic performance in their corporate social responsibility programs. The main theme is to make their corporate values a caring and visible in their corporate responsibility programs through collaboration with their stakeholders and deep organizational learning process with employees.

Case A

One Japanese company learned to provide public health, education, social security for its workers in China when the chief executive officer in Japan took the negative criticism about the workers' conditions in China seriously in 2005 and explored possible alternatives to improve the turn-over rate of labors in China through their corporate social responsibility program. Many Japanese employees subconsciously did not treat these workers in China as their colleagues even though 80% of the products were made by these Chinese workers. The CEO assigned a corporate social responsibility officer in Japan to persuade the internal staff in Japan and establish another CSR position in China. The CSR officer told the researcher that she first had to persuade her boss to allocate more resources for CSR activities in China even though she was supported by the headquarters. Fortunately, the company since 2006 successfully invested U.S. \$2 for each worker's training per year through a Chinese consulting organization. When the company succeeded in solving its labor problems in its subsidiaries in China through their corporate social responsibility program, it shared its experience to its Chinese suppliers in 2008 as they encountered similar labor problems. After having trusting relationships with its suppliers, the company in 2010 joined an industrial code of conduct and supported its suppliers to meet the code of conduct. This Japanese company is also a few one which does not experience recent rampant labor strikes in China in the summer of 2010. The capabilities for sustainability increased gradually through the commitment of top management, the dedication of CSR officers in Japan and China, and the internal education of employees and supply chain members about CSR practices that can reduce their operating costs. With persistence, compassion, and humiliation of these dedicated CSR officers, this becomes a synergistic progress.

Case B and C

One American and one German MNEs were really committed to implement their corporate social responsibility (CSR) programs and enhanced their brands through long-term CSR and corporate-wide CSR programs. Their initiatives and commitment were derived from their employees' cooperative rescue work in the Sichuan earthquake in May, 2008 and the commitment of top management. They did not follow other companies to donate money to the victims and earned quick publicity in the media mainly controlled by the Chinese government. The American company mobilized its corporate resources, including software system and expertise, to a project that restored the community in the Sichuan earthquake area. Through the project, the American company restructured its international organization learning teams and enhanced the team's capacity of working in China through one-year cooperative projects and training in its corporate social responsibility programs. The crisis generated many initiatives and dialogues among local stakeholders and its subsidiaries of these two companies around the world. The involvement of its employees coming from other countries in China also enriched their understanding of building a "holistic and integrative" sustainable development system in China. These enterprises also learned how to use their global crisis center and mobilize many volunteers in the global market economy through their corporate networks. They also learned how to provide public service and add substantiality to the government's capacity in dealing with

natural disasters and to manage waste water through collaborative projects (Lam, 2010b; Woodrow Wilson International Centre for Scholars, 2008). Thus, these two companies provided public services, enhanced the capacity of the local government, rebuilt the local community, institutionalized and shared the best practices, lobbied the local government, increased the solidarity of the employees, and increased dialogue among the headquarters and various subsidiaries during their rescue efforts in the Sichun earthquake.

Recommended Capabilities for Sustainability of Foreign Multinational Enterprises in China

When the Chinese government has gained more power and will demand more environmental and social performance from foreign corporations in the future, foreign MNEs need to develop their capacity to provide public service while increase their competitive advantages in China. During 2011 to 2016, the Chinese economy will shift from exporting to domestic consumption. Foreign MNEs must know how to develop new business models, new product designs, and to increase research and development investments in China in order to be competitive (Orr, 2011). The global supply chain cannot be sustained when the weakest parties, Chinese suppliers, have to absorb all or most of the cost of compliance and keep on fulfilling low-price and quick order requirements of global buyers, foreign MNEs from developed countries. Thus, foreign MNEs need to change their mindsets and learn how to integrate their corporate social responsibility programs through internal and external designs, and dialogues between local and international stakeholders. They need to know how to work with the public media which is mainly controlled by the Chinese government and use the media to mobilize their internal and external stakeholders effectively. They can use the platform created by the Chinese government or industrial association to have dialogues with decision makers of many local stakeholders. They can use their experience in China to know how to introduce sustainable products and processes to the poor who has not benefitted from the 20-year-economic prosperity of China. When corporations are committed to nurturing local stakeholders to be partners in their future business operations, they will empower their Chinese employees to develop collaborative work with local stakeholders without being afraid of losing control of their Chinese subsidiaries.

The recommended strategies of developing a “holistic, integrated CSR” program in China include: increase innovation and localization, change the poor consumers to be producers, develop collaborative capacity with internal and external stakeholders, use a public-private platform to lobby the Chinese government, and develop an internal culture of human flourishing based on the concept of sustainability.

Increase Innovation And Localization; Change Poor Consumers To Be Producers

Foreign MNEs must implement their policy of localization in China. They must use more local talents and local suppliers as these activities support the government’s plan to encourage domestic consumption and develop a “harmonious society.” They need to increase the capacity of selected local suppliers by enabling their poor consumers to be their producers. For example, one company provides training and supports to some local farmers to grow potatoes in a very poor area while this company can transfer its experience of managing barter or counter-trade in many developing countries to their subsidiaries in China. The practice also gets recognition from the local government and increases its brand equity in the local community. Foreign MNEs must treasure many insights in the local community and generate them as new business models that encourage local employees, consumers, and producers.

Increase Collaborative With Multiple Stakeholders

Foreign MNEs can mobilize other companies with similar interests and a shared identity to make environmental and social change through their corporate social responsibility programs (Davis and Thompson, 2004; Kostova and Roth, 2002; Kostova and Zaheer, 1999; McAdam and Scott, 2005; McAdam, McCarthy and Zald, 1996). These enterprises can create new industry standards and communicate their corporate social

responsibility practices to small and medium sized supply chain partners through a higher level of collaboration between MNEs' subsidiaries and supply chain partners in China (Vaill, 2007; Wood and Kaufman, 2007; Zadek, 2004). The followers may conform to similar corporate social responsibility practices according to institutional theory (DiMaggio and Powell, 1983; Oliver, 1991). These new industry standards might inspire other companies to increase their contributions in environmental and social sustainable programs in China (Gilbert and Rasche, 2007; Kanter, 2009; Logsdon and Wood, 2005; Schere and Palazzo, 2008). As the civil society in China is very weak, foreign multinational enterprises should develop some selected good non-government organizations as their overseers in the local community such that the transparency and good practices of these corporations will impose their reputations in the local community. They may consider hiring some CSR officers with experience in non-government organizations in China and empowering them to support many local community activities.

Use a Public-Private Platform to Lobby the Chinese Government

When the Chinese government supports sustainable initiatives by providing sustainable credit rating of corporations in the financial market and home-grown CSR standard, foreign MNEs can actualize these initiatives through discussion and collaborative work. For example, a few MNEs have used an international organization or an industrial association as a platform to have public and private collaboration. These corporations provide their five-year corporate environmental data to the Chinese government and enable the government to set up better environmental regulations. When several foreign multinational corporations are becoming more proactive to Chinese environmental laws and induce their Chinese suppliers to become social and environmental conscious by offering incentives, they are also advised to use their global presence to experiment in their journey of sustainability (Nidumolu, Prahalad and Rangaswami, 2009). These corporations not only set up industry standards but also allow higher degree of voluntary diffusion of institutional norms, values, or practices in the area of sustainable development.

Develop Internal Culture of Sustainability

Pruzan (2008) argues that the firm basis for corporate social responsibility is spirituality. Corporations need to facilitate employees' internalization process of corporate social responsibility (CSR) programs. Corporate leaders are called upon to have more responsibility according to their abilities of contribution to a sustainable operating system. Their responsibility is considered as a social connection model rather than a liability model. People are called to deal with the future, not to find out who is responsible for past problems (Young, 2008). Foreign multinational enterprises (MNEs) need to rely on the inherent potentialities of human beings rather than just on technology in their corporate social responsibility or sustainable initiatives. MNEs need to embrace sustainability as "the possibility that human and other life will flourish on the planet forever" (Ehrenfeld, 2008:6). Sustainability cannot be attained by getting rid of unsustainable elements or by pleasing the Chinese government. Foreign MNEs need to develop their corporate abilities to aware the hidden impediment of flourishing in other people's lives they encounter in China. Foreign MNEs need to develop leaders to know what are appropriate corporate political activities, and what is constructive engagement with political leaders.

Conclusion

Foreign multinational enterprises (MNEs) will be sustainable when they start to learn to know how to link with, leverage on, and learn from a network of internal and external organizational actors to manage environmental and social issues in the path of seeking economic growth in China. They need to increase their capabilities of sustainability through more local innovation, deeper organization learning process, more collaboration with non-government organizations in China, and more communication with their global resource center. Their sustainability programs in China must be driven by the spirit of caring and improving social connection models!

Consumer and Corporate Social Responsibility — Hand in Hand for Sustainable Development: A Fair Trade Example

How Responsible Buyer Behavior Increases Corporate Social Responsibility

Magdaléna Jurkovičová, magdalena.jurkovicova@fm.uniba.sk

Ján Rudy, jan.rudy@fm.uniba.sk

Comenius University in Bratislava, Slovak Republic

Abstract

Consumers decide on and influence the destinies of companies and individuals, as well as the development of entire communities. This can affect production and distribution systems and can include manufacturers, producers, employees and their families. The authors examine the concepts of consumer and corporate social responsibility in the light of sustainability requirement. An example of Fair Trade is used to demonstrate how buyers' purposeful decision-making fosters responsible corporate behavior. The sustainability requirement imposes a number of challenges on the consumer-company dynamics of today's economy. In the conclusion, the authors identify a positive relationship between responsible behavior on the part of corporations and individuals and summarize the ways in which they can reinforce each other.

Keywords: Corporate Social Responsibility, Consumer Responsibility, Sustainability, Fair Trade

Introduction

Under the pressure of climatic change, irregular migration and other global challenges, sustainability has become a prior objective of the global community. Agenda21, Millennium Declaration and many other international agreements call for cooperation of all actors on the international economic and political scene in this respect. A strong commitment of national governments, regional and global economic and political organizations, both multinational and local corporations, mass-media, NGOs, religious organizations, other interest groups and every single individual is required to meet the sustainability objective. Just like other current professional literature, management publications all over the world recall Brundtland's Commission definition of sustainable development, which set a challenge for businesses of today and tomorrow: "...meeting the needs of the present without compromising the ability of future generations to meet their own needs..." (Dunphy, Griffiths & Benn, 2007; Epstein, 2008). Business jargon has been extended in terms like "sustainable business" and "sustainable entrepreneurship". These should refer to such a way of doing business that takes into account economic, social and environmental well-being of the society in which the organization operates. Given the power of multinational corporations and the absence of a real global political authority, engagement in these three areas (economic, social and environmental) is increasingly seen as a part of corporate responsibility. How does this go together with various theoretical perceptions of corporate social responsibility (CSR)? What is the role of consumers in moving forward the sustainability implementation in general and in business in particular? These and other questions regarding sustainability of corporate practices and consumers' purchasing behavior, as well as their mutual influences, are addressed in the following paragraphs.

Corporate Social Responsibility

The concept of corporate social responsibility is not completely unknown, yet it is a hot topic in business theory and practice and its actual meaning is subject to a continuous evolution. Theoretical and practical approaches to CSR vary, also due to particular historical, social, cultural, economic and political background of authors and organizations. Melé (2008) divided CSR perspectives into four basic categories: (1) Corporate Social

Performance, according to which, in addition to economic and legal obligations, business has to respond to social expectations of the society in exchange for legitimization of its operations, (2) Shareholder Value Theory, that rests on Friedman's claim of shareholders' profits maximization by legal means being the only social responsibility of business, (3) Stakeholder Theory, based on the idea that companies bear responsibility towards all individuals and groups potentially affected by their activities; and (4) Corporate Citizenship Theory, suggesting that business is a citizen of the (global) society and thus should actively participate in promotion of human rights and general welfare, beside legal duties and social expectations. While the first two approaches fail to truly integrate sustainability into business, the latter two appear suitable for answering the sustainability challenge faced by today's companies.

Some authors prefer using the term "sustainable business" to refer to an entrepreneurship that accepts responsibility in all three areas: economic, social and environmental, and distinguish it from CSR which might not include all these fields. Others use these two expressions interchangeably (Willard, 2007, pp. 9), assuming that CSR involves each of the three above mentioned sustainability areas. In this paper, we adopt the latter stance.

As is the case of other types of change, there are internal and external drivers towards sustainability. Basically, we can say that there are three reasons to get involved in sustainable business: conviction (i.e. inner values), (external) pressure and business case. Some organizations become committed to sustainability voluntarily, because the companies' stockholders and managers believe it is the right thing to do and perceive it as their moral duty. Especially in the most developed countries of the world, organizations are compelled more and more by the state legislation¹, media, consumer boycotts (discussed in more detail later in the paper), labor union strikes, NGOs' and other interest groups' manifestations to consider the issue of sustainability and correct their behavior. Those, who have an entrepreneurial spirit, turn the overall change to sustainability to their advantage. Articles and books (e.g. Willard, 2007) have been written that underline the aspect of business case.

Some firms do not care for sustainability until they are forced to by enactment of stricter regulation. However, there are also companies that would produce more sustainably, if consumers were to buy their products and share the additional cost burden and/or if the government was to support them. Should companies take over the initiative in implementation of sustainability, how to ensure that it pays off? Going back to the foundations of profit organizations, which exist in order to yield profits by producing products and providing services in order to satisfy people's needs, we come across the requirement of sustainability in consumers' needs as a precondition to sustainable business.

Consumers, by their purchasing decisions, determine companies' existence. However, many consumers are not aware of their influence and even if convinced that companies should change their practices, they do not believe to have any impact upon it. In fact, their actual power is immense, all the more if their behavior is organized. Even though they do not bear the whole burden of sustainability implementation, we argue that consumers as part of the global business scene have a great potential to initiate and support the change for sustainability.

Consumer Responsibility

Power and responsibility perceived by consumers have an impact on their buyer's decisions. However, there is an incongruity between perceived and real power and responsibility. In the following text we introduce the idea of consumer responsibility, examine mechanisms of consumer influence and by the example of Fair Trade show the impact of deliberated consumer behavior on the way of doing business.

Heidbrink and Schmidt (2009) write about a "new consumer responsibility". They point out on the consumer tendency to pay ever more attention to moral aspects of their purchase as negative consequences of consumption become evident. Consumer responsibility as such is not new. With every man's decision, including buyer's decision, one bears responsibility for its consequences. The fact that we are not aware of something does not mean that it does not exist. However, the attribute "new" refers to the fact that consumers become conscious of their decisions' impact and, as a result, they start rethinking their purchasing and consumption habits. With environmental destruction, growing perceivability of consequences of social inequalities, financial and economic crisis, increasing occurrence of obesity connected with overconsumption and availability of information on undernourishment

on the other hand side, many consumers start asking: “Is our behavior fair and sustainable? (for our health, for the environment, living conditions of producers, their workers, families and community)”.

Spheres of consumer influence and responsibility are illustrated in FIG. 1 (adapted from Jurkovičová, 2010). The degree of influence (perceived or not by the consumer) goes hand in hand with responsibility. The picture displays consumer perception of the world based on proximity of individuals and groups that are influenced by consumption. It reveals influences and responsibilities which are normally unknown to the majority of consumers. To give an example, let us take a Slovak consumer Mary. She comes from Bratislava, which is a part of Bratislava region within Slovakia. Slovakia is an EU member state. When she buys a product, say a package of coffee in a multinational supermarket in Bratislava, she supports firstly the supermarket chain and the practices it applies to its employees, suppliers and customers not only in Slovakia but, although less directly, in all other countries where the company operates. Furthermore, Mary supports the whole production and distribution chain and the way profit is distributed among its participants. By her buyer’s decision, she also supports the working and living conditions of Gabra and her colleagues on a particular coffee farm in a district and regional state in Ethiopia, which is a part of the global region of Sub-Saharan Africa.²

FIG. 1: THE CONSUMER IN GLOBAL ECONOMY

Typically, a consumer first cares for well-being of himself and of his immediate surrounding (family). At the same time, he does not stop supporting particular producers, production and distribution systems and working and living conditions of employees and their families involved in elaboration and marketing of the products purchased. This impact seems invisible. Though, with a number of consumers, it becomes evident. However, any group consists of individuals and just like in parliamentary elections, also every individual’s vote at the cash desk makes a difference.³

Consumers can affect business practices if they, in their buyers’ decisions, pay attention to products’ ethical characteristics and value. *Ethical consumerism* refers to deliberated consumer behavior in reaction to a particular firm’s engagement or failure in CSR or because of societal causes (support for domestic products or boycott of companies having committed a religious offence (Smith, 2008)). Basically, there are two forms of ethical consumerism: positive and negative. When consumers, often encouraged by campaign groups, prefer certain products (frequently differentiated by a special label) that fulfill particular ethical criteria, we are talking about *positive ethical consumerism*. When they boycott products or companies they regard as unethical, they are involved in *negative ethical consumerism*. In practice, both of these forms occur simultaneously. That is to say, by purposely excluding particular products or brands from their shopping lists, buyers give priority to others and the other way around – by preferring certain goods, they refrain from the rest. In this way, consumers can

exercise their influence on sustainable business conduct. No company wishes for its products to be boycotted. At the same time, sustainable businesses can benefit from consumer boycotts that eliminate competitors who do not adhere to moral principles and rights and rules officially agreed on national, regional or international level. In this manner, consumers can make a more responsible company more profitable and thus give companies an incentive to behave in a sustainable way.

To give an example of ethical consumerism, we will take a look at Fair Trade. Fair Trade is a world-wide movement backed by consumers and their organizations, who strive for equitability in the world trade by purchasing certified products that meet economic, social and environmental criteria agreed on by international Fair Trade organizations. Trust plays an important role in the Fair Trade concept. Consumers believe in appropriateness of the certification criteria and compliance of Fair Trade certified products and companies with these criteria. Since its beginnings, Fair Trade has recorded a considerable increase in sales and revenue in the most developed countries of the world, in many cases even despite relatively high product price. Worldwide, Fair Trade reached € 3.4 billion in retail sales in 2009 (Fairtrade Labelling Organizations International, 2010). In Germany, a country with a relatively long Fair Trade history, consumers' expenditures on Fair Trade products in 2009 rose at 21% compared to the previous year and tripled within a five year period to the amount of € 322 million in the year of 2009 (Forum Fairer Handel, 2010). In Central Europe, it is not that popular yet, but this seems to be only a question of time.

Several studies of consumer behavior (e.g. Valio Ottowitz, 1997; Lehnert, 2009) surveyed consumer awareness of Fair Trade as well as existence, frequency and motivators of Fair Trade products' purchase. They also try to identify characteristics of Fair Trade buyers in order to better understand preferences for Fair Trade products and find opportunities for further expansion of the Fair Trade concept. Reasons for purchase of Fair Trade vary. Some do it because of conviction, for others it has become a life-style. Many consumers need yet another reason for purchase like, for example, high product quality. Nevertheless, even if consumers are enthusiastic about Fair Trade, their positive attitude does not automatically translate into actual product purchase. What are the reasons for this inconsistency between attitudes and behavior?

Sometimes consumers lack determination to express their disapproval of corporate practice. Furthermore, many consider unorganized individual protest totally meaningless and they lack the proper information or will to join a consumer association. Some factors that appear to determinate ethical consumerism were listed by Smith (2008). Among them, there is the company-issue fit, company communication of corporate social performance, consumer concern for the corporate responsibility issue, consumer perceived effectiveness (whether he/she thinks that he/she can make a difference), consumer sacrifice involved (constraints to consumption that require consumer's readiness to give up something), consumer scope of self-enhancement (whether ethical consumption makes the consumer more satisfied with himself/herself) and consumer recourse to contra-arguments. Nevertheless, with globalization, the ability of consumers to organize in the global scope increases and consumer voice gains importance in regional (e.g. EU) and global political (UN) and economic (WTO) discussions. Smith (ibid.) suggests that the effects of ethical consumerism should not be measured only by sales, but also by moral pressures and impact on company image. Furthermore, consumers support each other in their decisions and any organized consumer initiative serves as an awareness-raising event as well.

However, the primary reason why consumers do not purchase Fair Trade even if they are in favor of the concept might be much simpler: they cannot afford to buy it. The level of medium income varies even among the EU countries which results in unequal success of the Fair Trade concept in different countries. Let us return to the example of Slovak consumer Mary mentioned previously. Even if Mary read about scandalous living and working conditions of coffee farmers who produce the coffee she usually buys, her product purchase options are constrained by her monthly income. Even if she disposed of the double of medium income in Slovakia, it would be still below the poverty threshold in Germany (Jurkovičová, 2010). At the same time, prices of Fair Trade products in Slovakia are about the same if not higher than in Germany, which is largely due to the fact that Fair Trade products sold in Slovakia are re-imported from third countries as, until recently, there were no direct Fair Trade certified importers. As a result, the Slovak consumer has even less opportunities to exercise his/her influence upon business sustainability.

To behave responsibly, consumers need to realize the effects of their purchasing habits and be educated to sustainability. Sumner (2008) recommends using food for political education of the public to sustainable

consumption, as there is a direct connection between products consumed and consumer's health. In order to mobilize individuals for sustainable consumption, Fraselle and Scherer-Heynes (2007, pp. 189) suggest regarding them as citizens rather than consumers. This political meaning of consumption serves as cornerstone for alternative Fair Trade shops (e.g. Artisans du Monde boutiques in France or Weltläden in Germany) and organizations selling and supporting exclusively Fair Trade labeled products and dedicated to education of the public to responsible and sustainable consumption.

In addition to discordance between consumer attitudes and their actual behavior, there is another difficulty, which acts as obstacle not only to ethical consumerism, but to CSR and corporate sustainability in general: the problem of greenwash, sweatwash and fairwash. All of these refer to display of misleading information and advertising regarding sustainable product and/or company characteristics. *Greenwash* is connected to the environmental aspect of production. Organizations committing greenwash falsely publicize eco-friendliness of their business processes, products and production technologies. *Sweatwash* refers to whitewash of corporate sweatshop practices, i.e. employing people in conditions that violate human rights (working long hours, often in dangerous working environment for a miserable pay), by a change in corporate policies to fend off media and public criticism (Micheletti, 2007). Following the same logic, *fairwash* can be seen as unjust propagation of product "fairness", that is, adherence to generally agreed criteria of Fair Trade, usually without any certificate and, above all, without a real commitment to Fair Trade. Unfortunately, it is not rare that (especially large multinational) companies hide their unethical activities from media and public by drawing attention to some minor efforts for fairness and sustainability in an extent, which is less than symbolic compared to the volume of their overall operations and their negative externalities. By practicing fairwash, companies break the trust relationship with customers, which is at the heart of Fair Trade, harm the image of the whole industry and the concept of Fair Trade as such. Likewise, other forms of deceitful advertising destroy consumer trust in corporate social responsibility.

Therefore, in order for sustainable business to grow, customers need to be accurately informed on the way products are produced and distributed. Information of any kind has never been so close as today, in the age of information society. At the same time, information overload causes that it is difficult to find the right information. Proper certification and its reliability guaranteed by certification, governmental and independent institutions that regularly control adherence to the criteria may simplify consumer orientation. Media can also play an important role in informing and educating the public to sustainable consumption. In addition, NGOs provide an irreplaceable service in this field. Governments, EU and international institutions get involved in this process also by providing financial support for projects promoting sustainability.

Together for Sustainability - Responsible Consumers and Corporations

In previous sections, we examined possibilities of corporate and consumer behavior to contribute to the sustainability goal implementation. Even though it was done rather separately, it became obvious that they influence each other significantly. Sustainability implementation is a very complex and ambitious goal and requires joint effort of businesses and consumers. This part, underpinned by the example of Fair Trade, describes how businesses and consumers can work together for sustainability.

Fair Trade reestablishes a direct and a lasting relationship between producers and consumers. Consumers can be informed not only about the product's origin, but about production methods as well as the people producing them and stories of these people. In this way, the perception of products changes radically from the one looking merely at product price, material (Le Velly, 2007) and convenience it provides (Fraselle & Scherer-Haynes, 2007) towards a more humanized view – seeing human lives, efforts and destinies behind it. This holistic perception enables cultural interaction – meeting the producer's culture within store premises. The sales personnel in a specialized Fair Trade store may provide its customers with additional information on products sold. Photos, production tools and other artifacts may be displayed, so that people get to know those who produce for them. In this way, shopping may become a pleasure, an excursion to another countries and cultures.

While sustainability programs figure on MNCs' corporate plans, they are not implemented equally among the countries where these companies operate. This might be caused by differences in markets' maturity and their

readiness to appreciate sustainable product and company characteristics, as well as divergences in legislation that incur unequal pressure for sustainability. However, is it not also in the competence of a corporation to educate its potential customers? Marks & Spencer may serve an example in this respect. In May 2010, the company launched a campaign on Fair Trade in its stores in various shopping malls in different cities of Slovakia.

We have seen that sustainability cannot be achieved if companies and consumers do not work together. It is in the hands of companies to develop products that would be ethical, useful and affordable for customers. It is up to the consumers to choose products that are sustainable. For the beginning, they may decide to cover at least a part of their consumption by sustainable products; to reserve a part of their monthly budget to support ethical production; and to buy, for example, at least one product wholly from Fair Trade.

Because Fair Trade arose mostly from Christian charitable works, the first aim was to express solidarity with disadvantaged producers. So consumers were willing to donate without asking for a special value (utility or quality) in return. If Fair Trade is to become large-scale, other competitive product characteristics need to be developed in addition to the Fairtrade label. Tallontire, A., Rentsendorj, E & Blowfield (2001) stress that any good intention of companies can do without an effective management system, product quality adequate to the market targeted, efficient production system and effective marketing strategy. Furthermore, in order to be trustworthy, Fair Trade certification requires credibility, that would result from a regular and reliable control of certification criteria fulfilment.

In fact, organizations and individuals have many things in common – they behave in a certain way either because of their conviction, under a threat or due to benefits it involves. In case of an existential threat, i.e. when survival (of an individual or organization) is at stake, they are likely to change their behavior. To decide for such a change voluntarily, they need to see the connection between their decisions and consequences of these decisions to the self and to others. Parallels can be seen in individual decision-making (especially in cases of some important decisions) and managerial decision-making. Both are affected by various criteria with their particular weight. For example, in a situation of financial crisis, price is mostly more important than other criteria. As for consumers, they first try to take care of their family and only then think of producers and their well-being. As for corporations, these feel primarily responsible for their own employees and only then for those of their suppliers. In an effort to handle the costs, such a situation might result in a choice of suppliers who don't necessarily stick to values proclaimed by the company.

Sustainability may require short-term sacrifices on the part of both companies and consumers. For a sustainable corporate behavior to enable sustainable entrepreneurship, it needs to be accompanied by sustainable consumer behavior expressed in buyers' decisions that favor sustainable products. The ability to give up something for personal values and conviction is included in the ethical concept of virtue, which is further studied by moral philosophers.

Conclusion

Consumers are very important as stakeholders. In an effort to win their attention and earn profits, companies establish CSR programs that promote sustainable development. However, for a sustainable corporate behavior to be really sustainable, it requires consumer interest and support. Only if consumers appreciate the sustainability aspect of production and sales by concrete buyer's decisions (not only positive attitude), these "responsible" firms are able to survive and prosper. At the same time, in order to make deliberate and responsible decisions, consumers have to understand their role in global economy and be provided with accurate, rather than misleading, information about products and companies. Corporate marketing plays a major role in informing and even educating consumers. In addition, other actors such as government, media and NGOs influence consumer awareness and behavior. Also important is the responsibility of every consumer both to keep himself/herself up-to-date and to make his/her own purchase decisions. Company PR activities promoting ethics and sustainability can increase the value of an enterprise and its product(s) in the eyes of potential customers so that it (and its products) can be differentiated from competitors and their products. However, in the absence of a consistent system of corporate values and business practices, PR activities alone cannot create a long-term source of competitive advantage.

“Together, let us tear down the walls ... Between business, government and civil society. Between global security and global sustainability. It is good business – good politics – and good for society.” (Ki-moon, B., 2011) Given the urgency of sustainability implementation in all areas of public and private life, the concepts of corporate social responsibility and sustainability in business continue being discussed in academic circles, public institutions and among managers. The topic of CSR and sustainability represents also the field of dissertation research under the direction of Professor Ján Rudy. The main objective of the dissertation is development of a model of CSR and specification of principles for fair and sustainable entrepreneurship.

Whether development becomes sustainable depends on daily decisions of all participants in the world economy. Even with control and enforcement mechanisms on global scale, it remains up to consciousness of every single person – be it a manager, statesman, investor, employee or consumer. Therefore, inclusion of ethics as a basic principle of all human activity including entrepreneurship and consumption seems as „a to be or not to be“ question.

End Notes

¹Governments either use positive reinforcement (e.g. tax reliefs or subsidies) or they motivate businesses to contribute to sustainability implementation by means of threat (e.g. fines).

²The term “global region” is used for a country grouping based on close geographical location and other common characteristics, e.g. similar human development index. Various international economic, financial and developmental organizations use different county classifications.

³ The “shopping-basket politics” is at the core of alternative-trade and other consumer movements.

Ethical climate of Public Sector organizations in Australia

Theodora Issa, Theodora.issa@cbs.curtin.edu.au

David Pick, d.pick@curtin.edu.au

Curtin University, Australia

Abstract

The aim of this paper is to identify and analyse the ethical climate in the Australian Public Sector organizations. Using a mixed method design, data was collected from 158 employees of all ranks using an online survey. Data analysis suggests that public servants rate highly such values as integrity, honesty, support and compassion that act as a positive force for making the workplace more tolerable, flexible, and most importantly, in support of an ethical climate that is accountable. However, some respondents expressed concerns that management do not necessarily maintain or display such values. This is reflected in the doubt cast by respondents that an individual with a self-serving (selfish) ethical mindset can be changed for the better. This suggests that there are a number of different possible ethical climates. Furthermore, the analysis suggests that respondents display a high level of respect for belief systems different to their own. While there are those who stated that they do not 'wear their beliefs on their sleeves', those belief systems come out in the way they treat others and the way they view the world. To improve the ethical climate of public service organizations, the data suggests that it is important to combat feelings amongst staff that favouritism is being practiced. Interestingly, respondents concede that this too is in the hands of management who they say 'set the ethical scene'. Though limited to Australia, this research potentially adds to the developing business ethics literature generally and more specifically to the evolving theoretical perspectives on ethical mind-sets with the identification and development of ethical climate in organizations raising some interesting theoretical questions worthy of further research.

Introduction and background

The Public Sector comprises a powerful organizational sector that has been criticized for its lack of accountability to governments and their citizens (Andre, 2010). The Public Sector seems to be on the same footing as other organizations when it comes to transgressions and corruption incidents. In this respect, Perkumiene, Adamoniene and Merkiene (2005) argue that media outlets are inundated with stories about the officials' abuse of their position or corruption cases. They contend that the courts are at the receiving end more than ever before of applications concerning breaches of ethics and working culture. Andre (2010) argues that though these organizations are established to serve the public as a whole by targeting the needs of particular groups or fulfilling specific functions. They often seem to adopt practices from the business sector, and sometimes they enter the marketplace as profit-making enterprises, thus opening the way for further examination of the position in and impact of such sector on society as a whole. Calling for the need for responsible business practice, fair reward policy, stable business relations, job security and sustainable corporate policy, Aslander, Filos, and Kaldis (2011) stresses the need for ethical reflection as a foremost duty of responsible management arguing that the financial crisis has unsettled individuals' former rather, naïve, confidence in national sovereignty, seeing how whole countries may be adversely affected. Aslander et al. (2011) argue that the organizational context, pathos in the classical Greek sense that refers to passion and describes how passionately a person stands for his/her personal moral convictions is an indispensable element of (ethical) leadership and a driving force when striving for (business) excellence and (organizational) improvements. Aslander et al. (2011) go on to argue that pathos for ethics can influence business life or the way corporations unfold their corporate strategies and conduct their business. However, during the recent economic crisis, it became obvious that ethical passion is missing in many corporations.

Fleming and McNamee (2005) argue it is clear that a recognition of ethics and equity will move more closely to the heart of Public Sector organizations in the twenty-first century, and it did (e.g. Randall & Procter, 2008; Sementelli, 2007). There is evidence that the introduction of ethics will have the Public Sector organizations in some countries (e.g. USA) to rebound from corruption (Pelletier & Bligh, 2006). Fleming and McNamee (2005) conclude that the current climate of increased accountability in Public Sector organizations has brought to public

attention the ethical dimension of corporate governance. Presenting a conceptually informed method for undertaking an ethically focused audit corporate governance, Fleming and McNamee (2005) consider that this conceptual-theoretical terrain might be set out in three dimensions: ethics as applied moral philosophy; equity as social justice; and corporate governance as the moral health of an organization. At an operational level, their proposed conceptual model provides a framework to evaluate the overall integrity of an organization and embraces the interrelated themes of individual responsibility, social equity and political responsibility. In addition, they set out a method for ethical audits. It emphasizes the significance of key personnel in (re)producing and challenging the organizational ethos, while recognizing the necessary limitations placed on researchers' commitment to anonymity and confidentiality in the collection, interpretation and analysis of data, and in the eventual sharing of such data.

There is a continuous call to embrace, explore new paradigms, or generate new methods and have new concepts that might change the way management is dealt with in the corporate world that includes the Public Sector, (e.g., Bruch & Ghoshal, 2004; Cowton & Macfarlane, 2002; Ghoshal, 2005; Marques, 2009; Marques, Dhiman, & King, 2005; McDonald, 2004; Mele, 2008; Vasconcelos, 2010). Ashar and Lane-Maher (2004), argue that 'things are changing', and contend that the new global economic order is built on knowledge, intelligence, and innovation rather than planning, control and obedience. Providing empirical evidence, Ashar and Lane-Maher (2004) they state that in the new economy, the competitive advantage resides in its human capital, with its qualities - commitment, responsibility, creativity and energy of the employees that facilitates success. To foster and revitalize these qualities, business needs to nurture relationships to grow human spirit, which is the core of a new business paradigm. Ashar and Lane-Maher (2004) warn that it should be noted that twenty-first century business is about changing values and 'change of mind' that takes place within the business community. However, Ashar and Lane-Maher (2004) contend that in the new economy, competitive advantage resides in its human capital; it is the qualities, such as commitment, responsibility, creativity and energy of employees that determine success.

In their new paradigm Ashar and Lane-Maher (2004) intend to match the challenges of the new economy and changes that prevail. Calling for a need to look beyond materialistic meanings of success, they suggest that spirituality and the notion of success are associated, bringing to the forefront the concept of spirituality and its relationship with success and competitive advantage in business, thus forming part of the statements included in the online survey administered in this study.

Kinchin (2007) argues that the essential factors of a public service code of ethics can be divided into five categories. These categories or principles are fairness, transparency, responsibility, efficiency and conflict of interest. These principles are identified by Kinchin (2007) as being the basic elements of democratic accountability in relation to Public Sector decision-making. In this research, the modification to the recently developed research tool, through its thirty-five statements and eight questions, examined the respondents' evaluation of the existence of integrity, compassion, support; harmony and balance amongst spirituality, teamwork, peace, beauty and happiness were examined in themselves, their co-workers, leaders and the organization in the Public Sector at large.

Ethical Climate

In their discussion on the typology of the nine ethical climate types and the Ethical Climate questionnaire (ECQ), Maesschalck (2005) bring in Victor and Cullen's definition of ethical climate stating it is 'the shared perceptions of what is ethically correct behaviour and how ethical issues should be handled' (1987, p. 51-52). Maesschalck (2005) calls for improvement of the ECQ whereas the sources be made much more explicit in the survey items. While Jurkiewicz (2002) highlights the relationship between codes of ethics and Public Sector reform.

Based on Victor and Cullen's ethical climate model (1988), where ethical climate was arranged from lower levels to higher levels, Leung (2008) examined the relationship between organizational ethical climate and the forms of organizational citizenship behavior (OCB), including in-role and extra-role behaviours, examining the mediating effect of employee loyalty. This was mainly to examine the causes and implications of how various ethical work climates affect employee performance. Leung (2008) results suggest that lower levels of ethical climate (instrumentality and independence), characterizing a weak relational contract between employee and employer, are associated with negative extra-role behavior. In contrast, higher levels of ethical climate (caring and law-and-code), symbolic of a strong relational contract at work, are associated with positive extra-role behavior. Moreover,

normative commitment mediated a positive relationship between caring and identification with the company, whereas attitudinal loyalty mediated the negative relationship between independence and altruism.

Relying on Victor and Cullen (1988) and other theoretical models (e.g. Thompson, 1967), and in their replication of Weber's (1995) study of a large financial services, that found ethical sub-climates exist within multi-departmental organizations, are influenced by the function of the department and the stakeholders served, and are relatively stable over time, Weber and Seger's (2002) findings were contrary to Weber's original findings, their results implied that ethical sub climates may be determined by the strength of an organization's overall ethical climate, rather than the department's function. However, they did find support for Weber's earlier contention that these sub-climates are relatively stable. Weber and Seger's (2002) results also suggest that differences may exist across industries. It is worthwhile to note here that the theory of ethical climate continues to be under formation, following criticism in the literature, to which Martin and Cullen (2009) responded reviewing basic principles of meta-analytic research discussing the methodological context of their work.

More recently, and establishing a comparison between the public and the private sectors, and based on Victor and Cullen's ECQ questionnaire, Venezia, Venezia and Hung (2010) conclude that the Public Sector displayed a higher perception in 'rules/codes', 'caring', 'self-interests', 'social responsibility', and 'instrumentalism', while efficiency and personal morality were perceived higher in the private sector. In a similar fashion, Laratta (2011) argues that 'accountability' is a key element of ethical climate in not-for-profit organizations that is connected to five types of ethical climate namely: 'self-interest', 'individual caring', 'independence', 'social caring', and 'law and codes'. It is worthwhile to warn here and in line with Messner's argument that accountability itself may become a problematic practice, if it does not acknowledge its own inherent limits as an ethical practice. These limits are constituted by the burden that accountability may place on the accountable self who is expected to provide a convincing account even in situations where this is extremely difficult or even impossible.' (Messner, 2009 p., 919). Further, focusing on four systems dimensions: mission, organizational design, organizational outcomes, and the information feedback process, Andre (2010) presents a systems model that suggests how researchers might comprehensively assess the accountability of organizations in the Public Sector, that he terms 'gray sector', with respect to their government missions.

The aim of this paper is to assess the applicability of such theoretical perspectives in the context of public service organizations. To this end, we examine the state Public Sector (PS) in Western Australia.

Methodology

This data was collected through the administration of an online survey. The survey includes eight sections with thirty-five items. Respondents were required to indicate their agreement or disagreement with these statements using a 5-point Likert scale where 1 = strongly agree, and 5 = strongly disagree. These eight sections were followed by eight questions relating to demographic data. Respondents were also provided the opportunity to add their comments under each of the sections, either to qualify or explain their responses to the statements. One hundred fifty eight of this Public Sector employees participated, yet only one hundred and ten responses were considered eligible for further analysis.

In relation to the interpretive mixed-methods approach, Richardson & Fowers (1998) and Tashakkori & Teddlie (2003) argue that it allows researchers to incorporate the virtues and avoid the limitations of the sole use of either quantitative or qualitative methods and provides opportunities to access the feelings and motives of people and engage more fully with the meanings by which individuals live. These characteristics proved very useful for researching ethical mindsets, spirituality and aesthetics, which provided stronger inferences and the identification of a greater diversity of perspectives.

Philosophically, the mixed-methods research is the 'third wave' or third research movement, a movement that moves past the paradigm debates by offering a logical and practical alternative. The approach that has emerged during the past few years, considered by Denscombe (2008) as a 'third paradigm' for social research, develops a platform of ideas and practices that are credible and distinctive as a viable alternative to quantitative and qualitative paradigms. Philosophically, mixed research makes use of the pragmatic method and system of philosophy. Johnson and Onwuegbuzie (2004) state its logic of inquiry includes the use of induction (or discovery of patterns), deduction

(testing of theories), and abduction (uncovering and relying on the best of a set of explanations for understanding one's results).

The concepts under investigation are known of their complex nature, thus one needs to be careful of designing a methodology that assists in a holistic understanding of these concepts. In this context Morse and Niehaus (2009) provide a guidance to grasp complex phenomenon, research often demands that more than one research method be used in the same project. Consequently, researchers must be versatile and adept at many types of research and research methods, both qualitative and quantitative. A mixed-methods design is a scientifically rigorous research project, driven by the inductive or deductive theoretical drive, and comprised of a qualitative or quantitative core component with qualitative or quantitative supplementary component(s).

The analysis uses data collected during the second half of 2010 through an online survey from the PS staff. As highlighted earlier, the online survey was composed of eight sections with thirty-five items followed by eight questions. In section 'A' statements aimed at identifying the respondents' position in relation to values that they wish to see evident in their leaders, employees or work colleagues. The statements in section 'B' related to spirituality, while the statements in section 'C' relate to the respondents' degree of belief in change. Section 'D' concentrated on the workplace and the –presence of harmony and balance. Section 'E' included statements relating to happiness, peace and beauty, with section 'F' dealing with truth. The final two sections, section 'G' had statements aimed at reflection on the self, if the individual makes difference in the workplace, and the like, with section 'H' questioning the respondents' ability to deal with and be a member of a team in the workplace. While the ninth section (section 'I') contained eight questions seeking some demographic data for the generation of a profile of those responding.

In addition to the quantitative data, the respondents were provided the chance, and under each of the sections to provide their comments. Total comments under these sections came to 200 that either aimed to qualify the responses or explore such responses by clarifying why the respondent aimed to agree, disagree, or even be neutral towards any of the statements/items. A total of one hundred fifty eight participants responded to the survey. Details of these respondents are explored in the following section.

Though the online survey was the source of both the quantitative and qualitative data, yet the qualitative data played a major role in enhancing the value of the data collected, indeed, this qualitative data allowed the triangulation and expansion of quantitative empirical evidence and results (Bergman, 2008). The value of this qualitative data is further enhanced when considering Brand's (2009) argument, who states what might be obtained, in a qualitative sense, is access to the context of responses, insight into the perceptions underlying certain decisions, and a broader picture of the participants' understanding of an issue, which is at the heart of researching business ethics.

A total of 158 participants responded to the survey. Of these 61% were male with 39% female. The majority of respondents were born in Australia with 19.5% born in the UK, followed by India and New Zealand. The highest percentage of respondents was in the '45-54' age category followed by the age categories '25-34', '35-44' and '55-64' with the age categories 65+ and '18-24' the least represented. As for the highest level of educational achievement, those of high school and undergraduate qualifications shared almost the same position of 30% of participants followed by the postgraduate at 21% with the trade certificate being the least represented at 18%. The ages of the respondents were re-categorized into the following age groups

Table 1 Age groups

AGE GROUPS	PERCENTAGE
18-34	29
35-44	22
35-54	29
55 or above	24

Ethical climate

This study's quantitative analysis generated six factors with high factor loadings and high alphas (Table 1)

Table 2 Elements of Ethical Climate - Factors and alphas

FACTOR	MEAN	STANDARD DEVIATION	ALPHA
Religious spirituality	3.3182	1.14935	0.889
Pursuit of truth	2.2295	0.75505	0.878
Interdependence (self-efficacy)	1.7015	0.44399	0.799
Aesthetic (Balance, harmony and integrity)	1.6343	0.47182	0.842
Optimism	2.41591	0.666427	0.730
Fulfillment	2.0091	0.54702	0.712

These six components would identify the sample as being aware of religious and spirituality issues, yet with the mean at 3.3182 and a high standard deviation of 1.14935. As will be explained later, the qualitative data revealed a significant divergence of perspectives – one that accepts religion, spirituality ‘i.e. religious spirituality’ the other rejecting these as relevant to ethics.

The analysis of the qualitative data revealed six themes. These themes were (1) compassion &/or support joined by flexibility (2) happiness and peacefulness, (3) harmony, (4) integrity, honesty and truth (5) optimism, and (6) personal responsibility, recognition and religion.

The participants considered that the demonstration of compassion that might be substituted by support at the office would create better environment, which might ultimately create optimism. This was followed by happiness and peacefulness, the presence of which, it was perceived, would bring positive atmosphere to co-workers, including the impact of individual’s positive influence on others, though in some cases, and specifically in the Public Sector where an attitude of ‘do not care’ is cultivated, highlighting the importance of such investigation as this one in the Public Sector. Add to all this the fact that staff would spend most of their time at work, thus happiness while conducting your work is of great importance.

‘I firmly believe that you lead by example and Integrity/Honesty and Compassion towards others are qualities that I value in myself and others.’ (OS_PS 1)

‘I prefer to work in an organization where decisions are transparent and can withstand public scrutiny. While I understand that decisions for the good of all are not always possible, a certain amount of compassion is desirable.’ (OS_PS 2)

Without integrity, honesty, support and compassion, trust and respect cannot be developed within the team or organization. This will create problems and conflicts at work as without all these attributes, there is no team work among colleagues and manager. You cannot expect work/tasks to be completed efficiently. (OS_PS 3)

As for harmony, the results suggest the importance of this virtue being present at the leadership level which will create pleasant environment at the office promoting teamwork and higher morale, thus allowing the respect amongst co-workers. In addition, integrity, honesty and truth were valid themes in that these virtues, and especially honesty, would transform the office environment into being more comfortable, acknowledging that honesty brings in respect, with integrity improving morale. While truth sometimes hurts, it is the leader who would be the role model, insisting on the need of transparency in decision making.

‘If a leader of people does not show integrity then the rest of the workforce will follow. Professional integrity is important to an organization as a whole. Support and compassion from leaders and workers creates a cohesive work place.’ (OS_PS 4)

‘I find it difficult to work with or for people I do not respect. / I do not respect people lacking in honesty, integrity, compassion and the willingness to support those with whom they work.’ (OS_PS 5)

Following from these comments, there were rather some pessimistic opinions when respondents were questioned about change and if individuals would change.

‘Not sure that people can change to a great extent although human nature normally allows people some compassion when it comes to seeing others suffering regardless of how self-centred they are. Selfish, negative and cautious people may take longer to develop positive traits however.’ (OS_PS 6)

The survey revealed perceptions that some individuals can only change if they are faced with a life changing event or a major event that takes place in their lives.

‘Majority of people will not change their attitudes or approach. Generally there is a trigger (such as a major event) which may instigate change.’ (OS_PS 7)

‘Although I agree with all of these statements, change is a very hard thing to do. / Most people become set in their ways and do not change without enough reason to do so. (life change, trauma etc)’ (OS_PS 8)

Further, the analysis also indicate that the participants are optimistic, and have the belief that the majority of people can change, yet this change is governed by issues such as the individual nature, the circumstances and situations influences on these individuals. Nonetheless, there will be those who would have some traits that are more flexible than others that might assist in the change.

‘Anyone can change.’ (OS_PS 9)

‘All things are possible with God :).’ (OS_PS 10)

‘I believe all but the selfish can change given time or depending on the circumstances, again this is due to personal experiences, I haven't seen or met may Selfish people who have changed and become less selfish.’ (OS_PS 11)

Overall, personal responsibility, recognition and religion or rather ‘religious spirituality’ were featured too. While there was an indication that those surveyed would believe in the existence of a greater power than the human kind, yet they do not necessarily relate this greater power to any particular religion. Those surveyed expressed their worries and fear about overzealousness towards any specific religion, indicating that they would respect others’ religion, declaring that religion gives meaning to life, yet religion should not be considered as a prerequisite to morality. Some respondents however expressed doubt that spirituality and religion or ‘religious spirituality’, have no place when talking about ethics:

‘I have no set beliefs except to treat every one with respect; I disagree with teachings of organized religions and the divisions they create, but respect others who have such beliefs.’ (OS_PS 12)

As a secular individual I am not looking for a cosmic consciousness or deity to provide meaning to my life. This doesn't rule out the possibility of design in the universe or a first cause or prime mover (just not an anthropomorphic god that shares qualities with humans). (OS_PS 13)

I thought ethics is secular!!! Faith should have little or no role to play in honesty and ethical decision-making. (OS_PS 14)

Some of these values that are represented in these themes, in their essence, actually relate to or are derived from spirituality that is identified with religion or religiosity. In the majority, spirituality was interchangeably identified with religion, thus applying the concept 'religious spirituality'. This, in a way, echoes what Altman, Ozbilgin and Wilson (2008) whereas more and more people strive to find meaning, creativity and fulfilment in their work, spirituality in the workplace is becoming more openly recognised as an integral part of working life. These values resonate with being ethical, and in turn maintaining an ethical mindset that allows for the existence of ethical climate.

One of the general comments provided by the respondents would sum up the ideas coming through:

'I believe to be successful and happy you need to be surrounded by people with similar work ethics including integrity, honesty and compassion resulting in a team orientated workplace which works in harmony and minimal conflict.' (OS_PS 15)

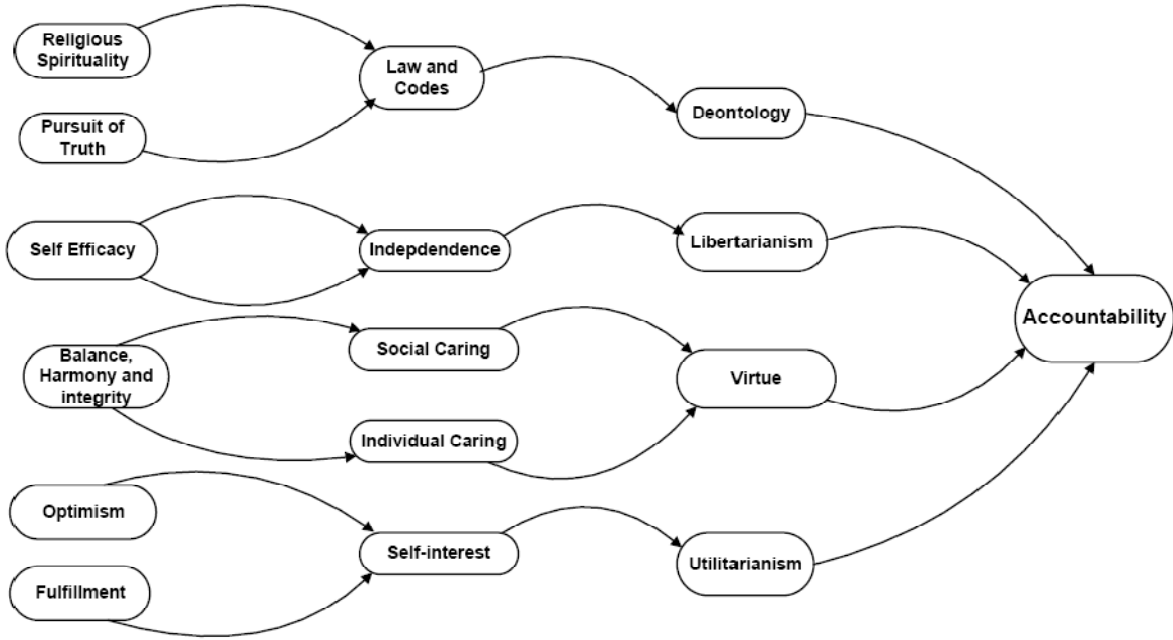

Limitations and Implications

While the analysis is limited to the Australian context at one-point in time, the analysis raises some interesting theoretical questions worthy of further research. It is clear that the ethical climate of the Public Sector in Western Australia can be characterized as being a tapestry of different ethical perspectives. This highlights the importance of values to employees with great emphasis on the importance of setting the tone from the top, providing directions that ethical leadership might hold the key to determining an ethical climate.

The seminal work of Victor and Cullen (1988) on ethical work climate (ECW) had identified several dimensions of ethical climate that exist in organizations and organizational subunits, and since then has been investigated by several scholars. For example, Wimbush, Shepard and Markam (1997) examined ethical climate and ethical behaviour identifying five factors (1) caring, (2) laws and rules, (3) service, (4) impence, and, (5) instrumental. VanSandt, Shepard, and Zappe (2006) and based on his empirical results conclude with an evidence that ECW is a primary predictor of individual moral awareness, and that the influence of social factors often overrides the effects of individual differences in a work group setting. More recently, Weber and Gerde (2010) looked at the ethical work climate in military units, and came with five factors that were named (1) law and professional code, (2) company rules and procedures, (3) instrumental, (4) independence, and, (5) caring. It is not only the names are different but rather the dimensions under these factors seem to change depending on the industry investigated and examined. While the use of the ECW had generated slightly different factors when different organizations are examined, this online survey had generated six factors that might in a way be the source of these factors identified through the application of ECW. These factors were: (1) religious spirituality, (2) pursuit of truth, (3) self-efficacy, (4) balance harmony and integrity, (5) optimism, and, (6) fulfillment.

When compared to this seminal work and the literature on ethical climate, this research provides unique factors and extends present theoretical understandings. When combined with the work of Laratta (2011) and Venezia, Venezia and Hung (2010) the following theoretical framework is proposed that could form the basis of hypothesis testing and further development.

Figure 1 Proposed theoretical framework for the examination of ethical climate

Conclusion

The main aim of this paper was to assess the suitability of current understandings about ethical climate, for examining Public Sector organizations. While this research supports much of the previous findings, the results suggest that further development is required. The proposed set of relationships between variables is not definitive. There is still more research required to develop understandings with special attention to the limitations of accountability. It seems that the best way forward is the applications of mixed methods, particularly quantitatively-driven hypothesis testing with supplementary qualitative data collection and analysis.

Abstract

The agricultural sector is one of the most important in Mexico, due to its contribution to the GDP and the number of employees that it creates. Nevertheless, the social and environmental challenges are issues that the agricultural sector has to resolve in order to maintain its own sustainability. Corporate Social Responsibility (CSR) as a business strategy can contribute to the solutions of these problems. The purpose of this paper is to explore CSR practices in Mexican agricultural companies, identifying the reasons and effects of the CSR distinctive requirement, awarded by the *Centro Mexicano para la Filantropía, A.C.* In order to get the information 12 Mexican agriculture companies (holders of the CSR distinctive) were surveyed between December 2010 and January 2011. Reasons for the CSR distinction requirement of these companies are basically strategic, while the effects are all positives mainly in corporate image.

Keywords: CSR, Mexican agricultural companies, exploratory analysis.

Introduction

CSR is a study field that has been mainly studied by developed countries. Increase of CSR research in universities, increase of enterprises implementing CSR practices and increase of public policies toward CSR issues, are some examples of the interest in this area in these countries. In order to produce a Nord-South effect, developed countries had tried to influence and promote CSR among developing countries (Müller and Kolk, 2009). Nevertheless, CSR in developing countries has arisen more as a business practice than as a discourse or questioning (Gendron, 2000). Mexico, like others developing countries, has follow also this pattern.

The number of Mexican enterprises implementing CSR has increase the last ten years. The *Centro Mexicano para la Filantropía, A.C.* (CEMEFI) is the main institution that promotes CRS in Mexico and each year gives a distinction to the enterprises distinguished by its CSR performance. This institution has awarded the *Distintivo de Empresa Socialmente Responsable* (ESR distinctive) since 2001 and the number of enterprises has increase from 16 enterprises in 2001 to 400 enterprises in 2010.

In Mexican agricultural sector the importance about CSR issues has emerge recently. Some reasons of this emergence have been: the critics to multinational enterprises operating in developing countries (child labor, low salaries and unworthy work conditions), the “boom” of quality and responsible consumption in developed countries, the economical crisis of developing countries, etc. (Centro Latinoamericano para el Desarrollo Rural, 2005)

Even if there are not a lot of companies undertaking CSR practices in this sector, the CEMEFI estimates that in agricultural sector there were 30 enterprises that own the ESR distinctive in 2010. But, why companies want to obtain the ESR distinctive? And which are the benefits to get it? The purpose of this research is to answer these questions by identifying the reasons and the effects of the ESR distinctive requirement in Mexican agricultural companies.

The paper is presented in five sections. The first one describes the economic and social importance of the agricultural sector in Mexico. Second one is the literature review about cause and effects of CSR. The third one is the method and the fourth one the results. Finally conclusions and recommendations are presented in the fifth section.

Agricultural sector in Mexico

Agricultural activity is as old as humanity itself. Due to agricultural activity it is possible to produce animal and human being feedings. In Mexico climatic and geographical conditions are appropriated to produce agricultural products all the year in the whole country. Nevertheless, in some regions, agricultural activity has been the principal economic and social activity.

Between 1990 and 2009, the sown area in México has remained an average of 21 million hectares (ha), while harvested area has remained an average of 19 million ha (SAGARPA, 2010). Agricultural products that occupy the larger agricultural surface in the country are cereals (corn, pasture, sorghum, beans, wheat, sugar cane, etc.) and fruits (orange, mangoes, lemon, avocado, etc.). The equivalence of cereal surface is 46% of the total sown surface and the 81% of the total harvest surface. Fruits surface represents the 3.6% of total sown surface and the 4% of total harvested surface.

Agricultural sector in Mexico has a marked economic and social importance. In economic terms it helps to the wealth creation. This sector contributes with the 6% to the National Gross Domestic Product (GDP). Its contribution locates the agricultural sector in the sixth position after the manufacture sector and the services sector as the financial, personal services, transport, etc. (INEGI, 2010a). In social terms, according to the INEGI agricultural sector in 2010 occupy 5,903,273 persons. This amount represents the 13.27% of the country's employed population and the 12.52% of the country's economically active population (INEGI, 2010b). Even if these percentages are low in a national context, in some regions agricultural sector is the principal employment source for its habitants.

Literature review

CSR concept

The concept of the Corporate Social Responsibility (CSR) has emerged in North America in 1950. It is a concept in constant evolution. Economics, Sociology and Business are some of the disciplines that had influenced in the CSR concept construction. As result, nowadays there is a huge diversity of CSR approaches and classification of these approaches. One classification of CSR approaches is by ideological posture: defenders vs opponents (Pasquero, 1995). Another classification is by geographical context: North America vs European (Belem, 2007). A third classification is by thought schools: ethic moralist, contractual and utilitarian (Gendron, 2000). Finally the classification by group of theories: instrumental theories, political theories, integrative theories and ethic theories (Garriga y Melé, 2004). As a consequence the number of definitions of CSR is as large as the amount of CSR approaches.

In order to operationalize CSR in this paper we adopt and present two definitions of CSR. The first one is the worldwide more accepted definition and the second one is the Latin America more accepted definition. The *World Business Council Sustainable Development* (2000) define the CSR like the continuing commitment by business to contribute to economic development while improving the quality of life of the labor and their families as well as of the community and society at large.

On the other hand, a group of institutions that promotes CSR in Latin America (AliaRSE, COPARMEX, CCE, CONCAMIN, USEM, CEMEFI, and another) define the CSR as the mindful and congruent engagement that the enterprise and the entrepreneur assume in order to accomplish entirely with the enterprise goals in the external and internal aspect, considering the stakeholders expectations (in the economic, social, human and environmental areas) also demonstrating, respect for the ethics values, communities and common good with social justice (Cemefi, 2006).

Cause and effects of CSR practices

Since the origins of the CSR theory and approaches, many researchers have tried to explain the causes and effects of the CSR practices in enterprises.

According to cause theory of CSR most of the enterprises call into question why to be a socially responsible enterprise? Isabel de la Torre (2010) set that there are a lot of explanations to this question and they can

be classified in two groups: economic and sociological explanations. In this research we focus only in the economic explanations.

The first explanation is the Porter and Kramer's theory. According to the authors the incorporation of the social dimension to the value chain changes the conventional economic vision and opens new frontiers to the competitive position of the company (Porter and Kramer, 2006).

A second explanation is the Cuervo's theory. According to the author, companies incorporate CSR for reasons that can determine the basic objective of maximizing its value: 1) the law and societal pressures accomplishment; 2) the market pressures for input products, as a form to avoid risk and as a change instrument in costumers' preferences; 3) as a part of competitive strategy to generate intangible assets and create a competitive advantage (Cuervo, 2010).

A third explanation is the Husted and Allen theory. These authors establish that companies adopt a CSR practice for many reasons. Nevertheless, they can be classified in two groups: strategic and institutional. In one side, companies that adopt CSR practices due to strategic reasons examine different issues regardless of market pressures. Also they respond to them according to the responsibility demands and integration of global NGO's, governments and local market structure. On the other side, companies that adopt CSR due to institutional reasons obey to three different pressures: the state coercion; the effects of the organizational field on the company's politics and structure; and the internal creation of politics and practices among organization (Husted and Allen, 2006).

Mexican researches in CSR theory are scarce. Some authors considerate that CSR theory in Mexico is not new (Logsdon *et al.*, 2006). While other establish that CSR theory is in an emergent phase (Weyzig, 2007). Husted and Allen (2006) made a research in 111 multinational companies of the Mexican automotive sector. They found that the reasons to adopt a CSR in these companies are mainly institutional. Nevertheless, future researches are needed in order to support the coercive and normative process in CSR practices adoption.

In the CSR effects theory actually there are a lot of theoretical papers on management literature. The main conclusions of the CSR effects in these are: 1) CSR contributes directly to the company's reputation and allows legitimacy to its operations; 2) CSR can alter the competitive environment contributing to increased the market cost entry and for competitors helping to raise their labor regulation, environmental or health standards; 3) CSR send quality signals to job offers, which can increase the number of qualified employees; 4) CSR has a positive role in the consumers' buying process because it can be perceived as an important product attribute; 5) CSR is a tool to manage risk that helps to reduce cost and improve efficiency, particularly in the environmental area (Gond, 2008).

Empiric studies in this field focus mainly in effects of CSR in financial and economic performance. The first research in this relationship was made by Editor Moskowitz in 1972 and Stanley Vance in 1975. These authors found both opposite relationships, one positive and the other negative. 30 years after, the numbers of researches and researchers that try to explain this relationship have increase enormously: Griffin and Mahon (1997) found 51 studies, Roman, Hayibor and Agle (1999) found 52 studies, Margolis and Walsh (2003) found 127 studies, Francisco Gomez (2006) found 140 studies and Pascal Gond (2008) found 160 theoretical and empiric studies.

Findings of the five authors reveal different conclusions that can be classified in three groups: negative relationship, neutral relationship and positive relationship. However the most number of studies (83) conclude that CSR has a positive effect in economic and finance performance (Griffin and Mahon, 1997; Margolis and Walsh, 2003; Gómez, 2006). In the Mexican context, Rodríguez *et al.*, (2010) made a research about the effect of the CSR in the financial performance in 12 Mexican companies. The findings were that the CSR has a positive effect in the financial performance.

In order to contrast the CSR theory in the agricultural sector in Mexico, we present in the next section the method applied in this research.

Method

The purpose of this research is to explore causes and effects of CSR practices in Mexican agricultural companies. Therefore, the nature of this research is explorative and descriptive. In order to recollect the companies' information a fifth section questionnaire (open and close questions) was design. The first section includes the general

information of the company. Second section is related with the CSR lines and its hierarchical importance. Third part is about the process to obtain the CSR distinctive. Fourth and fifth sections are about the causes and effects to obtain the CSR distinctive.

The 30 Mexican agricultural companies-holders of the CSR distinctive 2010- were chosen as the universe of study due to the economical and social importance of the sector. These companies represent the 7% of the total number of Mexican companies holders of the CSR distinctive awarded by the Centro Mexicano para la Filantropía, A.C. (CEMEFI, 2010). The universe was reduced to 25 enterprises due the lack of contact information of 5 enterprises.

The 25 enterprises were contacted by telephone and e-mail from December 2010 to January 2011. As a result only 12 enterprises (48% of the total) were surveyed during this period (complete list of surveyed companies are in the appendix 1). In fact, this number is a high parameter in Mexican survey research (Müller y Kolk, 2009; Husted y Allen, 2006; Robins, Tallman y Fladmie-Limdquist, 2002). Questioners were applied to managers of CSR area, which facilitated the data recollection as long as transparency is important issue in ethic aspect for CSR.

Results

Companies' profile

Location, firm age and firm size were the three aspects considered to describe the companies studied. The surveyed companies are located in the states of: Sinaloa (5 companies), Veracruz (3 companies), Distrito Federal (2 companies), Tamaulipas and Michoacán (a company each one). The average firm age is 21 years. The younger one is 3 years, while the older one is 53 years old. Finally in the firm size the average is 1100 employees. The smallest has 21 employees and the biggest has 3400 employees.

Principal CSR lines

The principal CSR lines for all the Mexican agricultural surveyed companies were: life quality, ethics, community relationship and environment. Furthermore, two more CSR lines were considered by some companies as important ones: value chain and responsible consumption (see table 1).

TABLE 1. PRINCIPAL CSR LINES IN MEXICAN AGRICULTURAL COMPANIES

CSR line	Number of companies	Porcentaje
Life quality	12	100%
Ethics	12	100%
Community relationships	12	100%
Environment	12	100%
Value chain	5	30%
Responsible consumption	3	10%

Source: Own elaboration.

The importance of the CSR lines in each enterprise was different. Nevertheless we found interesting results for each line: Life quality was the first priority CSR line for 5 companies, the second priority for 4 companies and the third for one company. Ethics was the first priority for 7 companies, the second for 3 companies, the third for one company and the fourth for another one.

Community relationship was the first priority for 3 companies, the second priority for 2 companies, the third for 3 companies, the fourth for another 3 companies and finally the fifth for one company. Environment was the first CSR priority line for 3 companies, the second for one company, the third for 3 companies, the fourth for 4 companies and the fifth for one more company.

As we showed in the last chart, chain value was a CSR line only for 4 companies. The priority of this CSR line was the fourth for one company, fifth one for 2 companies and sixth priority for another one. Also, responsible

consumption was a CSR line for 3 companies, of which was the fourth priority for one company, the fifth for one company and the sixth for 2 more companies.

The CSR distinctive

It is important to point out that all the Mexican agricultural companies surveyed have the CSR distinctive given by the CEMEFI. The year they participated and obtained this acknowledgment varied in each enterprise. However, the common point was that all the companies surveyed were engaged in CSR practices even before to obtain the distinctive.

A first analysis was the relationship between the firm age and the CSR engagement age (See chart 1). In the chart we observe that the oldest company began to engage in CSR at the second half of the nineties, as well as 8 more companies that formalize the CSR engagement at the same time period, which is congruent with the formal initiation of the CSR in Mexico. As a result no relationship was found in these two variables.

CHART 1. RELATIONSHIP BETWEEN THE FIRM AGE AND THE CSR INITIATION PRACTICES YEAR

Source: Own elaboration.

Companies didn't face with problems to obtain CSR distinctive, it means that the first time they applied, they obtained the acknowledgment. So, we can infer that for Mexican agricultural companies that were engaged with CSR practices were easier and faster to obtain the CSR distinctive than those that weren't engaged on it. In fact in opinion of some CSR managers, the distinctive was a "next step" to institutionalize the practices they were doing during some period of time.

Second analysis was between the CSR engagement age and the CSR initiation practices year. As said previously CEMEFI is the institution that gives the CSR distinctive since 2001. So, companies were separated in two groups: 1) companies operating before 2000 and 2) companies operating after 2000 (See chart 2).

CHART 2. RELATIONSHIP BETWEEN THE CSR INITIATION PRACTICES YEAR AND THE CSR DISTINCTIVE ACQUIREMENT YEAR

Source: Own elaboration.

No particular behavior was found in this relationship, so we can infer that companies obtain CSR distinctive for a particular reason and not only for a trend. However, more analysis with more companies is needed in order to reach general findings.

Cause and effects of CSR distinctive

Mexican agricultural companies have particular reasons to obtain a CSR distinctive. These reasons are: internal decision (11 companies), shareholder interest (8 companies), national and international requirements/exigencies (7 companies), public image improvement (5 companies), local needs (2 companies), clients' pressures (1 company) and ONG pressures (1 company). (See table 2).

TABLE 2. CAUSES OF CSR DISCTINTIVE ACQUIREMENT

Cause/reason	Number of companies	Percentaje
Shareholdersinterest	8	80%
National and internationalrequirements/exigencies	7	70%
Internaldecision	11	90%
Providers' pressure	0	0%
Publicimageimprovement	5	50%
Clients' pressures	1	10%
Local needs	2	20%
ONG pressures	1	10%

Source: Own elaboration.

Reasons were classified according to the Husted and Allen classification (2006) in two: strategic and institutional. In the first group are the shareholders interest, internal decision, public perception and local needs reasons. While in the second group are the national and international requirements, supplier pressures, consumers' pressures and ONG/government pressures. As result 27 strategic reasons were founded, whereas institutional reasons were only 9 (See chart 3).

CHART 3. CSR CAUSES CLASSIFICATION

Source:Own elaboration based on Hustad and Allen classification (2006).

The effects of the CSR distinctive acquirement can be classified in both positive and negative. As positive effects, all the companies have improved their public image. 10 companies have improved their external relationships and 8 the internal relationships, mainly between employees or collaborators. Also, shareholders have increased their investments in 5 companies and 2 companies have increased the number of shareholders. Finally, profits raise was another positive effect for 2 more companies.

Negative effects were minimal. Nevertheless 2 companies argued that CSR distinctive acquirement caused them an increase of management cost and for another company operation cost. It's logical and possible that management and operation cost increase due to the CSR distinctive acquirement. Nevertheless, these costs can be justified by the greater CSR positive benefits (See table 3).

TABLE 3. EFFECTS OF CSR DISTINCTIVE ACQUIREMENT

Effects	Number of companies	Percentage
Internalrelationships improvement	8	80%
Externalrelationship improvement	10	90%
Publicimage improvement	12	100%
Increase of shareholders number	2	20%
Increase of shareholders' investment	5	40%
Profits raise	2	20%
Increase of management cost	2	20%
Increase of operation cost	1	10%

Source: Own elaboration.

Conclusions and recommendations

- The main CSR lines in Mexican agricultural companies are: life quality, ethics, community relationship and environment.
- The priority of each CSR differs in all companies, issue that has been omitted by CEMEFI. We recommend considering the priorities in order to the CSR performance evaluation in Mexican agricultural firms.
- The firm age is not necessarily associated with the date of the CSR distinctive acquirement. The majority of these companies began to engage with CSR practices since the nineties, what is related with the introduction period of CSR concept in Latin America.
- No company had obstacles to get the CSR distinctive. We can infer a positive relationship between the previously CSR practices and the CSR distinctive acquirement. Further research in this area could be interesting.
- The reasons to obtain CSR distinctive to Mexican agricultural companies were classified in two: strategic and institutional. Strategic reasons were the majority, standing out the internal decision and the shareholders interest.
- The effects to obtain the CSR distinctive to Mexican agricultural companies were classified in two: positive and negatives. Positive effects as public image improvement, and internal and external relationships were the main.

Abstract

The present study examines the impact of Corporate Governance (CG) disclosure practices on firm performance in India. CG scores are computed from the annual reports of S&P CNX Nifty 50 companies as per the Clause 49 of listing agreements as issued by SEBI of India for a period of four years. Firm performance is measured in multiple ways like market capitalization, Tobin's Q and MV/BV ratio. The research hypothesis has been constructed to prove that CG scores have positive influence on firm performance. In this regard, pooled cross sectional time series analysis is used to test the hypothesis. It is evident from the analysis that overall CG scores are sub-grouped into various components like board composition, audit committee, ownership component and compliances. The results proved that CG disclosure practices in India have positive impact on firm performance. These results are statistically significant and survive a variety of robustness checks.

Introduction

Corporate governance (CG) is essentially the philosophy by which companies are expected to be directed and controlled. It deals with the policies and practices that directly impact on the organization's performance. Accountability, both internal and external, transparency or openness and recognition are the common principles of CG. In Asia, corporate governance practices have come under increasing scrutiny in recent years, particularly due to the Asian Economic Crisis in 1997. Observers divide the crisis in Asian and others like in South America and Russia frequently identify corporate governance as the underlying cause for the chain of reactions. A large number of literatures provide evidence of an association between corporate governance and firm performance using various approaches. But there is very limited literature examining the impact of various elements of CG on firm market value. Thus we contribute to the limited literature by examining such impact which is measured as market capitalization to book value ratio (Barnhart et al., 1994) and Tobin's Q (Yermack, 1996, Bernard S. Black, Woo Chan Kim, Hasung, and Kyung, 2009) by applying panel data analysis. The corporate governance practice is determined by manually computing corporate governance scores of S&P CNX Nifty also known as nifty fifty for the year 2004 to 2008 for the period of four years using corporate governance guidelines issued by Securities Exchange Board of India (SEBI) under Clause 49 of the listing agreements. The corporate governance index as per the SEBI guidelines consist of seven sub indices i.e. Board of Directors, Audit Committee, Subsidiary Companies, Disclosures, CEO/CFO Certification, Report on Corporate Governance, Compliance. Each of these mechanisms is allotted weight age out of aggregate of hundred (see Exhibit 1).

The remainder of the paper is structured as follows. The second section reviews the literature pertaining to impact of CG and its various components on firm performance. The third section briefly covers corporate

governance guideline in India. The fourth section describes the research methodology. Subsequently, the fifth section presents results and analysis. Finally, the last section concludes with future research directions.

Review of Literature and Hypotheses

A large number of literatures such as (Durnev and Kim, 2004; Hermalin and Weisbach, 1991; Bhagat and Black, 2002; Yermack, 1996; Eisenberg, Sundgren, and Wells, 1998; Loderer and Martin, 1997; Demsetz and Lehn, 1985 and Gompers, Ishii, and Metrick, 2003) studies the association between corporate governance and firms' performance or market value. There are many related studies of Russian corporate governance such as Black (2001) studies a small sample of 21 firms in 1999, with very limited control variables, but reports a strong correlation between CG and firm performance. He finds a correlation between market value and governance of $r = 0.90$, and a worst to best governance change which predicts a factor of changes in the market value. Thus, Black (2001) finds a strong cross-sectional correlation between governance and the market value of oil and gas companies per barrel of reserves.

Several other studies have also documented a positive correlation between performance measures and CG. La Porta, Lopes-de-Silanes, Shleifer, and Vishny (2002) document higher valuation of firms in countries with better protection of minority shareholders. Durnev and Kim (2004) and Klapper and Love (2004) use data on firm-level corporate governance rankings and find that companies with better governance and better disclosure standards exhibit higher Tobin's Q s. Thus, the first hypothesis: Virtually all previous studies concentrated on specific aspects of governance, such as board composition (Hermalin and Weisbach, 1991; Yermack, 1996 and Bhagat and Black, 2002)

H1: There is a positive impact of corporate governance on firm performance.

Board composition and Board Size

The board of directors has a fundamental role in a corporate governance system, considered a major internal mechanism along with ownership concentration; it is used to reduce agency costs. Board composition is used as a proxy for the quality of governance along with the governance index due to the important boards have in the Spanish corporate governance system as an internal control mechanism (Fernandez and Arondo, 2005). Lipton and Lorsch (1992) and Jensen (1993) were the first to hypothesize that board size is an independent control mechanism. Specifically, they argue that large boards may be less effective than small boards. The underlying notion is that large boards can make coordination, communication, and decision making more cumbersome than it is in smaller groups. Jensen (1993) suggests an optimal board size of seven or eight directors. Yermack (1996) was the first to investigate this proposition empirically. In fact, using a sample of large U.S. public corporations, he reports an inverse relationship between board size and firm value, as measured by Tobin's Q . Huther (1997) confirms these findings for a sample of U.S. electricity companies. Eisenberg, Sundgren, and Wells (1998) also find a negative size effect for a sample of small Finnish firms. Most recently, using a simultaneous equations approach for a sample of Swiss companies, Beiner, Drobetz, Schmid, and Zimmermann (2003) cannot detect a significant relationship between board size and firm value. They interpret this finding as evidence that Swiss firms, on average, choose the number of board members just optimally.

Hermalin and Weisbach (1998) offer a theoretical model with a variety of predictions with respect to board independence. For example, their model predicts that CEO turnover is more sensitive to performance when the board is more independent and that the probability of independent directors being added to the board rises following poor firm performance. More generally, the board of directors is responsible for evaluating the senior management of a corporation and to replace if it does not pursue shareholders' interests. Because inside directors' careers are tied to the CEO's, they are generally unable or unwilling to remove incumbent CEOs and, hence, this task is likely to fall on outside directors. Rosenstein and Wyatt (1990) provide evidence that the proportion of outside directors

positively affects shareholder wealth. In fact, they document a positive stock price reaction upon announcement of the appointment of an additional outside director. Additionally, the findings of Weisbach (1988) suggest that firms with outsider dominated boards are significantly more likely to remove the CEO on the basis of bad performance than firms with insider-dominated boards. In a related study, Hermalin and Weisbach (1988) find that outsiders are more likely to join a board after a firm performs poorly or leaves an industry. In contrast, Yermack (1996) finds no association between the percentage of outside directors and firm performance. Thus, the second hypothesis is:

H2: There is an association between board composition or board size and firm performance.

Audit committee

Cadbury's recommendation was that all listed companies should establish internal board sub-committees to oversee amongst other things like audit process. The audit committee's duties were to include the appointment of external auditors, reviewing the company's financial statements and advising on any significant findings of internal audit investigations. In addition to recommending that an audit committee should be established, Cadbury also proposed that the committee should have a minimum of three members and should consist only one of non-executive directors, the majority of whom should be independent. Relatively little has been reported about the impact of audit committees on performance. Wild (1994) found that the market reacted more favourably to earnings reports after an audit committee had been established. Klein (1998) found that the presence of an audit committee had no effect on a range of accounting and market performance measures. She also found that changes to the composition of the audit committee did not generate abnormal returns. Vafeas and Theodorou (1998) also found that no evidence to support the view that the structure of board sub committees significantly affected performance. Thus, the third hypothesis is:

H3: There is an association between audit committee and firm performance.

Disclosure

Disclosed information serves to reduce the unfavorable effects of moral hazard and adverse selection by capital markets first regarding the firm itself and then of the management team. *Ceteris paribus*, firms would disclose relevant information as fully as possible, especially when there are applicable legal requirements, to avoid adverse selection (Grossman, 1981). Patel et al. (2002) develop a model to measure transparency and disclosure of firms in emerging markets. A commonly cited benefit of disclosure is that by mitigating uncertainty, disclosure may reduce the magnitude of the impact of news about a firm's performance, which would reduce stock price volatility (Lang and Lundholm 1993; Bushee and Noe 2000). Ajinkya, Bhojraj, and Sengupta (1999) found a positive relationship between financial analysts' ratings of corporate disclosure practices with institutional stock ownership.

According to diamond (1985) the disclosures result in Pareto improvement in welfare because they reduce investors' need to search privately for information which has substantial costs. The empirical evidence suggests that levels of corporate disclosure are positively related to performance, quantified on the basis of the return on equity (ROE) (Meek et al., 1995; Ettredge et al., 2002; Haniffa and Cooke, 2002).

As per the survey by Healy and Palepu (2001), there is no unambiguous theoretical framework regarding corporate disclosure supply and specifically about the effects of regulation of corporate communications, despite of corporate disclosures playing a cardinal role in financial markets. Apart from this, there has been limited direct empirical evidence on the costs and incentives of corporate disclosures. Milgrom, 1981 focuses that companies would act strategically and disclose favorable items and suppress unfavorable ones, especially when such items affect managements' remuneration and, generally, the managers' position in the market for managerial talent. The model developed by Darrrough and Stoughton in 1990 predicts that firms that have less fear of potential entrants in their markets are more likely to respond to market demands for information.

Simple theories of market microstructure theory suggest that by increasing the amount of public information, disclosure is likely to reduce information asymmetries in the market that result in pronounced price

changes in response to changes in demand for the stock (Diamond and Verrecchia 1991). Disclosure may reduce heterogeneity of beliefs about the true value of the firm. It may thus reduce both the volume traded and the volatility of the stock price. Economic theory (Diamond and Verrecchia 1991) and evidence (Leuz and Verrecchia 2000) suggest that the amount of disclosure that a firm provides depends on its size as well as on the need for external funds.

Thus corporate disclosures are an essential element of well functioning markets including both the capital markets as well as the market for managerial skills, markets for goods and services etc. Firms disclose information to the capital market both through regulated financial statements i.e. annual reports and ad hoc voluntary communications such as their Internet sites, newspapers i.e. press releases and so on. In addition, one can locate disclosures about a firm made by third parties such as brokerage houses and, primarily, the financial press. Transparency and the quality of information released by firms are expected to exhibit a positive correlation with their performance, one reason being that good performers are more willing to disclose information. The number of auditors' comments are considered negatively correlated with information quality, and therefore negatively correlated with performance. Thus, the fourth hypothesis is:

H4: There is an association between firm disclosure and firm performance.

Similarly, various other items of Clause 49 of Listing agreements of SEBI are presented in the form of various hypotheses like

H5: There is an association between CEO/CFO certification and firm performance.

H6: There is an association between report on corporate governance and firm performance.

H7: There is an association between subsidiary companies and firm performance.

H8: There is an association between CG code compliance and firm performance

Corporate Governance Guidelines

The single most important development in the field of corporate governance and investor protection in India has been the establishment of the SEBI in 1992. The need for capital, led to corporate governance reform for which the Confederation of Indian Industry (CII), pressed the government to make the central elements of the code mandatory for public firms, which SEBI did the following year, by adopting a reform package known as Clause 49. The Firms that do not comply with Clause 49 can be delisted and face financial penalties. For the purpose of the study many authors construct corporate governance index and allotted score for each variable, in this study clause 49 is used as a corporate governance index. For the purpose of the study i.e. to know empirical impact of CG the scores for each sub clause is allotted based on its significance. Exhibit 1 shows clause 49 of the listing agreement issued by SEBI.

EXHIBIT I: CLAUSE 49 OF LISTING AGREEMENT

	Disclosures	Clause of Listing agreement	Scores allotted
I	Board of Directors	49(I)	30
(A)	Composition of Board	49(IA)	8
(B)	Non-executive Directors' compensation & disclosures	49 (IB)	4
(C)	Other provisions as to Board and Committees	49 (IC)	14

(D)	Code of Conduct	49 (ID)	4
II	Audit Committee	49(II)	15
(A)	Qualified & Independent Audit Committee	49 (IIA)	3
(B)	Meeting of Audit Committee	49 (IIB)	2
(C)	Powers of Audit Committee	49 (IIC)	3
(D)	Role of Audit Committee	49 II(D)	3
(E)	Review of Information by Audit Committee	49 (IIE)(4)	4
III	Subsidiary Companies	49(III)	10
IV	Disclosures	49(VI)	35
(A)	Basis of related party transactions	49(IV A)	10
(B)	Board Disclosures	49 (IV B)	4
(C)	Proceeds from public issues, rights issues, Preferential issues etc.	49 (IV C)	4

VII	Compliance	49(VII)	4
	Total Score		100

Source: Securities Exchange Board of India (SEBI)

Research methodology

In this paper, panel data analysis is used to find out independent variable i.e. corporate governance score influence on dependent variables i.e. firm performance (proxy by Tobin's q, MV/BV and market capitalization) and the dividend payout ratio, firm value, growth in sales, leverage and net profit margin are considered as the controlled variables. Each of these variables is assumed to have a positive impact on market performance of sample companies. Panel data analysis is an increasingly popular form of longitudinal data analysis.

For the present study, the sample consists of S &P CNX Nifty (also known as nifty 50 or blue chip) companies. The corporate governance scores of these companies are computed manually as per the SEBI corporate governance provisions under Clause 49 of the listing agreements by using annual reports of the companies for the years 2004-2008. Two types of data are used in this study i.e. financial and non-financial data, which are gathered mainly from prowest, a financial data base of Centre for Monitoring Indian Economy (CMIE). While extracting data, it was realized that the CMIE database has information only for 44 companies out of 50 companies belonging to different industries in India.

In this study, we applied the following Robust Random- Effect GLS Regression models with “firm” and year effects to analyze the determinants of firm value(proxy by Tobin’s q),Market to Book Value, Market Capitalization:

$$Y_{it(\text{Firm Value})} = \alpha + \mu_i + \lambda_t + \beta X_{it} + \beta' Y_{it-1} + \varepsilon_{it}$$

$$Y_{it(\text{MVBV})} = \alpha + \mu_i + \lambda_t + \beta X_{it} + \beta' Y_{it-1} + \varepsilon_{it}$$

$$Y_{it(\text{Market Capitalization})} = \alpha + \mu_i + \lambda_t + \beta X_{it} + \beta' Y_{it-1} + \varepsilon_{it}$$

Results and Analysis

Table 1 indicates the pooled sample descriptive statistics for all the variables considered for the analysis. Table 2 presents the correlation matrix among the variables. Whereas, Table 3 indicates the consolidated results of Robust Random- Effect of GLS Regression analysis for market capitalization. The total observations are 200 i.e. 50 blue chip companies for a period of 4 years. Due to lack of information, the total number of observations (N) is turned out to be 164. The overall corporate governance score is found to be positive and statistically significant. Board of directors, audit committee, disclosure, subsidiary companies, corporate governance, CEO/CFO Certification and compliance are found to be positive and statistically significant at 5% level of significance. The return on equity is positive and statistically significant with board of directors (Model 2) at 10% level of significance. The log of asset is found to be positive and statistically significant at 5% level of significance for all the models. The results are similar to black (2001) and La Porta, Lopes-de-Silanes, Shleifer, and Vishny (2002)

Table 4 indicates the consolidated results of Robust Random- Effect GLS Regression analysis for Tobin’s q. The overall corporate governance score is found to be positive and statistically significant. Board of directors, audit committee, disclosure, corporate governance and compliance are found to be positive and statistically significant at 5% level of significance. The CEO/CFO certificate is positive but not statistically significant were as the subsidiary companies are neither positive nor statistically significant. Sales Growth is found to be positive and statistically significant at 10% in model 3 and model 5 and 5% in model 7. Leverage is also positive and statistically significant at 5% for all the models and 10% for model 4 and model 5. Return on equity is positive and statistically significant at 10% for model 1,4,5,7 and 8 were as 5% for model 2 and 6. Log of asset is negative and statistically significant for all the models at 5% and 10% level of significance.

Table 5 indicates the consolidated results of Robust Random- Effect GLS Regression analysis for Market to book value. The total observations are 200 i.e. 50 blue chip companies for a period of 4 years. Due to lack of information, the total number of observations (N) is turned out to be 164. The overall corporate governance score is found to be positive but not statistically significant. Board of directors, audit committee, disclosure, corporate governance and compliance are found to be positive but not statistically significant were as the subsidiary companies and compliance are neither positive nor statistically significant. Return on equity is positive and statistically significant at 5% in all the models except for model 7.

Variable	Mean	Standard Deviation	Min	Max
CG Score	71.19	20.09	6	98
Board of Directors	23.33	6.73	0	30

Empirically it is found that the company performance measured in terms of market capitalization and Tobin's q is influenced by overall corporate governance score, Board of directors, audit committee, disclosure, corporate governance and compliance of the company. Thus, it can be concluded that better overall corporate governance practices as per the Clause 49 of the Listing Agreement will result into better performance. According to the general theory of finance, leverage should result into increasing the returns to shareholders and the sign of leverage is expected to be positive. To support this argument, controlled variables like leverage and return on equity are found to be positive and statistically significant. The empirical results of the present study are very useful to investors. It will help them in making more informed decisions. The results are also useful to management of the companies, regulators and policy makers.

Conclusion

The present study examines the impact of Corporate Governance (CG) disclosure practices on firm performance in India. CG scores are computed from the annual reports of S&P CNX Nifty 50 companies as per the Clause 49 of listing agreements as issued by Securities and Exchange Board of India for a period of four years from 2004 to 2005. In India, Clause 49 requires, in addition to other things, audit committee, a minimum number of independent directors, and CEO/CFO certification of financial statements and internal control. Firm performance is measured in multiple ways like market capitalization, Tobin's Q and MV/BV ratio. The research hypothesis has been constructed to prove that CG scores have positive influence on firm performance. In this regard, pooled cross sectional time series analysis is used to test the hypothesis. It is evident from the analysis that overall CG scores are sub-grouped into various components like board composition, audit committee, ownership component and compliances. The results proved that CG disclosure practices in India have positive relationship with firm performance. This result is highly statistically significant and survives a variety of robustness checks. This study provides evidence to support the relationship between CG disclosure and firm performance. This suggests that properly designed mandatory CG disclosures can increase in firm performance in an emerging market like India.

Macao: A Study on the Impact of Global, Regional and Local Forces

Alessandro Lampo, alessandro.lampo@usj.edu.mo

Leanda Lee, leanda.lee@usj.edu.mo

University of Saint Joseph, Macao SAR

Abstract

Over the years Macao has been exposed to different cultures and has been influenced by various political and economic interests. The booming casino economy has ultimately transformed the city into the largest gambling hub in the world. In spite of the consensus about Macao's shiny future, there are factors (such as the large reliance on a single industry) and socio-economic problems (such as labor shortage, unequal income distribution, and inflationary pressure) that moderate the optimism. By making use of the Chatterjee and Nankervis' convergent and divergent process model for management, this paper examines how global, regional, and local forces have impacted the economic development process, form and type of organizations in Macao. The paper also suggests that the government implement a framework that develops and diversifies the economy but also takes into consideration the social needs of the community.

Introduction

The aim of this paper is to describe the ways in which global, regional, and local forces have impacted on the economic development process, form and types of organizations in Macao. Situated in what is arguably the most vibrant region of South China, since the Portuguese first settled in the region the ex-colony has developed a dynamic culture that continues even now in a fusion of tradition and innovation. But behind the booming growth that has transformed the city from a fishing village into the world's largest gambling hub, there are factors such as the large dependency on a single industry, and the emergence of socio-economic problems that overshadow the optimism of the future of the territory. Although the government has made efforts to address and mitigate such problems, the lack of a skilled workforce, the unequal distribution of income, and ultimately the pressure from rising inflation remain the major challenges that city administrators and managers are confronted with on daily basis. Beside adopting modern management systems, boosting the local talent pool, reforming the educational system and broadening the range of economic activities, Macao should also maximize the opportunities for integration with its neighboring cities, and work to achieve the status of a global leisure destination in South-East Asia.

This paper makes use of the Chatterjee and Nankervis' (2007) convergent and divergent process model for management as the framework to investigate the unique complexity of the territory of Macao by understanding its macro-, meso-, and micro-level perspectives. This framework examines, at a macro-level perspective, the antagonistic relationship between global imperatives and the forces of heritage; the first representing the "push" factor towards a universalistic and convergent approach to management, the latter characterizing the local "pull" influence that constrains such global imperatives. According to the model, the macro-level forces affect and in turn are affected by the emergent contemporary societal factors. The latter describe the society from a meso-level perspective. Ultimately, the micro-level dimension is the representation of the influence of the global and national forces and their relationship with the organizational level of the society, mainly expressed through local management culture. Through the linkage between meso-, macro, and micro-level factors, this paper primarily contributes to the understanding of how the broad political-social-cultural patterns impact on local economic development.

The Macro-Regional Level: Local Issues and External Forces Influencing the Managerial Context of Macao

Macao has been an important gateway through which western civilization entered China. This section discusses how the forces of Portuguese heritage, the favorable location for commerce and the internationalization of Macao in the post-colonial era have shaped the key cultural, political and economic characteristics of Macao society.

A Brief History

Macao has for long enjoyed a favorable position at the mouth of the Pearl River, but developed as a major center for international commerce only when the Portuguese settled here in the 16th century. The earliest Chinese migrants were the seamen from Fujian and from Guangdong, who brought with them the culture of “A Ma”, the goddess worshiped by seafarers. Having established themselves first at Goa and Malacca, in 1513 the Portuguese reached “A Ma Gao” (place of A Ma), whose temple stood at the entrance to the sheltered inner harbor (MGTO, 2010) and adopted the local name that over the years was changed into Macao. In 1557, Portugal obtained the rights to administer the territory in return for tribute paid to China. Before gambling emerged as the main source of revenue, Macao had been a very active commercial entrepot. However, the rise of Hong Kong as the major trading center in South China marked the decline of the territory's economy. In 1847 the government decided to legalize gambling to increase revenue (Macau Business, 2009). Portugal continued to pay rent to China until 1849, when they declared Macao's "independence", and in 1887, with an agreement known as the Protocol of Lisbon, the Chinese government granted the right of "perpetual occupation and government of Macao" (Ministry of Foreign Affairs, 2005) on the condition that Portugal would never surrender Macao to a third party without China's consent. With the rise of communist power in China in 1949, it was declared that the Protocol of Lisbon was a foul treaty. After several rounds of talks a framework agreement known as “Joint Declaration” was signed in 1987, setting the ground for the return of the enclave to the motherland. Despite the fact that the Portuguese tried to return the territory in 1966 and again in 1974, when the new government in Portugal granted independence to all overseas colonies, Beijing preferred to postpone the question over the territory to a more suitable time, and waited until 1999, two years after the handover of Hong Kong, to cede control of the Macao. A decade after the handover, this small territory has maintained a unique multi-cultural identity unlike either Hong Kong or China and has been able to become the most vibrant casino city in the world. The following discussion highlights how global imperatives and the forces of the Portuguese heritage have contributed to the logic behind the territory's response to the changing macro-environmental realities.

Political and Economic Influences

Since Macao's return to the motherland, on December 20, 1999, the ex-colony has become the most dynamic city in South China. The 1987 “Sino-Portuguese Joint Declaration” provided for the Portuguese to officially terminate all the administrative rights over the territory, but most importantly it specified that Macao would become fully integrated into the People's Republic of China (PRC). The territory was given the status of Special Administrative Region (SAR) with complete autonomy and self-governance in internal affairs, economic policy and security. This status, based on the “one country, two systems” principle, provided a framework whereby the Chinese Government in Beijing, the local executive branch and legislative assembly combine to administer the territory. Clayton (2009) noted that Deng Xiaoping, the architect of China's economic reforms, developed this model to facilitate the integration of the SAR into the PRC which in turn was in the process of integrating itself into the world utilising a form of social- capitalism. The intervention of Beijing was set to be restricted to a basic legal framework, mainly foreign affairs and defense, leaving all other matters under the local government's control. Macao's legal framework is meant to continue for fifty years from the commencement of the agreement (that is, until 2049). In December 1999, after four and a half centuries of colonial rule, Edmund Ho was elected the first Chief Executive of the SAR.

If the nature of the Portuguese Governors ruling of Macao can be characterized as that over a borrowed place on borrowed time, Edmund Ho governed Macao by his pragmatism and with a developmental vision of the SAR based upon social harmony and economic diversification (Lo, 2008). The Chief Executive has great influence over the policy making process as well as strong executive powers, powers that are only constrained by the political framework that has on one side the central government in Beijing, and on the other side the legislative assembly. Having reached the limit of the two consecutive terms, Edmund Ho passed the office to Fernando Chui, who was appointed by Beijing Government in December 2009 as the third-term Chief Executive of Macao.

In the wake of the post-colonial period, Macao has experienced a booming economy. In 2010 the government ended its budget with a surplus of MOP 41.88 billion (USD 5.10 billion), a 22 percent year-on-year

increase. This increment was largely due to the increases in direct taxes from gaming, which represented 82 percent of public revenue (Macau Business, 2011). Macao's Gross Domestic Product (GDP) for the whole year of 2010 increased by 26.2% in real terms, totaling MOP 217.32 billion (USD 26.5 billion); per-capita GDP amounted to MOP 398,071 (USD 48,530). The increase was significant in comparison with 2009 during which the falling gaming revenues and shrinking investments totaled a mere 1.3% increase in real terms (DSEC, 2010).

In December 2009, the visit of President Hu Jintao of the People's Republic of China, emphasized the central government's concern about Macao's over-reliance on casinos, pointing out the need to diversify the economy and utilize a series of measures that have since been adopted to support Macao (Bloomberg, 2009) such as the release from Beijing of five square kilometers of Hengqin Island, a region off Macao's Coloane Island, to be used for joint development by the cities of Zhuhai and Macao.

The recovery of the economy in the post 2009 crisis and the positioning of Macao as gaming destination in the South-East Asia have drawn the attention of international companies and a flow of investments into this industry. In 2009, the foreign direct investment (FDI) in Macao reached MOP 22.12 billion, with the investment in the gaming sector accounting for MOP 15.64 billion, 70.7 percent of total FDI (Macau Daily Times, 2010). According to the 2011 Index of Economic Freedom, the score for Macao is 73.1/100, making its economy the 19th freest in the world and the 5th in South-East Asia. The SAR now seems to be heavily betting for its future on developing infrastructures and becoming a regional tourism and leisure center, with exhibitions, culture and creative industries as the engines of growth (China Daily, 2009). So far, much of investments have been in the gaming sector, but the opening of concessions into the telecommunications market (DSRT, 2011) signals the interest of the Macao government in pursuing economic diversification.

Religious and Cultural Influences

While the style and cultural flavor of the Portuguese heritage can still be seen in Macao, Chinese identity remains strong for the majority of the population. The people in Macao are generally open towards different religious views and rituals. Here diverse religions have been living side by side for centuries, preserving their own creed and avoiding conflict or bloodshed. Jesuits first settled in the region in the 1560s and were followed by Dominicans in the 1580s. Both orders set about constructing churches and schools, the most notable of which was the Jesuit Cathedral of Saint Paul (Cultural China, 2010). The early Jesuit missionaries took particular care to study Chinese cultural achievements and encouraged cultural fusion. At the end of the sixteenth century Matteo Ricci, an Italian priest, started his religious activities in Macao by wearing traditional Chinese monk clothes and calling himself "a Western monk" (Baolin, 1997). In fact, the aim of the Jesuits at this time was not primarily to win converts, but to earn for Christianity an accepted place in China (Chan, 2004). While presenting the western customs to the Chinese, Ricci also worked to introduce the local culture back to Europe. He translated famous Chinese philosophical publications into Latin and other European languages (Jeong, 1997). Substantial cultural exchange was one of Macao's greatest contributions to history made possible due to the mutual respect and tolerance of coexisting cultures. As Ngai noted, many Chinese influential thinkers such as Zheng Guanying, Liang Qichao, Kang Youwei and Sun Yat Sen had access to Western learning through Macao, bringing about great social and political changes in modern China (2007). In the words of the Cultural Affairs Bureau, the historic center of Macao remains today as a "solid testimony of the city's missionary role in the Far East while also reflecting the dissemination of Chinese folk beliefs to the western world" (2010). The Portuguese dominance has been culturally liberal, allowing the local Chinese population to keep their own faith and customs; that explains why Confucianism, Taoism and Buddhism have fused into one other, but still preserve their own characteristics (Baolin, 1997). Macao has a long history of western and Chinese cultural fusion that is reflected into the low levels of segregation that allowed for inter-racial interaction, including inter-racial friendship and intermarriage, at least among similar social classes (Mata, 2007).

An example of the fusion between two cultures can be found in the unique architecture that reflects the urban concept typical of colonial settlements (such as Goa and Malacca) with the Chinese spatial concepts inspired by the principles of *feng-shui*, the two elements representing harmony and balance. Macao can be seen as a small territory characterized by a high degree of tolerance within the community that was able to create a multi-cultural society that coexisted based on mutual respect and harmony. Over the years people of different nationalities came to

Macao bringing their own values, traditions and approach to life and businesses, thus creating locally a mixture of exchange and convergence between cultures. Due to proximity, from a cultural perspective Macao has been frequently associated with China or Hong Kong. However, the key characteristics that reflect the local practices need to be understood within the context of one small territory that is influenced from one side by a strong non-Anglo-Saxon colonial heritage, and from an immigrant flow of Chinese and Hong Kong people on the other. This complexity and interrelation of cultures had great impact on the shaping of typical Macao values, politics and economic development. The uniqueness of the society also reflects, on a micro-level dimension, the easygoing lifestyle and the attitude towards education and career development of Macao people.

The Meso-Societal Level: The Management of Macao Institutional Infrastructure

This section explores some of the key governance and management structures, systems and styles currently operating at the meso-level in Macao, and the kind of economic and political management strategies applied by the post-colonial government to boost the economy.

The Dream Factories

It is difficult to think of Macao without the association of gambling. Today the region has overtaken Las Vegas in gaming revenue to such an extent that the city in Nevada could now be called “the Macao of the West”. Further growth in Macao is predicted of between 17 and 27 percent in 2011 (Macao Daily Times, 2011). In 2010 there were 4,838 gaming tables and 14,316 slot machines available in Macao's 33 casinos (DSEC, 2011), and there are still new entrants building mega-resorts facilities in the recently reclaimed areas between Taipa and Coloane islands. Although illegal in China (Telegraph, 2010), there have always been some forms of gambling such as card games and mahjong, the latter of which is today regarded as a gathering occasion for family and friends. With the decline of Portugal's commercial power, and the rise of the British and Dutch over the major commercial routes, Macao turned to a fishing-based economy. To increase revenues and add another sector to its limited economy, in 1847 the government resorted to legalize the games of fortune (Macao Business, 2009). The casino franchise can be traced back to 1934 when a monopoly concession was granted to the Tai Xing company institutionalizing gambling as an industry for the first time. The gambling business emerged prominently in 1962 when the government opened the operation of games of fortune to a public bidding process and the “Sociedade de Turismo e Diversoes de Macau, SA” (STDM), a company founded by Stanley Ho and other partners in Hong Kong, was granted exclusive rights to manage all gambling activities in the territory. Although the triads in Macao threatened to endanger his life, in 1962 Ho succeeded in opening his new casino and hotel, while at the same time maintaining the Hong Kong-Macao ferry service (Lo, 2008). Stanley Ho remained the only casino magnate until 2002, when the government ended the STDM's 40 year monopoly and started looking internationally for investors. In the meantime, the transportation infrastructure was modernized with the introduction of a fast hovercraft service on the Hong Kong-Macao route. This had the primary effect of consolidating the casino industry in the region. With the established "Legal Framework for the Operations of Casino Games of Fortune" in 2001, the Macao government opened the gambling market for competition, and the gaming and service industry became the economic driving force of the SAR. Therefore a monopoly that was originally conceived as a means to sustain the declining economy of the territory has today become the major driving force behind it. Today it is evident how the gaming and service industry is entangled in the life and welfare of the local Macao community. Statistics show that the unemployment rate has decreased from 6.7% in January 2000 to 2.7% in January 2011 and that the median salary of the employed population increased from MOP 6,156 (about USD 750) to MOP 12,000 (about USD 1,460) over the same period (DSEC, 2011). If the booming growth has generated wealth and employment opportunities to society, it has also brought a number of drawbacks.

The Impact of the Casino Economy

It has been argued that since the handover, the rapid economic growth and the increase in the number of casinos

have resulted in new employment opportunities. But gaming and related industries have their advantages and drawbacks. The first and most evident influence on society can be linked to the rise of organized crime and illegal immigration. When in the mid-80s Stanley Ho decided to contract out the management of his VIP rooms to external bidders, triads such as the 14K gang saw the opportunity to infiltrate casinos operations, and loan-sharking proliferated in a context of violence, illegality and power that grew outside the STDM and government control (Lo, 2008) until 1998 with the arrest of the 14K leader. Today illegal activities take other and less obvious forms. As Chinese law forbids its citizens from taking more than RMB 20,000 over the border, wealthy Chinese deal with organizations in the mainland widely believed to be controlled by triad gangs (Collinson, 2011). Once in Macao such organizations give back to the gamblers the money received in China and extend their credit upon payment of commission. Another negative impact from the rapid development process can be found in the practice of several companies exploiting illegal foreign workers whose salaries are much lower than the local workforce. The building sector is notable for this practice which undertakes to supplement the inadequate local labor supply.

The development of Macao has profoundly altered the composition of society. Today the economy of Macao is fueled by the increasing number of visitors that every year sets new records. With the vast majority of visitors from Mainland China and Hong Kong, in 2010 the total arrivals were 24.96 million (DSEC, 2011), a number more than double the 11.53 million visitors registered in 2002 (Macao Business Guide, 2004). Immigration, particularly from mainland China, has also been boosted by the availability of work opportunities. The number of legal non-residential workers jumped from 25,377 in January 2002 to 77,903 in January 2011 (DSEC, 2011, approximately 1/5th of the total labor force). The number of jobs available in casinos has attracted many young people to work for salaries that commonly exceed those of the other sectors. For instance, in 2010 the median monthly wage in the casino sector was recorded at MOP 12,000 (USD 1,460) against MOP 6,000 (USD 730) in manufacturing and MOP 7,000 (USD 850) in hospitality (DSEC, 2011). One of the direct consequences is that many young workers forgo further education for the prospect of immediate returns in the form of relatively high paying jobs. The figures in the 2006 census showed that among the residents 20.9% had no schooling or did not complete primary school, 46.6% had junior secondary education or below, 21.2% had senior secondary education and 11.2% had post-secondary education. These numbers reflect a drop in primary education by 11.6% and a slight increase in junior, senior secondary and tertiary education of 2.2, 5.6 and 3.8 percentage points respectively over 2001 figures (2006). In spite of the increase in higher education, numbers in Macao are low compared to higher income regions such as Hong Kong, where in 2009 secondary education accounted for 52.1% and post-secondary education accounted for 25.7% of the population (Census and Statistics Department, 2011).

Another critical impact on society can be identified in the imbalance of income distribution. The prospects of employment opportunities did not bring well-being to all the people of Macao, especially to those outside the casino industry. Many locals are suffering from an increase in poverty with the rising inflation pushing up consumables and real estate prices. With the context of a year-on-year increase of 4.70% registered for the month of February 2011, 2008 was noteworthy when the Consumer Price Index (CPI) for February rose by 9.47% over February 2007, with the substantial change of +17.44% in the prices of food & beverages and +14.70% in housing (DSEC, 2011). Under these circumstances local workers have started raising their voices and pressuring the government for new housing units and a clear policy to protect local labor against the exploitation of foreign illegal workers. Symbolic are the episodes that culminated in the labor-police May 1st confrontation in 2007 which pointed out the gap between public expectations and government capacity to implement effective policy (Lo, 2008). In an effort to address the raising concerns of the population, the government launched a so-called Wealth Partaking Scheme in 2008 - a program aimed at easing cost of living pressures of Macao residents and redistributing the wealth of the SAR. Although only intended as a short-term measure, every Macao resident is entitled to receive a cash premium. In 2011 permanent residents received MOP 4,000 in a scheme that was estimated to cost the administration MOP 2.34 billion, 2.9% of the SAR budget (Xinhua News, 2011). In addition, despite the limited availability of land, the SAR is undertaking a major construction program to build 7000 new subsidized housing units by 2012, and has also introduced a subsidy ranging from MOP 750 to 1,100 to support qualified families (Macao News, 2011). While attempts by the government to attain economic growth and address the concerns of the population are visible today, in the colonial era the gap between the rulers and citizens was great. In this context emerged the roles played by three influential families and a number of interest groups and organizations.

The three “big families”

It is widely regarded among locals that the growth of Macao could not have happened without the *Ho, Ma* and *Chui* “big families”, as they are colloquially referred to, and their interests in the economic and political life of the city. United by the concern about the community and political life of the city, these families developed their business activities in different areas: the Ho family in finance and banking, the Ma family in industry and commerce, and the Chui family in the building sector. Ho Yin (1908-1983) was an important businessman and politician in Macao. His entrepreneurial activity included the establishment of the local public transportation company “Transmac”, and the Tai Fung money exchange that later became Tai Fung Bank. He was a member of the assembly and a nominated Governor in two legislatures. Ma Man Kei, born in 1919, is currently the chairman of Macao Chinese General Chamber of Commerce, and contributed to closer economic and trade cooperation between Macao and the mainland. Chui Tak Kei (1912 – 2007) was one of the founders of the Macau Construction Association and one of the leading figures of the Chinese Chamber of Commerce. The influence of the three families in Macao is distinguished by the strong connections with the Chinese government, the Macao government, and the community that regards them as philanthropists. One particular event in 1966, known as the “12.3 event” saw the three families cooperating together. Following from a dispute regarding the extension works of a local school, the Portuguese government arrested several dissidents, and, due to the vehement social reaction to those arrests, was forced to impose the state of Martial Law. On that occasion Ho Yin and Ma Man Kei mediated with the Portuguese for the release of those arrested, while Chui Tak Kei assisted with the bail payment (Hudong, 2011) With the establishment of the SAR, members of these families have all gained political status within the administration of the territory. In 1999 Edmund Ho was elected as the first Chief Executive of the Macao SAR and, after two consecutive terms, in 2009 was succeeded by Fernando Chui.

Interest groups and “Black Societies”

The history of Macao is characterized by a multitude of groups that represent specific interests in the population. The major interest groups can be classified into three types: business organizations, labor unions, and neighborhood groups. The most significant interest group is the Chinese General Chamber of Commerce (CGCC), whose leader by convention has a seat in the legislature (Chou, 2005). Chinese businessmen by virtue of these associations are politically influential. Two important interest groups that represent the working class are the Federation of Labor Unions, which include the unions of the most important sectors in Macao, and the Neighborhood Associations (*kai fong*). The *kai fong* originated from the spontaneous gathering of the residents in districts, in a society where the communication gap between the colonial rulers and citizens was large (Lo, 2008). As Chou (2005) remarks, the uniqueness of Macao’s interest groups lies in their role as the authorities’ executive arms in social service delivery, as they took the initiative to provide medical services, relief and education, to maintain hygienic living conditions and social order in the neighborhoods. The large number of associations that exist today in Macao (4,000) (Wang, 2010), not only reflect the freedom of affiliation guaranteed by the “basic law” (article 27), but also contribute to the development of the society as a whole. But while interest groups were active serving the community, another type of organization was operating underground. Before the return to mainland China, triad conflicts have been part of Macao history for centuries (Time, 1998) and of great concern for the Government in Beijing. Referred to as “black societies” among the local population, triads are family-run organized crime gangs that were involved in a range of activities which included drug trafficking, illegal gambling, usury, protection rackets and night club management. Very few political or economic decisions were made without the influence of this underground network (World Trade Press, 2010). In the late 1930s among a population of about 180,000 inhabitants, there were already more than 10 triads (China news, 2001). In the 1990s, there were three main triads: 14K, Shui Fong (Water Room) and Wo Shing Yee (Peace Victory Brotherhood) and several smaller ones that divided criminal activities among themselves. “Broken Tooth” Wan Kuok Koi, leader of the 14K triad, was considered to be the most powerful figure in the fight for the control over Macao's crime before the PRC took over the territory (China news, 2001). In 1998 Wan Kuok Koi was arrested, and the following year other members of the triad apprehended. Since then, Macao was able to clean up its image which had been reminiscent of gangland killing in Chicago in the 1920s (Hays, 2008) and

repositioned itself as a safe leisure destination.

The Micro-Organizational Level: Critical Traditional, Transitional and Transformational Issues in Macao Management

Organizational Culture

The cultural value system in Macao has been heavily influenced by Buddhism and Confucianism. As in many Asian countries, Macao's type of culture tends to be consensual and group-oriented, with emphasis on conflict avoidance and long-lasting relationships. Lam (2008) noted that for a foreigner taking up a new supervision position in Macao, there is a tendency to judge employees, customers or business partners based on his or her own cultural values, a tendency that can lead to management disaster. One source of conflict can be identified in the high-contextuality of the Chinese culture. Hall (1976) defined high-context as a communication or message in which most of the information is already in the person, while very little is in the coded, explicit, transmitted part of the message. As a result, the message itself carries less information and people do not openly say what they want to convey as the primary goal is to preserve and strengthen relationships by saving face and ensuring harmony. Another source of conflict is represented by the high-power distance dimension, which has important implications in workplace. Hofstede (2009) defined power-distance as the extent to which the less powerful members of organizations and institutions accept and expect that power is distributed unequally. In the Macao context Lam (2009) noted that Chinese employees are more willing to accept managerial authority and often try to avoid open confrontation with their superiors or peers. The role of trust is important and group harmony and relationships are stressed. Although this is sometimes used by Chinese managers to control their subordinates, the loss of face or shame (such as through open criticism) in the workplace is to be avoided (Lam, 2008). With the opening of gambling concessions to foreign operators and the expanding tourism sector, Macao is increasingly experiencing western corporate culture and management styles. Cheng and Lee have noted that the employment opportunities in the gambling industry have attracted large numbers of foreign workers and professionals to satisfy labor shortages at all levels (2008). The management styles of this immigrant workforce may influence and bring new changes and challenges to the workplace.

The Structure of Production

Macao is a mini-economy mostly surrounded by the sea and with few natural resources. At the beginning of this century, fishing was the largest form of production in Macao. In the 40s there were over 20,000 fishermen and 2,300 fishing boats (Ieong, 1997) and some other industries complementary to the fishing sector. In the 60s, with the granting of the gambling concession to a monopoly operator STDM, gambling in Macao became the pillar of the economy and enabled the government to upgrade public infrastructure. The 70s were dominated by the process of industrialization based on low-technology and labor-intensive industries. The role of Hong Kong was crucial as the majority of the investment came from factories which transferred some of their productive capacity to Macao where costs were lower (Hook, 2002). Major forms of production were garments, toys, furniture, leather products and shoes. However, the growth rate slowed down after 1987 when the rising costs of production, especially labor costs, forced many industries to relocate to the mainland to maintain competitiveness with South-East Asian manufacturers (Ieong, 1997). Consequently, textile and garment manufacturing, once mainstays of the Macao economy, have virtually vanished and efforts to diversify the economy have had limited success (US Department of State, 2011). To replace the manufacturing industry, the real estate sector emerged in the early 90s, but the intense speculation fueled by capital from mainland China and Hong Kong led to a structural crisis causing a major recession in 1994 (Hook, 2002). Macao has transformed itself over the past three decades from a manufacturing-based economy to one that is now dominated by the services sector. The economic transition was rapid but not smooth, which is reflected in the skills and capability of the current workforce.

SMEs and Management Style

Macao is a typical micro-economy. Enterprises are mostly Small and Medium-sized Enterprises (SME) and are often referred to the backbone of Macao's economy, providing a significant source of job opportunities. Chinese people have always occupied the majority position in Macao, and Chinese culture has become dominant in small and medium business activities. In Macao SMEs are dominated by family-type enterprises. Wang (2010) noted that in Macao an important characteristic of family enterprises is patriarchal succession; a deep-rooted concept that extends to property, official posts and honor. He also commented that the first generation of Chinese entrepreneurs was not well-educated but nowadays they attach great importance to the education of their children in the prospect of a better development for the family business. In contrast to the young generation of people that is leaving school to pursue an "easy" career in the casino industry, the first generation of entrepreneurs relied on hard work, and achieved today's success through step by step accumulation (Wang, 2010). It has been discussed how over the years people in Macao have set up various associations representing the business or social interests of the associates. Those interest groups very well served the local entrepreneurs in establishing and strengthening business relationships. In the Chinese society "relationships" are important, and businessmen in Macao attach great importance to establishment and expansion of their circles of relationships in order to create more opportunities for their companies (Wang, 2010). According to Confucian practice integrity of conduct brings more business which is a central value in business ethics. Wang's research has shown that although nowadays many Chinese entrepreneurs in Macao have gradually established a "legal sense" for resolution of conflict, local entrepreneurs still value the traditional norm that "a promise must be kept" when there is a contract dispute (2010).

Critical Managerial Challenges

One of the critical issues for Macao is the development of local human resources. Statistics indicate that in January 2011 Macao had an estimated total labor force of 332,000 people, but as MacDonald and Eadington (2006) have observed, severe strain has been placed on the local workforce with the rapid expansion of gaming in Macao. It has been estimated that today a large part of the labor force consists of less-educated immigrants who came from mainland China mainly in the 70s and 80s. This was beneficial at that time owing to the shortage of labor in the manufacturing industry (Jeong, 1997) but the consequences today can be seen in the inability of institutions to re-train those workers to operate in a service-driven economy. Currently there are many former manufacturing workers that are employed in casinos as dealers, a function that is commonly regarded as a low-skilled job. The clear a gap in terms of training forced the casino operators and the Government to offer the manufacturing workers training in hotel and gaming service (Macau Daily Times, 2010). The entry-level service industry in Macao is characterized by the import of many foreign workers, notably Filipinos, Malaysians and Vietnamese, who can speak much better English than the local workers (Lo, 2008). They are also more service-minded in comparison to local employees.

The difficulties for companies to attract and retain trained employees when new casinos are opening often results in salary increases and, in turn, inflationary pressure. It is commonly known that the opening of new establishments requires thousands of workers, and this has the effect of pushing average salaries upwards due to the forces of competition within the industry to acquire and retain skilled manpower. However the vast majority of vacancies in casinos and the service industry are low-skill jobs that can be covered by secondary diploma holders or below. A fresh high-school graduate can easily become a dealer in a casino, a position that is restricted to the local workforce, and earn over MOP 13,000 as a starting salary without the need to pursue further studies that cannot guarantee a comparable pay after graduation. But if low-skilled labor is a scarce resource that companies need to deal with in Macao, to recruit experienced and seasoned senior management becomes a real challenge. Many operators are finding it difficult to attract quality management from abroad. As Macao had a casino monopoly until 2003, it never developed an experienced and forward-thinking management cadre (Kale, 2006), and Macao people have not yet been trained in sufficient numbers to fill those positions that are still controlled by expatriates coming from the US, Hong Kong and Australia. To compound the issue, there is the tightly controlled government policy regarding immigrant labor that limits the ability to hire foreign personnel. The SAR government will be under pressure to solve this situation and reconcile the need for labor with the demands of the local workforce without

creating an inflow of lowly paid foreign labor from across its borders.

Conclusion

Macao has experienced for over four hundred years the exchange of different cultures, and since the return of administrative rights from Portugal to the People's Republic of China on December 1999, it has become the most vibrant casino city in the world. By making use of the Chatterjee and Nankervis' convergent and divergent process model for management, this paper explored how global, regional, and local forces have impacted on the economic development process of Macao. In particular it identified the forces of Portuguese heritage and the unique blend of socio-cultural factors that have shaped the Macao of today and created a multicultural society with specific traits. From historical facts we can reason that the fundamental driving force of the Macao's periods of economic prosperity have originated from the interests of foreigners in exploiting its resources. When the Portuguese first settled here, due to the favorable location, the region flourished as an international trading center. Later, with the rise of Hong Kong as major port, the Portuguese turned to legalized gambling to find alternative sources of revenue. Entrepreneurs from Hong Kong initiated the fortune of Macao as a gambling destination and were responsible for the process of industrialization in the tiny effort to diversify the economy. Families from mainland China here started businesses and become more and more involved in the administration of the territory. Foreigners were also employed in the companies that started operations in Macao after the gambling market was open for competition. But most notable is the interest of the millions of visitors that every year cross Macao's borders and direct a stream of cash into casino establishments, local enterprises and, in turn, the government's account. In this picture the interests from mainland China play the major role in the future economic development of Macao. After the handover, the government in Beijing has supported the local administration by controlling the flow of mainland Chinese visiting Macao and has granted land for Macao's future expansion and offers words of advice regarding the importance of economic diversification. The truth is that the expansion of the gaming market in the territory has been spectacular since the liberalization of the industry in 2002; a market that today is the pillar of the economy and contributes the majority of government revenue. When the Portuguese first settled here, they could not imagine the proportions that gambling would have reached today.

Regardless of the abundance of opportunities to pursue, there are several challenges that the government needs to address such as the widening gap between the rich and the poor, the lack of jobs for unskilled workers and the stress of a rising inflation on low-income families; challenges that have generated much discussion and concern among the population in recent years. The government has adopted an interventionist approach to tackle these social issues. The introduction of a wealth partaking scheme is an example of postponement of social unease rather than a plan for an effective and long-lasting solution. Therein lies the challenge for the legislators to operate in a framework that has to develop the economy but also take into consideration the needs of the population. Critical issues for Macao are the lack of a qualified workforce and the development of local human resources. The government should begin to view the gaming industry as the catalyst for other types of economic activities, instead of an end in itself. Consequently, there needs to be a planning and design agenda for Macao to create the conditions where entrepreneurs can explore and pursue new opportunities in different industries, and gaming revenue could be used to develop directly or indirectly Macao's infrastructure and other forms of economic development including education and welfare. Finally, Macao should develop close relationships with cities in the region to leverage complementary strengths, and show that a small territory can not only combine casino growth with historical heritage, but also become a driving force of the economic development in South-East Asia.

The drivers of Corporate Social Responsibility in the supply chain. A case study

Maria V. Ciasullo, *mciasullo@unisa.it*
Giulia Monetta, *gmonetta@unisa.it*
University of Salerno, Italy

Abstract

Purpose: The paper studies the way in which a SME integrates CSR into its corporate strategy, the practices it puts in place and how its CSR strategies reflect on its suppliers and customers relations.

Methodology/Research limitations: A qualitative case study methodology is used. The use of a single case study limits the generalizing capacity of these findings.

Findings: The entrepreneur's ethical beliefs and value system play a fundamental role in shaping sustainable corporate strategy. Furthermore, the type of competitive strategy selected based on innovation, quality and responsibility clearly emerges both in terms of well defined management procedures and supply chain relations as a whole aimed at involving partners in the process of sustainable innovation.

Originality/value: The paper presents a SME that has devised an original innovative business model. The study pivots on the issues of innovation and eco-sustainability in a context of drivers for CRS and business ethics. These values are considered fundamental at International level; the United Nations has declared 2011 the "International Year of Forestry".

Key words: Corporate Social Responsibility, Sustainable Supply Chain, Case study.

Introduction

The Italian market of pallet production (service industry for logistics - moving, storing and transport of goods) is a sector comprising small and medium size firms collocated mainly in the North of Italy (Brenda *et al.*, 2008). Italy is the second largest manufacturer of packaging and wood pallets in Europe despite not having an adequate forestry policy. This obliges national firms to import raw materials from abroad with evident repercussions in terms of costs and higher rates of Co2 emissions in the atmosphere. Furthermore, fierce competition in terms of costs has pushed many firms to de-locate their business to low cost Countries where the environment and social agenda is just developing. Sector profitability is also threatened by the parallel market which characterized by irresponsibility on the part of some components, is resulting in inefficiency throughout the whole supply chain and inevitably, the cost is loaded onto the end consumer. In other words, despite the EUR EPAL (European Pallet Association) system, on paper a "closed circuit system", high value cost losses are recorded in terms of pallets circulating in the system (i.e. not the result of breakage or damage but on the contrary, losses or no returns) consequently, there a general increase in the administrative costs for the firms involved (Dallari & Marchet, 2010). The absence of collaboration is evident among the various stakeholders concerned who tend to place responsibility on weaker subjects who in effect, are obliged to conduct business unethically, that ends up by enriching the parallel pallet market. Firms seem to privilege processes that temporarily resolve the problem of losses as opposed to devising solutions for the supply chain as such which would eliminate inefficiency and improve the system. Naturally the result is higher management costs the negative effects of which have a domino effect on all the stakeholders of the supply chain (manufacturers, the firms that use the pallets i.e. Large Scale Distribution LSD, and logistic and repairs operators). In other words, everyone pays more by virtue of pallets leaving the conventional circuit. Finally, repercussions in terms of environmental impact deriving from the use of pallets are evident. Use implies waste (and consequently pollutants) from the transport and movement of goods, as well as from primary and secondary packaging such as cardboard, plastic boxes etc. (Marien, 1998, Bernon *et al.*, 2007).

The outcome is competition based on costs and bereft of any guarantee of the product conforming to minimum standards of quality or to a compliance model in management of the supply chain.

However, the evolution of the concept of quality towards features linked to natural factors, impact on health and the environment and not least, the social consequences of action on the part of firms have led to an alternative model emerging of competition based on values, where the emphasis on quality and sustainability is predominant both anterior to the manufacturing process and in terms of relational outcomes relative to the supply chain. In other words, in the face of a general trend towards quality as a factor of differentiation, the effective management of supply chain relations based on cooperation and transparency, represents an effective opportunity for improvement. On the basis of this premise, the paper intends to analyze how a SME operating in the pallets market, integrates CSR into its strategies, the practices it adopts and how they are transferred to the supply chain.

The basic hypothesis is that a culture oriented towards the voluntary integration of social and environmental objectives into business strategies (Perrini & Tencati, 2008) shared and part of all the members of the organization, facilitates the coordination of activities and relations both in the firm and along the supply chain, in that it represents the sap of integrity and shared loyalty and transparency capable of encouraging virtuous and synergic conduct which contributes to the creation of sustainable value. As a result, the vision of an integrated supply chain (Christopher, 1998; Walters & Lancaster, 1999; 2000) emerges, involving essentially external operators, clients or suppliers, all of whom contribute to the creation of sustainable value. In order to intensify commitment in terms of social responsibility, firms require that all the partners in the supply chain act in a socially responsible way (Miles & Munilla, 2004). The economic, social and environmental advantages deriving from firms adopting responsible behaviour surpass in effect, the range of action of any individual firm. CSR is no longer the individual company's domain; increasingly, it encompasses the entire supply chain.

Literature review:

CSR in SMEs

Corporate Social Responsibility (CSR), broadly defined as the extent to which firms voluntarily integrate social and environmental concerns into their ongoing operations and interaction with stakeholders, is becoming an important issue as both researchers and managers are well aware.

Although CSR is a well-established concept, there is no general consensus on the meaning of CSR in practice (Roberts, 2003). According to some scholars (Hill *et al.* 2003), an exact definition of CSR is elusive because beliefs and attitudes about the nature of the relationship between business and society fluctuate with the relevant issues of contingency. (Hill, 2003). Besides, company diversity in size, products, profitability, resources, social and environmental impacts. etc., are factors that make the study of CSR complex and multidimensional.

While the size of firms affects the use of CSR instruments of communication, albeit not in a structured and documented way (sunken CSR - Perrini *et al.*, 2006) a "knowledge gap" also exists (Grayson, 2005). Consequently, socially oriented behaviors of SMEs are not designed and described as "CSR action" nor classified in a specific context of CSR (Morsing, 2006; Nielsen & Thomsen, 2006). Furthermore, a different perspective is needed compared to the conventional theories, which take into account the specificities of SMEs (Spence, 1999; Tilley, 2000; Jenkins, 2004). The increased use of formal strategies and communication tools by large businesses should not lead us to underestimate the importance of informal management approaches relative to CSR used in SMEs (Luetkenhorst, 2004) and consider CSR a prerogative merely of the former (Kvåle & Olsen, 2006). "There are basic CSR issues that all SMEs have a responsibility for, amongst them the creation of a good working environment where diversity is encouraged, the fair distribution of wealth in a community, and the protection of the environment. SMEs are often portrayed badly in relation to such basic responsibilities and are frequently seen as a problem within the CSR debate" (Jenkins, 2006:3).

Thus, although the prevailing view that considers SMEs a "minor" protagonist with respect to CSR in the global arena, from an empirical perspective (Vyakarnam *et al.*, 1997, Spence, 1999; Spence & Lozano 2000; Jeurissen & Rutherford, 2000; Spence & Rutherford, 2003; Zonin *et al.*, 2004; Longo & Mura, 2005; Minoja & Romano, 2006; Mandl, 2006, Perrini & Minoja, 2008) signs that attest to sustained social and competitive creativity and Special issues of Business Ethics: a European Review (2009) are specifically addressed to CSR in SMEs.

On the whole, recent research on CSR at the SME level suggests that the drivers, outcomes and rationales underlying the adoption of socially responsible behaviour in SMEs differ significantly from what research has revealed about large enterprises (Spence & Rutherford, 2003:4).

Specific features of SMEs imply: on the one hand the centrality of ethical guidance and entrepreneur values (Vyakarnam *et al.*, 1997; Jenkins, 2006); on the other hand, the importance emerges of particular approaches to CSR, focusing on the participation of SMEs in networks (Baldarelli, 2007) and districts (Molteni *et al.*, 2006; Fugazza *et al.*, 2006, Battaglia *et al.*, 2006). For the entrepreneur the pervasiveness of ethical evaluations in business problems is fundamental, as well as assessments of the inferences in the acts of ethical choice. "In SMEs the owner-manager is both the driver and implementer of values. Managers exhibit their personal values through the exercise of managerial discretion and SMEs owner-managers have the autonomy to exercise such discretion" (Hemingway & Maclagan, 2004).

The scale of business purposes (Sciarelli, 2007) mainly refers to the entrepreneur owner, for which the link between personal and business success is closer and more visible than is realized in the context of entrepreneurship and property delegated widespread and takes the form of ethical and responsible behavior regardless of the outcome.

In this context, the first issue is the sense of belonging on the part of the entrepreneur and his being part of a community which acts as a springboard for the creation of a platform for sustainable development. Secondly, the paths based on collaboration between SMEs and institutional, local and national, public and private (local authorities, chambers of commerce, universities, research centers and training, professional and trade associations, non-profit, banks) are fundamental to the implementation of strategies and policies to draw on CSR (Spence & Schmidpeter, 2003; Lepoutre, 2006; Orskov, 2006; Maass, 2006). Finally, a third issue linked to the others, concerns the contribution of CSR in terms of increasing the social capital of SMEs (Spence *et al.*, 2003; Perrini, 2006) and participation in building the common weal in the context of the territory (Del Baldo, 2010).

Other factors typical of SMEs are: independence, versatility, prevalence of interpersonal relations (Spence, 1999). In small businesses, the transmission of values together with the streamlined organizational structure are typical of a context in which the dissemination of ethical principles occurs through the selection of human resources often with an innate ability to identify ethical dilemmas and capable of assessing the sustainability of ethical decision making rather than balancing the interests of the company concerned.

However, a knowledge gap still persists: in fact, the processes underlying the adoption of responsible managerial practices and the effects associated with them are still at the centre of intense debate; in other words, how to integrate CSR into corporate strategy remains an open question and empirical evidence is lacking (Perrini & Minoja, 2008).

All this suggests the need for further research in order to better understand the extent to which existing theoretical and empirical perspectives apply in a such a specific, still largely unexplored context represented by SMEs and family-owned firms.

CSR in supply chain

The analysis of the literature on studies of processes and practices of Supply Chain Management (SCM) (Burgess *et al.*, 2006, Li *et al.*, 2005; Robinson & Malhotra, 2005) addresses attention to the growing issue of managing relationships across the supply chain.

The increasing difficulties involved in managing networks of production and global supply, the need to propose offers consistent with and able to incorporate the knowledge of the needs and requirements of end users and related investments, have led to innovative research models aimed at enhancing relations through the joint production of value.

The relational dynamics between customers and suppliers are considered synergies to mobilize resources and organizational capacities. They create value and meet the expectations that each actor places in such collaboration. The analysis of literature, therefore, implies the need to focus on the benefits of maintaining long-term supply relationships through the development of strategic supplier partnerships, the importance of the relationship management chain for customer satisfaction and the need to measure results and performance through key performance indicators (KPI) that go well beyond those related to lower costs (Shepherd *et al.*, 2005). These studies are based on the analysis of flows and communication processes at different stages of the production chain (i.e. plan,

source, make & deliver), on the classification of different types of information exchanged between the components of supply chain practices, timing, the minimization of waste, the search for conformity between specific processes and performance measurement. On the whole, studies tend to emphasize the complexity and multidimensionality inherent in supply chain management and the benefits associated with collaboration and transparency in the setting of objectives, strategies and market mechanisms, not to mention the joint management of innovation processes and evaluation and wide range performance. There is a tendency to enhance the processes underlying the supply chain and the relative interpersonal relations. In fact, the capacity to establish close and long-term relationships with suppliers and other strategic partners has become a crucial factor in creating social value and competitive advantage; management attention has moved from competition between firms to competition between supply chains (Christopher, 2005).

The company is at the center of a system of a multi-tier relations (suppliers at the first, second,, n level and customers at the first, second, ..., n level). A strategic process of defining the essence of SCM is based on the cooperation of all actors involved in the supply chain, thus maximizing customer value as greater profitability can be achieved only through a network approach. The upstream and downstream network of relationships envisages the direct engagement of the company, while the global network including suppliers and customers involves the indirect relational system of supply chain enterprise (Slack & Lewis, 2007). In this perspective, SCM has to optimize and build links and coordination between all the actors who make up the relational supply network. According to Christopher, SCM is “the management of relationships across complex networks of companies that whilst legally independent are in reality interdependent. Successful supply chains will be those which are governed by a constant search for win/win solutions based upon mutuality and trust” (Christopher, 1998). More recently, Mentzer *et al.* (2001) defined SCM “the systemic, strategic coordination of the traditional business functions and the tactics across these business functions within a particular company and across businesses within the supply chain, for the purpose of improving the long-term performance of the individual companies and the supply chain as a whole” (Mentzer *et al.*, 2002, pag.18) and Lambert *et al.*, (2006, pag.2), as, “the integration of key business processes from end-user to original suppliers that provide products, services and information that thus add value for customers and other stakeholders”.

Nevertheless, many business scenarios tend to maintain relationships in a win/lose perspective and encourage individualistic behavior aimed at maximizing the returns in the short-term (IBM, 2009) a model, apparently successful, competitively cost-based, that exploits intensively the advantages of reducing the cost of input, the possibility of de-localization and the construction of global production networks. However, empirical evidence suggests that the best strategy is to approach suppliers through closer and more traditional methods (O'Marah, 2009). Therefore forms of participation-oriented interaction and collaboration are much needed to reinforce intangible assets of knowledge and trust (Vicari, 1995; Ghoshal & Bartlett, 1997; Vicari *et al.*, 2000; Lev, 2001; Castaldo 2002) functional to the sustainability of the relational network. Relations, knowledge and confidence are the foundations upon which the survival of a business, the sharing of values, both upstream and downstream, become prerequisites to ensure adequate capacity to respond to changing needs. Starting with a new awareness and sensibility relative to the effects of production dynamics and socio-economic and environmental balance, the literature over the past decade, has shifted towards consideration of the role and responsibility for businesses of such impacts along the supply chain.

Research on supply chain social responsibility is multidisciplinary in nature and accordingly can be found in both the purchasing, supply chain management, logistics (Andersen & Skjoett-Larsen, 2009; Carter & Jennings, 2002; Walker & Brammer, 2009) and business ethics/CSR (Kolk *et al.*, 2008; Maloni & Brown, 2006; Preuss, 2000; Roberts, 2003) literature as well as in mainstream management (Munson *et al.*, 1999; Liker & Choi, 2004; Wright *et al.*, 2007).

The literature on SMEs mainly privileges a supplier perspective (Arend & Wisner, 2005; Holmlund & Kock, 1996). However, scarce resources, greater attention to safety and product traceability, increased outsourcing of activities to developing countries and low cost countries in Central and Eastern Europe, growing concerns about social and environmental impacts of production and consumption, have all led to a renewed interest in issues related to: reverse logistics, environmental management, both green and sustainable supply chains. Reverse logistics is mainly concerned with “the role of logistics in product returns, source preserving, recycling, alternative materials, reuse of

materials, waste disposal and refurbishing, repair, and re-manufacturing” (Stock, 1998). Reverse supply chains – or closed-loop supply chains – is a term which emphasises that the management of returns cannot be limited to a single entity in the supply chain, but has to encompass the entire supply chain from end customers and back to the original suppliers of raw materials. The concepts of green and sustainable supply chains take on a more holistic systems perspective relative to the total environmental impact of the supply chain on resources and the ecological footprint (Van Hoek, 1999; Sarkis, 2003; Bowen *et al.*, 2001; Preuss, 2005). Greening initiatives include proactive “design for disassembly”, “design for re-manufacturing”, use of sustainable raw materials (e.g. recoverable wood and recycled materials), use of recoverable energy resources (solar energy, wind and wave energy), use of environmentally friendly transport modes (e.g. trains instead of trucks or airfreight), and a focus on high capacity utilization of transport modes and production facilities. In short, research shows that environmental projects will inevitably lead to successful systems offering better quality, increased performance and enhanced manufacturing capabilities to create value by reducing waste and building a reputation as a reliable relational partner (Carter & Dresner, 2001). Clearly, companies interested in production value, based on the integration of voluntary social and environmental standards higher than those required by law, tend to prefer chains based on safety, traceability, and strong partnerships with stakeholders, from suppliers to distributors to end customers. However, the analysis remains mainly theoretical and often focused on the producer-supplier dyad (Perrini *et al.*, 2010).

Research objectives and methodology

Our research was based on an in-depth analysis of the relationship between CSR and supply chains.

The paper aimed to answer the following research questions:

- How is CSR integrated into corporate strategy?
- How are CSR practices implemented and managed in a company?
- How is CSR related to supply chains?
- What are the driving forces behind the development of CSR in supply chains?
- What are the most relevant contingency factors in relation to CSR practices in supply chains?

To this end, the research was developed using a qualitative approach and a case study methodology (Yin, 1994, 2003; Fayolle, 2004). The fieldwork approach, as suggested in the literature (Adams, 2002) has the dual aim of "grasping in detail the main characteristics of phenomena being studied" and understanding the dynamics of a given process (Ryan *et al.*, 2002). The methodology – the development of a case study - represents a "research strategy that focuses on understanding the dynamics that characterize specific contexts" (Eisenhardt, 1989, p. 532). Case studies address the research questions with an emphasis on qualitative approaches and forms of ongoing research (action research) and enable the description, explanation and comprehension of business scenarios in their dynamics and evolution.

Based on a non-probabilistic technique – a technique used in case studies (Neuman, 2000) - and opting for a purposive case (i.e. the presence of particular elements and content information - Saunders *et al.*, 2003) a specific case, Palm SpA, was chosen on the basis of the following criteria:

- several years of experience of working systematically with CSR in supply chains;
- a medium-sized firm;
- a brand-owner;
- the supply system is rated as high environmental impact.

With regard to the first criterion, Palm is generally recognized as one of the most proactive companies in this specific field in Italy (Santini, 2006; Bertoli, 2008). Regarding criterion two, several empirical studies have been made to investigate how firms work with CSR-related issues in their supply chains (e.g. Carter & Jennings, 2002; Welford, 2005). Most of these studies are not only confined to large multinational corporations, but also include SMEs. Consequently, it could be argued that a growing number of SMEs “walk the talk” of CSR in their supply chains. As a brand-owner, Palm is especially vulnerable to negative publicity relative to social or environmental conditions in its supply chain. In fact, it works in an industry (wood), characterized by high critical mass in terms of social and environmental impacts. Palm may be seen as a front-runner company within the field of CSR in supply

chains in an Italian context. At the same time, it is a family-owned company of second generation and as such, not accountable to shareholders.

Thus, it may be characterized as a “unique” or “extreme” case (Eisenhardt, 1989; Pettigrew 1990). Extreme cases facilitate theory-building because, by being unusual, they can illuminate both the unusual and the typical (Patton 2002). In other words, in extreme cases, the dynamics being examined tend to be more visible than they might be in other contexts. In this sense, the history and standing that characterize Palm SpA afforded an interesting opportunity to study CSR-related processes in the supply chain.

Data collection

In line with Eisenhardt's suggestions, we combined different methods of data collection, in that ‘triangulation made possible by multiple data collection methods provides stronger substantiation of constructs and hypotheses’ (1989: 538), not only in hypothesis testing but also in theory-building research (Glaser & Strauss 1967, Yin 2003).

The analysis presented below is based on the collection of qualitative and quantitative information obtained in the course of several interviews with the entrepreneurial team conducted on the basis of semi-structured questionnaires, direct observation during visits, analysis of documents (content analysis) available on the web (company website) and printed documentary sources such as the Company's Social and Sustainability reports, brochures, educational and promotional materials.

In more detail, the sources of empirical evidence can be divided into the following categories:

Semi-structured interviews: the primary method of data collection involved a total of seven semi-structured interviews with the following organizational members: Chief Executive Officer (CEO), Product Manager - Sustainable R&D, Accreditation System Manager, Supply Chain Manager, Logistics Manager, Human Resources Manager and Head of Management Control, Quality and Safety. The interviews were non-standardized with the dual aim of ensuring high involvement on the part of the respondents and the freedom to provide non prescriptive answers and insights (Kvale, 1996). The timing of interviews ranged from half an hour to two hours, and most were tape-recorded. Whenever this was not possible, detailed field notes were taken. Interviews were based on a list of open-ended questions developed on the basis of the main research questions, such as specific initiatives and relationships with business partners.

Annual reports and other external communication tools: the Corporate code of conduct was analyzed together with the ethics Code and the Social and Environmental Reports. The corporate website, press releases and other documents intended for external communication were also analyzed.

Field observation: the company was visited between September and December 2010 in order to observe day-to-day company life;

Corporate histories and other archival material: archival searches helped track the evolution of Palm over time and at different levels of analysis.

Data analysis

After organizing and preparing the data for analysis, on the basis of grounded theory the coding process proceeded in an iterative manner relative to data and the emerging theoretical categories. Initial codes were generated by identifying statements regarding the informants' perceptions about the meaning of strategic CSR conditions. In parallel, the strategic and management processes underpinning the integrated supply chain were analyzed.

As the initial codes became consolidated across interviews, they were aggregated and moved from open to axial coding. As a general consideration, and given the selected strategy of inquiry, theory was created iteratively from observation and data, but also by comparing emerging ideas with archival data and the existing literature in order to validate the findings and to inform interpretation. The coding was carried out separately by two researchers (Silverman, 2001). A comparative analysis was put in place to discuss and resolve discrepancies. Where these differences could not be resolved easily, clarification was sought from the interviewee.

Findings

The company and its values

Palm SpA is located in a small village in the province of Mantova-North Italy. The core business is designing, manufacturing, sales, recovery and reconditioning of pallets and wood packaging used in the process of handling and transport of materials. At the end of 2010, the company employed 81 employees with an estimated turnover of more than €17 million and a total budget of approximately €13 million. Supplies are targeted at a predominantly domestic market. The sectors addressed are mainly food, ceramics, biomedical, mechanical and instrumental logistics. The company has carved out a leading role in the Italian market in the design and manufacturing of every type of pallet customized or standardized - EUR EPAL (European Pallet Association) UNI 435/2 - used for national and international trade.

The first company was founded in 1960 by Guido Barzoni (father of the present owners) who was actively engaged in the wood industry. In 1980 four brothers of the family, founded Palm. Currently, all eight brothers work in the family firm. They are examples of understanding and harmonious agreement; an evolving scenario of social cohesion and corporate core values. The attention that the company has always addressed to social issues and respect for the environment, is the direct manifestation of Christian ethics in which the family believes. In particular, their reference values are equity, social harmony and safeguarding the environment through unity, respect and care for others, collaboration, mutual support, sacrifice and work for the common weal, love and conception of life as a unique and priceless gift. "The man at the center" is the motto of the CEO Primo Barzoni who states: "In the global economy the real challenges are equity, social harmony, the preservation of the world. We must all take responsibility for the sustainable development of the land so that we, our children and future generations can continue to enjoy our heritage". The human dimension and its enhancement is also confirmed by their creating in 2003, the Non-Profit Coopers & Palm Work Project for entry into employment for disadvantaged people. Palm and the Non-Profit Organization enjoyed fruitful cooperation right from the start: Palm commissioned the service call center, the graphics, printing and binding and web marketing. The CEO says: "This partner has not been selected but is the emblem of our CSR projects. The needs of stakeholders and in this case finding a work environment that allows them personal and professional growth while respecting their "Divers-ability". In 2004, the project received the Sodalitas Award for "Best Corporate Social Responsibility initiative created by SMEs".

Therefore, the responsibility that comes from the heart of the owner family, reflects the value proposition of the company. The CEO says: "The company is actively contributing to sustainable development of the system taking care of land preservation for future generations". In this regard, the 2005-2010 plan has scheduled a social agenda business called "Business on wings" the principle of which is based on interdependence or privileging actions able to create shared value for the company and the network of its stakeholders. The search for excellence and the awareness that the competition based on ideas, knowhow and expertise are summed up in the company's corporate vision: "To develop logistic solutions using environmentally friendly packaging/pallets with a minimum carbon footprint through strategy based on the knowledge economy and Life Cycle Thinking". The guidelines stemming from the corporate vision in explicating the underlying values are reflected in the strategies and policies of the company. Such strategies and policies are aimed at: differentiating their offering in a strategic market for wooden pallets and packaging; classifying the processes research and development, developing stable and cooperative relations with suppliers and customers and, not least, safeguarding the well-being of their employees, community and territory. These aims, emerging from the analysis converging on three main points, are strictly reflected in Palm's CSR strategies.

1) Environmental protection

Environmental protection is embedded in product development strategy and concerns the study and adoption of solutions that minimizes the need for raw materials and energy in production as well as when pallets are used.

The company's clear cut Mission reads: "We at Palm promote Italian excellence in innovation with the eco sustainability and compatibility of our pallets. We aim to become a 100% sustainable company by 2020 to meet the needs of the planet". Considerable investments are made in Research and Development (R&D) to discover new ways to make products that can be recycled and to make processes safer.

In particular, it should be noted that the company (consequently and also the processes of production) is powered by "green" energy from renewable sources (wind, hydro, solar and biomass with an annual saving of 400 tons of CO₂ emissions) thanks to agreements involving a partnership: Aux De La Vallée and Life Gate Energy. In addition, Palm was the first firm to implement eco-compatible production processes and is currently a national leader in the production of wood pallets accredited with FSC-certified (Forest Stewardship Council) and PEFC (Program for Endorsement of Forest Certification Schemes). Eco-design principles, (to optimize weight and packaging volume guarantee a reduction in the use of raw materials and lower environmental impact relative to transport) together with the Life Cycle Assessment (LCA) and the Carbon Footprint (environmental reporting in terms of CO₂) supply chain (ISO 14064) and product (PAS 2050) are summed up in pallets that are eco-friendly and reflect the Palm brand (ISO 14021) an accredited and certified product. The company, in its industrial development, has always been inspired by natural cycles and committed to becoming the reference point for a new way of eco design, to reduce the carbon footprint at every stage of the life cycle of its products while also ensuring traceability and origin. This set of values and knowledge are an integral part of the voluntary certification of FSC and PEFC for good forest management; Palm also adopts the chain of custody, is regularly monitored by third parties: thus cutting and planting are undertaken in respect of biodiversity and indigenous peoples. To complete the design of environmental protection, phyto-sanitary certification conforms to the international standard IPPC FAO ISPM 15 for protecting ecosystems from the proliferation of harmful wood organisms that can result from trade with other countries in the world.

Palm's intent is to achieve a lower environmental impact than from traditional pallets that perform the same function but are unable to respond to new demands of production and consumption, ever more oriented towards sustainable lifestyles. The CEO says: "Our pallet leaves the plant with a brand that guarantees total traceability, visible to the consumer who has the right to ask how the product they are buying is packaged and delivered. Firms have to be transparent and accountable to the consumer".

Sustainability is concretized into specific actions for each stage of the production process. The first is inherent in the development of product design. The design, intended as a focus on the environment on the part of the customer (through the optimized use of raw materials, eco-design) is the hub of the virtuous cycle in which all the processes and company policy are permeated. In addition, the processes of production (based on a general purpose technology) have an intrinsic design "cradle to cradle" production approach using only materials that produce neither short nor long-term waste or waste that is not reusable; encouraging reconditioning consequently, ensures the successful and repeated use of pallets over time. The striving for continuous improvement in eco-sustainability is reflected in several innovative solutions put in place by Palm. In particular, the project developed in collaboration with universities whereby a model for the calculation and management of the Carbon Footprint of the entire Palm chain of which the pallet is part, was designed. The project, which has an entirely innovative character as the experiences of reporting and management of the Carbon Footprint at the level of industry are currently very limited, provides for the involvement of transporters and producers of raw materials PALM through working groups that have enabled common routes and shared actions. The environment variable is therefore a key parameter in the design of products and processes for the lowest possible environmental impact. The CEO says: "The management of Carbon Footprint, as a driver across the organization for the environmental sustainability of our business, leads to the development of a new vision aimed at optimizing resources, with the involvement of all people and organizations working the different levels of the supply chain". Palm received the "Business Environment 2007" award in the "Best Category Management" for the attention given to environmental issues throughout the supply chain.

Another initiative, the project "Pallet KM0" i.e. the status of eco-pallets is achieved by virtue of taking the raw material wood from the local area, in addition the product is also delivered, reused and recycled locally. Through the study of LCA "pallet KM0" Palm has certified a 46% reduction in energy consumption (used in production processes) and 50% of CO₂ emissions (relative to local wood supplies).

Finally, the idea of extending the use of eco-pallet packaging from a mere packaging tool to an item of furniture has led to the development of a second production line called Pallet Design. The waste from cutting and processing, as well as post-consumer waste, is used for the development of systems of furniture and construction developed in two product lines: Legopallet (interior décor); Ortopallet (outdoor furniture). The CEO convincingly states: "creating

low environmental impact stores which to date, have been very successful, is a motive of pride for the territory and a stimulus for involving others in the process towards sustainability”.

2) Enlightened employee policies

The quality and values embodied in the product are closely linked to the quality of employees for whom great attention is paid to increasing their level of satisfaction through: a) economic advantages such as productivity bonuses, gross premiums related to the monitoring of a range of factors such as flexibility, punctuality, work sharing, ability to work in teams, ability to solve specific problems; b) training: over 200 hours of CSR update training and c) soft advantages such as the granting of extra leave/holidays, scholarships for the children of employees, involvement in cultural and artistic events promoted in the territory, in weekly meetings involving across the board all business areas where informal ideas and opinions are exchanged and suggestions and complaints made. The continuing efforts in this area have encouraged the development of high-skills, where innovation is seen as dynamism, or the conviction that a positive state of ferment can bring out talent and know-how thanks to relations based on respect, loyalty, transparency and sharing. Active employees as defined by the CEO of Palm an "intra-preneur" where bottom-up ideas and projects start and where each employee is considered a member of a community. This naturally feeds widespread entrepreneurship motivation and commitment suitably reinforced through enlightened policies.

3) Stakeholder awareness raising

By promoting informational campaigns for national authorities, Palm aims to support policies to encourage the safeguarding of forests and stricter controls aimed at combating the illegal market of pallets. The company, through the involvement of national representative bodies (i.e. Federlegno, Assoimballaggi), has promoted a code of conduct for the industry of pallet producers in order to sustain ethics and integrity. Intensive communication is also addressed to consumers. In this case, the purpose is to raise awareness on issues of environmental preservation and the dangers associated with the improper use of natural resources as well as to guide the choice towards eco-friendly products (food and non food) guaranteed to improve traceability. To this end, Palm is willing to share the costs of marketing campaigns realized in co-operation with its customers. Finally, many events (i.e. conferences, meetings, etc.) are organized directly by the company to educate and raise awareness in school children relative to the importance and respect for natural resources.

Managing supplier relationships

Accredited suppliers are based in North Palm Europe (60%) and Eastern Europe (10%) Italy (30%). Palm is the first company in Europe to promote and to implement a supply chain in which the identification and selection of suppliers is based on compliance with the specifications for the proper sustainable management of forests and forestry programs under the criteria of the FSC and PEFC.

Palm has put in place a strategy of going from “trading to purchasing”. The strategy implies that instead of engaging in short-term relationships with many smaller suppliers, Palm is increasingly engaging in long-term relationships with fewer suppliers. Since Palm puts so much effort into attention to its suppliers, the selection criteria are quite stringent:

- The wood must come from forests that are managed responsibly in accordance with the principles of managed forest (no wood from intact natural forests or high conservation value forests);
- The wood must be worked in factories (sawmills) where social and working conditions are respected and where work processes are achieved through the use of renewable sources. Suppliers are required to provide information on how they minimize their environmental impacts, and whether they have CSR plans for the future;
- The technical requirements of semi-finished products, and enterprise management systems must be certified by organizations through accredited institutions, the suppliers must guarantee not only the origin of wood, but also its identification at every stage of processing (chain of custody);
- Risk Assessment aimed at identifying potential suppliers to adopt sustainable behavior. New suppliers are required to complete a self assessment questionnaire and detailed analysis according to a predetermined weighted analysis of areas of vulnerability. Suppliers are not de-listed as a result of initial non compliance but a program of corrective action is agreed and monitored;

- Suppliers must share the values and business objectives in terms of sustainable development at the basis of the realization of the concept of the product. In other words, this philosophy of environmental sustainability for Palm is not an additional element but must be consistent with the behavioral aspects of providers in order to avoid dangerous situations of "green washing" the effects of which backfire not only on Palm, but also on Palm's customers, on customer accounts, and follow on to the end consumer.

Another main difference between the trading and purchasing strategy is Palm's way of relating to suppliers. Whereas the Company previously demanded a certain level of quality, service, price and environmental and social responsibility of its suppliers, the state of the art is that Palm is now developing these issues together with the suppliers. The purchasing manager says: "our supply chain strategy ensures security of supply and is linked to: foresters, sawmills, logistic operators and customers. Its success is based on efficient, well invested and innovative suppliers and the ability to take a long term view. Collaboration is the key to achieving our goal. Establishing a supply chain involves engaging in every stage of the process from: wood cutting, industrial manufacturing and logistics". Moreover, the company works with suppliers on quality as well as environmental and social issues. In fact, Palm offers formal training to suppliers in order to improve their understanding of the way Palm conducts its business, including its emphasis on environmental and social issues. Palm has developed a code of conduct related to its suppliers. It defines what suppliers can expect from Palm, and what Palm requires from its suppliers. In particular, it envisages a system of supplier management integrated with Palm's management control system to check the reliability of the process. Through periodic forums with suppliers, progress and improvement goals are discussed and joint action plans defined. Furthermore, Palm establishes a direct relationship with suppliers: they are visited by members of the purchasing teams approximately once a week and the implementation process can therefore be followed on a continuous basis. During their visits, the purchasing teams also offer more informal social and environmental training. In a continuous development process aiming to bring local suppliers to still higher levels of performance in cooperation with Palm, the CEO believes that "thanks to systematic collaboration with our partners we have achieved more sustainable practices and transparency and traceability throughout the supply chain".

Palm and local producers

Since 2000, Palm has embarked on a path of integration with suppliers. Strongly opposed to illegal logging, it has actively intervened in the first link in the chain supporting various national forest owners to implement sustainable management of forests, appropriate and consistent with the principles of FSC and PEFC. Numerous sector agreements have been concluded with various municipalities where national Palm is at the service of domestic producers in the thirty years of experience supporting the implementation of the same chain of custody of wood raw material. In addition, through advance payments, Palm also provides the necessary assets to facilitate the certification process (payment at sight/payments total 30%). To date, furthermore, Palm has adopted 1200 national hectares of poplar plantations. The active role played by Palm in the chain of supply, has stimulated the development of local agriculture with obvious benefits in terms of job creation, favoring a reduction of environmental impact from the transport of timber thanks to raw material obtained from areas adjacent to the company and also the avoidance of social costs related to the unfair exploitation of the workforce in low cost countries.

In general, the working relationships that Palm has with suppliers, in a relational logic of transparency, allows better distribution of costs throughout the supply chain, recognition of added value generated in each step of the supply chain, ensuring stability, security and sharing of profits. This choice is confirmed by the low turnover of the suppliers, analyzed over a ten-year period (2000-2010), where the highest rate of decrease evidenced in the period 2004-2005 (14%) stabilized at 5% in subsequent years.

Customer Compliance in reverse logistics

Palm's approach to sustainability involves the logistics and distribution system in a logic of ongoing enhancement of the services provided to clients. A permanent process of innovation has made it possible to develop a logistics system capable of combining efficiency (savings of direct costs); reducing the impact on the environment through green transport (use of bio-based fuels), and at the same time, meeting the needs of customers (i.e. timeliness,

reliability, punctuality, conformity). The transport of pallets is scheduled through a special software based on RFID technology. This streamlines and optimizes loads, reduces the weight/volume of pallets up to 23% and, consequently, by reducing transport, CO2 emissions are limited as well as additional costs for the customer. In addition, the information system ensures the traceability and accountability of each pallet identified by specific codes (bar code and RFID tag). Stock control procedures are also firmly in place. Finally, with the certified maximum pallet load capacity (UNI EN ISO 8611), safety measures (i.e. prevention of accidents) is ensured. In other words, knowing the pallet load capacity enables the logistics staff to safely carry out all the operational phases. Palm's ability to respond to customer needs, developing customized logistics solutions, based on an analysis of the peculiarities inherent in the processes of handling and storing pallets for the customer, has proceeded with the engineering and eco-sustainable industrialization of the product. With the majority of customers, 80% of turnover, is achieved by projects in which the packaging is integrated in the firm's client production cycles. In other words, projects are envisaged in the sense of functional tools to improve the whole supply chain for customers, to identify critical areas and for the creation of highly customized solutions.

In this respect, the CEO says: "The customer represents an active partner in a relationship that contributes to the growth of supply and hence the pattern of consumption and production that follows". The focus on transparency and fairness to the customer are summed up in the Service Charter endorsed by the company where formal commitment to the provision of services in addition to the sale of the pallets is guaranteed.

Besides logistics, Palm's reverse logistics platform (certified by independent accrediting bodies) recovers, reconditions and reuses pallets and disposes of non-reusable pallets. The platform not only cleans and sanitizes the eco-designed pallets used by the pallet company, but the whole park of pallets used by their customers. Even in the case of products in the circuit and returned recyclable pallets, Palm is in a position of accountability to its customers for the CO2 emitted as a result of reprocessing. The recycled pallets, in fact, are certified by ICEA (European Institute for Ethical and Environmental Certification) and reused under a certified label. For this initiative, Palm was awarded the "Sodalitas Social Award" 2010, for the category: "Innovative Products and Services". The project envisaged a label for sustainability, transparency and accountability and the communicating of informed environmental safeguarding relative to the use of the product.

The company through constant awareness and customer commitment, seeks to implement an "endless recycling process" encouraging the implementation of closed loop systems, and favoring an exchange of pallets in real time (in order to prevent vehicles travelling empty). It is obvious in this respect, the role played by customers becomes crucial in facilitating and ensuring the return process. The awareness that this commitment benefits both customer and company as well as the environment, is manifest and that the cornerstones underpinning such commitment are interaction, respect for customers, transparency, communication and information. Moreover, Palm's firm intention to create a closed loop system has resulted in a changed relationship with customers who are now strongly supported also in managerial and operational activities.

An intranet network has also been created to facilitate interaction between Palm, logistic operators and customers. The network envisages constant information flow control in real time, the consultation of reports and other useful documents, frequently asked questions (FAQs), etc.

From an eco-sustainable economic perspective, to date, Palm has recovered and reclaimed about 60% of eco-pallets sold.

A case in point concerns the synergistic and virtuous collaboration with Sterilgarda Foods, its supplier Tetrapak (world leader in the design and manufacture of food containers) and Palm. Through careful monitoring of production processes at Sterilgarda, Palm, collecting and buying up all the used pallets from the Sterilgarda plant, was able to regenerate and sanitize the pallets before reselling them to Tetrapak to put back into circulation for reuse.

The value network

In 2004, Palm promoted the project "Network Business friendly environment" (www.ecofriends.it). As their CEO states: "the scheme originated with the intent to accelerate the creation of a fair and ethical sustainable economy by

devising a relational and social platform for collaboration between firms which have set themselves the remit of responsibility for future generations”.

As an association, the network involves not only stakeholders of the supply chain linked to Palm as suppliers and customers, but aims to join other business scenarios (i.e. Sabox, Tetrapak) which, albeit belonging to completely different sectors, are particularly sensitive towards environmental sustainability issues. The objective therefore, was to pursue sustainable development by means of shared values and best practices. The associates in the network are recognized by the label “Business friendly environment”. Furthermore, they are members of the association of private and public institutes of research (Altis, national universities, etc.) national and international associations engaged in environmental business competition the Planet Life Economy Foundation). Finally in support of the Association, as its scientific research partner, is the international network denominated The Natural Step.

The firms in the network participate in or benefit from training workshops and environmental and sustainability consultancies; furthermore, the network shares information online relative to individual associations through their web site, guaranteeing ethical exchange of data. By consulting www.ecofriends.it the various players in the supply network, as routine practice, circulate and share information, knowhow and expertise developing jointly, new ideas and new knowledge, in order to increase the potential creation of value of the members of the community network. As a result, sequential relations are substituted by widespread reciprocal relations founded on an ethical vision capable of promoting the common weal. The network in effect, has enabled a series of cross-fertilization activities involving not only local firms supplying the national market but also large scale Italian and non-Italian firms supplying international markets (e.g. Mapei, Rolland, Stora Enso).

Discussion and conclusions

The purpose of the paper was to analyse the way in which a specific SME integrates CSR into its corporate strategy, which practices it puts in place and how its CSR strategies reflect on its suppliers and customers relations.

The research also helped to clarify the conditions and preconditions leading to a family-owned SME to embark on a corporate strategy approach to social responsibility.

In particular, responsible corporate strategy appears to be the result of a system of embedded values and beliefs on the part of the owners substantiated in the following features:

1. deep-rooted sense of belonging to the territory in terms of cultural and religious identity, but at the same time, readiness for change;
2. sharing of values and harmony characterizing the team owners;
3. person centric and respect for human rights as universal values, regardless of differences in timescales and space;
4. the values of firm ownership through the identification of clear vision and mission.

This system of values in terms of strategic orientation (Freeman & Gilbert, 1988, Hamel & Prahalad, 1989), converges on a set of issues designed to ensure maximum reliability and safety in relation to environmental protection, dialogue with stakeholders, skill and knowledge development and not least, responsible citizenship.

The historic link with the territory and the desire and determination to preserve a trademark of market value, within a industry in which this element has never been a variable of differentiation, were built and consolidated through a strategy characterized by multiple actions to increase reputation and reliability in the eyes of the firm’s stakeholders. In particular, an approach to product differentiation, based on high standards of quality and sustainability of the offer made through a process of continuous innovation and supported by a system of voluntary certification was made possible thanks to expertise, knowhow and specific human resources skills. The constant attention paid to the care of employees has naturally fuelled motivation and commitment. Furthermore, the company's explicit reference of value, vision and mission on which their corporate strategy is based, has enhanced employee awareness and reciprocal commitment. These resources are valuable and difficult to imitate and transfer (Grant, 2002). Not only do they require huge investments in the industry they also imply incorporated individual experience and learning over a long period of time. In addition, the particular competitive strategy adopted by Palm has demanded a management model that is closely integrated with the supplier and customer. The constant attention to relations, through

appropriate mechanisms for cooperation and coordination and reinforced by appropriate communication tools, has enabled greater sharing of values along the chain, resulting in specific knowledge-transfer processes.

In terms of the company-supplier relationship, the path pursued and integrated through stringent selection criteria and by means of ongoing dialogue, aims at increasing involvement and ensuring greater customer loyalty. In addition, the company organizes regular forums with suppliers, ensuring transparency in their relationships, as a source of enhancement for them not only to share and meet specific demands but also to improve their skills and experience to use in other relational contexts.

In terms of distribution, the value of the proposal bid is further supported through the development of stable and lasting relations based on the social quality of the products, trust and loyalty. The sharing of objectives, the result of highly customized solutions, is pursued through the joint management of issues in environmental, safety and ethical values. Long-lasting collaboration and constant dialogue facilitate the devising of initiatives for ensuring better management of sustainable value creation (i.e. reverse logistics).

Therefore, both upstream as downstream, the company in a strong spirit of commitment seeks to raise the overall level of trust relationships. The awareness of the strength of the network and its capacity as a tool to achieve sustainable development, were the reasons that led Palm to create the Association "Business friendly environment" (www.ecofriends.it). The circuit, powered by open flow of communication and information sharing, facilitates the exchange of ethics and encourages cross-fertilization of data aimed at a better value creation, which in turn, reinforces and increases the level of cooperation, reducing conflict.

Findings from case studies cannot be subject to statistical generalization or theory-testing, but case studies can be used to generate theoretical constructs, propositions and/or midrange theories (Eisenhardt, 1989; Yin, 2003). Thus, although the study is a first step towards achieving a more robust understanding of the relationship between the integration of CSR into corporate strategy and its repercussions across the supply chain, Palm exemplifies a type of enterprise a "business to business" medium-sized family owned firm in which, through well defined procedures and supply chain management relations as a whole, involves partners in the process of sustainable innovation. In other words, the research findings show a strong leaning towards a sustainable strategy the pillars of which are focused on engagement and cooperation on the part of its partners in order to facilitate the innovation process.

In short, the findings offer a variety of stimuli and many implications for further research in terms of responsible supply chain management; in particular, as concerns the innovative a process of simplification relative to the production chain (short chain), designed to promote eco-sustainability. In conclusion, the case study could inspire other companies to follow this eco-logical path and potentially facilitate the identifying of innovative factors for sustainable development.

A Content Analysis of Whistleblowing Policies In Indian IT Sector Companies

Madhusree Mukherjee, madh.mukh@yahoo.co.in
Madhu Agnihotri (Agarwal), madhu.cal@gmail.com
St.Xavier's College, Kolkata, India

Abstract

The Sarbanes-Oxley Act 2002 in the U.S. has upheld the status of 'whistleblowing' in the context of effective corporate governance throughout the globe. Institutionalized whistleblowing in the form of internal policies and code of conduct etc. generated far reaching effects to ensure better governance in the corporate sector of the developing nations. Not enough research reports are available on such policies and their repercussions in Indian industries till date. This study, therefore, addresses the following research question: What is the exact nature of institutionalized whistleblowing policy prevailing in Indian private sector industries in the background of the current framework of corporate governance in the country?

It concentrates on the Indian IT service companies in the private sector, as they are reputed for their "best practices" among the stakeholders worldwide. A content analysis is made by the classification of internal policies and codes of conduct available from top ten IT companies into several categories to make systematic and objective inferences. The study observes that this sector has shown proactive initiatives in this direction. This is expected to create an enabling environment for other private sector operators to replicate such internal system to ensure better governance within.

Introduction

On January 7, 2009 morning, India Inc. woke up at the news of a financial tsunami to the proportion of an Enron-like accounting scam in the Satyam Computers, winner of the much-coveted Golden Peacock Award for Corporate Governance under Risk Management and Compliance Issues in year 2008. The Chairman Ramalinga Raju had resigned from the Board of Satyam Computers by giving a notice to the Securities and Exchange Board of India (SEBI) confessing a severe falsification of Satyam's accounts for the year ended on 30th September 2008. It included, among others, the understatement of liabilities in the balance sheet to the extent of US \$ 1.19 billion and a misstatement of an accrued interest of US \$ 83.47 million, which was totally non-existent. There was a sharp reaction in the global stock markets with the New York Stock Exchange immediately halting trading in Satyam stocks and India's National Stock Exchange removing its stocks from the S&P CNX Nifty 50-share Index. The revelations put the credibility of Indian IT industry at stake.

According to the newspaper reports [The Economic Times, April 17, 2009], the confessions made by B Ramalinga Raju was prompted by a whistleblower action. It states that a former senior executive in the company, involved with its contract with the World Bank, acting as the whistleblower, sent an email to one of the Satyam board members that led to the chain of events culminating into the confession. It is also learnt that the company had an internal 'Whistleblower Policy' since 2005 (The Financial Express, March 2008). This case has triggered the question of the effectiveness of institutionalized whistleblowing mechanism in an Indian company in general, and the IT sector company in particular.

The popular definition of 'Whistleblowing' as given by Miceli & Near (1992) is the disclosure by the organizational members (former or current) of illegal, immoral or illegitimate practices under the control of their employers, to persons or organizations that may be able to effect action. Jubb's (1999) is a more explicit definition as he relates it to the act of dissent of an employee, which publicly implicates a company by disclosing wrongdoings externally.

Whistle blowing activities thus affect the image of a company adversely in the marketplace. As such, a number of companies in the U.S. have adopted internal whistleblowing policies, whereby the problems can be solved within. This is termed as the 'institutionalised whistle blowing'. According to Vanderkerckhove and Commers (2004), institutionalized whistleblowing refers to the set of procedure allowing potential whistleblowers to raise the matter internally before they become whistleblowers in the strict sense of the term.

During the post-Enron period, the famous Sarbanes-Oxley Act 2002 (SOX) has played a pivotal role to uphold the significance of institutionalized whistleblowing in the arena of corporate governance of publicly traded companies in the US. Section 301 of SOX requires: "each audit committee shall establish procedures for the receipt, retention, and treatment of complaints received by the issuer regarding accounting, internal accounting control, or auditing matters; and the confidential, anonymous submission by employees of the issuer of concerns regarding questionable accounting or auditing matters". Thus, the Act followed by a number of European laws and codes of corporate governance called for institutionalised whistleblowing policies and offered legal protection to the whistleblowers in the U.S. and Europe (Harold Hassink et al 2007). Such regulatory mandates have consequently influenced the whistleblowing behavior of employees within the organizations in the West.

Defining the Research Problem

In this backdrop, this study explores into the Indian corporate governance scenario to inquire into the status of internal whistleblowing mechanism, if any, existing in Indian companies. To narrow down the study and in view of the Satyam scandal as elaborated above, it selects the IT sector industries operating in the private arena for investigation. The Indian IT sector firms are global service providers and are generally acclaimed for their "best practices" throughout the globe. Many of them are enlisted with a number of stock exchanges, domestic and global, including NYSE and NASDAQ.

The research problem addressed here is therefore: What is the exact nature of institutionalized whistleblowing policy prevailing in Indian IT industries operating in the private sector in the background of the current framework of corporate governance in India? To find an answer to the above question, the study first goes for a literature review to examine the global studies as against the studies made in India. It then enquires into the prevailing corporate governance codes and their legal implications in the country. Finally, it goes for a 'content analysis' of the available whistleblower policies in the IT sector to ultimately make systematic and objective inferences.

Literature Survey

According to Hassink, Varies and Bollen (2007), there are five factors influencing the likelihood of whistleblowing actions – psychological factors, cultural and ethical factors, structural factors, retaliation and type of wrongdoing. Of the above, the present study looks into the structural factors including policies and regulations concerning whistleblowing, Near et al (1993) recommended in favour of corporate whistleblowing policies, facilitation the internal reporting of suspicious behavior. It shields the company from external whistleblowing, which in general is considered to be detrimental to all the groups, including the company, the whistleblowers (Callahan & Collins 1992) and society at large (Dworkin & Near 1997).

The empirical study made by Barnett et al (1993) showed that companies with internal whistleblowing procedures experience a significant decrease in the number of external disclosures after implementation as well as a significant increase in the number of internal disclosures. Lewis (1997) recommended it on the ground that internal reporting procedures are perceived by the managers as contributing to their image as both ethical and efficient organizations. In general, therefore, (Vanderkerckhove & Commers 2004) from an ethical and a practical view points, increased role of internal whistle blowing is preferred over external whistleblowing.

Schmidt (2005) argues in favour of internal whistleblowing as it helps avoid hesitant effects on organizational efficiency as well as binds the interests of an organisation's managers and its stakeholders. It ultimately makes use of self-regulation via governance code of conduct and flexible sanctioning.

The above studies establish the role played by the institutionalized whistleblowing worldwide. Such understanding necessitates a further in-depth analysis of the contents of the existing whistleblowing policies. In this context, two studies have been consulted. One is done by Lugli et al (2009) on the code of ethics of Italian companies quoted on the Italian Stock Exchange. The content analysis of the available codes was done to map out the main principles followed in writing the companies' code of ethics in the country. The other research on the same line was done by Hassink et al (2007), where the contents of whistleblower policies and parts of corporate codes of conducts and codes of ethics of 56 leading European companies were analyzed to create an exploratory framework. The present study finds the last one more relevant to replicate the same in Indian corporate scenario.

Objective and Scope of the Study

The literature review reveals the fact that no authentic research reports are available on such policies and their repercussions in Indian industries till date. Only one study is found to be made on whistleblowing in relation to India, where Keenan (2002) compares Indian managers with Americans on whistleblowing. He finds no significant difference between the two with respect to both organisational propensity for whistleblowing or fear of retaliation. The only difference he observes is in American managers having stronger personal propensity for whistleblowing than their Indian counterparts.

The study appears to be inadequate in terms of its sample size as well as the depth of the investigation. There seems to be a gap in the critical understanding of the Indian socio-legal factors which ultimately moderate people's whistleblowing behaviour. The present study therefore finds a deficiency in this field of study. It therefore attempts to address the following research questions:

1. What is the current status of 'institutionalised whistleblowing' in Indian corporate governance framework?
2. In the background of the above, what is the exact nature of institutionalised whistleblowing in the private sector industries in India?

Among the private sector players, this study concentrates on the Indian IT sector companies. For this purpose, it selects top 10 IT sector companies in India, as rated by NASSCOM (2008-'09) – National Association of Software & Services Companies - the premier organization setting the tone for public policy for the Indian software industry.

The present study therefore looks into the contemporary legal environment in India to ascertain the framework of corporate governance prevailing in the country. It then proceeds to make a content analysis of the available 'whistleblower policies' to make a qualitative assessment of the same in terms of their effectiveness. This study is expected to show results which will have practical relevance for the Indian companies to benchmark themselves as against the global firms.

Contemporary Framework of Corporate Governance encouraging Whistleblowing in India

The Public Interest Disclosure (Protection of Informers) Bill drafted by a former Supreme Court judge, Justice B P Jeevan Reddy in December 2001 as the Chairman of the Law Commission of India is known to be the first-ever attempt to give any protection to the whistle-blowers in the country. The former Supreme Court Judge suggested a number of measures to encourage and protect the whistle-blowers. (www.skdubeyfoundation.org/files/indianwhistleblowersact_179rptp2.pdf). The basic premise of the Bill as suggested by Justice Reddy was: "No corruption takes place without somebody somewhere coming to know about it. Hence are the measures to encourage and protect the whistle-blowers" (www.newindiaexpress.com dated 18th April 2004). This Bill, however, is now lying in cold storage.

The post-Enron Attempt: The Narayana Murthy Committee Report on Corporate Governance (www.sebi.gov.in/commreport/clause49.html):

The Sarbanes-Oxley Act 2002 (Sarbanes_Oxley_Act_of_2002.pdf.) in the US made exhaustive provisions to bring back the credibility of the corporations in society and give a boost to the investors' confidence during the post-Enron era. It gave special protection to the whistleblowers in publicly traded companies (Sec. 806 of the Sarbanes-Oxley Act of 2002).

The Narayana Murthy Committee on Corporate Governance 2003 formed under the aegis of the Securities Exchange Board of India (SEBI), followed the footsteps of the SOX Act of the US by adapting and incorporating whistle-blowing mechanisms for the employees of listed companies of India in its recommendations. This was a revolutionary attempt wherein the Indian capital market regulator, the SEBI, through its listing agreement, has been required to empower one of the important stakeholders of the listed companies - the employees. The recommendations are as follows (Recommendation 3.11: Whistleblowers Policy: Report of the SEBI Committee on Corporate Governance, India, submitted in Feb.2003):

- Personnel who observe an *unethical or improper practice (not necessarily a violation of law)* should be able to approach the *audit committee without necessarily informing their supervisors*.
- Companies shall take measures to ensure that this right of access is *communicated to all employees* through means of internal circulars etc. The employment and other personnel policies of the company shall *contain provisions protecting "whistle blowers" from unfair termination and other unfair prejudicial employment practices*.
- Companies shall *annually affirm that they have not denied any personal access to the audit committee of the company* (in respect of matters involving alleged misconduct) and that they have *provided protection to "whistle blowers" from unfair termination and other unfair or prejudicial employment practices*.
- Such affirmation shall form *a part of the Board Report on Corporate Governance* required to be prepared and submitted together with the annual report.
- The *appointment, removal and terms of remuneration of the Chief internal auditor* must be subject to review by *the Audit Committee*.

Corporate governance Requirement under Clause 49 of the Listing Agreement as designed by the Securities Exchange Board of India (SEBI):

On the basis of the above Report, Clause 49 of the Listing Agreement (Corporate Governance requirements) was amended in September 2003. The amendment initially required all listed companies to include Clause 49(iv) Whistle Blower Policy as mandatory information in the Report on Corporate Governance in the Annual Report of the company (www.sebi.gov.in).

SEBI, the apex capital market regulator in the country, however, in a master Circular issued in October 2004 (no. SEBI/CFD/DIL/CG/1/2004/12/10 dated Oct.29, 2004), withdrew the previous announcement and offered the status of a non-mandatory clause to the Whistleblower Policy. Such a revision (www.bseindia.com/cirbrief/notices.asp), which is still in force, requires that:

The company *may* establish a mechanism for employees to report to the management concerns about unethical behaviour, actual or suspected fraud or violation of the company's code of conduct or ethics policy. This mechanism could also provide for adequate safeguards against victimization of employees who avail of the mechanism and also provide for direct access to the chairman of the audit committee in exceptional cases. Once established, the existence of the mechanism may be appropriately communicated within the organization.

Other Recent Developments:

The Central Vigilance Commission Act, 2003 has been enacted under the Ministry of Law & Justice to empower the CVC to inquire into offences alleged to have been committed by the public servants in the public sector enterprises (PSEs) . The Right to Information Act, 2005 (RTI) is another piece of legislation to contain corruption

and to hold Governments and their instrumentalities accountable to the governed (http://commerce.nic.in/rti/rti_first.htm). These are, however, meant for the public sector companies and are not binding on the private sector industries in India.

The Public Interest Disclosure (Protection Of Informers) Bill, 2010 has recently received the approval of the Union Cabinet. It seeks to protect the identity of those exposing corruption and scams, officially called the Public Interest Disclosure (Protection of Informers) Bill, 2010. The Bill will now be tabled in Parliament and if passed and signed by the President, it will become an Act [Ibnlive.com as retrieved on 25 march, 2011]. The private sector industries are, however, not covered under this Bill.

The legal ambience in India as outlined above does not provide an encouraging picture for the potential whistleblowers in the country, especially in the private sector. Apart from the clause 49 of the Listing Agreement non-mandatory requirement, there is none other till date. As such, we cannot expect the private sector players, the IT sector in particular, in our context, to show much enthusiasm in this direction, excepting the global standard requirements, where they need to score in the level playing field with others.

With this background of corporate governance framework, we now proceed to investigate the initiatives taken in the Indian IT sector in terms of their whistleblowing policy (WB Policy). We take resort to the qualitative technique of 'content analysis' for this purpose.

The Content Analysis

This study follows the model designed by Hassink et al (2007). However, for practical purposes, the model has been modified and adapted in consonance with the situations prevailing in India.

Sample collection

The primary research population of this study is the private sector industries in India featuring the IT sector companies with business world-wide. The sample has been collected from the NASSCOM (the apex body monitoring the IT sector industries in India) Survey Report of 2008-2009 during the early phase of July, 2010 (<http://www.mphasis.com/news/newsroom/NasscomIndustryRankingFY08-09.html>). The Report provides the list of top 10 IT services exporters in India, where IT service exporters include IT services, engineering services, software products and offshore product development revenues. Ranking by NASSCOM is based on companies that have submitted the detailed form and does not include some companies whose revised audited results are not available. Also the list excludes some companies whose corporate head quarters are located outside India, but have significant India-centric delivery capabilities, as they have not shared their India-centric revenue figures.

The following process was then followed:

- i) The company website links were searched to find out the whistle blowing policy and code of conduct of the aforesaid ten companies.
- ii) For four companies, Whistle Blowing (WB) policy was readily available from company website. Two more WB policy documents were retrieved later from two other websites not directly related to the company websites (<http://www.secinfo.com/dr6nd.22dt.6.html> as retrieved on September 30, 2010).
- iii) For three of the remaining four companies, the WB policy document was not directly available. But the policy name was used in the company websites, while describing the code of conduct for the employees. For one of the ten companies, neither the WB policy nor the code of conduct / ethics was available.
- iv) Attempts were then made to retrieve the company contact information (email-id and phone number) in all cases, so that they can also be approached for interview and other relevant communications.
- v) Out of 10 companies, the required information was retrieved for 9 companies from their respective websites. For the remaining one company, no information was available.

Empirical studies

A questionnaire was prepared for interviewing the HR managers of the companies (5 in number) whose offices are situated in Kolkata. The questionnaire started with three basic enquiries:

1. Is your company listed? If yes, with which stock exchange?
2. Does your company have an explicit Whistle blower Policy?
3. If so, could you please provide us with a copy of the same for study?

The communication proceeded in the following lines:

1. Emails were sent to nine companies, excepting the one, no information of which was available in the net. None of the companies did respond to the emails.
2. Next was, therefore, the attempt to contact the nine companies through phone calls. Six companies agreed for interview. One of the companies declined to meet for interview or to share information. Remaining two did not respond at all.
3. Of the above, five having their company offices in Kolkata, were visited. Interviews could be arranged only with two companies, while other three, even after multiple visits, were unable to spare time for the meet. These two companies, where interview was conducted, however declined to hand over the WB policy document. One company (situated outside Kolkata), which initially agreed for telephonic interview, later on declined.

Hence, the sample collection findings can be **summarized** as follows:

- a) 40% of the companies display the WB Policy document on company website.
- b) 20% of the companies WB Policy documents are retrieved from websites, other than company website.
- c) 40% of the companies do not have WB Policy available in the website; these are, however, covered in their

Code of Conduct /Ethics.

- d) 90% of the companies display the Code of Conduct and/or Code of Ethics on company website.
- e) 10% of the companies do not share any data.

TABLE I: SAMPLE COLLECTION

Total No. of companies selected		10
Total WB documents required		10
Total Code of Conduct/Ethics document required		10
Total documents required		20
WB Policy		
No. of WB Policy collected from company websites	4	
No. of WB Policy collected from other websites	2	
No. of WB Policy unavailable on internet	4	
WB Policy collection rate (6/10)		60.00%
Code of Conduct/Ethics		
No. of Code of Conduct/Ethics document available from company websites	9	
Not available in the website	1	
Code of Conduct/Ethics document collection rate (9/10)		90.00%
Email		
No. of Email searched for companies	10	
Email id unavailable	1	
Email id available	9	
Email sent to company	9	
Email Response Rate (0/9)		0.00%
Phone Calls		
Phone contact searched for companies	10	
Phone contact available	9	
Phone contacts made	9	
Companies situated in Kolkata contacted through phone	5	

Companies outside Kolkata contacted through phone	4	
Companies not responded	2	
Response received	7	
Phone call response rate (7/9)		77.78%
Office Visit		
No. of companies visited in Kolkata for interview	5	
No. of companies cannot be visited due to offices not in Kolkata	5	
Total companies visited for interview(5/10)		50.00%
Interview		
No. of companies in Kolkata allowed interview	2	
No. of companies in Kolkata declined interview	3	
No. of companies outside Kolkata refused to give telephonic interview	2	
Useful interview rate(2/7)		28.57%

Empirical results

The available policies and codes were now analysed for their contents. The range of information gathered from the policies and the codes was classified into six groups of items:

1. General Contents, Scope & Tone
2. Nature of violations as mentioned in the policy for being reported
3. Reporting guidelines and formalities
4. Details concerning confidentiality and anonymity
5. Details concerning protection from retaliation
6. Details about the investigation of the complaint

It is to be noted here, that although the study tries to replicate the format of content analysis as done by Hassink et al (2007), the design has to be changed in the context of Indian situation. All empirical findings are summarized in table II.

Sample classification :

Initially the sample size was 10. But since no information is available for one out of 10, we take n = 9. This is further divided into two sub-groups:

1. Specific WB policy documents (for 6 companies) – **Sub-sample I**
2. WB Policy clause in Corporate Code of Conduct / Ethics (for 3 companies) – **Sub-sample II**

TABLE II: CONTENT ANALYSIS

Sl. No.	Description	Total Sample (n=9)	Sub-sample I (n=6)	Sub-sample II (n=3)
I	General contents, scope and tone			
	a. Listed companies with one or more stock exchanges	88.89%	100.00%	66.67%
	b. Compliance with national rules/regulations explicitly mentioned	88.89%	83.33%	100.00%
	c. Compliance with international rules/regulations explicitly mentioned	55.56%	33.33%	100.00%
	d. Motivation being the overall development including goodwill, work culture and standardization	100.00%	100.00%	100.00%
	e. Employees are explicitly encouraged to report	44.44%	50.00%	33.33%
	f. Reporting is a requirement/duty	55.56%	50.00%	66.67%
	g. Formed committees explicitly for listening whistle blowers	22.22%	33.33%	0.00%
	h. Audit committees, CS and/or Chief Compliance Officers listen to whistle blowers	55.56%	66.67%	33.33%
	i. Companies having single policy applicable to all employees under the	100.00%	100.00%	100.00%

	Group / Company.			
	j. Financial issues handled under the same policy	88.89%	83.33%	100.00%
	k. Allowing explicitly ex-employees to blow the whistle	11.11%	16.67%	0.00%
	l. Included a full secondary procedure with secondary contact details	11.11%	16.67%	0.00%
	m. Stated any result of the policy	0.00%	0.00%	0.00%
II	Nature of violations to be reported			
	a. Issues under the purview of WB policy mentioned explicitly:-			
	i> Financial reporting matters	77.78%	83.33%	66.67%
	ii> Legal violations(Civil/Criminal)	88.89%	83.33%	100.00%
	iii> Health/Hygiene guidelines violations	66.67%	50.00%	100.00%
	iv> National environment related laws(applicable laws)	44.44%	16.67%	100.00%
	v> Safety/Security infrastructure threats/damages	66.67%	50.00%	100.00%
	vi> Corruption	88.89%	83.33%	100.00%
	vii> Mismanagement	88.89%	83.33%	100.00%
	viii> Abuse of authority	88.89%	83.33%	100.00%
	ix> Conveying wrong/manipulated information intentionally	88.89%	83.33%	100.00%
	x> Insider trading, bribery or money laundering	88.89%	83.33%	100.00%
	xi> Fraudulent practices by third parties like suppliers or vendors	33.33%	50.00%	0.00%
	xii> Social misconduct	88.89%	83.33%	100.00%
	xiii> Unethical business conduct	77.78%	66.67%	100.00%
	b. General statement stating any unethical or improper activity shall be reported	44.44%	16.67%	100.00%
	c. Mechanism used for communication of information:-			
	i> Landline phone number	33.33%	50.00%	0.00%
	ii> Email Id	55.56%	66.67%	33.33%
	iii> Mobile number	0.00%	0.00%	0.00%
	iv> Postal address	11.11%	16.67%	0.00%
	v> Specific Department/Official for reporting	77.78%	66.67%	100.00%
	d. Emergency contact/hotline number	44.44%	33.33%	66.67%
	e. Email id as most common communication method	88.89%	100.00%	66.67%
	f. Availability of contact details through public website	44.44%	50.00%	33.33%
	g. Violation of code of conduct/ethics dealt under same system	100.00%	100.00%	100.00%
	h. Stated explicitly the officials or bodies to whom wrongdoing should be reported	100.00%	100.00%	100.00%
III	Reporting guidelines & formalities			
	a. Tools used to report violations:-			
	i> Phone Call	55.56%	66.67%	33.33%
	ii> Email	55.56%	83.33%	0.00%
	iii> Personal meeting	55.56%	33.33%	100.00%
	iv> Written document	66.67%	83.33%	33.33%
	v> Pre-specified form	0.00%	0.00%	0.00%
	vi> Hotline	55.56%	50.00%	66.67%
	b. Language to be used specified explicitly	11.11%	16.67%	0.00%
	c. Explicit mention of the following details while reporting:-			
	i> Subject	0.00%	0.00%	0.00%
	ii> Name of the target person / department	0.00%	0.00%	0.00%
	iii> Major issue	33.33%	50.00%	0.00%
	iv> Evidence	22.22%	33.33%	0.00%
	v> Identity of the complainant	22.22%	33.33%	0.00%
	d. Anonymous reporting is allowed	55.56%	66.67%	33.33%
	e. Anonymous reporting discouraged clearly	11.11%	16.67%	0.00%
IV	Confidentiality & Anonymity			
	a. Stated that the violations reported are treated confidentially	77.78%	100.00%	33.33%
	b. Stated that confidentiality cannot be guaranteed in certain circumstances	55.56%	100.00%	33.33%
	c. Stated that violations can be reported anonymously	77.78%	66.67%	33.33%

	d. Stated that third parties can also report anonymously	44.44%	66.67%	0.00%
V	Protection from retaliation			
	a. General statement (“There will be no retaliation”)	100.00%	100.00%	100.00%
	b. Stated clearly that protection is guaranteed through disciplinary action	77.78%	83.33%	66.67%
	c. Requirement of good faith	100.00%	100.00%	100.00%
	d. Knowingly making false or malicious report is punishable	100.00%	100.00%	100.00%
	e. Requirement of no personal gain	100.00%	100.00%	100.00%
	f. Requirement of reasonable ground or belief	100.00%	100.00%	100.00%
	g. Stated that same treatment will be given if the whistle blower is involved in wrongdoing	44.44%	33.33%	66.67%
VI	Investigation details:-			
	a. Guarantee of investigation or serious treatment of complaint	100.00%	100.00%	100.00%
	b. Obligation to cooperate in investigation	100.00%	100.00%	100.00%
	c. Stated the time-frame for providing investigation feedback to whistleblower	55.56%	66.67%	33.33%
	d. Investigation process is described	77.78%	100.00%	33.33%

Observations and Findings:

i) General Contents, Scope & Tone

- a) Of the total sample, 88% of the companies are listed with at least one Indian stock exchange. 50% of the companies stated clearly that they comply with international rules and regulations applicable in the line of the SOX Act 2002. 88% of the companies further declare their compliance with all national laws and rules applicable in India.
- b) Enhancement of company goodwill, improvement in work culture and benchmarking appears to be the dominant motivating factors for having whistle blowing policy in almost all cases.
- c) Only 50% of the companies under sub-sample I (where WB document is available) encouraged employees explicitly for reporting wrongdoings whereas the proportion is only 33% for sub-sample II.
- d) The WB documents available under sub-sample I reveals that only 33% companies formed committees meant for listening whistleblowers. Remaining ones have Company Secretary / Audit Committee / ombudsperson to listen to the grievances.
- e) In case of sub-sample II, the Code of Conduct / Ethics did not mention about the separate committees formed for this purpose. Concerns raised about wrongdoings can be lodged through either audit committee/ Company Secretary and/ Chief Compliance Officer.
- f) In case of a particular Group of companies, all firms are pursuing the same policy towards the whistleblowers. Interestingly, as per the WB policy document studies, only 16% of companies allow ex-employees to blow the whistle.
- g) In case the whistleblower is not satisfied with the proceedings of the investigation, he may want to raise the concern again. Even though the companies under study are serious about proper investigation, fair treatment of complains and the results thereon, 83% companies in sub-sample I and all in sub-sample II have not properly described the second time appeal procedure in their policy document.
- h) 55% of the total sample considers reporting as an obligation. 50% of the sub-sample I and 66% of the sub-sample II, mention employees “must”, “have to”, “should” or “are expected to” report violations making it mandatory part of their duty. Thus overall the tone is at least moderately authoritative for majority.
- i) In addition, at least 44% of the total sample, encourage employees explicitly to report violations, when they use the words - “employees are encouraged to report.” At several instances, the companies have used neutral statements like, “employees may report” or “employees can report”. The overall tone of the policies is found to be a mix of several tones.

ii) Nature Of Violations To Be Reported:

- a) In 88% of the cases, the common violations that can be reported included corruption, mismanagement, abuse of authority, information manipulation, insider trading, bribery, money laundering, social misconduct, and also the legal violations of all types.
- b) 77% of the companies were listening to financial issues as well as unethical business conduct under the same system. Though all the companies accepted the significance of reporting wrongdoings, about 44% companies gave general statement stating any unethical or improper activity shall be reported. All the companies mentioned clearly about the officials to whom wrongdoings shall be reported. All the policies studied included violation of Code of Conduct/ethics also.
- c) Email has been considered as most effective tool for 88% of the companies. Only 44% provided the facility for 24 hours contact through hotline.
- d) Majority (77%) of the companies mentioned only the official names/ designations or the departments to whom wrongdoings shall be reported. On the other hand, only 44% companies provided the relevant contact details through company website.

iii) Reporting Guidelines & Formalities:

- a) About 55% of the total sample study used phone calls, email, personal meeting, verbal communication and emergency contact numbers for listening whistleblowers. None of the companies under study had any pre-specified form / document for reporting but 66% companies expect to get the concerns raised in written form.
- b) The language to be used for reporting was not a major issue in the documents studied. Only one company (11%) mentions explicitly that the language to be used must be Hindi or English or the regional language applicable.
- c) Also, the details that must be part of the reporting are not mentioned very clearly. Of the sub-sample I, 50% of the companies expects that the complaint must be stated in clear terms, while the Code of Conduct/ethics (sub-sample II) have no mention about it.
- d) Also 33% of sub-sample I explicitly demands evidence and identity of the complainant disclosed mandatorily along with the complaint; otherwise proper investigation would be hindered. Sub-sample II has no such mention. Overall about 55% companies allows anonymous reporting.

iv) Confidentiality & Anonymity:

All the policy documents (overall 77% of total sample) states clearly that the reported violations will be treated confidentially. They have also made it clear that in certain circumstances (as per the demand of the situation e.g. in legal matters, for evidence in court etc.) confidentiality cannot be guaranteed. In 66% sub-sample I, anonymous disclosure is allowed though, majority of the companies expects the whistleblower to disclose their identity to facilitate fair treatment of the complaints lodged.

v) Protection From Retaliation:

- a) Generally, the employees are afraid of the negative reactions that may come up from seniors due to violation reporting. All the documents under study gives assurance on this aspect by generally stating, "There will be no retaliation." About 77% of the total study guarantees protection through disciplinary action.
- b) Whistleblowers should act in good faith, for no personal gain, and on reasonable grounds only. For all the cases studied, intentional, malicious reporting, manipulated information are not acceptable on any ground.
- c) About 44% clearly stated that whistleblower's malicious intentions will not be tolerated under any circumstances and if found guilty, they are equally punishable under the same system.

vi) Investigation Details:

- a) About 100% of the companies demand cooperation in investigation and assured serious treatment of complaint.

b) The investigation process is described in 77% documents of the total sample. About 55% of the total sample study stated explicit time-frame within which the investigation feedback must be provided to the whistleblowers and other employees. The time-frame for the selected companies varies from 14 days to 45 days.

vii) **Other observations:**

- a) Indian legal system, which is a crucial part of corporate governance framework, does not seem to be fully prepared to accept whistleblower policy as an integral mechanism to ensure better governance. This is evident from the fact that it still remains a non-mandatory clause in Clause 49 of the Listing Agreement.
- b) Moreover, the country does not have any legislation for whistleblowers' protection till date. The study reveals a number of Bills proposed from time to time since 2003. The 2010 Bill, that is yet to be enacted, does not cover the private sector organisations. Therefore, it has no implications for the IT sector firms under discussion.
- c) While 90% of the sample have publicly disclosed their WB policy either directly or as a part of the code of conduct / ethics, some companies are not ready to hand over the policy when asked for at the time of interview.
- d) Some other companies denied access to any sort of information, as they refused to give interview on this issue.
- e) One company out of ten, enlisted in a foreign stock exchange, but having India-centric activities as well as revenue, does not provide any information in the website.
- f) Further, in the absence of any legal compulsions as such in the country, till date, there seems to be lack of enforcement of the policy, even though it may be there in paper. This attitude becomes apparent at the time of interview as well as in case of denial of interviews. Some company officials are found not even being aware of the existence of such policy in the company, although it is put up in their company website.
- g) Some of the companies, however, have nicely drafted WB policies. The reason in some cases may be their bindings with the Securities and Exchange Commission in the US (as they are enlisted with foreign stock markets).

Conclusion and recommendations

This paper starts with examining the corporate governance structure prevailing in India, especially in terms of the internal mechanism for whistleblowing. It then analyzes the information on whistleblowing policies provided by the top 10 IT sector companies of India as graded by the NASSCOM, the apex body guiding IT related activities in the country. These companies represent the global best service providing private sector industry in the country. The legal environment relating to corporate governance and the content analysis combined with the interview experiences brings forth the fact that the Indian private sector companies are lagging far behind their western counterparts in so far as the institutionalized whistleblowing policies are concerned.

Based on the above observations, the following recommendations are made:

1. The whistleblowers' protection bill should be enacted without further delay. The bill needs to be redrafted to cover all listed companies in the country in the line of SOX Act in the U.S.
2. In every case, the protection of whistleblowers from all types of retaliation should be ensured. Although enactment does not guarantee the enforcement, this can surely create an ambience for its effective implementation and utilization in the industries in future.
3. Apart from the legal minima, the company executives need to be convinced about the effectiveness of institutionalized whistleblowing policy in enhancing the transparency of its functioning and thereby improving the public image. The Indian managers need to come out of their conservative outlook as is evidenced in this study.
4. Awareness programs must be regularly held sensitizing the employees about the effective use of such policy in good faith and without the fear of retaliation. Most of the time, the employees in the country

- avoid the use of whistleblowing mechanism in order to play safe. The attitude of indifference can be remedied only through regular awareness programs.
5. The Listing Agreement needs to be amended to make the whistleblowers' policy a mandatory requirement for the listed companies in the line of the Narayana Murthy Committee recommendations (2003). The Securities and Exchange Board of India (SEBI) should take positive move in this respect.
 6. It is not enough to just incorporate the policy and exhibit it before the public eye. Effective enforcement of the policy is important. The regulations are to be followed not just in letters but also in spirit. This requires spontaneity and self-governance, especially on the part of the leading businesses in the private sector.

This study finds that a few IT sector companies have started benchmarking themselves as per the global standards through the establishment, and effective utilization of the mechanism of institutionalized whistleblowing. They can be considered as the frontrunners. Their proactive initiatives in the soil of India may give some impetus to other firms to come up with greater transparency leading to better corporate governance procedures. This will not just give them competitive advantage through higher ethical grade in the market, but also create better work culture within. These firms are ultimately expected to create enabling environment within the country to be followed by others. Such steps are extremely important to prevent the repetition of Satyam-like catastrophe in future.

Limitations of the Study and Scope for Further Research

This is a Kolkata-based study which acts as its limitation. Some companies having their head-offices in Bangalore and Hyderabad could not be contacted for one-to-one interview with the officials. Perhaps, a better view could have been obtained otherwise. . The WB policies and Codes of conduct / ethics as available in the company websites were, however, consulted for the purpose. The next difficult part has been that none of the companies responded the e-mails. Otherwise, in a highly networked world of today, communications are not supposed to act as limitation.

The sample size in this study is very small (only ten). Future researches may be done on a bigger sample (say, at least 100 companies), to get a broader picture. Also this study is confined to the private sector enterprises. Future researches may highlight on firms in the public sector, as the Central Vigilance Commission of India overlooking the PSEs are expected to create a congenial atmosphere for internal whistleblowers.

Future researches can also be done to compare whistleblowing policies of India with those of the U.S. or European Union. This may bring out the similarities as well as dissimilarities, leading to practical suggestions about what the Indian companies can learn from its American counterparts. Finally, the data available in this study can be used to assess the impact of the internal WB policies on the whistleblowing behavior of the employees in the private sector organizations.

DIRECTORS MANAGEMENT IN THE ELECTRONIC INDUSTRY AND ITS RELATIONSHIP WITH ENVIRONMENTAL PERFORMANCE STRATEGIES

Case: Maquiladoras Companies located in the metropolitan area of Guadalajara, Jalisco, Mexico.

*Humberto Palos Delgadillo, humpalos@cucea.udg.mx, jafm55@cucea.udg.mx
Universidad de Guadalajara, Mexico*

ABSTRACT

In this paper is explained the entrepreneurial behavior of several companies involved in the electronic sector located in the metropolitan area of Guadalajara, Jalisco, Mexico, and its relationship with the general and task environments. The purpose is to identify the type of actions needed to improve the impact in the environmental protection. We founded that these companies developed different practices that influenced their organizational culture. However, they have unliked commitments with the current environmental legislations and consequently it exists a lack of legal and social commitment that includes the internalization of the externalities that causes the pollution of the environment. In that sense, we emphasized the importance of combining the business competitiveness and environmental protection, so we proposed various strategies that can contributes to improve the performance of these organizations. Finally it is necessary, that entrepreneurs, employees, government and society get involved in the sustainable development of the región.

INTRODUCTION

Environment business relationships is first and foremost, a relationship that implies that the second depends on the first, since for it to exist requires the use of the resources found in nature. In this sense, human intervention on the environment and the consequences resulting are not facts or phenomena that take place in isolation but within a time continuum. It must then understand the relationships that exist in the social system, hence the importance of talking about the economic entity called environmental management company. In this regard, this paper presents the relationship between the electronics industry located in the metropolitan area of Guadalajara (ZMG) Jalisco, Mexico, and the environmental management that occurs in it.

THEORETICAL FRAMEWORK

The meaning of this section is to clarify the essential concepts that deal with business relations and the environment. It is therefore necessary to establish the basic theory, which in this case is the science of ecology and then begin to define and then explore its many close relationships, (Manuel Ludevid, 2000, 23). The company is the basic institution of the economic system. It is the organization that transforms natural resources into goods and services valued by humans. The company is considered as an integrated economic unit in a natural system.

The Ecology Science

(Paolo Bifani, 1997, 145) notes, "The social system develops in a biogeophysical space, which is, ultimately, the men natural habitat. This system, that includes people, is called Biosphere and it is defined in more general terms as that part of the land where life exists. " Establishing in a better understanding, the biosphere is the combination of all living matter and the physical environment that surrounds it. The term ecology was established in the nineteenth century and was defined as "the science of habitat (from the Greek oikos, meaning home)¹. Ecology is defined as a multidisciplinary science that studies the relationships between organisms and their environment. If it is argued that the ecology is the science that studies and analyzes all the possible implications arising from the interactions between living things and the receiving environment and the relationships between them living under natural conditions, then, ecology is the science that analyzes the functioning of the biosphere.

General Administrative Theory

The administration either as an art, technique or science, is a basic task to do things through people. In this regard (Zacarias Torres, 2001, 11) states "Management is the process of planning, organizing, integrating, managing and controlling the efforts of all members of the organization and to assign other resources available to achieve the objectives. "

Administration from a position almost unknown in 1900, has become the central activity of this period, besides being an innovative and powerful force which supports the material welfare of every society. The simultaneous administration is a crucial resource, a guide for the effective management of organizations and individuals.

Almost until the eighteenth century, the production of a limited number of goods was characterized by the use of muscle power or a combination of skills, ingenuity and creativity. It was with the Industrial Revolution emerged a new kind of human organization: the industrial enterprise, an organization with a clear commercial objective, to obtain benefits through coordinated use of people and machines to produce and distribute goods and services. Today we faced challenges as growth of the organization, sophistication of technology, information management, context of globalization, increased social engagement, and greater commitments to the natural environment, ethics and accountability among others. However, you can't denied that human organizations are structured systems. This is precisely the difference between a mass and an organization called the company and consequently, to all businesses that produce identical or closely related, is called industry.

The company

An enterprise is an organization, a group of persons that coordinates their efforts under a management system to achieve goals and also it is a social system of action. The action is essentially to transform some factors (inputs) into products or services (outputs), adding value. That is, the company interacts with the environment constantly by changing or trying to adapt or influenced it. The company phenomenon can be approached from very different approaches and mutually complementary, since they are characterized by their complexity and strong impact on daily life. Indeed, in business takes much of the adult life of most people, and work is a conscious activity which devotes more time and effort. On the other hand, companies today are the result of processes rooted in time, processes of search for knowledge and satisfaction of needs, technological processes, such as the pursuit of security and welfare, wealth and power by individuals and communities, processes such as division of labor or spontaneous or forced the creation of human organizations aimed at achieving goals outside the scope of isolated individuals.

Sustainable development

The industrial progress that has been occurring in recent years has resulted in the "modern man" requires use of natural resources for progress, however, this requirement has caused problems because nature can't tolerate damage incurred such as, pollution of air, water and soil, among others, and the destruction of forests and depletion of natural resources.

In the early sixties, society begins to question the possible consequences of insensitive development with the environment. In 1972, the United Nations held a conference in Stockholm Sweden, whose central theme was human development and the environment. In 1987, recognizing the seriousness of ecological problems which had come so modern in the industry and through the World Commission on Environment, also known as the "Brundtland Commission", established a new concept called sustainable development which defined as "one who meets the essential needs of the present without compromising the ability to meet the essential needs of future generations (World Commission on Environment and development (1987)).

As greater understanding, sustainable development is a process of social change in which exploitation of resources, the direction of investments, the orientation of technological development and institutional reforms are carried out harmoniously, to expand the current and future potential for meet the needs and aspirations. That is why in recent years, social pressure has increased to the point where it is recognized that the company should take responsibility for the environmental damage caused in the production process. Although it is common to find some confusion in the use of the terms sustainable, sustainable and sustained to denote the temporal characteristics of an event or process, some argue that it is synonymous, resulting from the different translations of the word sustain. However, we can find little nuances that differentiate each of these terms, since sustainable describes a possibility, condition or characteristic of an event or phenomenon that is a base, stand or lift to ensure its permanence in time, on the other hand, sustainable understood as a process or event that happened once can be active in time or continue efficient operation, and ultimately, sustained, may be a fact or event that is maintained consistently over time.

Economic development and the environment is not only not opposed but are two different aspects of the problem. Thus, the concept of development takes on new dimensions, arguing that, economic growth is a necessary foundation, fairness is the guiding principle of economic distribution, and quality of life, defined specifically for each urban and rural social groups, is a societal goal.

The environmental management is a means of achieving rational management of resources, while controlling the impact of human activities on nature.

The sustainable business

Since the industrial revolution to the present, the industry has had an amazing growth, concepts of competition, productivity and quality among others have developed continuously, however, until a few years ago it seemed important to the environment and natural resources for the organization as these are becoming scarcer and more difficult to acquire.

Managers of companies with business vision begin to take into account the environment in their strategies to gain competitive advantage over those managers who are bent on the old ways of doing business. Now more than ever it becomes necessary to link the decisions of the company with the company, the company operates in an open system where stakeholders have expanded, previously enough to take into account shareholders, employees and suppliers Now there are environmental groups, NGOs and endless associations that monitor the activity of the organization does not affect the welfare of community life.

STUDY CONTEXT

The electronics sector is considered of a strategic importance and priority to the country's economy development. Today is increasing the use of a variety of electronic tools and processes in the manufacture of all kind of products and services. The total exports of this sector are the highest in Mexican industry. It is also the sector with the highest import volume reported, and their surplus is the second largest, the best is the automotive sector.

In Jalisco, one of the best economic sectors is the export maquiladora industry in the electronics products, this industry has reached a transcending national leadership, and internationally recognized as the Mexican Silicon Valleyⁱⁱ, where the largest global firms are established in the municipalities that belong to the Guadalajara metropolitan area (GMA) and mainly in the industrial corridor of El Salto. (Fig.No. 1).

RESEARCH DESIGN

Industrialization has been occurring in Jalisco, Mexico, and has brought many economic benefits. However, like any development process, has also brought consequences that affect society as a whole. That is, the use and abuse of natural resources, damaging the environment industry and also causes a deterioration of the environment, a situation not unrelated to the regional development of the state.

Core Problem

Growth models applied so far in Jalisco, not been commensurate with the expected sustainable development, so it is essential to provide new bases that are consistent with the paradigm of environmental decision-making processes as the company production within the economic system and its social and cultural demands of her performance according to the interests of the community in general, this without prejudice to their responsibilities for providing employment. In this sense, environmental management encompasses all aspects of business management typically hence the importance of knowing the behavior of industry and environmental management relationship that can exist in her particular situation and in particular manufacturing companies electronics industry located in the GMA by the economic importance it represents for the state of Jalisco.

Research Questions

- What relationship exists between the electronics industry located in the GMA with respect to executive management and environmental performance?
- What is the level of business culture in the electronics sector companies located in the GMA?
- What are the significant environmental aspects of the electronics industry that can best impact?
- What is the degree of compliance with environmental legislation electronics companies in question?
- What is the environmental commitment to be getting the electronics industry to be socially responsible in a sustainable framework?

Regarding the research questions, the objectives are to develop:

General objective

- Understand the relationship between executive management in the electronics industry located in the GMA, and their effects on the receiving environment that allows suggest strategies for improving environmental performance under a sustainable framework.

Specific objectives

- Determine the level of business culture based on the use of performance improvement tools that influence the competitiveness and meet market requirements.
- Identify the main production processes in the electronics industry, significant aspects that impact the environment.
- Assess the degree of compliance with environmental legislation requiring the electronics industry.
- Establish environmental commitment to be getting the electronics industry for it to be socially responsible in a sustainable framework.

Type of research

This was exploratory and descriptive. In the first part contextualizes the framework embodied in this research. In the second field work was conducted to ascertain the situation of the companies selected in the sample with respect to environmental management and presents them to observe the phenomenon under study to obtain information and interpret it under the approach qualitative case study.

Selected sample

In this regard we applied a questionnaire (see Attachment 1) which consisted of four sections: the first to know the profile and organizational development of the companies in question, the second to contextualize them in relation to the environment, the third relation its compliance with current legislation in the field and in the fourth environmental perspectives.

Through the Maquiladora Industry Association of the West, were able to confirm that the GMA were established until the year 2009 approximately 126 companies engaged in production of electronics. In this universe,

we determined the displays 32 electronics companies chosen at random from different directories from the different chambers and business associations (see Attachment 2).

RESULTS

As a result of questioning applied to the sample of 32 companiesⁱⁱⁱ, we have the following information concerning the profile of these and organizational development based on the use of improvement tools that together define the corporate culture of the latter (see Tables 1 and 2 .)

Profile and organizational development

TABLE 1: ELECTRONIC ENTERPRISES RESPONDENTS LOCATED IN THE GMA.

1 Avnet Mexico, SA of C.V
2 BDT of Mexico
3 Benchmark Electronics, Inc. de CV
4 Cables CST SA de CV
5 Electronica Pantera SA de CV
6 Hemex Automotive Equipment
7 Flextronics Manufacturing Mex. Inc. de CV
8 GPI Mexicana de Alta Tecnología, SA de CV
And 9 High Precision Moulding Tools, Inc. de CV
10 Honda de Mexico, SA of C.V
11 IBM of Mexico, Manufacturing and Technology, SA de CV
12 Jabil Circuit de Mexico, SA de CV
13 Modus Media International, Inc. de CV
14 Molex de Mexico, SA de CV
15 Multek Mexico, SA de CV
16 Pegasus Control
17 Pemstar de Mexico, SA de CV
18 Digital Power, Inc. de CV
19 Precise Dental International
20 Qapi, Inc. de CV
21 R.S.P de Mexico, SA de CV
22 Saleslink Mexico, S. of R.L. de CV

23 Siemens Plant Guadalajara
24 Solectron de Mexico, SA de CV
25 Sumida Electronics Mexico, Inc. de CV
26 Takata of Mexico, SA de CV
