Global Business & Regional Issues

Implications of Refreshed Regional Economic Integration for the WTO

Ying Yu
Zeshan Pan
University of International Business and Economics, China

Abstract:

Globalization and regional integration constitute the two main trends of the world economy today. Since the mid 1980s, Regional Trade Agreements(RTAs) have proliferated at an unprecedented rate throughout the world. Against this backdrop, it makes sense to explore the nature of the refreshed regionalism and its implications for the multilateral trading system. Based on the "Doha Declaration", we further explored the way WTO can face itself with the opportunities and challenges brought about by the refreshed regional integration. The analysis dwells upon provisions at both the multilateral and the regional level, including some matter-of-fact demonstration. It seems to us that multilateralism and regionalism enjoy a symbiotic relationship academically and practically. We concluded by suggesting that the multilateral trading system should compete with and benefit from regional initiatives. Since the 1980s, globalization and regional economic integration have become the two main trends of the development of the world economy and trade. On the one hand, the establishment and operation of WTO has advanced economic globalization in depth; on the other hand, regional economic blocs of all sorts are booming all over the world, setting the stage for the most dramatic episode of regional economic integration the world has ever seen.

1. New development of regional economic integration since 1990s

During this period, the development of regional economic integration has been taking on many new characters. Not only the number of regional trade agreements (RTAs) has increased exponentially, but their scope and geographical reach have broadened and expanded as well; and the mechanism of RTAs has diversified.

1.1 The proliferation of RTAs has developed at an unprecedented rate all over the world.

As of March 2002, 255 RTAs had been notified to the GATT/WTO, of which 173 are currently in force (see Fig.1).

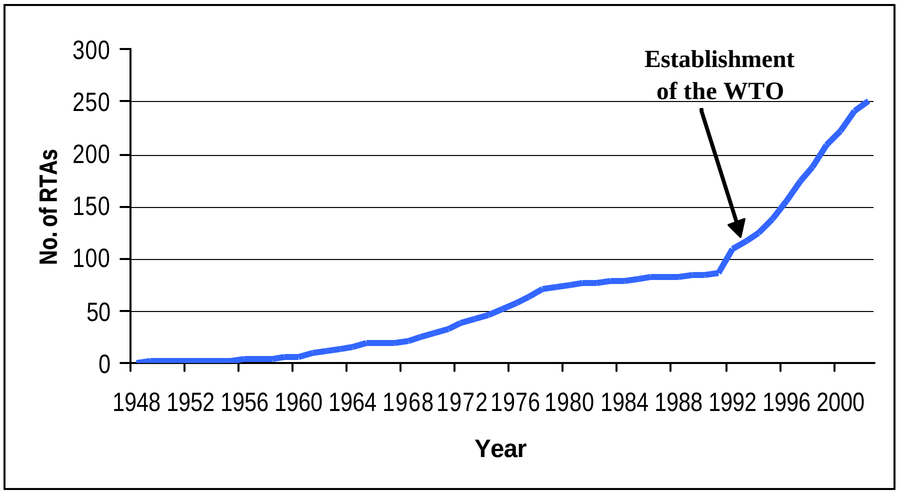

FIG 1: RTAS NOTIFIED TO THE GATT/WTO (1948-2002), CUMULATIVE
Source: "Regional Trade Integration under Transformation", WTO Secretariat, Feb., 2002

Among those RTAs in force, the bilateral free trade agreement signed by two parties (sovereignties or regional economic organizations), has surged in number and became the most common type of RTAs. The most successful example is the United States-Israel Free Trade Agreement reached in 1985.

1.2 New generation RTAs consist of members that may be geographically dispersed, staying in different stages of development and trade liberalization, and/or adopting various trading patterns.

The network of RTAs spanned within and across continents. For example, the Asia-Pacific Economic Cooperation (APEC) currently has 21 members across Asia, Oceania, North America and South America.

Also, RTAs consist of countries with different social systems or of different development levels. In America, the North America Free Trade Agreement (NAFTA) was founded by United States, Canada and Mexico, which stay in different developing stages, giving rise to a strong and positive rise in trade and investment within member economies and further influencing other countries in Latin America, namely Chile and Caribbean countries; in Asia, despite different social systems, ASEAN accepted Vietnam, Kampuchea and Burma as new members, aiming for a coordinated development within the Eastern Asia.

1.3 Many sub-regional preferential agreements have emerged, rendering the distribution of RTAs even more complex.

Consequently, a single country often has an overlapped membership, reflecting a policy mix adopted by the government. In other words, many countries have fostered flexible trade policies, emphasizing multilateral trading system and RTAs at the same time. For instance, Mexico not only joined NAFTA and LAIA, but also signed the bilateral free trade agreement with EFTA and most Asian countries.

1.4 There are two directions in the new development of RTAs.

First, following the exclusive logic, EU continues moving toward further enlargement and its intra-region cooperation is deepened and strengthened steadily. By the time when Poland.Czech and other 10 countries finished their entry in May 2004, the number of EU members will sum to 25, approaching its final goal of a "Large Europe".

Second, there came new-pattern RTAs of which APEC is a major representative. APEC is well-known for its persistent advocating of "Open Regionalism", which is characterized by unilateral, non-discriminating liberalization, openness to new members and the informal, non-institutional, and voluntary execution procedure. During the period between 1980 and 1992, trade linkages between APEC's Asian and non-Asian members strengthened considerably. As a result, the share of intra-APEC trade in total APEC trade volume climbed from about 58 percent in 1980 to about 70 percent in 1992.

1.5 In the light of the rapid development of science and technology, RTAs established various trade-related provisions going beyond traditional tariff reduction or elimination.

For example, the "new-generation" RTAs recently concluded or currently under negotiation has showed their ability of harnessing new technologies in developing approaches for risk management so as to facilitate the clearance of low-risk goods with minimal or no documentary verification and physical inspection.

2. Momentums of the new development of RTAs

2.1 Economic globalization facilitates the flow of commerce, technology and investment all over the world, which in turn promotes regional integration.

After the Cold War, international connection in production, trade and finance has strengthened with less political counterwork. And the globalization is accompanied by increasingly fierce competition. To consolidate their advantageous status in the world market, developed countries club together by institutionalizing themselves into RTAs. Meanwhile, developing countries also take deliberate steps to enter into RTAs in order to enhance their economic growth and increase their participation in international trading system.

Besides, economic globalization also calls for a harmonious cooperation among countries of different social systems and/or at different developing levels. Consequently, RTAs adjust themselves actively by drawing on new members, allying with other regional organizations, forming new RTAs or deepening existing ones. All these lead to diverse forms of RTAs.

2.2 In the late 1990s, the multilateral trade liberalization process had stagnated due to the pending of Uruguay Round negotiation, which in turn inspired worldwide enthusiasm for regionalism.

The pace of the course of the multilateral trading system is influenced by the fluctuation of world economy and the economic development cycle of each member country. During the 1980s and early 1990s, and from the late 1990s up to now, the slow pace of economic development combined with prevailing trade protectionism decelerated the process of multilateral trading system. Against this backdrop, each country attaches more importance to regional economic cooperation so as to share the fruit of regional liberalization and hedge against the uncertainties in the global economic environment.

2.3 RTAs had come into being before the establishment of GATT.

At the very start, GATT took a supportive stand towards RTAs due to the rooted benefits some GATT parties had in regional trade arrangements before its conclusion. Under the GATT/WTO, members are allowed to further market access they bound in the GATT/WTO by concluding RTAs, albeit subject to some criteria contained in GATT Article XXIV, GATS Article V and "Enabling Clause". For example, it is stipulated that "the purpose of a customs union or of a free-trade area should be to facilitate trade between the constituent territories and not to raise barriers to the trade of other contracting parties with such territories". And "Enabling Clause" agreed in Tokyo Round entitled developing countries to sign a favorable agreement of merchandise trade.

Note that, as implied in GATT Article XXIV 4, WTO hopes to balance regional integration goal with multilateral liberalization goals by formulating rules on regional economic integration (Joel P.Trachtman, 2002). In other words, RTAs are expected to pursue development strategies within the framework of global multilateral trading system.

2.4 Whereas WTO's regulations concerning RTAs have inborn deficiencies, countries had the access to various RTAs while bypassing WTO restrictions.

This point will be elaborated in following section.

2.5 The trade policy conversion of major traders is an important propellant.

In the late 1980s, large traders, such as the United States, Japan and Canada transferred their strategy and policy one after another from emphasizing multilateral trade liberalization to combining multilateral agenda with regional initiatives. This trend of policy conversion in turn influenced the trade policy of other countries and finally promoted the process of regional economic integration.

3. Implications for WTO

3.1 Refreshed regionalism opens some opportunities for the multilateral trading system.

3.1.1 RTAs share some goals of trade liberalization with WTO.

Regional liberalization efforts assist in WTO's goal of reducing trade barriers worldwide to the extent that RTAs set out to remove various trade blocks that hinder free flowing of goods, service and production factors within the region. And the new development of RTAs has reinforced this consistency between regional and multilateral goals in the following two aspects. One is that new-pattern RTAs, APEC to be specific, have put ever-increasing emphasis on "Open Regionalism" with an ultimate goal of global trade liberalization based on liberalizing efforts in the Asian-Pacific Area. The other is the "parallel processing" conducted by WTO and RTAs against the non-tariff trade barriers that excessively burden international trade. For instance, the technical barriers to trade and the sanitary and phytosanitary issues (collectively "TBTSPS" provisions) are addressed through "positive integration" (i.e. the "legislation" of harmonized rule or rules of mutual recognition) and "negative integration" (i.e. judicially-applied standards with the effect of striking down national regulation, such as national treatment, necessity or balance rules.) at regional level. The former results in lower cost incurred to foreign producers, while the latter works by forcing RTA members to take into account the cost to foreign producers in formulating their TBTSPS measures. This "RTA-driven 'autonomous' TBTSPS liberation", as named by Joel P Trachtman [i], is bound to enhance the multilateral trade liberalization.

3.1.2. The internal consensus of RTAs may aid in the conclusion of multilateral negotiations.

The constitutive base RTAs rest on has been expanded and deepened since the 1980s, rendering an even more extensive connection of interests on the base of which more countries are to cooperate in trade liberalization. Such a growing membership of individual RTAs means, instead of being conducted by over 100 countries, multilateral negotiations are actually led by several powerful country groups. On the other hand, extensive common interests within a RTA ensure ever-concerted action taken by its member countries. As a result, it matters a lot to the multilateral negotiation progress whether some major regional country groups can reach an agreement on certain issues. A good example will be the advent of NAFTA and APEC favoring significant progress in the negotiation between U.S.A, Canada, Japan and EU (EC before 1992), and ultimately leading to the conclusion of the marathon negotiation of the Uruguay Round at the end of 1993.

3.1.3 RTAs are key laboratories for the development and the learning-by-doing of new paradigms in the design and implementation of trade policies at the multilateral level [ii].

Regional agreements are based on reciprocity principles involving a smaller group of countries, which provides a better environment to reach consensus on the complex range of issues in modern trade agenda, to better evaluate the potential gains from the bargain, and to gain private sector understanding and support for the liberalization process [iii]. Deepened liberalization, as well as liberalizing measures concerning modern trading issues, can often be observed in RTAs. To cite an example, it took WTO almost ten years to schedule multilateral negotiations on the Singapore issues (i.e. investment, competition & trade facilitation issues) since it first placed them on the multilateral trade agenda during the Uruguay Round [iv].

On the other hand, although the regional pace of rules development with respect to these issues also began to accelerate during the 1990s, various RTAs have moved further and faster in making specific rules concerning these issues so far. Key Heydon (2002) pointed out that in each of the three areas there is evidence of provisions in RTAs going beyond those in the WTO. He cited electronic data interchange as an essential feature in Japan-Singapore Economic Partnership Agreement (JSEPA) to demonstrate that RTA negotiations has paid special attention to electronic commerce and the increase use of information & communication technologies. He concluded that the effects the patchwork of RTAs can have on non-members and on the process of dispute settlement, potential and real, can be seen as contributing to the case for a strengthened multilateral framework [v].

3.2 The proliferation of regional integration poses challenges to the multilateral trading system led by WTO.

3.2.1 Opportunities imply challenges.

3.2.1.1 RTAs may obstacle worldwide trade liberation when pursuing regional goals.

Discriminating treatment between members and non-members characterizes conventional RTAs, which will inevitably lead to the deviation of regional liberalizing progress from the multilateral goal. The new development of RTAs made this discrepancy even more complicated.

A typical example for this will be the "preferential rules of origin' implemented by RTAs. For RTAs with a discriminatory nature where parties grant each other preferential market access but have not yet harmonize their treatment for goods imported from third countries, rules of origin (RoOs) is necessary for determining whether such a good is eligible for preferential treatment in the importing country. However, diverse RoOs developed by various RTAs result in a lack of uniformity in preferential rules of origin worldwide. Also, the increased overlapping membership of RTAs means the coexistence of different RoOs in a single county. The considerable complexity of these roOs, added their often insufficient transparency, can "generate important administrative and operational costs" for the government, and burden producers with the work to acquaint with them and meeting the requirements [vi]. Some economists argue that the frequent use of preferential RoOs may compromise the established preferences under the RTA, causing potential inefficiencies in resource allocation [vii]; it may also increase the possibility of trade (or investment) diversion [viii].

Trade diversion (i.e. to promote intra-RTA trade at the expense of imports from outside the RTA) is often cited by economist to illustrate the conflict between regional and multilateral liberalization goals. The evidence for this empirical question is represented in Table 1which lists the proportion of intra-RTA trade in total export of RTAs. As the data show, the intra-RTA trade of some influential RTAs, such as EU, FTAA and APEC, has accounted for over a half of their total export. Besides, NAFTA, FTAA and APEC all see a striking rise in intra-RTA after their birth in the1990s.

TABLE 1: THE INTRA-RTA TRADE IN TOTAL EXPORT

Region	Group	Year of Founding	Intra-RTA Trade in Total Export of the Group (%)					
			1980	1990	1995	1999	2000	2001
Europe	EU (EC)	1957	60.8	65.9	62.4	63.3	62.1	61.2
America	FTAA	1994	43.4	46.6	52.5	60.0	60.8	60.1
	MERCOSUR	1994	11.6	8.9	20.3	20.6	20.7	20.8
	NAFTA	1994	33.6	41.4	46.2	54.6	55.7	54.8
Africa	UEMOA	1994	9.9	12.1	10.3	13.1	13.0	13.5
Asia	ASEAN	1967	17.4	19.0	24.6	21.7	23.0	22.4
	GCC	1981	3.0	8.0	6.8	6.7	5.0	5.1
Interregional	APEC	1989	57.9	68.4	71.8	71.8	73.1	72.5

3.2.1.2 Regional country groups as a whole are reluctant to compromise in multilateral negotiations.

The independence of a RTA member is limited by its membership in the RTA. The overlaps of membership confront a single country with entangled interests, thus make it tend to take a relatively conservative stand in multilateral negotiations. Besides, major RTAs are equivalent in power. Once the bargain on sensitive trade issues between them comes to a deadlock, so will multilateral negotiations, as illustrated by the lingering conclusion of Uruguay Round and the tortuous startup of the Doha Round.

3.2.1.3 Prosperous regional "laboratories" may hinder multilateral liberalization process, and distract people's attention from multilateral trading system.

For one thing, "laboratories" serve as examples or pathfinders for future multilateral practice, some of them may pre-determine the path of multilateral integration [ix]. This kind of path dependence may enable some RTAs to take advantage of "first mover" status and will finally give rise to an imbalance in multilateral trading system. Also, it is hard to choose among or to harmonize several distinct proven regional disciplines.

On the other hand, RTAs are often made possible and successful under specific regional circumstances which significantly differ from the global condition applying in the WTO. In other words, associated with a complex set of region-specific factors [x], measures proven in "laboratories" cannot always be adopted in multilateral trading system. Some RTAs even have had intra-RTA cooperation go beyond economic issues to include political coordination, exceeding the globalization process both in scope and in depth. Attracted by welfare gains at the regional level, a country may focused on liberalizing arrangements within the region, while became more conservative in multilateral negotiations.

3.2.2 In face of the refreshed regionalism, existing WTO rules concerning RTAs are even more problematic.

As implied in GATT Article XXIV 4, WTO hopes to balance regional integration goal with multilateral liberalization goals (Joel P.Trachtman, 2002). In order to achieve that, it laid out RTA-related rules in GATT 1994 Article XXIV (including the Understanding on The Interpretation of Article XXIV of the GATT 1994, i.e. the "Understanding"), GATS and "Enabling Clause". And Committee on Regional Trade Agreements was established in 1996 to take care of RTA-related issues. Despite all these efforts, WTO's accommodation to the RTAs is still open to question, in light of which WTO has designated rules concerning RTAs as one of the WTO rules to be discussed in Doha Round.

3.2.2.1 The definition of RTAs stated in WTO rules is too narrow to reflect the diversity of existing RTAs.

GATT Article XXIV (including the "Understanding"), GATS and "Enabling Clause" refer to RTAs in two forms: customs union and free-trade area, leaving a gap between the forms of RTAs being ruled and those of RTAs currently in force.

3.2.2.2 WTO rules ruling the formation of RTAs are ambiguous in expression and unclear in definition, causing many disputes in practice.

Of the 255 RTAs notified to the GATT/WTO [xi] up to March, 2002, most agreements are notified under GATT Article XXIV and/or GATS Article V (as showed in Fig. 2), reflecting the important status of these two articles. Notwithstanding, they are still problematic in practice and even more awkward in ruling modern RTAs.

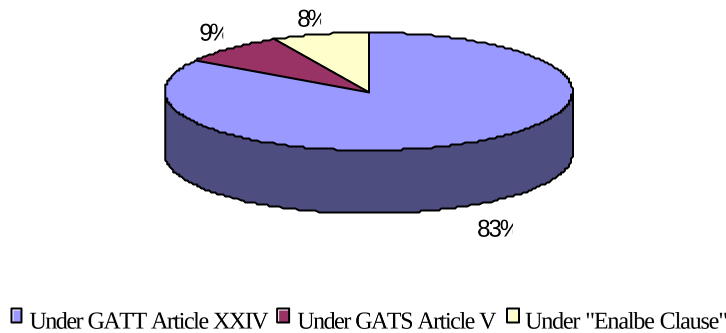

FIG.2: RTAS NOTIFIED TO WTO UP TO MARCH, 2002 (BY RELATED WTO PROVISIONS)
Source: WTO, "Report (2002) of the Committee on Regional Trade Agreements"

3.2.2.2.1 Some key words in GATT Article XXIV are ambiguous in meaning.

In Article XXIV: 8, the phrase "substantially all the trade" does not have any straightforward definition, nor does it set any specific criteria for judgments. As a result, its application is open to dispute. First, members hold different stands on whether "substantially all the trade" should be measured on the basis of quantity (i.e. the proportion in total trade volume) or quality (i.e. the inclusion of key industrial sector). Second, this phrase is often associated with restrictive rules of origin, that is, the adoption of preferential RoOs by RTAs may affect the assessment involved in this requirement. Third, once RTA members impose restrictive measures in light of the exception clause in Article XXIV: 8, the intra-region trade volume will inevitably change, which in turn will play a role on in the satisfaction of the requirement of "substantially all the trade".

And the definition of "other restrictive regulations of commerce" in Article XXIV: 5 is no more clear than that of "other regulations of commerce" in Article XXIV: 8. Besides, neither has distinguished policies applying to member countries and those to non-members. Meanwhile, as stated in Article XXIV: 7, "promptly notify" signals little cues about the specific notification time required, to some extent discouraging RTA members from notifying timely.

3.2.2.2.2 The problems with GATS V are just the extension of those with GATT Article XXIV.

The controversy on the phrase "substantial sectoral coverage" and "substantially all discrimination" in GATS Article: 1 include whether to quantify the standards for "substantially all discrimination", and which gauge, sectoral, sub-sectoral, or service property, the assessment of "substantial sectoral coverage" should be based on , and how to make sure that "substantially all discrimination" has been deduced or eliminated, etc.

3.2.2.3 Existing WTO rules are far from effective in regulating multifarious trade and investment measures taken by RTAs.

Apart from ambiguous reference in GATT Article XXIV: 8, there are no specific regulations concerning RoOs, TBTSPS, anti-dumping measures, or security measures adopted by RTAs. And current WTO provisions about the review of RTAs DO NOT cover investment issues, even though RTAs have increasingly covered them. WTO does have reached multilateral agreements on these issues respectively. However, the relationship between GATT Article XXIV and the special agreements, or the exception from obligations contained in the special agreements provided by GATT Article XXIV to RTAs, have not yet been explained and certified clearly. Thus what happens where Article XXIV permits what those other agreements prohibit? This could come up in many disputes among member and non-member countries, only to be settled one by one as individual cases.

It is important to note that the "Agreement on Rules of Origin" under WTO establishes disciplines only on RoOs which "are not related to contractual or autonomous trade regimes leading to the granting of tariff preferences going beyond the application of paragraph 1 of Article I of GATT 1994", often referred to as "MFN rules of origin". Apart from the Declaration in Annex II to this agreement where Members commit to ensure transparent administration of the origin rules related to the implementation of their preferential schemes, there are no multilaterally-agreed disciplines on RTA preferential RoOs [xii].

3.2.2.4 CRTA cannot function well enough so far.

Examination of the consistency of individual RTA with WTO regulations bottlenecks the full function of CRTA. The progress made by CRTA in its examination is listed in Table 2 below. The figures suggest that CRTA is occupied with factual inquiries and clarifications, but after that, it fails to draw a conclusion on whether the RTA in question is complied with the WTO requirements. As a result, by the end of 2002, CRTA still had to report that "NO progress was made…on the completion of the examination reports". Ambiguous WTO rules, members' reluctance to submit detailed data, and the complexity of RTAs are responsible for this.

TABLE 2.RTAS' STATUS IN THE EXAMINATION PROCESS IN CRTA (UP TO OCT. 2002)

Examination stage	**Number of RTAs**
Factual examination not started	22
Under factual examination	27
Factual examination concluded	76
Examination report concluded	0
Total	125

Source: "Report (2002) of the Committee on Regional Trade Agreements"

The review process drags on also due to late submission of RTAs' reports. RTA members are required by the "Understanding" to submit reports on a periodical basis explaining the implementation of the RTA. In 1998, CRTA suggests a two-year period basis which was accepted by the Council for Trade in Goods, the Council for Trade in Services, and the Committee on Trade and Development. Since 1999, CRTA has announced once a year the list of members required to submit the report during that year. However, not all members in the list can fulfill its responsibility. For example, all of the 11 reports considered by the CRTA at its Thirty-Third Session in 2002 were included in the list for 2001 and due to be reviewed during that year.

4. How will WTO face itself with the RTA proliferation?

4.1 To perfect existing WTO rules applying to RTAs.

In "Doha Declaration", ministers called for renegotiation on this field "aimed at clarifying and improving disciplines and procedures under the existing WTO provisions applying to regional trade agreements." The task may deal with two aspects.

4.1.1 To seek disciplinary betterment.

4.1.1.1 To clarify the wording of WTO rules.

It is necessary to establish a set of clear, consistent, and easy-to-operate criteria for the assessment of "substantially all trade", "substantial sectoral coverage", and for the specific forms of "other restrictive regulations of commerce" and "other regulations of commerce". And some plausible methods are also to be determined to indicate the elimination or deduction of restrictions and discrimination in RTAs required by WTO.

4.1.1.2 To strengthened the binding power of RTA-related WTO rules.

One way to achieve this goal is to enlarge the definition of forms of RTAs to include diverse forms of today's RTAs. The other way may be to accommodate complicated RTA trade and investment measures by formulating specific WTO disciplines with respect to RoOs, anti-dumping measures, safeguards and investment rules adopted by RTAs.

4.1.1.3 To explain the relationship of GATT Article XXIV, GATS Article V with other agreements and the "Enabling Clause" under WTO.

As for this task, precedent cases in dispute settlement need to be considered to make the final decision. For instance, Joel Trachtman (2002) consulted the decisions of the Appellate Body in the cases of EC-Bananas III, Canada-Periodicals, Indonesia-Automobiles, US-Line Pipe, and Korea-Dairy Safeguards and suggested that the obligations under the WTO agreements are cumulative [xiii].

4.1.2 To seek procedural improvement.

4.1.2.1 To improve the notification procedure.

What's to be worked out includes specific timing requirements in GATT Article XXIV: 7, notification responsibility under GATS V, and the requirements of completeness and validity of the documents submitted.

4.1.2.2 To reinforce the authority of the CRTA.

The aim is to help CRTA conclude its examination reports and to ensure the implementation of them.

4.1.2.3 To make full use of the dispute settlement mechanism in WTO.

To resort disputes concerning RTAs to the dispute settlement body in WTO is a way to avoid the escalation of inter-regional confrontations. By enhancing the credibility and security of multilateral trading system, it can alleviate the negative impact inter-regional conflicts may have on WTO.

4.2 To speed up the multilateral trading negotiations.

Besides preparing for the challenges regionalism has imposed on multilateralism, WTO should strive to gain renewed momentum from the advanced attempts in trade and investment liberalization at regional level. The Uruguay Round multilateral negotiations acts as an handy example on balancing the development of multilateralism and regionalism by setting even more stricter anti-subsidies disciplines for agricultural products trading than EU and NAFTA, and "multilateralizing" the rules of some RTAs like NAFTA in such new fields as intellectual property, technical and sanitary barriers.

Also, WTO needs some focused research in RTAs to pick up provident regional initiatives. In 2000, the CRTA instructed the Secretariat to prepare horizontal, thematic surveys on the treatment of various policy provisions in RTAs. And in April 2002, CRTA held a seminar on regionalism and the WTO to enhance the understanding of the impact of RTAs on the multilateral trading system. It is revealed that WTO has paid increasing attention on RTAs in an attempt to find a way out in the new development of the latter.

5. Conclusions

It should be noted that every country sees these two trends in a broader context of strategic and political considerations, resulting in an even more complicated relationship between the WTO and various RTAs in the real world. The fact that more and more countries have chosen to take part in both trends shows that regionalism is not necessarily an alternative course to multilateralism. On the contrary, as indicated in our discussion, "WTO-consistent preferential trade agreements can complement but cannot substitute for coherent multilateral rules and progressive multilateral liberalization" [xiv]. All in all, the two trends are and will keep enjoying a symbiotic relationship. We hold that both regional and multilateral mechanisms have their own limitations, thus WTO has to carry out its liberalization mission through competing with, as well as, learning from regionalism.

Achieving Synergy Effects in a Regional Economic Unity

Suck-Chul Yoon
Seoul National University, Korea

Abstract

This paper defines a Total Optimum as a decision that is optimal from the standpoint of the economic bloc as a total. Also, this paper defines Partial Optima as the optimal decisions in the interest of the sub-units comprising the economic block. Finally, this paper will show that a Total Optimum can only be achieved through the concession or sacrifice of the Partial Optima and vice-versa.

Introduction

The economic competition of today's world is becoming ever more severe as the competition increases among the regional blocs such as the EU of Europe, NAFTA of North America, ASEAN of Southeast Asia, etc. In the prospects of the continuation of this tendency, China, Japan and Korea feel like consolidating their economic efforts to cope with the pressures from the other economic blocs.

When consolidated efforts are needed, many leaders, political, social, or economical, have shouted a slogan, "United we stand, divided we fall." What will this slogan mean in the age of harsh economic competition among regional economic blocs? How can an economic bloc enhance its own competitiveness in comparison with others? A regional economic unity is usually comprised of many individual countries. The problem is how to unite these individual countries so that the competitiveness of the economic bloc may be enhanced most effectively. The aim of this paper is to propose a methodology to solve the problem using the concepts of Total Optima and Partial Optima.

This paper stipulates that the relationship between a Total Optimum and Partial Optima is one of conflict that often accompanies most organizational decision-making. Empirical evidence suggests that certain qualities are required of the leaders of an economic bloc if the leaders wish to implement decisions to enhance the bloc's competitiveness. Those qualities are: (1) the intellectual capacity to identify the real entity of Total Optima; (2) the persuasive capacity to attain concession from the sub-units by making the sub-units recognize this real entity; (3) the fairness to appropriately distribute the fruits obtained from implementing such Total Optima to the sub-units who have given their concession.

The method used in this paper is what they call 'problem-based learning (PBL)' in the fields of medicine, business, education, etc. The PBL method adopted for this paper starts with a hypothetical problem and through the process of solving the problem it provides us with the Total Optimum and Partial Optima of the problem. On the basis of the learning about these two types of optima we identify the relationship between the two types of optima.

Total Optima and Partial Optima

A family is the primary group of a society formed of members that share the same blood and this blood relationship acts as a very strong force that keeps people together. Thus, within a family, it can be expected that each individual will sacrifice themselves for the prosperity and future of the family. However, when it comes to a business organization, a national state, or a multinational community such as an economic bloc, it becomes increasingly difficult to expect the sacrifice of the sub-units in the interest of the community as a whole.

In today's harsh realities of global competition, the enhancement of competitiveness has become one of the most important goals for an economic bloc. In other words, it has become inevitable that some of the sub-units within the economic bloc are often required to sacrifice themselves to a certain degree in order to attain the ultimate goal of the bloc. In order to discuss this issue more analytically, let us begin our analysis with the following hypothetical case

A Hypothetical Case

Suppose that a regional economic unity, let's name it REU, is made up of three countries. Let's call these countries A, B, and C, respectively. Let's also assume that each of these countries can produce products W, X, Y, and Z. These products are produced using basically the same production facility. However, since each country has its own cost environment, the production costs per unit of each product are different from country to country as shown in Table 1. These three countries sell the products for standardized prices in the global market. The annual production capacity of each country and the aggregate worldwide demand for the products are as shown in Table 1.

TABLE 1

	Product W	Product X	Product Y	Product Z	Production Capacity
Country A	$19 per ton	$30 per ton	$50 per ton	$10 per ton	7 M tons
Country B	$70 per ton	$30 per ton	$40 per ton	$60 per ton	9 M tons
Country C	$40 per ton	$8 per ton	$70 per ton	$20 per ton	18 M tons
Capacity	5 M tons	8 M tons	7 M tons	14 M tons	

Now, our question is: Is there a way to minimize the total production cost for the three countries, A, B, and C as a whole while meeting the worldwide demand for the-products? In order to answer this question, let us first define controllable factors, i.e., the decision variables that can be manipulated by decision makers as in Table 2.

TABLE 2

	Product W	Product X	Product Y	Product Z	Production Capacity
Country A	X11	X12	X13	X14	7 M tons
Country B	X21	X22	X23	X24	9 M tons
Country C	X31	X32	X33	X34	18 M tons
Capacity	5 M tons	8 M tons	7 M tons	14 M tons	

As shown in Table 2, the decision variable X_{ij} is defined as the quantity of product j (while j=1 for W; j=2 for X; j=3 for Y; and j=4 for Z) produced in Country i (while i=1 for A; i=2 for B; and i=3 for C).

Our goal is to minimize the following sum:

$19x_{11} + 30x_{12} + 50x_{13} + \ldots + 20x_{34}$

The constraint conditions are as follows:

$x_{11} + x_{12} + x_{13} + x_{14} = 7$
$x_{21} + x_{22} + x_{23} + x_{24} = 9$
$x_{31} + x_{32} + x_{33} + x_{34} =18$
$x_{11} + x_{21} + x_{31} = 5$
$x_{12} + x_{22} + x_{32} = 8$
$x_{13} + x_{23} + x_{33} = 7$
$x_{14} + x_{24} + x_{34} =14.$

Now the task is to solve the above mathematical model and find the optimum values for the decision variables. The above mathematical model is a special form of linear programming, and therefore an application package can be used to find the optimum values as given in Table 3.

TABLE 3

	Product W	Product X	Product Y	Product Z	Production Capacity
Country A	5 M tons			2 M tons	7 M tons
Country B		2 M tons	7 M tons		9 M tons
Country C		6 M tons		12 M tons	18 M tons
Capacity	5 M tons	8 M tons	7 M tons	14 M tons	

According to Table 3, the values for the decision variables are as follows:

x_{11} = 5 M tons x_{14} = 2 M tons
x_{22} = 2 M tons x_{23} = 7 M tons
x_{32} = 6 M tons x_{34} =12 M tons,
with other variables all being zeros.

In physical meaning,
if Country A produces 5 Mega tons of W and 2 Mega tons of Z;
Country B produces 2 Mega tons of X and 7 Mega tons of Y; and
Country C produces 6 Mega tons of X and 12 Mega tons of Z;
then REU as a whole can minimize the total production cost of the four products while satisfying the worldwide demands for the products. The minimum value of the total cost is calculated as follows:

5 x 19 + 2 x 10 + 2 x 30 + 7 x 40 + 6 x 8 + 12 x 20 = $743 million.

However, the solutions obtained in Table 3 are not optimal from the standpoint of each country. For example, if one takes into consideration the position of Plant A, their production cost per unit ton is lowest (i.e., $10) for the product Z. Thus, the optimal solution from the standpoint of Country A is to produce only Z, with the following lowest possible cost:

10 x 7 = $70 million (1)

However, according to Table 3, Country A is required to produce 5 M tons of W which costs $19 per unit ton and to produce 2 M tons of Z. Doing this, the total cost for Country A becomes:

19 x 5 + 10 x 2 = $115 million.

This means that Country A has to accept the cost increase of $(115-70) =$45 million in order to make the total production cost of REU minimal.

Now, let us look at Country B. It would be best for Country B to produce 8 M tons of X for which the cost is lowest ($30 per unit ton) and 1 M ton of Y that is the next lowest cost ($40). By doing this, the possible lowest cost for Country B would be:

$$30 \times 8 + 40 \times 1 = \$280 \text{ million.} \qquad (2)$$

However, according to Table 3, Country B is required to produce only 2 M tons of X and 7 M tons of Y. This makes the total cost as follows:

$$30 \times 2 + 40 \times 7 = \$340 \text{ million.}$$

This means that Country B has to accept the cost increase of (340 – 280) = $60 million in order to make the total production cost of REU minimal.

Finally, for Country C, their best solution is to produce 8 M tons of X and 10 M tons of Z in which case the total cost will be:

$$8 \times 8 + 20 \times 10 = \$264 \text{ million.} \qquad (3)$$

However, Table 3 shows that Country C is required to produce only 6 M tons of X and 12 M tons of Z, thus making their total cost as follows:

$$8 \times 6 + 20 \times 12 = \$288 \text{ million.}$$

This means that Country C has to accept the cost increase of (288 – 264) = $24 million in order to make the total production cost of REU minimal.

Now, applying the definitions of Total Optima and Partial Optima as provided in the previous section, the solution as shown in Table 3 is the Total Optimum, while the solutions described in equations (1), (2), and (3) are the Partial Optima.

The Conflict between Total Optimum and Partial Optima

Ideally speaking, the sum of all Partial Optima should become equal to the Total Optima. However, such an instance is generally difficult to take place except by a sheer coincidence. In our case, the Partial Optima from the standpoint of the three plants do not match the Total Optima.

In general, there exist conflicts between the Total Optimum and Partial Optima. In other words, the Total Optimum may only be achieved through the concession or sacrifice of Partial Optima. The conflict between the two exists in all communities and organizations that comprise their sub-units.

How to Resolve the Conflict

For an economic community to increase its competitiveness, the Total Optimum should be sought at the sacrifice or concession of Partial Optima. However, we have to also admit that the whole cannot thrive on the destruction of its sub-units. Therefore, if the situation arises in which the very existence of some of the sub-units is threatened, then the sub-unit has to be allowed to realize its Partial Optima so that it may stay alive. The following example is such a case.

The 1984 L.A. Olympic Games Organization Committee

The 1984 Los Angeles Olympic Games Organization Committee headed by Peter Ueberroth had to prepare for the games without any financial assistance from the federal government. The federal government was not in a position to assist the committee since it was suffering from deficits. One of the ways to create the necessary funds for the Games was to ask for donations from supplying companies, and in return, give them monopoly in the supply of certain goods or services. Among the things that would be needed during the Games were films, but the L.A. Olympic Games Organization Committee had to go through a very difficult decision making process in giving official sponsorship for films. The company with the longest tradition and history was the American company Kodak and everyone expected that Kodak would become the official sponsor. However, being the strongest candidate, Kodak maintained a standoffish attitude and suggested that they would be willing to donate one million dollars. On the other hand, the Olympic Games Organization Committee had already come to the conclusion that they need to secure at least four million dollars from a film company. It was a dilemma.

At that time, Japanese Dentsu Inc. suggested a donation of seven million dollars for the sponsorship of Fuji films and added that they would develop all films for the Committee free of charge. Fuji Films was a Japanese company and at that time, the U.S. was suffering from trade deficits with Japan. Considering national pride and trade deficits, it was natural that the L.A. Organization Committee would give sponsorship to Kodak. This could be seen as a solution to achieve the Total Optimum for the U.S. Nevertheless, it was not easy for the Committee to reject its Partial Optima, a seven million-dollar donation. In the end, the Committee opted for the Partial Optima, and as a result, was able to stage the Olympic Games successfully. There was no blaming the Committee.

The Leadership for the Achievement of Total Optima

In today's world of global competition, the leaders of economic blocs should ask for the sacrifice or concession of its sub-units to give up Partial Optima so as to maintain the competitiveness of their blocs. The problem is how to achieve this. What are the viable methods? Let us look at the following case:

General Electric versus K Corporation

In the late 1980s, an anonymous company, let us call it K Corporation, in a developing country began to expand into the world market with cutting and grinding tools made with synthetic diamond. Technical knowledge to make the synthesized diamond was first developed by General Electric (GE). Thus when K Corporation appeared and began to expand their market in the area, GE began to take notice. GE believed that K Corporation had stolen their know-how in producing synthetic diamond and thus asked an American intelligence agency to begin surveillance on a Mr. K's visits to the U.S. Mr. K was an engineer who had retired from GE. Eventually, Mr. K. was arrested at an airport in the U.S. with the documents he was carrying confiscated, and was prosecuted by the American government. GE demanded that K Corporation immediately stop all sales of relevant products and that K Corporation should pay retrospective compensation for all the products that have been sold. K Corporation did not have any knowledge of the court procedures in the U.S. and it seemed to be a matter of time that they would lose the lawsuit.

At that time, GE was selling products such as jet engines, power plant facilities, medical equipment, etc. to the country that was the home country of K Corporation. Thus, Chairman J. Welch, then CEO of GE, visited the country, and asked about the public sentiments of the people on the case of GE versus K Corporation. Chairman Welch learned that if GE, a giant enterprise, were too harsh against K Corporation, a small company, people in the country would have a very bad impression of GE and that this might even lead to unfortunate social movements such as a boycott against GE products.

Chairman Welch, who had a good sense of global management, called his people of the department of synthetic diamond and persuaded them that they be lenient on the case against K Corporation. He managed to obtain their concession by making them see that it would be a better decision in light of the Total Optimum for GE. Eventually, GE began negotiations with K Corporation, and the original harsh demand of immediate end of sales and retrospective compensation was withdrawn. Rather, they reached a mutually agreeable solution at the level of K Corporation paying an appropriate royalty for future production.

This case of GE versus K Corporation shows how the Partial Optima from the standpoint of the synthetic diamond unit of GE was adjusted for the Total Optimum of GE as a whole.

The Political Philosophy of President Park Chung Hee

In the 1960s, Korea was one of the poorest countries that had just gone through the Korean War. The foremost priority for President Park, who had assumed his power after a military coup-de-tat, was to bring economic development to Korea through industrialization. Thus there was a succession of 5-year economic development plans and within 30 years, Korea was able to get into the level of a developing nation. However, this success was not without negative consequences. It resulted in widening the gap between the rich and the poor which, in turn, led to social side-effects.

President Park thought that the only way to achieve national unity was to reduce the feeling of isolation of the poor by suppressing the consumption of the rich. One way of actually implementing this thought was realized in the policy to postpone the broadcast of color television programs. Around the later part of the 1970s, Korea had already become one of the leading countries to export colour televisions. However, President Park did not allow broadcasting color television programs within Korea. Thus, the Korean people had to watch black and white television until after the death of President Park in 1979. This case is an example that shows how the Partial Optima of a sub-unit (the rich people) in the form of fulfilling the desire for color television was sacrificed for the achievement of the Total Optimum in the form of national unity through narrowing the gap between the rich and the poor.

This political philosophy produced a ripple effect down to the enterprise level. In companies that had factories without an air-conditioning system, the management offices also went without air-conditioning. This was done so that unity would be maintained between the laborers and the management under the catch phrase "Let us, the labor and management, work hard and overcome hardship together." However, it is perhaps the natural tendency of humans to strive for Partial Optima. The social atmosphere of consumption repression began to fall apart and the social gap between the rich and the poor widened. Politicians began to lose the trust of the poor people in the early 1980s. Thus began the serious conflict between labor and management in the mid 1980s.

Conclusion

Business organizations need to produce synergy effects by consolidating their sub-units and thereby increase competitiveness in order to survive in the global market. The word synergy comes from the ancient Greek word "synergos" which means "working together" (Goold and Campbell, 1998, p. 133). However, the synergy effect cannot be gained by simply working together. This paper has shown a way to produce a synergy effect by achieving what this paper called the Total Optimum. The Total Optimum, the best state of a system from the standpoint of the total, can only be achieved through the sacrifice and concession of the Partial Optima, the best states of the sub-units from their own standpoints.

Some scholars maintain that they will to sacrifice Partial Optima on the part of the sub-units in favour of the Total Optimum is in functional relationship with the culture. Geert Hofstede describes the society that has a relatively high will to sacrifice Partial Optima for Total Optima as "collectivism" and the opposite case as "individualism" (1991, pp. 49-67). In his 1991 book, *Cultures and Organizations*, Hofstede studied the strength of the tendency for collectivism in 23 areas around the world and came up with an index that showed this strength. This data showed that individualism was prevalent in the western countries while collectivism was strongest in Confucian cultures such as China, Japan, and Korea.

What kind of culture one may be in, however, it is never easy to pull out concessions of the Partial Optima in favour of Total Optimum. For each sub-unit, priority would be placed on matters that are concerned with its interest. Thus, if the competitiveness of the whole is to rise, there is a need for a strong and persuasive leadership to achieve the Total Optima by getting the concession of Partial Optima (Hunt, 1991).

Today's competition in the global market is becoming ever more severe as economic blocs are created. However, even economic blocs would have to meet the following conditions in order to achieve their synergy effects: (1) clearly identify the real entity of the Total Optima of the bloc; (2) persuade the individual sub-unit to make concessions for the realization of the Total Optimum; and (3) devise and maintain a trustworthy system that will distribute the benefits of the Total Optimum fairly to all participating sub-units that sacrifice their Partial Optima.

Conducting Business in Europe, Third Millennium

Juan Ribas Ariño
EADA, Spain

Abstract

This paper intends to discuss the response from the nationwide type of company to the European-wide market-model integrating the 15 member European Union, the 12 nations joining in 2004-2007, and the moving forward agreements with next candidates and neighboring Mediterranean nations. They are all integrating a new kind of multinational community sharing, totally or selectively, the free flow of trade, capital and people, and the euro currency. Cultures, languages, and economic background may differ, but the new model exhibits half a century of sustained advancement. It sits on an underlying commitment to mutual understanding, aiming to peace, stability and development. This cuts business transaction costs, hence encouraging interaction, investment and trading, and propelling long term prosperity. Consequently, the frontier is moving ever ahead, widening the opportunities for every step of the business value chain, but exposing to lifting competitive forces. Which is the answer from the nationwide type of enterprise?

Introduction

There is a significant group of mid size companies with limited geographical scope, i.e. the Iberian Peninsula (Spain and Portugal), and only sporadic activity in international trade. Actually, they find themselves before a major challenge: to assess their strategic position in relation to the spreading European Union (EU), taking into consideration the member nations as well as candidates and associates. Every EU step forward, like the transition of candidates into membership, or the upgrading of agreements with neighbor countries, is often perceived as a mix of open opportunities alongside threatening disturbances.

This analysis originated in Fall 2002, after a half a day seminar organized by the European Commission. It took place in its office in Barcelona, Spain. The subject was the enlargement of the EU from 15 to 25 members, to be effective by mid 2004 (see Section 1 below). The event was addressed to the corporate management of the Barcelona area that is a major business region in Spain. There were representatives of the European Commission, the local Government, and various Business Associations, as well as invited speakers. It was presented as an illustrative, updating session on a significant European evolution, but the number of attendants was extremely limited, in spite of ample publicity. The tenor of the presentations was optimist, but the audience looked visibly hesitant. At coffee break, the representative of a Business Association made a significant comment when expressing a growing concern in his milieu, related to the aggressiveness of new competitors from joining members, like Poland of the Czech Republic, based on relatively low salary levels and therefore providing a cost saving alternative to operations actually run in Spain. At the end, feelings were mixed. The reason for the lower cost alarm was certainly understandable, but, was it equitable? If listening to all speakers and trying to balance their reports, there appeared to exist two sorts of trends. First, an expanding marketplace, especially on the part of new members demanding unavailable technology and products. And second, newly emerging options for all types of joint alliances, starting with cost cutting subcontracting, that is true, but extending to all steps of the value chain, like valuable distribution channels opening commercial activities in new markets.

The following three sections intend to display the background, the present and the foreseeable future of the EU, to draw the extent of its effective frontiers, to discuss the corporate strategic response and, finally, to reason the kind of organization and team skills required for a successful action plan.

Section I asserts the forces leading to the initial establishment and to the persevering advancement of the EU. First was the European Economic Community. Next came the gradual enlargement to the present 15 member EU. The following step is the incorporation of 12 nations by 2004. At the same time, there are the commercial agreements with lining candidates and the Southeast Mediterranean countries. This evolution opens new areas of business opportunities, broadening the existing fields of action, and calling for attention to a quickly changing environment.

Section II states the vision, the strategic plans and the actual performance of a number of companies that hold a determined European wide perspective and search for adapting to, and take advantage of, the emerging, ever expanding, new experience.

Section III addresses the inside of the company and proposes a reasoning exercise aimed to designing the course of action that better suits the changing scenery. This comprises the culture and the structure of the organization, and the upgrading of all functions.

Section I: The European Union, a stepping up progress

The roots of the EU seem to lie in ancient times.

When looking at the social and economic progress of the Greek city, the *polis*, Aristotle (IV BC) understood that nature compels people to live in community, searching for a greater well-being than living or working in isolation. The philosopher described the *polis* as a perfect community of villages originating out of the necessities of life and existing because of granting a better living. He wrote: "The city is a reality of nature, driven by the social character of man." This argument may apply to a larger area than the city: the community of nations intended to assemble their citizens in a single political project fostering the cooperation in knowledge development, the discussion of joint propositions, and the economical welfare, within the overall objective of constructing an environment of peace and prosperity.

The Mediterranean Sea was the site of the first economic community in history. Its target was the expansion of trade. Around the 13th century BC, Phoenicia began its incursion into the Mediterranean. The Phoenicians were artisans, sailors and traders who had developed a flourishing economy in the Eastern Mediterranean and felt anxious to expand to the western coasts. Larnaca, Cyprus, *the island of copper*, was the first colony (10th century BC). They later reached Crete and Sicily, as well as Carthage (9th century) that became the predominant center for western trade. Gades (Cadiz), south of the Iberian Peninsula, was the main Phoenician port and trading spot for Iberian minerals. Greece took over, increasing the number of colonies and introducing the coined money as a means of exchange. Corinth was their center of operations. The port of Piraeus had depots used by merchants from eastern and western sides. The period between 400 and 350 BC was brilliant: mercantile exchanges were fluid, Athens acted as administrative center, and an increasing number of competitors struggled to gain market share and accumulate capital resources. Roma consolidated such a development by adding technology, organization and even a common currency, until collapsing as from 200 AD.

The birth and development of a new model

That historical event is duplicating. The first half of the twentieth century was a turbulent period where two world wars, originating in Europe, devastated the European Continent and inflicted major social and economical damage. Such a chaotic event encouraged a group of nations to search for a new framework restoring peace and stability, for these are fundamental conditions to promote the interaction between nations, eventually leading to the progress of science, technology and trade, and finally granting social and economic advancement. The first step took place in 1950. This was the “Schuman Declaration”, inviting the European nations to join the French-German initiative on a common market for coal and steel. Robert Schuman (French Minister for Foreign Affairs) based his statement on the enlightening design of Jean Monnet, the *architect* of the modern Europe. The CECA (standing for European Community for Coal and Steel), was signed in Paris (1951) by France, Germany, Italy, Belgium, Holland and Luxemburg.

This was the first step. The genuine departure took place in 1957 when the same six countries signed the Treaty of Rome, setting the foundations of the European Economic Community (EEC), and establishing a free trade area for 200 million inhabitants. This was the embryo of the actual 15-member EU. Nine nations adhered in between 1973 and 1995: United Kingdom, Ireland and Denmark (1973); Greece (1981); Spain and Portugal (1986); and Austria, Sweden and Finland (1995). All but three (United Kingdom, Sweden and Denmark) share the euro currency since 2002. R. Schuman and J. Monnet would have hardly dreamed of EU with 379 million citizens (2002) taking the free flow of trade, capital and people just for granted, and sharing an economical and monetary union. This has been an impressive development, as underlined[1]: “Compare Europe now with Europe 50 years ago, and you do not have to be a genius (...) to conclude that the EU has been one of the great political success stories of the post-war world”.

In the same report, *The Economist* added that: “is merely the story so far. Europe is still very much a work in progress”. Right, the progress is on the way. A new expansion will be completed by 2004, following the agreements approved in Athens (April 2003). The 10 new members are: Estonia, Latvia, Lithuania, the Czech Republic, Slovakia, Poland, Hungary, Slovenia, Cyprus and Malta. This will build a UE of 25 members and 454 million citizens (2002). Next will be Romania and Bulgaria by 2007, adding 31 million and achieving a 27-EU with a population of 485 million (2002), equal to 8 % of total worldwide.

The 15-EU generates around 20 % of world GDP. First results for 2002 [2]reported a GDP of 9.161 billion €, 1 % above 2001. Over the last four years, the 15-EU economy has increased by 9.2 %. The main contributors are three previous laggards –Ireland, Spain and Greece– that have grown by 37 %, 14 % and 17 % in the same period. The GDP per capita has risen to average 23.970 €. The four main nations –Germany, France, Italy and United Kingdom– run slightly above. Spain (17.000), Portugal (12.500) and Greece (12.900) find themselves in the lower positions, although gradually catching-up. In fact, the gaps are smaller when adjusting for market price differences, which are in terms of *Purchasing Parity Standard (PPS.* The adjusted GDP per capita are 19.900, 17.300 and 16.500 €, respectively.

The 12 candidates joining in 2004 and 2007 (CCS) achieved a GDP of 502 billion € in 2002, equal to 1.005 in *PPS* terms [3] They add 28 % to the EU population but only 5,5 % GDP (11 % in *PPS*). However, the group has grown by an impressive 43 % over the last four years, comparing to 9.2 % (see above) in the case of the 15-EU. In fact, the firm progression started in 1994, after a painful political transition. The *catching-up* race has clearly started before membership, in spite of many adjustments still in process regarding communication and technological infrastructures, as well as production equipment and organization. The leaders are the Czech Republic, Slovenia, Hungary and the Slovak Republic. Even after that quick step up, the average per capita GDP raised to 9.500 € (2002, *PPS* adjusted), comparing to 23.970 € for the 15-EU (see above). The gap is still remarkable, and then the *catching-up* will probably go on.

Turkey is the next candidate. The integration process may take as long as 10 years, but there is an increasing association to the EU by means of commercial agreements and direct investments. It has a population of 68 million, thereof 30 % below 14, a sharp contrast with only 18 % in the 27-EU. Turkey reported a GDP of 192 billion € (383 in *PPS* terms*)* in 2002[4]. It grew by 18 %, after a discouraging, negative, 2001. Last four years have aggregated 8 % growth. The GDP per capita (*PPS* adjusted) increased in 2002 to 5.500 €, comparing to average 9.500 for the 12 new members and to above 23.970 for the 15-EU. Given the existing interacting trend, and unless there are disturbing political or social uncertainties, the *catching-up* process should continue as in the case of the other candidates.

Following the above facts, the *operational* EU does stretch to 28 members, with 553 million citizens (9 % of worldwide) and 9.855 billion € nominal GDP (around 27 % of worldwide). Everyone’s willingness makes it a solid enterprise. There are open issues to deal with, as the agricultural policy, but a great majority feel like belonging to the *right club*, as proved by the affirmative answers to membership referendums than have taken place in 2003. When asking Jacek Saryusz-Wolski, the head of Poland’s office for EU integration, why his country wants to join the European club, he laughs: “I haven’t thought about that for ten years”. He will cite economic, diplomatic and strategic reasons, but the ultimate argument is “civilisational”, as one of his colleagues puts it: “Imagine there is a river running through Europe, dividing east from west. We have to make sure we are on the right side of the river”[5].

There are more in the party. Next is the Euro-Mediterranean partnership, launched after the Barcelona Convention, in 1995[6]. It comprised 12 Mediterranean Partner Countries (MPC). Actually, Cyprus and Malta are joining the EU in 2004 and Turkey is an official candidate (see above). This cuts the number of MPC to 9. They are: Morocco, Algeria, Tunisia, Egypt, Jordan, Lebanon, Israel, the Palestine Authority and Syria. Their population is 166 million, with 36 % below age 14. Excluding Israel, total GPD, at current prices, is 327 billion € (2000). The GPD per capita, *PPS* adjusted, is below 5.000 with the exception of Algeria and Tunisia, than run slightly above. Israel has a per capita DGP of 20.000 €, near the EU-15 average. There are two interesting facts insofar the Magreb is concerned. First is the economic growth during the five years after the Barcelona Convention (1995-2000), where Morocco, Tunisia, Algeria and Egypt have expanded by 20 %, 33 %, 17 % and 31 %, comparing to 5 %, 21 %, 1 % and 18 % for the previous 5 years to 1995. Second, the investment in equipment and infrastructure was the biggest contributor to GDP in year 2000, laying the grounds for continued development.

A continent of opportunities

This state of affairs points to five issues calling for business management attention. First is the *catching-up* effect that drives the relatively higher advancement of modest nations. Second is the rising flow of direct investments, that responds to the opportunities perceived by a number of companies, even mid size ones. Third is the fast growing intra-community trading flow, that is related to the emergence of cost and technological clusters, and builds entry barriers to non-community parties. Forth is the regional compensation gap. Finally, there are the population and immigration trends.

The first issue is the *catching-up* effect. Following a study conducted by the Harvard Institute for International Development[7], global patterns of growth during the period 1965-1990 were shown to depend on four factors: initial conditions, physical geographic, government policy, and demographic change. Initial conditions matter in the sense that, other things being equal, poorer countries tend to grow faster than richer ones. This is the *catching-up* effect. Economic policies proved crucial to support its development, for open economies grew 1,2 percentage points per year faster than closed. The basic condition is good government, granting stability and contract compliance. The world GDP grew by annual average 3,4 % during 1981-1990, but the developing countries reported 4,2 % in front of 3,1 % for the leaders. China and the Pacific *tigers* escalated to top places by achieving 6,9 % annual growth. This applies as well to modest EU new members. During the period 1986-1991, just after incorporation, Spain and Portugal achieved a GDP growth of 23 % and 29 %, comparing to average 17 % for the whole EU. Spain and Greece still held the *tempo* during 1999-2002, with 14 % and 17 %, that is well above 9 % for the EU. The CCS have undertaken their particular *catching-up* process, as proved by their superior economical growth (see above) during 1998-2002. Various analyses anticipate a similar future, for the CCS is far away from balance in relation to their partners. The "potential future growth rate" of the 12 candidates is estimated at around 5 %[8].

The second issue is the foreign direct investment (FDI) into CCS. Their growing trend requires a sustained inflow of FDI, for they miss the accumulated savings that would grant the required financial resources. They need to upgrade their knowledge and technology, too. Indeed, FDI into the 13 CCS (including Turkey) raised from 10 billion € in 1995 to 25 billion in 2000. There is a correlation between the FDI and the degree of economic openness (calculated as the relation between foreign trade and GDP), which progressed from 69 % to 85 % in the same period. The FDI have increasingly financed the deficit of the current accounts of the CCs, from 54 % in 1994 to 80 % in 1998 and 71 % in 2000[9]. It is clear that stability and fair government open borders and reduce transaction costs, so encouraging free trade that subsequently calls for increased FDI on the part of multinational companies to produce for domestic and export markets, eventually engaging the economy into a lively circle. All are interrelated.

The FDI flowing into the 12 MPC that signed the Barcelona Convention in 1995 (see above) is still modest and varies in relation to prevailing opportunities, i.e. privatization plans. But it heads the MPC to GDP growth rates high enough to reduce unemployment and improve the social situation. FDI run below annual 0,8 billion € until 1995. Then, it steadily increased to 2,2 billion in 1998, to drop to 0,7 in 1999 and finally set record amounts in 2000 and 2001, with 3,7 and 2,3 billion. This analysis includes Turkey, that went up from 0,3 to 1,3 billion in 2001. The Magreb countries have kept at annual 0,5 billion. FDI to Egypt is unimpressive with the exception of 2000, when reached 1,2 billion [10]. The lack of stability, coupled with uncertainty, highly attach FDI to prevailing opportunities. However, the flow is permanent and generates a progressive impact on the trade flow (see above).

The third issue is the trading between partners. The European environment drops political and financial barriers, builds trust, opens communication and, consequently, reduces transaction costs. This encourages intra-trading. The 15-EU share of world trade, in between 1980 and 1999, increased from 37 % to 39 % in exports, and declined from 41 % to 38 % in imports. The extra-EU share dropped in both, from 15 % to 14 % in exports and from 19 % to 14 % in imports. Therefore, 64 % of *international* trade was in fact *intra-trade*. At the same time, the EU achieved a balanced trade flow (export less import) with nations across community borders, replacing *extra-imports* with internal transactions (WTO, 2000). Checking an specific example, the EU share of Spanish exports increased from 54% of total worldwide in 1986, when joining, to 71% in 2000, while the share of imports from the EU developed even more sharply, rising from 39% to 63% in the same period, maintaining this ceiling in 2001 and 2002 [11].

At the same time, the CCS share of the 15-EU extra community-trade just doubled from 1992 to 1999, from 5 % to 10 % in imports and from 6 % to 12 % in exports. The shifting to the new partners, in the case of the 15-EU imports, responds to favorable manufacturing and transaction costs, and to proximity. Exports often relate to providing technology and equipment. Multinationals have played a visible role[12]. See related cases in section 3 below.

The fourth issue is labor cost, where the divergence is sizeable. The average cost per hour in the 15-EU (annual salary plus benefits and social contributions, divided by annual hours) was 22.19 € in 2000. The top is at Financial Intermediation (34,28) and Energy (30,02). The lowest is at Construction (19.09) and Hotels-Restaurants (14,63). Average of CCS is 3,47 €, one sixth of above 15-EU, with a similar scale by sectors. There are significant disparities between countries. In the case of the 15-EU, Sweden (28.56) is at the top, followed by Germany, while Spain (14,22), Greece and Portugal (8,13) are at the bottom. Regarding the CCS, Poland leads (4.48), whereas Rumania and Bulgaria (1,45) are at the low end. In manufacturing, averages are 22.75 and 3.95 €, with similar country rankings. However, the study underlines that "lower levels of labor costs per employee are associated with lower levels of labor productivity", supporting that theory with the correlation between salary level and total value added in the 15-EU, which signals that the combination of the two significantly reduces the labor costs advantages[13]. In summary, the right strategy must balance labor cost with training and technological applications.

The fifth issue is population, in particular its age distribution and the immigration trend. As shown above, the 27-EU (15 actual members plus 12 CCs) will have 485 million citizens, with only 18 % below age 14. Turkey, the next candidate, has 68, with 30 % below 14. The 9 MPC sum up 166, thereof 36 % below 14. Worldwide, the segment below 14 accounts for average 30 %. As a result, the 27-EU gets older, for the segment above 65 is close to 13 % in front of 7 % worldwide. This development may have various implications, i.e. the contraction of the labor force and the consequent economical regression, the distressing of social security and public retirement programs, and visible shifts in market demand. But it also impels to re-balancing, either increasing fertility rates, or immigration, or turning to Turkey and to MPC for increased supplying of labor intensive products and services.

Immigration is a fact. The EU attracts rather young, determined citizens from deprived areas, mainly Africa and South America. At the same time, Eastern European increasingly presses on moving to the West. The size of net immigration is hardly measured, but most probably exceeds one million per year (2000-2002). During 1995-2002, net immigration has added at least annual 0.2 % to EU population, equal to in between 5 and 6 million citizens for the complete period. Natural increase just counts for 0.05 %, as a result of a low total fertility rate (average number of children that would be born alive to a woman during her lifetime if the current rate were to continue), that maintains at around 1.47[14].

The defining traits

All in all, the European development may be highlighted by the following traits [15], that intend to clarify the end of XX century's global trends:

First, "the Cold War system was characterized by one over-arching feature: *division*", for the world was a divided-up place. The symbol was "the *Wall*". The new system has another "overarching feature: *integration*", for the world is increasingly interwoven. The corresponding symbol is "the *Web*".

Second, "the defining document of the Cold War system was "The *Treaty*". Again, there is a different document for the globalization era: "The *Deal*".

Third, the Cold War was known as "a world of *Friends and Enemies*". Now, "the globalization world, by contrast, tends to turn all friends and enemies into *Competitors*".

Friedman also writes that such changes require a clear democratization in four areas: technology, finance, information and decision making. Then, good governance should grant the free flow of technology, finance and information, and "the best CEO will be that who understands that their job is to chart the broad corporate strategies, to establish the broad corporate culture, to get the balls rolling on the right paths and then let those closest to the customer and to the rapidly changing marketplace manage those balls on their own". The management's response will be further discussed in the next two sections.

Then, *Web, Deal, Competition and Democracy* seem to be the traits that support the progression of the EU model.

Further expanding the Web

A final addendum to this section: the EU is signing agreements with members of other communities. The first was the Agreement on Free Trade between Mexico (member of the North American Free Trade Agreement: NAFTA) and the EU, signed in Lisbon in March 2000. It anticipated the gradual elimination of tariffs, in such a way that all Mexican products shall have free access to the EU by 2003, whereas a top 5% duty will remain in place for 40% of European goods. By 2007, trade shall be entirely free. The second was the Agreement with Chile (member of the *Mercado Común del Cono Sur:* Mercosur) and associated to NAFTA as from 2002. Until recently, such accords used to take place between nations. Actually, a Community of Nations is involved. The *web* is expanding.

Section II: The Corporate perspective

Actually, the first bunch of corporations fully determined to expand its operations in the European Economic Community (EEC), born with the Treaty of Rome (1957), was not European, but American. As a matter of fact, the Department of Commerce, Washington D.C., found it astonishing that American business investments, 1966 opposite to 1965, had increased by 40 % in the EEC, comparing to just 17 % in the domestic Market and 21 % in the rest of the world. The EEC "becomes the new frontier of the American Industry"[16]. In 1963, the American companies were already leading the new and starring electronic field, with 15 % market share of consumer appliances like radio and TV sets; 50 % to 80 % of components for the newly born computer industry, and 90 % of integrated circuits. Their knowledge superiority was widely recognized. By the end of the sixties, the American firms had conquered top positions in the European Chemical, Electronic and Automobile industries –in sales and profits. According to Servan-Schreiber, the Americans brought to Europe a new management style, entrepreneurial and pragmatic. They made mistakes but "the time needed to correct them is negligible comparing to local competitors". They demonstrated "a quick adaptation capacity allowing them to fully understand the local environment". In fact, "the flexibility, rather than the superior financial resources, is their basic arm". The list of *invaders* was headed by such names as Du Pont de Nemours, Union Carbide, General Electric, IBM, General Motors, Ford, and many others.

Next cases illustrate the corporate answers to the European model. The first management drive, when shifting from nationwide to continent-wide, may be associated to a variety of reasons, i.e. the short term need for corrective action in relation to revenue, operational cost, or both; the opportunity to benefit from either technological or commercial alliances; the decision to expand into unknown markets; and the decided enhanced, long term, planning vision.

The answers of Braun, Poliglas, Saint George and Mango

In the late seventies, Braun Spain was a modest manufacturer of small electrical appliances for kitchen and home use. Even being a subsidiary of Braun AG, Germany, since 1963, the Spanish management was largely self-ruling insofar the local industrial and commercial operations were concerned. 95 % of sales were achieved in Spain, that experienced a terrific expansion during the first half of the seventies. The company was more than pleased with domestic results, paying little attention to export opportunities that were sporadic and accounted for just 5 % of turnover. This state of affairs changed drastically after 1977 as a result of a double crisis that caused a major impact on the domestic market: the oil price jump and the transition from dictatorship to democracy. The reaction consisted of searching for opportunities within the EEC. The natural partners were the Braun commercial subsidiaries distributing the products made in Germany, but they were little aware of the Spanish range. Then, the initial step was persuading the new commercial partners by showing them the Spanish success story, and demonstrating the competitive advantages of the Spanish appliances. Next was gradually adapting the local products to the specific European market demands. Another key condition was an accurate logistics service. At the same time, the Spanish team applied hard to upgrading their skills in a number of areas, i.e. foreign languages, understanding international standards, meeting specific market demands, and upgrading practices guaranteeing the targeted quality and cost levels. Italy, France and the Netherlands were the first positive experiences. In parallel, the preferential agreement signed in 1970 opened the door for Spain to full membership of the EEC that was effective in 1986. This eliminated barriers and eased the expansion to all West Europe. By the end of the eighties, turnover had more than doubled, with *exports* to Europe already exceeding the domestic's sales volume. Then, a Corporate Business Management team was created to assure the European coordination in product planning and distribution, regardless of manufacturing source.

Poliglas is a mid size Spanish company founded in 1952. They have developed a solid knowledge in thermo and acoustic isolating materials used in the building industry. By the mid nineties, their commercial and industrial operations covered most of Western Europe. Factories were based in Spain, Italy and Germany. This was the time for the Hungarian operation that was started in 1997. The company was determined to widening its technical and commercial horizons. The Hungarian base material was *rock wool,* while Poliglas had specialized in *glass wool*. The combination of the two technologies would most probably expand the number of product applications. On the other side, Hungary might provide two benefits: the expansion in growing Eastern Europe markets and the cooperation with the existing German Plant in knowledge development, with the subsequent impact on EU markets. The acquisition of the Hungarian Plant demanded a strong management commitment to a range of issues. First, the understanding of the local cultural (starting with language), as well as the political and the working environments. Second, the correction of limiting factors like the low productivity and the unstable quality level resulting from a long period of poor management. Third, the elimination of certain costs connected to sourcing uncertainties and unfair bureaucratic practices. Another area of concern was the financial area, for inflation was as high as 12 % and interest rates were escalating. Finally, the international trade was still far from free. On the positive side, the nominal salaries were low in relation to EU standards, although the cost of living and the low productivity were probably to limit this advantage. Looking at the future, Hungary had been accepted as candidate to member of the EU and was opening a restructuring process. The action plan consisted of a precisely organized and controlled transition period, managed by a mixed Spanish and Hungarian team. It succeeded to correct and upgrade every function of the Plant, along with improving the planning and logistics of cross country operations. At the same time, the Eastern demand actually increased, partially compensating for lost jobs. Finally, a productive interaction with the German Plant was fully running in just one year. To maintain a fair social atmosphere, redundant employees were even offered financial and technical assistance to start their independent business.

Saint George's Mills Commercial (SGMC) was incorporated in Greece (1996) by two shareholders: Sant George's Mills (SGM) and Commercial Capital (CC). SGM, founded in 1926, was the leading milling company (consumer packaged flour) in the Greek market. CC, founded in 1993, was the asset management branch of the Commercial Bank of Greece. SGM was prospecting the Eastern and Central European (ECE) market to invest in mills and bakeries. CC considered ECE as a unified region of which Greece was a part, for historical ties. Additionally, its major transition to joining the UE qualified Greece to understand the challenges that ECE was experiencing in its own turnaround. Then, the two shared the same strategic direction: a long term alliance covering the full region, aiming to acquire companies that could be restructured to increase profitability. They pointed at the markets unfocused by most Western investors, in particular Albania, Bulgaria and Romania. The first identified target was Titan, the largest flour mill and bakery in Bucharest, Romania. Over the last three years, Titan management had succeeded to improve the quality of its products and raise sales significantly, crafting an excellent brand name. In 1997, the Romanian government opened a privatization process, allowing SGMC to proceed with a bid. Then, the deal was in progress. SGM knowledge could be transferred to the new acquisition, with good potential for launching new products into the Romanian market. The Romanian state control on foreign trade still limited the exports from Greece, but the increasing interaction with Central Europe was bringing a gradual change. On the other side, there were rumors on an eventually joining the EU. Then, this was the time to start the partnership[17].

Mango is a Spanish fashion clothing company. Its retail strategy is based on 600 own or franchised outlets (2002) located in 70 East and West Europe countries, Latin America, Middle East, Asia Pacific and North Africa. Sales have tripled during the period 1993-2000. Mango's management has identified two basic strategies to support its successful advancement. First is the permanent upgrading of the company's organization. This includes the quick flow of information, the continued training, the coordination of worldwide activities, and the effective interaction between all functional teams. This applies to a worldwide organization integrating 6.000 own employees plus 31.000 in franchised stores and subcontracted manufacturing and logistics operations. Mango's management fully asserts that depending on such a multitude demands an overwhelmingly open, building oriented mind, devoted to innovation and to learning from diversity. The second strategy addresses the support to two core competences: product design and logistics. Product design includes global fashion trends, new textile materials, and design technology. The right combination is key to a continued flow of innovative products, at reasonable prices. The other flank is the clear command of logistics technology, for flexible planning, and quick distribution from plant to retail outlets, is mandatory conditions. According to Mango, manufacturing (80 % of full cost) is a *commodity* available to all competitors. Then, the keys are mastering core competencies and building a strong technical and commercial partnership, for this leads to excellent design, fine tuned manufacturing operations, and on time delivering for commercial achievement.

Going East and South

Multinationals go east, again, but not only the American ones. The Slovak Republic's GDP increased 16 % during 1998-2002, comparing to average 12 % for both the 13 CCS and the 15-EU. This has raised the GDP per capita up to 11.350 € in 2002 (*PPS* adjusted), still half the 15-EU but well above the average 7.950 € for the 13 CCS[18]. The reason for this positive development lays in the business oriented environment created by the Slovak government – i.e. political stability, free trading and lower taxes– along with well trained employees making salaries well below their Western colleagues. Examples of companies moving operations to Slovakia are Sony, Volkswagen, Siemens, Motorolla, Rhône Poulenc, Unilever, Coca-Cola and Nestlé. Poland, the Czech Republic and Hungary follow the same direction. Even Romania and Bulgaria (to join in 2007) already share the course, with companies like Procter and Gamble, Pepsi Cola, Reynolds, Daewoo, Siemens and many more already installing there. This generated a FDI to CCS of 20 billion dollars in 2000 [19]

Following the agreements of the Barcelona Convention (1995), the partnership between Spain and Morocco has strongly developed. During 1995-2000, annual Moroccan exports to Spain have increased from 432 to 965 million €, and imports have equally grown from 590 to 1.368 million €. About 800 Spanish companies have opened operations in Morocco. They have permanently increased their FDI from the mid nineties. Some are major industries, like Gas Natural, Endesa (electricity), Repsol (oil), Sol Meliá (hotels), Cortefiel (textile) and Roca (bathroom equipment). But many are small. Most activities are related to textile and agriculture connected industries. Moroccan tomatoes are a subject of debate, for Spain is a major producer, too. On the other side, joint ventures in fishing are on the right track.

Confecciones Catalanas, near Tanger, employs 500, working 50 hours per week, with salaries slightly above 1 € per hour. The company makes 25.000 garments weekly that are shipped directly to European outlets. Productivity is consistently improving, according to the company's management, because of caring for permanent training. But other Spanish companies in the textile industry have elected to turn to around 500 subcontractors in the Tanger area, employing 30.000 with salaries below official minimum (0.90 € per hour) and no social security coverage[20]. Corporate responsibility is under scrutiny. A complementary example of determination is STE, a Spanish engineering and manufacturing company in the packaging industry. According to its management, "the market is changing in Tunisia and Algeria because of privatizations, and this is a unique opportunity". STE has operations in highly competitive places like France and Germany, whereas Magreb prospects are brilliant, for "some of these countries are like Spain 40 years ago. There is a lot to do and we intend to introduce our products and services there"[21].

The above empirical cases add to the economical analysis of Section 1. The EU has been under corporate focus from the 1960s, when the American companies realized the opportunities associated to the just born EEC. Over the following four decades, the field of action has clearly expanded, encouraging to, or even rushing management reaction.

Section III: The transition from nation-wide to continent-wide type of company

After considering all above, viewing the widest scope of the EU like a single operational unit seems, at least, an attractive proposition. There are four compelling reasons. First, the EU model is overwhelmingly settled. Second, further enlarging steps are ahead, pressed by a number of willing candidates. Third, the agreements with neighboring countries expand the effective frontier farther away. And forth, a growing number of corporations do care about the European proposition. In summary, if the model is willfully strengthening, then it is time for the nationwide type of company to pay attention, too.

How to focus the transition on the part of a company with a fair position in its domestic market, but hardly crossing the border? This section is intended to display a reasoning concerning the steps to follow.

The departing question has to do with the long term viability of a given nationwide business when evaluating two alternative directions: either holding the traditional domestic orientation, or expanding in line with the EU proposition. If holding, than the company is exposed to *foreign* competing forces that may expand into its domestic market and deteriorate its local franchise. If expanding, the feasibility depends on possessing the proper knowledge and organizational conditions. These options suggest three answers.

Answer one is defensive and consists of searching a proper competitor to merge with. The power of the combined capabilities should exceed the simple addition of each one's actual performance. The new entity should have a much greater knowledge in product innovation, manufacturing and marketing.

Answer two is pulling ahead independently, building on own potential. Porter pointed out (1990) that domestic demand and the nature of domestic competition shape corporate competitive capabilities. Then, firms with sophisticated customers and stiff domestic competition are likely to do well when they market their products overseas. Similarly, those that compete successfully in one environment should also be successful competing in overseas environments.

Answer three is mixed. It proposes to keep an independent stance along with setting partnerships for the better management of the successive steps of the value chain, from material sourcing and contract manufacturing up to distribution. The hypothesis here assumed sticks to answer three.

The Management orientation

Then, next is defining the corporate management orientation in two senses: geographical extent and organizational approach.

The *old paradigm* [22]was "Management's [geographical] scope is *politically* defined". It was generally assumed, and largely taken for granted, that the domestic economy, as defined by national boundaries, "was the ecology of enterprise and management". This assumption underlined the traditional "multinational". Increasingly after the 1900, the multinational company derived a larger part of its sales from outside its own country, but "insofar as produced outside its own national boundaries, it was produced within the national boundaries of another country". The country was the "business unit". But the industries of the second half of the century are increasingly run as a system in which all functions are interrelated, but shaping an interwoven system with global view. Therefore, the *new paradigm* states that "the scope of management can no longer be politically defined", for the practice of management "will increasingly have to be defined *operationally* rather than *politically*".

What operational scope are we dealing with? The extended European Map shows three groups of nations economically and politically diverse, but increasingly interconnected. The groups are:

a) *Developed:* The 15-EU plus Norway, Iceland and Switzerland
b) *Catching-up:* The 12 Candidates to join by 2004-2007
c) *Associates:* Turkey, North Africa and the Balkans

They differ in culture, market demand, transaction costs, competitive forces, and partnership chances. However, all of them share, to a growing extent, the same frontier.

In relation to the company's organization, the *old paradigm* [23] was "Management's [organizational] scope is *legally* defined". One reason for this assumption was the traditional concept of management: "command and control". The chief executive of an institution had no authority beyond the legal confines of the institution. This has gradually changed. The Japanese are usually credited for the invention of the *keyretsu*, the concept where the suppliers are tied together with their main customer. However, the *keyretsu* concept was actually invented by William C. Durant, the president of General Motors (GM). Durant begun to buy up and merge into GM one parts builder after another, until controlling up to 70 % of everything that went into a GM car. It was the world's most integrated large business, and the world's most profitable manufacturing company, too. But this type of *keyretsu* "was still based on the belief that management means command and control". That is gradually changing, for the economic value chain "brings together genuine partners, that is, institutions in which there is equality of power and genuine independence". This is the true partnership, the *new paradigm*. It redefines the scope of management to "Management has to encompass the entire process", therefore it "has to be *operational*", therefore focused on the results and the performance across the entire economic chain".

The Organization

That was for management. At the same time, the extended scope demands a revised corporate culture, broadly understood and accepted throughout the organization. It has to encompass the entire system: the internal team and the interaction with outside partners, i.e. suppliers, subcontractors, contract manufacturers, distribution channels and the like.

To bring the new orientation into practice, the internal team should comprise three groups of closely cooperating professional groups, taking care of Business Management, Country Management, and Functional Management [24]Business Management has one overriding responsibility: to further the company's global efficiency and competitiveness, implying the ability to recognize opportunities and risks across national and functional boundaries and, in addition, the coordination of global activities and capabilities. The Country Management plays a pivotal role in meeting local customer needs, being sensitive and responsive to the local market, paying attention to government's requirements, and defending their company's market positions against local and external competitors. The Functional Management provides knowledge and expertise to areas like product developing, manufacturing, human resources, and finance. Finally, the task of the Corporate Management is uniting the three categories in a common purpose, assuring coordination and encouraging learning and building from everyone's knowledge and empirical experience.

Building relationships is the next challenge. The international expansion may increase the risk of discrepancies within the entire business system, resulting from misunderstandings, lack of on time communication, inefficient flow of information, or limited skills in listening, understanding and building upon common interaction. The risk is even higher when incorporating outside partners. In this area, establishing a long term *win-win* approach is an essential condition for continued positive results. The successful companies look for agility, adaptability and alignment within the supply chain, for it is necessary to align the interests of the functional groups and multiple partners, so that they have common values and goals, and move forward in unison. Focusing on cost, flexibility and speed is important, but long term adaptability and success is highly associated to the ability to manage transitions – changing market conditions, evolving technologies and requirements as the product moves through its life cycle[25]. Managing changes, and the corresponding transitions, should better be part of daily life, becoming a routine exercise supported by the organization's ability for analysis, planning and team interaction.

A research [26]comprising 252 Spanish companies (thereof 96 affiliated to foreign multinationals), confirmed three conditions for best adapting to enlarged European relationship and best understanding the dynamics of change. First is centralized decision making, intended to deep involvement on the part of top management in the setting of clear and well supported strategic actions. Second is precise definition of everyone's responsibilities in order to facilitate relationship and interaction. Third is increased communication, intended to open discussion, clarification of propositions, and providing of best inputs for decision making. Furthermore, the best adapted companies are in favor of continued training and quick flowing of information.

The market demand

After discussing the cultural and organizational implications, next is evaluating the market demand. The quantitative and qualitative demand for any company's products may differ in every single market, in accordance with its social and economical parameters. The *Developed* are mature markets, so launching there implies identifying specific niches, competitive advantages, distribution alliances, or a combination of all. The *catching-up* group is highly attractive, for demand will probably keep growing, although particular product and market requirements are to be considered. *Associates* are certainly farther away, but it is time to know them and search for entering opportunities, for commercial agreements and FDI are to lift their economies, making them new *catching-ups.* Turkey is probably the first country to bring into consideration.

Buyer utility and strategic pricing are two underlying sets of economic conditions that successful ideas have in common[27]. This is applicable to both new products and introduction into new markets. There are at least three *utility levers* to fulfill: customer productivity, simplicity and convenience. If there is a compelling reason for customers to buy the product, next is the price persuading to actually go and acquire it. Then, utility levers and adequate pricing do win customers. Strong distribution is the immediate condition, hand in hand with communication via advertising, merchandising and trade promotion.

Competition is a parallel factor. The state of competition in an industry depends on five basic forces: the industry (actual position among current competitors), the bargaining power of suppliers, the threat of new entrants, the threat of substitute products or services, and the bargaining power of customers (the trade). The collective strength of these forces determines the ultimate profit potential of an industry. The knowledge of these underlying sources of competitive pressure provides the groundwork for strategic action[28].

Measuring actual and potential demand, establishing product and market strategies, and surveying competition are key activities for Business Management and Country Management, closely cooperating and building on everyone's knowledge and findings. The Functional Management will then involve in product development, manufacturing and distribution. This internal team activity shall be complemented with outside partnerships for specific functions. All form a system with a determined mission and vision, where all parts are expected to harmoniously contribute to the benefit of the whole.

Demographics plays important role in evaluating the market demand. There is an unprecedented massive immigration and any strategy that is any commitment of present resources to future expectations has to start with demographics[29]. The developed countries of Europe and America have a week pyramidal base, contrasting with the sound position of their modest southern neighbors, like Africa and Latin America. Then, the immigration flow is likely to continue.

A final remark

The reader may find a sign of optimism in the above analysis, especially in 2003, when the EU economy is stagnant, the members find it difficult to agree on a common foreign policy, and Denmark has just refused to adopt the euro currency. At the same time, there are discrepancies in relation to agricultural policies and distribution of development supporting subsidies. The reader may also feel inclined to criticizing the displayed strategic directions. Both reactions are correct. This paper is intended to encourage the corporate and college debate about the EU model and its future within the global scenery. It is also addressed to nationwide companies, encouraging an open analysis of their strategic positions.

Thinking on Establishing Free Trade Area of Central Asia

Lunzhi He
Ping Cai
Economics and Management School of Xinjiang University, China

Abstract

With the economic integration all over the world, it is necessary to establish the free trade area of central Asia, including Xinjiang. This paper analyses the demands on establishing free trade area in central Asia. According to the present statues of Xinjiang and five countries of central Asia, the developmental patterns are suggested. Furthermore, some policies and suggestions are proposed about the existing problems.

1. The Need of Establishing Free Trade Area of Central Asia

1.1 The Trend of Economic Integration

World's economic situation has changed greatly since 1980's. Each country in the world participates in the system of international division of labor, which makes the international trade and investment develop rapidly. Therefore the increasing economy of transnational boundaries is coming into being. The integration and internationalization of world economy makes economic relationship among countries come into a new stage of permeating, combining, cooperating and sharing interest each. China and five countries in central Asia stand in the centre of Asia-pacific area and they are major countries that the second longest land bridge crosses and radiates. Japan and Korea are to the east of China and central Asian areas. From the west of China and central Asian areas, people can go to Russia and European countries. Hence central Asian countries play important roles in international economy and trade. Under the background of regional economic cooperation and international economic integration, strengthening the bilateral cooperation and establishing free trade area between north-west of China that is facing the western development and central Asian countries that is eager to develop economy are the needs of times and economic development of them. So to establish free trade area in central Asia will have great effect on economy and trade of Asia and the world.

1.2. The Need of Developing Economy Respectively

The formation of any regional economic group is related to the geographic position, the natural resources, the economic development of every country in the area, the foreign trade, and the economic and technical co-operations among them. Since China's opening up to the outside world, the economy of China's western areas develop rapidly. However, there are great differences comparing with the eastern areas. Under the background of China's entering WTO and the western development, accelerating the economic development of western areas, especially of Xinjiang and making it the new growth point of China's economy are the eager desire of every government in western area. Western areas, especially Xinjiang should cooperate with five countries of central Asia in economy by sharing the common of geographic position, the nationality, the culture and the customs in order to promote the economic development. But five countries of central Asia have not yet free from the crisis since they separated from Soviet Union ten years ago. At present, every country is developing economy gradually though there are many difficulties. So it is necessary for central Asian countries to strengthen cooperation with China, especially with Xinjiang so as to extricate from the economic difficulty.

2. The Economic Cooperation Condition of Five Countries of Central Asia

The total area of five countries of central Asia that includes Kazakhstan, Turkmenistan, Uzbekistan, Tajikistan and Kyrgyzstan is 4 million square kilometers with the population of about 53 million. Five countries of central Asia are integrated in the economic region of the Soviet Union. The infrastructure that formed in the past, the division and cooperation of labor make them close and integrate in economy. Although five countries of central Asia have independed after the break-up of the Soviet Union, the economic condition of five countries worsen because the economic contact with other republic unions is stopped. In order to extricate from the economic difficulty, five countries of central Asia have carried out the economic reform. Each of them determines the policy of opening up to the outside world in all respects to accelerate the economic development. After 12 years' economic transformation, each country has basically established the economic system.

Central Asia that played important role in the history of culture exchange of the western and eastern world is a place that the old Silk Road must go through. Five countries of central Asia have plentiful natural resources and are the base sources of agriculture, raw materials and energy. They have become the region that have tremendous potentiality in economy in world economic structure with wide land, important position, plentiful natural resources, the growing population, the complex nationality composition and the transforming political and economic system, and the ideology although there are many undetermined factors in central Asia.

After the political and economic transformation, five countries of central Asia have focused on developing economy. At the same time, a series of economic legislations are carried and the national cooperation in central Asia is strengthened in order to accelerate the local economic development. The shape that is as an economic cooperation of sub region has formed. In May,1995, the president of Kazakhstan, Kyrgyzstan and Uzbekistan met at Almaata and reached an agreement of establishing integrate economic region. Ten countries such as Pakistan, Iraq, Turkey, five countries of central Asia and Afghan signed DECLARATION and JOINT COMMUNIQUE and decided on establishing free trade area in Istanbul in March, 1995. Five countries of central Asia and Azerbaijan held a second meeting to establish cooperative organization of regional economy like the eastern union. Since 1994, with the promotation of China and every country of central Asia, the intertrade, the economic and technical cooperation have come into a new stage.

3. The Practical Foundation and Condition of Establishing Free Trade Area of Central Asia

The first is the geographic vicinity between Xinjiang and five countries of central Asia. Xinjiang is near to central Asian countries in geographical region. In Xinjiang, the front line is 3500 kilometers. 1700 kilometers of it is adjacent to Kazakhstan, 1100 kilometers to Kyrgyzstan and 550 kilometers to Tajikistan. Although Xinjiang is not adjacent to Uzbekistan and Turkmenistan, it is near to them. Seven of ten frontiers of Xinjiang are adjacent to central Asian countries. By the end of 2002, China has opened up 15 ports to the neighboring countries. 11 of them are trade ports that open up to central Asian countries, which is the exclusive that other countries and regions don't have. In particular, with the link of the new *Silk Road* and the running of the second land bridge, Xinjiang's blocked and hard-reaching transportation are changed and roads to other countries are opened. This is convenient for Xinjiang to cooperate with other regions such as central Asian countries, the west and east Europe in economic and technical cooperation and in trade. Therefore, Xinjiang must become the important passage and material distributing center.

The second is the national understanding of Xinjiang with five countries of central Asia. By the end of 2000, the population of Xinjiang is 19.25 million. The population consists of 47 nationalities. Among them, Han nationality is 39 percent, the minority is 61 percent. 13 of 47 nationalities such as Uygur, Han, Kazak, Hui and so on live in this area from generation to generation. 10 of 13 nationalities such as Kazak, Uzbek and Tajik live in central Asian countries. They share the common in living and nationality customs, religious believes and clothing with nationalities in central Asian countries. The minority nationality of Xinjiang and central Asian countries can understand each other. There are over 300 thousand people in central Asia and western Asian areas, who go abroad from Xinjiang. Many of them concern China's development and often contact with relatives in China. They often exchange each other and trust each other.

The third is Xinjiang is a very important assemble region where China's minority nationality live. Many nationalities in Xinjiang are the same as that in central Asian countries such as Uygur, Kazak, Tajik, Uzbeki and Kyrgyz. Major nationalities' share the common in living customs, traditions, religious believes, languages and characters. Hence they are easy to approve, to understand, to communicate and to trust each other, which are the best privilege for them to cooperate in economy and trade. Since the second land bridge that is 10937 kilometers long from Lianyungang to Rotterdam runs, the old Silk Road has recovered and the transportation of goods and materials have become convenient, which make the trade cooperation easier.

The forth is Xijiang's opening up to five countries of central Asia. China and five countries of central Asia carry out the same policy of opening up to the outside world. Under the guidance of the strategy of opening up in all respects of China, Xinjiang has formed the new economic structure that is along the bridge and depending on the bridge, introducing from abroad and cooperating at home, coming from east and going out of west, sloping down to the western areas. In order to develop economy and extricate from the difficulties, central Asian countries also desire to achieve the aim of economic development by introducing technologies and capitals and striving for economic aids. China's and central Asian countries' policies and strategies of opening up to the outside world lay a political foundation for economic cooperation.

The fifth is the economic complement of Xinjiang with five countries of central Asia. The industrial structure of central Asian countries is irregular. The industries such as petrel chemistry, metallurgy, electric power, traffic transportation are developed but the light industries are less developed. Daily consumer goods such as spinnings and weavings, foods and home appliances are very short. While the industrial structure of Xinjiang is harmonious. The spinnings and weavings and foods in Xinjiang are more developed and have developed into major industries. Agriculture is in a harvest for several years. So agriculture goods are very plentiful. The differences between Xinjiang and central Asian countries have promoted the economic and technological cooperation.

Therefore, from the mentioned above, that is the vicinity of geographic position, the understanding of nationality, the policy of opening up and the complement of economy, I think it feasible to establish free trade area of central Asia.

4. The Developmental Pattern of Free Trade Area of Central Asia

Drawing on the experiences of group development of regional economy in the world, we think the general strategic aim of establishing free trade area is perfect infrastructure, larger scale, harmonious industrial structure and larger central city. The developmental pattern of free trade area of central Asia should be carried out in different stages. It can be divided into three stages:

The first stage is the loose economic cooperation. Every country in free trade further desires to strengthen the cooperation while trading at home or at the frontier. Establishing free trade area in frontier can attract economic resources such as manpower, capitals and materials to cooperate in the international market. Some policies of the developmental region can be coordinated to some degree and economic cooperation can be developed fundamentally. The cooperative pattern that develops economy without reaching an agreement is called loose cooperation.

In this stage, every country need to have a trade relationship based on the frontier trade and have a sound trade net to enlarge the trade scale and decrease the obstacle of commodity circulation. Every country should also need to build important infrastructure, especially to select and construct central cities in free trade area and to build traffic road that links central Asian region to neighboring developed cities and to central cities.

The second stage is the semi-compacted economic cooperation. In addition to carry out the favored policies that are decided in loose economic cooperation, every country in the area should consult widely in policy, sign bilateral or trilateral agreements, reduce tariffs, cancel the trade quotas, cooperate closely in traffic transportation, resources, industrial policies, communications, traveling, commerces and trades, tariffs and develop favored trades each other. At this stage, the most important task is to adjust the industrial structure in all the trade area and build important enterprises. According to industrial privileges and the need of industrial structure, construct new enterprises and reform old enterprises, including constructing and reforming the first, the second and the third industries. In particular, constructing the enterprises of second and third industries are the important part of the strategy because the enterprises' foundation of the second and the third are not sound, some enterprises have no foundation.

The third stage is the free trade stage. Free trade stage is to cooperate further based on the semicompacted corporation. The premise of free trade is to guarantee the sovereignty. Then every country in the area cooperate closely about all the regional developments, signing free trade and tariffs alliance agreements, or building more higher regional economic groups such as common market, economic alliance and so on. Furthermore, a president committee is formed to execute the agreement, to deal with the important questions on home trades, technical corporations, labor corporations, capital flow, resource allocation and tariffs.

Generally speaking, central Asian countries have enjoyed the favorable conditions given by the countries participating in the cooperation because the superegional economic group has been formed. In particular, Xinjiang has made great progress in trading at frontiers and in economic and technical cooperation. And Xinjiang has established economic cooperation region at frontiers such as Yining city, Bele city and Yecheng city. At the same time, China has enlarged trades from central Asian countries to east Europe, west Europe and far east areas while central Asian area have expanded its trades from Xinjiang to west-China, mainland and coastal areas of China. Now there are 20 provinces participating in corporations with central Asian areas. However, there are no agreements in essence between China and central Asian countries. The cooperation between China and central Asian countries is in a transition stage from loose cooperation to semicompacted cooperation. As an imperfect market system of China and central Asian countries, the government and national organization should strengthen the interference and guidance to domestic and local enterprises, corporations, and individual trades. They also should offer chances of cooperation and convenience for domestic and local business organizations. As it a foundation, every country in the area should establish arbitrating organizations cooperatively to deal with trade disputes, to perfect legislations, and to attack all kinds of commercial swindles to reach common understanding in the end.

Therefore, the establishing of free trade area of central Asia is not only good to China and central Asian countries, but also good to economic development of Asia and to the formation of synthesis entity of economic region of Europe-Asia continent center. As a result of synthesis, the economic development of central Asia will accelerate economic development of free trade area of central Asia and neighboring areas and promote economic combinations and mixture growths between free trade area of central Asia and neighboring areas. In the end, free trade area of central Asia will develop into a synthesis entity of regional economy.

5. The Safe Questions on Establishing Free Trade Area in Central Asia

The twenty-first century is an age that world's new situation is taking place of the old one. World's situation is confronting severe challenge. Every country in the world pays more attention to its safety than before. So the international environment that central Asia faces is so severe. Although some political, economic and social foundations, intrinsic necessity and real feasibility lay a foundation for the establishment of free trade area of central Asia, there are some specific questions, such are as follows:

In regarding to political safety, central Asia is in the central of Europe-Asian continent, so the position is very important no matter in history or at present. Furthermore it is easy to be affected by the change of international relationships. Firstly, as developing countries, central Asia countries are troubled with the economic integration of the world; Secondly, with large countries competing each other in the world, central Asian area will be a place that large countries contend for the important strategic position and plentiful resources. Thirdly, central Asian area is a multinational region, so the national relationships are so complex. Recently, three bad phenomena such as the national splittism, religious extremism and international terrorism are rising, which have become a threat to the safety. At the same time, the permeation and impact of external force are also increasing. And there are some interest conflicts between central Asian countries, between central Asian countries and Russia, between central Asian countries and other countries, which are not good to central A sian area's stability.

In regarding to economic safety, under the background of economic integration, world economy develops rapidly and the interdependence of every country increase further. Though central Asian countries have plentiful resources and great potentiality in development, the reform has not succeeded at present and economy develops slowly. Furthermore, as the foreign debt increasing, the technology falling behind, the people's living standards being not high, the society is unstable. Meanwhile, world's economy is not so optimistic. Within ten years, the situation of five countries of central Asia will not change, probably it will worsen. Although there are some economic complement between Xinjiang and central Asian countries, the economy of them is still undeveloped with imperfect law mechanisms and the worried credits. The economic undevelopment will be an impact on the political stability of central Asian areas.

In regarding to the culture, western large countries quicken to permeate central Asian countries by the ideal and ideology of western value. However, with the economic development and increasing power of China and Russia, the safe situation of central Asian area will become better. The reason is that American, Russia, China and other countries all desire central Asian area to be stable in the view of their own interests. At the same time, with the help of international society, central Asian countries strike intentional crime severely. Furthermore, the combination of China, American and Russia is also good to settle regional disputes peacefully.

6. The Suggestions of Establishing Central Asia Free Trade Area

In order to settle existing disputes on establishing central Asia free trade area, we can take measures from such aspects as follows: First, desire China's government to pay more attention to the establishment of free trade area of central Asia and cooperate actively at home and abroad. Next, increase investments in western area, especially in Xinjiang. Accelerate innovation in science and technology, speed up the introduction and cultivation of qualified personnel and give the privilege of local resources play by knowledge economy to strengthen growth motive and international competition of local regional economy.

Transition Economies' Multinationals - Are They Different From Third World Multinationals?

Marjan Svetlicic
University of Ljubljana, Slovenia

Abstract

The article first evaluates the recent expansion of selected Central European firms' outward FDI and compares this expansion with that of the third world multinationals. Differences and similarities are identified. In both cases the most advanced countries proved to be the biggest investors abroad. The motives were similar although there are some differences particularly those that are specific to the system/transition and starting base. Similarities are stronger if we compare the starting phases of both groups of firms. Both groups of investors followed certain stages in which the macroeconomic strategy of the home countries proved to be important. There are also many differences between groups and within them. One is the more important role of pull factors [globalisation] in the case of late-coming investors abroad stemming from transition economies. The scarce data still do not allow any robust generalisations. Some modification at least in terms of the specific weight played by different factors can be identified in the case of Central European investors abroad.

Introduction

So far, when discussing transition most attention has been given to inward foreign direct investment [FDI]. Outward FDI or outward internationalisation has almost been left out of considerations. Nevertheless, since 1997, firms from more advanced transition economies [TEs] have started investing abroad at quite substantial levels even though they were devoid of any previous experiences from the socialist period [see Macmillan 1987, Hamilton 1986, Artisien, McMillan and Rojec 1992]. Firms from certain TEs have now established themselves as major investors in some host TEs. Even now the enhanced internationalisation of firms from TEs has not attracted much attention either, again with few exceptions [Svetlicic's two ACE projects[1] gathering a group of authors, Andreff 2002 and 2003, Kalotay 2003, Liuhto and Jumpponen 2003].

The situation has also been similar regarding the third world multinational companies [TWMNCs]. Only a few authors started in the 1980s to look at the emerging international expansion of the third world firms [Kumar and McLeod 1981, Wells 1982 and 1983, Lall 1983, Khan 1986, Dunning 1986, Svetlicic 1986 and 1987].

Originally the TWMNCs literature concentrated on the "exotic" nature of such corporations. Recent literature has started to look into such internationalisation in its own right; why they expand internationally, what are their characteristics, driving forces etc. [see Mathews 2002]. This is also the case of multinational companies with Central European transition economies [CETEMNCs].

In spite of this benign neglect both types of firms are putting themselves on the map of multinational companies [MNCs]. Third world ones are already competing with the largest multinationals in the world, they are already global firms while those from former socialist countries are still lagging much behind Western companies and TWMNCs. Yet they seem to be catching up quite fast. Therefore, they deserve much more attention particularly since the external environment is quite different which might give rise to some theoretically different explanations. Although the data is still limited, it is nevertheless important to look into such outward FDI trends in order to see to what extent they are different or similar to TWMNCs which developed much earlier at first glance at a similar development level but in different systemic environments.

The aim of this paper is limited to identifying the similarities and differences between TWMNCs and CETEMNCs in different aspects from the timing of internationalisation, the motivations to the type of competitive advantages and the role of the external environment. On this basis we can start exploring some ideas as to whether there can be a general explanation of the internationalisation of less developed countries' firms or whether there is a need for differentiated approaches due to the different internal and external conditions involved. The paper will compare the similarities and differences between CETEMNCs on the basis of our own survey[2] of outward FDI by 5 Central European economies/CEEs [Czech Republic, Estonia, Hungary, Poland and Slovenia[3]], and general data on FDI flows abroad. Secondary sources were used in the case of TWMNCs. We will confine our analysis mostly to manufacturing firms' expansion abroad. The different types of sources and the availability of data prevented the application of any more robust statistical methods. The structure of the paper is as follows. After this introduction stating the objectives, the limitations and background of the paper we proceed in the second chapter to the theoretical framework. The third chapter is devoted to the characteristics of outward FDI by CEEs. The fourth chapter provides a short overview of third world firms' investments abroad merely to set the stage for the fifth chapter, namely a comparative evaluation of the two types of MNC identifying the similarities and differences between the two. The paper ends with some generalisations in the conclusions.

Theoretical Framework

The eclectic paradigm [Dunning 1973 and 1993] predicts that a firm has to possess firm-specific advantages [FSAs] to be able to invest abroad[4], that the foreign location should be better than the one at home and that internalisation is the best mode for the maximisation of such FSAs. The issue therefore is whether firms from TEs possess strong enough ownership-specific advantages to invest abroad, where they can best complement such advantages with location-specific ones and whether they are able to internalise them.

The investment development path paradigm [IDP, Dunning 1981a] postulates that, before investing abroad, countries first host FDI and that investing abroad is a function of GDP per capita. Later it was established that the changing net outward investment position of a country could not only be explained by rising GDP but also by the changing configuration of a firm, location and internalisation advantages and macro-organisational policies. The new version of the IDP model [Dunning and Narula, 1998] postulates that in a globalised world outward FDI starts earlier and the amplitudes of the stages are shorter.

The evolutionary approach of internationalisation is also a characteristic of the Upsalla sequential internationalisation process model[5] [Johanson and Vahlne 1977 and 1990, Johanson & Wiedersheim-Paul 1975] predicting a "normal" sequential step-by-step learning process of internationalisation in stages. Critics of the sequential internationalisation model claim that internationalisation is not necessarily sequential, that 'internationalisation' knowledge can be gained from other firms instead "without having to go through exactly the same experience" [see Eriksson, Johanson, Majkgård and Sharma 1997, Turnbull 1987], and by networking with others [Mattson 1985, Johanson and Mattson 1986 and 1993, Vissak 2000].

The fourth stage of the product life cycle, proposed by Balakhrishnan [1975] in his Ph.D. dissertation, predicts investment among countries at lower stages of development. His argument is that in the fourth, post-mature stage FDI takes place among developing countries and here we can also add among TEs. In the third stage of the product life cycle, technology gets adapted to local needs. Smaller producers acquire certain FSAs based on adapted more labour-intensive technology and by using less standardised local inputs. Large multinationals simply may not be interested in such adaptations, being more preoccupied with innovating new products and/or technologies and/or small, less developed countries' markets are not enough attractive for large firms.

Many studies indicate that management is crucial for the internationalisation of firms and that investing abroad has been strongly influenced by managers courageous enough to undertake such a risky operation at the early stage of their firm's development in the very risky markets of less developed countries [LDCs]. Therefore, outward FDI cannot be explained without looking into [strategic] management theories or "why micro-management superiority of foreign investors over their domestic counterparts is more pronounced when the corporate governance in the host country is weak and financial institutions are not so well developed" [see Razin 2002, p. 17]. This is precisely the situation in TEs where institutions are still weak and their activities not transparent enough and frequently unpredictable. This has two main implications. First, that managerial superiority plays a relatively more important role in the case of investing in transition than in developed industrial countries and, second, that firms from more advanced transition countries have developed transition-management-specific advantages which they can 'cash in' in other TEs still waiting to undergo certain changes [privatisation etc.].

Let us see whether we can agree with L. Wells' old statement that "the theories have done little to answer why firms from developing countries [or TEs for that matter, op. SM] invest abroad" [Wells 1983:13] or whether we should be less pessimistic and conclude that the empirical data do confirm some of the major internationalisation theories indicated above. Mathews [2002] also found the "inadequacy of "most leading theories of TNCs growth and expansion" and offers "a process oriented account of dragon multinationals' transnationalisation in which three key elements are emphasised: outward orientation, leverage through building linkages and achieving organizational efficiency through integration" [Wai-chung Yeung 2002, p. 192].

Outward FDI by Five Central European Transition Economies[6]

Although investing abroad by state-owned enterprises started decades ago in socialist times today it is a totally new challenge. The early 1990s saw slow progress in outward investment activities by large exporters with substantial international experience from the previous regime, whereas post-1997 has speeded up outward FDI also with seeing the involvement of newcomers. Nevertheless, the total stock of the outward FDI of the five CEE transition economies [USD 5.5 billion in 2000] is still very modest. This is, however, only a small part of overall outward FDI by all TEs which had accumulated to USD 29 billion by the end of 2002. The biggest investor abroad is Russia [accounting for 62% of total outward FDI stock by TEs end 2002; [UNCTAD, 2003, P.265], which is a very specific case. Its investments abroad are mostly by natural-resource-based firms and are to a large extent of a speculative nature[7]. Therefore, our analysis will concentrate on CETEs and manufacturing firms.

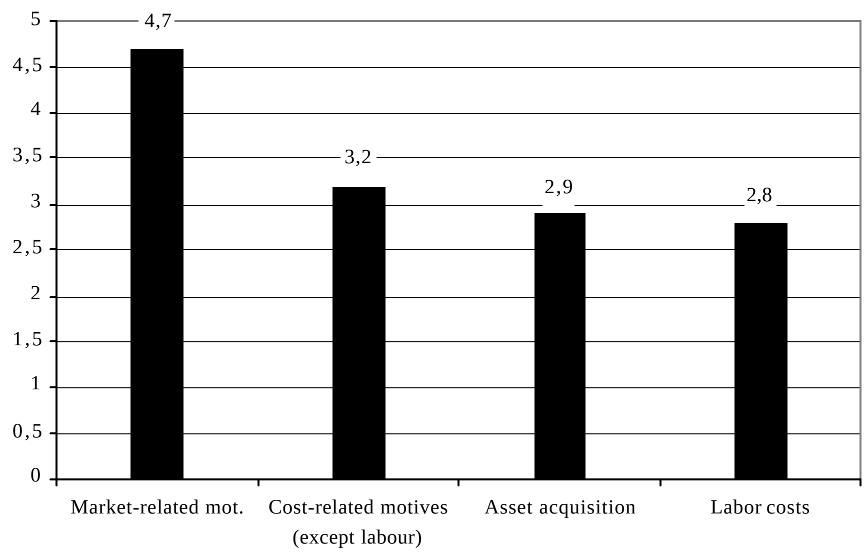
Investors in the sample are nearly 28 years old on average with some dating back even to before World War II, while many are spin-offs of old socialist, now disintegrated companies. They inherited management, brand names and business contacts and can hardly be regarded as totally new firms. Although big companies represent the smallest share of the number of investors abroad, they are the most influential, quickest and most successful in their internationalisation in terms of volumes. Investors are on average large although the majority of sample companies have less than 250 employees.

The majority of outward investors from the analysed countries are manufacturing firms – 51 percent [20 percent are in trade and 29 percent are in other services], which does not necessarily mean that the firm also undertakes manufacturing investments abroad. Trade is the prevailing activity of foreign affiliations, followed by other services and only then by production activity.

The total number of affiliations established abroad by the sample firms was 293 in 1997 and had almost doubled to 477 in 2000.

The gradual enhancing flows of outward FDI following previous exports but jumping over most other forms of co-operation, the distribution of stock and the location of affiliations confirm that the sequential pattern of penetration does matter. Neighbouring countries, countries with strong trade relationships or cultural and/or historical ties have priority in investment location decisions by all the surveyed countries[8].

The market-seeking motive was the most important motive of outward FDI. This is also reflected in the predominance of trade units among affiliations abroad. Investing abroad is regarded as an additional way to keep and increase market shares abroad. Lower labour costs were, on average, the least important motive for investing abroad, also reflected in the modest frequency of locating production units abroad. Even if investing companies decide to produce abroad, lower labour costs are more a facilitating and not a decisive factor. Investors are primarily looking for business opportunities and ways to exploit their ownership-specific advantages, which often have limited time duration.



Note: 1= Not important, 5 = Very important.

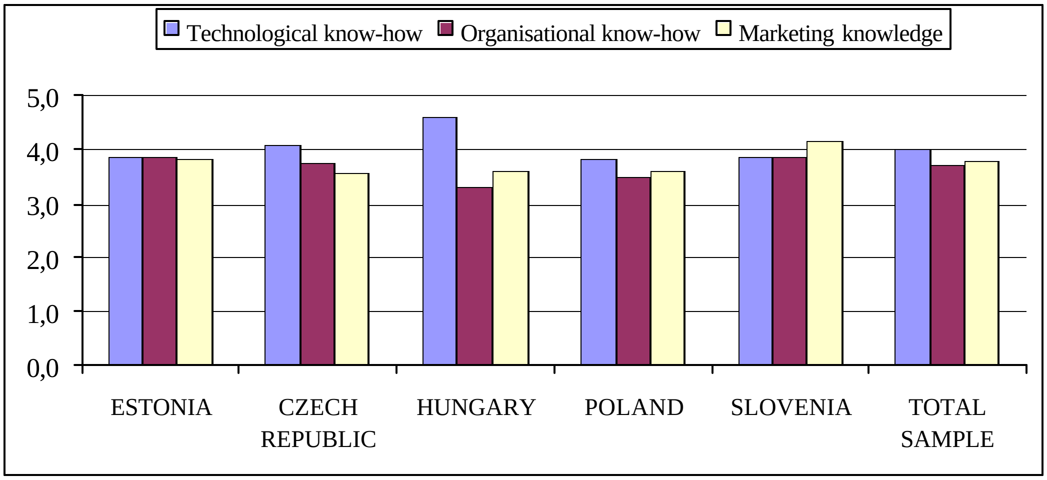
Figure 1 THE IMPORTANCE OF INDIVIDUAL GROUPS OF MOTIVES FOR OUTWARD FDI BY 5 CEE'S FIRMS: AVERAGE SCORES

What Are the Investor's Competitive Advantages?

The reasons for the rapid rise in outward FDI by selected CEEs can be classified into push and pull factors. The two push factors are the existing FSAs coupled with the limited opportunities to increase market shares in existing [small domestic] markets. Firms have realised that by exporting alone they can no longer keep market shares abroad and that they also have to upgrade their foreign presence by establishing subsidiaries there in order to be closer to customers. On the other hand, the march of globalisation forcing firms to 'race costs to the bottom', the need to acquire economies of scale and scope, and the ongoing privatisation and other aspects of less advanced TEs have all been attracting investors to grasp the new opportunities emerging there. These opportunities are also home country location-based due to having once lived together in the same country [Slovenia, Czech Republic, Estonia or minorities' connections in the case of Hungary].

Firms themselves claim that, among the relatively equally weighted different advantages, technological ones were the most important ones, followed by marketing knowledge. There is, however, no systematic evidence as to whether such technological advantages are based on new products or new technologies or more on the adaptation of products and processes to local conditions. In the case of TEMNCs it was more standardised technology [65% of subsidiaries were established up to the 1970s in low research intensity activity; Svetlicic 1987, p. 75].

The second crucial source of FSAs of the investing companies surveyed is the management of those companies. The capabilities of the managers who undertook investments abroad before the theory would have predicted, that is before all the necessary capabilities are accumulated, have been crucial. Managers have frequently demonstrated a strong vision at times when investing abroad was considered unpatriotic or at least unusual [in socialist times and the first years of transition]. Some managers have developed a very specific management style based on personal contacts and highly assimilated to the culture of the host countries.



NOTE: 1= not important, 5=very important
Source: Survey on outward FDI in CECs, 2001.
Figure 2 THE IMPORTANCE OF COMPETITIVE ADVANTAGES BY COUNTRIES

On average, organisational know-how, as a specific type of FSAs, was assessed as somewhat less than 'important'. However, the case firms claimed they have developed specific management advantages partly as result of faster privatisation compared to the core destination countries. This type of advantage is temporary. Firms have to exploit it fast, before other competitors can catch up or outperform these advantages through other stronger competitive advantages. It is therefore crucial to achieve a *first-mover advantage* already in the rebuilding phase of these countries and to upgrade other advantages before the advantage of how to do business in a specific environment expires.

The more risky environment found in other CEEs, less stability and predictability make firms choose FDI [internalisation] as a safety-net solution in spite of the larger sunk costs. One incentive is to achieve the better protection of intellectual property, which is still very poor in this region. Companies have found it easier to control their intellectual property and defend their original products against imitations when they have a direct presence [see Jaklic and Svetlicic 2003].

The Greenfield investment [the majority was totally owned or majority owned] strategy that dominated in the early and mid-1990s was later combined with an acquisition strategy. The explanation of the desire to acquire control is not so much a reflection of their strong FSAs but of some weaknesses, the unavailability of appropriate partners abroad or different uncertainties. Privatisation processes and the favourable prices of companies available for acquisition were the key reason for this. The rise in acquisitions after 1998 was also easier because the acquisition process in the domestic market had gained some momentum.

Third World Multinational Companies

The first internationalisation of third world firms dates back to 1928 when the Argentine manufacturer S.I.A.M. di Tella established a subsidiary in Brazil to produce gasoline pumps [Wells 1983, p. 1]. But this was more an exception than a rule. Real internationalisation started in the 1960s [see Wells 1983, Lall 1983, Kumar and McLeod 1981, Khan 1986, Svetlicic 1986, Dunning 1981, White 1983, and Tolentino 1992].

Dunning and Narula [1998] and Chudnovsky and Lopez [2000] distinguish three waves of such outward FDI by third world firms. The first wave started from Latin America in the seventies. It was going on alongside an industrialisation strategy based on import substitution in home countries. Latin American MNCs have spread abroad thanks to products meeting the needs of their growing domestic markets. The second stage is markedly characterised by predominant Asian MNCs in the eighties, namely those from South Korea, Taiwan, Hong Kong, Singapore, and then Malaysia, Thailand, China, India and the Philippines, while Latin American MNCs have stepped back relatively. Outward FDI from Asian newly-industrialised countries [NICs] accompanies their home country strategy of export promotion, growing markets in LDCs but also in order to benefit from the cheap labour there. The third stage, in the nineties, exhibits the recovery of Latin American outward FDI in the context of globalised competition in all manufacturing and service industries, on one hand; whereas on the other hand the biggest Asian MNCs now compare to and compete with Western MNCs as demonstrated by their investments in developed countries [see Andreff 2003, p. 19]. Chudnovsky and Lopez [2003] found in such development a confirmation of the IDP paradigm, as did Andreff [2003].

As in the case of CETEMNCs we also obviously have wide heterogeneity among TWMNCs. They differ in terms of the timing of their internationalisation as well as the characteristics of their competitive advantages, motives or other characteristics [see tables]. What is also important to note here is that the general development strategy, a kind of systemic characteristic, also proved to be highly important for internationalisation as clearly demonstrated in the case of Asian and Latin American firms originating in totally different strategic backgrounds like the system had been in the case of TEs.

Comparing Third World and Central European Transition Economies' Multinational Companies

Both groups of countries are so heterogeneous that any comparison is highly subjective and could be highly biased. The most important general conclusion is that there are many more similarities than differences in internationalisation development between the two groups of countries' firms although TE lags 31 times behind in terms of outward FDI stock. Therefore, it is not surprising that many authors researching into both phenomena confirm the validity of the IDP paradigm since both groups of countries firms investing abroad do share many similarities in terms of the timing of internationalisation, its evolution [by stages] and development level. LCDs' outward FDI stock was at today's TE level approximately 20 years ago.

Table 1 KEY DATA AND CHARACTERISTICS OF THIRD WORLD AND CENTRAL EUROPEAN TRANSITION ECONOMIES' MULTINATIONAL COMPANIES

	TWMNCs	CETEMNCs
Beginnings and developments	Three stages: a) 1960s to 1970s, mostly L.A. firms; b) 1980s [Asian firms] ; and c) 1990s onwards. [see Wells 1983, and Chudnovsky and Lopez 2000] External incentives; ASEAN integration Incremental expansion [Matheus 2002, p. 192] Exports preceded in 85% cases outward FDI [Wells 1983, p. 68]	Three stages: a) pre-transition infant stage; b) early beginning till 1996; and c) Real upswing after 1997. Specific system escape motivation in socialism [Svetlicic, Rojec and Lebar 1994] or institutionally-based [Andreff 2003, p. 10] Later EU integration accession, and increased globalisation pull factors, exports almost always the first step before FDI
Data on OFDI and	Stock 2002 for all developing	stock 2002 USD 29

MNCs	countries USD 849 billion[9] [UNCTAD, 2003, p. 264] USD 5-10 billion by 1980s [Wells 1983:2] USD 29-34 billion estimated stock of FDI by selected LDCs in 1982 [Dunning 1986] 1,964 subsidiaries abroad but estimate goes up to 6,000-8,000 [Wells 1982 and 1983, p. 2] 1% of outward FDI stock in 1960, 3.2% in 1978 and 11.9% in 2000 [Andreff 2003, p. 18] USD 23-26 billion of Inter- Arab and Arab investments in other LDCs [Svetlicic 1987, p. 22]	billion for all TEs [UNCTAD 2003, p. 265] USD 1,483 million in outward FDI by PETs[10] or 0.1% of world outflows of outward FDI in 1990 [Andreff 2003, p. 4] USD 2.5 billion in outward FDI stock of 5 CEEs in 1997 increased to USD 6 billion in 2001 [Svetlicic and Jaklic 2003[11]] 863 affiliates in developed countries in 1992 [Andreff 2003, p. 4, 10] outward flows from TEs increased from 0.29% in 2000 to 0.56% of total worldwide flows in 2001 USD 20 billion in 2000 or 0.38% of world outward FDI flows [12] [Andreff, 2003, p. 7]
Ownership of subsidiaries	JVs and 100% owned [57% in manufacturing; Wells 1983, pp. 3 and 108] In other LDCs mostly joint ventures [90%; Svetlicic 1986, p. 80], 65% of subsidiaries in other LDCs private, 20% state 15% mixed [based on Wells' data bank, see Svetlicic 1986, p. 81]	Mostly 100% owned and greenfield
Ownership and type of investors	Mostly private large, old firms Only 6 qualify for large MNC having more than 6 manufacturing affiliations abroad [Wells 1983, p. 9] 43% of investments in other LDCs are small, 20% medium and 16% large [Wells' data bank, see Svetlicic 1986, p. 77]	Originally state-owned trading companies After transition private or mixed Mostly manufacturing firms but expanding in trade Major investors by capital invested are large old /experienced firms while by numbers SMEs prevail
Type of activity	Trade units [Wells 1982] In other LDCs mostly manufacturing [Wells 1983] Now some real global firms	Sales units prevail pre and during transition Production units more of a client-follower type to preserve [export] market

		positions
geographical orientation	High regional concentration [Wells 1983, p. 4] Mostly other LDCs, increasing in ind. countries	In socialist times advanced countries [system escape and export promotion] and production in LDCs [also political motives] Now high regional concentration in less developed and neighbouring TEs
Transnationality index	39% for 50 biggest TWMNCs and 53% for largest 100 [UNCTAD 2001]	32% for 25 biggest MNCs from TEs in 1999 [UNCTAD 2001]

In both groups of countries large firms are the dominant investors abroad and flows are highly concentrated within the region. That also applies to inter-Arab investment which is much less known among those within the developing countries group [see Svetlicic 1987]. In both groups of countries systemic characteristics play an important role in the internationalisation of their firms albeit for different reasons. Socialism was to a certain extent a push factor for internationalisation while in the capitalist economies of developing countries' firms there were more limitations to the full functioning of market economies. In most countries the exporting of capital was initially de-stimulated if not prohibited. Many countries restricted imports [even by quotas], which stimulated firms to circumvent such barriers by tariff factories in such countries. Market-seeking has been the major driving force behind internationalisation together with other home country push factors.

Table 2 MOTIVATIONS

	TWMNCs	CETEMNCs
Motivation	Originally systemic based, avoiding quotas... [Wells 1982] Market-seeking less important [large domestic markets the most important], acquiring strategic assets, improving responses to customers, lower labour costs as a defensive instrument [against the introduction of quotas; Wells 1983, p. 78] Diversification of risks [Wells 1983; p. 68]	dominantly market-seeking outward FDI [small domestic markets], but also strategic-asset-seeking, and other lower labour costs as a defensive instrument [against the introduction of import limitations due to huge trade deficits by host countries; utilisation of temporary FSAs [knowing how to do business knowledge]
Domestic push factors	Major determinants of outward FDI Home country factors push internationalisation Later own innovations with industrialisation which also became a push factor [Tolentino 1993]	Small domestic markets a major determinant of outward FDI Bad domestic investment climate, prohibitive taxation, political instability and high inflation and circumventing export quotas [Andreff 2003, p. 18] Exploitation of specific

		knowledge and brand names reputation
External pull factors	Less important than internal factors Regional integration schemes	More important than in the case of TWMNCs due to enhanced globalisation and other external changes including accession to the EU

Similarities in motives should have led to similarities in strategies as well. However, one can see more differences in strategies than in motives. The Balakrishnan hypothesis [see theory] has proved quite relevant to both groups of countries [relatively more in the case of early TWMNCs], meaning that it may be of [temporary] relevance in the infant stages of internationalisation. Firms start by building on advantages more in areas Western multinationals are not interested in pursuing, more on assimilating or adapting their technologies but simultaneously upgrading their own specific advantages although initially more in organisation, design than of totally new quality products. TWMNCs are much more advanced in their domains but there are signs that CETEs are following in their footsteps and will, because of their better starting level, soon catch up and start evolving as truly global companies. At the moment, they are more oriented to becoming regional multinationals.

The eclectic paradigm clearly states that investors must have some FSAs in order to qualify to invest abroad.

Table 3 ADVANTAGES AND STRATEGIES

	TWMNCs	CETEMNCs
Competitive advantages	Location-specific, some brands, small series, adapted technology, cheaper overheads [managers' salaries are lower], more use of local inputs products/services more suited to the local environment [Wells 1983, p. 48] Specific skills in marketing, productive or technological knowledge [Lall 1983a] Intensive-intensive technologies and small-scale production [Lecraw 1977, Wells 1983, Agarwal 1986] Innovations in strategy and organisation [Mathews 2002, p. 191] Tapping into external advantages and networks [cellular »clusters« among strategic units of dragon multinationals, efficient managing of them [Mathews 2002, p. 192] FSA are changing along the IDP from the adaptation and assimilation of technology towards more own innovative FSAs [Cantwell and Tolentino 1990]	Macro-location-institutionally-based [politically the same systemic background] knowing how to do business in a similar environment, established networks based on previous [export...] co-operation Cultural vicinity, languages
Strategy	Cost- and following-the-customers based [Wells 1983, pp. 54 and 63]; Adaptation of products/processes to fit the prices and quality requirements of LDCs; Niches abandoned by conventional TNCs [Wells, see Chudnovsky and Lopez 2000, p. 37]; Ever increasing inclusion in global production chains; No specific international strategies until the late 1990s;	Defensive, defending previous export markets; Following the [industrial] clients supplying intermediate products; Efficiency-seeking strategy [low wages] very rare but growing [see also Andreff 2003, p. 17] regional trading multinationals; leapfrogging internationalisation, even some born globals No specific international strategies until the late 1990s

Comparing investors from the third world with those from TEs demonstrates there are substantial similarities particularly if we compare the initial stages of such investments. New entrants among investors abroad can hardly compete on highly sophisticated technologies or know how if they come from less developed countries as is happening with firms from former socialist countries or more advanced third world countries. Both firms gradually upgrade their FSAs from more assimilated adapted technologies to the specific conditions of investment destination-countries to more original innovation-based knowledge[13]. The process of such upgrading was faster in Asian countries because outward-oriented development strategies and targeted industrial policies forced firms to meet targets in order to qualify for specific assistance. Import substitution strategies of Latin American countries dissimulated such efforts so it is therefore no surprise that they started to lag behind internationalisation after their initial pioneering role. Former socialist firms have found themselves in a similar situation to Latin American countries, living behind high-protected tariff walls. Very few firms with ambitious and visionary managers, in spite of such protection, started to strengthen their capabilities and invest abroad, even in the 1960s. Now the process of the catching up of "dragon investors" is very rapid due partly to the better starting position of such firms in terms of technical manpower. Therefore, we can expect that CETEs' firms will soon join the many TWMNCs first as regional [as they did first] and also increasingly as global players. Membership in the EU will also stimulate this process. It seems that a certain convergence is also going on in strategies where lower labour costs have not played a major role. Erosion of its role by technical change can only be one explanation today.

Differences

The huge differences within both groups of countries make comparisons very difficult and prevent any reliable generalisations. Firstly, there is a huge difference in the number of countries and the size of their economies. MNCs from Latin America are quite different from those from Asia. TEs' firms also differ in terms of the development level of countries, their size, stage of EU membership, privatisation and previous development strategies. Firms from small countries are more driven into going international than those from large ones like Poland or Russia.

The stronger involvement of small and medium-sized enterprises [SMEs] in the case of CETEMNCs can be traced to macro location-based factors, previously established networks in the common market of now disintegrated countries. Previous experiences of managers of the larger state monopoly firms which later established their own firms but inherited all the experiences and networks from previous international businesses is an additional explanation. The new information technology infrastructure also makes it easier for SMEs to internationalise today, particularly as suppliers to large MNCs [client-driven internationalisation]. It was not so important when integrated global production was not as advanced.

The timing of the starting period of internationalisation was also different. TWMNCs started earlier, in the 1960s, while only very few firms from socialist countries started to invest abroad then. The time lag of the internationalisation of CETEs' firms is therefore about 25 years[14]. After 1997, the internationalisation of CETEMNCs seems to be faster, firms are leapfrogging over stages, some can even be considered born globals. This can be explained: i] by globalisation pull factors which are now much stronger than in the period of the first wave of TWMNCs' expansion and when electronic communications make it easier to internationalise; and secondly ii] due to better human capital capabilities. It can be expected that within some 10-15 years the convergence particularly of firms from new EU members will come about.

Due to the specific historical context not so few CETEMNCs have evolved as "inherited investments" [Svetlicic and Jaklic 2001] or what Andreff called "institutionally founded MNCs" [2003, p. 10] established overnight as a consequence of the disintegrating of countries in which those firms operated before. In this way such firms evolved from large domestic firms to small international ones by the simple new political reality. Ethnic ties are much stronger in the case of Asian TWMNCs than CETEMNCs. The large Chinese population outside of China and strong traditional family ties in their society make ethnic ties much more important. There are minorities outside homelands in CEEs but they are not so strongly or traditionally interconnected. They more facilitate than induce outward internationalisation in infant stages.

Trade names have not proved to be a major driving force for outward FDI by either TWMNCs or CETEMNCs, although they are not nonexistent. Its relevance is of a somewhat different nature. TWMNCs initially designed some brand names to serve the specific tastes of developing countries' populations [now already global brand names] while, in the case of CETEMNCs, we see more the exploitation of general brand names of investors established originally by exporting [customisation]. This is more the defence of existing brand names by upgrading entry methods when threats of import limitations emerge while in the case of TWMNCs we can talk more of the offensive penetration of brand names first suited to local tastes, and later also of a global nature. CETEMNCs are also less inclined to regard their FDI as an instrument of the differentiation of risks while this argument is stronger in the case of TWMNCs.

The ownership structure of subsidiaries abroad also differs: TWMNCs are much more keen to enter into JVs with local partners [see Wells 1983:115] than CETEMNCs which firms have wanted to control their operations abroad [partly out of weaknesses not strengths, [see Svetlicic and Jaklic 2003]. Explanation is partly system-specific [late privatisation in host countries, non-transparent systemic conditions and other instability] which would increase risks in the case of shared ownership. The other explanation is the type of FSAs. They are similar to those a local partner might bring in to a venture therefore there is no need to acquire them. The summary relative weight of the different factors of internationalisation is different although similar factors play a role.

Conclusions

The lack of reliable data and the heterogeneity of both groups of countries prevent us making any robust generalisations. Investing abroad is a relatively new phenomenon for TEs' firms. Therefore, it is also too early to draw generalisations although a more robust test of the IDP model on the two groups of firms has confirmed there are no significant differences among them in terms of sequencing internationalisation [see Andreff 2002, p. 377]. Comparing CETEMNCS with TWMNCs 20 years ago we can find several common features. Similarities prevail over the differences, which may indicate that outward internationalisation is less systemic, but more specific to the macro development level, location [transition] and firm[15] and is more contingent on external environment conditions.

In the early eighties, TWMNCs were comparatively small, their small-sized foreign affiliates were less numerous than those of Western MNCs and less scattered over a great number of host countries, like MNCs from TEs are today. In Latin America the small size of the home country and domestic market is a factor pushing local firms to invest abroad so as to enlarge their outlets [Chudnovsky and Lopez, 2000, Andreff 2002, p. 375]. The internationalisation of CETEMNCs was pulled more by the external environment and globalisation trends than pushed by home market factors. FSAs are largely location- and system-based and originated in a common history or in similarities of systems, cultures/languages and related factors. Many of their competitive advantages could gradually "evaporate". Therefore, firms are stimulated to start exploiting them very fast [first-mover advantages].

It is beyond serious doubt that CETEMNCs have established themselves as new players in the global reconfiguration of the structure of industry and services in the world and the ways in which firms pursue their objectives and by newly slicing their value chains. For some authors internationalisation by firms from less advanced countries only confirms the mainstream FDI and internationalisation theories. There are, however, also differences which may call for new theoretical approaches. Differences are more systemic and transition based. It seems that a certain productive combination between the Reading school and evolutionary approaches to internationalisation [the Scandinavian school] is needed which could result in a "leapfrogging eclectic investment path paradigm". Although TEs are still confined to more competitive "national champions" and/or a small number of new entrants are still relatively small, they are likely to be developed faster than TWMNCs which needed some 20 years to enter the really big league because TEs' inherited stock of capabilities is bigger. It seems that vertical integration, following the client-driven type of internationalisation, of vertical efficiency-seeking may prove to be the most dynamic dimension of the internationalisation of CEEs' firms in the future substituting today's prevailingly market-seeking defensive operations, defending previously attained export markets.

To conclude, it is still impossible to say whether CETEMNCs are a totally new "animal" substituting the previous "red multinationals" [Hamilton 1987]. There are not yet any clear-cut robust data to confirm or refute that such multinationals have their very specific characteristics or even that new theories are needed. Much of such outward FDI is still associated with capital flights, are related to transition instability and cannot be explained by deeply rooted economic rationale alone. Western multinationals needed several decades to grow into real global companies. The third world ones needed a much shorter time to become world competitors albeit they are still lagging behind the Western ones. The question is whether firms from transition economies will need even less time to become real multinationals. Our research seems to confirm this prediction.

End Notes

[1] This resulted in two books, Jaklic and Svetlicic 2003, and Svetlicic and Rojec 2003.

[2] The survey contains data on 168 investing firms in 2000 with 477 subsidiaries abroad. In the absence of ready-made national statistics in transition economies on outward investing this was the only reliable source for qualitative but also for most of the quantitative data.

[3] When available and appropriate we will also refer to internationalisation by other TEs, particularly Russia which is a major investor abroad in terms of volume.

[4] Similarly also the resource-based [based on Penrose, 1959] and evolutionary theories of internationalisation [Cantwell 1989 and 1994; Lall 1993, Kogut and Zander 1993, Wernerfelt 1984, Rumelt 1984] argued that a precondition for investing abroad are resources and capabilities and that the accumulation of firm-specific advantages is a cumulative process.

[5] Based originally on Carlson [1966] also called the Uppsala Internationalisation process model or Nordic school or Stages Theory of Internationalisation. Broadly speaking, it is also based on behavioural theory of firms [see Aharoni 1966].

[6] Based on Svetlicic and Jaklic 2003.

[7] Much of outward FDI refers to “round-tripping” [see Kalotay 2003, p. 14]. According to Liuhto and Jumpponen, the recorded outward FDI stock of Russia is some 10% of capital flight.

[8] Slovenian outward FDI is concentrated in the successor states of former Yugoslavia, Czech’s in Slovakia, Hungarian’s in Czech Republic, Slovakia and Romania [strong national minority], while Estonian outward FDI gravitates towards the Baltic countries, mostly Lithuania and Latvia.

[9] Latin America and Caribbean 173, and Asia USD 632 billion.

[10] Data refer to post-communist economies in transition [PETs].

[11] If not otherwise stated, all data on 5 CEECs are based on Svetlicic and Jaklic 2003.

[12] Data refer to post-communist economies in transition [PETs].

[13] At first it is mostly organisational.

[14] The stock of outward FDI by TWMNCs was then similar to that of CETEMNCs today.

[15] It is interesting to note that Indian firms also started to invest abroad in the mid-1990s. This may confirm the importance of external factors [globalisation] as well as the development strategy starting to be more outward oriented. There are also striking similarities in terms of the sources of FSAs [see Pradhan 2003].

Opportunities and Vulnerabilities in Mercosur: Looking for Room for Peripheral Regions

Abraham B. Sicsú
David Rosenthal
Frederico Katz
Catholic University of Pernambuco, Brazil

Abstract

Over the last years the Center for Latin-American Studies (NEAL) of our University has been focusing on the analysis of the prospects for consolidation of Mercosur. One of the results of that effort was a book, published last year[1]. The team, in association with researchers of the Catholic University of Uruguay, is now concentrating on the impacts of the Block's implementation upon the less-developed regions encompassed by it. The fulcrum idea is that such consolidation process creates a new framework of microeconomic conditions, which might offer new business opportunities, by means of changes in the operating environment of some production chains in those regions and, at the same time, can also endanger viable schemas presently in operation. This paper sums up some relevant findings from our previous work and presents the justifications for the present study. It describes our first steps towards establishing an adequate approach to analyze the changes in the microeconomic framework, and to try to detect new opportunities and vulnerabilities.

I. Introduction

The debate on how to improve the state of our economy, and the prevailing social conditions in general, has been long attracting much attention. The majority of the efforts are directed at defining postures and activities that, most of the times, are fundamentally linked to our domestic reality. As regards the rest of the world, the predominant themes are related to our connections with the central countries and with the institutions led by them. At the same time, and rather as a political and personal effort of the President, the subjects of Mercosur, and the need for some other kind of integration in Latin America, have been emerging more often recently. This text intends to discuss some aspects of this third focus of attention, without any concern as to ranking them by their order of importance. In this item, we will refer to some results of a previous work of ours and, in the following ones we will describe the first steps of a research we are at present carrying on.

At the beginning of 2002, in a period of widespread discredit relating the possibilities of consolidation of Mercosur, we decided to study this theme, focusing exactly on the specific difficulties related to the stability and continuity of the block. The starting point of the study was the consideration, from an economic point of view, of the type of structure of correlation of forces, which characterizes the relationship among the countries of our block. Such relationship is bipolar, and thus different from those prevailing in other economic blocks, as in NAFTA, which is unipolar, and in the European Union, multipolar. To analyze the implications of this background, we used qualitative elements of the Theory of Games, as well as elements of recent contributions to the Theory of International Economic Relations.

A Theory of Games' model, that foresees the possibility of one, or some, of the players becoming "Veto Players" (or "Dictators"), was applied, to explain why this bipolar structure of correlation of forces has been constituting, over the last years, an additional problem, even if not the most important one, for the consolidation of Mercosur. Clearly enough, the two poles are Brazil and Argentina. If we accept that such configuration of correlation of forces, among the countries that now constitute Mercosur, is one additional stumbling block in the way of its consolidation, then we should try to suggest some way to overcome it. As we concentrated on the core of the problem, an idea arose naturally and led us to discuss a different arrangement for the regional integration. The proposal consists of moving as far away as possible from the present situation, evolving to a new format that, at least from the point of view of the Theory of Games, would be approaching the multipolar configuration of the European Union. This would be achieved by means of the amplification of the number of elements in the group. That is to say, it would mean striving to involve, as soon as possible, more South American countries - all of them, if possible - in the arrangement, within a more flexible structure, forming a broad block of economic cooperation.

Even so, and in the same way as it happens in the European Union, there would be countries that are much larger than the other ones, but, in case one of these decides to leave the coalition, the rest of the group would still be large enough to ensure the block's feasibility. This would reduce both Brazil's and Argentina's individual muscle - their veto power - and could facilitate the overcoming of deadlocks. Evidently, these two countries would continue to have expressive economic weights, but, from both an economic and political point of view, the decisions could be mediated by the participation, and even pressure, of the group of smaller countries. It is interesting to note that this same conclusion has been arrived at by many analysts, although, obtained through different approaches. Also, it is necessary to make clear that we are not, of course, considering here the premature admission of another potential "Veto Player", with far more individual power, implied in an anticipation of ALCA.

Another aspect that we remarked was that in a structure like that, bipolar, which we suggested should be driven closer to a multipolar one, the existence of supra-national institutions, with real power to monitor the economic relationship among the countries, inhibit distortions, arbitrate divergences and, above all, direct, as required, compensatory financial flows, enhances to a great extent the likelihood of advances in the integration. The European Union offers good instances of operation of such mechanisms. Several of its successful endeavors vindicate the validity of the use of "lateral payments" as a mechanism to help to achieve and maintain stability in coalitions, as foreseen by the Theory of Games.

As concerns these supranational structures, the first move to come to mind would be to copy the model of the European Union. Indeed, it is a rich experience that should be studied and that will, no doubt, collaborate with inspirations for Mercosur. However, the discussion on what to do in relation to this subject should take into account the understanding that there are heterogeneities within each block, with respect to the real conditions of the member countries. Furthermore, their ranking of priorities and goals will not always be the same, which implies differences among the blocks, regarding which arrangements can be more efficient to obtain success in each case. Thus, the European Union can be useful as a blueprint, or even present elements that could be adapted to Mercosur conditions, but should not be taken as a formula to be adopted in its totality. The ways of Mercosur must have the hallmark of its specificities.

Indeed, when Mercosur was conceived, its creators proposed a schedule to be followed in its establishment that, in relation to several aspects, would be, roughly, a copy of the model of the process of constitution of the European Union. For many reasons, this seems to us to have been a mistake. One of such aspects refers to the sequence of phases foreseen in the agreement. We believe that this was not an appropriate choice, if the specificities of the countries involved are taken into account. That is so because, on the one hand, it contemplated a rather bold and quick schedule of advances, in what concerns the legal and political structure of the block, as well as some economic changes; and, on the other hand, it did not determine the development of supranational structures. This unbalance is a problem for the block, and we consider that the retaking of the project demands immediate actions in the sense of reconsidering this model. In one front, in order to rapidly create those structures and in another, for turning the arrangement more flexible, incorporating only the mechanisms those are useful to fulfill the requirements arising from our specific situation.

It seemed to us, then, that the creation of these supranational structures is a far more indispensable and urgent step, than, for example, the establishment of a Latin-American parliament or a common currency, so often raised by politicians. The reason is that it is likely to bring about the desired results more quickly than the first of the latter and, being broader than the second one, it will be able to deal also with other problems, besides the monetary ones, facing and trying to minimize turbulences[2].

As it relates to turbulences, it is worth reminding one of the advantages of the constitution of blocks, one that is usually less commented, but very important at the present to all countries of an enlarged Mercosur: in times of great volatility, there have been many cases of crisis in our economies caused by events generated out of our subcontinent. The unipolar structure prevalent in the world context, also in terms of hard currency, propitiates this to a great extent. In contrast, the supranational structures can, and should, stimulate the growth of the volume of intra-block trade, because, as it is known, this decreases our need, and dependence, of hard currencies, and therefore gives us a better degree of insulation from certain turbulences.

But there is another development, even more daring and promising, that such a structure might provide and guarantee, so as to turn the project into a source of more sustainable dynamism. We are referring to the negotiation and establishment of more stable prices, or terms of trade for the more strategic commodities and services traded among the countries of the block. It is strange that we buy gas from Bolivia, oil from Venezuela and Argentina and electric power from Paraguay and, at the same time, these countries buy from Brazil several goods, many of which "commodities", and that all of these goods are priced in US dollars. This brings instability to our countries, every time the value of this currency oscillates, due to the most diverse, exotic and distant reasons, generated out of our area and, certainly, falling out of our control and responsibility. Thus, the existence of special agreements of intra-block trade conditions could lead to steadier and durable bases, providing more viability for the planning and for obtaining of a sustainable development.

If, from the beginning, all of these measures seem to be more beneficial to Brazil than to the other partners of the block, on the other hand this country will certainly have to accept the role of contributing more heavily with funds and resources for the "lateral payments". And, there is a lot that can be done based on Brazilian initiatives, if the decision of really supporting our partners' development existed. The crisis is by no means a valid excuse for the inertia regarding this issue, not least because it is through undertakings (in a Keynesian sense) that crises can be overcome.

Financial, material and technological resources that are capable of solving crucial problems affecting member countries can be mobilized taking Brazil as a base. Of course it is not meant that the Brazilian State would take upon itself all the responsibilities. Even though the government does not have enough resources for that, its action, participation, interest and guarantee, can be decisive to mobilize private agents, both Brazilian and/or regional, in addition to supranational financing institutions, and together with the partners, raise the means to accomplish important achievements. At last, there is no point in 'beating the bush', Brazil can and should take, together with other countries that are ripe for it, initiatives to launch that process. Exempt of any purpose of dominating, or even leading the block, we must understand that the magnitude of our effort, as well as the sheer size of the country, will end up being proportional to the results that we will be able to reap.

Still in relation to our book, it comes out with other findings, derived from the analysis of the reality of the ways of operation of Mercosur in the last years, which are worth mentioning, as they shed light on some features of the concrete situation, and reinforce the reasons for the new study that we are developing. Such findings are the following:

1. The examination of the data of the intra-block trade, during the “good times” of Mercosur, shows beyond doubts that there is a great deal of complementarities among the four countries’ economies, portrayed in the significant increase in their exports. Each country takes advantage of its comparative advantages, in the industries in which it is more competitive, and benefits from trade. It is known that there are conflicting issues, but those are circumscribed. In relation to each one of the countries, it can be argued that:

2. A substantial share of Brazil’s exports to Mercosur involves manufactured products, whilst its imports are, mainly, of primary products, along with and “transport equipment”. This fact can be explained by the higher (broader) level of integration reached by the Brazilian industrial sector, as compared to the other countries of Mercosur.

3. As for Argentina, the list of goods exported comprises mainly primary products, one important exception being the automobile industry. Its imports are, in their majority, manufactured products. One can understand this fact by recalling the de-industrialization process, which Argentina went through during the last years, and its specialization and higher efficiency in the production of primary products, among them oil.

4. The economies of Paraguay and Uruguay share some similar characteristics: both of them export primary and manufactured goods with low technological density and they also import primary products and, in a smaller scale, manufactured products. These are less industrialized countries, which found a large market for their primary products. They import manufactured products because, due to scale limitations, they could hardly reach advanced levels of industrialization.

5. On the basis of the data referred to above, we can perceive that, in spite of many positive movements, Mercosur’s operation didn't manage to bring about substantial changes in the internal logic of development of each country. Obviously, this would not be modified just by the existence, even if more efficient, of Mercosur, since such features

are also heavily marked by the influence of a historical and economic past, as well as of the rest of the world. Just to give an example, the fact that Argentina imports manufactured products and exports primary products is due to the process, referred to above, which this country has been experiencing since the decade of 1970, and which led it to become not very competitive in the industrial sectors, but very efficient in the production in the primary sector goods.

6. These facts reinforce the argument we have put forward, concerning the need to implement some kind of compensation payments among the countries of the Block. Such schema would allow for counterbalancing part of the problems commented above, and some others as well. There are situations whereby countries that export products of higher technological content may be reaping the larger benefits stemming from higher added values, which lead to increased disadvantage for smaller countries, as well for those with lower degree of industrialization. A concrete fact to be faced, in this context, is that the two smaller countries have never been able, during the years of full operation of the Block, to decrease their negative trade balance, in relation to the rest of Mercosur.

Conscious that the discussion concerning the strategic importance, for Latin America, of the consolidation of a regional block, and the difficulties to reach it, is not exhausted - not least because the reality changes every day - but, also, that there is already some clearness as regards the general lines of the problem, we decided it was time to begin another investigation. It would already be an opportunity for us to redirect our attention to a specific aspect of this issue, which concerns the peripheral area where we live, the Brazilian Northeast. This is the object of our current efforts and its discussion is presented in the following sections.

II. Justification for the new study

It is only natural that the majority of the current panorama's analysis, as well as of the prospective studies, regarding the economic relationships among the member countries of Mercosur, have focused, both in space and industrial sectors terms, on the areas and branches which constitute the actual or obviously foreseeable sources or destination, for the most sizable economic transactions between those countries. It is these weighty polarizing flows that will possibly lend the main thrust for the justification and consolidation of the Block. However, this does not mean that the effects of the integration cannot come to be important, as well, for other areas and segments, of lesser dimension and visibility in this global scenery.

Within this context of a prospective consolidation of a wider regional block having the Mercosur as a starting point, our concept of peripheral areas encompasses both countries of lesser economic dimensions and less developed areas of the larger countries, provided that they do not constitute neither the most important sources nor destination of the current, or foreseen, flows of economic transactions among the countries of the Block.

A first reference to this line of argument appeared in Sicsú and Katz, 2000, whereby we argued that, besides the more obvious, and often referred to, potential advantages accruing the most dynamic poles of the economies of Mercosur, even an area as the Brazilian Northeast could benefit from its consolidation[3]. Of course, one does not think that insertions of this kind can become generalized, or that their aggregate impact will come to have a dominant weight in the process. Most certainly, they will rather concentrate on specific segments and in localized productive chains, although they can be very important for those involved with them.

As mentioned earlier, in a more recent work, Katz et all, 2002, we had the opportunity to verify that countries of smaller dimensions, and therefore peripheral in terms of the ensemble, did not get large gains from the integration and, in some aspects, may even have incurred in losses, as a result of the process. In discussions with colleagues of the Department of Economics of the Catholic University of Uruguay, we concluded that Uruguay is an example of such kind of outcome. But, at the same time, we agreed that this result is not a necessary, nor the only possible one. From this understanding there arose a commitment to engage in a joint effort, aiming at further and deeper exploring these issues.

The central idea of the research we are now carrying on, in relation to Brazilian Northeast, Uruguay and, possibly, other peripheral areas - in the sense we are using the concept of "peripheral", i.e., as related with the integration of Mercosur - is that the latter creates a new scenery of microeconomic reality, that can offer new and varied business opportunities. That is so for many reasons, an important one being the lowering of tariffs and the elimination of other barriers in intra-block trade. As stated in the title of this text, new opportunities, and vulnerabilities, will possibly arise, regarding peripheral relationships in Mercosur, which are prone to alter the functioning of productive chains in these areas. A study of these possibilities can allow for a timely identification of some problematical points and the elaboration of propositions for facing them. Also, it can indicate areas that should be explored, either by the private or public sectors, with a view to maximizing the gains of the process. And, even more interestingly, it seems to us that opportunities can be spotted for new connections with mutual gains, between peripheral areas. The identification of one or two of such potential trouble points, or of such opportunities, would undoubtedly justify the study. In any case, it is important to ponder whether such insertions are sustainable or if they are excessively vulnerable to abrupt changes of the situation. It is also fundamental to detect who, or what, defines the strategy of the productive segment and the amount of bargain power one has in the process.

With the objective of clarifying the main idea subjacent to this work, let us refer to a fact that conforms to the type of situation we have in mind, and actually will be one of the concrete cases contemplated in our study. This is the case of the poultry farming industry in Brazil's northeastern state of Pernambuco. As it is known, this sector had a good and steady growth in recent period, and has already reached an important position in our economy. However, more recently, it has plunged in a deep crisis that began to revert to its trend performance, jeopardizing its ranking as an important economic activity. In fact, there is news that many plants are being transferred to other states. One of the central problems lies in the supply of feeding grains, an essential input for the activity. The difficulties derive both from the irregular availability of cereals and from their prices and freight fees. It happens that the provision of cereal for the poultry farming industry of Pernambuco does not originate from local agriculture's production and depends, to a great extent, on production from distant regions. Now, in the context of the integration of Mercosur, when the barriers and tariffs on grain imports would stop being an impediment, it is positively conceivable a scenery whereby conditions might be created for a coastal sea freight flow, which carry products from our area to Uruguay or Argentina, and bring grains for the poultry industry of Pernambuco and of northeastern Brazil. Of course the feasibility of such scenery must pass the test of, among others, costs, markets dimensions and demands microeconomic analysis. Nevertheless, considering the importance of all the elements involved in this question, it no doubt deserves the toil of the exercise.

At last, one aspect that should be stressed again is the need to institute supranational structures, so as to confer stability and equilibrium to the operation of the Block. Such institutions have been created in blocks that are not unipolar, and one of the ways they operate is promoting lateral compensations to countries, and areas of countries, which would be otherwise losers. Of course, support and incentive to opportunities and connections among peripheral areas would be, par excellence, the ideal ground for this type of action.

III. The on-going research

Our main methodological objective is systemizing an approach for the analysis of changes in the microeconomic framework, due to a process of multinational regional integration. This approach will be used to analyze the conditions of insertion of two peripheral areas of Mercosur, Brazil's state of Pernambuco and Uruguay. Concretely, we will try to detect opportunities and vulnerabilities that might come about thereby. The analysis will unfold in the stages described below:

- ?? Detection of the main productive chains, with relevant operations in these economies;
- ?? Detection of those chain's logic of operation and of the factors that condition their evolution;
- ?? Identification of the exports and imports flows between these economies over the last years;
- ?? Comparison of data from the tables of inputs of several productive chains of Pernambuco and of Uruguay, with a view to detecting new feasible interactions and, thus, selecting which of the chains to focus in the study;
- ?? Analysis, from a microeconomics point of view, of the concrete possibilities of occurrence of interactions, and the opportunities and vulnerabilities that might emerge thereby, for the most important cases;
- ?? Analysis of the role public policies could or should play, in order to support the consolidation and competitiveness of those segments;

Modeling of a framework of foreseeable features of the social and economic impacts resulting from the integration as well as their likely reflections in terms of changes in the conditions of life of the populations of those areas. To accomplish the work, we are performing the following research stages:

a) Survey and analysis of bibliographical material of reference in the fields of international trade, regional and global productive chains, formation of economic blocks and socio-economic impacts of new productive arrangements;

b) Starting from an analysis of the imports and exports register of the areas under study, and of the inputs of the productive chains, detection of the more relevant productive chains for the integration;

c) For some of those chains, the ones we consider to have more vulnerability and or offer positive opportunities, delve the investigation down to four levels, which are:

I. Detection of the logic of production and of integration, characterizing the agents with strategic decision power.
II. Characterization of the productive chain 'governance' and of its enabling institutional arrangements.
III. Characterization of the productive flows and commercialization channels, attempting to underscore main partners and insertion in the global and or regional productive chains.
IV. Characterization of the dynamics of innovation and of the actors that define the technological paths of the sector.

By this way, and once put together such frame for the cases presenting real possibilities for the interaction to emerge, we will try to define and to characterize those chains' relevance for the economies under consideration, with respect to both income generation and employment opportunities. At this stage, we will organize all these pieces of information and prospective views and promote workshops, in Pernambuco and in Uruguay, in order to discuss them with relevant representatives of the public and private sectors. In these seminars we will submit the findings to the screening of business' and workers unions' leaders of the industries concerned, experts from the academy and relevant public institutions staff. Hopefully, such discussions will come up with pertinent conclusions, concerning insertion strategies able to attract the private sector, and or providing guidelines to public policies of intervention.

Finally, we will promote a conclusive conference in Recife, Pernambuco, when a comparative analysis of the Uruguayan and northeastern Brazil cases should allow us to summarize and systematize the most important aspects that can influence the tendencies of those economies.

End Notes

[1] The title of the book is "Mercosul: Mudanças Necessárias", referred as Katz et al, 2002. The authors are the same as the ones of this paper, plus the economists Keila Sonalle and Romina Paradizo.

[2] The last important conflict in Mercosur hinged around exchange rates. But, in any other occasion, confrontation may arise from many other different sources. The idea we advocate here is a general approach towards striving at anticipating and bypassing conflicts, rather than a possible treatment for a specific problem, no matter how important it may be. But quite independently of all these reasons, the supranational structures are indispensable because, to guarantee the cohesion of the block, it is necessary to assure that all the countries, even the less powerful ones, also benefit from the integration, and it will only be possible to have this for sure through the establishment of the "lateral payments".

[3] Mercosur has been operating, with highs and lows, since 1991, and now confronts a phase characterized by uncertainty. As we refer to its consolidation, we have in mind the moment when all doubts about its continuity are dispelled and its operation's characteristics are strengthened.

The Role of Asia in the New World Economic Order: New Opportunities and New Challenges for World Markets

Guy Schulders
University of Paris, France

Abstract

Western economists observe with a quite particular interest the very inequal, —sometimes very fast— and the new orientation of the economic evolution of Asian countries since the beginning of the reforms of the 80s. Since then, these countries present the industrial and commercial world a major interest for investors of the rest of the world. The focus of this paper is not to explicate Asian economic growth to regional experts but rather to take stock of key issues that are of concern to outside observers such as academic economists in regions such as in Europe.

In this paper, we note the importance of risk in the economic transitions now taking place in China and in other East Asian economies. How East Asian economies choose to manage this risk is of central importance not just to academic economists but also to prospective investors and trading partners. With China as a case study focal point, we note that China's accession to membership in the WTO has momentous consequences for its participation in the global economy, and more particularly how it chooses the transition to a more privatized and free-market economy. Some countries, including Vietnam, Cambodia, and Laos, have yet to embrace the full panoply of free-market institutions, and face the additional risk of slower growth than in a more reforming economy such as China.

In looking at the Chinese experience, we note that even with its emphasis on market-based reforms, it may not be able to sustain the rates of economic growth that it has enjoyed since the earlier years. Measurement problems make it difficult to track these issues, but we conclude that China may well provide a new model for economic growth from which East Asian and other newly emerging economies may learn.

Introduction

Western economists have noted with particular interest the rapid evolution of the Chinese economy following the reforms begun by Deng Shiao Ping in the late 1970s. Since then, China has become a commercial and industrial world power, and has begun to assert its weight in international affairs. The focus of this paper is not to provide an analysis of Chinese economic growth through a repetition of processes that are already relatively well-known. Instead, I plan to concentrate on how European economists interpret this extremely rapid economic transformation, and to spell out what Europeans expect from this process as economic and commercial partners.

The important reforms undertaken by the Chinese administration have been adopted within the framework of a market socialist economic model. As such, China has moved to open its markets to international investment while expanding its trade with other parts of the world, while at the same time preserving the political dominance of the Chinese Communist Party. While China has not yet embraced the kinds of democratic political institutions that many other developed countries take for granted, it has been able to pursue rapid economic growth through market-based liberalization.

Chinese economic agents, especially the young emerging business leaders, have figured out how to adapt quickly to the new flexibility and growth of their economy. They have been able to respond quickly to incentives and to the possibilities offered by the new international economic framework in which they are participating.

For more than a year now, China has been a full member of the World Trade Organization. In so doing, it has embraced a path of modernization of activities and the adaptation of institutions to the rules of international trade. As a result, China is positioning itself to compete on a global level and is preparing itself to respond to the challenges of modernization and competition. Indeed, no one doubts the entry of China on the global stage.

In observing China's economic transformation, western economists have asked three types of questions:

1. In terms of domestic economic performance, has China found a way to avoid the traditional business cycle?
2. With its 1.3 billion consumers and its membership in the WTO, has China become one of the most important economies in the world?
3. Finally, on a scientific level, are currently available statistics sufficiently valid to track and predict the continuing evolution of the Chinese economy?

1. Thoughts on the Sustainability of Chinese Economic Growth

1.1 Fluctuations and Mastery of China's Economic Growth

Most economists would agree that the kind of robust economic growth that one observes in China cannot endure indefinitely. With rates exceeding 7.5 percent (9.4 percent in 1999, 7.9 percent in 2001), over a period of twenty years, such growth makes one think of overcoming more developed economics but at the same time, raising the question of secondary effects with which the Chinese will have to contend or master. These effects arise especially at the social and cultural levels.

Social and cultural pressures are increasing as China's relatively high rates of growth take place unevenly across sectors and geographic regions. Coastal areas, and those favored by special economic legislation, are experiencing the most rapid economic growth, while communities farther in the interior are growing much less rapidly. As this takes place, productivity norms and competitive standards in a global economic environment generates rising unemployment in less advanced areas, especially among the less well educated members of the labor force. This is further exacerbated by the shift to privatization of industry, hitherto a source of guaranteed employment in a once closed economic environment.

1.2 Adaptability of the Administrative and Institutional Framework

The institutional framework of China remains very removed from the traditional framework of market economies in other parts of the world. We note in particular several distinctive features.

1. China's markets have experienced a progressive but thus far only partial economic liberalization;
2. Functional boundaries of responsibilities between the public and private sectors remain largely porous and weakly defined;
3. China's once centralized planning system has evolved in a quasi-independent fashion in relation to free market reforms that are coming to dominate the economy;
4. Privatization of enterprises has thus far been relatively limited;
5. Economic reforms are producing a transfer of government responsibilities to local government institutions as well as to private markets, and local government institutions are acquiring these functions based largely on geographic proximity independently of any rigorous economic criteria;
6. As a general rule, economic reforms in China are increasing the efficiency of the allocation of resources as well as an increase in the productivity of firms.

Despite these changes, the reform of public enterprises has resulted in a substantial contraction in public sector employment and a corresponding increase in unemployment. Informal estimates suggest that the number of unemployed may be as high as 17 million. In addition, economic growth in China is tied to the rapid development of the industrial sector, and as a result, drives and anticipates the modernization of the agricultural and rural sectors of the economy. In response, Chinese authorities have focused on the development of township and village enterprise initiatives to assist in the process of economic reform. The purpose of this initiative is to slow the degree of urbanization of relatively unemployed members of the labor force who most likely would not be able to compete in the international economic environment. In turn, local authorities have looked to state-funded support to ease the fiscal burden of local level enterprise initiatives.

1.3 Regionalization is a Necessary Pre-Condition for Successful Globalization

As noted above, China's economic growth is unfolding in a geographically uneven fashion. Successful strategies thus most focus on the development or geographic regions. Geographic regions provide an information framework for major economic decisions as well as for potential foreign investors. They do so in terms of participation in the development of local institutions. This includes cantons, municipalities, and individual provinces as the location of productive sites for employment, and thus in terms of local purchasing power.

The Central Region of China is the one targeted to provide a bridge between the dynamic coastal regions and the interior during the next ten years. It is expected that the Central Region will help to avoid bottlenecks in production, investment, and employment. It is very spread out and encompasses a population roughly equal to the Coastal Regions.

The principal objective of this initiative is that it will lead to a diffusion of economic wealth. Redirected economic investment will help channel wealth from the coastal zone toward the interior through both direct and induced effects. However, only through the detailed feasibility studies that are thus far difficult to undertake can one determine if this strategy will lead to the successful outcomes that Chinese officials hope will occur.

Any redirection of investment and production toward Central China will depend on several considerations. They include:

1. If it is undertaken in an economic zone that already has a suitable infrastructure, such as the Yangtze river basin;
2. If it is undertaken by firms that are sufficiently well established and capable of absorbing the likelihood of unanticipated financial loss over an extended time horizon.

The accelerated transformation of China leaves little time to develop a more balanced framework of internal economic and social relations that link hitherto isolated communities to the national and international level. Secondly, China will have to pursue a rational development of resources and advantages that will provide dynamic growth in the provinces with those of the coastal regions. In so doing, rural communities will be forced to embrace commercial, economic, political and social norms that are already required by an interdependent global economy.

2. China's Growing Role in International Markets

China's admission to the World Trade Organization brings new concerns to Chinese nationals and to their economic partners. We list below some of these key factors.

2.1 Implications for the Chinese

Access to international markets and the adherence to established international rules will undoubtedly create new hierarchies and a re-orientation of economic activity in China. Some of these changes will have more promising effects if they are directed toward international markets. Out of this process, a veritable "adaptability rent" will be born by the speed with which a Chinese firm can respond efficiently to the demands of international markets.

If China's provinces constitute a new economic network linking them to the global economy, this will undoubtedly weaken some of the inter-regional links that used to tie various rural regions with each others. As a result, some rural provinces will acquire competitively dominant positions in contrast with the cooperative relations that used to prevail. The eventual unlinking of inter-regional rural ties, while promoting a deepening of vertical links to the global economy, may work poorly in those regions where investments are poorly coordinated and in which highly uneven economic growth takes place.

a. Implications of China's New Role for its International Economic Partners

China's new participation in the global economy will produce differential effects not just on markets but also on its trading partners. Since we are talking about globalization, these partners include:

1. Rich countries and newly industrializing countries;
2. Relatively undeveloped countries and other emerging economies.

In turn, different countries will find that the distribution of world income will depend on part how each adapts new policies in response to the growth in global economic interdependence.

b. Implications for Rich and Newly Industrializing Countries

International firms from industrial economies and newly industrializing economies have generally tended to redirect part of most of their production from existing industrial markets to emerging markets such as in China. Some, such as Japan, experienced considerable difficulties in this process, such as what took place during the 1990s. In the Japanese case, social costs increased rapidly, a strong currency reduced export growth, unequally competitive salaries in relation to their Asian trading partners, and high consumer prices all contributed to economic stagnation, rising unemployment, and business failures.

Western firms, as well as Japanese firms, when faced with non-competitive domestic conditions, often chose to relocate operations in a more favorable environment such as China. They were able to take advantage of relatively low labor costs in comparison to their Asian trading partners, to enter new local markets, and to establish valuable networks for prospective new markets and consumers.

In terms of prospective markets, consider some basic comparisons. First, as of March 2002, there were 162 million cell phones in China and 5 million automobiles for which demand has been expanding by 1 million each year. At the same time, western firms have developed new marketing strategies in order to adapt to more complex local conditions, conditions often misunderstood by Western firms but now viewed much more carefully. In turn, production by rich countries and by newly industrializing countries have focused on the choice of goods that integration their production with a high value added, often intermediate goods. In 2001, such goods accounted for more than fifty percent of exports and roughly equal to China's total imports.

For Western and neighboring Asian countries such as Japan, Thailand, South Korea, Singapore and Malaysia, the entry of China into global markets is a natural complement to many of the products that these same countries are also in the process of producing, though sometimes at different stages of transformation. Rich and newly industrializing economies thus generally benefit from China's opening of its markets to their products.

China's entry into the World Trade Organization provides global markets with a framework that is sufficiently flexible for the expansion of global trade and production. The establishment of free trade zones in which there is a subtle and disciplined coordination of trading partners helps avoid a fallback to older protectionist measures in which competing countries would engage in beggar-thy-neighbor tariff and quota restrictive policies.

As harmonious as this may seem, one fallback that should be noted is that if Chinese firms engage in producing exports that contain high value added, this may spell trouble for the kind of partnership relations that have characterized international trade and investment thus far. Nevertheless, in the present environment, there is a productive and positive atmosphere in which Western firms seeking to do business in China may learn more about local customs and traditions.

c. Implications for Other Emerging Economies

Unfortunately, for many emerging and developing economies, their activities are much less complementary to China in that they are engaged in efforts to replicate too many similar types of low value added goods. We note in particular that for many member countries in ASEAN, as well as for India, Sri Lanka, Bangladesh and Pakistan, the effects of China's entry into global markets may not be as beneficial. These countries possess similar advantages relative to Western developed economies: firms engaged in traditional textile production, high hourly costs of production (40 to 50 cents per hour of labor), and thus lower than in China (62 cents per hour). This suggests that the real competition in textiles and clothing will be among Chinese and East Asian producers. This is particularly so for countries such as Thailand, Malaysia, Indonesia, and Vietnam, not to mention, Laos and Cambodia. Outside of Thailand and Malaysia, these countries are relatively poor and their prospects are dimmed rather than advanced by the entry of China on the global economic stage.

3. Measuring Economic Fluctuations and Their Effects

Quite naturally, economists are interested in measuring fluctuations and their effects on the balance of economic power that is taking place in Asia. We note some key dimensions of this change as well as the implications they represent for economic relations between China and her Asian neighbors as well as between China and her trading partners in other parts of the world.

3.1 Domestic Economic Fluctuations

Tracking China's economic performance is a daunting task for both Chinese and outside analysts. The main reason for this situation is the lack of dependable statistical gathering and validation institutions, many of which rarely, if at all, take into consideration China's large informal sector. As a result, estimates of China's global economic growth rate, as well as wages and salaries, should be treated with considerable caution in any formal economic analysis. In our view, despite the difficulties in deriving more precise statistical estimates, in general it seems clear that China's opening to the rest of the world has placed it in a position of incontestable leadership in East Asia. Its influence in the global economy will be felt with increasing weight over time.

3.2 China in the International Arena

Turning to China's international performance, we note some cautionary concerns. Central to this concern is once again the question of measurement, in particular:

1. The external re-orientation of Chinese markets, and thus the growth of exports and imports of China;
2. Induced effects brought about by China's admission to the World Trade Organization.

This said, it is increasingly clear that China is becoming the dominant economic power in East Asia. How rapidly and to what extent this will take place depends in part on improvements in the quality of statistical data, which we view as essential to a better understanding of this process.

4. Theoretical and Policy Considerations Relevant to China's New Economic Policies

The theoretical framework of international economic integration can be traced back as far as the 18th century. At the time, countries on the eve of the industrial revolution in Western Europe faced the challenge of whether increased dependence on international trade would abet or hinder the process of economic growth. As debate unfolded and experience in the industrial revolution and economic growth expanded, economists extended the earlier discussions to take into account new insights that are pertinent to the context of China's new economic policies today.

Let us note how the theory of international trade has evolved. We cite the following theoretical contributions:

1. Comparative advantage (Ricardo)
2. Trade creation and trade diversion (Viner)
3. The law of factor proportions (Heckscher, Ohlin, Samuelson)
4. The gravity model of international trade (Tinbergen, Linnemann)
5. The "wild flight" or random effects model of trade (Akamatsu)
6. Intersectoral Linkages in international trade (Helpman, Krugman)
7. Factor endowments and gravity factors (Bergstrand)
8. Frontier effects (McCallum, Head, Mayer, Poncet)

This list is not meant to be exhaustive, nor is it our intent to test any particular version as it applies to China's new economic growth. We note again that any effort to develop empirical estimates for the Chinese economy is limited by the incomplete and inadequate statistical sources that we have already noted. Rather than attempt such a modeling exercise, then, we propose an institutional model that takes into account cultural and behavioral characteristics that in our view are essential to understanding China's economic success.

4.1 A New Approach to Understanding China's Economic Growth

In our view, there are seven key dimensions to China's economic success. We note the following:

1. **Causes of Economic Fluctuations**. The standard framework is in a constant state of flux as China's dependence on globalization expands. It is important to analyze non-synchronous patterns of China's economic fluctuations. We consider that part of this behavior is to be found in natural elements within the Chinese economy, by which we mean demography and natural resources among others. In addition, we also point to the role of cultural forces in shaping Chinese responses to economic growth. In particular, we consider the religion, ideology, established habits, and traditions can explain part of the responses we find within Chinese society as new economic growth and fluctuations occur. We add to this the importance of material elements such as living standards and the economic and financial infrastructure as key factors that can explain major fluctuations in China's economic growth.
2. **The predominance of dis-equilibrium states**. China, as many other countries have experienced, does not enjoy economic growth along a neat mathematical continuum. In

fact, dis-equilibrium is more typically the norm. This is due not just to inadequate statistical estimates, but to the basic process of globalization in the economy.

3. **Emergency Strategies**. China is perforce required at the present time to adopt short-term strategies for globalization. Moreover, it also must do so step by step and region by region, often building institutional links between governmental institutions and small and medium-size firms.
4. **The Necessity of Pragmatic Policies**. China can not face globalization with a closed-mind set that reflects historical ideology. The current leadership recognizes full well that its legitimacy derives in no small part from improving living conditions among the vast majority of the population.
5. **An Understanding and Willingness to Take on Risk**. Any type of major economic reform poses inherent risks. Such risks are at the same time economic, political and social. Again, China's leadership recognizes that there are inherent risks in globalization and is determined to find ways of anticipating them, devising suitable responsive strategies, and implementing them in ways that avoid a larger upheaval.
6. **Shifts in the Balance of Power**. China's leadership recognizes full well that economies that fail to adopt a positive approach to globalization are likely to fall behind in the effort to improve living standards and to achieve a position of influence in the global economic community. As can be noted in the declarations from Beijing, there is a full recognition that at present the weight of global economic policies still lies with richer and well organized economies and that in order to participate in such policies, China will have to increase its economic weight through sustained economic growth.
7. **Integrating Actions**. As we move into the 21st century, it is clear that no country can prosper independently of others- we are all globally interdependent. Reorganization of the economy is a response to globalization. This requires a reorganization of the balance of power within the economy, as well as a modernization of the infrastructure and capital stocks. The process of internationalization, of globalization, represents powerful forces that will bring the world much closer together than ever before.

Conclusion

Countries such as China are experiencing systematic rapid evolution in which their economies are being transformed in a relatively short time. This places pressure on their social structures, on existing traditions, on the balance of relationships between urban and rural populations, on the relations between agriculture and industry, and on the relationships between the formal and informal sectors. This is especially true in China which has developed an original model for modernization, growth, and development, and which is increasingly atypical of a socialist market economy. China's experience will undoubtedly transform the structure of both economic theory and policy, not just in terms of the choice of an economic system, but in terms of a model for our times.

Regional Innovation Systems in Mexico and Canada: A Comparative View

Ricardo Arechavala
Claudia Diaz
Universidad de Guadalajara, Mexico

Abstract

Innovation systems arise when firms realize that, in order to compete and innovate, they need knowledge that is beyond the capacity of any individual organization to generate or assimilate. As they begin to collaborate, they need specific social capital on which to draw, in order to complement their resources in a competitive fashion.

The economies of British Columbia and Mexico are in transition, from being resource-based, into industrial and service ones. However, they draw on different resource pools and social capital. How do these two countries' social capital compare? Which are their relative strengths and weaknesses in this area?

This paper presents results from research conducted in innovation networks in British Columbia and Mexico. Fieldwork includes interviews with members of organizations that actively participate in those networks. Underlying institutional principles governing their development in both countries are identified. Policy implications are derived, with particular emphasis on the Mexican case.

The Name of the Game: National and Regional Innovation Systems

As the concept of the knowledge society has become commonplace, research on how the relevant social structures and processes support economic competitiveness has increasingly gained in importance. Specialized research has gone on to develop an understanding of the role that national and regional systems of innovation play in economic competitiveness. Identifiable components of those systems, such as universities, major R&D labs, skilled labour markets, venture capital and science parks, for example, are closely scrutinized, in order to assess their role in those systems, and to identify ways in which to enhance their performance [see Salter and Martin 2001, McKelvey et al. 2003, de la Mothe 1994, for example]. The World Bank and OECD [OECD 1997, 1999] have explicitly endorsed the national and regional systems of innovation approach to the development of policy measures in industrialising countries.

This approach has been relatively uncontroversial in countries with an advanced industrial context. However, its relevancy to developing economies like Mexico is not as clear yet. It is usually understood that countries like Mexico should not attempt to blindly follow or copy policy measures that have been successful elsewhere. But there is always the need to spell out the reasons for which some measures have been successful in a given context, so as to provide a firmer basis on which to devise policy measures in less-developed countries. Can those reasons be identified in field research in a useful way? Can *a posteriori* explanations of successful development of given innovation systems provide a sound understanding of what is needed to *create and develop* new innovation systems, where only some of the ingredients seem to be present?

In many countries, a strong interest in the relative effectiveness of federal and regional relevant policy measures has ensued. Whilst some countries (like the Netherlands) are small enough so that their innovation systems can be strengthened through national level policies, others (like Italy, for example) have their regional systems of innovation (RSI's) highly differentiated at the regional level. This concern is usually related to that of the relative influence that external (exogenous) efforts, resources and policy measures may have in the development and viability of a certain RSI. Frequently, these influences are distinguished from endogenous factors, such as a certain level of economic and technological activity, or the presence and nature of social capital, for example, that arise out of processes that are not centrally (at a federal level) or locally managed. In the specialized literature this issue is also generally associated with that of the relative efficacy of policy measures, as opposed to more spontaneous economic and social processes.

Canada and Mexico, as signers of NAFTA, are also involved in a common set of economic ties, in a system driven by the US economy. NAFTA calls for complementary roles (like those of resource and labour providers, for example), but also for similar competitive capabilities. Both countries share a significant need for the development of endogenous technological and innovation capabilities.

Canada and Mexico share a common characteristic: they are large federal countries, in which economic activity and industrial clusters may in varying degrees be responsive to policy measures at both the federal and the regional level.

Canada's current drive for innovation-based competitiveness is a very strong effort to close the "competitive gap" with the US. Among the Canadian provinces, British Columbia shows strong parallels with the Mexican context, which makes it an interesting and relevant case for understanding the development processes of RSI's. Such understanding may have important implications for the design of policy measures in Mexico.

The Process of Development of a Regional System of Innovation

A significant proportion of the specialized literature [Longhi 1998] argues for the existence of a set of preconditions for the development of a regional system of innovation. These preconditions include: a) a coherent set of territorial relationships among all economic actors, b) a specific culture, and c) a shared representation system, implying a strong consensus and integration among them.

A second level of preconditions emphasized in the literature is the existence of a local technology resource base, or knowledge base. This may be a large firm, a research institute or a university, that gives rise to the development of distinct core competencies in the region. This resource base spreads locally and in strong interaction with other actors through the process of spin-off formation and integration in strongly interacting networks. These elements are frequently reported in the literature as being complemented by later arrival of firms and organizations that reinforce the networking interactions and learning processes among all actors.

According to some authors, these enabling factors need not be present simultaneously, nor is there necessarily a specific sequence for their development. Judging by the accounts presented in the specialized literature, there are many different pathways through which a RSI can grow.

A different approach is held by other authors, who hold that a set of key factors, should foster the growth of a high technology district. Among the factors commonly identified as providing the appropriate conditions are:

?? "A leading scientific university and associated research complex
?? A prestigious industrial or science park
?? A desirable social environment to attract and retain high calibre personnel
?? Provision of venture capital
?? Public support for innovative technology
?? A facilitating labour market providing requisite skills". [Garnsey 1998, p 361]

Still, there is the problem of explaining "How and why some places develop expanding industrial complexes while others move along other trajectories or even remain stillborn". (p 361).

Other approaches emphasize that it is not the set of factors or facilitating conditions that gives rise to a RSI, but rather the sequence of cumulative interactions between them and feedback effects, where cumulative causes are at work and each sequence of outcomes is shaped in part by prior events.

Even though detailed specification and rigorous empirical identification of conditions characterizing successful high-technology milieux would not provide easily generalizable results, the examination of a specific system may help understand common processes that nevertheless produce distinctive trajectories.

Research Questions

Which are the most salient characteristics of the British Columbian and the Mexican context, those that best illustrate the relevant systemic processes in the development of their RSI's?

What are the institutional arrangements that explain the relative differences in the development of their RSI's, in the view of their most relevant actors? Which are the roles assumed by local network actors? How do they learn to play those roles, and to articulate them in a complementary fashion?

The literature on RSI's resorts frequently to the notion of "path-dependency", in order to explain, *a posteriori*, the relative success, of innovation clusters. In this case it might therefore be useful to explore whether the effectiveness of policy measures was determined by specific variables in the previous development of the corresponding RSI's. Is current progress in their development due mostly to policy measures, or to endogenous processes that may have been acting earlier?

Moreover, as in many contexts, field research in the Mexican case has shown that it is easy to identify many pieces of the system that are in place. However, stable networks have so far failed to develop consistently. Interaction among actors in the system is not occurring as expected. Why is this so?

As discussed by Niosi and Bas [Niosi and Bas 2001] show, the problem is not whether a given region has a specific set of resources or not, but HOW it assembles those resources into specific *competencies*. How do the right interaction patterns develop? So far, the specialized literature has discussed the presence of social capital, in the form of a common language or representation system [Longhi 1998] that permits learning, as well a trust and honesty, that enable the shared and complementary search for knowledge and innovation [Camagni 1991]. But how do are those elements of social capital developed? In which ways do they enable the right kinds of interaction?

A RSI is a system of interdependent actors. However, there is no central coordination mechanism. An alternative is to view the system as a self-organizing system, as a *complex system*. In it, each actor makes decisions that guide his actions according only to his own interests, and to locally available information. What is it that gives coherence and directionality to the whole system?

In what follows, we present results from two parallel research projects. One of them was done in Vancouver, British Columbia, in Canada. It dealt specifically with the composition and the processes that give coherence to its biotechnology innovation cluster. The second research project deals with the emergence of innovation networks around public research centers in Mexico. From the comparison of these two cases, policy implications are discussed.

Methodology

In both cases the studies have been built through semi-structured interviews. In Mexico, interviewees included relevant actors in innovation networks in Central Mexico:

- R&D personnel in public R&D laboratories, whose mission is to develop technology and transfer it to
- industry.
- Former and current public R&D laboratory managers;
- Representatives from firms that have hired the labs' services or that have contracted technology
- development and transfer projects with them.
- Business trade associations' leaders.
- In British Columbia, the study focused around the development of the biotechnology innovation cluster.

Interviews were held with:

- Government officials in agencies responsible for the enhancement of business environment;
- Trade associations' leaders;
- Leaders of NGO's dedicated to the promotion of high-technology industry;
- Dedicated biotechnology firms' CEOs;
- University – Industry Liaison (technology transfer) Officers;
- University research officials;
- Science and Technology policy analysts;
- University researchers in high technology areas.

Content analysis of interview transcripts was conducted with QSR5 – NUD*IST software, in order to identify, code, and group relevant response categories. The focus of the analysis was to identify *patterns* in responses to questions.

The British Columbian Case

Mostly for geographical reasons, British Columbia can be thought of as an economy that in many aspects is similar to that of Mexico:

a) It is a transition economy. From being a resource-based, BC is moving towards a service-based economy, without going through a major manufacturing phase, by attempting to use its competitive advantages of scenery and climate to promote tourism, film production and high-tech industries (industries where lifestyle is a major factor in attracting highly skilled employees).

b) As part of this effort, BC's organizations display very explicit efforts to rely on innovation, rather than on natural resources, as a strong economic driver.

c) It is being successful identifying and promoting the development of specific and competitive RSI's.

In BC, as in the rest of Canada, technology development initiatives have been in effect for decades. Mission-oriented[i] views of science and technology have oriented initiatives that fuel technology and innovation, and guide them towards well-defined social and economic goals. As reported by interviewees in the study, these views were developed in a vein similar to that of the US and European countries, where scientists played an important part in the war [Bush 1945].

Thus, initiatives in the country are a way to harness the power of S&T to satisfy major social needs in areas like biotechnology, environment, and so on. Initiatives are designed and developed on the basis of continuing consultation processes in which the scientific researcher community, research institutions, business leaders, and ONG's, for example, participate. Initiatives at the federal level are frequently mirrored at the provinces' level.

A national review S&T was conducted in 1994. Among the goals stated in a guiding document released prior to the review, the government's goals in the process were:

1. "To keep interested Canadians informed about the review exercise and the development of a new federal science and technology strategy."
2. "To provide opportunities for focused debate among Canadians on federal policy options for science and technology."
3. "To listen to the ideas and suggestions of interested Canadians which can be used to improve the new federal science and technology strategy."
4. "To identify and describe the issues which are priorities to Canadians."

(…)

Even though the process has been criticized by analysts, the analysis of written submissions to the process, they could be grouped into a small group of core issues identified by various stakeholders. Among them, were the following:

5. Third party steering of S&T policy.
6. Focus public funding and policy to maximize return on investment.
7. Increasing partnerships among stakeholders.
8. Fostering linkages between science and social issues.
9. Funding federal core research as the backbone of Canadian R&D.

(…)

As examples, these elements may give a fair idea about the way in which Canadians think about the role of S&T in their economy and society.

Components of BC's Biotechnology Innovation Cluster

According to informants interviewed for the study, the province has invested in science and technology for close to a hundred years. The University of British Columbia was founded in response to community interest in having its own university. From the beginning, faculty was expected to conduct research. Moreover, UBC's faculty selection criteria have always implied nationwide (and eventually in the US) search and selection of the best researchers available funds could afford. Although not as old, other major universities in the province share this characteristic.

Even though always expected to generate useful knowledge, pressure for social returns on investment increased in the eighties. In the view of our informants, universities respond to the same mission-oriented view of science. Some of our interviewees regard the culture of support for S&T as a consequence of the role that scientists played in WWII.

Canadian universities informally embraced the Bayh-Dole Act, whose aim was to encourage the utilization of inventions produced under federal funding, and to encourage collaborations between universities and commercial concerns to promote their utilization, for the benefit of the national economy.

The federal government provides funds for development of research infrastructure in universities through the Canadian Foundation for Innovation (CFI). Its mission is: "To strengthen the capability of Canadian universities, colleges, research hospitals, and other not-for-profit institutions to carry out world-class research and technology development". An important issue is that most of its funds are provided on the condition that they are matched with equivalent funds from provincial governments and business. An important ingredient in its mission is the set of criteria with which it evaluates projects for funding [CFI 2003]:

"Infrastructure funded by the CFI supports research that:

?? leads to major breakthroughs;
?? improves our quality of life;
?? helps clean and protect our environment;
?? generates results that will lead to economic growth;
?? generates results that will be transferred to health practitioners, community groups, teachers and decision-makers."

Taken only as an example[ii], this text shows the degree to which both the mission-oriented view of S&T, and the requirement of interaction among actors in the system is built-in, in the functioning of major components in the system.

Funds for research itself are also closely associated to matching funds that must be provided by beneficiaries of their results. As different organizations in the provinces vie for funds provided by the federal government, they must ensure that their provincial government matches those funds, and that business provides another portion.

Even though there are funds available for basic research, many scientists have shifted to more applied fields. As reported by researchers interviewed for the study, this has been a change that hasn't taken place at universities because of directives born within them, but rather they are the product of a gradual shift in the availability of the funds they compete for. This change has taken place in the last two decades. In adapting to this shift, they have developed a network of contacts with industry that has provided with a wide range of research topics, in a relationship that has grown stronger with time.

In BC diverse organizations have been created within this context, with explicit goals for linking industry and academia. Organizations like the *Advanced Systems Institute* (ASI) dedicate a significant portion of their resources to create links between industry and scientists in the natural sciences.

On the other hand, new spin-off firms grow out from universities, in order to commercialize technologies developed in research projects. They are not necessarily created by researchers themselves, since a significant proportion of them are researchers by vocation. Enterprises can be started by their graduate students, or they may rely on support provided by university-industry transfer offices (UILO's) in order to license their technologies. Sometimes new firms are created to exploit the new technology, with the UILO's providing help in IP management, finding venture capital, and in building the right business team. Other times they help in patenting and setting up arrangements for licensing of the new technology. At some institutions, the university and the researcher share property of the patents, but in others they remain the researcher's.

At larger universities, the UILO cannot possibly have the capacity to process all of the invention disclosures made by research personnel. This work requires a set of competencies in order to understand high-level technologies and to quickly assess their commercial value. These liaison offices train high-level personnel for the task, and work through a network of personal contacts with business men and venture capitalists, with whom they collaborate in assessing the commercial possibilities of the technologies.

In BC it is clear that the knowledge base that fuels the growth of the innovation cluster, through the creation of spin-offs and through continuous contacts with businesses. Differing from what has been reported elsewhere

[Longhi 1998, Lindholm Dahlstrand 1999], no major “anchor” firms are performing such function in the case of the biotechnology cluster in BC, although big league companies have spun out of the university and grown to be world-class pharmaceutical firms. Rather, the biotechnology cluster has grown from knowledge “spillovers” coming out of the university [Goldfarb and Henrekson 2003], that economic opportunities. The quantity of young and more mature firms increases with time, since the density of firms attracts others, for which business and technological opportunities are also created.

Around this core set of firms many other organizations of different types have developed, among whose major objectives is to facilitate networking and alliances between other participating organizations and individuals. Also because of the quantity of young firms, as well as the special character of their needs (such as the specialized recruitment of high-talent personnel in the international market, for example), other organizations have also appeared within the cluster, or arrived to it. They supply firms with all kinds of support services: contract research, clinical trials, market intelligence, intellectual property management, specialized human resource management, scientific and technical information, high-technology component supply and development, and so on). It is this density of service and support organizations what enables firms in the network to remain technologically and business-wise competitive. But, in order to achieve that competitiveness the cluster, as a cluster, must remain competitive with respect to other jurisdictions.

Venture capital has consistently been available for the biotechnology industry in BC for close to two decades. Even during the economic hardship of recent years, there is capital available for this industry, although not as plentiful as it used to. Venture capital, as other resources and processes in the system, also works fundamentally through personal contacts among those who play complementary roles in interacting organizations. Uncertainty inherent to technology development, to the assessment of its future commercial value, and to the possibility of assembling a business team capable of realizing it, make the use of formal interaction rules all but irrelevant. Among those interviewed, it was unanimous that it is honesty and trust what enables them to collaborate repeatedly. Trust means two things: confidence that opportunistic behavior will not be incurred, and confidence in the technical ability to achieve results agreed upon.

Venture capital and human talent are attracted to BC by another factor that province government officials and trade association leaders are acutely aware of: tax incentives. Venture capitalists, young firms, mature firms investing in BC’s biotechnology cluster, and specialists that arrive in the province have significant tax incentives available to them. Province government officers and business leaders interviewed report that the province government is perfectly aware that the province is competing with other regions, in other countries as well as within Canada. And this variable is carefully monitored by business analysts [see MacKay-Dunn et al. 2002, for example].

Both federal and province governments are very sensitive to issues raised by trade associations and by ONG’s. Government officers not only are accountable for rapidly responding to them, but they also promote business associations that can articulate those issues, in sectors where networks are only beginning to emerge. Government officers also carefully monitor the needs of industry, since the economic vitality of the province depends enormously on its capacity to attract and retain business talent and capital.

A representation of the system as described, and of its dynamics, is presented in Figure 1.

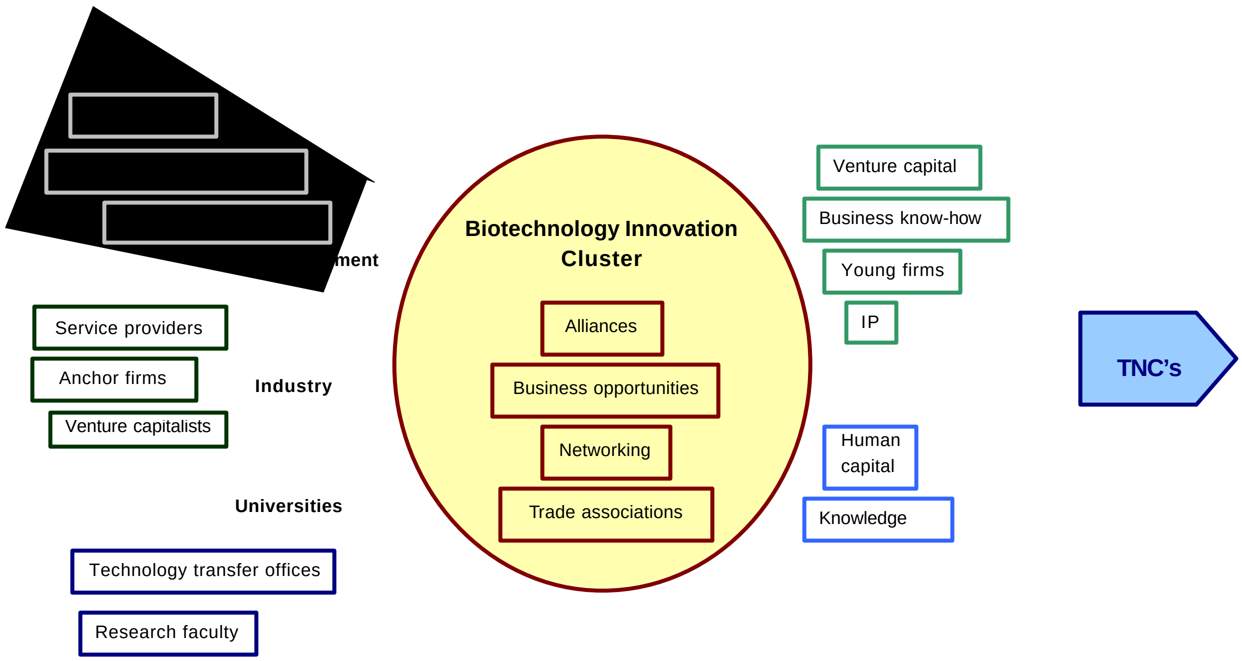

Fig. 1: A MODEL OF THE BC BIOTECHNOLOGY INNOVATION CLUSTER

What is it that gives coherency to the system? An outstanding aspect throughout it is that, according to our interviewees, their interactions are not governed by formal rules, or by explicit or clear cut signals among organizations or among individuals. However, it is not a chaotic system, or one that behaves randomly: there is a principle that governs its coherency. In the words of the leader of a non-lucrative organization dedicated to the development of biotechnology in the province:

"That coherency does come down to one thing. And that one thing, I think, is a system of values. And those values deal with what we want for our children, and for our children's children. We want the best opportunities in British Columbia. Most of us have come to BC from somewhere else. And most of us have kids. (…). British Columbia doesn't have a deep industrial background. BC is a great place to visit, and a great place to have your resort, and a great place to live. But it doesn't have the same job opportunities as other places, in the terms of the knowledge based economy. And people who look ahead (…), and say yes, I want to make some money, and that's fine. But more than that, I want what I do to count. Then, what you want to do is to leave a legacy that is better for your kids, and I think that is a common value that keeps this rolling; and it is the fact that, unless we invest in the right things today, and some of that may be painful, we have to give up spending on other things. And unless we invest in the right things today, we won't have the right opportunities for our kids, for our grandkids, and so on. And we won't be able to have a social structure that makes sense. We have been living with a social structure because we have been able to sell trees and dig up minerals, and we would not have that standard of living, and I don't think we would have that social coherency of the country, the culture of the country if we didn't have that ability to invest in it (…) and I think that is a collective understanding of the people involved".

The Mexican Research Centers Network Case

In spite of their resemblances, there are sharp differences between the BC case and the Mexican case. Among the most obvious is the fact that the first one displays a full-fledged effort to develop its innovation capabilities, with a strong network of interacting organizations that operate in complementary roles. Interorganizational learning is a full blown and explicit effort among them.

In the Mexican case, these processes are in their initial phases [Cimoli 2000, Casas 2002]. A few universities and public research labs, for example, have lead in the development of innovation networks. However, fieldwork has produced data that not only points to a severe instability of those networks, but that also points in the direction of structural barriers that undermine their development. Though these barriers grow out of many aspects that are cultural in nature, our aim is rather to concentrate in those interaction patterns (structural arrangements) that occur among actors in the system, that are not functional for its development.

In trying to explain problems observed in the development of innovation networks in Mexico, it is evident that many institutional arrangements are not conducive to that development. We use here the term "institutional arrangements" in its conventional meaning in the literature on institutionalism. Rather than reviewing that literature still another time, we hope to make our use of it clear by operationalizing it to be applicable to the Mexican case.

As has been reported in general for Latin America, "(…) results of the top-down mechanisms have been well below expectations of policy makers, in the sense that the historical low involvement of industry in knowledge and innovation activities — the reversal of which is one of the main goals of such mechanisms — has not substantially improved." [Sutz 2000, p. 279]. Latin American national innovation systems have developed into weak entities [Alcorta and Peres 1998], with only partially working policy measures, and weak ties among their components. Countries in the region have lost ground, relative to others with whom development indicators were similar a few decades ago. Indeed, the question we want to explore is why, given the presence of many elements needed for an innovation system in several parts of Mexico, those few networks that have arisen have proved to be unstable and, in many cases, ephemeral.

In our exposition, we start with the public R&D labs in the country, and build around them by identifying those other organizations with which they are interacting. In the process we hope to show that those interactions have only *some* of the characteristics that have proven useful elsewhere. In contrast, we will also attempt to show that many interactions in fact represent *structural barriers* to the development of regional systems of innovation.

Public R&D labs in Mexico have been created in the last three decades. Their mandate is to develop and transfer technology to industry. In some cases, small and medium manufacturing industries should be the preferred customer. Each one of them is dedicated to certain technologies, and to certain industries. However, it has not been easy for them to define their vocation. Some of them have had unstable periods that have set back their efforts to develop mature and productive research groups, and to develop significant technological competencies, with the corresponding infrastructure.

In the necessary learning that this process implies, public research labs have lacked role models to follow. Their interactions with other organizations have not been able to set into patterns that their long range development requires. This is not necessarily a consequence of a lack of internal resources in order to be able to define development strategies, but it is rather a consequence of the instability and the weak correspondence between those strategies have with what other organizations provide to, and expect from them. The specific inter organizational configuration (as an organizational field) that is needed requires a series of processes at the organizational and institutional level [Barley and Tolbert 1997] in order to develop. Once they are in place, interaction patterns begin to act as a network in which organizational forms tend to converge.

Once stabilized, these patterns of interaction become "institutional arrangements" [Niosi et al. 1993] that provide support, momentum, information, and incentives to the development of local, regional or national strategies, which in turn make the consolidation of regional or national systems of innovation possible. Paralleling Niosi's phraseology, the system of interaction patterns among public and private, large and small firms, research institutions, and government agencies responsible for the development of S&T has not developed consistently. In as long as these interactions can be of a technical, commercial, legal, social or financial nature, research labs will be faltering on these domains, as the flow of those resources fails to become stable in any direction. And to the extent that this is the case, the funding, regulation, and development of S&T, will be failing. Put in other terms, what is happening in Mexico is that a set of clear and "understood" rules that organizations need for productive interaction is still not present.

Components of Innovation Networks in Mexico

According to official documents, and as reported by interviewees, the National Council for Science and Technology (CONACYT), has had a good disposition for the creation of public research labs. However, in view that some research labs operate profitably in other countries, and following recommendations from the World Bank, for example, CONACYT officers persistently press public R&D labs in order to become profitable, or at least to constantly increase their direct income from the services provided. However, this expectation seems to loose sight of the fact that those research labs that are taken as models operate within mature industrial markets, in which R&D is taken for granted as survival strategy for industrial firms, a situation which is not the case in Mexico.

Diverse government agencies, whose mission is to administer resources, promote economic development, and enforce applicable regulations, interact with public labs through individuals that have a training that can hardly be thought as adequate to understand their specific needs. As can be seen through the analysis of documents that record their participation in the research centers' boards of directors, their participation is very limited. The same is true for industry associations' representatives. This participation is usually limited to overseeing that bureaucratic norms are being complied with. From interviews with administrative and higher management in the labs it is clear that they must frequently be very daring and imaginative in order to comply with those rules, and at the same time be able to honour in time commitments to clients.

In more than one way, it is clear that not only do actions of government agencies lack coordination among them, but also that they disregard objectives and priorities set forth in the National Program for Science and Technology. This becomes clear not only from the interviews, but from the analysis of S&T indicators that are well known. Halfway into the present administration's period, it is clear that the goals set forth in that document were defined without consultation with stakeholders and parties involved (the scientific community, as well as industry and even some governmental agencies). Goals were unrealistic, to the degree that they lack connection to government agencies' day to day activities.

Client firms have hired centers' services mostly in two kinds of contracts: a) for routine technical work, not part of their main production processes, but for secondary functions, such as complying with routine environmental requirements, and b) modernization of equipment (using off-the-shelf technologies), and expansion of production facilities. As reported by their representatives interviewed for the study, client firms do not seem to have technology development as part of their competitive strategies, but rather to assimilate available technologies in order to exploit less value-added markets. In the case of subsidiaries of transnational corporations, technology is developed in their headquarters, and transferred to their foreign subsidiaries, where cheap labor is the main benefit.

Industry associations are currently in a transition phase. Until a few years ago, by law all firms should be affiliated to them, which ensured for them stable and numerous memberships. This fact prevented the development of skills needed to read and promote attention to industry's interests. As this requirement was withdrawn, trade associations have worked hard to develop those skills, but the corresponding learning process is still slowed down by a natural and deep-rooted skepticism in firms. As described below, however, in a few cases trade associations begin to have a significant role in technological issues.

Universities have for decades dedicated themselves to solve massive educational needs derived from demographic growth. In order to do that, their recruitment processes have been designed almost exclusively to expand teaching capacity. Faculty hiring practices having nothing to do with scientific and technological productivity and, consequently, only a very small research capacity has developed. Their budgets all but ignore this function. There are a few interesting examples of interaction between research personnel in public labs and university faculty, mostly around graduate programs.

Only in very few universities has a significant development of intellectual property management and technology commercialization capacity taken place. What researchers that eventually develop some technology usually do is to search by themselves the way and means to commercialize it. Or else, they simply let the patents (where there are any) expire.

Some Relatively Successful Networks

In spite of barriers such as those describe above, some innovation networks have grown, in which many of the processes of trust, joint learning, and knowledge flow can be observed. They meet many of the requirements identified in the specialized literature. Some examples can be cited from what field research has found in the central part of Mexico, where recent industrialization of middle-sized cities is taking place:

Large mechanical power transmission in agribusiness, were sold to the sugar industry, in an effort to start a modernization process in it. The corresponding research lab assimilated and adapted the required technology, in order to produce some of their largest components. As manufacturing of those components required the participation of industry, the technology was transferred to some firms, and a trade association started around common technological problems. The research lab was the main driving force in the process. However, as major economic decisions, made at the federal level, completely changed the outlook for this industry, the association languished and had all but disappeared at the time of the study. Sugar plants lost interest in modernization along this path.

Repair and service of turbo machinery has been an opportunity to an R&D center in order to respond to external pressures to increase its income. Engineering services were offered to a transnational corporation. As sound technical performance was demonstrated, new contracts grew and gave way to a high-technology joint venture, located in the same region. The company has eventually been able to contract R&D projects, with considerable success, and research personnel collaborate with higher education institutions in the region. The research lab has also contracted with other firms that provide design and repair services of turbo machinery to federal corporations. However, this market has not been consolidated, due to (not necessarily legitimate) entry barriers, created by TNCs' in an attempt to lock out local firms. However, a strong joint learning process has taken place between these firms and the lab's research personnel. This process deals with the way in which to commonly identify and state firms' needs, and with the development of solutions. On the other hand, this learning process is occasionally set back by changes in the lab's personnel assigned to the project.

Anti-corrosion treatment for metal surfaces is a technological need for some other firms in the region, that are served by a different research lab. The R&D center has been able to enter that market, by helping firms that need that technology to produce domestic appliances. Its services have been contracted in order to identify and solve problems in the production process and to design, installation and expansion of production lines. However, most firms that are subsidiaries of TNC's require only technical routine services from a certified laboratory, and occasional use of expensive specialized equipment available in the lab. Product technology is usually the property of the company's headquarters abroad. Besides, expansion and installation of production lines is done by using off-the-shelf mature technologies. Income is significant, but services provided do not represent a real opportunity for the lab to develop higher-level technological competencies. This R&D center is also active in providing short courses in anti-corrosion technologies, which gradually strengthens trust and knowledge flow between the center's personnel and technical personnel in the firms. In turn, this has helped researchers to understand the firm's current technological needs, and their operating rhythms, which are not easy for the center to deal with.

Another R&D lab has worked with a transnational company which at the time was partially controlled (50%) by Mexican capital, in the development of an agricultural machinery prototype. Services provided started with engineering projects for production line facilities and machine tools. As confidence in the center's capacity grows, the company contracts its help in the development of a new generation prototype for one of its main products. However, in spite of the joint learning process that ensued among the firm, its (mostly foreign) clients, and the lab's personnel, the prototype did not make it through preliminary market clinics, at the time the company's control changed hands in favour of transnational capital. The corresponding network did not continue to develop common technological competencies, and services fell back to routine engineering projects.

A Metal mechanical process equipment modernization project was contracted for a formerly Mexican-controlled TNC. The firm needed equipment modernization and development as an alternative to off-the-shelf but expensive machinery available in the international market. The joint learning process initially seems to grow into capital goods development but, as reported to our research team by company's representatives, the firm is not planning to continue with it. The reason stated is that, even though price and technical quality of the service is satisfactory, development time is too long for it to meet market entry and competitive pressures. Also, price advantage is reduced because the center needs to rely on components not available in local markets, and their procurement increases costs and delivery times. As technology in the industry continues to advance, the center's competencies will fall behind, unless it invests considerably and specializes in it.

Seeking new markets and technological opportunities, a center is entering the market of flow-measurement processes and equipment for non-standard fluids. Services provided to a government corporation are directed to expert third-party assessment of services and equipment delivered by TNC's, with the aim of providing the government corporation with a validation that they meet promised performance. The R&D lab has worked in developing the corresponding expertise, in order to design and build measurement equipment, but local component suppliers have been unable to deliver them with the quality, cost, and time-delivery required. Some local suppliers have disappeared from the market, leaving the center unable to comply with contracted warranty parameters. Again, the foreign component suppliers option increases costs and delivery times, and the supply-development process seems long and uncertain.

Even as these problems are not necessarily different from those reported in the literature for other regions [Revilla-Diez 2000], they clearly illustrate how the absorption capacity of firms around them becomes a structural barrier for the development of the corresponding networks.

Industrial and S&T Policy Challenges in the Mexican Case

Possibly the most fundamental need in Mexico for effective S&T policy would be the recognition of the economic value of investment in S&T. Overall R&D expenditure is well below standards for OECD countries, and not precisely in the first places for Latin America. Investment should consistently be directed, to the strengthening of research infrastructure. A greater proportion of its GNP% (currently at 0.4%) should be consistently invested in S&T.

Due to the country's barely new democracy (it was ruled for 7 decades by one party), its institutions are still struggling to learn new patterns of interaction, while political parties are still more worried with access to power, than with long range economic and social programs for the country. It has fallen to state and municipal authorities to develop more direct programs, like tax incentives, for example, in order to attract foreign direct investment, and foster innovation. A learning process is still in place, since many initially successful regional programs falter, as international competition obscures volatile advantages in this field [Palacios 2001].

Even though recent federal administrations have set forth six-year programs in the area of S&T, interviews with public R&D labs' research personnel and higher management consistently point to the consequences of lack of coordination among government agencies. This lack of coordination deeply undermines their ability to contribute significantly to goals set forth in national S&T programs.

Research is needed in order to better understand the processes through which organizations in the system (such as trade associations, for example) can articulate their interactions with others, in order to seek common programs and policy issues that should be pushed in this domain. Efficient inter organizational learning will not occur spontaneously. Only knowledge-driven policy measures can ensure the right economic and regulatory environments for innovation and R&D, and for the development of regional systems of innovation.

Another set of problems lies around the set of industrial and economic policies that may accelerate the evolution of the country's entrepreneurial culture in the direction of investment in R&D. Businesses have operated for decades in a context in which it is easier to buy or licence foreign technology, transferring economic and social costs to the customer, or else to use off-the-shelf technologies, in order to exploit low value-added markets. The fist generation of industrialists in the country is handing over control to the second one. The capacity to build up innovation and technological competencies depends on the arrival of a new generation of managers to the firms, since those entrepreneurs whose firms grew up in the import-substitution period lack vision and capacities in this area. Our alternative is to head into direct competition with Chinese labour.

Policy Challenges in the Canadian Case

"Canada's Innovation Strategy was launched in February 2002. Its goal is to move Canada to the front ranks of the world's most innovative countries.

"Between May and November 2002, more than 10,000 Canadians gave their views and ideas on creating a culture of innovation and learning across Canada. The input from this process will go towards a national action plan to be developed following the National Summit."[3]

Canada's *Innovation Strategy* has been assigned to address four major challenges:

1. "Creating New Knowledge and Bringing it to Market More Quickly"
2. "Developing Skills for the New Economy"
3. "Setting the Right Business and Regulatory Environment"
4. "Strengthening Communities Across Canada"

In response to this initiative, organizations like *Canadian Manufacturers and Exporters* have taken to themselves the task of closing the "excellence gap", which is the distance between Canadian levels in several economic and innovation performance indicators, and that of the best in the G7 group. Many other organizations throughout the country continue to generate actions and programs in the same spirit.

However, in the view of Canadian policy analysts interviewed for this study, Canada does not have a well-defined, S&T policy. *De facto*, three areas have been favored by governmental budgetary decisions: a) strengthening research infrastructure, b) facilitating immigration of highly-skilled personnel, and c) expedient use of R&D tax credits in favor of Canadian-controlled, privately held firms. Both, policy analysts and government officials, view government agencies' roles as responsive towards needs expressed by community NGO's and business associations.

Coupled with the mission-oriented view of science and technology, this system would seem to lack a process-oriented view of S&T policy: the design and operation of organizations, whose roles would be related mainly to the promotion of S&T *per se*, with economic and social goals set in the range of several decades. Process-oriented S&T policy systems are exemplified by those of Mexico and Korea. However, only the second of these countries has set long range goals, and a set of institutions whose mission is to constantly evaluate progress toward those goals.

Would a process-oriented S&T policy system, with long range goals be a real need? According to leaders of some arms-length government organizations related to science and technology in British Columbia that were interviewed, it is. In their view, programs fail as ideological swings in government officials take place, and benefits of long-range programs fail with them. According to some interviewees, for example, programs that have two decades functioning, and out of which world-class firms have grown out, completely lose momentum as newly arrived politicians discontinue them for ideological reasons.

The outlook for the biotechnology innovation cluster seems positive in the short run, but it may prove to be fragile. Its major attractor is not industrial infrastructure, but the social and natural environment. Since it is an "industry" that consists mostly of trade in intellectual property, it is quite mobile. So far, emigration to the US has not proven to be a significant danger, since many of the scientists that formerly moved south of the border are beginning to come back. So far, the industry has been able to hire business talent from the US, but it continues to depend on its capacity to attract people from abroad, since the needed expertise in international arenas is not available in Canada:

"All of our senior people are imported. And that's hard. It's hard to move Americans (…) boy, … to get someone to move across that 49th parallel, … it's tough going (…) but once they're here, fortunately Vancouver is a lovely place, so fortunately, when they have been here for a year, then they never want to go back, so …".

So far, inflow of talented scientists has been steady, even replacing researchers that have earned enough from their technologies for early retirement.

However, Taiwan's efforts to develop its own biotechnology industry by recruiting top notch scientists at all costs, is a danger looming in the horizon.

On the other hand, competition for federal resources and for venture capital, firms and talent, is strong among jurisdictions within Canada, and it seems to be getting stronger by the day. British Columbia depends, as all of them, on federal government's subsidy, through the allocation of funds for research, for example. In order to retain its biotechnology innovation cluster vitality, it must continue to be more attractive than other jurisdictions, whether within the country or internationally.

In spite of the current success of the BC biotechnology innovation system, or maybe precisely because of it, it seems that it will be hard to avoid the current globalization trend [Buctuanon 2001], as the system integrates with the international flow of knowledge [Leydersdorff and Meyer, forthcoming]. Part of this flow of technology is in terms not only of intellectual property that is transferred to more developed economies, but also in terms of people and, most importantly, firms. All of these components and products of innovation systems flow from less to more developed economies, where institutional arrangements that facilitate de development and commercialization of new technologies. Beyond the jurisdictional strategies for competition in preserving and developing its innovation system, the global system's dynamics develops forces that may be beyond local or national policy measures to constrain.

The asymmetry and differentiation in the global system of innovation provides the networked system with complexity for a next round of competition for innovative integration. Is the BC biotechnology innovation system ready for it?

As it happens, interviewees repeatedly reported the emigration of firms that carry intellectual property and technological and business expertise with them, as they are being bought by transnational (US controlled) firms.

British Columbia's ability to retain trained talent, entrepreneurial vocation will increasingly depend on a close partnership between industry, provincial and federal governments.

End Notes

[i] We distinguish between mission-oriented views of science and technology and process-oriented views. The first are in use when social, economic goals are first set in public policy, and then S&T are recruited in order to harness their power in achieving those goals. Process-oriented views are in use when policy instruments are put to work in order to promote scientific and technological development, with the implicit aim of eventually deriving beneficial consequences from them. The set of policy instruments, be they programs, funds, institutions, have as their main task to oversee the functioning of the system.

The Economic Effects of Mexico's Integration into NAFTA: Seven Years After its Operation

Agata Michalska-Haduch
Instituto Tecnológico y de Estudios Superiores de Monterrey, Mexico

Abstract

In the short term, the creation of free trade zones results in two different effects on foreign trade: Trade Creation and Trade Diversion Effects. The net effect of the economic regional integration is the comparison between Creation and Diversion Effects. If the Trade Creation Effect is higher than the Diversion one, the economy benefits from the integration process.

The main purpose of this investigation is to show the economic effect of the regional economic integration within NAFTA for the Mexican economy. The Effect of Trade Creation in trade between Mexico and the USA and Canada will be compared with the Trade Diversion Effect obtained in Mexican trade with its other principal trade partners: EU countries, Japan and ALADI members. The effects will be measured by total trade as well as by industry. Additionally, the changes in the intra-industry trade between Mexico and the USA, and Mexico and Canada will be studied as another positive result of Mexico's integration into NAFTA.

Free Trade Agreement and its Effects

According to the integration theory, a free trade agreement is the simplest way of achieving the idea of regional free trade and is considered the second best solution of the free trade in general .(Balassa, 1964; Ladyka, 2000).

The previous statement defines a free trade agreement theoretically. In addition in the real free trade agreements the member countries have total liberty on the duties imposed on the non-member countries. Besides this kind of agreement, there are so called real free trade agreements the members of which have the complete liberty to determine the customs duties with other countries completely eliminating the customs duties or other barriers in the commerce between them which permits the insignificant flow of the production means and the harmonization of the economic policy. (Lawniczak, 1974)

WTC defines two kinds of real free trade agreements: bilateral and multilateral. .P. Kindelberg and W. Röpke, developed this economic integration theory (Bozyk, 2003). They assume the integration process as another way of expanding the market in terms of free trade and free market; in other words, this way company of different countries can collaborate with each other as if they belonged to the same country without inner frontiers that make the flow of labor, capital, products and services between countries more difficult.

According to the concept of free market and trade, the highest world level of well-being can be achieved when the invisible hand of the market decides on the collocation of different production methods, the optimum location of the production according to the world scale and the international trade size and structure. In the case of a free trade it has to do with the curtain simplification considering the few number of member countries conforming them. From the point of view of the member countries, a free trade agreement is attractive principally for two reasons:

1. Member countries have the freedom of applying its own economic overseas policies to the non-member countries without affecting their sovereignty.
2. It can increase the efficiency in the management of the resources and also, the living standard of the habitants.

Free trade agreements have a wide range of positive effects over its member countries such as:

- ?? Static and dynamic
- ?? Allocation
- ?? Accumulation

?? Location

From the theoretical point of view, the so called static effects which appear when there are no structural changes (for example, available means of production or changes in the production or consuming structure) or changes in the available technology (changes in the technical progress and its structure) are of major importance. One important feature of the static effects is that they appear in short periods, that's why they are also known as short term effects (Misala, 2001).

Short Term Effects

The short-term integration effects are subdivided according to different criteria. The most useful division is the one that divides the commercial effects and non-commercial ones (effects on investments, production and consuming).
In free trade agreements, the short-term there are following commercial effects:

?? The effect of the trade creation
?? The effect of trade diversion
?? The effect of trade deflection

The trade creation effect is the only one of the three mentioned above that affects only the member countries, while the other two effects are about changes in the trade with non-member countries. (Misala 2001)
The trade creation effect consists of the appearance of new flows of commerce that did not exist before because of the market liberalization. This effect is the result of the differences between the production costs and the appearance of the new incentives in the exchange between the member countries of a free trade area caused by the elimination of the barriers that slowed down the trade development between them, but maintain the trade barriers with other countries.

The trade creation effect is related to two other effects: production and consumption. The production effect analyzed by J.E. Meade (Bozyk, 2003) consists of a marginal case after the trade liberalization in the least efficient country (higher production costs and less consumption diversification), the production of goods disappears and becomes the subject of the imported goods. The domestic goods are then substituted by the cheaper ones with better quality produced in one of the member countries which means that in a parallel way they are a part of the consumption.

The size of the production and the consumption effects as well as the intensity of the trade creation depends on several factors. They basically rely on the supply and demand flexibility of the member countries. Within a regionally integrated group, the offer multiplies (as well as the demand) and its flexibility is normally higher than the one of each the member countries if they operate independently. That's why the duty for different countries can be changed: fiscal duties, for example, can be seen as expansion or protection. From this point of view the appearance of the creation effect is very important.
According to the international trade theory, the development takes place when the partners receive measurable benefits of their development although they are not divided equally.
The benefits are given:

?? When the available production facilities between the partners are different; as well as the production intensity, allowing the development within and between the industries.
?? Differences between the partners from the point of view of the possibilities of achieving the benefits according to the scale of the economies in the production and distribution process, and the probabilities of satisfying the changing preferences of consumers and investors. The difference plays a major role in the situation where similar production functions appear or the ownership of facilities and their use intensity results as the trade development within the industries.

Several factors determine the importance, intensity and structure of trade between and within the industries. One of them is the Gross National Product per capita: the higher and more equal level between the member countries, the greater is the importance of the commerce within the industries.

The second effect of the trade liberalization is the trade diversion effect which means the change of direction of the commerce flows. This occurs because of the substitution of the suppliers from the non-member countries (although they can be more effective, with lower production costs) by the protected less efficient ones from the member countries, which competitiveness grows because of the non-trade barriers within the FTA.

The production and consumptions effects appear because of the diversion effect, related to member and non-member countries. Its importance relies on the intensity and the development level of specialization: the higher intensity and importance of specialization within the industry trade, the less negative for the non member countries the diversification effect including the effect of production and consume.

The reason is because in the specialization and trade within the industries, the adjusted costs of the structural changes (related to production and consumption) are lower.

The comparison of the size of the trade creation effect versus the trade diversion effect shows the net effect of the regional integration. If the trade creation effect is greater than the one of the diversion, it means that the creation of the free trade agreement area has a positive effect on the resources allocation. On the other hand, when the trade diversion effect is greater than the creation one, the loss from the lower trade between the member countries and the non-member countries is higher than the benefits result from the increase in the trade between the member countries.

The difference in the production costs between the member countries should be analyzed before the creation of a free trade agreement. If the differences are greater than the differences between the member countries and the other ones, even the major reduction in the commerce exchange with the other countries, which increased inside the area, can have a positive influence on the resources collocation in it.

The sum of the trade effects of creation and diversion is known as the gross trade creation effect and can have the form of the trade expansion or trade suppression, The gross effect is a way of measuring the global integration without considering if it is caused by the duties suspension or another trade barriers or because of the change in the importations from non-member countries with the goods bought from the member countries.

The deflection of the trade is related to the self-determination right of each member country in the creation of the importation conditions applied to non-member countries. As a consequence, member countries can impose different duties on the same products from the non-member countries. This allows the importation of products (and services) from non-member countries with higher trade barriers. Member countries have less trade barriers imposed to the importation of goods and services.

The deformation trade effect in a free trade agreement is possible only theoretically because in practice, to counteract this effect countries use different forms in probing the origin of the products that are the subject to this kind of agreements.

The appearance of the deflection trade effect is not the only result from the creation of a free trade agreement without the clear specifications of the original rules. Another effect is the deflection in the production structure. When the trade deforms, one can’t exclude the structural changes of the production that might be irrational from the economic point of view.

The deflection effect in trade and production can be accompanied by deformations in the international flows of production facilities especially in the capital investment and technical skills. In this case, we are talking about the dynamic effects.

From the 60’s of the XX century, the necessity of preventing the deflection trade effect called the attention applying certain laws such as the rules of origin. Investigations related to this problem was started by B. Balassa (Balassa, 1964) and continued later by H. Shibata (Shibata, 1967) who introduced the term indirect deflect trade into the literature which means that a member country of a free trade agreement applies high duties (or other discrimination tools against imports) to the products from a member country, and lower duties to the same product from non-member countries.

The attempts to offset the deflection trade effect in the free trade agreements applying the original rules produce high costs and are not very effective. Besides the application of the rules of origin, the total supply of manufactured goods in the member countries and the trade between them can be complemented by the non-member countries imports; but the different import duties apply are not the same within the zone. This results in an artificial differentiation of price of the imported product, the one produced domestically in the trade between member countries.

The difference in costs and prices of goods within the member countries of a free trade agreements allows the appearance of certain effect: suppose that in one of the member countries the supply for goods increases provoking a decrease in its price. This makes the domestic producer limit the goods production (production effect) while the consumers increase their purchases (consumption effect). The difference between these two effects implies the appearance of the creation of trade effect in the zone.

With a greater goods demand in that country, the new domestic price increases in comparison to the previous price. The domestic good producers increase the production (production effect) but according to the original rules it is not possible to reduce the price of the goods to prevent imports without achieving the consumption effect.

Long Term Effects

The dynamic effects in a free trade agreement reflect the incentives in the economic growth. The clue is the growth rate of investment, employment and the investment yield and work, in free competence conditions. The positive effect of these factors is the result of:

?? Efficiency improvement in the usage of the production facilities and a change in the economic structure and trade between the member countries.

?? The achievement of the scale economy and the production area, and the distribution and increase of the technical area.

The economic rate of growth also depends on the level and growth of the effective demand because a free trade agreement might cause:

?? An increase in the demand of the imported goods (at the same time the dynamic of importations and exportations increases because of the accelerated development between the member countries).

?? An increase in the demand of investments because of more competitors, the tendency of the rationalization of production increase because of the new investments; and also the probabilities of the suppliers of capturing part of the demand that used to be reserved for the products of the non-member countries.

?? The creation of multiplying effects focused on better use of the production facilities, an increase in the Gross National Product, the consumption and maybe on the workers competitiveness.

The influence of the demand and supply factors in the economic growth cause additional effects, in particular those related to the creation and diversification of the investments analyzed by Machlup (Machlup, 1986). The names given to these phenomena are similar to the effects in the trade area, but they are not the same. They are the answer to a question: if after the creation of a free trade agreement the investment volume within the group increases, is the sum of investments and the group higher or stays the same? On the other hand, when the investments go from the non-member countries to the member-countries we are talking about the diversification effect. When free trade agreements are created, the total sum of investments in the global economy increases because of the creation effect.

A difference in the interpretation of the trade effects is in the case of investments. Not in all the cases the diversification effect is negative, while the creation effect is considered positive. It depends on the marginal effectiveness of capital. If the marginal capital effect is bigger in the zone than outside it, the investment diversification from the non-member countries to the member countries can mean a more effective use of capital.

An increase in the partners investments can influence the growth of their total gross product only when the potential savings are greater than the volume of investments or if they can induce a major ability in savings and maintain this at a high level.

The dynamic effects of the free trade agreements are reflected also in the external and internal benefits in the day to day companies operations.

Some of the external benefits are:

?? The growth of the size of the companies that allow them better negotiations, easier access to the capital, more efficient use of labor and a better position in the non-member markets.

?? The development of more efficient production skills and also a bigger quantity of competitive products on the international markets.

The external benefits for the companies in a free trade agreement are the result of a dispersion of different economic effects. A company achieves a better position in a market (i.e. offering products with better quality), the positive effect is transferred to the companies that cooperate with it, the suppliers and the consumers, stimulating technological innovations. The integrated markets of the zone also accelerate the rate of technical knowledge trade between the companies and households.

Commercial Short Term Effects in NAFTA

The objective of the following investigation is to analyze the commercial effects in the short term that appeared in Mexican foreign trade as a result of North American Free Trade Agreement after 7 years of its coming to force. One of the important aspects to consider is the importance of the trade creation effect with the free trade agreement countries on the changes in total foreign trade of Mexico. Another one is to analyze the influence of the mentioned effect on the intra-industrial trade. The last but not least one is to revise the trade diversion effect as a result of the agreement.

TABLE 1: THE COMPARISON OF TOTAL EXPORT AND IMPORT IN MEXICO IN 1993 AND 2000 IN MILLION DOLLARS ACCORDING TO THE HARMONIZED SYSTEM CLASSIFICATION.

	Export			Import

Total	166,454.9	52,525.1	113,929.8	174,457.5	72,764.5	101,693.0

Source: self-calculated data on the base of the Mexican foreign trade statistics, INEGI 2002.

Since the effect of the trade deflection appears when the rules of origin do not exist in NAFTA case it's difficult to detect it since the treaty includes very precise rules of origin as to the goods importation.

According to the statistics of the Mexican foreign trade in the year 2000, i.e. 7 years after NAFTA came to force, Mexican export increased from 52.5 thousand million dollars in 1993 to 166.4 thousand meanwhile import increased from 72.8 to 174.5 thousand million dollars as it is shown in table 1.

Some of the branches of economy contribute to the increase of both, export and import in total Mexican trade. These branches are: tool machines and electronic equipment, the transportation equipment, textile industries, mineral and chemical products, steal and not-oxidant metals and the products made of them. During the same period of time significantly decreased the participation of the following Mexican products: fats and oils, paper and carton and their derivatives.

In its quantitative presentation, the trade creation effect clearly indicates that the changes in total Mexican foreign trade are result of NAFTA.

As one can see, after 7 years NAFTA came into force 94% of the increase of Mexican exports and 82% of its imports are due to the treaty. It's important to emphasize that the increase in trade with the USA has the major importance while Canada is still behind despite the fact that it is the second commercial partner of Mexico.

Because of the trade creation effect the participation of the countries that belong to the group on total Mexican trade increased 6 percentage points in exports and 10 in imports (reaching accordingly 91% and 74%).

TABLE 2: THE COMMERCE CREATION EFFECT IN MEXICO AFTER 7 YEARS (1993-2000) NAFTA CAME TO FORCE IN THE QUANTITATIVE PRESENTATION (IN MILLION DOLLARS).

Source: self-calculated data on the base of the Mexican foreign trade statistics, INEGI 2002.

Analyzing the effect of the trade creation in its indicative (table 3) presentation it is possible to conclude that Mexican export to NAFTA markets increased more than import. It can be explained because of the better access that Mexican products received when entered the market of the partners in comparison to the access offered the USA and Canada (the asymmetry in the deduction calendar).

The branches of the manufacturing industries such as industrial textile (especially the wool products, knitted and complete garment) showed the highest increase in export. Also the branches like transportation means (first of all automobiles), machines, tools and electronic equipment (computer equipment and the spare parts, electronic and electric devices, record and sound equipment), equipment and devices of different kinds (especially the optical ones: photocopying machines, photo cameras, glasses and products that contain fiber optical lenses) and food industry (alcoholic drinks- beer and tequila, sweets without cocoa, refined sugar and food prepared on the cereal base)presented rapid growth while the increase in the traditional branches (agriculture, footwear, wood and paper industries) was slower. As to the agriculture products the least increase was observed in the export of live animals and animal-derived products, fats and vegetable and/or animal oils.

TABLE 3: THE EFFECT COMMERCE CREATION IN MEXICO AFTER 7 YEARS (1993-2000) NAFTA CAME TO FORCE IN THE INDICATIVE PRESENTATION.

Source: self-calculated data on the base of the Mexican foreign trade statistics, INEGI 2002.

As to the major increase imports, it was presented practically by the same manufacturing industries: transportation (passenger automobiles thanks to the liberation of the import politics), machines, tools and electronic equipment, textile, diverse equipment and devices. One of the products, which caused import considerably, increase and is not shown on the export list, is precious metals and stones.

In case of Canada there are some differences in trade in comparison to the USA since in Mexican exports of this market the major increase was shown by such industries as: precious metals and stones followed by plastic and its manufactures (boxes, cages and decorations), paper and carton and its manufactures, especially paper and carton boxes and containers. The chemical industry products take the second place (organic and chemical products, soaps and detergents, photographic products) and foodstuffs (sweets without cocoa, food preparations and alcoholic drinks). Precious metals and stones showed major increase in both import and export. The following industries were wood and its manufactures, paper and carton products, manufactures of ceramic stone and glass (ceramic products for chemical and technical usage, mirrors, security glass, and ampoules). Similarly to the USA, textile products and automobile industry showed high increase during this period.

One of the conditions for intra-industrial trade to be more intense is the income per capita in the member-countries which needs to be high and according to similar levels. In case of Mexico and its NAFTA partners this condition cannot be complete so no significant changes in intra-industrial trade between Mexico and the USA, Mexico and Canada can be observed. In trade between Mexico and the USA the number of branches with the intra-industrial trade indicator Ri (Grubel &Lloyd, 1975) Ri > 0.5 increased from 61 in 1993 to 64 in 2000, while the number of branches for which this indicator is Ri > 0.7 passed from 30 to 38. Similarly there were registered the changes in the intra-industrial commerce between Mexico and Canada: the number of branches where the indicator Ri>05 increased from 23 to 33 while Ri >0.7 increased from 16 to 21.

The intra-industrial commerce between Mexico and the USA deals with: food industries, mineral and chemical products, rubber and its derivatives, leather and its derivatives, textile, stone, ceramic and glass manufactures, computer equipment, electric and electronic devices, telephone devices, stoves, optical devices and toys. In the industries such as: gunpowder and explosives, carpeting, accessories, hats and headdress, furniture and watchmaker devices the indicator Ri<0.5 in 2000 in comparison to 1993 which shows the decrease of the intra-industrial commerce in these branches.

On the contrary, in case of live animals, fertilizers, essential oils, soaps and detergents, editorial products, umbrellas and parasols, zinc products, vehicles for train roads, automobiles, Ri increased over 0.5 which means the increase in intra-industrial commerce. In case of Canada intra- industrial commerce deals with such industries as: fishing products, processed food, chemical, organic and inorganic products, essential oils, photographic and textile, stone, ceramic and glass products, automobiles, musical instruments, furniture, and others. As to agriculture, cotton in the textile industries, iron/steal smelting, zinc, optical products, instruments and devices, the indicator Ri decreased from 0.5, which means that intra-industrial trade in these areas decreased as well. On the other hand, this trade intensified during the analyzed period in such branches as: automobile industry, electronic devices, industries that produce boilers, motors, stoves, heaters, conditioners, zinc manufactures, and essential oils among others. (see the indicator of intra-industrial Mexican commerce with NAFTA countries in 1993 and 2000 according to the Harmonized System table in Appendix).

Analyzing the trade diversion effect in Mexican foreign trade due to NAFTA it is possible to conclude that because of the relatively little importance shown by countries from the rest of the world in the Mexican foreign trade this effect is almost invisible. This is due to the fact that in real numbers Mexican trade increased with the three groups of countries.

Analyzing the trade diversion effect in Mexican foreign trade due to NAFTA it is possible to conclude that because of the relatively little importance shown by countries from the rest of the world in the Mexican foreign trade this effect is almost invisible. This is due to the fact that in real numbers Mexican trade increased with the three groups of countries, but comparing the percentage participation of those countries in the total Mexican trade the decrease of trade with them is obvious (table 4)

According to the analyzed period the trade with the European Union, LAIA, and Japan increased although its rhythm was different for each country. As it’s shown in table 5, in exports the major increase was achieved in sales to the countries of European Union (the diversion effect appeared in sales to Austria, Belgium and France as the exports to those countries decreased the level in comparison to 1993), followed by countries of ALADI while export to Japan stayed practically at the same level even in some branches like mineral, chemical and plastic products, footwear, transportation equipment, instruments and optical devices the decrease was observed which proves the existence of trade diversion effect.

The behavior of Mexican export to different regions of the world can be explained through the access difference of Mexican products to different markets, i.e. in case of the UE it is important to consider the Free Trade Agreement signed by these countries that came to force in the middle of 2001 as well as the treaties signed with some countries of LAIA such as Chile, Columbia, Venezuela. The import behavior was similar for three groups of countries, i.e. all the products they bought increased in the similar quantities except for Japan where import increased more.

Source: self-calculated data on the base of the Mexican foreign trade statistics, INEGI 2002

As to the rhythm of increase, it was very similar for both export and import (oscillated between 1.17 in case of export to Japan and 1.97 in export to EU) but it was found out inferior of the increase in trade with the countries of NAFTA (3.41 in export and 2.77 in import). What calls the attention is that the least affected branches in Mexican trade with the countries outside the treaty were those of minor importance inside the NAFTA. According to table 6 in exports to Japan the sales of wood pasta, paper and carton, stone, ceramic and glass manufactures, precious stones and metals increased faster.

In export to the UE countries the major growth was registered in processed food, leather manufactures, pieces of art besides the transportation equipment and diverse devices that constitute an important area for NAFTA and experimented the increase in their sales to these markets. The export to Latin American countries presented the highest rhythm of increase and concentrates on the products with less transformation degree, for example, agriculture, wood and its derivatives, footwear and headdress.

The diversification effect is very clearly presented in the imports form the European countries since their total increase was the slowest and besides the imports of different areas has declined which shows that they were substituted by import from NAFTA countries. The following industrial branches affected by this phenomenon are: agricultural products, fats, vegetable and animal oils, precious stones and metals, machines, tools, electronic equipment. In case of Japan, the most affected industries are the following: processed food, textile, footwear and headdress. The import to LAIA countries was the least affected since the only negative effect is shown in the import of fats and vegetable oils, footwear and headdress industries.

Conclusion

NAFTA caused the appearance of the commercial effects which appear in case of the formation of a free trade area such as diversification and creation effects. Since the volume of total Mexican commerce with all its partners increased after 7 years the Treaty came to force, the first effect that can be noticed is the trade creation effect due to the fact that commercial exchange with NAFTA partners almost tripled. The USA market continues to be the most important one for the Mexican products as well as a supplier for the national industry. Despite the increase of the trade volume the importance of Canada for Mexican economy is still low.

The increase of trade with the USA let Mexico become the second USA commercial partner (after Canada and before Japan, China and Germany). The commercial exchange with this country is concentrated on automobile and electronic sections, textile industry and chemical and plastic products. The importance of the processed food increased as well. The intra-industrial commerce analyzed from the point of view of the number of participating industries doesn't show any significant changes although analyzing it according to the type of industry point of view it is possible to conclude that this trade has intensified more in the industries which the participation in the Mexican foreign trade increased more.

Despite the fact that the trade diversion effect in trade with non NAFTA members countries cannot be seen clearly because of the increase of the exchange volume it can be concluded that imports coming earlier from the EU, Japan or LAIA countries was partially substituted by the products coming from NAFTA countries even when the majority of them signed different free trade treaties with Mexico during this period. The increase of Mexican trade with the partner countries can get worse in the near future due to the change of the preference conditions it still primarily in the US market. China's joining WTO and the free trade agreements negotiated by the USA with Chile and Central American countries can cause the erosion of the privileges that Mexican exports receive and decrease the competitiveness of Mexican goods in the same market. On the other hand, the future enlargement of the European Union can affect the interest that European investors might have in Mexico which can also cause the decrease in Mexican trade with those countries.

Growth of the Spanish Multinational in Latin America during the 1990s

Bernardo Bátiz-Lazo

Sara Urionabarrenetxea Zabalandikoetxea
University of the Basque Country, Spain

Abstract

During the 1990s, Spain changed from a net recipient of foreign direct investment (FDI) to one of the most important investors in Latin America. Cultural ties and market opportunities in countries such as Argentina, Brazil, Chile and Mexico, proved to be fertile ground for Spanish FDI as measured by alliances, co-operation and mergers and acquisitions. Fieldwork in this article identifies trends and directions of Spanish acquirers targeting Latin American companies with an emphasis on the 1990 to 2001 period. The relative strength of market size, wage differentials and cultural affinity helped in explaining the link between strategic decisions of the Spanish acquirers and their choice of geography and industrial sector.

Introduction

The emergence and growth of the multinational corporation (MNC) is intimately related to foreign direct investment (FDI). According to Ietto-Gillies, Meschi & Simonetti (2000) and Cazorla (1997a), an interesting example of this process is the 'late' arrival of the Spanish MNC and the predominance of their FDI decisions throughout Latin America during the 1990s. Going international is a complex decision resulting from internal and external factors and which can take different organisational forms including agency contracts (e.g. indirect exports), alliances, co-operation, acquisitions, and 'greenfield' investments. The research that follows identified systematic differences in the trends and directions of Spanish acquisitions in Latin America. These trends reflected strategic decision-making with regards to targeted industrial sector and targeted geography while, at the same time, allowed testing for the predominance of alternative explanations of competitive advantage in the expansion and growth of Spanish MNCs. The assessment then provided a basis for some speculation about the evolution of Spanish firms as multinational corporations.

The document proceeds as follows. Section 2 reviews the context of internal and external incentives that explain the emergence and growth of multinational companies in general and of Spanish MNCs growing in Latin America during the 1990s in particular. Section 3 details the data set and research methods. Section 4 offers an assessment of trends and directions mergers and acquisitions involving Spanish MNCs in Latin America from an industry, country and individual company perspectives. Section 5 is the final section offering a summary, tentative conclusions and potential for future research.

International growth and the rise of the Spanish MNC

Cross-Border Growth through Acquisition

The standard model of internationalisation has the firm moving abroad incrementally as it acquires knowledge about distant markets. Incremental growth certainly occurs as envisioned by the so called 'Uppsala Model' (Johanson & Vahlne, 1977 and 1990; Johanson & Wiedersheim-Paul, 1975). According to the reviews documented by among others Levi (1990, 392-6) and Martínez Mora (1998), cross-border growth has also been explained as resulting from processes encompassing issues around non-transferable knowledge, capital availability, protecting secrecy and indirect diversification (i.e. provide portfolio diversification for shareholders). Internationalisation has also been rooted in strategic moves such as anticipating (or responding to) foreign firms establishing in domestic markets, and anticipating (or responding to) close competitors establishing in foreign markets. In other words, internal incentives leading to international growth are intertwined with visionary strategies and the search for competitive advantage (Kim & Mauborgne, 1993; Lyles, 1990; Melin, 1992; Peng, 2001; Stimpert & Duhaime, 1997; Werner, 2002).

Decisions leading to FDI have been closely associated with trends and directions in cross-border mergers and acquisitions. In particular, Andersson, Johanson & Vahlne (1997) has extend the incremental internationalisation framework to incorporate “organic” acquisitions. This as the mode of the evolution of the firm’s geographic scope often involves the acquisition (i.e. buyer initiated purchases) and divestiture (i.e. seller initiated purchases) of whole operations. Decisions leading to FDI, however, have been far from immune to perceived host country risks and target market conditions (such size and potential growth of the market). Empirical work around the behavioural concepts of risk and specifically the risk perceptions and propensities of decision-takers, has pointed to the importance of behavioural aspects in the process by which acquisition candidates are selected, the characteristics of pre-acquisition evaluation and negotiations, and their effects over post-acquisition integration (Pablo, Stikin, & Jemison, 1996). Hence, rather than responding to the merits of the proposed investment, the development of cross-border activities could respond to managers' preferences for control (Petrou, 1997) and even the whims of the chief executive (Davies, 1987).

Fieldwork amongst European and North American firms, therefore, has suggested that the selection of investments leading to internationalisation could result from opportunistic and even fortuitous strategies. Research on FDI and cross-border growth, however, has primarily built using country or country-industry level data to determine whether firms are 'leading' or 'lagging'. In practice, this has implied that all firms from a country or country-industry are considered to have homogeneous strategies - they are either all responding to visionary, opportunistic or fortuitous diversification moves. There is thus an extant need to enrich explanations offered by FDI theories to incorporate questions of 'who', 'where', 'why' and 'when', particularly around the study of how MNCs conceive and execute their strategic diversification moves through the link between the acquisition processes, internationalisation and their outer context (Chesnais & Simonetti, 2000; Ietto-Gillies et al., 2000 ; Kim & Mauborgne, 1993; Melin, 1992; Rivoli & Salorio, 1996; Stimpert & Duhaime, 1997)

Competitive Advantage and Internationalisation

In acquiring or divesting operations firms are rearranging the ownership of assets. As Lichtenberg and Siegel (1987) point out, firms rearrange ownership of assets when one firm lacking a comparative advantage relative to another firm with respect to a given operation sells it to that second firm. According to Porter (1987, 46), an enterprise can profitably expand its activities abroad provided its corporate strategy succeeds in truly adding value, that is, in providing tangible benefits that offset entry costs. For instance, diversifying in a way that shareholders cannot replicate. Otherwise, the cost of entry (either through start-up or through acquisition) would be greater than any potential future prospects. Since a) an organisation must bring some significant competitive advantage to the new unit (or the new unit most offer a potential significant advantage to the parent organisation) and b) the more attractive a new industry, the more expensive it is to get into, then it is more likely that international diversification takes place in an industry where the organisation has a proven track record and managers have industry-specific knowledge and experience. However, global presence by itself does not confer competitive advantage (Gupta & Govindarajan, 2001). International or even global presence allows the MNC opportunities to adapt to local markets differences, to exploit economies of scale and economies of scope, to tap into optimal locations for activities and resources, and to maximise knowledge transfer across locations. But each of these opportunities can be associated with significant obstacles and challenges that prevent MNCs from exploiting them optimally.

Whereas Porter (1987; 1990) emphasised the achievement of a 'rent' or superior (i.e. above-average) profitability, Hu (1995) emphasised a firm's ability to compete as the source of competitive advantage in international markets. Crucial for that ability is the transferability of a firm's advantage between different units. The transfer of capabilities (or key ingredients), however, must result in advantages relative to competitors and relative to alternative modes of operation (Hu, 1995, 74). Success is contingent to the organisation gaining an advantage relative to rivals at home and abroad, relative other forms of organisation, relative to actual and potential competitors, and relative to the ability of the firm to sustain the source of differentiation through time. Firms will gain an advantage abroad to the extent that unique-, firm specific, industry specific and country specific advantages (or their ingredients) are successfully transferred and the resulting advantage is, at the same time, unavailable to indigenous players.

Advantages at home may be different to competitive advantages abroad when the advantage (or a key ingredient thereof) is not mobile internationally, the advantage itself loses value in the target country or requires the presence of complementary assets[1] (Hu, 1995, 75-6). For this view, international growth could result in unrelated diversification (across industrial sectors) when, for instance, firms transfer the results of an innovation process (rather than the innovation capability itself) or superior management capabilities.

Hu (1995, 85) also considers that, in selecting a foreign production model, firms should consider factors of relative geographical and cultural proximity, which make for a better understanding of local conditions. Indeed, the relevance of cultural proximity in FDI decisions has been viewed as fostering or hindering location decisions (Kogut & Singh, 1988) as well as having an impact in MNC performance (e.g. Gomez-Mejia & Palich, 1997). The influence of cultural proximity in FDI decisions implies that on going relationships between firms and amongst individuals (i.e. social networks) or between value-adding activities (i.e. technological networks) could influence the choice of partners and FDI targets (e.g. Hennart & Larimo, 1998), the nature and purpose of co-operation agreements as well as the contents of information flowing through that agreement (see further Ellis, 2000; Gulati, 1998; Rauch, 2001). If taken to its extreme, the role of cultural proximity could suggests that competitive advantage has little to do with internationalisation decisions because trade is more likely to emerge from social or technological affinity than from market research.

On balance, however, neither market-driven nor cultural affinity dimensions have been able to fully explain trends and directions of FDI. It is thus an empirical matter that which will ascertain whether the emergence and growth of MNCs responds to market or non-market incentives as well as the role of cultural affinity in those decisions. To test the relative strength of different views depicting sources of competitive advantage of MNCs we considered the following formulation:

$$S^n = f(s^n, M_{ij}, W_{ij}, C_j, ?_{i-1j}) \quad (1)$$

where

S^n	Value of FDI decision.
s^n	Financial characteristics of individual transactions.
M_{ij}	Demand (i.e. market size) effect.
W_{ij}	Wage differential effect.
C_j	Cultural affinity effect.
$?_{i-1j}$	Trend (lagged).
N	Transaction number.
i	Year.
J	Country.

Assessing the determinants of individual FDI decisions (S^n) is still full of challenges and an area worthy of attention. Empirical research is inconclusive as to the links between diversification and superior financial performance (Martin & Sayrak, 2003; Palich, Cardinal, & Miller, 2000; Palich, Carini, & Seaman, 2000) while debate also prevails as to the accuracy of constructs to measure diversification (Hyland & Diltz, 2002; Nayvar, 1992; Sambharya, 2000). The nature of FDI decisions also grew in complexity when, as a result of changes in the world economy during the last quarter of the 20th century, MNCs were encouraged to expand into 'emerging' economies (Arnold & Quelch, 1998; Luo, 2001). 'Emerging' markets were perceived to offer significant growth opportunities for MNCs as inefficient markets for corporate control in less developed countries suggested there were opportunities for an acquirer to pay a price not fully reflecting the prospects of a new unit. Indeed, firms from countries lower down the technological ladder can develop transferable advantages relative to firms (existing or potential) in even less developed countries since the former could benefit from advantages associated to a more advanced stage of development and industrialisation (Hu, 1995, 84). Possibilities to exploit market-value and operational differences emerge as in less developed countries large companies are few, financial resources are less abundant and professional management is scarce (Hu, 1995, 84-5; Porter, 1987, 49 and 52).

Growth into 'emerging' markets, however, could poise strategic questions that established frameworks could not resolve (Arnold & Quelch, 1998; Cuervo & Villalonga, 2000; Dharwadkar, George, & Brandes, 2000) and hence attraction of looking at individual decisions of FDI through acquisition. Namely, the potential to learn more about who owns the assets, who is making the investments or what is the motivation to pursue such investments. As mentioned above, the assessment of FDI acquisition decisions is often based on aggregate data and fieldwork typically assumed that all firms in one country and/or in one industry were equally likely grow across borders and for similar reasons. s develThe research that follows compares and contrasts individual and aggregate MNC behaviour. FDI acquisition decisions into lesoped countries were explored by looking at the interaction between idiosyncratic elements of individual transactions (s_{ij}) with demand (M_{ij}), wage (W_{ij}) cultural affinity (C_{ij}) effects. It is worth noting that empirical research around FDI decisions into less developed countries has emphasised cross-border growth into Asian economies (e.g. Chen & Chen, 1998; Luo, 2001; Makino, Lau, & Yeh, 2002; Wong & Ellis, 2002), former communist countries in Eastern Europe (e.g. Beyer, 2002; Buck, Dyomina, & Wright, 2001; Meyer, 2002; Uhlenbruck & De Castro, 2000) or US investments in Latin America (e.g. Grosse, 1992; Len, Daniels, & Arbelàez, 2002; Love & Lage-Hidalgo, 1999a; 1999b; 2000). As a result, a neglected area of research has been to consider and explore diversification decisions of firms in 'recently' industrialised countries into even less developed countries as portrayed by growth of Spanish firms into Latin America.

Emergence of the Spanish MNC

With the exception of Brazil, which was considered an 'independent', firms in most other Central and South American economies have been grouped into a Latin American cluster, that is, grouped into a meaningful category based on shared features such as geography, language, religion and management practice (Ronen & Shenkar, 1985). Whereas Spanish firms have been grouped together with those of France, Italy, Portugal and Belgium in a related but somewhat different cluster of 'Latin European' countries (idem).

Links between Spanish and Latin American firms have a long history as Spanish FDI in the region dates to the 17th century. More recently and as documented in Salmon (1997), López Duarte and García Canal (2002) and Rodríguez (2002), trends and directions of direct investment in Spain have been influenced by globalisation of the economy, European integration, and the role of the public sector. Together these three themes portray the changing character of the economic environment in the last quarter of the 20th century resulting in a continuous process of restructuring in the Spanish economy (mediated through structural and regulatory innovations). At the same time, regulatory changes in many Latin American countries resulted in extensive privatisation of public enterprises and substantial investments from firms whose headquarters were established outside that region (Calderòn, Loayza, & Servèn, 2002; for instance La Porta & Lòpez de Silanes, 1999; Len et al., 2002; Love & Lage-Hidalgo, 1999a; 1999b; 2000)

From the 1980s onwards, Spain (and Portugal) gradually moved from a position of being overwhelmingly a host country to an intermediate status (Chesnais & Simonetti, 2000, 9). Through out this process, growth of Spanish firms characterised by little co-operation with other organisations, relocation (and high degree of control) of resource abroad and full exposure to environmental turbulence in the host country (see further Lòpez Duarte & Garcìa Canal, 2002). For instance, Spanish firms could have entered foreign markets through direct or indirect exports. Indirect exports offers the most secure route for an international trayectory: the firm distributes through an intermediary and while there is little control over commercialisation and resource implications are low. Instead, FDI associates with control of distribution, commercialisation and resource allocation but also with greater exposure to non-diversifiable risk.

Although the internationalisation of Spanish firms accelerated during the 1990s, both Tolentino (1993) and Lall (1996) identify Spain as 'late investor'. In other words, given the relative size and growth of Spain's Gross Domestic Product (GDP), there should have been greater stocks of investments abroad than the level observed at the turn of the Millennium. Some arguments traditionally put forward to explain 'late investor' include limited technological capacity, barriers to international trade, low skills, and poor labour mobility. Among others Canals (1991) and Cazorla (1997a, b) identified a lack of financial sources as the main obstacle to the internationalisation of Spanish firms, particularly for small and medium-sized companies which were often marginalised from government support promoting foreign investment.

Fig. 1 illustrates the country distribution of Spanish FDI during the 1990s and grouped by members of the élite Organisation for Economic Co-operation and Development (OECD), Central and Oriental European Countries, Africa and Asia. According to Fernández and Norniella (1998), a stable macro-economic policy at home and the inclination of Spanish entrepreneurs towards an 'international culture' played an important role in the steep increase of FDI activity at the end of the decade.

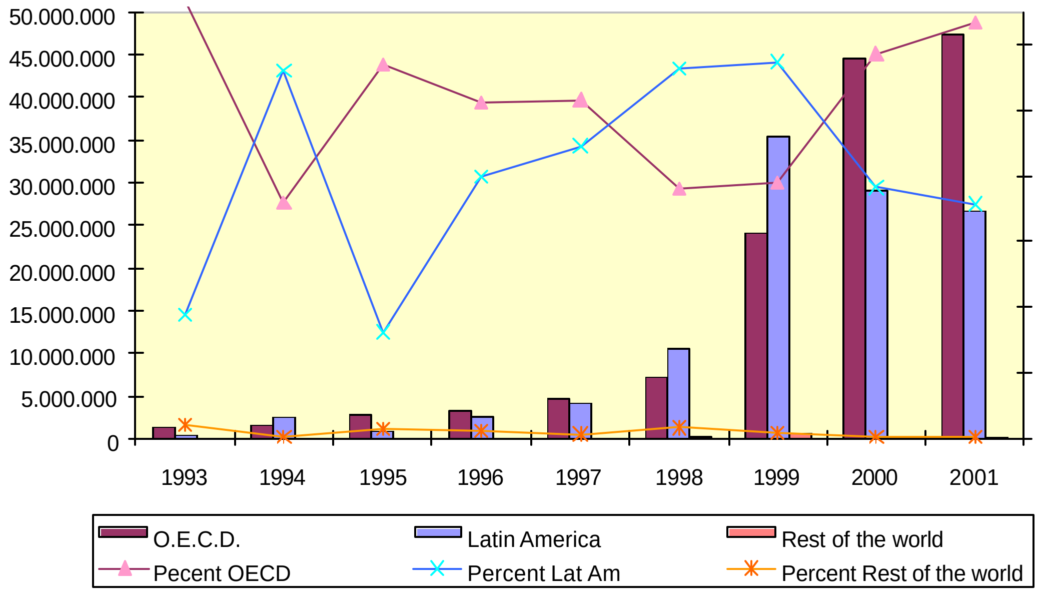

Fig 1: GEOGRAPHIC DISTRIBUTION OF SPANISH FDI , 1993-2001.
(Total amount in thousands of euros at nominal prices and percent of total Spanish FDI per annum)
Source: Spanish Ministry of Economy, Department of Commerce and Investment; and UNCTAD[2].

As measured in nominal prices and as a percentage of total cross border investments, most Spanish investments abroad aimed at OECD countries and Latin America, with a sharp fall in that oriented to OECD countries at the end of the decade. Trends in Fig. 1 also suggested that Spanish FDI in Latin America peaked in 1999 at 35.504.382 thousands of euros (57,4% of total Spanish FDI for that year). Trends in Fig. 1 were consistent with systematic analysis by Ietto-Gilles Meschi & Simonetti (2000, 60), which documented evidence of Spanish FDI (together with that of Portugal and Greece) observing a preference for global links rather than greater integration within the European Union (EU).

Sector distribution of Spanish investment in Latin America for the last decade was also atypical. Investments in financial services (41% of total) and utilities (namely transport and communications at 36%) stand out from investments made in other sectors. Targets of Spanish foreign operations in Latin America during the 1990s were quite different from economic activity in Spain, which was dominated by tourism. Sector distribution of FDI during the 1990s also showed marked differences with cross-border growth of Spanish manufacturing during the 1980s as documented by Nohria and García Pont (1991), Rubalcaba and Gago (2001) and Bajo Rubio and López Pueyo (2002). At an international level, growth of Spanish financial service MNC's was also atypical. Similar organisations in other OECD countries (and particularly for US-based firms) usually 'lagged' rather than 'lead' manufacturing firms in their degree of internationalisation (Focarelli & Pozzolo, 2001; Tschoegl, 1987, 2002). Moreover, data for US companies supported the idea that banks and other financial organisations 'followed' manufacturers outside the US, and while financial services firms may not locate in the same country they would establish in the same region (see further von der Ruhr, 2000).

Succinctly, growth of Spanish MNCs in Latin America is an interesting phenomenon and one in need of systematic attention. Spanish trade in that region involved relocating non-trivial quantities of resources. For individual organisations this processes represented the greatest level of internationalisation. Anecdotal evidence of trends and directions in aggregate flows of Spanish FDI into Latin America would suggest that the competitive advantage of Spanish firms abroad is different from that at home, pointing to the need of examining the sources of competitive advantage for the Spanish MNC. However, inferences on FDI decisions from macro-economic data risks biased results because aggregate data offers little insights as to who owned the assets, who undertook the investments or what was the motivation to pursue such investments. At the same time, cultural affinity and shared histories between Spain and Latin America offer a unique opportunity to explore how market-based opportunities (namely demand size and wage effects) scored against the potential to build social networks as determinants of FDI.

Sources

The Data Set

Since the late 1980s and by the mid-1990s three quarters of the world's FDI took the form of mergers and acquisitions (M&A). Given that only a quarter of world-wide cross-border growth takes the form of new ('greenfield') investment, one could take the view that FDI pertains more to changes in the ownership of capital and to industrial restructuring than to the accumulation of capital (Chesnais & Simonetti, 2000, 5). This is consistent with the view by Kogut (1983; 1991), Buckley and Casson (1998) and Meyer and Estrin (2001) which considers FDI acquisition decisions as leading to the creation of growth options *ex ante* and sequential growth *ex post*. For these reasons the research on the growth of Spanish FDI focused on M&A activity of Spanish firms in Latin America.

However and as noted by Calderón, Loayza & Servén (2002, 6), direct comparisons of FDI data compiled from balance of payment sources with M&A figures is subject to a number of caveats namely the timing of the transaction, their scope, and the definition of target and foreign countries. First, while FDI is measured on an accrual basis by national accounting systems, M&As are recorded at the time of announcement or closure of each specific transaction. Second, individual transactions may include a sequence of payments over several years. Third, traditional FDI accounting considers net financial flows, that is, outward FDI from a given country is adjusted by the dis-investment abroad undertaken by firms from that country. Unlike FDI accounting, M&A transactions report only the total value of the acquisition abroad, without subtracting any possible sales of foreign affiliates (which would be reported as an independent transaction). Fourth, data on cross-boder M&A may include funds raised in local and international financial markets which would not qualify as FDI. And fifth, there may be methodological differences between M&A and FDI accounting regarding the countrys of origin and destination. Namely, FDI flows are usually compiled on the basis of *immediate* host and *immediate* home countries, whereas data on cross-boder M&A may use different combinations of *immediate* and *ultimate* country. All these facts suggest caution when comparing cross-boder M&A and total FDI for a given country. However, trends and directions of FDI flows and cross-boder M&A transactions reach the same conclusions as to the direction of change rather than its magnitude (Chesnais & Simonetti, 2000, 5).

Empirical analysis presented below is based on a data set created from the SDC International Mergers and Acquisitions database provided by the Securities Data Company and sorted by Standard Industry Classification (SIC) criteria of the US Department of Labor. Data was available between January 30th 1987 to December 31st 2001. A total of 512 cross border acquisitions involving Spanish and Latin American[3] firms[4] were identified, of which 459 considered Spain a bidder[5] (acquirer nation) and Latin America[6] a target. Information regarding the financial value of deals was available for only a sub-set of the data (228 transactions or 50% of total). For this reason the assessment initially moved forward using only the number of deals to test for unrelated diversification while the value of deals was used when different patterns emerged (more below).

Data was also available for the share of total equity owned after individual transactions (399 transactions or 87% of total). Using ownership data, 26 transactions were excluded from the total. This to consider transactions purchasing more than 10% of equity (i.e. "capital social"[7]). Excluding transactions of 9.99% or less allowed distinguishing between investments leading to or creating 'options to expand' from simple financial investments. There were 96 transactions with no data regarding per cent owned after acquisition and these were also excluded. As a result, the assessment moved forward using data for 337 transactions when assessing the number of deals (while testing for related/unrelated diversification) and 228 transactions when assessing the value of the deals (while testing for trends and directions of cross border acquisitions).

Empirical Model

The data set on individual transactions was sorted to include specific characteristics of each country and year to form a panel as specified in model 1 above. This database was the basis to proceed with the empirical assessment of the value of FDI decisions (S^n).

The interaction of financial characteristics of individual transactions (s^n) and the effects of demand (M_{ij}), wage (W_{ij}) and cultural affinity (C_{ij}) constructs was tested to investigate systematic differences between trends and directions of FDI decisions using aggregate and individual transaction data (details of data of 110 constructs used in assessing determinants of the value of individual FDI decisions, S^n are available from the corresponding author). Succinctly, 39 different constructs (35%) provided details as to the financial characteristics (s^n) of each and every one of the 228 transactions were the financial value was available for acquisitions involving Spanish MNCs in Latin America. There were 16 constructs (15%) dealing with terms of trade and degree of openness were identified as potential measures of market size (M_{ij}). Six constructs (5%) considered relative income measures and an index for the intensity of union militancy throughout the work force and were identified as potential measures wage effects (W_{ij}). Eight constructs (7%) considered trends and directions of M&A activity ($?_{i-1}$) and thus accounted for issues such as 'herd effects', growth in the stock of FDI and a reduction in the number of potentially suitable acquisition targets.

Instrumental variables were added to identify transactions involving the most active companies as described in Table 1 and Fig. 3 ($?_1$). Another variable modelled the main recipients of Spanish FDI in terms of number of transactions as described in Fig. 2 ($?_2$). There were eleven instrumental variables (10%) as specified below.

Cultural compatibility has increasingly been sought to provide an explanation as to why domestic and cross-border acquisitions succeed or fail. While favourable financial statements or product synergy may be the initial attraction to an acquisition candidate, it has increasingly been argued that whether an acquisition actually works may have more to do with how well the two organisations' 'cultures' match up. Data to assess 'cultural affinity' (C_{ij}) included dimensions external and external to the firm. External to the organisation, it was important to model the market for corporate control. In particular, 26 (24%) constructs were identified to represent the rights granted to the shareholders by the legal environment as well as the effectiveness of the judiciary to uphold these rights (La Porta, Lopez-de-Silanes, Shleifer, & Vishny, 1998). Dimensions which seem to have been critical to explain growth of MNCs in some Latin American countries (La Porta & Lòpez de Silanes, 1999). At the same time, the internal environment was represented by difference between the rank of Spain and the rank of each individual county as scored in Hofstede's (1991) four indexes of national culture (4%). Stylised features of corporate culture such as those emerging from grounded work by Hofstede are not without critics (Baskerville, 2003; Hampden-Turner & Trompenaars, 1997; Hennart & Larimo, 1998; McSweeney, 2002). However, these indexes have been used extensively in empirical research as measures of national culture and explanations of the interaction between national culture and management (Hofstede, 2002; Williamson, 2002). As a result, the empirical assessment of the 'cultural affinity' construct (C_{ij}) assumed differences between countries were greater than differences between different organisations or differences between organisations in the same industry or sector.

Comparative Analysis

Trends and Directions of Mergers and Acquisitions

Table 1 summarises cross-border acquisitions of individual Spanish firms in Latin America. Data in Table 1 suggested Spanish MNC activity in Latin America could have been the result of a handful of companies as by financial services and utilities stand out from investments made by other sectors. However, an average value per transaction of US$426.08 million for all 228 transactions (with details regarding the transaction's value) suggested that, although most Spanish firms had been involved in six or less transactions, M&A activity between 1987 and 2001 distributed throughout a broad range of sectors. This was corroborated in Table 1 which shows Spanish firms sought equity control in their cross-border growth although the size of individual investments was wide ranging (from US$17.60 million to US$1,420.23 million).

TABLE 1: TOP SPANISH ACQUIRING MNCS IN LATIN AMERICA, 1987-2001
(Major acquirers with seven or more transactions)

	Two-Digit SIC	M&A Transactions				Ownership		
		Num. Trans.	Accumulated Value (US millions)	Rank Value	Average Value (US millions)	Average % of Equity	Std Dev	Rank Equity
Telefonica	48	37	$24,692.18	1	$987.69	60.68	37.37	5

Banco Bilbao Vizcaya A	60	34	$7,765.524	4	$277.34	59.31	31.61	7
Banco Santander Centr	60	27	$12,269.59	3	$766.85	59.66	35.19	6
Repsol	13	17	$17,042.80	2	$1.420.23	65.52	29.11	3
Corp MAPFRE SA	63	11	$123.20	7	$17.60	63.18	22.35	4
Endesa SA	49	9	$3,574.75	5	$397.19	72.59	28.64	1
Union Electrica Fenosa	49	9	$389.68	6	$77.94	67.98	25.00	2

Geographic distribution of transactions also raised questions as to the concentration of Spanish investments in Latin America around a few selected companies in a handful of countries. As summarised in Fig. 2, Argentina (87 transactions), Brazil (72 transactions), Mexico (50 transactions) and Chile (44 transactions), were the preferred markets for Spanish firms. These four countries represented 75% of total cross-border acquisitions in the region (253 transactions), with activity in other 13 Latin America countries accruing 25% (84 transactions) of the total.

Figure 3 summarises M&A activity in Latin America per industrial sector (as measured by two-digit SIC Code of target firms). These figures show the most popular sector was Depository Institutions (60 SIC Code) with 48 transactions; followed by Electric, gas and sanitary services (49) with 45 transactions, Communications (48) with 38 transactions, Business Services (73) with 27, and Insurance carriers (63) with 25 transactions. Together these five sectors represented 183 transactions or 54% of total, with 46% of activity in other 21 two-digit sectors (averaging 6.4 transactions and standard deviation of 3.47). Clearly, there was a preference for a reduced number of sectors in a limited number of countries, concentration which did not seem to have played at the strengths of the home country and which suggested that the competitive advantage of Spanish firms abroad was different to that at home.

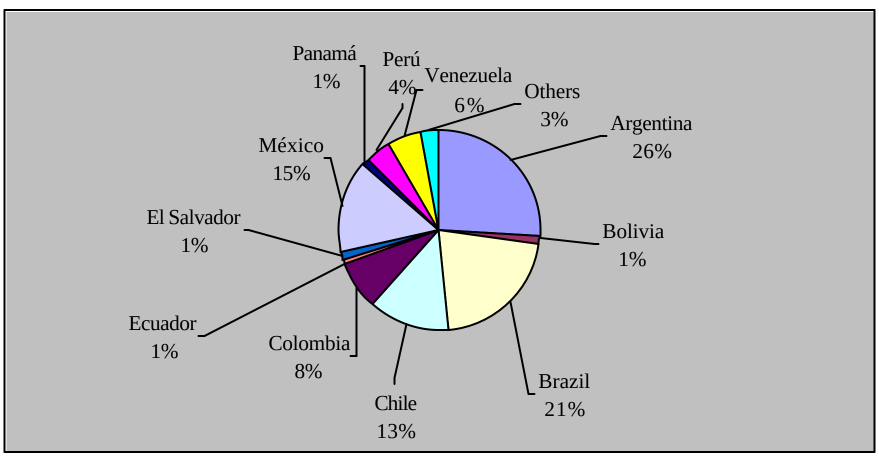

Fig .2: SPANISH ACQUISITIONS IN LATIN AMERICA - DISTRIBUTION BY COUNTRY, 1987-2001
Others: countries with two or less transactions (Guatemala, Guyana, Honduras, Nicaragua, Paraguay and Uruguay)
Source: International Mergers and Acquisitions database 2002, Securities Data Company.

In summary, the review of trends and directions in cross-border M&A suggested that the growth of Spanish multinationals could have been driven was driven by the search of new market opportunities such as unsatisfied demand abroad rather than playing on home country strengths or an excess installed capacity in

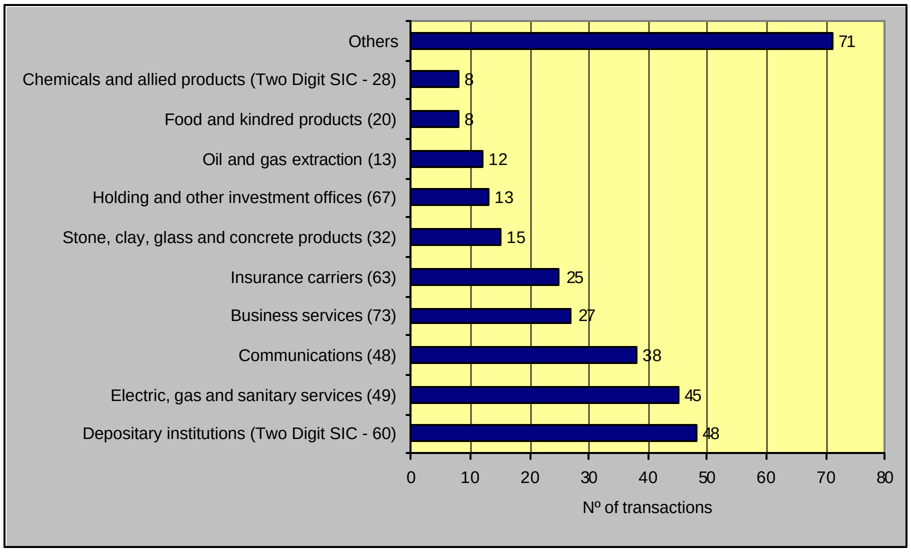

Fig. 3: SECTOR DISTRIBUTION FOR THOSE WITH MORE THAN SEVEN TRANSACTIONS, 1987-2001
Source: International Mergers and Acquisitions database 2002, Securities Data Company.

Spain. In the following section these trends are reassessed to examine the statistical significance of the determinants of FDI investment decisions. In this process, the analysis would shed light as to whether the competitive advantage of Spanish firms in Latin America was different from that at home and the extent to which these decisions responded to visionary, opportunistic or fortuitous diversification moves.

Sector Level Analysis

Following Ietto-Gilles Meschi & Simonetti (2000, 62), an indicator of ´abnormal´ M&A activity (either more or less than expected), was developed while comparing the matrix with M&A flows with another matrix that considered ´theoretical´ frequencies that would appear in the absence of any particular strong link between two sectors. The ´theoretical´ matrix represented the M&A flow that would occur in the absence of any factors that would favour particular relationships (i.e. particularly high or particularly low) between two sectors. The matrix for actual flows and the matrix for ´theoretical´ flows were compared using an indicators based on the chi-squared, where

$$A_{pq} = (? \ (O_{pq} - T_{pq})^2) / T_{pq} \qquad (2)$$

where

p Total number of transactions for SIC code of targets (in Latin America).

q Total number of transactions for SIC code of acquirer (in Spain).

The indicator, A_{pq}, resulted from the square value of the difference between the observed flow, O_{pq}, and the ´theoretical´ flow, T_{pq}. As in the case of the chi-squared statistic, the ´theoretical´ frequency for each cell was calculated by multiplying the row and column totals relative to the cell and dividing by the product by the overall total.[8] A single indicator was estimated for all combinations where the targeted two-digit SIC Latin American industry was the same as the two-digit SIC Spanish acquiring industry. This indicator was labelled related diversification. A second single indicator was estimated for all combinations where the targeted Latin American industry was different from the Spanish acquiring industry. This indicator was labelled unrelated diversification.There were 183 transactions involving related diversification (A_{pq} = 118.0) and 154 involving non-related diversification (A_{pq} = 59.2). Given the ´theoretical´ value, T_{pq} = 83.6, it was impossible to reject the null hypothesis of equal distribution for a chi-squared of 3.84 (with 1 d.f. and 5% significance). Results thus suggested that international investment of Spanish firms were indeed limited to a few sectors, some of these sectors played to their competencies in Spain (i.e. related diversification) while others looked for competitive advantage in a different industry (i.e. unrelated diversification).

To explore which were the most active sectors of Spanish M&A activity abroad, a value for the indicator, A_{pq}, was then estimated for each individual combination of target industry in Latin America and its Spanish acquirer. These indicators allowed insights into specific patterns of diversification then compared to reject the null hypothesis of equal distribution for a chi-squared of 68.77 (with 45 d.f. and 5% significance).[9] Following the US SIC classification for the 1987 census, there were 31 two-digit SIC industries (39%) without any activity at all (see further the Appendix 1 for detailed results). At the same time, there were 14 industries (18%) in where target (in Latin America) or acquirer (in Spain) was active but the indicator, A_{pq}, was not statistically significant. There were 11 industries (14%) where target and acquirer were active but only one was statistically significant. Table 2 summarises these results.As shown in Table 2, MNCs from six Spanish industries pursued unrelated diversification. This trend is perhaps more evident in investment in five Latin American industries where companies were acquired by an unrelated Spanish industry. These are target and acquirer industries with extreme values and one should avoid taking these results to portray the only industries observing unrelated diversification. However, visual examination of individual transactions suggested these transactions were not far apart within the value chain. For instance, Banco Santandar Central Hispano (SIC 60) acquiring a security broker (SIC 62). Results in Table 2 could thus be biased because of the classification method used when sorting by SIC criteria.

TABLE 2: M&A ACTIVITY OF SPANISH FIRMS IN LATIN AMERICA BY INDUSTRY, 1987-2001
(SECTORS WHERE TARGET AND ACQUIRER WERE ACTIVE BUT ONLY ONE WAS STATISTICALLY SIGNIFICANT)

		Target (Lat Am)		Acquirer (Spain)

95	Environmental quality and housing	335**	2	0	0
Sum			*38*		*32*

** = Significant with a 95% confidence interval.

Table 3 shows 24 industrial sectors (30%) where target and acquirer were both active and both were statistically significant. These sectors encompassed most of the industries making related diversification and show that cross border activity of Spanish MNCs in Latin America is concentrated in but a handful of industries.

Succinctly, in order to investigate the pattern of foreign investment through cross-border M&A, a matrix was created examining the flow of M&A (number of deals) between pairs of industries (as measured by two digit SIC codes). The aim was to asses whether trends in M&A transactions could help in ascertain links between M&A activity and the competitive advantage of Spanish firms in Latin America. As suggested by descriptive evidence in the previous, an approximation using the chi-square suggested that foreign investment of Spanish MNC´s in Latin America during the 1990s was heterogeneous and concentrated in a few industries. This test, however, was uanble to tell whether related diversification associated with with the successful transfer of competencies, market opportunities and accessing resources to supply foreign markets. In the following section an assessment is made as to the growth of Spanish MNCs in Latin America in terms of market opportunities and environmental risk.

Country Level Analysis

A second statistical test looked at the empirical significance of model 1 above through a regression model.

$$S^n = ?_j + ?^n ?^n_j (s^n, M_{ij}, W_{ij}, C_j, ?_{i-1j}) + ?^m ?^m_j ?_j + ? AR(9) + ?^n \quad (3)$$

where

S^n	Value of FDI decision.
s^n	Financial characteristics of individual transactions.
M_{ij}	Demand (i.e. market size) effect.
W_{ij}	Wage differential effect.
C_j	Cultural affinity effect.
$?_{i-1j}$	Trend (lagged).
$?_j$	Instrumental variables a) Value of 1 when purchaser was either Telefonica, BBVA, BSCH, Repsol, Endesa, Mapfre or Union Fenosa and 0 otherwise. b) Value of 1 when country was Argentina, Brazil, Mexico or Chile and 0 otherwise.
AR(9)	Autoregresive adjustment
$?^n$	Residual.
n	Transaction number.
m	Number of instrumental variables.
i	Year.
j	Country.

The 110 constructs identified as potential determinants of the value of individual FDI decisions (S^n) were reduced to 20 constructs. See Table 4. Firstly, pre-regression test used cross sections by year (1999 and 2001) as well as countries (Argentina and Colombia) and found 28 constructs were unable to contribute to the assessment.[10] For instance, most of the details as to the financial characteristics of the transaction (s^n) were lost as these constructs overwhelmingly had a value of zero. The reason being that cross-border acquisition of Spanish firms usually involved payments using internal resources (using cash rather than issuing debt or new equity) and were non-contested acquisitions (i.e. transactions were completed the same day they were announced and therefore lacked the need for sophisticated protection mechanism such as pacman, poison pill, lock up, etc.) Secondly, during test for linear correlation loss of constructs came about in order to avoid the potential spurious relation between some of them (i.e. multicolinearity) as the model had to be corrected for autocorrelation and heterocedasticity.

As a result of the careful screening, five constructs (25%) provided details as to the financial characteristics of the transactions (s^n). There were three constructs (15%) dealing with terms of trade and degree of openness were identified as potential measures of market size (M_{ij}). Three constructs (15%) considered relative income measures and an index for the intensity of union militancy throughout the work force and were identified as potential measures wage effects (W_{ij}). There were three constructs (15%) to represent the market for corporate control and four (20%) national culture. Three constructs (15%) considered trends and directions of M&A activity ($?_{i-1}$). One instrumental variable (5%) was added to identify transactions involving the most active companies (financials) as described in Table 1 and Fig. 3 ($?_1$). A second instrumental variable (5%) identified the main recipients of Spanish FDI in terms of number of transactions as described in Fig. 2 ($?_2$).

Conclusion

Statistical analysis of M&A activity suggested most transactions were concentrated in a handful of countries and led by a few firms. Hence we found that during the 1990s, Mexico, Brazil and Argentina were, in general, the countries which received most Spanish FDI. Related to sector distribution, Electric, gas and sanitary services (49) and Communications (48) took the second and third places in terms of M&A activity while the most active sector was Depository Institutions (60). The importance of the financial sector was based on the strong development in Latin America of the main Spanish banks: SCH and BBVA.

The prominence of the corruption index (CORRUP) as well as number of days to finalise the transaction (DAYSPPPP and DAYS%) suggested MNCs were happy to accommodate the institutional environment provided there was certainty their rights would be protected. Corruption impinges designing solutions on a case by case basis both when selecting the target and to implement systems of information and control. It would thus be very hard to run international operations if each and every time local managers were to devise unique solutions. The propensity for unions to influence negotiations (UNION and LFORCE) had a positive effect on the value. At the same time, the development of the stock market seemed important (K2GNP and OPEN) as a mechanism to clear transactions rather than to help finance the deal. Of course the larger the size of the local companies the less likely to find suitable candidates (i.e. negative sign of K2GNP). This would be consistent with the idea that possibilities to exploit market-value differences emerge as in less developed countries (Hu, 1995, 84-5; Porter, 1987, 49 and 52).

Given that most trend variables were discarded while market and wage effects remain (including instrumental variables for the four biggest economies), suggesting that buying into the right market was more important than acquiring the right target. This result was consistent with poorly developed financial markets and a strong preference of Spanish MNCs to acquire control (i.e. average ownership after transaction equal to 67%). However, the nature and intent behind this acquisitions is still a topic that requires attention.

Appendix 1: Diversification of Spanish MNC by Industrial Sector

TABLE A.- SECTORS WITHOUT CROSS-BORDER ACTIVITY

SIC Code	1987 U.S. SIC Description
2	Agricultural production- livestock
7	Agricultural services
8	Forestry
9	Fishing, hunting, and trapping
12	Coal mining
14	Nonmetallic minerals, except fuels
23	Apparel and other textile products

30	Rubber and miscellaneous plastics products
31	Leather and leather products
43	Postal Service
46	Pipelines, except natural gas
52	Building materials, hardware, garden supply, & mobile
53	General merchandise stores
54	Food stores
56	Apparel and accessory stores
64	Insurance agents, brokers, and service
72	Personal services
75	Automotive repair, services, and parking
79	Amusement and recreational services
81	Legal services
82	Educational services
83	Social services
84	Museums, art galleries, botanical & zoological garden
86	Membership organizations
88	Private households
89	Miscellaneous services
91	Executive, legislative, and general government
92	Justice, public order, and safety
93	Finance, taxation, and monetary policy
94	Administration of human resources
96	Administration of economic programs

End Notes

Helpful comments from Pawan Budhwar, Chris Carr, Jim Love, Arturo Rodriguez, Adrian Tschoegl, participants at the 1st Emerging Markets Finance Association Conference (University of Salford, UK) and the 8th Conference on Global Business and Economic Development (Universidad del Valle de Atemajac, México) are gratefully acknowledged. The usual caveats apply.

[1] Defined as assets or capabilities that need to be build up or acquired in the target country in order to fully exploit the firm's advantages in that country.

[2] http://www.unctad.org/en/subsites/dite/FDIstats_files/FDIstats.htm

[3] Target or Acquiror Nation : Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba, Dominican Republic, Ecuador, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, Panama, Paraguay, Peru, Uruguay and Venezuela.

[4] A caveat similar to other assessment of companies' data with a sector breakdown, is that service sector might be under-recorded because companies are classified according to their main line of activity. For instance, companies such as IBM generated over 40% of income from services in 2001 yet the parent-company's main line of activities was classified under hardware manufacturing. This bias against service industries is, perhaps, mitigated by the fact that industry classification of the deal refers to the unit whose ownership has been transferred rather than to the whole group (i.e. the parent company).

[5] Country classification of the deal refers to the nation state of the unit whose ownership has been transferred and the unit who has acquired rather than the whole group (i.e. the parent company).

[6] Target or Acquiror Nation : Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba, Dominican Republic, Ecuador, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, Panama, Paraguay, Peru, Uruguay and Venezuela.

[7] Art. 4.1., Real Decreto 672/1992, 2nd July, considers Spanish foreign investments and establishes that "it's presumed that effective influence exists in a foreign firm management when the investor's participation, direct or indirect, is equal or superior to 10% of the social capital".

[8] Note that using the average number of transactions to calculate the theoretical flow (T_{pq}) was equally problematic given the cyclical nature of both M&A and FDI decisions (phenomena which is well documented).

[9] For 30 d.f. or more the chi-squared statistic is considered to distribute as a normal with mean 1 and variance 0. An approximation to 45 d.f resulted from adding the values for the chi-squared with 15 d.f. (25) to that with 30 d.f. (43.77) for a 5% level of significance.

Subordination and Creativity in the World Economy

Dayr Reis
Leticia Peña
University of Wisconsin-La Crosse, USA

Abstract

This paper describes the relation of forces that govern the international economic order and suggests how it can be altered in order to make it possible for countries in the periphery to neutralize the weight of technological subordination and advance on the path of development. However, the struggle against economic dependence is just one aspect in the development process. True deve lopment does not exist without first liberating the creative capacity of the people in the developing economies of the periphery.

Historical Antecedents

Comprehending the problems faced today by the developing economies requires an historical and structural view of industrial capitalism. The wealth accumulation that is responsible for its generation was preceded by an increase of the commercial surplus. The discovery of the maritime route to India by the Portuguese at the end of the 15th century was based on considerable investment of science and navigation techniques, naval construction, cartography work, and training of highly skilled personnel. More than a century of consciously planned actions separate the first exploratory maritime expeditions in the African coast from the arrival of Vasco da Gama to India.

Once the trade route was inaugurated, the reduction in transportation costs and the elimination of a whole chain of intermediaries brought considerable profits to the Portuguese. The opening of the commercial lines of planetary amplitude in the first half of the 16th century is at the root of the accumulation process that would lead to the industrial revolution. The observation of this period, during which the industrial civilization was being generated, is the key to comprehending the most characteristic features of the capitalist societies of our days.

The rich markets of Southeast Asia that were initially pillaged, the formidable reservoir of labor discovered in Africa and the Americas, and the reserves of precious metals of the latter increased enormously the base of European economy for its capacity of generating the surplus. During this phase of the economical evolution of Europe, there is considerable increase in the surplus without a corresponding change in the productive forces. In the regions they “discovered”, the Europeans exacted a surplus by authoritarian means in addition to the profit resulting from commercial operations. The conquest of the Aztec and Inca empires, among many other conquests, brought them substantial wealth in the form of precious metals while the production organization was based on slavery. The native populations of the Americas and the millions of Africans transplanted to the New Continent against their will paid the highest tribute in the phase of European accumulation of wealth.

The subsequent transformation in the system of social domination-the bourgeois revolution-constitutes the decisive step in the formation of the capitalist societies of our days. A consequence of the industrial revolution, the bourgeois revolution represents the triumph of the bourgeoisie over the agrarian aristocracy and the consolidation of the capitalists and proletarians as social units.

The industrial revolution and the advance of capitalism first happened in the European regions where the ascension of the bourgeoisie, based on the expansion of the surplus of mercantile origin, was facilitated by its cooperation with traditional dominant groups. Trading companies with great powers delegated by the states appeared in England and The Netherlands at the beginning of the 17th century. These companies made possible the direct cooperation of kings and the aristocracy in general with the merchants in their lucrative overseas operations.

From powerful financial positions that it was consolidating, the bourgeoisie reached the decision centers and obtained (or imposed) institutional changes like the free initiative, free contracting, free circulation of goods, etc., that were extended to new areas of social life. Thus, the medieval guild system, with its cramping restrictions on trade and industry was gradually dismantled, while the rigid control of the rural population by the landed oligarchy was totally abolished. It was the subordination of the production activities to the logic of the market that led to the industrial revolution. In the society that emerged from this transformation, the economic activities assumed considerable autonomy and acquired an important role in all dimensions of culture. To accumulate, to increase the surplus became objectives by themselves. The elimination of all obstacles to productive efficiency was considered “rational” (Gehlen, 1989). The industrial revolution results in the establishment of a new social order in which not only the physical power but also the intellectual capacity of human beings is increasingly subordinated to market criteria (Habermas, 2003). The last quarter of the 18th century and the first half of the 19th century can be viewed as a transition between the startup of the new social order and the industrial capitalist society. In the latter, the accumulation process is incorporated into the production organization and external relations are auxiliary lines that add flexibility to the whole system. Increasing the surplus does not depend any more on the opening of new commercial routes. The surplus can now be increased by increasing production efficiency. The innovation of production methods is now the shortest path to surprising competitors and therefore becomes an instrument of power.

The Diffusion of the Industrial Revolution

After its beginning in England, the diffusion of the industrial revolution was a comparatively slow process, with France and later Germany (mid 19th century) joining its process. Other European countries, with the exception of Belgium, did not keep pace with France and Germany. Italy became partially industrialized late in the 19th century. Spain, Portugal, Russia and the Balkan countries remained relatively untouched by the great drive toward industrialization, though some advances were made in each country. Russia was modernized in the 20th century, under the communist revolution.

Of the non-European countries, the United States and Japan took full advantage of industrialization. By the middle of the 19th century, American-made machines began to be imported into Europe. Agrarianism persisted in Asia, Africa and Latin America until the 20th century. The transference of labor from activities of self-subsistence to coffee, cocoa, rubber, and sugar cane plantations give origin to a purchasing power in the international market, through which certain populations in those agrarian areas started having indirect access to the benefits of technical progress. Through indirect means, consumption is diversified without any significant evolution in the productive techniques of those underdeveloped areas.

The ideological values that appeared with the bourgeois revolution-liberalism, individualism, rationalism-that were used as levers to displace the old domination structure and promote the ascension of the social agents committed to the accumulation, when transplanted to the developing nations, were the same values that served to reinforce the state of dependence.

The industrialization of the economies that had access to the industrial civilization through indirect means manifests itself as an evolution of their international relations. Industrialization happens as an answer to tensions in international relations caused by problems with the trade balance of those countries. When the ability to import is contracted, these economies will start industrial activities complementary to their import activities. Therefore they go from importing the fabric to importing the thread, from importing the car to importing its parts and “nationalizing” its final assembly, and so on. When later on, the local industry is called to generate part of the payments in the exterior (without which its growth cannot materialize), access to external markets poses limits to internal industrialization. This process reinforces the position of the transnational companies.

In the framework of dependent industrialization, the determinant of the technology utilized is the degree of diversification of demand (the nature of final products) generated by the social groups that had indirect access to the industrial civilization. The industrialization process in these developing countries will assume the form of an adaptation effort of the productive systems of those countries to this sophisticated demand. A productive system of high capital density and low capacity for generating employment was thus created that does not correspond to the level of accumulation of the whole developing society. Since this subsystem is structurally linked to the advanced economies, the dependence continues to exist.

The increasing infiltration of rationality criteria into the social body would ended up producing in Europe a civilization style with the following characteristics: Industrialization, i.e., the technical nature of all productive activities; urbanization, i.e., spatial structuring of the population to satisfy the demands of the labor market , and secularization, i.e., prevalence of reason in the legitimization of power systems. The rapid process of accumulation and technological advancement that are inherent to the industrial civilization enabled certain European nations and later the United States, to control the quasi totality of the planet. Modern history and the history of our days is in great part a reflex of this enterprise of planetary domination and the resulting effort on the part of the dominated peoples of the Third World to liberate themselves. The next section deals with some of the possibilities opened to the developing countries to alter the balance of forces that seems to perpetuate the subordination of most of the world nations to a small group of countries that were favored by the industrial revolution.

The Resources of Power

The large enterprise that alone or in the framework of an oligopoly is the one that administers prices, conditions the habits of consumers, and modifies the markets through credit, thereby exerting unequivocally ample power. In its transactions with the exterior, the large enterprise is simultaneously representing its own interests and also the interests of the economic system in which it resides. The situation is different when the same enterprise is implanted in more than one economic system. In this case, it has at its disposal resources of power that can liberate it from the constraining action exerted by the national centers.

The large enterprise is an entity of social relations, hierarchically organized, that serves a programmed will in order to condition the behavior of chosen segments of society. It is at the international level that the innovative capacity of industrial capitalism is the most fecund. The expansion of the large enterprise overseas is the most complex when the industrial activity is decentralized geographically, where the units located in several countries specialize in one or more processes that are part of the same productive activity. The labor-intensive processes are located in those countries where there is easy access to cheap labor, the assembly processes are located near the consumer market, the polluting processes in places where the environmental legislation is less restrictive, etc. This type of business structure is called *transnational*. The struggle against dependence will happen with more intensity in the framework of international business and transnational companies. If one assumes that for a developing country isolationism is not an option, the strategic objective is to minimize the cost of dependence and to explore paths that would lead to substituting dependence for interdependence. What are then the real resources of power that would enable the peripheral countries to modify the present configuration of forces in the international market?

Among the resources of power that are the base of the present international economic order, the following are particularly relevant: (1) Control of technology, (2) control of finances, (3) control of access to internal markets, (4) control of access to non-renewable resources, and (5) control of access to cheap labor. These resources, in significant amounts, and/or combined in various proportions, create positions of power occupied by states or important economic groups in the struggle for appropriating the surplus generated by the international economy. Coalitions of peripheral countries allow them to obtain initially the critical mass required to control one resource or to articulate combinations of resources of high effectiveness in creating positions of power. Let us review one by one, all the mentioned resources of power.

Control of Technology

The struggle against dependence is the effort to neutralize the effects of the monopoly of technology in hands of the developed countries. Technology has the property of substituting other resources of power. In the industrial civilization, technology is the final expression of human creativity. The industrial civilization is the resultant of certain orientation of human creativity that favors accumulation and leads to the reinforcement of certain social structures. The product of creativity is modern technology, the basic ingredient of the accumulation process. To confront these positions of power by using adequate combinations of other resources, or the critical mass of some of them, is the essence of the struggle against dependence. Technological domination tends to deepen as the network of interests of the transnational enterprises becomes denser. Ultimately, these companies control the diffusion of technology around the globe. The cession of technology through licensing contracts has no interest to the firm that can explore directly this technology, using it to form the capital of subsidiaries, to amass local financial resources and enlarge its scope. This is the reason why instead of forming a "technology market" at the international level, during the industrialization phase of the developing countries, the area of transference of these leading edge technologies was limited to transactions between groups that could insure each other adequate compensation in terms of technology.

Control of Finances

With regard to financial resources, the changes that occurred in the last decades are considerable. On one hand, development of banking networks and direct action of the state are channeling large sums of money. On the other, the direct access to international financial markets has allowed many developing countries to maneuver with a degree of freedom, unknown in the times of the rigid control exerted by the International Monetary Fund. It has become evident that transnational enterprises installed themselves in developing countries with resources that are in great part raised locally (profits from trade operations, association with local groups, government subsidies, etc.) and with resources from international financial markets that usually have a return on investment guaranteed by the local monetary authorities. The large investments in infrastructure that make possible the implementation of subsidiaries of transnational enterprises are financed with compulsory local savings and external resources guaranteed by the state. Summing up, there is a pool of financial resources that can be utilized by the states, this way increasing their leverage in international relations. After 1973, the emergence of a considerable surplus in the trade balance of a small group of oil exporting countries is another important event in the pursuit of financial power. For the first time it became feasible to start important projects of common interest to peripheral countries without the sponsorship of developed countries or international financial institutions controlled by those countries. The periphery was transformed into an important player of the international financial markets.

Control of Access to Internal Markets

Here is another source of power in international relations**.** Trade barriers have been used as defensive or offensive weapons in confrontation of external interests. In the present phase of the rush of the transnational enterprises to control positions all over the planet, access to internal markets has become crucial. This is easier for those transnational companies that already have a commercialization network, that control a segment of the market through imports, and have connections with local financial systems. Given the small investment required for installing a subsidiary in a peripheral country, barriers to entry of transnational in these countries are minimal. Consequently, the market forms that emerge are similar to what is called "monopolistic competition" in economic theory, much different from the oligopolistic forms that prevail in the developed countries. This situation requires the states to exert tighter control of these enterprises and, in certain cases, to demand participation in their direction.

The relatively limited internal market of many developing countries has lead them to join together with other countries into "free trade zones," "common markets," and other similar schemes , all aiming at augmenting the space within which the enterprises organize their activities. The necessity of coordinating local policies in the face of transnationals has become more urgent, if one wishes to avoid that these enterprises take advantage of possible rivalries between countries regarding the location of economic activities. The articulation of economic policies and the joint financing of projects of common interest strengthen the position of the smaller states in their dealings with transnationals.

The basic policy that emerged aiming at preserving control of internal markets in the face of offensive strategies by transnationals was to limit the time of control of a market segment by a transnational. Control is inevitable in a first phase, given the difficulties of accessing the necessary technology. The contract to explore a segment of the market for an indefinite period of time is thus replaced by a contract for a limited period of time. The control by the enterprise of its production, marketing, and finance departments (not only the stocks) should be gradually transferred to decision centers in the host country. Financial resources cannot be raised in the internal financial market unless this condition is fulfilled. The objective is to have the transnational to be a part of the local economic system (regional in the case of a coalition of countries). If local control is extended to other sectors, a critical mass is formed that enables the states or internal groups to put pressure on transnationals to make their technologies available in less onerous terms. The larger the internal market, the easier is to reach a positive outcome. In the case of small countries, the coalition is a *sine qua non* precondition for this policy to succeed.

Control of Access to Nonrenewable Resources

This type of control has always been considered one of the principal sources of power in international relations. The logic of the accumulation system, with its short time horizon, tends to put an increasing pressure on the so-called nonrenewable resources. In developed countries, powerful interests try to create the illusion that exhaustion of those resources will never happen because technology by itself will be able to solve all the problems that it creates. Developed countries continue to explore their own reserves within private criteria that reflect the short time horizons already mentioned. Therefore, barriers are created that impede the organization of the global supply of those resources. The elevation of relative prices of most of the nonrenewable resources is a necessary condition for reducing the present waste of these resources and for reorienting the technology in order to gradually save those resources. The policy adopted by certain developed countries with respect to their own resources is going to help the peripheral countries in the medium and long range. Coalitions of developing countries will be the most effective means for exerting control over their own resources of nonrenewables. To this effect, the ability to control the local financial markets is also crucial as explained before.

Control of Access to Cheap Labor

The vast reservoir of cheap labor that exists in many peripheral countries have been a source of weakness in their international relations with countries of the center. Cheap labor is responsible for the low prices of many agricultural products exported by the developing countries. Organizing the supply of these products was the first step in the struggle against dependence. Cheap labor also appears in the form of manufactured products produced by subsidiaries of transnationals in strategic locations of the developing countries. Presently, all the countries that have abundant cheap labor are willing to make their labor supply available to transnationals under the most favorable conditions. The only obstacle to expansion of transnationals in this direction is posed by the developed countries themselves, preoccupied with the direct and indirect effects upon their economies of exporting their jobs by the transnationals. If this trend continues and cheap labor remains important to the transnationals, the former weakness of cheap labor can be transformed into a new resource of power. Even a substantial increase in the price of this labor will not make it too expensive when compared to the alternative of the developed countries where salaries are five to ten times higher for identical work. The countries that have cheap labor can introduce a tax in the exports of manufactured goods using that labor, in order to cover (at least partially) the differential between their wage rates and those of other peripheral countries competing in the same market. In the present situation, the transnationals can choose from among several countries and therefore exert pressure on each one of them.

Where to Start?

The resources of power should not be considered in the same level. In different degrees, all of them have been used by many developing countries. But only recently they have been used in an articulated form with the explicit objective of changing the order of international relations so as to benefit the countries of the dependent economy. Since technology is the only resource that can substitute for the others and is the one monopolized by the developed countries, it is correct to say that dependence is first technological. To gather the other resources of power to neutralize the weight of technological dependence is, therefore, the goal of the developing nations in their advance through the path of development. The struggle against dependence starts by regaining control of their own sources of nonrenewables. This is followed by occupying positions that enable the developing countries to control access to internal markets. From the success obtained in these two fronts, a critical mass of financial resources could be achieved that would allow the consolidation of the positions conquered and to increase the area of action. The struggle in the technological front is only feasible when important segments of the international market have been secured and achieved a critical mass of financial resources. In all phases of the struggle, coalitions of developing countries are essential.

Conclusion

The doctrine of international specialization was presented to the developing countries as the shortest path leading to the enrichment of a region or country. According to this doctrine, the country should place itself in the system of international division of labor and specialize in producing one or a few agricultural products. The delay in the diversification of consumption would be eliminated and the country could then advance to the front line of the civilized nations. Later, after the collapse of the exporting model of primary products, a new pact between external interest groups and internal agents on which dependent industrialization is based would substitute the idea of development for the myth of international specialization. Gradually deprived of historic memory and sense of identity, and gauged by a measurement system conceived with the objective of accumulation, the developing countries were classified, ranked and labeled as abstract entities whose behavior is tentatively explained, based on limited and inadequate data. Since development is equated to *international performance*, totally ignoring the cost of accumulation in terms of cultural values, the history of the developing countries is seen as a competition where the award is to be increasingly like the countries that lead the accumulation process. The idea of development as international performance is detached from the social structures since it is the result of a pact between some internal and external groups interested in accelerating the accumulation process. The most fundamental impulses of human beings, generated from the need of self-identification and locating themselves in the universe-impulses that are the matrix of creative activities such as philosophical reflection, mystic meditation, artistic invention and scientific research- one way or the other were all subordinated to the process of transformation of the physical world required by accumulation. The limits of creativity to human life conceived as an end unto itself were atrophied while its links with the tools used by human beings to transform the world were hypertrophied. Marcuse illuminated an important aspect of this discussion by arguing that because of its own methodology and concepts, science projected and promoted a universe where the domination of nature remained linked to the domination of human beings (Marcuse, 1992). In a capitalist economy, accumulation marches on two feet: <u>Innovation</u> that allows discrimination between consumers, and <u>diffusion</u> that leads to the homogenization of certain forms of consumption. The consumer has a passive role. Its rationality consists in responding correctly to each stimulus. Innovation always points to a higher level of expenditure that is the distinctive mark of the privileged consumer. But what is standard will have to be superseded and diffused so that the market can grow in all its dimensions. Creativity is then conditioned by the laws of this growth. The struggle against dependence is just an aspect of the development process. This will not materialize without first liberating the creative capacity of the peoples in developing nations. The most negative aspect of control of productive systems in the developing countries by transnationals is the transformation of the ruling elite of those countries into simple transmission belts of cultural values generated in the developed countries. The dependent nation looses the capacity of conceiving its own objectives. This is the reason why political authoritarianism fits dependence very nicely. Economic dependence, cultural control and political authoritarianism complement each other and reinforce one another.

Main Inadequacies in Strategic Planning Process in Jalisco: Case Studies

Silvio Hernández
José Sánchez
Universidad de Guadalajara, México

Abstract

For many managers the challenges of the competitiveness, the globalization, the new technologies and the uncertain development of the markets take them to doubt on the future and if they will be able to coexist in that atmosphere or they will simply disappear. Strategic Planning Process and their coherence with the focus and administrative system that one has, they are a key factor to face these challenges. The results that we are presented is a synthesis of the research carried out in 60 companies of Jalisco's State, directed to identify, to describe and to value the processes of strategic planning and their coherence with the processes of: formalization, leadership, organizational culture, motivation and the workers' implication. The research one, carries out in three stages among the months of December 2001 to august 2002, in the same one, 60 students at Universidad de Guadalajara in MBA's major were collaborating The approached problem was that of the inadequacies that present the strategic planning processes and its lack of coherence to give answers to the new conditions of competitiveness. Besides the general research methods, the techniques of documental research were used, surveys, interviews and in accordance with the possibilities and specificities of each company another group of techniques to value the processes of administration. A Diagnose Guide in the one that 95 main categories of the investigated processes were valued they facilitated their prosecution and presentation in charts. In the work, the results are presented obtained in the 95 elements investigated in the 60 companies, contained by four aspects:

1. **Backgrounds and Profile**
2. **Organization and Culture.**
3. **Strategic Planning.**
4. **Human Resources.**

This information is accompanied of an analysis of the results in accordance to: the company size, type of property and administrative styles used. It is included the conclusions with the main inadequacies. A summary of the main SWOT results is also included carried out by each company, where the highest frequencies in coincidence are pointed out, of the weaknesses, opportunities, strengths and threats that perceive the same ones in common way.

1. Introduction.

The world in that we live is a world in crisis, but crisis in the sense of moments of big changes in the humanity's development, important qualitative and quantitative jumps that will open the way to a new era, to a revolution of the productive forces and big changes in the production relationships.

For such a reason the processes of managerial administration in the current world are characterized by a great uncertainty, a high risk and an insecurity of how to proceed before the group of threats and difficulties that should face in the business. This uncertainty is even bigger in the countries in development, increased by multiple factors that influence in the same ones

In turn they should be coherent to each other and in consequence they impact and they change the whole system of productive and not productive relationships that they conform the base of the society.

The formation and structuring of the new technological system

To move strategically we have to understand in all their reach the development of the new technologies and to establish their influence in the branch in which our company is unwrapped and starting from this which there is possibilities to have competitive advantages, because periods of time can maintain those advantages which we have to change.

Not all the tendencies in the formation of the new technological system are clear, the necessity of coherence will give origin to other big groups of technologies that contribute to form the net or mesh technology of the Third Industrial Revolution.

A very important phase of the development of the new technological system constitutes it its structuring. The same one consists on the establishment of new relationships between those technologies and the application until obtaining products and processes of extensive use. In this phase the conditions are believed you stop the disappearance on behalf of the old technologies, the regeneration of another part and the emergence of other new ones. The characterization of the new system can be analyzed through the following processes:

?? The formation of technological meshes.
?? The new group logic.
?? The social changes.

It is on this part of the development of the new systems, where the strategic planning of the company and their interrelation with other key process of the administration, it should deepen but to reveal their futures markets and the distinctive advantages that one will be able to use to win in the fight for the competitiveness.

The social changes

It is the most complex in all the process of the structuring of the new system, because in him the new lists that played the men and their organizations intervenes. The first great consequence of these crises is the imp act of the new technologies in all the productive processes and of services presenting a quick change in the productive technologies, the second consequence is the globalization of the production and of the trade, the third are never before the growth of the fights of the competitive forces in levels, methods and reach seen, the fourth is the meaning and importance that the average man acquires as client, as worker, like object and subject of the managerial processes in interrelation like I hold and object of the conduction of all the social processes, the fifth is the growing abyss among the rich and poor countries, Latin America increased to 40% its population mass in serious poverty.

The changes in the forms of administering

The forms of administering traditional that characterized to the second industrial revolution they are disappearing quickly and giving space to a new form of administering. that gives priority to the strategic thing on the operational thing in a dialectical application that integrates both in a development in hairspring. This change gives a new dimension to the forms of administering. We will call it Strategic Administration to mean the integration of the strategic thing and the operational thing in a constant replanteamiento. Three pillars of this new conception under the conditions of Mexico will be to understand, the strategic thought, the leadership transformational and a coherent organizational culture.

The new form of administering does not arise overnight, neither it is manifested in all its magnitude and integrity in some few months, with the result that the leader aware of those deep changes, begins a process but or less slow according to the conditions of her company and to the possibilities of the personally, her community and the environment.

In that beginning process, the development of the strategic thought and the materialization of a process of strategic planning believe the favorable conditions to reveal the needs of a change that it integrates all the signal elements and that it allows him to compete in the new mark of globalization of the economy..

The economic development of Jalisco in its beginnings was eminently agricultural and it served as base for the development of an autochthonous capital that moved fundamentally to the cities in the trade sector, giving origin to a tendency toward the small and medium companies in that sector that taking advantage it magnifies geographical position in the center of the country, it served as channel of the trade toward the north and the center of the country. The derived industry of the agriculture, mainly the tequila, the lumberman and the footwear, they were also important rubles, together with the craft. Reaching to be the third economy of the country, after the Federal District and the State of Mexico.

2. Possible Scenes

The interpretation of the pointed out documents can give origin to multiple interpretations, all them polemic. Where surely all or most would coincide, it is that the same ones were carried out in a much more promising context that the current one, from an economic point of view.

Later events as the events of September 11 and the war of Iraq, as well as the own mark of current address of the United States that is the ship badge of the world economy in these moments, is pointing toward a much slower recovery of what was expected, factors of strategic character and of national security, they are slowing and committing the dynamics of the North American economy and increasing the problems of the economies of the South Cone, that that together to a devaluation of its currencies and to the entrance in the NAFTA, that that together to multiple collateral factors, they point out that the possibilities of competitiveness of many producing of Jalis co are more complex, that which forces us to a much more visionary, scientific strategic projection and transforming.

You threaten and limitations

The agriculture faces big derived dangers of the entrance in vigor of different paragraphs of the TLC. That it places in evident competitive disadvantages to the sector, especially in poultry, bovine products and their derived, as well as in grains and forage.

In the last two years it is noticed in the industry assembly plant a decrease, for the triple action: of the step of some productions to the automation and being assimilated in the countries of the main houses; for the displacement of the investors toward other regions of Latin America with less problems in the movement of the generated capital and in the union actions and of labor regulations and the growing increase of the cost of the manpower and other expenses of the companies, in comparison with Asian regions or of Center America.

Another threatening factor is manifested in the industry of the footwear and of the piece of furniture, with the entrance of China and other countries of the Southeastern Asian countries with very competitive prices

The small and medium company also faces an accumulation of contracted debts when the lost ones derived of the devaluation of the weight in 1994 and that at least it could face the interest payments with the growth had up to the 2000, but after the process of paralyzation of the economic development in the last two years, this situation believes very difficult conditions for the companies that suffer them. The foreign investments in the country have a decrecimiento, what can stay for such negative factors as: the fear that the economic processes in Argentina, Uruguay, Brazil and Venezuela know they make worse and affect to the whole region.

The advantages in wages and deregulations in the systems of labor protection in other countries of Central America and Asia that with the extension of the NAFTA, they allow displacements to Center and North American and European and Asian investors' South America and from those countries to compete but advantageously. The educational level is a factor that has favored as competitive advantage in the past to the region, but of not being assisted, it can become a threat to medium and I release term, because the covering of alone 91.4 percent in primary and a 86.8 in secondary, with efficiencies of 85.5 and 69.8 respectively that they were had and the proportion of 11.8 of university population in older than 18 years. They are insufficient for the objectives of competitiveness that you/they love each other to reach. To these elements they sink others that we will analyze but ahead.

Another element that becomes a potential threat is the potentialities and participation in the investigations, evidently the possibilities that he/she has the region are very superior to those that are in march and they don't give answer to all the necessities of the managerial sector. Later on we will see other elements that point out but limitations in this field delay sciences and the techniques.

Most of the local sectors of the industry, the trade and the services have not been able to carry out capital investments that allow them to be modernized and to be developed successfully in an environment of growing international competition.. Presenting problems of competitiveness.

A broken into fragments productive structure subsists in Jalisco, defined by a managerial culture that is characterized by an attitude and not very aggressive acting as for its competitive participation in the open market.

Companies with little opening to the asociacionismo and with companies that you/they have not been able to be modernized due to low investment flows and to the limited access to the financing.

The limitations that present the micro and small companies to incorporate innovation strategies and technological development, their restricted negotiation power, the access difficulty to competitive financing, their reduced diversification of markets, the expensive regulation that affects their operations and the lack of appropriate fiscal treatment, among other factors, they affect the competitiveness of the same ones.

The integration of the chains of value constitutes perhaps, the main limitation of the composition of the economic base of Jalisco, in that sense had special attention the association of the small and medium agricultural producers in the chain of value of its products.

The disloyal competition that the officially constituted companies, they suffer on the part of the submerged economy. All the factors before mentioned, they give as a result that the competitiveness of the companies of Jalisco can it turns seriously affected in a future, the analyses of the productivity for nations, dice to know to the beginning of the 2003, point out a setback of Mexico of the position 40 to the position 45.

3. General Considerations on the Investigation

The purposes in this investigation of university character, it is the relevancy sense that you/they should have the investigations carried out by the professors and students of these institutions and that they should try to contribute to solve the urgent problems of the country and the region to that you/they belong. In this sense we have identified that in the current moments the companies of Jalisco face circumstances very different to other historical moments of their development. Those circumstances require adjustments and changes in many of those companies to face the new challenges and next we expose some of the results obtained in the first part of the investigation process carried out in 59 companies of Jalisco, about the main inadequacies in the processes of strategic planning and their interrelation with the organization and the existent leadership.

Process of investigation

The process of strategic planning is a very wide and complex topic in the one which the dynamics of its development, the limitations that the actors of the study object impose (The Company); the impossibility of controlling the extrinsic variables, the quantity of independent variables and clerks and another great number of factors conditions the possibilities of experimental, random investigations and with a certain grade of dependability, for what we design for this first stage a fundamentally qualitative investigation, of exploratory and descriptive character that using the trial of experts, they combined different methods and techniques to describe and in an approximate way to estimate the grade of behavior of the most significant variables in the processes of strategic planning. And of their interrelations with the organization, culture and leadership.

As all exploratory investigation he/she doesn't have a final conclusion and therefore they are informative elements to clear incognito and to present tendencies that logically can be accepted or not for the in agreement specialists with their attachment to the investigation focuses Positivistic or Hermeneutic that the same ones profess.

The approached Problem was that of the inadequacies that you/they present the process of strategic planning and you outlines as: Which is the grade of application of the Process of Strategic Planning in the companies of Jalisco in correspondence with its integration to some main components of the Strategic Administration?

The general objective was: To describe the grade of realization of the processes of strategic planning in the companies of Jalisco in correspondence with their necessity of coherence with the processes of strategic administration of the same one and the demands of the environment.

One of the specific objectives was the one of to identify which was: the one Diagnoses Strategic of each one of the companies by means of the identification of their main Strengths, opportunities, weaknesses and threats and their agreement valuation the development grade and coherence that I know observed in the process of strategic planning.

The investigation process was designed assisting to the limitations that are presented in this study object, like an exploratory investigation that used the general methods of the observation, induction, deduction, analysis and synthesis, in which they collaborated but of 70 students of the last semesters of the Master in Administration, with the due theoretical preparation and one practices in the processes of strategic administration, those that besides the general methods of investigation, they used the techniques of documental investigation, surveys, interviews and in accordance with the possibilities and specificities of each company another group of techniques to value processes of strategic administration. The investigation was made as general tendency in companies that the students worked and that they knew their processes, including the administration processes.

When outlining the investigation, we find the difficulty that most of the companies didn't authorize to that the identification of the same ones appeared in publications, to contain information that could be used by the competition among other reasons, of equal it forms the content in detail of the processes that they carried out.

Data reception and processing

Next we will present the results of summarizing the four components of the main SWOT carried out by the 54 companies about the main strengths, opportunities, weaknesses and threats that face the same ones. , as well as the summary of the valuations that the 70 students of the results made obtained in the I Diagnose of the situation in the investigated companies .

4. SWOT Analysis in the Companies.

In each one of the investigated companies they were asked them to carry out an exercise of determination at least of: the strengths, opportunities, weaknesses and threats that the leaders identify for the development of the same one.. Its realization of being possible would be made with the main actors of the strategic projection of the same one and in the face of the impossibility of executing it in that form that was carried out for the investigator on the base of the opinion interviewed with the executives, the results of the whole process of the diagnose and the investigator's own conclusions.

The main SWOT can be a very useful element, when to specify which is internally the real state of the organization and in connection with the environment. It is a diagnosis of each company and it is not possible to extrapolate to other companies. The result should be expressed in the identification of the five factors that more it influenced in each analyzed quadrant.

We carry out a classification all the factors identified in the 54 companies that you/they carried out the analysis and envelope the coincidence base in the fundamental and alone writing differences they decreased the same ones. Next they left writing down the identification of the factor for each company in the listing. Next we present the obtained results, in what the factors are included that you/they were identified among the five main in at least 20% of the companies.

Strengths

After the reduction they were 20 factors like strengths

	Companies’	%
?? Image of grateful mark and appreciated by the clients	26	48
?? Tip Technology	21	39
?? High quality of the product	21	39
?? Qualified Human Resources	20	37
?? Company’s Healthy Finance	12	22

It is of pointing out that the companies identify as their main strengths those competitive advantages that they understand that one has given them their positioning in the market.

- ?? The investigators identified that the three main strengths mark Image, tip technology and high quality of the product were based under the current conditions and not with relationship to future projections. These being still influenced by the diverse forms of protectionism that they enjoy with relationship to foreign competitors. For what they do not really give a competitive advantage distinguished in a future.
- ?? Regarding the qualified human resources, it is of pointing out the insufficient incentives and recognitions, as well as its low implication in the processes doesn't allow its appropriate use.
- ?? Alone 25% recognizes of preparing a solid financial system.

Opportunities

After the reduction they were 29 factors like opportunities

	Companies	%
?? Clients' potential growth	30	56
?? Opportunities to Export	14	26
?? Skills to develop new products	12	22
?? Joint Ventures	10	18
?? Alliances with competence	9	17

?? Most of the companies do not identify common opportunities and you specify them they do not really constitute opportunities, they were but well declarations of how to improve their internal capacities and non opportunities in the environment, what reflects a tendency of pessimism about the future possibilities.

?? It is significant that the main opportunity comes it in the potentialities of growth in number mainly of clients in base to the expansion in the national environment and in an exit toward the exterior.

?? Also comes it in the association with other, mainly to find solutions in the logistical chain and to achieve the commercialization of the product abroad.

Weaknesses

After the reduction they were 28 factors like weaknesses

	Companies	%
?? Inadequate administrative system	39	72
?? Low motivation and conflicts	16	30
?? Low Compensation to the workers	14	26
?? Ignorance of the market	11	20
?? Insufficient information systems	10	18

?? In the case specifies of the weaknesses, it is very significant that of the 28 factors identified by all the companies, 7 were expressly of administrative inadequacies, as the main weaknesses of the organization. In first I finish 39 companies, for 72% it recognized as a main factor the inadequate of the system in their group, while 30% identified the drop motivation and 26% the drop compensation of the workers. An analysis of these last two factors to exclude the repetitions in two factors for the same company, I hurtle that 22 companies, 41% identifies the motivation of the workers for diverse causes as a key factor in its weaknesses, Excluding the repetitions in taking more than a factor like nail of the weaknesses, we have that 45 companies, 83% identifies among the five more important factors from their weaknesses to inadequacies in the forms, methods and execution of its administration system or of some of its subsystems.

?? The analysis of the results obtained in the weaknesses and the results of the I Diagnose carried out they corroborate that indeed that the inadequacies in the development of the administrative systems are the main obstacle to reach the competitiveness that requires the new conditions.

Threats

After the reduction they were 20 factors like threats

	Companies	%
Foreign Competence	39	72
National Competence	30	56
Economy Problems	21	39
Peso Devaluation	6	11
Changes of Law	7	13

?? It is very significant the high level of identification of the companies like main threat that of the competition of the foreign companies with 72% and the competition of the companies in Mexican territory with 56%, when eliminating the companies that repeated these two threats, gives us that 44 for 81% of the companies that come among their main threats the competitions which reveals the uncertainties of how to improve the competitiveness of their own companies.

Attached: Analysis Results of Each One of the Investigated Elements, In Each One of the Carried Out Clusters

Profile and antecedents
In this chart they were eliminated for the publication the identification of the company and their classification according to the INEGI at the request of the management. (To see annexed TO for the results of each one of the analyzed companies).

TABLE 1. – CLASSIFICATION ACCORDING TO THE NUMBER OF WORKERS

	COMPANIES	**%**	
SMALL COMPANIES	19	32	1-50 EMPLOYEES
MEDIUM COMPANIES	19	32	51-300 EMPLOYEES
BIG COMPANIES	10	17	301-1000 EMPLOYEES
MULTINATIONAL	11	19	MORE THAN 1000 EMPLOYEES
TOTAL	59		

TABLE 1.1. – CLASSIFICATION ACCORDING TO THE FOUNDED YEAR
Three of the analyzed companies didn't specify their year of foundation, the result of the cluster gives us:

	COMPANIES	**%**
BEFORE 1980	0	0
1980 TO 1989	3	17.5
1990 TO 1999	12	67
2000 TO 2001	3	17.5

These results point to that the micro and small companies spread to disappear or to grow and to pass to another classification group, since 83% of the current ones was founded after 1999, mainly because Jalisco had been traditionally a state in the one that many small companies are believed.

If we analyze the 19 companies that have among 51 and 300 workers and the one that he/she has between 301 and 1000 the following thing it was observed

TABLE 1.2. – CLASSIFICATION ACCORDING TO THE FOUNDED YEAR AND NUMBER OF WORKERS

	51-300		**301-1000**	
	COMPANIES	**%**	COMPANIES	**%**
BEFORE 1970	1	6	5	46
1970 TO 1979	4	25	3	27
1980 TO 1989	5	31	1	9
AFTER 1990	6	38	2	18

In the first group the proportion is very small and in the second they are not able to represent a tendency of growth of the micro and small companies with the one of studying of the years, for what they spread to disappear, this means that the possibilities of survival of the micro and small companies in the last years are very limited.

Conclusion

The new conditions that they impose the third industrial revolution, the quick globalization processes and deregulations of the economic processes, they impose new and dynamics forms of administration the companies if they want to achieve competitiveness. Three key elements for this development constitute the development of a strategic thought, a more flexible organization and dynamics and a leadership shared with the workers. It becomes necessary the research of the administrative processes in the companies, even amid the difficulties to obtain the information that they are derived of cultural concepts and managerial secrets. Without the total representative ness, non deliberate samples and not slanted to will, they can reveal tendencies. The results obtained in 59 companies investigated in the Jalisco State with preliminary character and to indicate tendencies, they corroborate us the inadequacies that in the processes of strategic planning and organizational, cultural changes and of leadership they exist to face the challenges of the competitiveness. It deepens on the possibilities of subsistence and development of the micro and small company, if we endorse that in the 15 companies with less than 51 workers, none existed before 1980 and in the 16 medium companies (between 51 and 300) investigated, alone one existed before 1970. The researchers identified that the three main strengths mark Image, tip technology and high quality of the product were based under the current conditions and not with relationship to future projections. Most of the companies do not identify common opportunities and you specify them they do not really constitute opportunities; they make but well declarations of how to improve their internal capacities and non opportunities in the environment, what reflects a tendency of pessimism about the future possibilities. In the case specifies of the weaknesses, it is very significant that of the 28 factors identified by all the companies, 7 were expressly of administrative inadequacies, as the main weaknesses of the organization. In first term 39 companies, for 72% recognized as a main factor the inadequate of the administrative system in its group. The companies, 30% identified the low motivation and 26% the low compensation of the workers. An analysis of these last two factors to exclude the repetitions in two factors for the same company, I hurtle that 22 companies, and 41% identifies the motivation of the workers for diverse causes as a key factor in its weaknesses. Excluding the repetitions in taking more than a factor like nail of the weaknesses, we have that 45 companies, 83% identifies among the five more important factors from its weaknesses to inadequacies in the forms, methods and execution of its administration system or of some of its subsystems. It is very significant the high level of identification of the companies like main threat that of the competition of the foreign companies with 72% and the competition of the companies in Mexican territory with 56%, when eliminating the companies that repeated these two threats, gives us that 44 for 81% of the companies that come among their main threats the competitions which reveals the uncertainties of how to improve the competitiveness of their own companies.

Financing and Access to Medicines in Latin America: The Case of Mexico

Rosalinda Arriaga
Raul Molina
Universidad Autónoma Metropolitana, Mexico

Abstract

In the industrialized countries the forms of financing of medicines, like the financing to the services of health, is not done by the out-of-pocket money of the households, and most of those expenses are made by some scheme of co-payment or direct subsidy to vulnerable groups. But in the non-industrialized countries the main form of financing comes from the out-of-pocket money of the households, as it is it the case of Mexico. For this reason is important to analyze the prices, since its level conditions the access to a suitable therapy.

In this work some characteristics of the financing of medicines and the practices of fixation of prices of the pharmaceutical industry in Mexico appear. Also some characteristics of the forms of access to medicines are examined according to the cost of the families stratified by deciles in the case of Mexico for period 1992-2000.

1. Background

In the industrialized countries the forms of financing of medicines, like the financing to the services of health, is not done by the out-of-pocket money of the households, and most of those expenses are made by some scheme of co-payment or direct subsidy to vulnerable groups. But in the non-industrialized countries the main form of financing comes from the out-of-pocket money of the households, as it is it the case of Mexico. For this reason is important to analyze the prices, since its level conditions the access to a suitable therapy.

The oligopoly characteristics of the pharmaceutical market in Mexico allow them to fix the prices of medicines to the companies of the sector. There are many examples of price variation at local level as well as at the international one. At local level there are different prices for equal products, also it has been documented the ample divergence of prices between brand-name products and the presentations with generic formulation. At the international level there is found a similar variation, but extended its magnitude. A crucial question about the right price of medicines is still remaining, because the access to medicines continues being limited in the countries non-industrialized like Mexico.

In general terms the options of financing to the health are not neutral in relation to the fairness. The public financing of services for the health with extended schemes of social security either via taxes is equitable forms the more of financing. On the other hand, the direct collection constitutes the most regressive form and inequitativa of financing, the experience indicates that the high quotas represent a high economic barrier for the access the services of health. Of this form, the concept of inequidad in the financing can be tied with the proportion of the familiar entrance that each group destines in attention to the health.

In this work some characteristics of the financing of medicines are discussed as well as the practices of fixation of prices of the pharmaceutical industry. Also some characteristics of the forms of access to medicines are examined according to the expenditure of the families stratified by deciles in the case of Mexico for period 1992-2000.

1.1 Forms of financing in health

The financing form defines the characteristics of the protection of the population as opposed to the health risks. This can happen in three directions, of healthy to patients, young people to old and rich to poor men. The securing supposes the disposition of bottoms to cover the expenses that an anticipated disease cannot cause. The saving means the disposition of bottoms to cover the expenses, which it is going away to incur the oldness inevitably, period in which the weight of the diseases is greater. The redistribution has a social component. It supposes the disposition of bottoms on the part of which they must more to cover the less the most favored necessities with, and than in addition they have a greater frequency of diseases. The redistribution degree varies according to the financing form.

In the form in which each patient one pays the service of attention to the health (payment by event) does not take place any protection to the familiar entrance. If a cousin based on the risk pays itself that is had at every moment (as it happens in most of the systems of insurances of private type) it provides a level of protection to the familiar entrance, as opposed to the financial effects of possible future diseases, according to the conditions of the contracted policy. If the financing is of public origin (imposed and/or schemes of social security) the protection to the familiar entrance is greater than in the previous cases, since in this form of financing it incorporates redistributive elements in the population.

From the point of view of the financing the fairness of the health system can be moderate analyzing to what extent the necessity to pay the service of health is inversely proportional to the financial resources of the individual. It can be understood of two ways: a) the inequalities must be different form and b) that all those that is equal are treated in the same way. In case of countries as England and Canada the evidence sample that its form of financing is more progressive, because the groups of greater income pay a greater proportion to the systems of health in relation to the groups of smaller income. The opposite happens in the case of the United States since its system of health finances with base to deprived insurances, in where the groups of smaller income have a limited access.

The defined fairness as equal treatment for equal necessity also varies. In general in all the countries the classes very socioeconomically more worked against are those than worse indicators of health have? Nevertheless, its consumption of services of health is not directly proportional to the necessities. The evidence sample, that England is more equitable than other countries of Europe. For the case of Latin America, in Peru, the number of hospitable, which debits by 1000 inhabitants, is three times superior in the quintil of greater income in relation to the quintil of smaller income.

1.2 Expenditure in health and medicines

The expenditure in health as much in relative terms as absolute shows one narrow relation with the level of economic development of the countries. Whereas in the industrialized countries the expenditure in health as a proportion of the GNP of the 8.3% is reached, in the AL&C region it is reached 6,1 %, and in absolute terms $1.777,00 and $367,00 would be spent respectively.

TABLE 1. HEALTH AND MEDICINE EXPENDITURE BY REGION

Source: Taken from: Velazquez German ET Alius. The Sanitary Reformation and financing of medicines. Series: Economy of the health and medicines, Not 6. The WHO, 1998. WHO/DAP98.3

Like the expenditure in health, the expenditure in medicines tends to be higher in high-income countries, of such form that near 80 % of the medicine market is concentrated in the industrialized countries. The annual expenditure per capita in medicines is very heterogeneous, because while in the industrialized countries has an average consumption per capita of $138.00 in the non-industrialized countries the expenditure is sensibly smaller, thus for the LAC region it is $26.00, and in Asian countries it is $12,00 and Africa it is of $8,00 dollars. One is due to make notice that the cost annual average in medicines of Japan and the United States are of $368.00 and $311.00 dollars respectively. The expenditure in medicines absorbs a significant part of the expenditure in health in the non-industrialized countries, which has turned it a fundamental problem of public policy, because it is still had to great segments of the population that still lack a regular access to essential medicines, in good measurement by the price of such and by its forms of financing. For example, in the case of Africa it is estimated that one third of the population does not have access to essential medicines. The access to essential medicines could lower the rates of mortality caused by the respiratory diseases, of malaria and tuberculosis, as well as of the episodes of diaorrhea for which the essential medicines have an answer in union of the services of health.

The expenditure in medicines in Latin America represents 17 % of the total expenditure in health, unlike the industrialized countries where the expenditure in medicines represents 8%. According to the estimations of the World-Healt Organization (the WHO), the cost in medicines as proportion of the cost in health reaches 40 % in Thailand and Indonesia, and some African countries east percentage is superior to 50 %. Additionally the relation of the expenditure in medicines in its relation with the GNP per capita for some selected countries, where it stands out that countries as Mexico and Argentina have a high proportion of the expenditure in medicines in relation to the expenditure in health, of pocket, the homes in the acquisition of medicines very are elevated.

The average expenditure financed by the household is 40 % in the industrialized countries (Picture 1), in addition is due to consider that most of this financing is under co-payment schemes. Still in the United States there has been a change in the form of financing of medicines, because for 1965 the 92.6% of medicines were bought with the direct payment of the households and by 1998 this mechanism it only represented the 26.6%. The opposite happens in the countries of low income where the expenditure by household out-of- pocket is elevated, in contrast to countries like Japan, England where this relation tends to be very low.

3. Price of Medicines

3.1 Pharmaceutical Market: size

The global pharmaceutical market ascends to $ 337 billion dollars in 1999, the 55 % of which it is consumed in only 8 industrialized countries; the market of the United States represents 25 % of the worldwide market. The market registry, a rate of annual growth: 7 % in Europe, 12% in Japan, and 15 % in the United States. With this rate of growth, the expenditure in medicines as proportion of the total cost in health in the United States happened of 5.4 % in 1990 to 7.9 %

TABLE 2. LINAMERICAN MEDICINE MARKET (US MILLIONS 1995; MANUFACTURER PRICES**)**

Country	Private market (a)	Total Market (b)	% (a/b)
Brasil	5,416	6,908	78
Argentina	3,173	3,681	86
México	2,205	3,223	68
Subtotal	10,794	13,812	78
Colombia	1,047	1,341	78

Ecuador	200	254	79
República Dominicana	170	201	85
Total	14,471	18,058	80

Fuente: Pharmaceutical Research and Manufacturers of America. Washington, D.C., PHARMA, 1996

For 1999, the participation of Latin America and the Caribbean in the worldwide medicine market are of 6.6 %, with a projected growth of 8 % annual for the following lustrum. Brazil, Mexico and Argentina participate with 72 % of the total market of AL&C. The private sector absorbs 80 % of the market according to the data in picture 2.

3.2. Structure of Market and prices

The price of medicines, like in any other good, is determined by the market structure. The level of prices of the competitive markets will tend to be smaller to the one of the noncompetitive markets, because the barriers to the access as the patents or the registered brand names have a smaller weight, as it would be the case of medicines with generic formulations.

A recent example on the elimination of the patents in the prices is had with the victory of the patent of the Zantac (ranitidina). In April of 1995 the price of the Zantac and the product in their generic formulation were very similar, but at the en d of the patent, the price of the generic product had been reduced in 80 %, and its market had expanded 55 times in a year time.

The medicine market is a market in where the great transnational companies erect barriers to the entrance due to their elevated cost of investigation and development as well as to its elevated cost in promotion and trade, which prevents the competition in prices in this market.

The annual expenditure in (R&D) of the 8 bigger transnational companies is superior to one billion dollars. Pfizer destined to R&D $2,279 million dollars in 1998, which represented 18.6 % of the value of its sales, and an amount very similar to the value of the total medicine sales of the Mexican private market in 1995. Nevertheless the expenses of marketing and promotion are superior to the one of R&D on new products; the cost of the trade of the first year of sales of a medicine is considered about the 85 % of the value of the sales. The cost of marketing and promotion represents between 20 % and 30 % on the value of the total sales. The market control that have the big pharmaceutical companies gives the capacity them of fixation of the prices of medicines. In Literature one sees that there are different prices for similar products between different countries, prices different for same products and the great difference from prices between generic and brand-name products.

In a study of Foundation ISALUD is shown the difference of prices for equal products, with the same pharmaceutical presentation and brand-names, between the Argentine market and the Brazilian, to see table 3; for example, the Voltaren shows a difference of prices of 208 % between both countries. Carlos Galdón shows similar information for the European countries, to see table 4. The simple average of the sample selected by Galdón throws that the prices of Holland and Germany register prices 189% and 169 % superior to those of Spain. It cannot have a countable explanation for the difference of prices of 221 % for the Ventolín between the Spanish market and the German.

3.3 The case of Mexico

The medicine prices in Mexico has been analyzed comparing the prices of the public sector, with products in generic formulation and the ones of the private sector based on of brand-names products. From 1993 to 1999 the price difference of prices in the Mexican market has come extending significantly (picture 3). The evolution of the prices of medicines in Mexico as of 1993, date of the liberation of the controls of prices, shows a tendency of clear growth in the case of medicines of the private sector, against a reduction in the prices of the public sector. In the private sector the purchase is made on the basis of brand-names products, and through the direct payment of the household for the purchase of medicines.

Whereas the price of medicines of the public sector is sensibly smaller to the one of the private sector, due to the diminution of the barriers to the entrance, due to its generic formulation without differentiation of products, and with base to offering a opened manifold bidding.

TABLE 3. AVERAGE PRICES PER UNIT: PRIVADO AND PUBLIC SECTOR 1993-1999

Year	Private	Public	Difference %
1993	3.04	0.83	266
1994	3.41	0.56	509
1995	2.74	0.50	448
1996	3.58	0.54	563
1997	3.46	0.55	529
1998	4.10	0.60	583
1999	4.80	0.56	757

Source: CANIFARMA

For the analysis of the prices of medicines, also are due to detail the margins of operation of the different agents who distribute the medicine. For the Mexican market, the level of prices of medicines is determined from the price of the product in the manufacture laboratory, to which it assigns to 18.5 % for the wholesale distributor and 21.5 % for the margin of operation for the pharmacist in new products (b) and of 18.3 % for the old products (a) (picture 4); in the case of Mexico the rate of the added value tax is 0.

TABLE 4. MEDICINE PRICE STRUCTURE

	A	B
Manufacturer prices	100.0	100.0
Wholesaler prices	118.5	118.5
Retail price	140.2	144.0

Source: IMS Pharmaceutical Index Mexico. A: Products with launching to the market previous to February 15 of 1975 B: Products with later launching to the market to February 15 of 1975

Foundation ISALUD shows the structure of the margins of operation and the tax rates with which the commercialization of medicines for European Argentina, Brazil and several countries is made. This table it is come off that while in Argentina a tax is applied to the consumption of 12.8 %, in Brazil the rate is of 0 %, but in Denmark reaches 20 %. The same dispersion is had as far as the operation margins and in retail sales

4. Access to Medicines in Mexico

The financing forms subordinate the access to the services of health, since a private financing corresponds with a limited access. The inequity in the financing to medicines is related to the proportion of the familiar income that each group destines to the attention to the health. In Mexico, the financing is basically private, which conditions the form of access to medicines since its consumption is not related to the necessities of health but to the availability of household income, most of the medicine is acquired as household out-of-pocket money. 17% of the medicines are dispensed through institutional channels without the direct collection of payment.

4.1 Household medicine expenditure

In this work the access to medicines in Mexico is analyzed through the economic information that is reported in the National Survey of Income and Expenditure (ENIGH) that publishes the INEGI. With this information the patterns of medicine consumption are shown in Mexico, by income levels. For this intention the most relevant results of medicines expenditure in relation to the health expenditure by groups of income for years 1992 and 2000 appear, additionally is elaborated the curve of Lorenz and the coefficient of Gini for the mentioned periods, like measurement of the expenditure concentration. The survey allows us to compare the expenditure in health with the remaining expenditure that the families make in Mexico. The classification registers eight headings of expenditure (Picture 5) that make the homes, such as: Feeding, Dress, House, Articles of cleaning and equipment of the home, Taken care of Doctors, Transport and vehicles, Education and Tourism, Articles and Services for the personal care. The health expenditure represents for most of the layers of income around 4%. It is possible to indicate that the low layers spend more in Foods with around 50%, whereas the high layers around 25% of its total expenditure. The results are different when analyzing the participation of the medicine expenditure with the rest of the expenses in health that the families make, the income layers spend of more heterogeneous way and the medicines expenditure is very significant, in relation to the hospital attention, dental consultations, doctor's care, etc.

Source: Own elaboration from the information of the ENIGH that publishes INEGI. Third Trimester the 2000 so important increase that it has meant the cost in medicines for the different layers (deciles) from entrance, in the selected years, largely is a consequence of the increases in the prices that the pharmaceutical industry has registered, as it were in the previous chapter.

4.2 Indice of concentration

The coefficient of Gini is a concentration measurement, founded in the curve of Lorenz. This coefficient is used frequently to measure the inequality in the income. In this work the coefficient of Gini like measurement of concentration of the health expenditure and the medicine expenditure is considered. This coefficient takes values between zero and one, when the value approaches one indicates that there is a greater concentration of the expenditure, however, when the value of Gini approaches zero the concentration of the expenditure is smaller, is to say that exists a more egalitarian expenditure distribution. The curve of Lorenz is a graphical representation that shows the accumulated percentage of the income, in relation to the accumulated percentage of the households.

The estimations show that the coefficient of Gini reached in 1992 a value of 0.40 for the health expenditure of the households, whereas the coefficient for the medicine expenditure is of 0.29; which indicates that, the expenditure in health has a higher index of concentration than the expenditure of medicine. In 2000, the coefficient of Gini of the health expenditure is 0.42 and the one of medicines is 0.34. The previous results both indicate a growth in indices of concentration, but of more significant way the index of cost in medicines. (Cuadro 6)

TABLE 6.

COEFICIENTE DE GINI		
	1992	2000
SALUD	0.40	0.42
MEDICAMENTOS	0.29	0.34

Source: Own elaboration from the information of the ENIGH that publishes INEGI. Third Trimester 1992 Picture 7

In Fig. 1 and 2 are shown the curve of Lorenz for health and medicines in the mentioned years. These graphs reveal the dispersion of the expenses subjected to analysis in relation to the line of equidistribución; this line shows that to each decil of the homes would correspond 10% to him of the cost. For 1992, the results indicate that the first decil participated with the 2.2% in the health expenditure and with the 3.4% in the medicine expenditure. On the contrary, the decil of greater incomes reached 36% and 25% respectively. On the other hand, in the year 2000 shows to us that the first decil participated with the 2.7% in the health expenditure and with the 3.3 in the medicine expenditure, on the contrary the last decil reached 34.7% and 30.6% respectively.

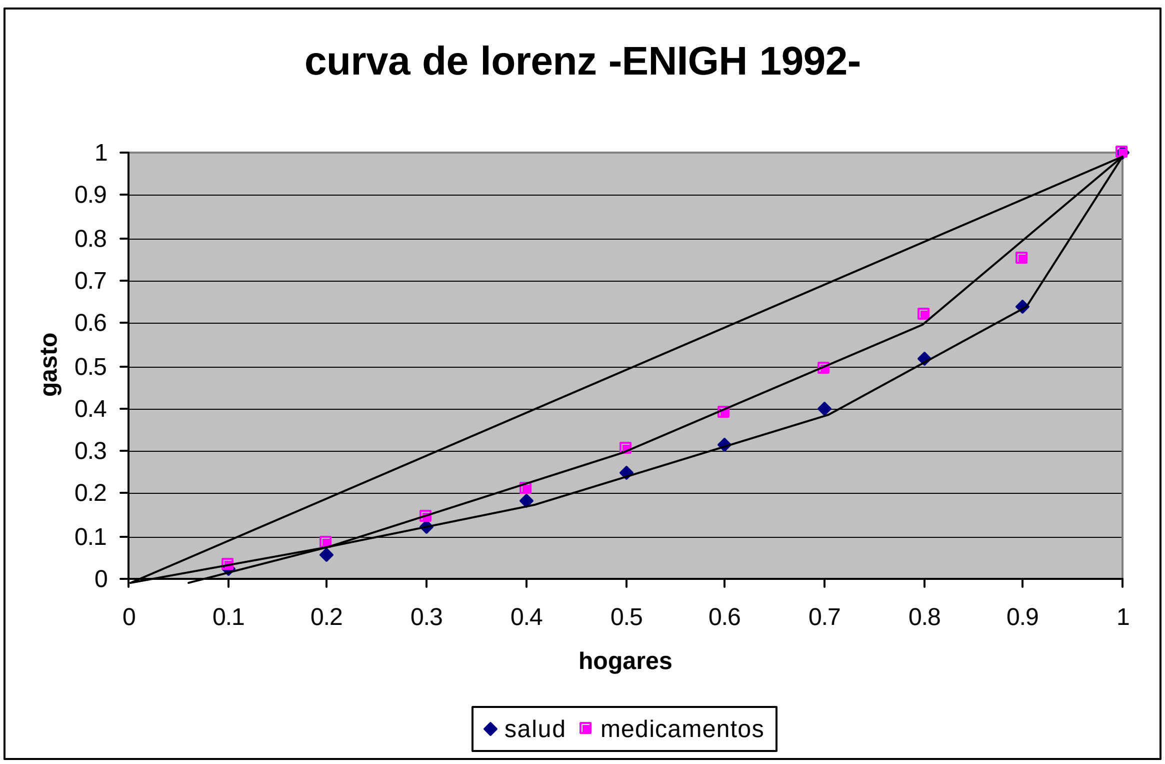

FIGURE.1.

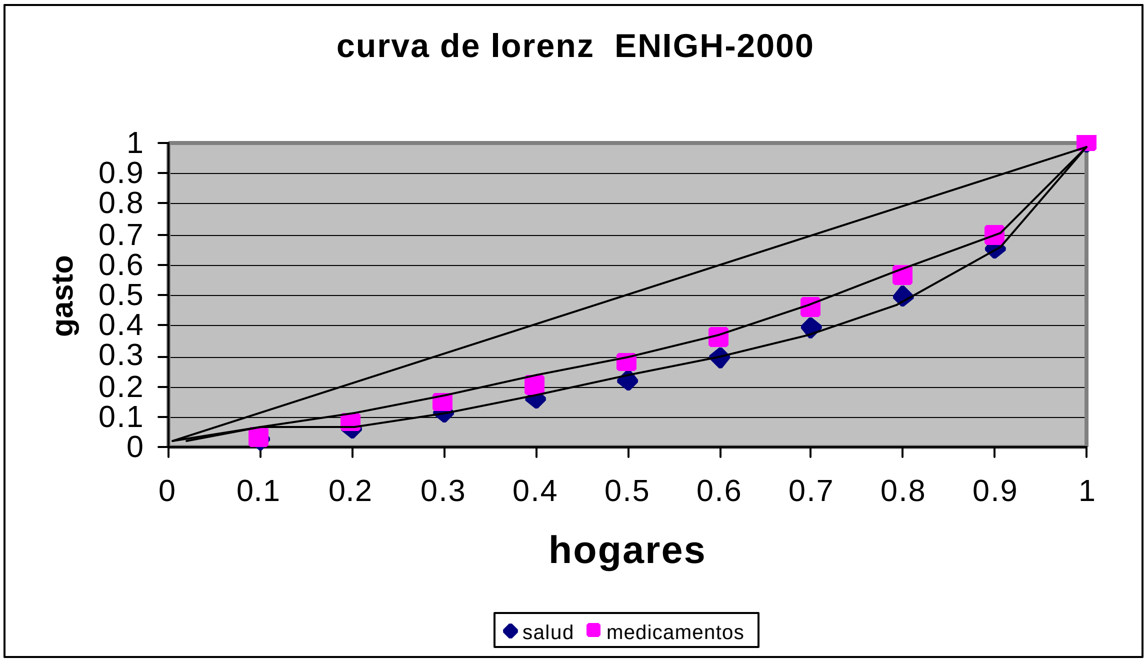

FIGURE 2.

In the period of study, the coefficient of Gini, and the curve of Lorenz shows the high concentration in the health and medicines, tendency that is accentuated in year 2000. The health expenditure in 1992 indicates that the decil of greater income is superior in 16.5 times in relation to the first decil. In the case of medicines this relation has a value of 7.3 times. For the year the 2000 health expenditure indicates that the decil of greater income is superior 12.9 times in relation to the first decil. On the other hand, the medicine reaches a value of 9.3 times.

5. Conclusion

The financing forms define the characteristics of the protection of the population facing the health risks. In the non-industrialized countries the main form of financing to medicines and in general to the health services of is by out-of-pocket money, which limits the access to a suitable therapy. The price of medicines is fundamental to define the access to drugs.

In Mexico, the pharmaceutical market is characterized being oligopolical. The great transnational companies erect barriers to the entrance with base to their elevated expenditure of R&D as well as to its elevated expenditure in marketing and promotion, which prevents the competition in prices in this market. The market control that has the big pharmaceutical companies gives the capacity them of fixation of the prices of medicines. As it is shown in this work, there are different prices for similar products between different countries, prices different for the same product and between generic and brand name products.

The evolution of the private prices of medicines in Mexico has shown since 1993 an important growth against a reduction in the prices average of the public sector. As the public sector buys the medicines in an open tender on a generic formulation without differentiation of registered brand names their prices tend to be lower than in the private sector where the purchase is made on the basis of brand names and by means of the direct payment of the families.

In Mexico, the financing is basically private, which conditions the form of access to medicines since its consumption is not related to the necessities of health but to the availability of household income; the public services only provide 17% of the medicine through institutional channels without reimbursement.

In Mexico, the private expenditure in medicines as proportion of the expenditure in health increased 37% in 8 years since 1992 to 2000. The patterns of medicine expenditure by income quintiles show that the low quintiles spend more in medicines than the high quintiles.

The coefficient of Gini for health is greater than the coefficient for medicines, in 1992 and 2000. What indicates that the cost in health is more unequal that in medicines, nevertheless deserves to stand out that the index of Gini in medicines increased in significant way by 2000.

These results show the increasing tendency of the cost in medicines that make the homes in all the deciles of income in Mexico, with a greater impact in the pocket of the poorest homes, without a doubt this growth responds largely to the characteristics of fixation of prices of the pharmaceutical market in Mexico.

For the countries of the Region of America it had to be clear that the objective of the extension of the cover and fairness in the access cannot be obtained through a financing that is sustained in the market mechanisms, in which the payment capacity depends on the level of familiar income. Still in the United States a change has been had in the form of financing of medicines, because for 1965 the 92.6% of medicines were bought with the direct payment of the household and in 1998 this mechanism only represented the 26.6%.

The expenditure in medicines in Latin America represents 17 % of the total expenditure in health, unlike the industrialized countries where the cost in medicines represents 8%. One has been that according to the estimations of the World-wide Organization of the Health (the WHO), the expenditure in medicines as proportion of the expenditure in health reaches 40 % in Thailand and Indonesia, and some African countries this percentage is even superior to 50 %.

Additionally, the relation of the expenditure in medicines in its relation with the GNP per capita for some selected countries is shown; where it stands out those countries as Mexico and Argentina has a high proportion of the expenditure in medicines in relation to the expenditure in health

The Citizen Participation in Jalisco Regarding a Social Problem of Health: The HIV/AIDS

Roberto Govela
Bernardo Bustos
Ignacio Bastidas
Universidad del Valle de Atemajac, Mexico

Abstract

In our presentation, we will expose the form as is organized the participation that have the citizens in the Technical Counsel of Ngo's with Work in Aids, of COESIDA (*State counsel Against the Aids*) Jalisco, this is determined in certain form by the international agencies, especially Unaids (United Nations Aids) Mexico and the international instances that offer financial supports. Therefore in a first moment we will speak of the general factors that supported the rise of the Mexican Ngo's, being the most important that the state has not covered satisfactorily the multiple needs that have been generated for the expansion of the HIV/AIDS; that is the vision in which the civil organizations arise and that we do reference in this study. In a second moment, we will detail some epidemiological information that will give us a referencial context of the gravity of the illness. In a third moment, we will emphasize the way in which the international instances (especially UNAIDS) have influenced in the politics of health in respect of Aids in Mexico and Jalisco. In a fourth moment, we will describe the organizational structure of COESIDA, the Ngo's that integrate the Technical Counsel and the way that the4 international instances determine their operation. Finally, we will conclude doing emphasis in the advantages and disadvantages that involves for the Ngo's analyzed, to form part of the gear of the globalization.

Introduction

In recent years in our country, the presence of the citizen participation has increased and diversified in numerous organizations, establishing links among the State and the citizens. Actually in Mexico a big part of the population, who are in situations of extreme poverty, and with their expectations not satisfied through the undertaken actions by the governmental institutions, they have been obliged to look for alternatives. Though the private institutions are constituted like an option, turn out to be inaccessible for a great majority of the population. Consequently, the Ngo's arise as a viable and accessible social alternative, since, on one way, are conformed like organized groups of citizens that negotiate with the State, that its attend properly the needs of the population and either cover in a peripheral way multiple social needs. Another factor that has determined the growth of the Ngo's in Mexico, has been the democratization processes of the national life that have permitted the expression of the people to propose alternatives to the governmental initiatives; aspect that until the end of the 70' decade of the Twenty Century was unthinkable.

In Mexico the use of the term "organization of the civil society is very recent. Some analysts have aimed the earthquake of 1985 as a critical time in the development of the Ngo's in Mexico. The reason is that the social organizations began to play, in that active moment, one more active role. In 1988 many Ngo's found political expression. Protest and daily demonstrations after the presidential elections of that year, cause that many citizens, especially in Mexico City, realized the formation of a third sector. The awake of a real and tangible opposition to the presidential Government and counting with the tested capacity to mobilize human resources and matters for the democratic cause. This event permitted that they became in assets for the organization of a diversity of groups. (Olvera 1999)

In the National Plan of Development (PND in Spanish) of the actually president, Vicente Fox, the new role of the Ngo's is mentioned explicitly and is recognized into the interaction of the State with Society. The PND promote the participation of the Ngo's in the conformation of Counsels Citizens that evaluate and monitoring the programs of the National Plan. It Said that not governmental organizations, should be for excellence the mediators among the Society and the State. The importance of the constitution of these citizen agencies is situated in the change of paradigm in the Civil relations State-Society, established in the articles 25 and 26 constitutional, these articles was proposed to reform for the table of studies of the Reform of the State, prompted by Fox and directed by Muñoz Ledo (Bastidas 2002:31).

Concretely, for the problematic of the HIV/AIDS, embedded in a social and health setting of multiple shades that have complicated the epidemic control and surpassed the strategies implemented by the Secretary of Health, the Ngo's have worried to contribute individual solutions far away of the logic and the institutional speech to the problem of the Aids, but at the same time, complementary at its. It by means of the acquisition and retro-viral distribution of medicines to subjects with VIH/AIDS; the organization of information strategies on measures of prevention oriented to the population in general, as well as, the training to voluntary groups and others.

However, it given the limited reach of the structure and operation of the own Ngo's, these have presented the need of search work alliances so much toward the interior of the different organizations dedicated to the problem of the HIH/AIDS, as toward the health sector . To this respect, the authorities of health, product of the international actions and of the resources destined to Mexico to fight the Aids, have included or taken up again in their work agendas the development of a cooperative work with said organizations.

Product of the complex social and health problematic that includes the Syndrome of Immunodeficiency Acquired in the Mexican context, concretely in Jalisco, demand the existence of proposals and multidisciplinary studies that permit to establish bonds of analysis and comprehension of said reality and that they bind the contributions provided by the medical and social areas. To such effect, the present document shows the analysis of our local context, specifically in the metropolitan zone of Guadalajara, Jalisco talks about the role and participation of the citizenship understood this as an actor that is capable to develop in a organist way and not passive, alternate solutions to the private and governmental logic that permit to integrate in complementary form, the efforts directed to the prevention and attention of the VIH/AIDS , which, for Its sociocultural and medical complexity, requires of a plural approach.

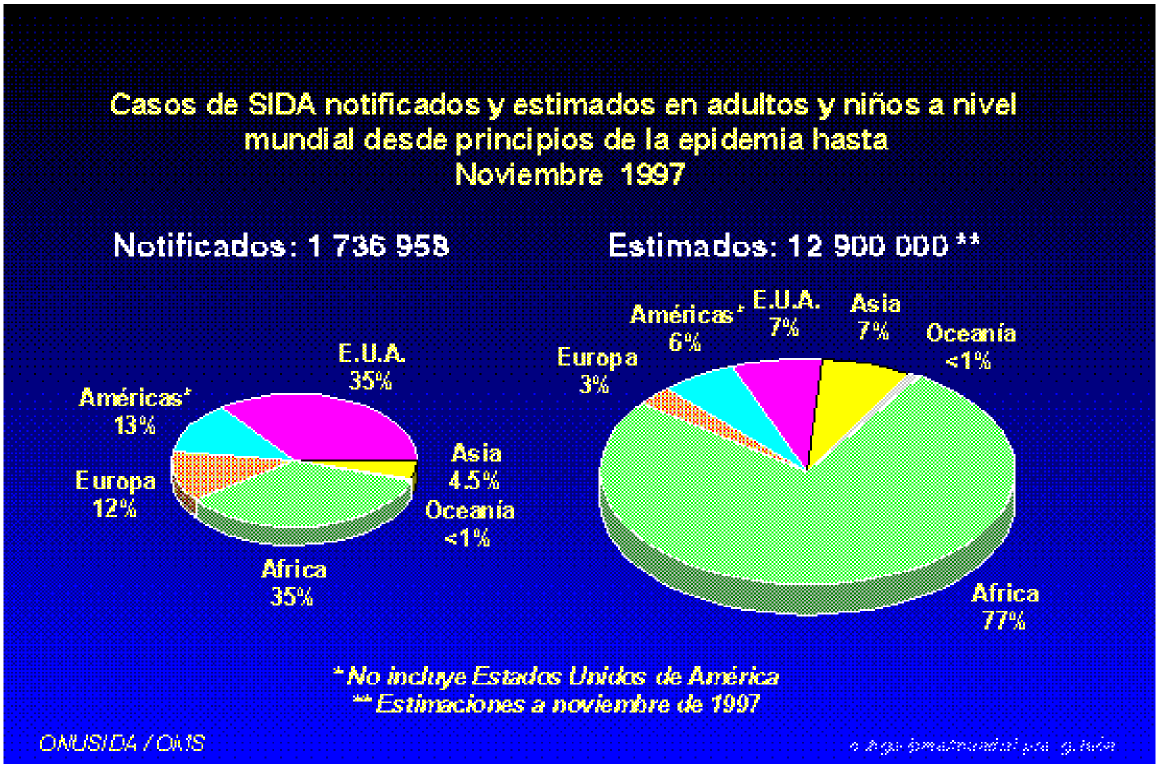
1. The Epidemiologic Problem of HIV/AIDS

At the beginning of the decade of 80´s in the Twenty Century, the first symptomatic patients of the virus of the human immunodeficiency (HIV) in a homosexual subjects captive population, and product of its quick dissemination to other groups of risks of the population in general, as the statistics show, it has obliged to carry out the unfold of large economic resources and of specific sanitary actions in a big scale, introduced first in the United States and promptly in the remainder of the world, directed to contain the expansion of the virus of the Aids. The carried out actions were directed primarily to the development and utilization of a specific pharmacology products oriented to fight the multiplicity of opportunistic pathogenic agents, as well as the installation of antiviral medicines capable to diminish the viral reproduction in the infected subjects. In second_point, carry out the epidemiological implementation of actions directed to the identification of the sexual contacts and the preventive creation of actions in viral terms of dissemination.

Nevertheless, the expansion of the HIV/AIDS covered in progressive form all the groups and social strata of the world, obliging the organizations involved, to reconsider the illness as an infectious syndrome acquired of pandemic scale: until 1997 he data reported by the UNAIDS (United Nations Aids), branch of the United Nations, responsible for coordinating the world sanitary actions in term of the Aids, registered 1,736,958 (notificated cases) comparing with 12,900,000 estimated. (Table 1)

In Mexico, the worry and sanitary aid in matter of HIV/AIDS, preferably has been oriented to the preventive development of strategies in epidemiological aspects, and of specifies attention to the health of bearers subjects groups of the virus of the human deficiency, not achieving with it to impact significantly in the development of new cases: In 1998, continuing with Ramos Jiménez (2000:16) in our country the official figure went of 38,000 cases, nevertheless the figure is undervalued, since the same one UNAIDS registers around 180 thousand cases. Besides in our country an expansion of the virus VIH/AIDS has been observed toward the rural zone by means of a phenomenon called the "ruralizatión", finding an algorithmic growth due to the shortage and limited health services presence in said zones, by the under educational level of the settlers and the difficulty of speaking of sexuality and sex. Finally, the main middle of broadcast is the sexual contact done not protect, observing a decreasing broadcast of man-man, man-woman, woman-man, and rare times woman-woman.

TABLE 1: AIDS CASES IN THE WORLD



Specifically, in the case of Jalisco, the extension of the illness, to June 30, the 2002 (period 1983-2002), situates to our state, in the third place in the national environment, with a total of 5,768 official cases. To understand the magnitude of the problem, of the total of cases registered since 1983 to the 2002 in the national environment, the 58.3% of the patients pass away and the 5.8% its state does not know itself, what adds a 64.1%. Likewise, in the 90.4% of the cases, the medium transmitter is the sexual one; therefore the blood broadcast has gone decreasing (9%) (National Counsel for the Prevention and Control of the HIV/AIDS)

As shows the Fig. 1, the zone of red that corresponds to the municipalities of Cuquio, Ixtlahuacan del Rio, Zapotlanejo and Tonalá are the areas that have the highest rate with 7. continue in order of importance, the municipalities of Tlajomulco de Zúñiga, Ixtlahuacan de los Membrillos and the municipalities that surround to the ZMG (Metropolitan zone of Guadalajara) (in blue but in smaller size) (Tlaquepaque and Zapopan) as well as the municipalities (in yellow) that surround to the Lake of Chapala. (In blue, but of greater size) The interesting thing is that the interior of the areas in red and yellow, concentrate a little more than 3 and medium millions of persons, by which, the number of persons infected HIV/AIDS is very high, since in the remainder of the municipalities we situate near two million of inhabitants.

In that sense, the majority of the civil organizations that have been created around the problematic of the Aids have its headquarters in the ZMG and implement its strategies in base to its relation with COESIDA and have like spatial framework the City of Guadalajara and its outskirts (Zapopan, Tonalá, Tlaquepaque, Zapotlanejo, Tlajomulco of Zúñiga,, El Salto and the municipalities close to the lake of Chapala) that mean, areas with more cases.

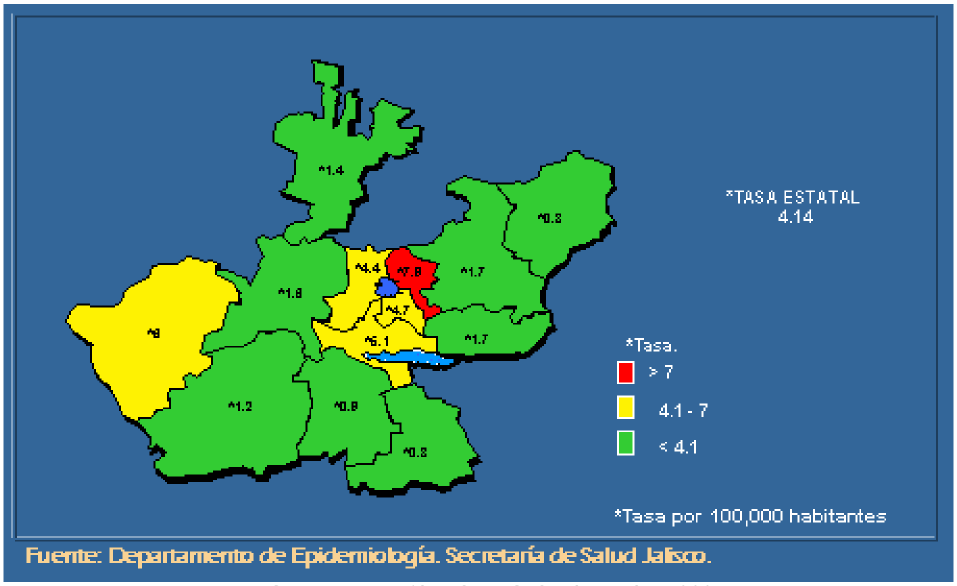


FIGURE 1: HIV/AIDS REGIONAL MAP 2000

The tables 2 and 3 represent, perhaps the most worrying data of the Aids: Its direct impact in the youth and in the adult phase, since the highest incident of cases is given among the 25 and 44 years, that is to say, during the most productive periods for the human society. From there not being strange, that the persons that compose the organizations of the civil society worried about this problematic, been in a majority way, youths and adult youths.

TABLE: 2 AGE GROUP INCIDENCE 2000

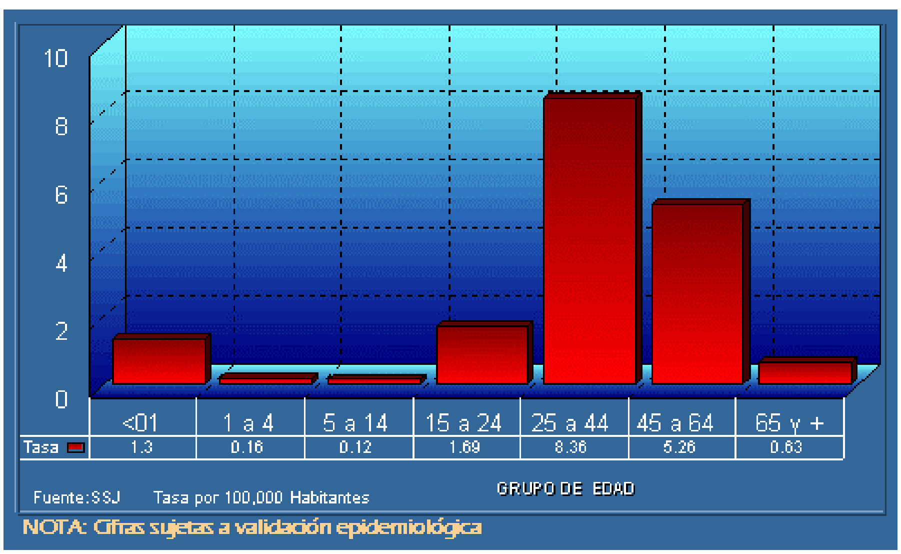

TABLE: 3 AGE GROUPS CASES

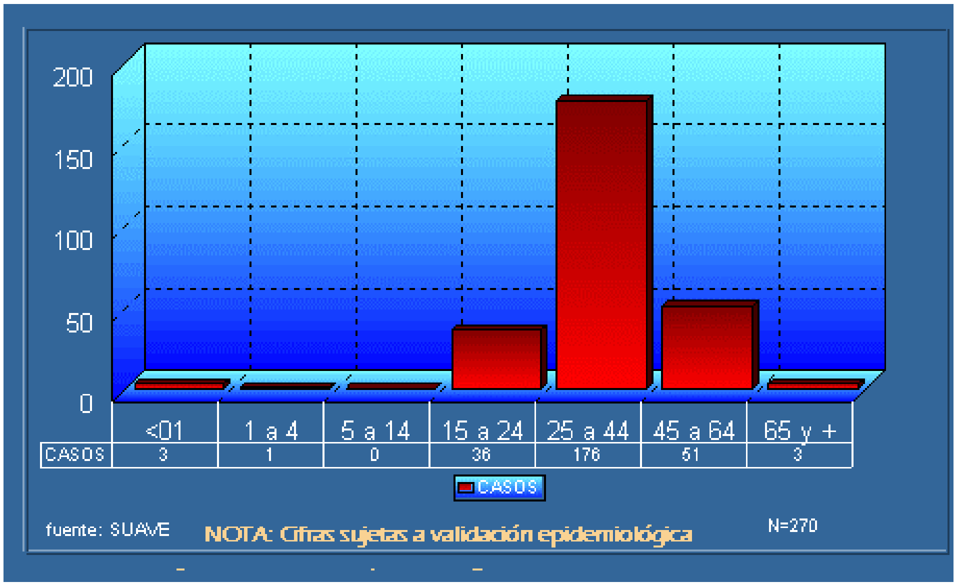

2. The Influence of International Organizations in Mexico Opposite to HIV/AIDS.

The HIV/AIDS being a world illness of reaches, obliged the international rise of instances linked to the United Nations, which, to be more efficient, have sought - since 1987 when the "badly of the century" obliged various countries to request supports - strategic alliances with international agencies financiers. Likewise, especially because of the rise of UNAIDS (at the beginning of the 90) and its installation in Mexico (1995) the fight against the HIV/AIDS in our country and Jalisco have been determined by these global instances, spreading like center of its strategy, the participation of the citizens in Ngo'. We see the details.

The participation of the United Nations in the fight against the Aids is mended in 1987, when the "United Nations Development Programme" (UNDP) began to receive of the governments support petitions –among them the Mexican - to the programs of fight against the HIV/AIDS (www.un.org/organismos/grupos/SNU23106.html) In answer to those petitions, that same year was formed in Mexico the first Mexican agency specialized in the fight against this badly: The National Committee against the HIV/AIDS. A later year is created the National Counsel Against the Aids (CONASIDA) with financing - among others international instances - of UNDP and the World Bank Continuing the tendency of the central Mexican political of the epoch, they arose to way of retorts, the State Counsel Against the Aids in the states, among them COESIDA (State Counsel Against the Aids) in the state of Jalisco. (www.conasida.org.mx)

At the beginning of the decade of the 90' of the century XX, the instance by excellence in the fight against the Aids is created: UNAIDS which takes up again the idea of the red tie that in 1991 a U.S. group of artists utilized to call the attention on that problem and it was incorporated to the logo of this world organization, being at present symbolic. In order to establishing a connectional cooperation more specialized, UNAIDS promoted the multinational integration of agencies of regional type, to create fronts of fight better orchestrated. One example of them, in case of Latin America, is the creation in 1994 of the Latin-American and the Caribbean Council with organizations that work with HIV/AIDS (LACCASO) having in their first members Mexico, Costa Rica y Venezuela. Being incorporated a later year (1995) Mexico to the countries where UNAIDS has presence.

A transcendental event inside these efforts of world strengthening against it pandemic, happened in 1996 on January first with the integration of the sponsor member that gave it an important financial support.The eight UNAIDS cosponsoring agencies are:

- ?? United Nations Children's Fund (UNICEF)
- ?? United Nations Development Programme (UNDP)
- ?? United Nations Population Fund (UNFPA)
- ?? United Nations Office on Drugs and Crime (UNODC)
- ?? International Labour Organization (ILO)
- ?? United Nations Educational, Scientific and Cultural Organization(UNESCO)
- ?? World Health Organization (WHO)
- ?? World Bank

Speaking of the influence that has UNAIDS in Mexico we find that since its foundation in our country has sought to give him, on the one hand, a direct support to CONASIDA (spreading for result, a weight in the restructurings, decisions and strategies of this public agency) and by another, supports to Ngo's that perform works in Aids.

Inside the first aspect we can comment that the Framework of Action of the Operating System of UNAIDS Mexico is supported in three parameters: 1) Objective of the P.N.D. 2) The Strategic Note of the Country (SNC) that is the document that orients the politics of the Government of Mexico for the mobilization of resources of the outside, particularly, the coordinated through the United Nations system.

As for the second aspect, we situate the program of "Institutional Strengthening of Ngo's with work in Aids" for to be supported, should cover the following requirements:

a) Coherence in the design, implementation and evaluation of projects
b) Location in strategic geographical areas where there be greater incident of the pandemic, in order to facing the fight against the Aids in Mexico
c) Collective Benefit in its projects (not exclusive for specific groups)

(www.un.org/organismos/grupos/SNU23106.html)

An example of both aspects, can be illustrate with the role that has UNAIDS Mexico as for the negotiation of resources with the financial system Breton Wood (formed by the I.M.F and the World Bank.) was the credit of $ 350 MDD that the World Bank offered to Mexico to develop – from the 2001 –of the "Program of Quality, Equity and Development" where is oriented the fight against the VIH/AIDS, on the one hand, to the health attention networks creation that seeks that all the instances of health of the country be involved in this fight and by the other, the utilization and training of the Ngo's as to apply different suitable media actions of information, education and communication in Well of the community. (www.un.org/organismos/grupos/SNU23106.html)

As for the case of the networks of Health, we find that one of the main proposals of the new National Counsel for the Prevention and Control of Aids (that replaces CONASIDA from July of the 2003) is the inclusion of all the public instances of Health of the country in the fight against the Aids, together with the acceleration of decentralization processes of the health public services, political established for to be executed through the lending of the World Bank. Speaking of the intervention of the Ngo' s in the governmental actions, we situate the case of the inaugural Meeting in November 2001 of the Committee of Monitoring and Evaluation of the CONASIDA where was integrated to the civil Society ; the academy; the federation companies; the health institutions (IMSS/ISSSTE/SEDENA/PEMEX) (Mexican institute of the Social, Insurance Social Institute of Security for the Workers of the State, Secretary of the National Defense, Petroleos Mexican, respectively); other instances as the National Institute of Medical Sciences and Nutrition Salvador Zubirán and the Program of quality, equity and development in Health. (PROCEDES); and the CENSIDA (National fund for the patients of Aids), with the objective to structure an evaluation that permit to link the actions and the proposals of this agency. (www.conasida.org.mx)

It is interesting to make out how the credits of the international instances, of some way they have been related to the changes of the governmental instances of health, as for that promote a greater citizen participation in their actions, on the one hand, and by another, restructure their structures orienting them each time to the support networks idea and the decentralization. Subsequently we will speak of COESIDA, Jalisco and the influence that has this international context in their organization, and their bonds with the Ngo's local.

3. The Operation of the COESIDA and Its Bonds with the Local Ngo's

In Jalisco State , by decree of the governor Enrique Álvarez del Castillo,, the State Counsel for the Prevention of the Syndrome of immunodeficiency was created (COESIDA) in 1988, that works in coordination with the national programs and with the national Agency CONASIDA; and in 1995 was restructured, being conformed 3 General Co ordinations: Sub counsel , Admo. and Accounting and Decentralization, just as the Figure 2 illustrates.

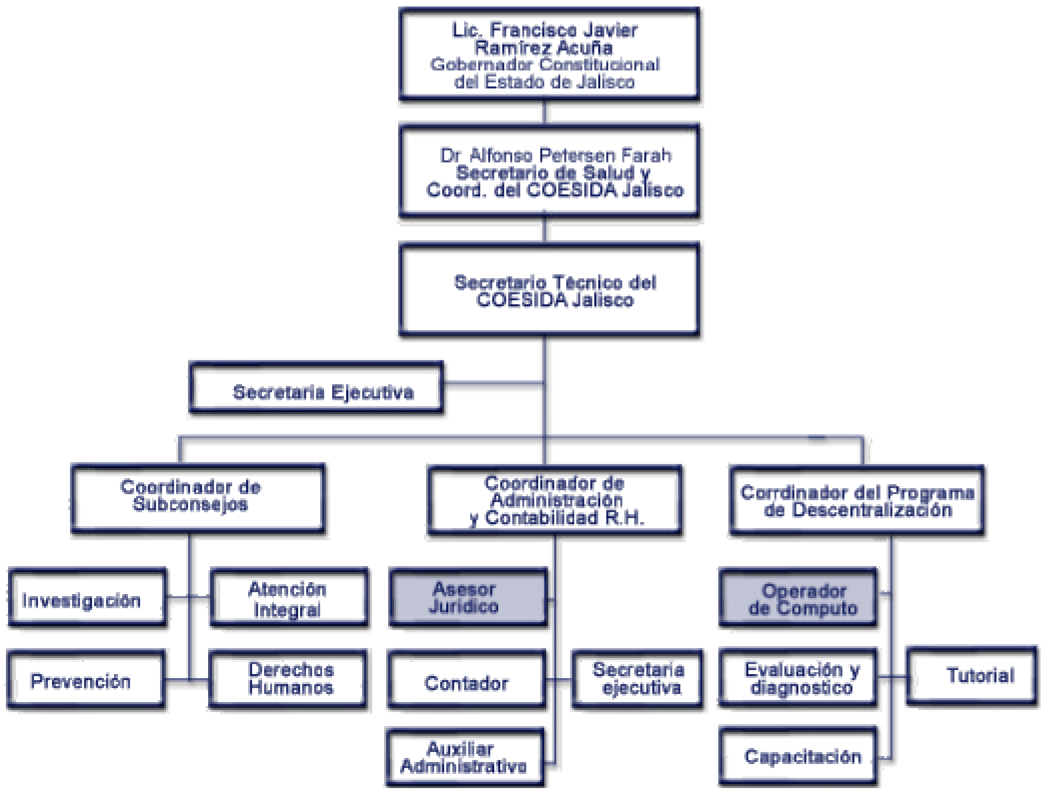

FIGURE: 2 CHART OF COESIDA

Of the first one, four subcounsels are removed directed to undertake the different areas of the priority work in VIH/AIDS in the State:

· Investigation
· Prevention
· Integral Attention
· Human Rights

The Administrative General Coordination counts with a legal area of advising, takes charge of the correct application of the financial, material, and human resources as well as of the legal matters of the COESIDA. Finally the Coordination of the Program of Decentralization three departments depend: Tutorial, Training and Advising, Evaluation and Diagnostic, that take charge of the work to municipal level with the COMUSIDAS. (Municipal Counsels of the Aids)

Of complementary form, was structured from the 2001, a Technical Counsel of Ngo's With Work in Aids, composed of 11 civil organizations representative of the Jalisco's Society that are entrusted, in a priority way, in the work in favor of the Aids in coordination with COESIDA. The organizations that conform them, and that are our subject of study are:

- Amigos Previniendo el Sida
- Colega
- Checos
- Homo Sapiens
- Lazos Unidos por la Vihda
- Mesón de la Misericordia
- Proyecto Azomalli
- Ser Humano
- Vida Positiva
- Vihas de Vida
- Viva la Vihda.

At present the Coesida, presents to the interior of its organization activities that permit to add efforts since different perspectives of analysis and work. With it, the incorporation of forty-seven representative ecclesiastical, university, and governmental instances of the Society in Jalisco, as for example: the CEDH (State commission of Human Rights), Civil Hospitals of Guadalajara, IMSS (CLÍNIC MENCHACA) S.S.J (Secretary of Salubridad of Aid)), S.S.A., I.S.S.S.T.E., CODE (State Counsel of the Sport) Jalisco, The City Hall of Guadalajara, Zapopan, Tlaquepaque, Tonalá, PGR (Procudaduria General of the Republic), SEDENA, ITESO (Technological Institute of Upper Studies of West) U.D.G. (University Of Guadalajara) and D.I.F (Integral development of the Family); as well as diverse civil organizations as Azomalli A.C., Homo Sapiens A.C., Vihas de Vida, Mesón de la Misericordia Divina, Vida Positiva A.C., Colega, Amigos Previniendo el Sida A.C, Checcos. A.C. Frenpavih, Voluntariado de Tanatologia A.C, Medical Association of Jalisco and Mexican School of Civil Sexuality Association (ssj.jalisco.gob.mx/coesida/index.html)

As for The fear of discussion, we observe, on the one hand, that the restructurings that had COESIDA in 1995 and the 2001, coincide with the installation of UNAIDS Mexico (1995) and on the other hand, with the strategy of this world agency to utilize to the Ngo's, on the one hand, as intermediaries among the global instances for the obtaining of supports, and by the other, as a middle so that the citizen integrated in Ngo's carry out activities that previously were developed for the state (in its charitable phase).

Is curious, the existing coincidence among the program of UNAIDS of "Institutional Strengthening of Ngo's with work in Aids" and the name of the instance of COESIDA that works directly with the local not governmental organizations , named "Technical Counsel of Ngo's With Work in Aids". Also is worthy to note that the organizations integrated to this technical counsel, receive supports of the Government of the State of Jalisco (that at the same time receive funds of the Government of Mexico and of course of the World Bank.) by which develops a chain of commands, where the politics against the Aids are gestated in international instances and contextualized according to the strategic note of the country, the health Objectives contemplated in the PND, to finally arrive to the state instances of health. While Ngo's of Mexico City, as "Collective Sun of Mexico" of some way has himself "globalized" (in the sense that since 1995 guard bonds with Latin-American Ngo's and of other countries) the organizations that fight against the Aids in Jalisco, does not have a clear tie with organizations of other countries. The interesting thing of this, is that in spite of not existing these relations, these instances of citizens, are affected for the globalization, but in a passive form, that is to say, orchestrate part of their continuity, in base to the financial supports that receive of COESIDA, but without questioning them or to seek supports of all types in Ngo's of other countries that permit them to have a vision of assembly in this problematic .

Conclusion

Today is undeniable the exponential growth that the Aids epidemic has come presenting everywhere. In Mexico this quick and maintained expansion of the illness has caused an on health services demand in the different governmental institutions, causing that these institutions be found in a situation of cover and insufficient service. Before these limitations in the quantity and quality of the services offered to the population of patients with Aids, the civil society is organized in Ngo's since a different logic to the institutional speech, with complementary actions oriented to supply said lacks: acquisition of antiviral medicines, obtain of cares and psychological accompaniment to terminal patient, legal advising, hospitalization and preventive programs of education toward the illness. In Jalisco, as in the remainder of our country, the different Ngo's have come developing a presence and progressive participation each time more noticeable in our society, product of the efforts and actions undertaken during its period of existence. Nevertheless, the international pressures of economic character toward Mexico and the external influence on the health politics planning in matter of HIV/AIDS, have installed the conditions and adequate social settings capable to promote and to maintain the citizen participation and to include the civil Society in the supervision of the governmental actions and in the decisions' takes to the interior of the state counsel against the Aids. However, to be inserted the Ngo's in the processes of globalization, It involves specific advantages and disadvantages, that as already was mentioned, keep a passive relation with the same one, simply continuing the established politics by the international instances, in which receive, in an indirect form, the financial and technical supports. This is a disadvantage since its survival, in one way, depends on these politics and the supports that accompany them and if don't adapt themselves, they wont have a continuity. So, that this relation was profitable, have to be established linking with International Ngo's that will open financing opportunities alternate to UNAIDS, as well as processes of contribution and exchange of experiences and points of view on the development of the HIV/AIDS in other latitude. Because of it, we consider that the citizen participation could exercise a strategic and significant intervention since the present problem of health and to guarantee its continuance, upon meeting four conditions:

1. Creation of an adequate system of structure and organization with clear definition of positions and functions.
2. Utilization of adequate sustainable of auto financial mechanisms through the fiscal exercise of donations and perceptions.
3. The professional training of each member in specific activities indicated in the profiles of positions.
4. Establishment of work alliances to the interior of other not governmental agencies as toward the different governmental dependences of health.

Foreign Direct Investments and Efficiency of Structural Changes in Local Economy: The Case of Lithuania

Manuela Tvaronaviciene
Vilnius Gediminas Technical University, Lithuania

Abstract

The paper deals with foreign direct investments (FDI) in Lithuania. An issue of priority is to determine if inflow of foreign capital in all cases contributes sufficiently to development of national economy. Investigation of controversial impact of FDI on Lithuania is based on theories presented by concise review of the literature examining the role of FDI in transition economies. The detailed analysis of FDI directed to different sectors of Lithuanian economy let to determine cases when globalization retards economic development of host country.

Introduction

In the context of European Union enlargement and economic restructuring of national economies transition countries usually see inflow of foreign capital as an issue of priority. Such an approach to FDI, as a rule, dictates appropriate policy of government directed to providing of various stimuli to foreign investors. Meanwhile, certain cases raise doubts if globalization unconditionally guaranties growth of productivity, increase of quantity and quality of provided goods and services.

Presented analysis of FDI in Lithuania is aimed to segment inflows of foreign capital and quantitatively evaluate impact of different investments on growth of Lithuanian economy. Analysis of segmented by sectors of economy FDI in Lithuania would let to identify cases when globalization represent certain risk for transition countries.

Theoretical background of analysis

Theoretical discussion concerning impact of FDI on host country economy focuses on whether globalization of foreign enterprises contributes or retards development of local economic entities.

Positive approach to globalization is dictated by a most cited possibility that FDI generates productivity spillovers for the host economy [1]. One idea is that multinational enterprises possess superior production technology and management techniques, some of which are captured by local firms when multinationals locate in a particular economy. A related source of spillovers is forward and backward linkages between multinational and host-economy firms [3], which may result from multinationals providing inputs at lower cost to local buyers or by their increased demand for inputs produced by local suppliers. Despite spillovers are key factor supporting positive impact of globalization, but their existence and magnitude difficult to establish empirically.

Negative approach to globalization is represented by view, according which multinationals mostly are oligopolistic companies, locating in protected markets with high barriers to entry and increasing market concentration. They extract rent, siphon off capital through preferred access to local capital markets, and drive domestic producers out of business [2]. To continue presented view we could add, that special favorable conditions guarantied by high barriers of entry don't encourage increase of productivity in terms of increased quality or volume of production. That finally means that globalization in such a case don't contribute sufficiently to development of host country economy. Despite presented view is more characteristic for earlier researchers, as we will show later it still can be attributed to very topical issues.

To summarize key results of the literature on globalization impact on host country economy, we have seen that in theory FDI impacts national welfare in two diametrically opposite directions: on the one hand it raises the productivity of domestic economy but, on the other hand, it drives domestic producers out of market, endeavors favorable uncompetitive position in the market, which can lead to appropriate loses conditioned characteristic by monopoly.

Controversially evaluated role of cross-border capital flows dictated the angle of presented investigation. The assumption has been made: the composition of capital flows finally dictates impact of FDI on development of national economy. Hence, it's composition of FDI by sectors of economy and magnitude of investments, what ultimately matters, when impact of globalization is scrutinized.

Methodology of research

In quantitative terms economic growth the most accurately could be expressed through increase of volume of produced goods and services provided during specific period of time, or to put it into another words, though increase of Gross Domestic Product (GDP). Aiming to evaluate impact of segmented foreign capital inflows on growth of host economy the following approach has been adopted. A premise has been made that the correlation between GDP and separate inflows FDI, expressed as percentage share of total FDI directed the country, represent a most accurate measure of efficiency of globalization of separate sectors of economy. Hence, in presented paper emphasis has been put on percentage composition of FDI rather than on absolute values of FDI expressed in monetary terms. Such approach finally lets to take into account change in magnitude of FDI flows directed to certain sectors of economy, when absolute value of the same indicator doesn't provide possibility to focus on impact of dissemination of FDI on national economy. Finally, concentration on FDI structure leads to comparison of it to present structure of GDP by economic sectors, and, consequently, to prediction of future trends of restructuring economy of host country.

Analysis of FDI tendencies in Lithuania

Foreign Direct Investments according methodic of International Monetary Fund (Detail Benchmark Definition Foreign Direct Investment) are such investments on basis of which long-term relationships and interests between FDI investor and host enterprise have being formed [4]. Limit of 10 and more percent of common process of management of enterprise-recipient of capital. Hence, only investments exceeding the pointed out limit are considered as foreign direct investments and represent target of our investigation. Characterizing definition of FDI, it should be noted, that criteria applicable to FDI identification don't involve aspects related with mode of investments have been made. Hence, "green field" investments in these terms have been equalized to privatization revenues, what from the point of view of economic grow, the most probably, will generate quite different effect.

There could be distinguished three stages of globalization process in Lithuania. The first stage continued till 1991, the second lasted from 1991 to 1996, and the third stage has started in 1996. The laws regulating processes of globalization in Lithuania have been adopted comparatively later than in other transition countries. This factor is considered to be not of the least importance when trying to identify main reasons of globalization tendencies presented below.

Hence, the more significant inflow of foreign capital started only Lithuania regained its independence in 1990. In this year economic reform started and the main laws regulating economic activity in market conditions were adopted. This point in time is held as the actual beginning of transition and globalization processes. Notably, that in year 1991 it was recorded seven times more joint ventures than during three previous years and FDI reached 32 mln. Litas. During the very first years of transition rate of FDI growth was insignificant, most probably due to instable economic situation on country: the first years of independence were characterized by high inflation, series of bank crises, vague conceptions of future economic reform etc. Situation gradually improved and in year 1994 completely stabilized. Therefore we have chosen this year as initial point for our more thorough analysis of FDI tendencies.

Since 1994 speeding up economical reform, growing GDP and more stable economical environment measured by significantly reduced rates of inflation played key role in attracting foreign capital into country (FIG. 1). Intensive privatization stood for the main form of foreign investment and could be identified as one of the most important channels of FDI inflows.

More close view to FDI dynamics in Lithuania leads to observation that the major part of interested in globalization foreign firms entered market of the host country during the first several years after independence regaining. According poll organized by Lithuanian Development Agency [4], e.g. in 1996 more than 60% of new FDI were made by investors, who were increasing scale of their activity in Lithuania, i.e. only 40% of capital inflows came from new foreign firms. Scrutinizing process of globalization in numerical terms we have to emphasize that in 1998 total amount of foreign capital flows equaled to one, which was directed to Lithuania during a whole period from 1994 to 1997, and up to year 2001 FDI increase compared with 1996 was several times greater. Again, privatization in years of higher FDI played rather important role in attracting capital flows.

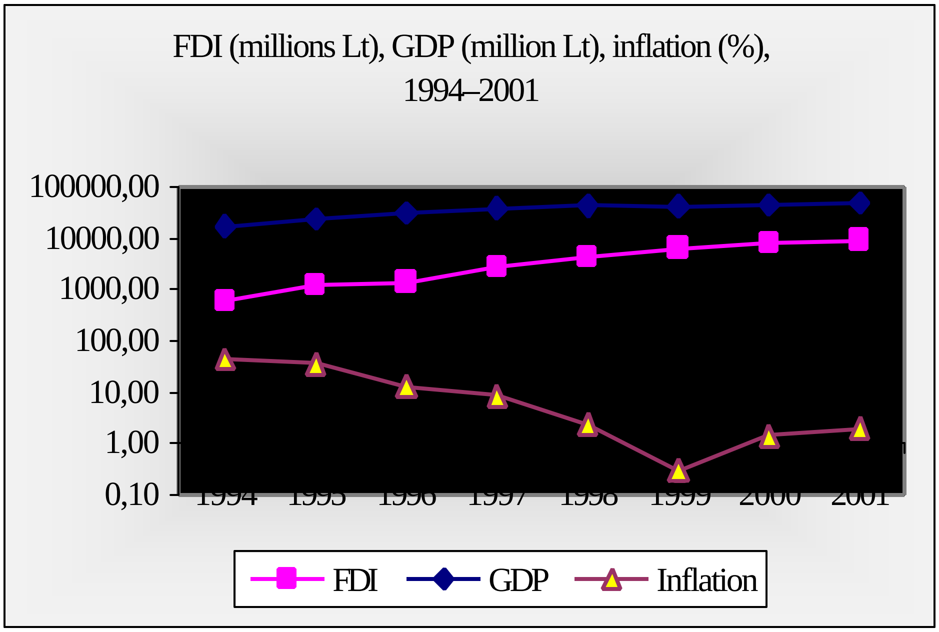

FIG. 1: FDI, GDP AND INFLATION DYNAMICS IN 1994-2001

Final target of presented investigation is to determine if inflow of foreign capital in all cases contributes sufficiently to development of national economy. Such approach to globalization efficiency requires detailed analysis of FDI composition by different sectors of economy. Detailed analysis of FDI composition should start from identification of main targets of interest of foreign investors. Lithuanian GDP structure by sectors of economy (Appendix 1) lets to distinguish four main branches of Lithuanian economy: services, industry, agriculture and construction.

Close look to FDI structure (FIG. 2) reveals that foreign investors have found those branches of Lithuanian economy not equally attractive.

Distribution of FDI among main for Lithuania sectors of economy has been quite uneven. As we see, foreign investors have expressed obvious interest in service sector. Notable, that comparatively higher investment into services vis-à-vis production corresponds to tendencies of global economy: in many countries structure of economies shifts towards services sectors. In Lithuania percentage share of FDI put into service sector in 1995-2001 increased from 47.95% to 66.0%. Especially increased FDI share directed to financial intermediation (FIG. 3). Privatization of Lithuanian Savings Bank and Agricultural Bank significantly contributed to latter increase of FDI share. Telecommunication sector also attracted comparatively high FDI. Privatization of such public monopoly as Lithuanian Telecom and intensive development of mobile communication have conditioned significant inflows of foreign capital. “Green field” investments have been more characteristic for wholesale and retail trade sector (in FIG. 3 dynamics of FDI into main activities of interest comprising service and industry sectors is presented).

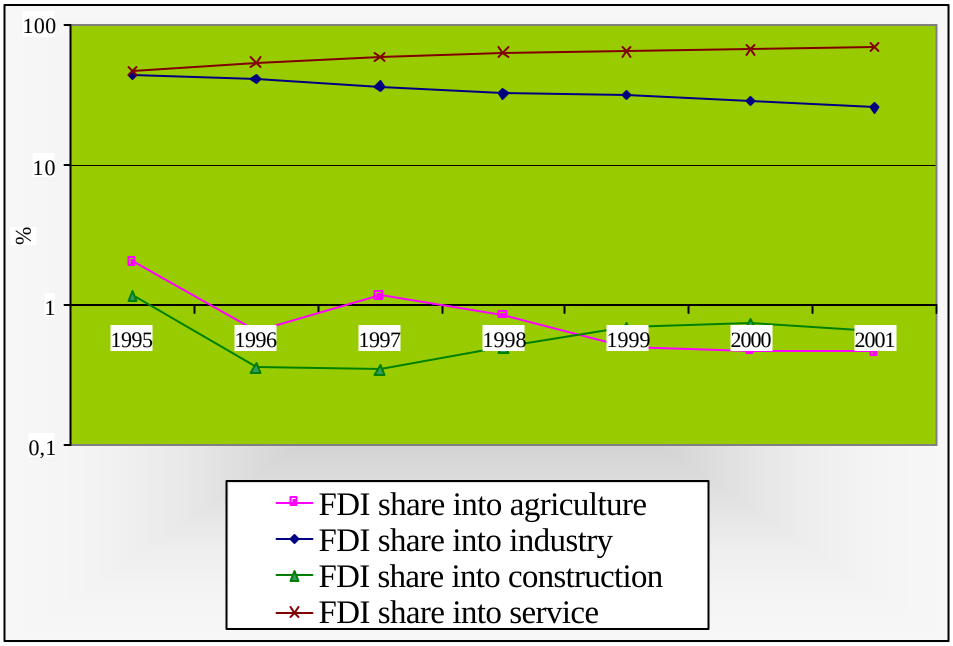

FIG. 2: FDI STRUCTURE BY MAIN SECTORS OF LITHUANIAN ECONOMY IN 1995-2001, %

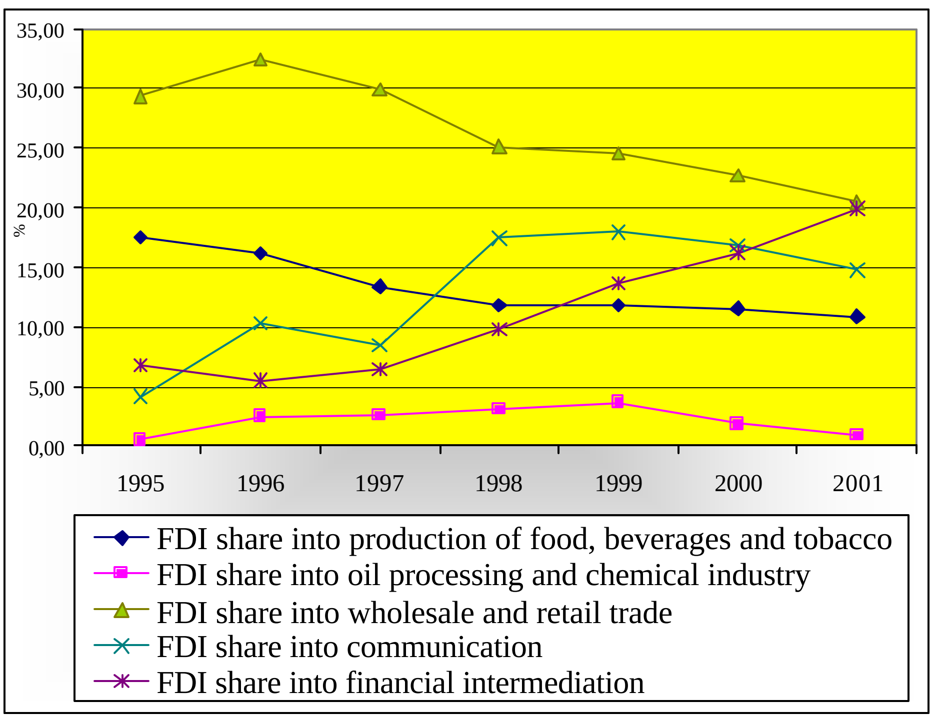

FIG. 3: FDI PERCENTAGE DISTRIBUTION AMONG THE MAJOR TYPES OF LITHUANIA ECONOMIC ACTIVITIES.

Inflows of FDI into industry sector in 1995-2001, in contrary, diminished from 44.13 to 28.0%. Foreign investors expressed interest in food, especially milk, processing, electronics, electrotechnics, light, chemical and oil processing industries. Nevertheless, the major part of investments in this sector has been directed into food processing, while interest in other activities was rather vague (FIG. 3).

As concerns such important for Lithuania sectors of economy as agriculture and construction, they, alas, as it has been shown in FIG. 1, attracted comparatively small capital inflows: share of FDI to each sector during period of 1995-2001fluctuated about 1%.

Agricultural sector historically has played very important role in Lithuanian economy. Now it comprises only 6% of GDP, but in this sector more than 21% of labor force is engaged. Hence, obvious low productivity of agricultural sector remains an urgent issue. Lack of interest from the side of foreign investors means that Lithuanian situation continue to be quite complicated and have to be improved by engaging local scare resources. Joining EU with all restrictions and regulations and high competitiveness in agricultural sector even more sharpens question of dealing with unproductive sector.

Analysis of composition of capital inflows of foreign capital showed that it doesn't correspond to composition of GDP. That means that FDI finally conditions restructuring of national economy. Tendencies of GDP restructuring (FIG. 4) in principle correspond to FDI dynamics what lets look at globalization processes as one of the main factor determining shifts in composition of national economy.

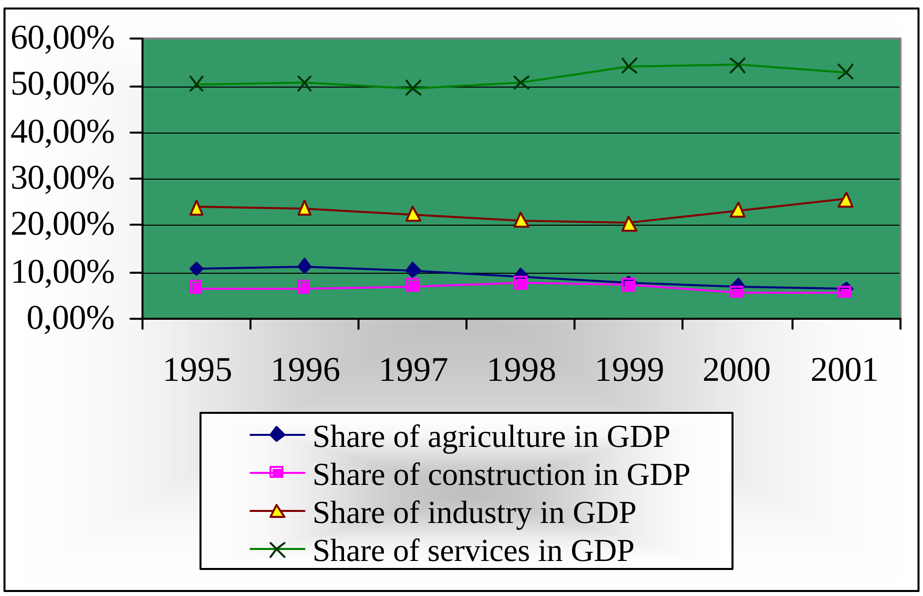

FIG. 4: DYNAMICS OF GDP PERCENTAGE DISTRIBUTION ON ECONOMIC ACTIVITIES DURING 1995-2001

The question, how globalization of separate sectors of economy impacts growth of general welfare of host country, remains key target of presented investigation. Below we present quantitative evaluation of influence of separate inflows of FDI on GDP growth and comparison of FDI and GDP structure, what lets to identify sectors in which foreign capital reached the highest level of penetration.

Quantitative evaluation of FDI efficiency

Quantitative evaluation of impact of separate foreign capital inflows on growth of national economy is very important as results would let to reveal certain cases and circumstances in which globalization represents threat to growth of national economy, and therefore should be prevented rather than stimulated by local government.

We repeatedly emphasize that, despite the majority of politicians and economists point to the positive sides of globalization, it doesn't mean, as it has been shown in scientific literature review, that each capital inflow finally stimulate economic growth. Our investigation tends to identify how FDI structure conditioned by objective factors (such as costs of production, level of consumption) and subjective ones (economical policy) affects GDP. Strength and direction of relationship between FDI structure and GDP would present direct answer to the question about efficiency of FDI directed to the different sectors of economy.

Method of correlation-regression analysis has been chosen for quantitative evaluation of FDI efficiency. Application of it lets to determine type of relationship between GDP and FDI flows into separate sectors of economy. Value of correlation coefficient nearing to 1 indicates that relationship between variables is strong, and sign of correlation coefficient – negative or positive – shows if, in our case, considered FDI flows negatively or positively effect economic growth. Data used for calculations and results presented in Appendix 2.

At the first stage of economic interpretation of calculation results lets concentrate on relationship between FDI into main sectors of Lithuanian economy (FIG. 2) and GDP. Correlation coefficient between FDI share to agriculture and GDP is negative (-0.81) and insignificant. That lets to state that specific and unfavorable business environment conditioned low and, even more, diminishing share of FDI (during period 1995-2001 it diminished from 2.06 to 0.47%), and contraction of this sector (in 1995-2001 sector contracted from 10.7 to 6.9%) . Hence, conclusion is that FDI to agriculture in Lithuanian case doesn't affect properly growth of GDP. Very similar interrelation between FDI to construction and GDP was found: here correlation coefficient also is negative and insignificant (it equals to -0.37).

Considering insignificant values of correlation coefficients between FDI share to agriculture and construction, in the further analysis we will put emphasis on FDI into services and industry, which in 2001 both together comprised 95% of total amount of foreign capital inflows. Interrelationship between FDI into those sectors and GDP is strong and significant: correlation coefficient between FDI share into services and FDI is equal to 0.99, and between FDI to industry and GDP accordingly equals to -0.814.

Hence, application of mathematical method confirmed theoretical premise about controversial impact of globalization of separate sectors on economical growth. In our case we received negative relationship between FDI share directed to industry and GDP, what indicated that globalization of industry sector retards development of economy. This aspect we will scrutinize thoroughly below.

A multidimensional linear equation lets to evaluate quantitatively impact of FDI shares directed to services and industry on GDP growth (determination coefficient of the equation 99%, what confirms reliability of calculations):

$$GDP = -23\,217{,}08 - 31{,}27 \times X_1 + 1\,044{,}57 \times X_{2;}$$

here: X_1 – FDI share into industry; X_2 – FDI share into services

Presented equation indicates that FDI distribution between sectors of economy plays quite important role in stimulation of GDP growth. The following comments could be brought. Positive strong relationship between share of FDI into service sector and GDP could be conditioned by increasing inflows of capital into this sector. Now it accumulates 69.0% of all FDI, what contributes to development of the sector and increasing share it comprises in GDP (now service share in GDP reached 54.3%). Generalizing we can conclude, that globalization of service sector is efficient from the point of view of host economy. Converse result characterizing impact of FDI share into industry on GDP could be partially caused by contraction tendencies of industry sector (during period 1995-2001 share of industry in GDP fluctuated from 23.9 to 25.6%, but in year 1999 it contracted up to 20.4%). Contraction of industry sector could be due displacement of local firms out of the market by foreign players or due to globalization processes of monopolistic firms, what objectively don't properly contribute to growth of GDP.

Evaluation of globalization efficiency in service and industry sectors should be done taking into account variety of activities, which have been embraced by considered sectors. Hence, the final conclusions about efficiency of separate inflows of foreign capital could be drawn only after scrutinizing relationships between FDI into those partial activities and GDP. Further analysis would involve two steps. At first, determination of relationship type between GDP and FDI shares into separate service activities would be done, and, the second, the same between

GDP and FDI into main industry branches would be repeated. Interpretation of the results would provide quite accurate evaluation of different facets of globalization.

We will concentrate on activities, which attracted the most significant capital inflows. In service sector the following ones could be distinguished: wholesale and retail trade (20.4% of FDI), financial intermediation (19.9% of FDI), and communication (14.8% of FDI). Statistical data on FDI distribution according economical activities presented in Appendix 2. Using the data pair correlation coefficients have been determined. However, Student coefficients signalized that FDI share taken separately into each considered activity doesn't affect GDP. Application of multidimensional correlation analysis let to receive linear equation showing impact of all service activities (even including not very significant ones) on economical development:

$$GDP = 1\,203\,127{,}74 - 34\,741{,}80 \times X_1 + 47\,5482{,}26 \times X_2 - 122\,875{,}01 \times X_3 - 83\,112{,}72 \times X_4 + 58\,419{,}61 \times X_5 - 41\,301{,}91 * X_6 - 475\,433{,}89 \times X_7$$

here: X_1 – FDI share into wholesale and retail trade;
X_2 – FDI share into hotel and restaurant activity;
X_3 – FDI share into transportation activity;
X_4 – FDI share into communication;
X_5 – FDI share into financial intermediation;
X_6 – FDI share into real estate;
X_7 – FDI share into education, health care , leisure and culture.

Presented multidimensional correlation equation enabled to reveal quite controversial from the superficial sight relationships. According the equation, relationship between FDI share directed into trade and GDP is negative, what could seem hardly possible. Nevertheless, closer look into considered activity provides appropriate explanation to the negative relationship. Share of trade in GDP is quite significant, but it have been diminishing: e.g. while in 1995 it comprised 16.3% of GDP, in 2001 share of trade contracted to 13.9% of GDP. Despite that this activity attracts quite big share of foreign capital inflows (in year 2001 up to 20.4%), attractiveness of it seems to be decreasing: in 1995 trade attracted 29.4% of FDI, while in 2001 accordingly 20.4%). Specifics of Lithuania suggest the following interpretation. FDI have reached such "saturation" of activity, which due to limited purchasing capacity makes further investment economically inefficient. Instead of increase in volume of sales additional investment started to lead only to redistribution of existing market share and to displacement of comparatively weaker firms. Hence, increase in FDI share wouldn't mean increase in GDP. FDI into trade activity diminishes, GDP, in general, grows, what conditions negative relationship between FDI into trade and GDP. Listed above arguments leads to a conclusion that here foreign capital reached high concentration and replaced local players.

Investigation also indicates negative relationship between GDP and FDI share into communication. Contrary than in trade activity, FDI share during considered period has been increasing and, at superficial glance, should positively impact GDP growth. Negative relationship could be caused by FDI, which had come via privatization of very important object for Lithuania – Lithuanian Telecom. Monopolistic position of privatized Telecom conditioned favorable uncompetitive situation in providing of fixed telecommunication service. It is notorious, that regulation of public monopoly is comparatively easier task than regulation of private monopoly. Hence, privatized Telecom, being private monopoly considerably increased prices, what, in its turn, caused some loss of consumers and decrease in volume of services provided, but, at the same time Telecom's revenues haven't diminished. In this case globalization in principle started to retard development of all sector of communication. This tendency of slowing down of development has been partially neutralized by sharp increase in demand of mobile communication [6]. Finally, we need to admit that Lithuanian case of globalization of telecommunication sector confirms theory about certain jeopardy to host country from the side of multinationals located in protected markets.

Notable, that some negative tendencies, traced in activity of Lithuanian Telecom, share of whole communication sector in GDP has been growing, and in 1998-2001 increased from 8.5 up 11.1%. Growth of sector has been reached due to increasing of activity scale of such foreign capital mobile companies as Omnitel, Bite GSM, and Tele-2: e.g. revenue of Omnitel during only year 2001 increased by 44.4%, Bite GSM managed to grow almost at the same extent (Lithuanian Bank, 2001). Growth in sales and constantly decreasing prices witness, that competitive environment in mobile telecommunication activity leads to increase of efficiency. Hence, we encountered situation when different capital flows into the same – telecommunication – sector of activity controversially impact development of national economy. Foreign capital flows directed into Lithuanian Telecom exceeded all other FDI into sector, what, finally determined negative impact of FDI share in communication on GDP.

Results of presented above multidimensional correlation equation indicate that FDI share into financial intermediation initiates development of this branch and contributes to GDP growth. It is peculiar, that foreign capital into the sector flew through different channels, among which privatization wasn't prevailing one. In 2001 Lithuanian Savings Bank was privatized. Differently, compared to Lithuanian Telecom, this bank didn't occupy monopolistic positions and its financial results were far from the leading banks. Even more, after privatization in result of reevaluation of material assets expenses increased by 85.5 million litas, what indicated that Lithuanian Savings Bank actually worked at a loss [6]. Hence, inflow of foreign capital through privatization in this sector didn't provide favorable conditions for investors. Additional FDI came to Vilnius Bank and Hansa Bank (previous Lithuanian Savings Bank) through channels not related to privatization. Financial intermediation sector started slightly to grow in year 2000. The growth was caused such factors as globalization and increase in demand in services of insurance companies due to introduction of compulsory civil insurance of cars. Nevertheless, globalization in sector of financial intermediation played the most important role in strengthening of key players and contributed to development of national economy.

Close look into globalization of service sector revealed that, despite, FDI share into services, in general, initiates development of national economy, separate capital flows retard economic growth of Lithuania. The most positive effect has foreign investments into financial intermediation, and the most negative effect have been traced in sphere of communication.

The following step of analysis will involve analogical determination of relationship type between GDP and FDI shares into main industry branches. Interpretation of the results would provide evaluation of different aspects of globalization in industry of Lithuania.

For detail analysis have been chosen those branches of industry, which, from the one side, attracted the major share of FDI, and, from the other side, have been considered as being of prime importance for Lithuanian economy. Received, and selected according Student coefficient (Appendix 2), correlation coefficients indicated that GDP is mostly effected by globalization of following branches of industry: processing of food, refining of oil and chemical industry, production of rubber plastic items, production of electrical and optical equipment. The extent and direction of interrelation between FDI share into listed activities and GDP is presented by received multidimensional correlation equation (determination coefficient 99%, what means that equation is significant:

$$GDP = 79\,566.68 - 2\,144.11 \times X_1 - 598.20 \times X_2 - 4\,666.23 \times X_3 - 1\,488.17 \times X_4$$

Here:

X_1 – FDI share into food processing industry;
X_2 – FDI share into oil refining and chemical industry;
X_3 – FDI share into production of rubber and plastic items;
X_4 – FDI share into production of electrical and optical equipment.

Calculations verify that globalization of industry don't initiate growth of economy enough, despite this sector of economy attracts significant share of FDI. Meanwhile, statistical data indicate recovery of food processing and other industries as increase of productivity and volumes of production were recorded [3]. Negative impact on economic development of country obviously had losses of such privatized strategic object as Mazeikiu Oil Refinery, which during period 1998-1999 increased from 32 272 thousand litas to 134 552 thousand litas. That confirms that globalization of monopolies, especially retard economic growth.

Investigation showed that globalization process of monopolies in Lithuania take place mainly through privatization. Privatization policy directed to so called "strategic investors" in principle conditions further restriction of competition in industries characterized by high concentration and big barriers of entry. Later on privatized enterprises enjoy favorable business conditions and aren't orientated enough to increasing of efficiency. Hence, government policy in field of regulation of globalization processes should put emphases on complex of economic tools making "green field" investments more attracting for foreign investors.

Evaluation of globalization process would be more thorough if FDI impact on restructuring of economy was taken into account. Hence, below globalization level of separate branches of economy will be scrutinized.

Impact of FDI on restructuring of Lithuanian economy

Impact of globalization on Lithuanian economy could be analyzed from another point of view. Comparison of FDI distribution between various sectors of economics and economical activities, from the one side, and GDP structure, from the other side, would let to indicate main directions of restructuring of national economy conditioned by globalization processes. We propose to perform the comparison by calculation ratio of percentage share of FDI directed into certain activity and percentage share of GDP generated by considered activity. If calculated ratio is greater than 1 that means, that appropriate activity attracts comparatively more foreign capital flows and, therefore, is more saturated by foreign capital. If globalization of considered sector, according presented above analysis, positively impacts GDP, then in the future the sector will be developed more rapidly. In FIG. 5 dynamics of ratio reflecting comparison of FDI and GDP structure is presented.

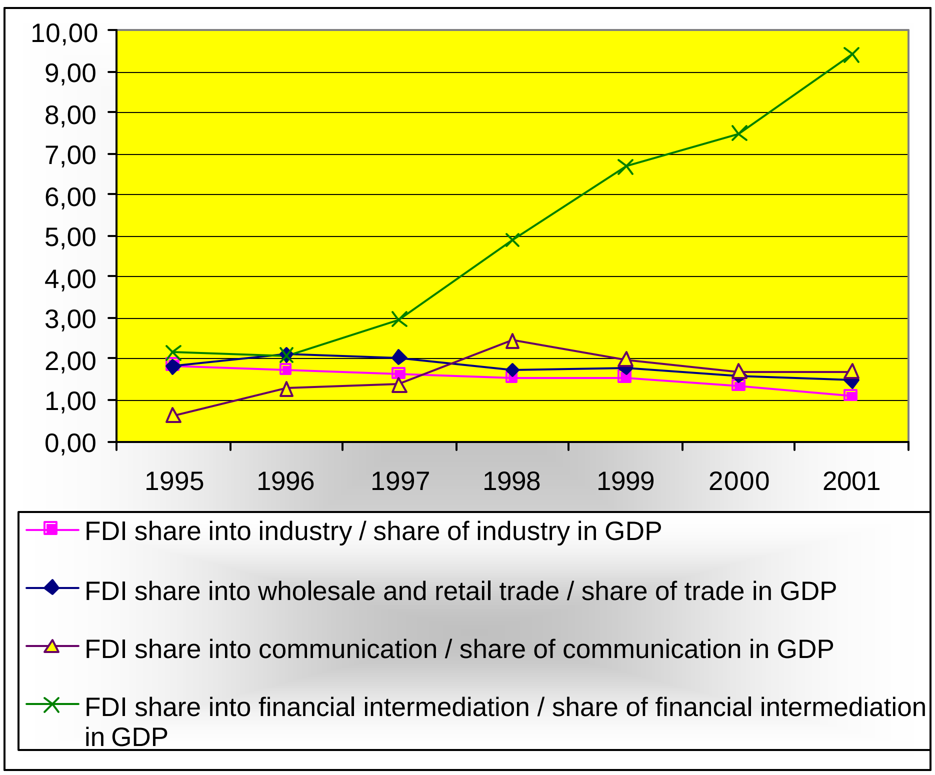

FIG. 5: DYNAMICS OF RATIO REFLECTING COMPARISON OF FDI AND GDP STRUCTURE DURING 1995-2001

The highest values of ratio were recorded in such activities as trade, industry and, especially, financial intermediation. Considering results of performed analysis we can expect that globalization processes will especially condition expansion of financial intermediation sector.

Probability that economy will be restructured towards trade and industry is treated as being quite insignificant as doubtful impact of FDI into those sectors on GDP growth has been determined.

Analysis of globalization processes in transition countries should involve especial emphasis on privatization processes. Pure fact of privatization couldn't be treated nor positively neither negatively. Meanwhile, occupation of monopolistic position by foreign investor doesn't lead to increase of efficiency and, as investigation show, finally negatively impact development of host economy.

Basing on poll of the biggest firms of foreign capital (Appendix 3) performed by Institute of Free Market Economy (The biggest investors) analysis of FDI sources has been done (FIG. 6).

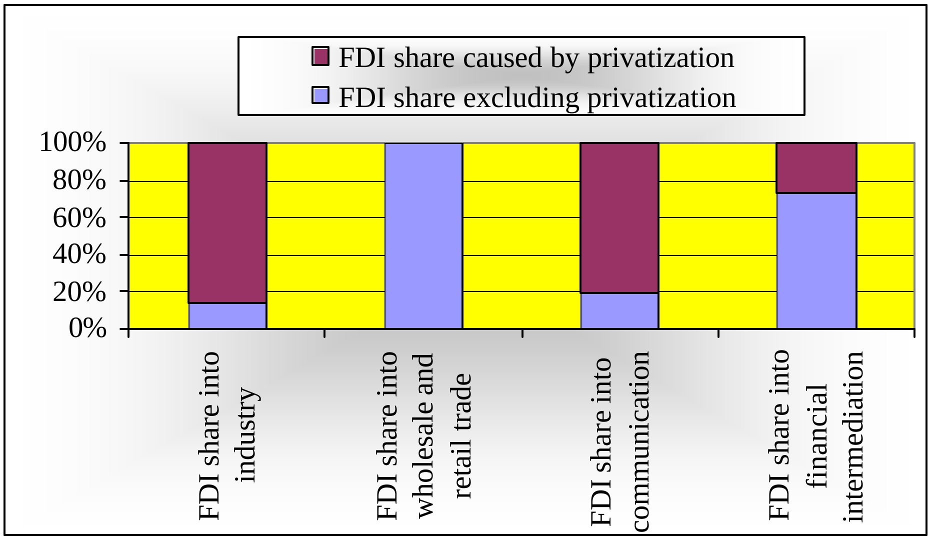

FIG. 6: SOURCES OF FDI INTO MAIN ECONOMIC ACTIVITIES

Results of current analysis indicate that in those sectors, in which significant share of FDI came via privatization, the most probable outcome of globalization is negative (in Lithuania in two out of three cases, where privatization played important role – in industry and communication sector – globalization results have been evaluated as negative). Foreign capital inflows reached country through other channels better impact growth of national economy.

Conclusion

Review of economical literature leads to conclusions that impact of FDI on development of economy of host country could be different and, even, quite controversial. In one case globalization can initiate growth of GDP through increase in quality and quantity of goods produced and services provided. It conditions spillover of knowledge, technologies experience to local companies, what enable them to survive even in environment of increased competition. In another case, globalization in sectors with high barriers of entry can enjoy favorable business conditions, extract rent and replace local economical entities out of market.

Performed economical analysis revealed that in Lithuania globalization of service sector positively impact economical growth, while globalization of industry sector doesn't.

Investigation has led to corollary that positive and negative impact of globalization is concurrent. Some inflows of foreign capital into the same sector of economy can be efficient from the point of view of host country, and some not. In transition countries, negative result of globalization most probably will be traced in privatized monopolies.

Generalizing Lithuanian case it should be stated that the highest level of globalization has been determined in trade, financial intermediation and industry. In some cases replacement of local firms took place, what confirms theoretical premises about malign impact of globalization.

Globalization process effects restructuring of national economy. Considering results of performed analysis we can expect that in the future sector of financial intermediation will expand significantly.

Despite overall effect of globalization is positive, government of transition country should more responsibly form privatization policy and put more emphasis on "green field" investments.

Firms in a Regional Financial System: Asymmetries, Globalization, and New Financial Instruments. The Case of North-West of Italy

Monica Cariola
Institute for Economic Research on Firms and Growth, Italy

Abstract

The Small and Medium Enterprises (SMEs) despite having great potential and flexibility, are still subject to extensive limitations in terms of financial resources: in fact, their size is not often able to sustain and reach the limit threshold to invest in innovation and R&D.

The last two decades have witnessed a strengthening awareness of the SMEs' contribution to production, consumption, and transferal of technological innovation. In Europe there are around 2,000,000 of SMEs (a quarter of which are in Italy); of these, only 1-2% are strictly producers of technological innovation, but a considerable 85% are buyers/users of technology to varying degrees and 10-15% are users that would like to produce it internally, but do not have the sufficient resources to do so. The role carried out by the financial system becomes consequently more and more important.

The aim of this work is to analyze the role carried out by a local financial system, which in the North West of Italy (Piedmont), in supporting the SMEs of its region. Specifically, it will analyze the evolution of the SMEs financial requirements and of the financial services supply in the region. Also, the paper will look into the debts structure of the SMEs. Moreover, the analysis will include the different kinds of financial relationships between the banks and the SMEs systems in the region, as well the possible role of venture capital and new financial operators in support of their stock capital.

1. The Evolution of the SMEs Financial Requirements in the New International Competitive Scenario

In the age of globalisation, enterprise competitiveness amounts to four main key factors: technologies, entrepreneurship, financial and institutional factors. Modern information technologies lower the entry barrier to global markets, giving SMEs a new role; but technology is not enough if it is not supported by finance, which plays a basic role in determining the switch from local enterprise to global one. In the United States, digital economy is based on a critical multitude of small and medium enterprises and innovative-networked *start-ups.* Thanks to easy access to venture capital, these small companies can rapidly become *leading* global enterprises in their industry.

Issues concerning structure of capital and re-allocation of ownership and control are of paramount importance for SMEs, because they are directly connected to the processes of accumulation and growth, and can therefore help overcome the chronic difficulties linked with the high level of borrowing characterising Italian SMEs. Dynamic SMEs on the real level and in terms of exports, but not up to times from the financial point of view, are facing increasing problems that concern the challenges represented by the globalisation of markets and the European single currency.

The globalisation of financial markets is changing the structure of capital of companies, particularly of the medium-large ones, from the most industrialised countries. The level of capitalisation of American and British companies, traditionally high, is decreasing and debt is being discovered, while European companies, typically under-capitalised, show a growth in venture capital.

Anglo-Saxon financial systems are characterised by their focus on the market, whereas the European ones focus more on intermediation. This type of evolution apparently mostly reflects the need to manage savings, with a view of increasingly mobile international markets, managed by institutional investors pursuing the strategy of risk diversification. In this respect, the Italian financial system, historically bank-focused, is also starting to open to innovative financial instruments, such as *merchant banking*, *venture capital*, participation loans, and *project financing*, but access to this type of instruments for Italian SMEs is, as we shall see, still very limited.

Italian SMEs, having to face higher difficulties than big companies in finding financing sources, have been cut off from the new financial circuits and still resort to bank borrowing, especially short-term, and self-financing as main sources of fund-raising. The constant under-capitalisation of companies, particularly of SMEs, the lack of venture capital and the high level of borrowing – while in the past did not limit growth, also thanks to particularly favourable leverage conditions – are now, in an increasingly competitive international environment, a major constraint instead. On the other hand, in Italy, the crisis of the welfare state, the reduction of public debt and consequent fall in treasury bonds yield, together with the widespread trend towards family saving, seem to be favouring a strong development of new types of institutional investors such as closed-end and pension funds, of course providing accurate and effective action is taken by the legislator.

The following section will deal with the potential role of these new financial instruments in the support and development of SMEs, as well as the evolution and current status of the banking system and its relationships with SMEs, highlighting its strong and weak points, all particularly relating to the region of Piedmont, in the northwestern part of Italy.

2. Financial Offer in Italy: the Banking System

In the 90's the Italian banking system underwent a thorough process of transformation and concentration, mostly driven by the liberalisation of banking activities, the integration of markets and the subsequent increased competition among brokers; at the same time, public presence in the ownership of banks was reduced (from 68% in 1992 to around 10% at present). From 1998, it has been also permitted to increase the offer of products for savings management, giving brokers higher autonomy in terms of organisational choices.

All this resulted, between 1990 and 2001, in 386 mergers or incorporations among banks and 166 acquisitions of the stock-holding majority, which reduced the number of banks in Italy from 1,061 to 769. The availability of banking services, however, has increased, thanks to the substantial rise in the number of branches, which in the same period has risen from 16,500 to 29,200 (+76%); in Piedmont alone there are 2,439, with 54, 8% of municipalities having at least one bank

We are therefore witnessing a market which is concentrating more than what may seem; acquisitions, contrary to mergers, do not cause the disappearing of the acquired bank: yet, even though the number of banks does not decrease, the acquired local bank has in fact disappeared, having become part of the distribution network of the bigger group.

Within two years from now, the Italian banking system will complete the re-organisational stage of ownership, which has led to the concentration in four large groups with other forms of aggregation being constituted at their margins, including those of credit societies.

2.1 Structure and evolution of the banking system in Piedmont

The above-described changes and concentrations significantly affected the north-west of Italy too, and particularly the region of Piedmont with three of its main banks: the Banca Popolare di Novara, the Cassa di Risparmio di Torino and the Istituto Bancario San Paolo di Torino. Since June 2002, the Banca Popolare di Novara S.c.r.l. has merged with the Banca Popolare di Verona – Banco S. Geminiano e S. Prospero S.c.r.l., constituting the Banco Popolare di Verona e Novara S.c.r.l. The bank, after a period of activities mainly aimed at the large industrial and financial groups, has gone back to its traditional customers, made of families, professionals and small and medium enterprises.

The Cassa di Risparmio di Torino has instead become the part of the UniCredito Italiano, the biggest banking group in Italy as regards Stock Exchange capitalisation. Formed in '98 by the aggregation of Credito Italiano and Rolo Banca 1473 with Cariverona, Cassa di Risparmio di Torino and Cassamarca, in '99 the Group also incorporated the Cassa di Risparmio di Trento e Rovereto and the Cassa di Risparmio di Trieste. A multi-specialised business model was chosen, with strong international orientation and an organisational structure aimed at leveraging competitive advantages deriving from the rooting in typically local markets of the Casse di Risparmio, but through the joint management of the individual customer segments (*corporate, retail and private banking*).

The Istituto Bancario San Paolo di Torino, on the other hand, has merged with Imi in 1998, thus forming the San Paolo-Imi Group. The Group is strongly specialised in financial services for the *retail* customers, in managed saving and in *Corporate Banking* and *Investment Banking* activities. In May 2002 the company completed the merger with the Cardine group, which will allow the creation of the second largest banking group in terms of assets, behind IntesaBci and ahead of Unicredito.

Besides those concentrations there are still many small and medium credit societies and local banks with strong territorial connections, such as for instance the Banca Sella or the Banca del Piemonte.

Tab. 1 summarises the territorial distribution by administrative districts of Credit Institutions operating in Piedmont, divided by institutional groups. The district of Cuneo has the highest number of operating banks, 13 compared to the 10 of Turin (but not of branches), as well as the highest number of co-operative credit institutions, reflecting the local trend towards production.

2.2 Relationships between SMEs and local banks: strong points and development prospects

Despite the above-mentioned processes of concentration of the financial system, in Piedmont there is still a comprehensive network of local banks, which have always had a privileged relationship with the SMEs in the region. The typical characters of these local banks can become towers of strength for the future too, especially if appropriately directed.

The main advantages characterising local banks in their relationship with SMEs typically are:

?? strong links with their customers and personalised relationships,

?? generally motivated staff,

?? fast decision-making,

?? in-depth knowledge of the production framework and of individual operators deriving from their territorial rooting and long-running business relationships. This element is very important because, while the large concentrations of banks normally imply the moving of decision-making centres to distant places, in small independent banks those in charge of decisions and long-term strategies live in the same areas, which will be affected by the decisions, made.

Anyway, these strong points are not sufficient to ensure by themselves the long-term success of local banks and their support of SMEs, within an environment that is much more competitive and rapidly changing than in the past.

However, the simultaneous presence of three new instruments, such as technology, globalisation and outsourcing, can allow, also in the financial field, to switch the focus from the critical variable constituted by the small size to a new key factor for success: the ability to manage complexity, in the case of SMEs particularly facilitated by their higher flexibility.

Technology nowadays allows applications which where unimaginable up to a few years ago; globalisation and technology together allow a small bank the distribution of the best existing products in the world, in the most diverse financial sectors, achieving the most accurate detail and reaching the smallest customer. Outsourcing, moreover, allows to delegate externally (possibly by setting up specialised companies, forming alliances with other small banks or companies of other industries) the activities requiring particularly big investments or different from the "*core business*".

Case studies are available on the effect of bank concentrations in two countries, Italy and United States, and show that banks, after the merger or acquisition, reduce the portfolio percentage invested in loans to companies of small size; it may therefore happen that big banks leave a growing space to the smaller ones, particularly in the support of SMEs.

The new strategies of big banks entail the creation of stand-alone *retail*, *private* and *corporate* departments and, as a strategic response to competition by big international banks, *corporate banking*. The *corporate banking* department manages relationships with medium enterprises according to a logic of *relationship banking* with high consultancy contents. The price of credit to *corporate* clients depends on a personalised *rating* assigned by the bank and by the profitability of the relationship with the client.

Small enterprises are instead assigned to *retail* departments with logic of *transactional banking*, characterised by multi-assignment, offer of standardised products, low consultancy contents. The price of *retail* credit depends on a mechanical *rating* (*scoring*) assigned by the bank according to product-based pricing policies and existence of collateral guaranties.

A possible way for local banks to respond to such a policy by the bigger ones may be based on maintaining a single distribution network and control over clients who are potentially overlooked by big banks (small business - advanced retail), which entails two types of challenge: maintaining an adequate personalisation of relationships, by strengthening the consultancy contents, and conforming pricing policies to "Basle2" (the new European financial rules from 2006), by introducing a reasonably-priced system of *internal rating*.

Most likely, the most critical aspects of *retail lending* after "Basle2" will be transferred on the Confidi; guaranties will probably have to absorb those risks which cannot be assessed analytically in a cost-effective way, and improve *rating* of *retail* portfolio through the reduction of loss in the event of insolvency.

2.3 Structure and features of the financial structure of SMEs in Piedmont

On the financial level, as regards the current situation, all data show a strong liquidity crisis for companies, particularly SMEs; this crisis is further worsened in Piedmont by the crisis of *Fiat* (the main Italian automotive company just located in Piedmont) and its side business, particularly for those companies which at the end of the 90's could not diversify their production and customers.

Data from the Central Bank of Italy (Banca D'Italia) for the June 2001 – June 2002 period confirms that the banking system of the region perfectly matches such difficult economical situation. In this period it shows both an increase in lending (that is, of indebtedness towards banks), rising from 80.43 to 80.897 billion Euros (+ 0.58%), and in rectified overdue payments (that is, of unpaid debts), rising from 2.286 to 2.38 billion Euros (from 38,873 to 39,346 in terms of number of beneficiaries) with a run-up in the second quarter of 2002.

The rise in lending by Piedmontese banks is even more remarkable (amounting to 19.34%) if credit granted to industry alone is considered, rising from 18.876 to 22.572 billion Euros; the increase is less substantial (+7.94%) if funds granted to companies for investment in machines and equipment are only considered, which however rose, in the same period, from 9.465 to 10.207 billion Euros, with a strong up-rise between April and June 2002 (5.043 billion Euros granted, compared to the 1.272 of the same quarter of 2001).

This type of investment, useful to the economic recovery of Piedmontese companies, is a first faint positive sign in a not too promising general frame, together with the increase by 6.86% of deposits in the banks of the region, risen from 38.56 to 41.209 billion Euros from June 2001 to June 2002.

The situation is also confirmed by the survey carried out by the Central Bank of Italy on the economic trend of the type of financing granted to meet the needs of Piedmontese industrial enterprises for current assets investments. According to these data self-financing has continued to be the main source in 2001 as well, covering

58% of the need, followed by short-term (18.3%) and mid-long-term (15.9%) bank debt, while recourse to the venture capital market was still very low (1.6%).

Among the few positive data there is the interest rate offered by Italian credit institutions, which showed a general decrease between 2001 and 2002, and Piedmont was among the regions with the lowest cost of money: both in 2001 and in 2002, however, it was Lombardy that reported the lowest interest rate for short-term financing (respectively 6.02% and 5.07%), while Piedmont established itself around 6.49% in 2001 and 6.08% in 2002. For mid- and long-term, the interest rates in 2002 go down to 5% in Piedmont and 4.67% in Lombardy.

In addition, a recent survey (Piccolaindustria Report - Unione Industriale di Torino, 2003) on 212 Piedmontese companies, 70% of which with less than 100 employees, has highlighted one of the effects of the crisis of the automotive industry in the region: 18% of the small enterprises analysed has suffered the reduction or writing off of bank loans, with average cuts of 54%; the 25% of them has shown an increase by more than one percentage point in cost of credit.

The difficult relationship with bank is more evident in companies whose sales in the automotive industry are higher than 10%. Half of the sample sells part of its production in the automotive industry and almost a third derives over 30% of its turnover from the automotive sector. Their relationship with the credit system is mostly characterised by short-term loans, amounting to 72.8% of the total. Guaranty consortiums on bank loans cover only in 11.8% of these reported cases.

Also according to the survey, indicators such as economic advantage (18.5%), reliability (8.2%), rapidity (16.9%), flexibility (13.3%), and professionalism ((18.4%) all influence the choice of banks (on average each company has lending relationships with three or four credit institutions). The quality of interpersonal relationships, however, prevails over all the above factors, as indicated by 22.1% of the sample.

The cut in loans has been explained by banks mainly with the crisis of the automotive industry, mentioned in 55% of cases. The rate paid decreases inversely proportionally with the size of the company, descending from 7.3% of small enterprises to 3.7% of the largest. In general, however, interest rates have gone up for almost a quarter of the companies, differently from what is indicated by the above-mentioned official data from the Central Bank of Italy, and small enterprises linked to the automotive induced business are mostly affected.

Credit institution has been already heavily hitting SMEs long before *Basle2* comes into force. In fact, credit rationing affects small and medium enterprises more heavily, and the availability of the banking system to grant credit to small and medium enterprises decreased significantly, going down to as much as one third. Credit granted to companies with up to 50 employees amounts to about 14% of the total. This percentage, though, goes down to 5% for handicraft enterprises and Piedmont equals the national average with 4.9%.

Several reasons are accountable for this difficult situation: the processes of concentration of the banking system have caused a decrease in the number of small local banks, favoured interlocutors of SMEs and craftsmen. Prospects concerning guaranty consortiums, such as the Confidi system, seem to be better. Data shows that the interest rate applied by banks in the event of cases supported by a Confidi reaches the level of the bigger customers. Without the guaranty consortiums, instead, entrepreneurs pay at least one third more for a loan. The level of insolvency, i.e. when loans are not paid back, also decreases significantly if a guaranty consortium (from 5.5% to 1.5%) supports the case. In Italy, there are 898 Confidi in total, 49 of which in Piedmont (5.5%), compared to the 108 of Lombardy, the 96 of Veneto or even more the 115 of Puglia. Despite the not so high number of organisations, in Piedmont the guaranty activity of the Confidi (Eurofidi and Unionfidi) in favour of SMEs is constantly growing, amounting to around 2.7 billion Euros in 2001 and further growing towards 3 billion Euros in 2002.

The regional administration, to counter liquidity crisis of companies, has implemented new actions, among which a *plafond* of 2.5 million Euros allocated by Eurofidi for SMEs of the automotive industry, in order to offer the Piedmontese banking system the necessary security to open credit lines. Furthermore, from the political point of view the region has required the institution of a guaranty fund of 50 million Euros by the Italian government, while for the regional financial law a special revolving fund of 15 billion Euros is being studied, also for the purpose of credit guaranty for SMEs of the automotive side business.

3. Alternative Ways to the Development of SMEs: the Potential Role of New Financial Instruments Supporting their Stock Capital

As described above, a fast evolution is taking place in the Italian financial market. The need for higher long-term allocation efficiency has led to, besides concentration processes, the introduction and spreading of new financial intermediaries for venture capital, which could become important for the future development of SMEs.

Investment in venture capital contributes to the development of the industrial system, by selecting companies with high growth rate and giving them the necessary means for development. The existence of operators who can offer mid-long term financial resources helps the companies find valid support in the most delicate stages of the life cycle (*start up*, development, M&A, etc.). More particularly, the companies to develop new products and new technologies, to expand liquid assets, to fund acquisitions, or to strengthen the financial structure of the company, can use such capital. *Private equity* can also be used to solve the problems connected with the ownership of an enterprise or with the generation transition aspect. Furthermore, it is the preferred instrument to carry out *buy out / buy in* operations by experienced managers.

The stable and continuous flows of resources guaranteed by these type of financial instruments can constitute the way to break the balance of a financial system that is too focused on financial brokers, whom Italian SMEs are inevitably linked to (because of the high levels of indebtedness) causing the switch to a more market-oriented financial system of Anglo-Saxon type. The advantages of this change could be significant for smaller enterprises, not only for the higher availability of sources of finance, which can help solve the problems of under-capitalization of companies, but also in terms of executive support to management and of reduction of information asymmetries, which small enterprises would benefit greatly from. According to the Anglo-Saxon terminology, new brokers are essentially divided into two broad categories:

- *Venture Capitalist*, if they mainly invest in companies in *seeding* and *start up* stage*;*
- *Private equity investor*, if they invest in companies at more advanced stages of their life cycle and can therefore help solve the many problems connected with the ownership structures and with *buy in* and *buy out* operations.

The type of investors currently active in Italy on venture capital investments (to this day still mainly favouring medium-large companies) are: banks, public operators, closed-end movables funds, pension funds, non-institutional *venture capital* initiatives, *business angels* and enterprise incubators. We shall now examine the role of some of them and the relative potential for support of SMES, both in general terms and as regards the Piedmontese situation.

Closed-end funds in Italy have only been regulated by Act no.344\1993 and will be able to play an increasingly important role for SMES, as they are characterised by a remarkable stability of collection, since shares can only be redeemed after a high number of years (max. 30). They can consequently allow long-term investments in movables that are difficult to liquidate such as shares of small not publicly traded companies. In Piedmont, as regards this, the *Sviluppo Nord Ovest* project is being implemented, to which the "*Nord Ovest*" closed-end fund will be connected; the following are taking part in it: Unicredito for 80%, Unione Industriale di Torino for 10% and Unionfidi Piemonte (which will provide security up to 60% of the value of the various investments and any capital loss in the event of unsuccessful operations) for the remaining share. The fund will provide 50 million Euros to be allocated for operations ranging from 500,000 to 3 million Euros in favour of innovative SMEs of the north-west of Italy, to be performed through the underwriting of their shares of capital increase or the participation to the issue of their convertible stock loans. 80% of the fund will serve the *private equity* for the funding of existing enterprises, while 20% will be destined to *venture capital* to support *start-ups* in the *high tech* industry.

San Paolo IMI, through San Paolo IMI Private Equity, is also developing the market of closed-end funds and, among these, one has already been scheduled to be specialised on SMEs of the north-west (Fondo Nord Ovest), following what has already been achieved with a closed-end fund for investments in small and medium enterprises in the south of Italy.

Another financial instrument with high potential is represented by **Pension funds** which are, among institutional investors, the most suitable to channel family saving (Italy, and Piedmont in particular, have one of the highest rates in family saving in Europe) towards venture capital. In countries where pension funds have enjoyed a widespread diffusion, they have actually played a major role in *venture capital* funding.

The saving gathered by them is of social security-contractual type (financial resources set aside and invested to guarantee workers future income through a capitalisation process), and therefore, it shows two significant features: stability of collection flows and long time of use, yielding the following advantages:

- It allows the investment in financial activities with high expected revenue but low level of liquidity;
- It can contribute in a qualified way to the management of participation companies;
- It allows portfolio diversification (also in *venture capital* activities) which becomes more efficient thanks to the lower information asymmetries.

Generally, however, pension funds only invest a small percentage in venture capital for companies, because they often lack the necessary skills in the choice of real investments. On the other hand, they indirectly invest in venture capital through closed-end funds and *venture capital* associations, who have the necessary expertise.

Pension funds instead invest in the various initiatives according to a purely financial view. A strong bond among pension funds, closed-end funds, *venture capital* companies and participation companies is thus established. The development of pension funds in Italy, however, is still drastically limited by fiscal problems, as an increase of their current limits of deducibility from income would be needed.

Pension funds could achieve a certain drive through a different way though. At present the TFR (Trattamento di Fine Rapporto – the severance indemnity) Fund acts for Italian companies, especially SMEs, as a form of stable and substantial "facilitated financing" (at the expense of workers). A heated economical-political debate is however taking place as regards replacing it through the development of pension funds and the capitalization of companies.

The possible elimination of the TFR fund would increase the recourse by companies to the much more burdensome bank debt, and pension funds could play a major role in avoiding financial crises for the smaller enterprises (where the TFR seems to have a higher impact on the composition of debt), which would certainly also be those that would face the bigger difficulties in finding alternative source of mid-long-term financing.

Only recently non-institutional *Venture Capital* companies have started operating in Italy, with a strong delay compared to other countries and the United States, where they have been the basis for the development of the *new economy*.

These companies can be generally divided into three categories:

?? *enterprise incubators*, supplying resources to new companies in *seeding* and *start up* stage; in Piedmont a few incubators are already active, such as the one at the Polytechnic of Turin and those connected to the Scientific and Technological Parks existing in the region;

?? *Business Angels*, consortiums of managers or entrepreneurs with deep knowledge of the industry they invest in, organised in networks (Business *Angel Networks*) allowing for the meeting of investors and entrepreneurs; they differ from *Venture Capitalists* as regards the sums granted, which normally do not exceed 250,000 Euros (thus making them particularly suitable for the smaller enterprises) and from incubators, because they also offer managerial support to the companies they fund. This reality is still quite rare in Piedmont, while it has instead found fertile ground in Lombardy;

?? The *Corporate Venture Capital* initiatives, still scarce in Italy and in Piedmont, put into effect by big companies interested in investing in new initiatives aimed at finding new markets in different industries.

After the halt in 2001, the Italian *venture capital* and *private equity* market has shown some signs of recovery. In 2002, 2,626 million Euros were invested by operators in Italy, amounting to a 20% increase compared to 2001. The number of operations instead has shrunk further, decreasing from 489 in 2001 (-24% compared to 2000) to 301 in 2002 (-38% compared to 2001). As far as the geographical distribution of investments is concerned, concerning the operations directed to Italian companies (amounting to 87% of the total), operators have indeed mainly focused on the north of the country (82%), but not on Piedmont yet; the highest levels of intervention have in fact been recorded in other Italian regions: Lombardy, Emilia Romagna and Friuli Venezia Giulia.

In Piedmont, however, *Buy out* activities are enjoying a good deal of fortune, thanks to big acquisitions made by institutional operators and to large investment funds towards already mature companies with good industrial projects, but suffering from financial problems: in 2002 the total amount was around 180 million Euros, as opposed to just over 28 million in 2001. These figures arise from big operations such as the acquisition of Teksid by a group of international investors, as well as from operations performed on Piedmontese SMEs such as for instance Sparco (by the Paneuropeo Argo Soditic Italia fund).

Conclusion

To conclude, it can be said that in an industrial system such as the Piedmontese one – suffering from a deep crisis of identity and liquidity and burdened with heavy debt, as well as inserted in a vice versa more and more competitive and innovative environment – the role the regional financial system plays is becoming even more decisive than in the past.

Following the important concentration processes of the banking system, new areas of support for local SMEs can be preserved or created from scratch thanks to two types of subjects: small and medium local banks and new investors in venture capital of companies. Local banks must learn to turn those that at first glance may now seem weak points- the smaller size, the deep territorial rooting and focus on local industries- into advantages. This is possible thanks to their higher flexibility and to the use of new technologies and outsourcing, as well as trying to cover quickly the areas left free or difficult to occupy by the big banks, particularly in the relationship with SMEs.

On the other hand, new institutional investors in stock capital of companies can be an alternative and/or parallel outlet to traditional instruments providing SMEs with long-term resources with low level of liquidity to help them overcome the *standstill*. Moreover, these resources can be helpful in reducing SMEs' level of indebtedness and the information asymmetries that almost invariantly characterise the relationship between SMEs and financial institutions, and achieving higher competitiveness at international level, through this course.

Italian SMEs have always had to come to terms with a scarcely distributed financial system, with strong information asymmetries and lacking intermediaries able to bring them closer to the new funding channels.

The banking system concentration processes of the last decade, which have had significant impact on the north-west (Piedmont) - although a reasonably good network of local banks and therefore closer to the needs of SMEs has been maintained – have however promoted the creation and/or specialization of new financial intermediaries: in particular pension funds, closed-end funds and *venture capital* companies. These instruments can be expected to play a decisive role in the process of modernisation and development of the Italian industrial system over the next few years, helping generate new opportunities also for the Piedmontese SMEs, thanks to a constantly increasing integration between the more traditional financial route to development and the new course of venture capital.

The Application of Creativity in The Thinking of Managers and Entrepreneurs and The Possibilities for their Development under the Prevailing Conditions in The Czech Republic

Milan Mikuláštík
Tomas Bata University in Zlín, Czech Republic

Abstract

This piece of research was devoted to the possibilities of developing the creative potentials of managers and the methods that it is possible to consider as having been the most effective in their training. It compared the Simulation and Case Study methods and traditional forms of preparation in the form of lectures and discussions in seminars. The outcomes indicate that most optimal form is that of a compromise, i.e. the rotation of all of the afore-mentioned methods, since each of them develops a differing aspect of the personality of a manager. What is important, however, is to develop not only their divergent, but also convergent forms of thinking (cogitation). The person concerned with the solution of this problem must come to a single concrete conclusion at the conclusion of each of the definite and pre-defined stages chosen.

Introduction

The term or concept "Creativity" is often used as a magic formula - which also serves as a form of alibi. It is a fashionable conceptual term that is currently much used (overused) and in vogue. For many, it is a conceptual term with a very universal form - and for that very reason, it is also difficult to delimit, define, and specify. It is universal in the sense that it is applied to a whole varied range of activities. Especially those who are professionally interested in this term and its underlying concept(s) have doubts and reservations about how to come to terms with this conceptual term, as well as how to precisely define it on a generalised level. Differing criteria hold true for the creativity of an artist, musician, or writer; and a completely different set are relevant to the work of a scientific research worker and for scientists than hold true for the endeavours of a manager, for example.

One should not forget that creativity is as individual as each individual, and manifests itself spontaneously and in all forms of activity. All that is necessary for it to appear is whether a person has a barrier-free space around themselves which allows them free rein to use it. It is therefore necessary to guide people to a point where they are not only able to exploit the potentials of their creativity, but concurrently to further develop them too.

Creativity is, without a shadow of a doubt, the most effective means for solving problems, to making activities more effective – and to discovering new, innovative approaches and opportunities in the market environment. It is a reservoir for the further development and evolution of society, since it represents an opportunity, which simply cannot be replaced by anything else. It all depends on whether such an activity is positively oriented. The ways and means for its more effective exploitation begin with its development and evolution in the pedagogical-educational processes from the earliest days of one's schooldays. It also continues in the course of the employment and work processes and within the overall framework of Lifelong Learning (Continuous Education). Managers further develop their own creativity, but also should support its development in their co-workers. They should know how to seek out the creative employees under them, how to retain them (in their posts), and how to further develop this creativity in their fellow employees.

A whole range of psychologists have interested themselves in the phenomena of "creativity in the working processes of managers and entrepreneurs" for a number of years. They have endeavoured to find correlations between a manager's work and an entrepreneur's activities and the factors governing or related to creativity. Let us mention a few of them in passing: B.G. Whiting, N. Lodge, E.P. Torrance, Winslow, Solomon, Fry, B. Gilad, M. Jurcová, W. Scharf, J. I. Reynolds, M. Pollick, I. Nueten, J. Culvenor, D. Else, M. Basadur…

The most significant condition for the further development of creative potential is one's genetic gift for a given branch and favourable conditions for their development in the periods of one's childhood and maturation. Later influences are not so significant – but this does not mean a latent creative potential cannot be awakened and developed. In Science, it is important that one gets into the right university, is granted access to research opportunities, and that one is granted sufficient time, material, and even social conditions for one's investigations, as well as the opportunity to be in constant contact with other researchers.

In an enterprise, it is necessary that one find a place where the fundamental underlying principle is a support of creativity, where the Top Management are willing to believe in creativity per se as a valid entity in their own endeavours and in those of their subordinates. Creativity is an expression of a whole complex of systems, which is an expression of the synergy arising out of a whole range of internal and external factors – and often, a single missing link may thwart the positive development of new thoughts, discoveries, and products.

The internal factors have a very singular structure, which often appears highly disorderly, like unintelligible chaos – but this is only because the whole structure is so complicated. Human creativity is expressed through contradictory polymorphism, extreme expressions, and an individual uniqueness. A creative person on the one hand may be more aggressive than the average person, but at the same time, and under certain conditions, even be cooperative. A complex creative personality exploits to a greater extent than is usual a wider palette of characteristics than is usual for the average person. For this very reason, a creative person may come across as an individual full of contradictions and extreme forms of expression. But this is only an expression of their greater potential, not their inconsistency.

Creative people have a lot in common with the type of person that K.G, Jung typified as "Mature Personalities". What is meant here is that the strengths of that personality strike one as if they were precisely the opposite, as if they were suppressed sides of that personality – which the average person usually denies about themselves, whether consciously or subconsciously. Thus, a very orderly and prim and proper person secretly desires to be spontaneous; a humble person longs to govern others; a closed (introvert) person yearns to be open (extrovert) - and on the contrary, the open (extrovert) person yearns for a meditative spirit and an empathic understanding of others...

Should such personality traits be suppressed however, the individual will remain unsatisfied and so frustrated. They guard themselves, in order not to drop out of their role, in order to respect all of the rules (written and unwritten) with which they have been confronted in the course of their lives. They often fight an internal battle with themselves, which is precisely what leads to their being average and to the fact that they are not spontaneous and thus cannot fully develop their own potentials.

A creative person is capable of experiencing both extremes with the same degree of intensity and without internal conflict.

A creative person abounds in physical energy, but at the same time, is capable of being still, calm and relaxed, or even passive. A creative person may be highly intelligent – but at the same time, naïve in some respects. They are capable of fantastic flights of fantasy – but on the other hand, of a down-to-earth realism. They are able to be open, while at the same time being closed – at its extreme even autistic. Within them are enjoined a mixture of humility and pride. They can be ambitious, competitive – but also willing to sacrifice themselves and to be cooperative. They are capable of being independent - but also of being conservative; passionate - and objective; sensitive and vulnerable – but they are also able to intensively experience the depths and heights of joy/happiness.

A creative approach is especially appropriate when resolving unstructured and strategic problems, i.e. crisis problems and situations.

Organisations which are successful, resolve their problems through a creative approach to the same. They are able to react to changing situations, are capable of innovation, in short – they are competitive. In the EU, less developed regions only chance to make an impression and place for themselves is through the development of the creative potential of their labour force, i.e. when they learn to guide this force towards this goal and to so train them in their schools and enterprises. It is essential that creativity be applied at all levels of management, i.e. that the Top Management expend especial efforts on supporting creativity, innovation and change. That they seek ways and means of possible improvement because in change lies competitive advantage. Professional skills and abilities are not enough, what is essential above all is creative skills and abilities (e.g. the breaking-down of habits, the abandoning of obsolete systems), and task-based and oriented motivation.

It is essential to support creativity through the creation of optimal internal conditions within an enterprise, i.e.:

?? Unambiguous support on the side of the management, the creation of a supportive internal climate.
?? A greater degree of autonomy, delegating powers to others.
?? The unambiguous differentiation of remuneration according to performance.
?? Greater leeway for risk-taking (even the Top Management must accept a greater degree of risk)
?? The training of creativity.
?? A tolerance for variance from the norm, the respecting of individual alternative solutions.

Enterprises which train their employees towards an attitude of creative thinking can expect the following benefits:

?? A staff, which is supported in their creativity will better understand the ideas and opinions of their co-workers and will communicate better.
?? Employees will be capable of an easier cooperation with other members of their working teams.
?? The level of competition will increase within the framework of a team and between different teams.
?? Apart from developing their high-tech strategic skills and abilities in their thinking processes, a global perception and thought pattern will also evolve.
?? The final effect will be expressed in innovative changes, which will lead to the enterprise being better placed to assert itself on the markets of the EU.

Methodology

Our researches were concentrated on comparing the differentiated conditions governing preparations, in that we tried to discover how these are expressed in the development of the individual factors of creativity and also on the training of creative thinking that prepare managers for a more effective way of working and at the same time, lead to increasing self-satisfaction and self-realisation. Apart from this, we also evaluated other factors designated as decisive for certainty. The comparison was of activation methods with traditional means of preparation (training) – simulation methods and role-playing, case-studies and traditional forms of preparation. It is true that the training methods were, in certain cases, quite heterogeneous and that in certain situations it would be possible to designate to some degree some of these methods as simulation methods, since case-studies were used. But, the case-studies used were used because the criteria by which the methods used were classified, allowed a greater degree of freedom in ranking them among the case-study methodology. A further weak point in this project is given by the Export Sales Departments which took part in this experiment only underwent 2 hours per week of differentiated forms of training over the course of a year, which represents a mere 10 % of the overall training time that the course participants went through. In total, 159 test subjects took part in this research. Of these, 110 were men and 49 were women. In the course of one year, three measurements were carried out.

Interpretation

In comparing the development of the individual factors influencing creativity, it was shown that the most effective in influencing the development of creativity proved to be the simulation and role-playing methodology (i.e. the Kruskal-Wallis Test). And this was true for three factors: fluency, originality and sensitivity. Where the values were compared with the Friedman Test, then this was true for four factors: fluency, originality, sensitivity, and elaboration. Demonstrable changes in fluency apply only to certain elements – i.e. verbal fluency and expressive fluency. The outcomes in the sub-test of associational fluency and idea/conceptualisation fluency did not demonstrate any significant changes.

As regards originality, it was demonstrated that changes were achieved in the outcomes of the sub-test: Outcomes of Fictive Events, but it was not demonstrated in the sub-test: Entitling Tales/Stories. For sensitivity, demonstrable results were noted in the sub-test: Seeing (Perceiving) Problems; while it was not demonstrated in the sub-test: Improving Instruments. These all have to do with changes which are compared to the original/inception state as at the time of initial measurement (of these factors). It was also demonstrated that change occurred in Decisive Certainty – which is of course the expression of the degree of a belief in oneself (self-confidence), a belief in one's abilities and a certainty about one's competence.

In the selection of those prepared with the assistance of case-studies methodology, an effect was shown for two factors: fluency and sensitivity. These demonstrable changes also affected only some of the sub-tests used in this study. For fluency, these were the sub-tests which measure expressive fluency and idea/conceptualisation fluency. With sensitivity, this was demonstrated in the Seeing (Perceiving) Problems sub-test.

A significant improvement in performance was noted in one sub-test as well in the selection of traditional training methodologies. This was in the sub-test: Expressive Fluency. Should we consider the evaluation outcomes of the investigations using the Friedman Test, then there was also a significant growth in the sensitivity sub-test: Seeing (Perceiving) Problems.

In those sub-tests, where a demonstrable result in all three groups can be noted, it is possible to say that the effect on a significant growth in performances is not influenced by the tuition methodology used. And if it is, then this is an element which uncontrollably occurs in all the methodologies used. If we compare the effect of the influence of the individual methodologies between themselves in each of the 3 measurements, then the growth rate in the 2nd and 3rd is significantly different, when comparing all three selections, then this differentiation is somewhat less evident.

In the course of the 2nd measurement, i.e. in the middle of the whole experiment, a demonstrable difference appeared in the Idea/Conceptualisation sub-test – in the sense that a growth in performance in those selected for preparation with the assistance of case studies significantly differed from the 1st. Group (i.e. the group training using the Simulation and Role-playing methodology) and from the 3rd Group (i.e. the group prepared using traditional training methods). This means that the Case-study Method develops resourcefulness, i.e. the ability of knowing how to react to new situations, much more than does the Simulation and Role-playing methodology, or traditional forms of training.

As regards the longer-lasting effects of these differentiated training methods further differences in their effects were also noted in the outcomes. At the end of the experiment, i.e. in the course of the third measurement phase, a demonstrable differentiation was shown in the Verbal Fluency sub-test, the Originality sub-test (i.e. Consequences of Fictive Events), and in the Decisive Certainty sub-test.

For the Verbal fluency sub-test, there was a significantly better performance in the 1st and 2nd Selections. This means that both activation methods function (affect) verbal production much more significantly than do traditional training methods. It was not anticipated that there would be such an occurrence of phrases and learnt formulations, which tend to predominate in traditional training methodologies. This outcome did not confirm our expectations in full measure. The presumptive outcome, that all selections would have approximately the same growth (improvement) in performance, is in contradiction to the hypothesis, which flowed from a comparable communication burden, with an approximately similar extent of the language used.

In the Originality sub-test (i.e. Consequences of Fictive Events), a significant improvement in performance was noted for those selected for preparation by means of the Case-study methodology. Even in this case, the hypothesis was not confirmed in full. We had anticipated that the group prepared using the Simulation and Role-playing methodology would also have a similar growth in their performance levels, since the Simulation and Role-playing method frees-up spontaneity, playfulness, frees a person from their fears of the reactions expressed by others and of a lack of success. The outcomes of the research conducted by Parlett and Hamilton (c.f. Parlett, M., Hamilton, D., pp.120, 1987) confirms that the Simulation and Role-playing method leads to the strengthening of alternative thought-processes, strengthens a more initiative-led approach to pragmatic thinking and in seeking possible ways of arriving at solutions to problems.

For the Decisive Certainty sub-test, a significant improvement occurred in the third measurement phase (i.e. at the end of the whole period) for the groups selected to undergo the Simulation and Role-playing method and the case-study method. It can be said that hypothesis ? .12 was confirmed in full and that the activation methods have a much greater influence on the degree of self-confidence, relaxation, and a willingness to take more risks, than traditional forms of tuition. This is confirmed by the outcomes of the investigations conducted by Parlett and Hamilton (c.f. Parlett, M., Hamilton, D., pp. 120, 1987) in the form of increased decisiveness, motivational interest, and increased self-confidence.

If we were to compare the development of the potentials of the individual factors of creativity who are highly creative and those with lower expectations, it would be possible to see differences in a whole range of sub-tests.

The Fluency factor shows overall a high degree of similarity in the development trends of both selections. Both Expressive and Idea/Conceptualisation Fluency grew in a similar manner for both selection factors. The changes that occurred in the course of a year are, in both cases, significant. The differences are only in the time frame of this growth and the slow down in performance. More creative individuals have a markedly greater growth in the Expressive Fluency sub-test than before, in the first half of the year. The less creative individuals have an accelerated course of growth in the second half of the year. This pattern is similar for the Idea/Conceptualisation Fluency factor.

Associational fluency was significantly improved in the selected category of highly creative individuals. From individuals with a lower creativity potential, growth in performance was remarked in the second half of the year, but the changes cannot be interpreted as having been demonstrated.

Semantic Flexibility was demonstrably improved only for the selected category of highly creative individuals.

This is similar for the results of the Originality (Consequences), Elaboration, and Decisive Certainty sub-tests. This means that the activation methods work with greater effect and more influence upon more creative individuals, especially in the initial phase. Change also occurs with those in the less creative test group; it is only that the whole course of events has a more gradual character, which is expressed in a greater growth rate (in an evincible measure) only in the second half of the annual period. This is a definable indication, which differentiates the two groups from each other, i.e. the Highly Creative Individuals and the Less Creative Individuals. The less creative individuals probably require a lowering (freeing-up) of their barriers and their creative development needs more positive stimuli, as well as more time for their activation and self-development.

In the following two sub-tests, these demonstrable changes are comparable in both selection groups, i.e. the Sensitivity (Seeing/Perceiving Problems) and the Anagram sub-tests. This means that, for these two factors, the positive influence of the activation method expressed itself in a comparable measure in both groups. Their effectiveness however has no differentiable effect according to the degree of latent creativity.

Of the overall sum of 13 hypotheses, only two were fulfilled in full measure. A further five hypotheses were partially fulfilled, these were Hypotheses ? s. 1, 8, 11,12, and 13. All of the other hypotheses were therefore repudiated.

Conclusions

The sense of this experiment was to respond to the question, whether it is possible to increase the effectiveness of the influencing and development of creativity in the educational process, when preparing (breeding) managers and directorial employees of manufacturing and commercial enterprises under the conditions prevailing in the Czech Republic. The aim was to determine whether the development of all the selected factors was equally effective. Which preparation methods had a greater positive influence on Fluency, Flexibility, and which on Originality or Transformation, or on Sensitivity; i.e. what aspects of a creative personality is it possible to develop through the application of training method.

In view of the differences in the individual methods, it is possible to state in conclusion that none of the tuition forms has a universal application, and that it is not possible to say which of these is the best. The most effective approach to this form of tuition is an optimal compromise, the rotation of the application of all of these approaches, and the smooth transition from one form of tuition to another, since each of them has its own specific effects, but also a complex of effects, since they function in a generative manner on creativity as a whole. It makes sense that one set out to create habits in the ways of thinking which develop differentiation and independence.

The specific benefits of the Role-playing Method are expressed in improvements in Verbal Fluency, in Originality, in the Resolution of Anagram-type Problems, and in Decisive Certainty. The Case-study Methodology's influence is positively felt in the development of the Sensitivity Factor in the sense of Understanding

Problems and Circumventing Complications. All of the above methods have a positive influence on the development of Expressive Fluency. The specific effects of the Case-study Methodology are expressed in the Idea/Conceptualisation Fluency Factor.

For the Traditional Training Methodology, no specifically positive effects were demonstrated, but they play a positive role in the complex positive effect on the development of Expressive Fluency.

Rotation of the methodologies used also makes sense since it creates an atmosphere of change and novelty, which in and of itself has a motivational effect; it is creative and helps to develop creativity.

Performance Appraisal as a Form of Formal Communication: A Case of Slovakia

Branislav Vargic
Comenius University in Bratislava, Slovak Republic

Abstract

The article seeks to find in what forms performance appraisal is presented in Slovak organizations and to depict how its presented forms are linked to other human resource management activities. In addition, we examine whether the managers comprehend and utilize performance assessment as a tool to motivate their subordinates and whether it influences communication within an organization. The findings of the article are based on research examining a sample of 52 companies operating within the Slovak Republic. A total number of 718 questionnaires was sent with the final count of returned questionnaires amounting to 512 from 35 organizations representing 432 respondents from Slovak companies and 79 from those with capital investments from abroad. Overall, the enterprises involved in the research cumulatively employ 11,765 people.

Introduction

Communication among members of an organization, as well as between them and the external environment, is one of the most critical organizational processes, influencing overall performance and effectiveness. Internally, communication is presented in organizations in two channels, formal and informal. Formal communication is most frequently used in the form of policies and procedures; the informal helps to create social communication networks[1]. From the managerial point of view formal means of communication, presented by different managerial activities, play an important role in setting the standards for various procedures and activities in a given organization. Moreover, their content and form contribute to enhancing the justice and fairness of the system of management, and thus improve employee satisfaction and motivation.

Performance appraisal, as a formal mean of communication, is an indivisible part of an efficient human resource management system in any given organization. On the individual level it represents a crucial tool to foster participatory objective planning, to improve employee motivation and to encourage high quality work performance. On an organizational level, it links other human resource management (HR) activities, such as compensation, training and development, as well as career management, making it a backbone for the management practices within an organization. As a result of these many faceted roles, performance appraisal has become a part of a more complex managerial tool, performance management. The concept of performance management considers three areas: defining performance, measuring performance and feeding back performance information[2]. From the perspective of managerial communication, providing feedback is the most critical aspect of performance management, requiring high quality formal communication skills. The performance feedback process, however, is complex and provokes anxiety for both the manager and the employee. On the other hand, if individuals are not made aware of how their performance is not meeting expectations, their performance will almost certainly not improve. Thus, an effective manager must posses the ability to provide specific performance feedback to employees in a way that elicits positive behavioral responses. This criterion is most often met by providing objective and fair feedback. The process of feeding back information to employees also often represents a procedure of setting future goals, through which managers can improve employee motivation. Noe, Hollenbeck, Gerhart and Wright identify three approaches to the feedback session: a) *tell and sell* (managers tell employees how they have rated them and then justify these ratings), b) *tell and listen* (managers tell employees how they rated them and then let the employees explain their part of the story) and c) *problem solving* (managers and employees work together to solve work performance problems in an atmosphere of respect and encouragement)[3]. In spite of the research demonstrating the superiority of the problem solving-solving approach, most managers still rely on the tell-and-sell approach[4]. When employees participate in the feedback session, they are consistently satisfied with the process[5]. Research has demonstrated, that employee active participation in the goal setting process is one of the most effective motivators[6]. Further on, it has shown that it results in increased satisfaction, motivation to improve and performance enhancement[7]. Overall, the purposes of an effective performance management system are to link employee activities with the strategic goals of an organization, to furnish valid a useful information for making decisions about employees and most importantly to provide employees with developmental feedback. To fulfill these purposes, communication is a critical aspect.

Aim of the Research

In 1989, there was a significant change of the political system in Slovakia that was followed by a transition from a centrally planned to market economy. This transition caused a shift in the nature of business environment that has moved from being relatively stable and predictable towards a more competitive and frequently changing system. The employment mode has shifted from egalitarian towards a tournament – there has been growth in usage of pay-for-performance compensation models where seniority matters less than ability to perform along with decline of average age of managers, and more mobility between jobs[8]. Such a shift has called for more flexibility of managers and workers, for market orientation in designing HR activities, and for redefining the role of human resource management as a strategic partner within the managerial activities in the companies. Within the redefined HR system, quality of work and performance are the key success indicators. In the past decade, it has been mainly foreign multinational companies entering the Slovak market, which have been introducing different managerial practices and influencing the changes in the business environment. Slovak companies, in order to stay competitive, have had to introduce different style of management and change the attitudes and skills of their managers. The new required managerial skills include participative decision-making, active listening, providing feedback, counseling, coaching, and conflict resolving[9]. All of these skills are crucial in the process of assessing performance, placing a heavy emphasis on communication abilities of managers. Thus, as the concept of performance appraisal is a fairly new phenomenon in the Slovak business environment, we seek to find in what forms it is presented in Slovak organizations and to depict how its presented forms are linked to other human resource management activities. In addition, we examine whether the managers comprehend and utilize performance assessment as a tool to motivate their subordinates and whether it influences communication in an organization. Moreover, we looked at the ways managers communicate feedback to their subordinates, focusing on its content.

Survey Data

The findings of the article are based on research that examines a sample of 52 companies that operate within the territory of the Slovak Republic. There were a total number of 718 questionnaires sent with final count of returned filled out questionnaires amounting to 512 from 35 organizations. The enterprises actively involved in the research cumulatively employ 11,765 people. There were 432 respondents from Slovak companies and 79 from those with capital investments from abroad (in one case the respondent did not state, whether he/she worked for Slovak or foreign company). We have considered this sample sufficient to generalize the main trends in a particular HR practice within the business environment of Slovakia. To achieve an objective view, we have addressed companies from all regions of Slovakia, companies of different sizes, and both Slovak and foreign in terms of capital investment [Note: further in this text companies with foreign capital investment are often referred to as "foreign" for simplicity of terminology]. We have addressed managers at all levels of management. We have not addressed employees who are not in managerial positions and do not supervise any subordinates. Moreover, as the questionnaire was in Slovak language, foreigners working in the Slovak Republic were not included in the sample.

Research Methodology

We created a questionnaire that is comprised of three parts. The first section regards the demographics of the respondents, asking their gender, position in the company (top, middle, low level management), type of ownership of the company (Slovak or with foreign capital investments); the number of employees in the company as well as the number of direct subordinates. We have also asked the respondents to identify their age by choosing one of the following categories: less than 30 years of age, 31-45, and 45 and more. Additionally, we asked the respondents to indicate their tenure with the organization. We have included four categories: working with the company for up to one year, two to five years, six to twelve years, or more than thirteen years. The second part of the questionnaire consists of 30 statements evaluated on a 1-5 Lickert scale, where '1' indicates the least acceptance of the statement and '5' indicates that the respondent fully agrees with the statement. There are various statements from different areas that evaluate the attitudes of managers towards their work, their managerial style, and communication style. For the purpose of this paper we have analyzed only questions related to performance appraisal, its forms, links with other human resource activities and the awareness of the importance of the content on the manager's part.The third part of the questionnaire consists of questions where the respondents were asked to evaluate statements qualitatively, indicating all the responses that are relevant or those that are the closest to what they think about the statement. There was also space available for personal responses/comments. For the purpose of this paper, only those questions were analyzed that were relevant to the topic. In these questions, we have not received any individual open-ended responses, so there was no need for additional grouping and coding.

Research Results

Demographics of the Respondent Group

The demographic characteristics of the respondent group were as follows. There were 115 (22.55%) top managers, 205 (40.2%) middle managers, and 190 (37.25%) line managers. The group consisted of 390 (76.32%) male respondents and 121 (23.86%) female. Out of the sample, 64 (12.52%) were younger than 30, 190 (37.18%) were from the group 31 – 45 years of age, and 257 (50.3%) people were older than 45. There were 432 respondents from Slovak companies and 79 from those with capital investments from abroad. There were 511 respondents who identified their tenure, out of which 33 (6.46%) have worked less than one year for a company, 101 (19.77%) who have worked 2-5 years with the company, 123 (24.07%) who have worked 6-12 years with the company, and 254 (49.71%) who have worked longer than 13 years with the company.

Performance Appraisal Techniques in Slovak Organizations

The *first goal* of our research was to *identify the performance assessment techniques used* in Slovak organizations. The selection of the technique is an important factor influencing the success of the overall process of performance appraisal. The most often used techniques in our sample as a whole were appraising employees without their knowledge of being evaluated and an appraising interview (Table 1). The interaction between a manager and subordinate in a form of interview provides a platform to clarify the performance quality requirements and at the same time aids in identification of training and development needs. Additionally, it presents an opportunity for further goal setting and establishment of a working relationship between the manager and the subordinate. However, it demands high quality communication skills from the manager, especially in terms of objectivity and fairness. Also, an interview provides a better environment for linking assessment of performance with other human resource management activities, thus creating performance management. Last but not least, following "interactive" assessment interview, future goals can be mutually agreed upon. There proved to be a major difference in using assessment techniques requiring communication skills, when looking at the sample from the perspective of the ownership of the company. Here we see a dramatic shift in the preference of the selected technique. In foreign companies, the interviews outnumber all other techniques – they are used in 69.62% cases (Table 2). This indicates a certain level of reluctance from the Slovak managers to communicate on a "person-to-person" basis the results of the performance assessment, which also has significant consequences in terms of setting future goals with the employees. More in-depth analysis of the sample shows, that Slovak managers, when assigning tasks to the employees, prefer to do so in a written form, even if a dialogue precedes it. This does not provide space for managers and their subordinates to clarify expectations and and also to discuss possible steps to enhance or correct performance[10].

TABLE 1. PERFORMANCE APPRAISAL TECHNIQUES USED IN SLOVAK COMPANIES

WHAT FORM OF PERFROMNACE APPRAISAL IS USED IN YOUR COMPANY?					
	A	*B*	*C*	*D*	*E*
Employees write their own self-evaluations **A**	1.75 %				
Evaluation interview **B**	0.97 %	**23.24%**			
Superior evaluates subordinates without their knowledge **C**	0 %	0.42%	**27.14%**		
Superior ranks the employees according to their performance **D**	0 %	1.56%	1.36%	18.16%	
Employee is evaluated by multiple parties **E**	0.19%	1.56%	0.42%	0.97%	14.06%

Respondents were allowed to mark multiple answers if applicable; the chart is of matrix type, i.e. cell AA represent a single answer, whereas columns represent all possible combinations of answers

TABLE 2. COMPARISON OF THE PERFORMANCE APPRAISAL TECHNIQUES USED IN FOREIGN AND SLOVAK COMPANIES

	SLOVAK	FOREIGN
Employees write their own self-evaluations	2.31%	7.59%
Evaluation interview	**20.37%**	**69.62%**
Superior evaluates subordinates without their knowledge	32.87%	10.13%
Superior ranks subordinates in order of their performance	24.31%	11.39%
Employee is evaluated by several parties	18.06%	15.19%

*Respondents were allowed to mark more than one answer

Content of the Feedback – Managerial Role in Performance Appraisal

The *second goal* of our research was to *identify, whether or not managers realize the importance of the content of the feedback process* in order to provide objective information and thus fulfill the motivational aspect of performance management. Performance appraisal provides an environment for both manager and subordinate to learn, explain and clarify each other's expectations and attitudes. What is important for a manager to learn during performance appraisal reflects his or her style of management, their inclination towards achieving goals and/or understanding their subordinates. In our questionnaire we asked managers to indicate their preferred approach to the quality of the message and interest in the relationships among the employees and in the personal life of the employees. Here, multiple answers were also possible, and we have seen them more among managers from foreign companies than from Slovak ones. Only approximately 10% of managers from both groups think that they should evaluate only achieved goals. Although both groups of managers agree that the evaluation should be factual and not biased (70.37% from Slovak companies; 63.29% from foreign), managers in foreign companies put more stress on the fact that they should provide both positive and negative feedback (77.22% compared to 32.64% of Slovak managers). They also show more interest in personal problems of the employees (15.19% compared to 9.72%) and in the relations among the employees (30.38% compared to 15.28%). The form of performance assessment, again, enables this: the interview, as a dialogue, can give rise to issues of interpersonal relations of the subordinates and thus a more complex understanding of their work-related attitudes. Moreover, the results show, that there is overall awareness on the manager's part that objectivity and fairness are important features of the performance assessment process, yet a certain gap exists in practices between Slovak companies and those of foreign capital ownership.

TABLE 3. MANAGERIAL ROLE IN PERFORMANCE APPRAISAL

IN YOUR OPINION, DURING PERFORMANCE APPRAISAL EVALUATION, THE MANAGER SHOULD			
	Total	**Slovak**	**Foreign**
Evaluate goals	9.78 %	9.72 %	10.12 %
Show interest in personal problems of subordinates	10.56 %	9.72 %	15.19 %
Evaluate matter factually	69.27 %	70.37 %	63.29 %
Show interest in the relationships among subordinates	17.61 %	15.28%	30.38 %
Provide both positive and negative feedback	39.53 %	77.22 %	32.64 %

*Respondents were allowed to mark more than one answer

Use of Performance Appraisal Results Within the Human Resource Management System

The *next goal* of our research *focused on depicting how performance management systems in organizations in Slovakia link with other human resource management activities*. The link of performance appraisal with other human resource management activities is important from multiple perspectives: a) it fosters person-to-person communication within organization on a formal level and establishes relationships b) serves an employee developmental purpose and c) creates a performance management system and enables the organization to align individuals with its strategic goals.Almost 40 percent of respondents stated, that the information obtained from performance appraisal is solely used in compensation; 12.69 percent of respondents identified that the results are used in the goal setting process. Less than 5 percent of the organizations use the information in specifying the needs of further training or career development (Table 4).We consider this insufficient utilization of the information about the employee performance, which the Slovak organizations possess. If the performance assessment is to serve its multiple purposes within the HR system, it needs to be linked to other activities, specifically assessment of the trainings needs and setting the future goals for the employees. Moreover, some of the used techniques (mainly 360 feedback and self-evaluation) are more frequently used in career development and assessment of training needs and are not suitable for decisions about compensation because they tend to become less reliable[11]. Thus, it is necessary for organizations to re-evaluate the suitability of the selected performance appraisal technique. Additionally, the selected technique influences the feedback communication style.Following these findings we decided to look at the differences between the practices of Slovak companies and those of foreign capital ownership. The main difference in using the information obtained in performance appraisal was in using the information for identifying further training needs, career development and goal setting (Table 5). Foreign companies use performance appraisal as a strategic tool; not only to evaluate past performance of employees, but also as a developmental practice for future growth of their employees. This finding is important particularly from the perspective of the communicational role of performance appraisal. If consistency is to be reached within the HR policies of the organization, communication of the results of performance assessment along with their utilization is a mean to obtain it. It is also interesting to see that almost all foreign companies apply the information from performance appraisal in some way, while Slovak companies slightly lag behind with 8.56% of them not utilizing information from performance appraisal at all. This finding is in correspondence with the above-mentioned difference between Slovak and foreign companies in using interview as the main feedback practice. The analysis of training needs, career development and setting further goals requires intensive communication from both parts, the manager as well as the subordinate, and should be mutual to achieve consensus and further employee development.

TABLE 4. USE OF PERFORMANCE APPRAISAL RESULTS IN SLOVAK ORGANIZATIONS

INFORMATION FROM PERFROMANCE APPRAISAL IS USED IN						
		A				
Compensation	**A**	**38.28%**	*B*			
Analysis of training needs	**B**	4.88 %	3.51%	*C*		
Career development and career growth	**C**	2.92%	0.39%	1.36%	*D*	
Setting of further goals	**D**	6.64%	0.78%	0%	12.69%	*E*
Are not used for any of the above	**E**	0 %	0%	0%	0%	7.42%

*Respondents were allowed to mark multiple answers if applicable; the chart is of matrix type, i.e. cell AA represent a single answer, whereas columns represent all possible combinations of answers

TABLE 5. COMPARISON OF THE USE OF PERFORMANCE APPRAISAL INFORMATION IN FOREIGN AND SLOVAK COMPANIES

	SLOVAK	FOREIGN
Compensation	65.05%	73.42%
Analysis of training needs	16.20%	**51.90%**
Career development and career growth	9.26%	**46.84%**
Setting of further goals	27.08%	**44.30%**
Are not used for any of the above	8.56%	1.27%

*Respondents were allowed to mark more than one answer

Motivational Aspects of Performance Management

The final goal of our research was aimed at finding out whether managers see performance appraisal as a tool to enhance the motivation of their subordinates. If performance appraisal is to have a motivational character, it is important that it is communicated in a factual manner, objectively and on time (it has more motivational effect, if it is communicated right after a certain performance takes place). Moreover, it is very important from the motivational perspective, that the employee does not feel his/her performance is appraised using double standards; in other words, employees have the tendency to compare each other and it is important they feel the appraisal is just. From the communication aspect, the style of communication plays important role; more accepted the message of the rater, more motivational it is for the 'ratee'; increasing trust, satisfaction, organizational commitment and citizenship on the subordinate part. Vast majority of the respondents of the sample feel that performance appraisal has motivational impact on the employees. However, here we came to interesting conclusion. Even though almost 83% of the respondents think that performance appraisal is motivational, only 66 % percent evaluate performance on regular bases. The difference between the practices of Slovak and foreign companies were apparent here, where there was much stronger relation between the practices and realization of motivational aspect of performance appraisal in foreign companies than in Slovak ones.

Discussion and Limitations

This study has proved that performance appraisal is used on Slovak companies as a mean of formal communication, because it is used as a basis for other HR activities and managerial decision-making. It also shows that performance appraisal is a source of feedback for the employees and helps foster consistency of other human resource management activities. It has showed, that performance appraisal is present in Slovak organizations in various forms, however it also depicts that there is adifference in usage of performance assessment between Slovak companies and companies with foreign capital investment, with the later being more advanced, especially in relation to person-to-person communication. Slovak companies show tendency to be reluctant to a "personal" approach of communicating feedback to their employees. If performance appraisal is to be an effective tool of human resource management, increasing employee motivation and satisfaction, it is to be based on two-way communication between he manager and the subordinate. Additionally, the result of the research showed, that if feedback is communicated personally, there is more tendency to link the performance appraisal to other human resource management activities (as in case of foreign companies present in the Slovak market), creating environment for management by objectives (MBO) approach along with setting the platform for employee development; as in the case of foreign companies. Moreover, it aligns the individual employee development with strategic goals of an organization, contributing to creation of competitive advantage. Performance management, especially its feedback providing part, places high demands on managers in terms of communication skills and the organizations (specifically those of Slovak capital ownership) have to pay attention to the management "communicational" development, as it promotes person-to-person communication channels, establishes relationships and serves employee developmental purpose. Thus, the Slovak companies should focus on management development, promote "personal" ways to provide feedback and to use performance appraisal as a "future oriented - developmental" tool rather than focusing solely on past performance.

Conclusions

Communication among members of an organization, as well as between them and the external environment, is one of the most critical organizational processes, influencing overall performance and effectiveness. Performance management, as a mean of communication in organization, informs the employees of the quality of their work and often of the performance of a department or a team or even the results of the whole organization. It is used to ensure that employee activities and outcomes are congruent with the organization's objectives resulting in the company's successful implementation of strategy. With performance as success indicator, the need to assess performance and benefit from the gained information has become a vital part of managerial job and a common practice in the Slovak business environment. Managers in Slovakia understand it as a tool to motivate their subordinates and incorporate it into activities they regularly perform. It is necessary, however, to ensure, that the techniques used in the process of performance appraisal are chosen in a way, that validity and reliability of the selected performance assessment practice are of the highest possible scores. In Slovakia, performance is assessed on regular basis and the gained information is then used for decisions about compensation, training and development, and for setting further goals. However, there is a gap between managerial practices of companies that have foreign capital investment and those that are Slovak, especially in the person-to-person communication used by managers.

Trends of Flexible Work Arrangements and their Applications in the Slovak Republic

Lubica Bajzikova
Comenius University in Bratislava, Slovak Republic
Helena Sajgalikova
University of Economics Bratislava, Slovak Republic

Abstract

The issue of labour flexibility is currently prominent in industrial relations across the European Union and beyond. It is in this context that this research seeks to examine: the background to the growing importance of this theme in Europe; the view and strategies of the parties (employers, trade unions and governments); and occurrence of different flexible work arrangements in use in the Slovak Republic.

Given the scope of the changes, which have occurred, in the area of labour market over recent years, the research finds that it is unfortunate that only incomplete and disparate statistics and analyses are currently available. An international comparison in this area can thus be only of a qualitative nature.

I Flexible Work Arrangements Overview

1 Introduction

Over the quarter of a century of rapid growth with almost full employment, which followed the Second World War, the regulation of working time in Western Europe followed a number of rules, which steadily became general throughout the continent. These basic rules were as follows:

- for full-time workers, the law set maximum and normal durations for hours worked and companies adopted stable collective work timetables. The margins for flexibility were provided by the use of overtime working and temporary unemployment (lay-offs and short-time working);
- the only role for collective agreements was to improve on statutory provisions, mainly by reducing the length of the working week and increasing the length of paid holidays;
- the reduction of working time was seen as a part of social progress. It was one way, along with pay increases, of sharing productivity gains; and
- atypical working hours were used only to solve specific problems. First, night and weekend work fulfilled certain technical needs related to production, or the needs to keep some public services open at all times. Second, part-time work, which accounted for an increasingly large proportion of the workforce, especially in northern Europe, fitted a widespread social model of women's economic activity, and it was the same logic which brought about, at the end of this period, some experiments with flexible working hours ("flexitime") for office workers.

For the past 25 years, this framework has been in the process of profound transformation due to the conjunction of developments of varying nature, such as: new forms of organisation of production and marketing; the intensification of international competition; increasing unemployment; and new needs and preferences among male and female workers regarding the organisation of their working time. The disparate nature of these changes explains why the move toward introducing flexibility into working time has reflected different, and often contradictory, interests and objectives, depending on the economic and social actors concerned.

The theorists have tried not only to identify the most appropriate forms of work arrangements, but also to class the layers of employees concerned.

Thus, any survey of non-standard working from the employer's perspective must start with a description of the now classical work of John Atkinson (1984) and, in particular, his proposed model of the "flexible firm". Its main feature is the suggestion that a flexible firm (by which Atkinson means one that is competitive in the modern business environment) is composed of three basic groups of employees: core workers, peripheral workers and a third group who are employed only on some kind of subcontracted basis. The basic model is illustrated in Figure 1.

Central to the model are two distinct types of flexibility: functional and numerical. The former is applied specifically to the core workers – that is, people who are employed on standard, permanent, full-time contracts and who undertake the tasks that are central to the success of the organisation. They are functionally flexible, in that they do not work to rigid job descriptions but carry out a broad range of duties. Moreover, they do not restrict their activities to work of a particular level. Instead, they carry out complex tasks associated with managerial or professional jobs as well as more mundane activities, depending on the day-to-day needs of the organisation.

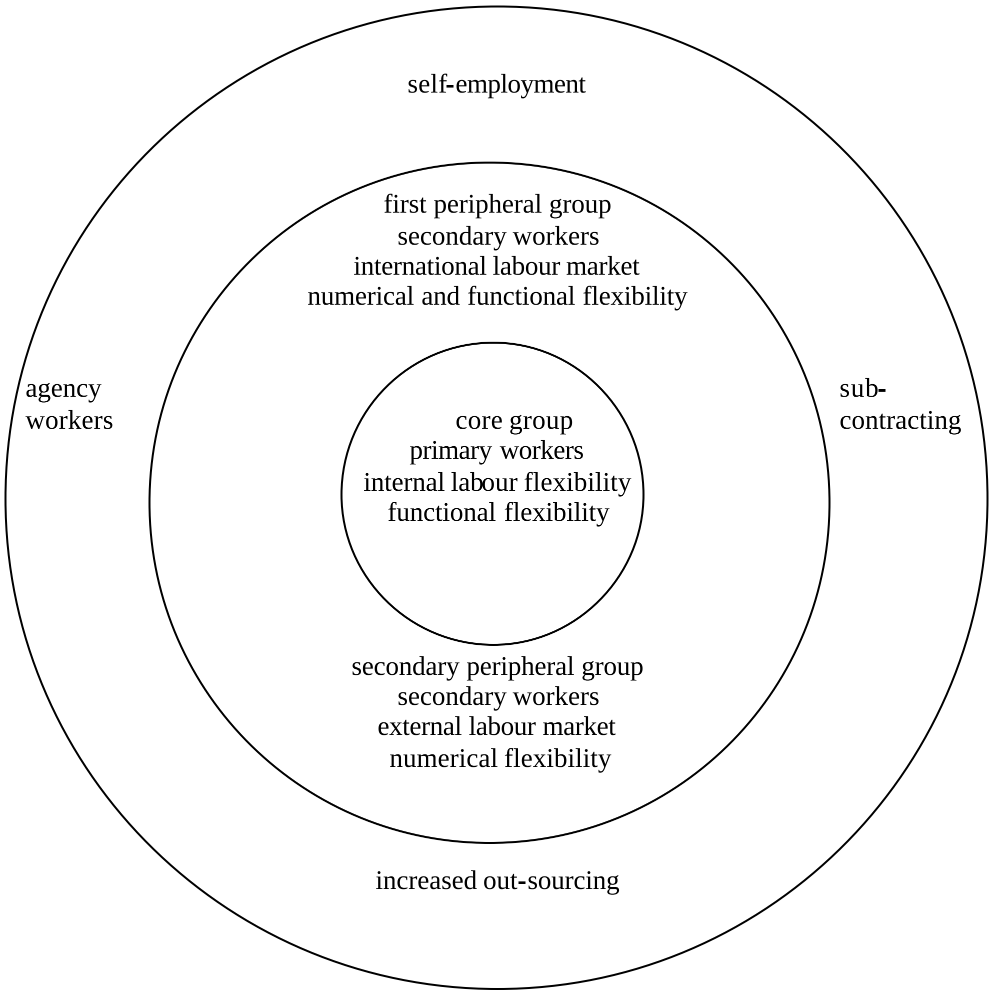

FIG. 1: THE FLEXIBLE FIRM

Source: Atkinson (1984)

The peripheral group can also be functionally flexible, but in the model is more strongly associated with the term "numerical flexibility and temporal flexibility". Atkinson divided peripheral workers into primary and secondary categories, the first forming part of the firm's internal labour market. These people are mainly full-time and have a certain degree of permanence, but tend to have lower skills than colleagues who enjoy the status of core employees. As individuals they are less central to the organisation's success because their skills are more widely available in the labour market. They therefore enjoy lower job security than the core workers and will be among the first to have their hours cut or to be laid off when business downturns are experienced. The secondary peripheral group members are in an even more precarious position, because they are brought in mainly to help cover peaks in business or short-term needs resulting from the absence of other staff. They are employed either on a part-time or temporary basis.

The final group, located beyond the periphery, consists of people who are not employees of the firm but who are hired on a subcontractual basis to undertake a particular task or set of tasks. In the vast majority of cases this will be temporary, and hence insecure, although it is possible for a series of fixed-term contracts to follow one after another. Some may be professionally qualified people working on a self-employed basis; others may work for an agency or some other service provider. In both cases they are perceived by the other groups as being external to the organisation and thus readily replaceable by a competitor should their work prove to be unsatisfactory or more cheaply provided elsewhere.

Over recent years others have proposed similar models (eg Loveridge and Mok 1979, Handy 1989). In *The Empty Raincoat* Charles Handy (1994) suggests that employers will increasingly wish to buy a specific *service* from a worker rather than that person's *time*. The result will be a situation in which, for most people, there will be little opportunity to enjoy the security of a long-term, full-time job. Instead, Handy believes, people will have to develop portfolio careers in which they earn money by "looking for customers, not bosses". Employers will be both far less willing and able to employ people (especially professionals or "knowledge workers") to come to their premises for a fixed number of hours each week. Rather, they will say, "Do this by this date; how you do it is up to you, but get it done on time and up to standard." The term "job" will thus revert to its original meaning of a specific task or project rather than an occupation or profession, while individual ambitions will focus more on the achievement of employability than the status of being an employee. The same kind of analysis also underlies other influential publications concerned with the future of work, some writers going further than Handy in respect of the speed with which and the extent to which they believe these developments will occur (eg Bridges 1995, Rifkin 1995, Davison and Rees Mogg 1997).

A number of others have come out in opposition to some of these ideas, and particularly to Atkinson's model, such as Anna Pollert who has argued in a series of books and articles that there is nothing particularly new about flexibility as it is described by Atkinson. Firms have always had to slim down their workforces when faced with difficult business circumstances, and they have always shed subcontractors and peripheral workers first. What is new, according to Pollert (1987, 1988), is the promotion of flexibility in the form of a model intended to guide management actions. In other words, it is the idea that organisations should deliberately develop core and peripheral structures as part of a considered strategy that represents a departure from past practice. However, she goes on to argue that there is little evidence that managers are in fact adopting such strategies. Her point of view appears to be backed up by the survey evidence, which has persistently shown that while the extent of self-employment, temporary and part-time work has increased in recent years, this results from managers' reacting on an *ad hoc* basis to specific needs (Hakim 1990, McGregor and Sproull 1992), reflecting a continued demand for part-timers in retailing, catering and publishing. Since 1994 has in fact seen the creation of substantially more permanent jobs than temporary ones (Donkin 1997).

Moreover, we can see that trends in different kinds of non-standard working affect different industries unevenly. For example, there is relatively little part-time working in manufacturing, but there is a good deal of subcontracting. By contrast, the use of fixed-term contracts has grown most in the public services, where funding to undertake specific projects is limited in terms of time. Such contracts are also used extensively by employers whose workload increases and decreases on a seasonal basis (eg in tourism and agriculture), and have necessarily become highly significant in sectors where most employees are female, as a result of the greater take-up of the right to maternity leave in recent years.

Thus, the interest in flexible arrangements of work go far back to the history. However, for a long time its various forms were used by individual employers or were typical just for particular sectors. Only at the end of the last century the more systematic approach shaped into consistent research into the field on the one hand and the first legislative steps on the other. Back in 1998, the European Commission's Green Paper on Partnership for a new organisation of work devoted considerable space to the question of a new approach to working time, examining both reorganisation and reduction. The EU Guidelines for Member States' employment policies 1998 underlined the importance of work flexibility, and the social partners' role in achieving it, in employment creation/preservation. The guidelines invited the social partners "to negotiate, at the appropriate levels, in particular at sectoral and enterprise levels, agreements to modernise the organisation of work, including flexible working arrangements, with the aim of making undertakings productive and competitive and achieving the required balance between flexibility and security". However, it was still too early, according to the Commission's May 1998 review of the National Action Plans developed by EU Member States in response to the guidelines, for the social partners' response to be fully developed.

2 Categories of Flexible Organisation of Work

Working time flexibility may be defined as permanently variable and adjustable working time in terms of structure and length. Working time flexibility is closely associated with the notions of the flexible firm on the employer's side and time sovereignty on the employee's side.

Working time in an employment relationship concerns two dimensions, the length (e.g. in hours) and the structure (e.g. working in shifts or on demand) of individual working time. Points of reference may be daily, weekly, monthly, annual or life working time. Means to achieve working time flexibility in an employment relationship are as follows:

- variable working time regarding length and structure;
- flexi-time;
- working time accounts;
- overtime;
- working time corridors, which gives companies the possibility, within a certain limit, to reduce or to extend working time;
- job sharing;
- sabbatical leave;
- early and partial retirement;
- weekend work;
- part-time work;
- temporary work;
- parental/maternity leave;
- homeworking;
- telework.

3 Purpose of Implementation of Flexible Work Arrangements

3.1 Employer Perspective: The Flexible Firm

The idea of the flexible firm suggests that the firm is flexible in terms of its adaptability to expansion, contraction or change in the product markets. Among others, flexibility serves as means to improve productivity and to cut unit labour costs, to adjust to unpredictable fluctuations, and to allow for the introduction of new manning practices to match new technologies. The flexible firm involves the notions of financial (and pay) flexibility, functional flexibility (e.g. by multi-skilled employees), subcontracting, outsourcing and distancing strategies (employment relationships are replaced by commercial ones), and numerical flexibility.

The numerical flexibility of the firm concerns the firm's ability to adjust the level of labour inputs, employment and the wage bill to meet fluctuations. Practices include:

1) the use of additional or supplementary labour resources such as part timers, temporary workers or casual workers;
2) the alternation of working time patterns of existing labour resources.

For the firm, working time flexibility allows to increase the general flexibility of the organisation to adjust to unpredictable fluctuations. It may allow to detach the company's operating hours from the individual working hours. Furthermore, some flexibility models, e.g. working time accounts, avoid that working time is counted as overtime and thus the employers does not have to pay the regular overtime bonuses.

3.2 Employee Perspective: Time Sovereignty

From the employee perspective, flexible working time provides an opportunity for more individual "time sovereignty" which could help to organise working time more in relation to the individual needs and interests. Important issues in this respect are the individualisation and differentiation of employees' interest and the dependency of these interests on the respective situation in life. A further important perspective concerns gender and the reconciliation of family and work.

4 To Sum-up

To summarise, the theme of flexibility of work organisation is currently coming to the fore, with varying degrees of intensity, in all European countries. In some countries, the debate began as early as the late 1970s, while in, others the matter only really arose a few years ago. However, in almost all cases work flexibility is seen as an important topic for the future. The emergence of this new factor in collective bargaining can only be understood in the light of economic, technical and social changes over the past 25 years. Governments and social partners have had to adapt their analyses and strategies to this new issue, and as a result, there have been changes in the content of the rules framing the length and utilisation of working time, and also in the character of these rules, whether statutory or collectively agreed, compulsory or optional.

Although the situation varies a great deal from country to country, it must be emphasised that in the majority of them, procedures for gathering statistics and analysis provide only incomplete, disparate and piecemeal information on the processes of implementation of forms of flexible organisation of working time, on their content and on their results. Statistics on working time and collective bargaining usually correspond to traditional categories which do not enable the character and scope of innovations to be identified. Analytical work provides contradictory results, which disparate methodological approaches do not allow to be compared with one another. It would be desirable that, in an area in which major changes are already under way or just starting, relevant and comparable information should be put at the disposal of those involved (Jacques Freyssinet, IRES).

5 The Future

It is necessary briefly to consider what the effects will be if the management gurus who have predicted sweeping change in work organisation turn out to be right. What will the effects be in employee-resourcing terms if non-standard working become the norm and people too seriously cease to expect, or even to seek, long-term, full-time employment with a single employer, preferring instead to work on a self-employed consultancy basis for a number of clients? The straightforward answer is that there will be a need for employee-resourcing specialists to find ways of managing through or round some of the disadvantages associated with atypical working described above. However, there are other potential consequences too – some of which can already be observed in industries where there are lucrative freelancing opportunities for people with particular skills. Examples include computer programming, some branches of engineering and the provision of some specialised business service.

The most obvious result is increasing difficulty in finding people to undertake work at the rates of pay currently being offered. The organisation is thus faced with three options:

?? to accept that it is necessary to employ freelancers at whatever cost

?? to hire untrained staff and then to invest substantial amounts in training them

?? to compete more effectively in a tighter labour market, giving particular attention to the retention of valued staff.

For many organisations this will require fundamental changes in the approach taken towards employee resourcing. It will no longer be possible simply to assume that, if someone leaves, they can readily be replaced by another person with similar skills. In other words, it will be necessary for managers to accept, to a far greater extent than is often the case today, that competitive labour markets exist, and that they need to develop effective strategies for competing in those that are vital to the success and survival of their organisations. Secondly, there is a need to redefine the psychological contract that is developed with employees by fostering relationships that facilitate high trust but that are not expected by either side to last for a long period of time. This involves acknowledging that employees will have different expectations from employers. Instead of seeking furtherance of a career inside an organisation, they will be looking instead for opportunities to increase their employability. To attract and then to motivate the best, more attention will thus have to be given to skills acquisition and to finding opportunities for employees to deepen their experience.

A third possibility that arises if key labour markets become much tighter than they are at present, could be need to alter the perspective from which strategic business planning currently takes place. Instead of looking for product market opportunities and then devising employee-resourcing policies to permit their realisation, there will increasingly be a need to start the process by assessing the organisation's labour market position. Strategic planning would thus commence with questions being asked about the pool of staff and skills on which the organisation can draw. Product market strategies would then be based on the results of this analysis, rather than the other way round.

II Flexible work arrangements in Slovakia

1 Methodology

The research utilises structured questionnaires and semi-structured interviews covering the application of various types of flexibilities as well as the willingness of the employers of the employers and employees to participate in these schemes.

Within the research there were 1423 questionnaires sent out to 67 organisations of different sizes, different industries and different ownership as well as managers of 46 companies were interviewed. The returned questionnaires accounted for 62 %.

The only flexible form of work arrangements, which is consistently recorded and reported, proved to be flexi-time. The other forms were commented on in the interviews as being applied or planned to be implemented, however, no relevant recording was offered to provide reliable evidence on their implementation in the view of the ratios of such flexible arrangements versus regular traditional work arrangements. Thus, only qualitative evaluation of the research could be provided.

2 The Findings

The most common flexibility form appears to be flexi-time. The other forms – part-time and temporary contracts are mostly used for peripheral groups of various categories of employees, primarily in services and media. They – as it is mentioned above – include well-paid positions as well as those in less glamorous ones.

In addition, part-time and temporary contracts are used in probation period as well. The managers argued that these forms of flexibility facilitate the termination of the employment relationship and prevent from the potential conflicts and cut administrative procedures and costs necessary for appropriate termination of the employment contract. Telework as a flexible form has not been introduced by any of the contacted organisations.

2.1 Flexi time

In Slovakia the framework for utilising flexi-time is set by the Labour Code. It assumes that both the beginning and the end of the work shift is set by an employee within so-called daily, weekly or four-week working cycles while the obligatory daily spell of presence at work (minimum 5 hours) is established. The presence at work is at the employee's discretion. In the case of daily working cycle, the employee is obliged to work for a preset number of hours within a day (it is the same amount of hours every day)and flexibility relates just to the beginning and end of the working block. The weekly variation presets the number of hours to be worked weekly, but the number of working hours can vary daily. If the four-week working cycles are applied, the number of hours to be worked is based on the weekly figure multiplied by four. Here, a number of hours to work can be shifted also from one week to another.

The employer here benefits primarily from the fact that all out-of-work commitments of the employee can be covered outside the working hours.

While numerous employees use mass transportation to get to work, the general benefit of flexi-time can be seen also from the perspective of transportation organisation in large cities. On the other hand, if commuting depends on particular lines (buses, trains) and the employees cannot get to work otherwise, the employer will not have chance to introduce flexi-time. As mentioned above, flexi-time is difficult to implement in some industries, eg manufacturing. If it is introduced, it mostly applies to the back offices in companies. Nowadays, flexi-time is used in less than 10 companies (approx. 5,000 employees) in metal industries, mostly owned by German capital.

The implementation of flexi-time on the part of the employer relates mostly to the industries with predictable or unpredictable fluctuation of work loads. The predictable fluctuation of work load occurs in agriculture, forestry, construction and the like. The Labour Code allows for flexi-time arrangement in a longer horizon, i.e. four-week or yearly arrangement. It means that in the busy season the employees work longer hours or more days a week while in the troughs they work less hours or even less days.

Unpredictable fluctuation occurs when the employer is forced to react to the unpredictable demands of the environment, eg loss of orders or large number of new ones. This is mostly the case of subcontractors. Such a case is not covered by the Labour Code in force at present and therefore the situation can be solved partially just through flexi-time arrangement. In Slovakia, the German model of flexi-time application is used, mostly in the subcontracting companies of large automobile producers. Here, if the employee does not work the full number of working hours within a particular month, a bank of working hours is created with either plus or minus balance. The employee is paid as if they worked full monthly time in either case. If the employee worked more, as compensation they can utilise time off in the future when the work load is lower and vice versa. The zero balance must usually be reached within a year. Of course, the implementation of the model must observe the general provisions of the Labour Code, such as the maximum length of the work shift, rest between two shifts, obligatory days for rest etc.The disadvantage here is that the implementation of such a model cannot be covered by a general agreement (e.g. collective agreement), but is always part of the employer-employee contract/relationship. Thus, the relationship is not neutral. The employer is usually more powerful. While the employer lowers the costs related to overtime, the employee may experience even raise of the costs, eg for transportation or childcare. In addition, a conflict can emerge if the employer needs the employee to be at work at the same time when the employee is forced to take time off because of external commitments. Again, infrastructure can also has its say in the introduction of this model in some regions.

2.2 Part-time Work

The part-timer if not working more than 20 hours per week exercises the position as that of a full-timer under the terms and conditions of the current Labour Code of the Slovak Republic. It relates primarily to the contributions to the social funds (e.g. pension scheme, health insurance etc.). The only disadvantage seems to be job insecurity, while the employer can terminate the contract without any notice.

2.3 Temporary Work

The implementation of the temporary contract cannot exceed 3 years. The employer, even if decides to terminate the contract earlier, is obliged to pay the agreed-upon reward fully. This contract's disadvantage is that termporary workers are not considered as potentials in terms of training and career development. The other form of termporary work covers the contracts limited by 300 hours per year. In that case, the temporary worker is paid just for actually carried out work. This form is frequently utilised while there are no contributions to the funds and thus labour costs are substantially lower. There is no obligatory recording and reporting of such contracts and therefore they are frequently misused, e.g. by the unemployed who may acquire regular pay along social welfare, or by employers who are able to dovetail several temporary workers positions to cover a full-time position and simultaneously cut the obligatory payments.

Conclusion

As mentioned above, the most used flexible work organisation is flexi-time, part-time and temporary contracts are used primarily because of economic reasons, such as cutting costs, no need for contributions to social funds, no need for redundancy payments in the case of closing jobs/positions, remuneration includes only base pay, frequently it means just the minimum pay. From the cultural point of view, there is no surprise that telework has not been introduced yet. Moreover, low mobility of workforce and usage of mass transportation and its availability can influence the introduction of this or that flexible form in spite of the wish of employers or employees. The Labour Code and its restrictive character can influence the way how flexible forms can be utilised as well.

The Impact of Privatization on the Economic Reforms in the Kyrgyz Republic

Jyldyz Aknazarova
Osh State University, Kyrgyzstan

Abstract

This paper seeks to demonstrate that privatization, if well implemented, will have a positive impact on economic development and democracy. Privatization is presented as a process of transferring assets from the public sector to the private sector. The world privatization experience has shown that successful implementation of privatization creates an environment for stabilization and structural reforms. Over the longer term, there is a clear need to assist the Kyrgyz Republic to ensure that privatized enterprises have the opportunity to remain viable and grow, and respond to their shareholders. Without attention to corporate governance and increased corruption, privatized enterprises could miss opportunities, expose their reputations to greater risk, and find themselves at a competitive disadvantage. Under this arrangement, the country creates favorable conditions to attract foreign investments and will foster further privatization and impact successfully on the economic reforms as a whole.

Introduction

The policy of privatization is based on the idea that activities of enterprises being implemented under free market economy with equal competition and commercial approach are more effective than those within administration limitations and instructions. The market is considered to be the source of social economic progress, the level of which depends on how competition is encouraged to increase production and consumer services.

Notwithstanding the depth and scales of revolution in the area of privatization, it remains an obscure notion to the majority of population. Actually, privatization includes many different approaches, goals and results. Some authors point out a necessity of good reasoned and consistent steps on the way to privatization, which would match a carefully developed conception[i]. The authors emphasize that "low effectiveness of production and inevitability of privatization are obvious"[ii]. Further, analyzing role of privatization in implementation of economic reforms, the authors write that "denationalization and privatization are, for sure, powerful mechanisms, which can enable the country to obtain in a new image, transform into a new quality of social and economic organization"[iii].

The problem of privatization is presented in discussions of its advisability. While such discussions take place, it is pointed out that consequences of privatization often appear to be negative in terms of the nation's wellbeing and social justice. In other words, privatization results in unreasonable enrichment of a narrow circle of the population and pauperization of the majority of the society. Actually, it is true, but in a short-term aspect. If privatization is considered not as a quick action, but as a long term and very complex process of changes, over a long period of time, its final aim is creation of effective economic public system.

In 1992, the Kyrgyz Republic embarked a broad program of stabilization and structural reform, including price liberalization, mass privatization and liberalization of the trade regime. Most prices were liberalized with the removal of all direct and indirect price controls, and as for trade policy, all non-tariff barriers to exports and imports were removed. A mass privatization program has placed approximately 1000 primarily medium-sized and large enterprises and several thousand small businesses under private control.

In Kyrgyzstan, the mass privatization was conducted in the following way: the whole adult population was given privatization coupons on a free and equal base, with further rights to purchase apartments or exchange them for shares of state owned enterprises. The coupons were easy to trade. But the market prices of the coupons were very low. The price of 100 coupons was 1.22-1.35 soms, one coupon being approximately 0.0008 US$. Thus the distributed coupons equaled 0.625 US$ per capita in the Kyrgyz Republic. As a result, the coupons were not considered seriously by their owners.

This method was widely used in the Czech Republic, Romania, Poland, Russia and Byelorussia. Unlike other ways, it does not require financing, and it does not gain budget revenues. The main peculiarity of this method is that the privatization process is quick and socially acceptable by the population. But the weak point of it should be admitted: that is the fact that the real situation of enterprises after privatization remain the same with all its related problems: difficult financial situations, low profitability, out-dated technology, and insolvency.

According to our viewpoint, the difficult situation of the industrial sector is due to the following reasons:

First, lack of joint tax, financial, capital-credit and currency policy with the NIS;

Second, differences of law regulations which effect cooperation and direct relations of enterprises;

Third, lack of common price and customs policy;

Fourth, low effectiveness of the management system resulting in slow and poor decision making, inadequate control of decision making and irresponsibility of managers;

Fifth, permanent increase of price of energy, raw materials, materials, and spare parts, which have worsened the problem of the payment of balance;

Sixth, underassessment of the necessity of state regulation in order to study the conditions of the effective functioning of the economy.

For the period of January 1, 1991 to 1994, in the Kyrgyz Republic, 5168 enterprises were privatized: in the industrial sector – 324 units, agricultural sector – 319 units, construction sector – 307 units, transportation sector – 102 units, trade and public catering - 1756 units, public service – 1878 units, non-production sector –218 units. But since 1994 (the second phase of privatization) the correlation of privatized enterprises has changed in terms of the ways of privatization. Transformation into joint stock companies was most common, which reached 40 percent. As for purchase by employees, it was only 3,7 percent, and purchase by private business – 16,2 percent. This correlation of ways of privatization is due to the fact that by 1994 big plants, factories and enterprises remained unprivatized, and later were transformed into joint stock companies. The table below provides a breakdown of the privatized enterprises in the Kyrgyz Republic:

	1993	1994	1995
Industry	259	324	462
Consumer Services	1,811	1,878	1,899
Trade and Catering	1,616	1,756	1,801
Agriculture	235	319	342
Construction	232	307	390
Transport	82	102	136
Other branches	192	482	856
Total	4,428	5,168	5,895

Fig.1 PRIVATIZED ENTERPRISES IN THE KYRGYZ REPUBLIC, 1993-1995
Source: Kyrgyz State Statistics Committee, 1996.

In 1996 the private sector in the Kyrgyz Republic was 50 per cent of GDP. As for other Central Asian countries, it was 20 per cent in Tajikistan, 30 percent in Uzbekistan, 30 per cent in Turkmenistan and 30 per cent in Kazakhstan.

The market oriented reform policies implemented by the government over the past years have promoted multiple sources for competition in the Kyrgyz Republic. The demonopolization of specific sectors (such as transportation and agro-processing), including the dismemberment of formerly vertically and horizontally integrated state companies, has allowed for the creation of competing markets and the liquidation of non-viable firms. The lowering of tariffs to a flat 10 percent and the elimination of quotas and other non- tariff barriers have made imports an important element of priced discipline to domestic producers. Finally, the liberalization of major restrictions to internal trade and foreign investment have created incentives for private entry, and, therefore, to expand and develop new markets.

Despite these reform efforts, private sector growth has been hampered by a number of factors. Markets are small and dispersed, the cost structure is high and the number of risk-takers small. There are important sectors, still run by state owned monopolies, where competition could be an important source of private sector development. Little restructuring has taken place at most privatized enterprises, which remain largely under the control of the same managers that directed them as state-owned entities. Foreign investors, who could offer new technologies, modern management methods, and access to world markets, are presented in only a handful of companies, and the securities markets lack sufficient liquidity to facilitate ownership change. Many new commercial laws have been adopted , but the judicial system is weak and court decisions are often unenforceable, and licensing requirements are often excessive. The system of corporate taxation lacks many of the incentives necessary to stimulate growth. Coupled with managers' fear of outsiders and loss of control, these factors have contributed to the general lack of investment and growth in Kyrgyz firms. John Nellis emphasizes that ironically privatization's present reputation in many transition countries as a prime cause of increased corruption[iv]. Privatization, sometimes, was conducted in a bureaucratic, corrupted and 'broadly-giving-away-for-nothing' way. According to the Institute of Statistic Researchers, share of black economy was 3,2 per cent in 1993, 6,0 per cent in 1994, 10,3 % in 1997, 11,9 per cent in 1998 and 12,3 per cent in 1999[v].

In 1997, the financial situation of industrial enterprises remained unimproved. This, in its turn, has been due to low quality of management of enterprises, lack of really market management of enterprises. Many managers have no idea how to plan activities in market economy. They had " neither the ability to modernize the enterprise nor the market experience to cope in a competitive environment, nor the drive and vision to guide the radical restructuring often required improving enterprise performance"[vi]. Nothing has been done to renew the main production funds. No measures have been undertaken to improve financial situation of enterprises. All these result in low profits, big losses and financial problems.

The privatization process in the Kyrgyz Republic can be divided into four distinct phases:

Phase 1 1991-1993

This phase focused on establishing the legal framework and institutional infrastructure required to enable ownership of private property (other than land) and private enterprise. Land

reform began with 17,000 peasant farms and new agricultural cooperatives being formed from a number of state and collective farms.

This period also saw two principal approaches to the privatization of companies:

(1) A small-scale privatization program. By the end of 1993 more than 3,400 small-scale enterprises in retail trade, catering and services had been sold via cash auctions.

(2) A mass privatization program (MPP). The Kyrgyz mass privatization program was designed to encourage ownership by outside investors in order to stimulate rent restructuring of enterprises. Enterprise managers have, however, not only effectively maintained control of the majority of privatized firms, but have been able to increase their holdings since privatization. This is the result of the purchase of majority positions by enterprise managers directly from the state during the privatization process, or from other investors during the several years following privatization.

Special payments were issued, the amount each citizen received depending on employment records. The vouchers could be used to buy public housing or partial payment for the privatization of medium-scale or large enterprises. The percentage of equity of such enterprises reserved for sale for vouchers was determined on an individual basis, but could not be less than 24%.

Negative aspects of this phase:

This voucher program turned out to be an inefficient and restrictive instrument of mass privatization because:

(1) vouchers were not tradable and therefore had no market value

(2) vouchers distributed only a small percentage of the equity of individual enterprises and offered no opportunity for change in control and management

(3) vouchers were time-limited and most of them were not even used

Positive aspects of this phase of privatization:

(4) destroyed state monopoly in retail and services

(5) introduced competition

(6) eliminated deficit

Despite these positive aspects, they did not bring any decisive changes in ownership and control structures within the economy.

Phase 2 1994-1995

This phase began with the adaptation of a new privatization strategy, which brought about important changes.With some key exceptions, all medium and large scale enterprises (MLE) became immediately available for privatization. Private investors, Kyrgyz or foreign, were allowed to own up to 100% of the equity of the MLE.

The MPP vouchers, most of them still unused, were replaced by privatization coupons. Coupons could be used to purchase equity in state enterprises at coupon auctions where typically up to 25% of an enterprise's equity was offered. Coupons could also be used to buy the stated-owned dwelling in which the coupon holder lived. Coupons were transferable, and both Kyrgyz nationals and foreigners – including institutional investors – could trade freely in them.

In addition to the coupon auctions, individual privatization, cash auctions (which typically took place following an enterprise's coupon auction) and investment projects were the main methods of privatization used during this stage. Phase 2 also saw the creation of the Enterprise Restructuring and Resolution Agency (ERRA) in May 1994 under the World Bank- supported Privatization and Enterprise Sector Adjustment Credit (PESAC) to deal with 29 large loss-making enterprises. This group of companies needed either radical restructuring or liquidation. Diagnostic studies were conducted on each of the enterprises, and liquidation was begun in those determined to be unsalvageable. The ERRA shut down production at these enterprises, instituted "care and maintenance programs", and placed the bulk of their employees on paid leave. Within the group judged to be salvageable, there was restructuring to relieve the companies from the burden of old debts and non-core assets. Some received rehabilitation assistance in the form of loans from the PESAC program and have successfully resumed operations. One completely resuscitated after controlling blocks of shares were offered for sale by tender to strategic investors.

All told, phase 2 encompassed the complete or partial privatization of an additional 1,000 enterprises. Disposition of the 4,4 billion privatization coupons which were printed during this period has been as follows: 41.26% were used at auctions by individuals and companies; 9.82% were used at auctions by investment funds; 0.20% were used to purchase apartments; 0.72% were used to purchase property; 27.55% were distributed but remain uninvested; and 20.45% have yet to be distributed (as October 10, 1996).

The main objective of this stage of privatization was transformation of medium size and large enterprises in industry, transportation and construction. They were privatized in the following manner:

- 5% of the equity distributed to the employees
- 25% sold for coupons in auctions
- 70 % sold to individuals or corporate investors at cash auctions.

All these figures demonstrate there is a serious problem of "coupon overhang", which can be attributed to the following reasons:

(1) The MPP vouchers were time-limited and a proportion of the population lost their entitlement to convert them into coupons because they did not do so prior to their expiration date.

(2) The general population had little confidence in the values of the privatization coupons. At a current market price of 1.22 – 1.35 soms for a bill comprising 100 coupons, each coupon is worth approximately 0.0008 US$ making the distributed coupons equal to only 0.625 US$ per person in the Kyrgyz Republic.

(3) While the Government's motives for retaining a portion of the coupon issued are not known to the author, it is known that the government has periodically sold small groups of coupons into the market. At their current market price, 20% of the coupons which remain in Government hands are worth approximately $0.75million. However, each time a group of coupons is sold, the market price has fallen and effectively diluted the value of the outstanding

coupons held by Kyrgyz citizens. This auction effectively transferred part of the value of the Kyrgyz Republic's assets back into the hands of the State.

(4) A significant amount of the coupons in circulation remain uninvested. Thus, portions of those companies to be sold in phase 3 of the privatization program (see below) must be offered to the general public in exchange for the outstanding coupons; otherwise the uninvested coupons will be useless.

Phase 3 1996-1997

This phase focused on restructuring large objects of monopolized sectors of the economy, privatizing non productive spheres, and restructuring and rehabilitation work with heavily indebted enterprises by units of the State Property Fund. Phase 3 is distinguished from phase 2 by the nature of the companies involved, which are predominantly large scale enterprises in mining, construction, transport and tourism, public utilities and infrastructure. Also 100 MLE that had been partially privatized, but in which the government continues to retain significant share holdings.

Phase 4 1998-2000

The current stage of privatization lays emphasis on restructuring monopolies in the basic and strategic sectors of the economy – telecommunications, civil aviation, printing and publishing, electricity generation and distribution, coal mining, natural gas import and distribution, engineering, antimony production, natural gas import and distribution. Because of the size and diversity of these largest properties, there will be specific arrangements in every case. Each of the entities will be subject to thorough feasibility study.

Thus, the Center of International Private Entrepreneurship conducted the research on economic reforms in 32 countries, including all the main developing countries, as well as the former socialist countries of Central and Eastern Europe. The research has shown that those countries which successfully implemented privatization programs – Thailand, Malaysia, Singapore, Mexico, Argentina and Jamaica, have succeeded much in their reforms. But successful implementation of privatization programs does not necessarily result in successful economic reforms. The main point here is that successful privatization creates an environment for stabilization and structural reforms.

Although some degree of macroeconomic stability has been achieved by the government, the macroeconomic reality of the Kyrgyz Republic has yet to be improved to the levels necessary so that privatization and restructuring would be considered as a positive impact on the economic reforms.

Why is privatization an important element for economic reforms?

Privatization can improve the economy and create favorable conditions for local and foreign investors which are obligatory conditions of economic reforms at present. In other words, privatization is profitable for state and private sectors and consumers, not only for those enterprises being privatized.

Privatization will be successful if accompanied by reforms targeted to create more open and competitive markets. Despite economic difficulties, which are temporary, privatization is a huge step toward economic growth and lasting prosperity.

To draw foreign investment, notwithstanding the fact that in the direct perspective, privatization and implementation of economic reforms have a destabilizing impact, effective privatization programs can stabilize the monetary situation and economy of a country in the long perspective.

Macroeconomic stability is a key factor in drawing foreign investments, which bring many advantages to countries receiving investments, that is sharing technology, increasing employment and developing exports. These three aims are crucial for the economic growth and development.

The climate for foreign investments in the Kyrgyz Republic at the enterprise level is not ideal. Despite the adaptation of a foreign investment law that guarantees the rights of the foreign investor, enterprises have limited experience and interest in investment by foreigners. Owners frequently overestimate the value of their companies, not understanding the relatively high level of investment risk perceived by foreigners and the investment alternatives available to them in other markets, particularly as the "global market place" continues its expansion. Local managers and owners fear a loss of control and are reluctant to disclose enterprise information essential for investor analysis They are also unwilling to undertake the restructuring methods set by foreigners as conditions for investment.

Foreign investors and local managers alike bemoan the loss of tax holidays available under the old foreign investment law. Without the inclusion of compensatory investment incentives in the Tax Code, government officials continue to grant tax concessions and privileges in an effort to remain competitive in attracting foreign investment vis-a-vis neighboring countries.

Although the Kyrgyz Republic has entered into international trade agreements with its neighbors, enterprises report various difficulties in transporting goods across borders. Vehicles face frequent and extensive delays at border crossings and Custom Union countries often do not recognize duty-free entry of machinery and equipment in transit to the Kyrgyz Republic through their countries, or they require payment of VAT before goods are released. Companies complain of arbitrary enforcement and interpretation of rules at borders and claims of improper documentation. Transparent complaint and appeals procedures are lacking.

Weaknesses in the legal and judicial systems also hamper investment. Foreign investors as well as domestic investors demand control of enterprises in part due to the difficulties in adjudicating claims in the Kyrgyz Republic. While most major pieces of commercial legislation are now in place, enforcement of judges' decisions is difficult and a workable system of appeals non-existent. Courts suffer from a lack of transparency, poor procedural processes and the absence of qualified judges and other legal professionals. This is the result of poor training and low compensation. An honest court system is essential for encouraging and supporting the restructuring of enterprises, as the legal protection of the rights of creditors and other collateral holders, the enforcement of liquidation and bankruptcy rules and the guarantee of property rights are strong incentives for managers to put their houses in order.

Despite the adaptation of a licensing law in 1997, the system of enterprise licensing, in particular the lack of appropriate procedures for exacting penalties for violations or of a transparent appeals process, remains a source of harassment for firms. Abuses in the administration of licenses, frequent changes in government practice and criteria, and the recent proliferation of licensing requirements can provide significant power to officials to thwart the rational flow of business. The securities markets in the Kyrgyz Republic have played a limited role in fostering ownership change. Trading on the stock exchange is strictly regulated, but almost all trading takes place "off-market", in an unregulated environment fraught with potential risk, and the largest infrastructure companies most likely to attract investor interest have yet to be privatized. As a result, exchange liquidity is particularly low. For most people who became shareholders during the mass privatization program, opportunities to sell securities are limited.

Why has privatization implementation appeared to be difficult and contradictory?

Here four groups of reasons could be pointed out, which slow down the process of privatization:

(1) First, the policy of the opposition, which resists the process of privatization, presents a non-homogeneous environment, not supporting the policy of the government;

(2) Second, the private sector is not strong. Therefore, an inadequate level of financial markets, and laws, as well as on finance and poor credit and securities mechanisms badly effect privatization of large enterprises, the main way of which is share sales;

(3) Third, technical difficulties and large material expenses of privatization are common in developing former socialist countries, including the Kyrgyz Republic, with lack of both finance and highly qualified specialists to fulfill targeted projects;

(4) Fourth, conflicts in the aims and conditions of privatization itself.

For instance, in the Czech Republic, privatization received more support than in Poland and Hungary (where the process was considered as an encouragement of foreign investments). In other words, the Czech public was much more interested in privatization than was the public in Poland , since people had the choice of how to use their vouchers[vii]. Privatization in the Kyrgyz Republic showed, that bureaucracy, which comprises heads of former state owned enterprises, have too much impact by adopting forms of privatization to their own interests, or, as commonly said, they turn privatization into 'personal privatization' – "prihvatization".

The experience of privatization in the developing countries, for instance, in Thailand, Indonesia, Singapore, enables us to make a number of general conclusions concerning privatization:

?? introduction of competition in sectors, being monopolized by state owned enterprises in the past, enables large enterprises to be more effective and provide services of better quality;

?? private pension funds will assist in easing privatization processes since they strengthen capital market and enable individual share holders to manage their shares and participate in programs. Elements of this experience were used in the Czech Republic and Poland;

?? privatization programs are implemented faster if the state does not make attempts to reconstruct enterprises before putting them on sale. Private investors, as a rule, can take more effective measures of reconstruction. Delay of privatization causes doubts towards the government and decreases public support of privatization.

?? delay of privatization is costly for the state as well, which can cause or prolong misbalance on a macroeconomic level.

The result of this research enables me to make the following conclusions:

The world experience of privatization has shown that privatization, if well implemented, will have a positive impact on economic development and democracy.

The Kyrgyz Republic has made good progress in privatization compared to other types of reforms performed in the country. However, privatization program could have been even stronger. The degree of nepotism involved in the sale of companies needs to be reduced . The pace of privatization could be quickened and the quality improved if:

(1) Defined prices for international securities are on more realistic levels and time frames are longer.

(2) Government sells more companies on an "as-is' basis, and the object of restructuring (state debts, financial statements of enterprises) is prepared according to international standards, and the legal status of enterprises is clarified.

(3) Created rule of law and culture of honesty.

(4) Corruption is reduced.

(5) The policy of privatization is clearly defined and procedures followed more strictly and transparently.

(6) Created an adequate institutional framework that would include strong mechanisms of corporate governance, including rules to protect minority shareholders, rules against insider deals and conflicts of interest, and adequate accounting, auditing, and disclosure standards.

(7) Developed infrastructure.

(8) Opened an access to appropriate, sustainable technology.

Over the longer term, there is a clear need to assist the Kyrgyz Republic to ensure that the privatized enterprises have the opportunity to remain viable and to grow, and to respond to their shareholders. Programs to assist in restructuring newly private enterprises, developing capital markets and financial institutions, raising capital from foreign investors, and developing effective corporate governance will be the major components of that assistance. Without attention to corporate governance, privatized enterprises could miss opportunities, expose their reputations to greater risk, and find themselves at a competitive disadvantage. Ultimately they will become less attractive to foreign partners and investors. Privatization, if implemented effectively and in a well organized manner, evokes trust towards the government among potential capital investors inside and outside the country. This, in its turn, will foster further privatization and will impact successfully on the economic reforms as a whole.

Electricity Sector Reforms in Transitional Economies with Specific Reference to Latin America and India

V. Ranganathan
Indian Institute of Management, India

Abstract

There are significant differences between the electricity industry restructuring in the advanced economies of the West and the 'reforms' that are carried out in the transitional economies like those of Latin America and India. While competition and consumer interest is the focus of the former, privatisation and investor interest is the focus of the latter.

Introduction

Electricity sector reforms have had different reasons for their coming about in different countries. In the USA it was because of what Paul Joskow called 'price gap', i.e. different prices prevailing in different States [Joskow 1997]. Here the industries in the high priced States wanted freedom to shop around from States where the price was lower. Thus the focus was on wholesale competition. In the UK it was based on the premise that 'government should not be in business'. The Coal miners' strike also helped the resolve of the Thatcher Government. The focus was on privatisation, though they took care to introduce competition simultaneously.

Initially there was pool-based competition and later it was dominantly based on bilateral contracts with the pool serving the residual market. However in the transitional economies the 'reforms' were more or less force-fed and were not always to be advantage of those economies. Here privatisation rather than competition was the dominant theme, since the consultants regarded that these countries were not yet fit for competition. In the Latin American case this meant predominantly US multi national companies buying up State owned firms in electricity generation and distribution, some times at manipulated low prices[1]. In the Indian case also they started with independent power producers (IPPs) at the generation end, after unbundling the integrated State Owned Utilities (SOU) and introduced what is called a 'single buyer model'. In this all the IPPs were to sell their electricity forcibly to the single transmission company, which was a State owned entity.

Because the IPP power was very high and because the buyer entity was near bankrupt, the model failed. Now the World Bank and its consultants are switching to privatisation of distribution. Unlike in the Latin American case, in India there is not much interest among foreign investors in managing distribution, because (1) distribution is a much more messy affair having span over a very large region some of which may be geographically as big as a smaller country, (2) it is more difficult to extract high margins, since part of the existing inefficiency of the SOUs was offset by low wage costs and (3) so far no one has figured out a way to handle the agriculture sector consumer in rural areas which consumes about 30-40% of the total power and highly subsidized under the public sector regime.

The present paper discusses the motivation for reforms and the methodology of reforms in both Latin America and India and offers some possible lessons.

Motivation for Reforms

According to International Energy Agency's forecasts, electricity demand in OECD countries had reached a plateau at 3% growth and two-thirds of the incremental demand was to come from the developing countries, notably from China and India. This lead to a scenario of visualizing the power market, with North as the supplier of equipment and South as the consumer.

The equipment had to be sold and also the payment received. Reforms, seen in this context, would be to create market for power equipment to satisfy the demands, and tariff reforms to make the buyer of equipment a financially viable entity. Such an agenda then automatically gives primacy to opening up the generation, rather than deal with the cancer of corruption and inefficiency at the distribution end. Distribution reforms are also messier, requiring political will to confront engineer's associations and an area where the foreign investor is much less interested.

Thus the reforms started at the generation end. From the Indian side, the motivation for reform was that the demand was growing at about 9% requiring installation of additional capacity of the order of 50 GW and in an environment of wanting to control the fiscal deficit, the Government was looking for private sector involvement in meeting this expansion target. On the distribution side, each State Government was subsidizing the SOU of about US$ 300 to 400 million partly for subsidizing rural electrification but mainly to cover the huge losses due to theft incurred by the SOUs.

Indian Electricity Reforms

The Bank started the reforms with the State of Orissa. The rationale of choosing Orissa was that it was not stymied by the agriculture tariff subsidy problem with only about 10% of energy being supplied to agriculture as against 30 to 40% in other States. Secondly, it was also likely to have less opposition from the staff unions, since most of the engineers were in fact from the Government and hence statutorily immune to job loss fears.

The motions of unbundling, corporatization and setting up of the regulatory body were gone through. In the first instance, distribution was given to private sector on a management contract, as a prelude to privatization and also to test the waters. This turned out to be a failure as enhancement of revenue by plugging the leakages, did not materialize. As a result, the Gridco, the State owned transmission utility, cancelled the contract with the private sector, midway. The main reasons for failure were: improper specification of the contract, management's lack of control over employees, and the inherent lack of incentive in a management contract to make investments for loss reduction. Undaunted, the Bank counseled outright privatization—selling 51% of shares-- of the distribution zones. Coincidentally the same BSES of Mumbai with whom the management contract was abrogated, was awarded 3 zones and AES, an US firm, the remaining zone.

AES took that zone as it was also an Independent Power Producer (IPP) in that area and it thought that control over distribution would mitigate some of the payment risks in generation. Later AES realized to its chagrin that unbundling generation, transmission and distribution, with a public sector Gridco in between would annul this advantage of payment risk mitigation. The privatization process was marked by insufficient investor interest, with only three bidders finally submitting the bid [Sinha 2001].

The main reasons for insufficient investor appetite cited by the consultant (Frontier Economics) were: high level of losses and collection risk; problems of inherited staff; low size of the system that that could not support the estimates of fixed costs (eg. 3 to 4 expatriate employees in India); tariff uncertainty (the regulator never made clear what investment would be allowed under the rate base for earning returns); poor information from Government of Orissa and GRIDCO and returns being too low for the risk. It is interesting to note that investors did not see the big losses as opportunity for better returns through improvements, which is the basic argument for privatisation.

During the operations for 1999-2000 and 2000-01, all the privatized Distcos were making losses. More importantly, private sector has not been able to achieve what it was supposed it would, viz. plugging of leaks. Ratio of billing to input energy was only 56%, implying that 44% of the input power was not billed. In addition, the ratio of collection to billing was only about 77%. To be sure, there was improvement in efficiency, but the pace of improvement was below expectation.

The private sector discovered that the actual losses were even higher than the losses assumed at the time of bidding. Tariffs based on low T&D loss bench marks were inadequate for the distribution companies to cover their costs and earn a return. There is also the possibility, that the Distcos may not have the incentive to declare the improvement, even if they do improve, since gaming the situation would yield them greater tariffs from the regulator. There was a systemic flaw here in regulation. Unlike in the UK where they follow an incentive regulation, with a cap on price increase percentage given by (RPI – X) along with a review period of 5 years, during which the utility has an incentive to reduce costs and make improvements, the Indian regulators have adopted a cost plus guaranteed return based pricing, which is determined each year, thus totally giving no incentive for the utility to make improvements. The more zealous the regulator is to pass on the benefit of improvement immediately to the consumers, the more information asymmetry he has vis-à-vis the regulated, the more s/he is likely to lose the purpose for which s/he set about.

The power sector problems in Orissa reached such a pass that AES, one of the private sector partner of Distco, threatened to withdraw from the company, since its generator IPP was not getting paid by GRIDCO. The OERC, fearing an emergency situation, had stripped AES of the management control of the Distco and vested it with two government nominated IAS officials.

The World Bank's reason for privatization was the belief that it would improve performance by reducing the T&D losses, based on evidence of lower loss figures for *existing* private sector distribution licencees in Mumbai, Calcutta and Ahmedabad. But in the case of Orissa they failed to reckon that privatizing the Public Sector is quite different from having the Private Sector ab initio.

The new management under private sector is finding the task of improving collection a daunting challenge and overcoming the corruption inertia takes a while. This is because, the whole incentive system is based on the philosophy that the person in charge of distribution would return a Re.1 revenue to the firm for a 10 to 15 paise incentive for him. But as the privatized managements may have found out, this does not apply to those who are chronically used to covet the full One Rupee without any fear of consequences. As Nigel Lawson [1992] famously remarked on the impossibility of restructuring the public sector: `you cannot change a mule into zebra by painting stripes on its back.'

In Karnataka the reform consultants faced a similar problem, viz. lack of investor interest in distribution privatisation. To overcome this, they have come up with a new formulation called "Distribution Margin" concept. According to this, the private sector will not take the revenue risk, but the distribution company will get a payment that will cover its cost plus a return on its investment and this payment they will take it as the first charge on revenue.

The return on investment will be low initially corresponding to the present level of T&D losses. For any improvement, there will be additional incentive payment, thus improving the return. The eventual deficit that will occur when payment is to be made to the generator will have to be borne by the Government, in the hope that this deficit will fall over time, with improvement in losses.

The biggest flaw, which is in fact claimed as its virtue, is that the normal business risk in revenue collection which the distribution firm is best able to handle, is now removed from it and passed on to the Government, with no corresponding guarantee from them as to when they will show improvement. This is, in short, privatisation of public sector theft! In addition, the consultants are coaxing the regulator for a multi year tariffs, to remove regulatory uncertainty, but the regulatory commission is (rightly) not agreeing, since at present they are at a tremendous information disadvantage.

In Haryana, the reform was started with a $600 million bill, with the consultant (National Economic Research Associates, US) chanted the same mantras of unbundling, corporatization, privatisation and setting up of regulatory body, but not introduction of even wholesale competition. The Bank made one innovation in its lending here. They came up with a new Adjustable Lending Programme, whereby the project was broken up into several milestones and completion of each milestone, made the borrower eligible for the next tranche of loan. [Mostefai (1998)]. The process saved the borrower from embarrassment in case he is not able to proceed with the reform mandate.

The prophecy was self fulfilling, and after availing of $60 million, the Government withdrew from the reform programme over the issue of increasing the electricity price for farmers. 'Since then, the Government has chartered its own course of reforms and shown quite a few systemic improvements (though critics claim these are on paper only)'[Powerline (2002)]. They have unbundled, but not privatized. If the official claims are true, the Haryana example suggests that governance—read, a kick in the pants—works where incentives fail. A determined and formidable lady Government officer with a couple of engineers as colleagues Managing Directors has reduced losses (i.e. theft) by resorting to technology and management control. We have an apparently paradoxical situation here, where States like Uttar Pradesh and Karnataka are going through the motions of reform, getting ticks on a

World Bank's check list, but without any improvement whatsoever, and only increasing the transaction costs, and Haryana which is labeled as having backed out of reforms, but embarking on substantial and real reforms.

Another recent example in the improvement of SOUs is the Andhra Pradesh Central Discom where again the engineer Managing Director from Haryana was brought to this discom and he has reduced the losses by about 12% in two years through IT enabled services, offered by World Bank loan and with Multinational consultants. Three lessons on this: (1) It is the governance rather than ownership which is vitally important. (2) It is possible to have good governance under public management also, though this cannot be either designed or guaranteed. For instance, the same ITES were offered to other discoms also in Andhra Pradesh, but the CEOs of those discoms did not take the help. (3) It is always better to improve the SOU before selling, to realize a higher value, but most of the time the improvements will not come through system changes but only by a change in the CEO.

In all the other States where electricity 'reform' is on, there is unbundling, corporatization and regulator in place, but without distribution privatization and without any sign of competition. The Bank seems to be following what is known as the 'single buyer model' with all the generators including IPPs being forced to sell to a single buyer, viz. the State Electricity Board or its corporatized avatar the GRIDCO, all of whom are uniformly bankrupt. Even the Electricity Bill 2001 vests with the regulator the discretion to decide as to when to permit the generator to sell power to any one other than the SEB. This is done with the sole interest of protecting the SEBs who earn the cross subsidy by overcharging the industry, (i.e. other than those, in industry, whom they undercharge for a consideration).

The present situation of partial, more specifically half baked, reforms is actually worse than under central planning, because under the earlier regime investment and pricing were neatly decoupled, with financial losses not affecting generation expansion, being funded from Central Government and with Bank assistance, optimal location and mix decisions being taken exogenously by the Central Electricity Authority which enunciated such policies like pithead power generation in large scale by Central sector plants, discouraging small scale and captive plants which did not enjoy economies of scale etc. The World Bank's *project based* approach helped 'provide 13 loans and 3 credits to help the National Thermal Power Corporation (NTPC) rapidly expand generation capacity and become the largest generator in India.'(OED 2001).

With the shift in Bank's emphasis to *sector based* approach, and with partial reforms in place, the central government's budgetary investment is drying up, along with funding from the World Bank; the NTPC which was a low cost producer all along as a central Government PSU, and was once the favorite borrower of the Bank, has no funds for expansion , but wants parity in returns with the IPPs, with no parity in risks; the IPP's want an unaffordable price for their power for they face severe payment risks from the sole buyer SEB; and with increasing input power costs and continuing revenue leakage in distribution, the SEB's are breaking down. The World Bank should hardly take credit for what it has done to India's power sector.

Progress on 'reforms' is measured on the parameters: SOU restructuring, constitution of the State Electricity Regulatory Commission, Commercialization of Distribution as a prelude to privatisation, reduction of cross subsidy and Memorandum of Understanding with the Central Government. In the absence of the political will to privatize and lack of enough number of entrepreneurs coming to bid for distribution privatisation the intermediate steps involve enormous transaction cost and appear wasteful.

For instance, under the Bank's tutilage, the Karnataka Power Transmission Corporation Ltd. gave a 'capacity building' contract to one Multinational consulting firm, for Rs.14 crores ($.3 million), and Privatization consultancy to another multinational firm for a similar amount. In the Delhi distribution privatisation case, a recent World Bank study by Agarwal, Alexander and Tannenbaum [2003] concludes that SOUs cannot be improved and hence 'capacity building' is a waste of money; as regards privatization KPTCL was told that private sector would not be interested unless the Government gives various guarantees. But then one of the conditionalities of the World Bank is that the State must agree to spend if the State wants the bigger amount of money for the hardware portion of 'reforms'. Yet the Bank's internal auditor (OED 2001a) applauds its efforts in the sector saying :

> "OED strongly supports the South Asia Region's strategy for the energy sector, initiated in 1993, that concentrated all its power sector resources into promoting SEB structural reform and only financed distribution system upgrading. The strategy is highly commendable for its relevance to India's development objectives, its efficacy in rehabilitating a critically weakened

sector, its efficiency in use of Bank resources, and its mobilization of private sector resources (where are they?). In the light of the radical institutional changes that are being implemented, the reform is likely to be sustainable. OED deems this a best practice model that should be emulated throughout the Bank's energy sector portfolio".

On the whole, the Banks' attempts at power sector reforms are not yielding results. The only sound advise that stands out is their refusing to approve Enron's Dabhol project on the grounds that importing gas is inferior to making use of domestic coal and that Maharashtra grid may not be able to absorb the 2000 MW of Dabhol power without injuring itself. World Bank itself possibly has greater knowledge and intimacy with the Indian power sector than the consultants appointed by them. Perhaps they could have done a better job if they had taken up the task themselves than entrusting piecemeal to different consultants, one for each State, which totally missed out the benefits of wholesale trading.

While there has been unbundling, corporatization and appointment of regulators, almost in all SOUs in India, and the new Electricity Act (2003) has provided for open access and wholesale competition the latter have not yet come into existence. Thus the benefit of reform in terms of competition in generation has not been achieved in India.

The benefits due to privatisation are not yet ready to be measured. What is clear is that distribution privatisation has not attracted abundant investor interest either internationally or nationally and in Delhi where it has been done, a heavy price has been paid by writing off liabilities of SOU by 85% from a total liability of US$. 4.6 billion, and further promising Government subsidy to the transco US$ 690 million over a 5 year period.

Latin American Privatization

The AAT [2003] study cites the example of Latin American distribution privatisation where the regulators set a multi year tariff (MYT) in the beginning of privatisation, and also provided for full taking of benefits when the discoms beat the targets of performance, in effect adopting the (RPI – X) type of regulation, as in the UK. The benefits will pass on to the consumers at the end of the tariff period when the regulator will set new values of X based on past performance.

In India, the regulators, in general, seem to insist on an yearly review based on cost of service regulation and do not agree for MYT because of serious data problems which prevent them from setting MYT on any rational basis. It is also true that being newly appointed to these statutory positions, they want to use the power of regulation tending to over-regulate. But then, the Latin American case of setting an MYT and taking no share in the (excess) benefit may virtually amount to writing a blank cheque for the discoms. Whether these regulators have sufficient information to set these MYTs fairly tightly is a point to be considered.

In the Latin American case, one sees a large diversity. In Argentina the regulators are chosen by public contest and public hearing is important. In Bolivia also the regulators are appointed by the Country's senate and there is political independence. But in Columbia and Chile the regulator is under government control. In Argentina wholesale competition brought down the prices. In Bolivia and Columbia still a significant share of generation was traded in the contract market where efficiency is not clearly provable[2].

Conclusion

The main thrust of this paper is to suggest that the reform priests have often one set of rules for the developed countries and another for transitional economies, not just because the different rules are more appropriate but because of a wide variety of extraneous considerations. Thus it is in the countries' own interest to make use of the think tanks in their respective countries and arrive at optimal policy decisions.

End Notes

[2] For instance the distribution company at Sao Paulo was sold at an unexpectedly low price to AES. Later Financial Times' investigation revealed that AES had persuaded Enron to drop out on the eve of tender opening. [Agarwal, Alexander and Tannenbaum 2003]
[2] Even though the recent BETTA model of UK is also based on assuming that bilateral contracts definitionally are efficient, being arrived with the consent of two parties, there can be problems in this assumption for transitional economies since both parties may not have equal bargaining power and option to exit.

Public Private Partnerships (PPP) in Pharmaceuticals:
A Shift toward Hybrid Forms of Governance

Antoine Bureth
University Louis Pasteur, France
Chantale Mailhot
HEC Montreal, Canada

Abstract

The contribution presents Public Private Partnerships (PPP) as key tools in the valorization, both from an individual and from a collective perspective, of the revolutions undergoing in the pharmaceutical sector. They lie at the core of the processes of production of knowledge and insure the accumulation and the diffusion of the advances achieved in the field of the biotechnologies. But they gathered together a large variety of actors, with differentiated when not opposed incentives and objectives. Successful PPP thus imply to activate coordination mechanisms able to establish stable compromises. Using the conceptual tool of the "cities", derived from the Economics of conventions, the paper stresses the peculiarities of those modes of governance and the main domains on which they are challenged to produce an hybridization of cooperative and competitive modes of interaction.

Introduction

In the pharmaceutical sector, the increase in the production of scientific knowledge (due both to genomic advances and an extensive use of ITs) goes along with a clear dynamic of overlapping of the academic and market-oriented objectives, associated with an hybridization of knowledge (Carayol, 1999, Gibbons et al., 1994). It blurs in particular the distinction between fundamental knowledge and knowledge supporting market activities.

In that perspective, fundamental research is not just a way for a firm to reinforce absorptive capacities (Mowery, 1983, Cohen & Levinthal, 1989). The output of this kind of research can be sold. Conversely, universities can generate knowledge through forms of targeted research, and directly incorporate those outputs into other processes of production of knowledge (furthermore, universities are more and more faced with a strong financial constraint, which can be partly solved by going on the market).

There is herein a fascinating paradox. Universities and public research centers, which were used to be the exclusive producers of scientific knowledge, are now faced to new forms of competition, as private actors challenge them. But at the same time, because of the specialization of the learning trajectories, and the need to recombine complex pieces of knowledge, the interdependencies are reinforced; public research needs results produced on the market side, and vice versa.

The multiplication of Public-Private Partnerships (PPP) and the raise of new collective modes of knowledge production have been underlined in the literature (Shinn 1999, Callon 1995, Gibbons and al. 1994, among many others). Nevertheless, the dominant view about university/industry relationships generally emphasizes the difficulties to implement PPP by opposing two clearly contrasted worlds_ submitted to differentiated objectives and values. On the one hand, the industrial actors produce knowledge, driven by commercial interests. On the other hand the logic of academic science and basic research is described as a quest for truth in the processes of accumulation of knowledge (Buchbinder & Newson, 1985; Slaughter & Leslie, 1997). Such a dichotomy implies strong differences in the behavioral norms, especially with regard to the disclosure of knowledge (Arora & Gambardella, 1997), or to the feature of the reward system (Dasgupta & David, 1994).

We adopt in the paper a slightly different position. The aim is to explore deeper the features of the "co-opetitive" interactions between public and private actors, the "unavoidable necessity" of such partnerships being largely admitted through the literature. Looking to the pharmaceutical sector, the contribution tends to demonstrate that if conflicts exist in PPP, they are more related to a lack in terms ot coordination devices, rather than to intrinsic and irreducible differences between the protagonists of the cooperation (Mailhot, 2003. Mailhot & Mesny, 2002). In particular, the diversity of the output of the research processes, and the complex and contextual nature of knowledge (Ancori and al., 2000) imply to mobilize simultaneously several competencies, differentiated spaces of negotiation and different modes of legitimization. We claim that, because the diverse and heterogeneous incentives and rationales of the public and private actors at least partially converge, the knowledge production regimes need to mix different types of coordination mechanisms and issue on hybrid forms of governance (Joly, 2001). The question thus bears on how to coordinate distributed pieces of knowledge - i.e. how to solve knowledge asymmetries in a perspective of creation of resources- instead of focusing on the sole information asymmetries and the eventual optimality of the allocation process.

The pharmaceutical sector stands actually at the crossroads, and is compelled to exploit the new opportunities provided by the rise of biotechnology (section 1). Referring to previous works (Bureth, 2002, 2003), we claim that new discoveries in molecular biology, even if they have not modified the nature of the scientific output, drastically affect the organization of the R&D processes. They have smoothed some of the "traditional" oppositions evoked in the literature on innovation - market based vs. science based approaches, demand pulled vs. technological pushed developments, fundamental vs. applied research processes, etc (section 2). But the most salient feature is the certainly the width and the intensity of the interactions induced by the collective nature of the research processes (section 3).

In such a context of intense collaboration undertaken under high competitive pressures, PPP appear as a keystone of the process of innovation. They bring together the largest range of interests, and are real triggers of the scientific knowledge production (section 4). But PPP also concentrate conflicts, due to the encountering of differentiated actors. We draw uppon the work of French conventional ists Boltanski & Thevenot (1987, 1991), as well as Boltanski & Chiapello (1999) and extend their approach in order to identify the diversity at stake within PPP (section 5). It leads us to identity three main sources of conflicts, and to explore the conditions for achieving stable compromises between the different logics mobilized by heterogeneous actors.

1. The Pharmaceutical sector: between fear and hope

Even if it still exhibits attractive ratios of profitability, the pharmaceutical sector is actually faced to heavy crisis factors. Three problems at least have been largely underlined by the analysts: there is firstly an urgent need to renew the portfolio of products. Thereafter, decreasing returns in the traditional research methods, based on "discovery by serendipity", limit the opportunities of innovation. Finally, the sector has to deal simultaneously with an increase in R&D costs and a drop of market returns. By 2005, half of the hundred most prescribed drugs in the world, representing about 30 billion dollars of annual sales, will fall into the public domain (Serusclat, 1999). Considering the specific structures and strategies of the sector, the impact of the losses of patents is significant. Due to high R&D costs, pharmaceutical firms rely on a handful of flagship products: the blockbusters'. For instance, Prilosec® (patent expired in 2000) represented 39.8% of AstraZenecca's global turnover; 26% of Eli Lilly's turnover was generated by the famous Prozac® (patent expired in 2001) (Hamdouche & Depret, 2001). The entrance of generic drugs on the market rapidly and dramatically erode the position of the pioneers (Beynon, 2000, Sellers, 2002). And the consequences are not circumscribed to sales values; for instance. when Wall Street was informed that Eli Lilly could not extend its patent on Prozac®, its shares suddenly decreased by 30%.

But the changes in the pharmaceutical industry are not only induced by the need to renew the portfolio of products. Some contributions have underlined the decrease of productivity in pharmaceutical R&D processes. It is particularly noticeable in the methods of identification of molecules suitable for the production of new drugs (Drews 2000). Traditionally, the way to obtain new drugs relies on two parallel investigation processes. First, research aims at identifying new molecules (using the so-called methods of deductive design. random drug design, random screening, blind screening). The second part of the job is to find out the fields of application of a candidate molecule, by assessing its properties, its toxicity and its related side effects. But such processes based on "discovery by serendipity" (Drews 2000, Quirke 2001) exhibit strong limits. If in the early sixties, a new drug was selected on the average basis of 3000 synthesized molecules, 10000 candidates were needed some ten years later (Dumoulin 1994). Drews and Ryser (1997) emphasized a clear limitation in the variety of the therapeutic targets. In the US, the National Institute for Health Care Management (NIHCM) stated that out of 857 new applications authorized by the Food and Druc Administration in the 90s, only 311 of them were new molecules. In terms of products. Serusclat (1999) indicated that 62 new drugs were launched in 1987, 37 in 1996 and 47 in 1997. A third salient feature of the sector is the tremendous increase of the costs of R&D combined with the drop of market returns. The average cost to develop a new drug is estimated between 500 and 800 millions dollars (Serusclat, 1999, Hamdouch & Depret, 2001, Tollman et al., 2001). The average development time fluctuates between 12 and 15 years. But at the same time, fewer and fewer products are able to cover their development costs (Glover, 2002). Consequently, no actor is able to support alone the risks of the research and the financial weight of such projects. This aspect is reinforced by the low concentration of the sector: despite intensive external growth operations, only three groups (GlaxoSmithKline, Pfizer and Merck) achieve worldwide market shares over 5%. Finally, the competitive pressure leads the pharmaceutical groups to devote more resources to advertising. The situation can thus be roughly described as follows: the value of R&D expenses is increasing in volume, but decreasing in relative shares, expressing that marketing strategies more and more often dominate innovation strategies.

In opposition to the difficulties evoked above, the pharmaceutical sector has benefited in the last two decades from huge opportunities opened by the development of genomics and recombinant DNA technology (Gambardella, 1995, MacKelvey, 1995, Henderson et al. 1998, Galambos and Sturchio, 1998). The bio technological revolution has produced (and the process is still going on) scientific results that have largely pushed further the comprehension of the mechanisms governing diseases.

Hence new solutions have emerged (at least from a theoretical perspective) in terms of treatment, detection and prevention of diseases. 50% of the new drugs are already linked to biotechnologies, and 90% of the biotech firms are acting in the pharmaceutical field or in related technologies (Lenoir, 2002). 16% of the drugs are produced by biopharming - pharmaceutical products are produced by plants or animals programmed genetically. And the efficiency of biopharming over the traditional synthesis techniques is estimated at a factor 1000 (Pastor, 2003). Till the end of the decade, the markets in which Life Science and Biotechnology are involved could represent more than 2000 billions of dollars (Tollman et al., 2001).

2. New constraints in the organization of R&D processes

Nevertheless, notwithstanding a drastic evolution of concepts, genomics has not modified the content of Science or the output of R&D processes, but has deeply transformed the way research is conducted and organized.

A first point is a progressive change from "D&R" to "R&D" processes. The formulation is somewhat excessive, but expresses the reversal occurring in the relation between Science and industrial applications. In the bio-chemical paradigm, Science is often considered as resulting from problems encountered in the production field (Rosenberg 1990). The discovery of a molecule using random screening methods is the starting point of the scientific process addressing its properties. As stated by Hitchings (1980), " Much of the basic research supported by industry is, in a sense, retrospective. A semi-empirical discovery of a useful drug provides the stimulus for deeper probing into how and why it works, and thus to a deeper understanding of the underlying disease. This may in turn give rise to new concepts and new discoveries " (Hitchings, 1980, p167).

The discovery of the DNA structure by Watson and Crick in 1953 paved the way to a powerful stream of research identifying the biochemical and molecular mechanisms hidden beyond the observable symptoms of diseases. This is quite different from discovering an active substance. By highlighting general properties and building theoretical models, Genomics has replaced Science upstream: the conceptualization of the structure of a molecule is now based on the causes of human disorders, the properties of chemical components and their impact on organisms (Hamdouche and Depret, 2001).

A second rupture can be observed in the organization of the research processes. Until the late 70s, research in Biology was essentially fundamental and conducted by academics under public financing. In 1976, the foundation of the first biotech firm, Genentech, by Herbert Boyer, is the beginning of an important trend of firms creation by researchers.

Knowledge is actually produced in structures mixing public and private actors, multinational firms and start-ups, with very close relations to the domestic and the financial markets. Extensive development and use of ICTs have largely supported those changes. By increasing the throughputs of research, by lowering the costs of experimentation, ICTs provide increasing returns in the constitution of genomic data banks (Nightingale, 2000). The combination of scientific advances, identifying new fields to be explored, and the rise of technological tools, providing strong exploration capabilities, have pushed firms (and especially New Biotechnology Firms) toward specialization trajectories in the production of knowledge. ICTs also favor the exchange of, and the accessibility to data, and provides furthermore the possibility to control those exchanges. Henceforth an important consequence derived from advances in genomics is the creation of markets of genomic and genetic knowledge. Because knowledge produced in research processes can as such be sold, market and upstream research become more and more interwoven, and generate intricate and highly uncertain innovation patterns.

Classifying the actors of the sector following the distinctive criteria of information production, technology development and product manufacturing is less and less relevant. As seen by Orsenigo et al (2001), "two main search regimes have started to coexist within the industry. The first regime is essentially based on biological hypothesizes and molecules that tend to be specific to given fields of application (co-specialized technologies), while the second regime is characterized by the emergence of new generic tools (transversal technologies)" (ibid. p488). But under both regimes, the actors are often simultaneously producing knowledge, using/improving technologies, and incorporating knowledge and technology into products.

If we refer to the representation of the chain-linked model proposed by Kline and Rosenberg (1986), innovation is not built upon interactions between functions (research, marketing, production, distribution) performed by correspondingly specialized actors, but rather between actors covering several of the innovation functions within a specialized domain of application.

The consequence is an extension of the competition far beyond the traditional market borders. Research undertaken in the pharmaceutical sector often gathers the willingness to develop a practical application and the need to improve the comprehension of some fundamental mechanisms. Such mixed research objectives generate strong tensions (Foray, 2000), expressed clearly in the use of Intellectual Property Rights. IPR are more and more averted from their initial function - to reward an innovator - and become strategic devices activated in order to lock competitors. There is herein an important risk, especially for a knowledge intensive sector like the pharmaceutical sector. The cumulative and sequential nature of the whole innovation process can collapse (or at least the costs for the innovators of the second generation can greatly increase) because of patents initially taken by a first mover to protect his market

Following the brief description given previously, the pharmaceutical sector is mainly characterized by a "co-opetitive" context, in which every actor is compelled to co-operate with potential competitors. As heavily underlined by Depret and Hamdouch (2000), the economy of the genome which seems to emerge nowadays implies a radical re-definition of the pharmaceutical markets and a renewed industrial organization, both in terms of management of the innovation processes and in terms of technological and competitive relations between the actors. The capacity of those actors to promote efficient scientific and industrial collaborations will determine how the economic and therapeutic potential of genomics will be made real in the coming years.

3. The need for and the implications of collective modes of production of knowledge

The evolution of the pharmaceutical sector, driven by advances in biotechnology, has multiplied the actors and their links, through various forms of cooperation, agreements and partnerships. But the reinforcement of the intangible nature of the output of the research and innovation processes has also dramatically complexified the organization of those interactions.

For instance, in the traditional schumpeterian model the incentives to innovate rely on the possibility for the innovator to enjoy monopolistic returns at the product level, and this argument seems to be highly relevant in the pharmaceutical sector (Coombs & Metcalfe, 2002). Nevertheless, it also raises difficult questions when the innovation product is "new knowledge", as in pharmaceuticals.

A piece of knowledge -a new gene for instance- can be used by several actors, for different purposes or further developments of Science. Concerning DNA and proteins patenting, there is a subtle balance to find out, between encouraging innovation and stifling research. Protecting the innovator without inhibiting further research implies thus the creation of contextual rules and local coordination procedures, generally implemented in cooperation devices.

To the same extent, a patent on an industrial process is generally applied to a defined field of activity. Concerning biotechnologies, the processes involved in the production of scientific knowledge are often transverse and are applied by agents pursuing different objectives. To give an example, biochips can be applied to fundamental research (proteomics, sequencing) or to commercial applications (drug design, diagnosis). Affymetrix (owned by G1axoWellcome and Bristol Myers Squibb) is the main producer of biochips, and locks the market of that basic technology using its patents. Furthermore, Affymetrix does not produce chips to meet demand, but collaborates to what it considers relevant and interesting scientific projects (Serusclat, 1999). There is thus a clear threat to impact on the production of knowledge in many different fields following the strategic options of one single actor. Here again, the problem has to be solved through specific coordination procedures and regulation principles, allowing or compelling the patent owner to adapt his behavior. As claimed by Binns (2001), such an issue is outside the ambit of patent law; "a patent gives its owner the right to prevent use of the patented invention by others, but it does not constitute approval for the patent owner to use the invention" (Binns, 2001, p274).

The traditional pharmaceutical industry was producing drugs. The rise of biotechnology has oriented the activity toward the production of an explanation of the mechanisms of life, issuing on new solutions in terms of diagnosis, prevention and treatment of existing or potential diseases (Hamdouch & Depret, 2001). It goes far beyond the sole technical perspective of the therapeutic approach, and raises ethical, sociological and economic questions. In other words, the pharmaceutical improvements and their impact on public health bear on some general concerns which can not only be assumed by the scientific or professional community. The globalization of the interests related to pharmaceutical innovations appears clearly in the multiplication and the ever-growing' phenomenon of regrouping of the actors involved in the production of scientific knowledge.

R&D processes heavily rely on collaborations, partnerships, cooperative agreements (Feldman & Hopkins 2001 for a survey of the studies on pharmaceutical agreements). The biotechnological sector exhibits the highest rate of creation of alliances (Hagedoorn, 1993). Fisher (1996) registered more than 20 000 agreements, with a 25% growth rate per year. In 1994, the 10 biggest pharmaceutical firms externalized 4% of their R&D expenses. This share soared to 30% in 2000 (Serusclat, 1999). In other words, pharmaceutical innovation is fully a collective process of invention despite of a strong competitive context.

But the pharmaceutical labs are part of integrated networks including more than just industrial partners of the sector. The patients are considered as products and services consumers, and act through associations and groups of pressure. Pension funds, institutional investors. agro-food or micro-electronic industrials are seemingly part of the network. As stated by Hamdouch and Depret (2001), the new environment of the pharmaceutical industry is more unstable and uncertain than ever. The overlapping and the telescoping of scientifical, industrial, financial and ethical logics reduce the visibility of the actors. Some principles have to be constructed in an environment without pre-established norms, even if endowed with heavy legal constraints.

Whatever the issue under discussion - intellectual property rights, diffusion of knowledge, conditions of competition - the question of how to achieve and to rule the cooperation is constantly raised. Following Callon, the question is all the more crucial as i) the role of each actor is not clearly defined, and ii) some of the actors are groups and not individual agents. In such a context, "it is vitally important that public and private sector discussion, engagement, and partnership are raised to a global level" (Ridley & Roberts, 2001, p79). The present contribution aims at insisting upon the concerns related to the public-private interface in the pharmaceutical field. We assume that it is the privileged vector to reconcile the private and the collective interests, to manage the risks at a collective level by creating independent expertise capabilities, and to avoid a myopic valorization of extremely radical innovations.

4. "Why are conflicts within PPP so important and where do they come from"

We have tried to emphasize above some of the outstanding features in the recent evolution of the pharmaceutical sector. The advance made in molecular biology and genetics in the sixties have triggered intense collaboration between universities and industries m the late seventies. At that period of time, when the industry became aware of the commercial potentials opened by advances in biotechnology. they were unable to exploit the research results using their in-house research capabilitiesil. In order to fill up the gap and to diffuse the new biotechnology knowledge, industry supported (and government encouraged) in the eighties the creation of biotech firms founded by university researchers. As outlined by Dalpe (2003, p176), "the expectation was that the pattern would shift over time because industry was supposed to gradually internalize the creation of new knowledge (Orsenigo, 1989, Pisano et al., 1988, Zucker and Darby, 1997)". But the trend did not decrease, and the universities still play an important role considering innovations and commercial developments.

Bodin and Gingras (2000)lll show an increase by 155% of the collaborations of universities with industries, hospitals and government laboratories from 1980 to 1995. 2/3 of the collaborations are dedicated to the fields of clinical medicine, biology and biomedical research. Seemingly, Arora and Gambardella (1994) notice the upholding of the number of strategic alliances between large pharmaceutical firms and public research organizations. Almost all leading biotechnology universities are linked to firms (Zucker et al., 1995). Movery et al. (2001) highlight an increase in biotech academic patenting related to market opportunities.

The situation in Life Science is thus unique, although some feature are shared by other sectors, like ITs (Kenney, 1986). The sector is highly "co-opetitive" (Brandenburger and Nalebuff, 1996), and all the actors are simultaneously using competitive and collaborative strategies in a knowledge driven business environment. "Co-opetition is exercised through the formation of "value-nets", where the firm interacts with suppliers, customers, competitors and complementors to maximize its own added value through managed relationships with other players in the net" (Carayannis etal., 2000, p478). The concept of co-opetition can even be extended, especially regarding biotechnologies, to other levels of the actors' strategic environment. As proposed by Carayannis et al. (1997) in their "bull's eve framework", there is a need of mixing competitive and cooperative relations at the market level, but also at the political level (between firms and institutional actors) and at the ecological level (between firms and their industry ecosystem). In other words, competitiveness and innovation capabilities - both from the individual or from the collective point of view - are dependent from the participation in networks gathering together "broad, diverse communities of players who must become intimate parts of a far-reaching process of co-evolution" (Moore, 1996, p61). Without being exhaustive, such extended networks include university researchers belonging to different disciplinary fields, small biotechnology firms, large pharmaceutical firms, hospitals, as well as venture capital, law firms, chemical or microelectronics firms, consumers associations, regulation institutions, governments, actors from the stock market. "Such large networks are a prerequisite for risky and very costly projects, such as the development of new drugs representing a major shift from current medical practices and which need regulatory approval" (Dalpe, 2003, p182).

The dynamic of those networks lies at the heart of new patterns in the innovation patterns. As claimed by Arora, Gambardella and Rullani (1997), knowledge production capabilities are enhanced, specialization is reinforced, and the locus of innovation may be spread across heterogeneous agents. But at the same time, such complex systems bring together differentiated preferences and objectives. heterogeneous norms, conflicting interests, and entail problems in terms of opportunistic behaviors and costs of coordination. Solving internal conflicts can also issue on problems in terms of fitness'" of the whole system: multiplying "conflicting compromises" may prevent the network from attaining an optimal configuration (Schilling, 2000) In that context, PPP appears as keystones of the collective innovation process. First, they are at the core of the production of new knowledge, insofar as the university researchers still seems to be the main source of knowledge, despite a diversification of the loci of production. Second, they are the privileged form to achieve "learning alliances" (Doz, 1996)", within which scientific knowledge is exchanged against expertise in production, management and commercialization. Third, they are the place in which economic and social concerns encounter. This last point is in our view especially important: indeed, as long as the processes of hybridization between market and science increase and become more and more irreversible, they leave the delimited space of the economics of science to become central objects of the public debate (Hamdouch and Depret, 2001).

PPP are important instruments to innovate. But their output can not be assessed under the sole market rules. Because they are involving public resources, i.e. a collective investment, they should generate some collective returns. Treating cancer for instance cannot only be interpreted as a demand or a supply expressed on the health market: it also corresponds, even before the product exists, respectively to a right or a duty. This latter aspect has to be defended by the public actors, representative of and relaying the collective interests. Pharmaceutical discoveries generate important risk and/or uncertainties which can not be managed, neither only under market forces. nor following the sole sound science. There must be room for the authority of science, for a democratic participation of the public, for independent administrative regulators (Joly, 2001). PPP are the tools to create mixed expertise capabilities, by benefiting from distributed knowledge and controversial assessment processes. Those mixed expertise capabilities are necessary to feed the construction of efficient regulatory frames, in which the policy maker is faced to what David (1986) called the "narrow policy windows paradox"" and the "blind giants quandary"". PPP are thus privileged support for policy decision-making, insofar as they are mainly focused on fundamental research. Sustainable innovation implies to integrate some long run perspectives in the processes of valorization of discoveries. The importance given to the property rights system in the sector raises the question of intergenerational spillovers (Scotchmer, 1991). Patents protecting a discovery can deter further innovation. There is thus a need for adapted patenting behavior, considering the breadth and the length of the patents not only in terms of immediate profitability, but also in terms of incentives to innovate when research is cumulative"". The latter perspective should be more easily taken in account by public actors holding property rights, partly because seeking for profitability is not the main concern of the public research, but also because "patents on government sponsored research rewards successful innovators twice, once through government funding and again through the patents" (Scotchmer, 1991, p40). In other words, the aim of implementing PPP is not only to produce and to diffuse valuable knowledge for innovating on markets. There are related issues in terms of regulation, following economic, scientific and ethical considerations. Joining academia and industry is in our view the best way to constitute robust expertise capabilities, obeying simultaneously to criteria of scientific quality, of economic efficiency and of independence. Nevertheless, following Morris (2000), "the constitution and governance of such jointly tunded bodies need to be carefully drawn up so as to provide the benefits of partnership without losing independence of judgment, or falling into the murky ground of conflict of interest" (Morris, 2000, p164). PPP obviously gather together actors following different sets of norms, The opposition made famous by Dasgupta and David (1994) between the Republic of Science and the Realm of Technology" clearly points out the difficulties raised by such forms of collaboration. For instance, the degree of codification of knowledge - which impinge upon the intensity of exchanges and interactions - expresses different ways of coordinating and organizing collaborations, different representations of expertise, different incentives schemes and reward modes. Nevertheless, by emphasizing heavily the opposition between fundamental and applied research, the new Economy of Science underestimates the "gray zone" (Hamdouch and Depret, 2001, Callon and Foray, 1997) where science and market are overlapping. One of the conclusions of David and Dasgupta (1994) was to recognize the benefit for the society to obtain scientific outputs using two distinct channels, despite of the irreducible tensions existing between them. "Indeed, we will argue that in order to ensure a reasonably efficient allocation of resources in the production of knowledge, modern societies need to have both communities firmly in place, and attend to maintaining a synergetic equilibrium between them" (Dasgupta and David, 1994, p519). Especially in the pharmaceutical field, that equilibrium is more and more replaced by complex interactions. And the reasons exposed above are pleading in favor of a further intensification of those interactions. Our understanding of the biotech sector implies to take some distance with a dichotomize lecture in analyzing PPP. As convenient as it might be, viewing academic science and industry as two worlds relying on opposite rationales is at best a convenient simplification. We aim at exploring how an organizational device can cross (and not only host) different sets of incentives and interests. To the same extent, we assume the existence of points of convergence, shared by actors from different communities. We will draw upon the work of Boltanski & Thevenot (1987, 1991), who have identified `cities', which correspond to the various ways a person, an action, a decision, an object, an organization - including, thus, a public/private partnership - can be situated, justified and legitimated. Those conceptual tools are useful m identify the different logics at stake within partnerships, and pave the way to discuss why and how seemingly differentiated actors can collaborate and interact.

5. PPP as hybrid organizational object and mode of governance

The collective nature of the knowledge production in the pharmaceutical field endorses a variety of organizational constructions. Among all the forms of collaborations, PPP exhibit strong peculiarities. More than other forms of collaboration, PPP imply to find ways of collaborating despite different and sometimes contradictory interests. Within industry (as within academia), partners share at least a context and some behavioral rules or norms. In the course of the co-operation, conflicts might arouse because of asymmetries of information, opportunistic behaviours, and differentiated objectives. The resolution of such divergences will be at least facilitated by the existence of a kind of shared culture. In the case ot PPP, the differences are apparently much more salient, and exist from the very beginning. The following table sums up the features of academic science and industry assumed in most of the literature about the new forms of partnerships between universities and firms (Mailhot and Mesny, 2002):

TABLE 1 : LOGIC OF INDUSTRY VS. LOGIC OF ACADEMIA (source: Mailhot & Mesny, 2002)

Industry/Technology	**Article I. University/Science**
Development and commercialization of applied knowledge in order to produce technological artifacts	Production of abstract knowledge and basic research
Logic of heteronomy (norms: efficiency, control, etc.)	Logic of autonomy (norms: freedom, auto-control, etc.)
Logic of efficiency: search for the optimum return on investment consistent with stable growth.	Logic of discovery: the pursuit of knowledge is more important than the development of products.
Knowledge as a private good: protection of information and knowledge	Knowledge as a public resource: diffusion of knowledge
Market evaluation (criteria: time-to-market, cost, quality)	Peer evaluation (criteria: methodology)
Search for immediate profits, attainment of specific goals for a particular company or industry	Search for long-term gains for the benefit of the society, fulfillment of altruistic ends

Because of, and through the bringing together of actors belonging to contrasted worlds, the output of PPP overflow the frame of their exploitation by the involved partners. As we have seen previously, PPP are mainly dedicated to the production of knowledge liable to feed the cumulative process of innovation. They thus generate important spillover effects. They also are a melting pot to create improved expertise capabilities. Beside positive effects, autors have equally pinpointed some dangers. The debate about new forms of collaboration between industry and university often boils down to wondering how `impure' science can become, and if the dangers of this `hybridization process' do not far exceed its benefits (Slaughter & Leslie, 1997). Increasing funding of academic research by industry `may alter the norms and values of the scientific community' (Arora & Gambardella, 1997: GS). For example, the scientific community might become less open, might try to protect more forcefully its information and behave more like rent-seeking firms. Conflicts in PPP thus appear to be unavoidable. But hence, the resolution of those conflicts strongly impacts on the global innovation trajectory of the sector. In other words, PPP involve the construction of durable compromises, made viable through hybrid coordination mechanisms which, in our view, can be grasped through the work of French conventional ists Boltanski & Thevenot (1987. 1991). Although these authors do not directly address the issue of science and technology, their typology of forms of legitimacy can be used and extended in order to shed light on the hybridization mechanisms taking place within PPP. Boltanski and Thevenot (1987, 1991) address the long-lasting issue of how actors with divergent interests manage to cooperate (Amblard et al., 1996). They assume that a durable agreement always implies a common framework, or a `convention', under which actors can conceive, discuss and solve problems. Partners might disagree upon particular solutions and assertions, but they need an agreement upon a general representation frame delimiting the scope for decision and action. The focus is thus placed on situations in which collaborations are implemented between actors referring to a priori different frames. In our view, PPP precisely corresponds to this sort of situation, in which actors call upon differenciated forms of legitimacy in order to promote their interests and to reach an agreement (Mailhot & Mesny, 2002). In the biotechnological sector, we have argued elsewhere that the multiplication of data and scientific knowledge also implies the production of associated forms of meta-knowledge (Ancori et al, 2000, Bureth, 2002). Meta-knowledge refers to general and universal issues expressed in questions such as: what kind of knowledge should be develop and why'? for whom should that knowledge be develop and what objectives will be pursued`? Such a questioning leads the actors to develop general conceptions of science and to explicitly discuss the features of the link between science and industry. The use we make of Boltanski and Thevenot' typology aims at identifying the forms of legitimacy at stake in PPP, the conception of science they carry, and the conditions required to bridge them. Boltanski and Thevenot' typology is build on seven `cities', which correspond to the seven forms of legitimacy that are used in out - modern society, namely the inspired city [cite inspiree], the domestic city [cite doncestique], the city of opinion [cite de l'opuzioy, the civic city [cite civique], the industrial city [cite uidustr-ielle], and the merchant city [cite rnarcharrde]. Each city is a `world' in itself, with its objects, its subjects, specific types of relations between them, its ruling, etc. For reasons of space, we shall not detail here each city. The following table sums up their main characteristics:

TABLE 2 : THE SEVEN CITIES

	Founding principle	**Investment Formula**	**Repertories of subjects and objects**	**Relations between subjects**
Inspired City	Burst of inspiration	To question, to risk,	Subjects: artists, children, monsters, Objects: the unconscious, dreams, spirit	Creating, discovering, imagining, searching
Domestic City	Tradition, generation, hierarchy. The development and preservation of science as a distinct sphere	To serve, to be in harmony. To defend science and its autonomy form the rest of society, to dedicate oneself	Subjects: parents and children, chief Objects: good manners, gifts, titles, ranks. Member of a scientific community, peers, scientific methodology	Reproducing, educating, to criticize, to form, peers relationship
City of opinion	The others, the public, Public recognition by the international scientific community	To reveal, disclose, to give up secrecy. Submitting manuscripts, asking for financial support from big funding institutions, participating to congresses	Subjects: celebrities, leaders of public opinion, spokesperson Objects: messages, campaigns, trademarks Scientific with a good reputation, publication and citations.	Persuading, influencing, convincing, propagating., citing
Civic City	Precedence of the collective, general will	Solidarity, struggles	Subjects: representatives, public, public communities and organizations Objects: rights, legislation, procedures, codes	Mobilizing, excluding, debating, speaking, informing
Merchant City	Rivalry, competition	Freedom, detachment	Subjects: seller, buyer Objects: valuable goods	Buying, selling, paying, competing
Industrial City	Performance, efficiency, the future	Progress, investment	Subjects: expert, specialist Objects: tool, plans, resources, methods, tasks	Analyzing, measuring, implementing
Project-oriented city	Activity, projects, proliferation of links. Proliferation of scientific networks and research projects	Adaptability, flexibility, tolerance, lightness. To put oneself on an equal footing with others, to tolerate uncertainty, to be open	Subjects: mediator, coach, expert, project leaders, innovator Objects: new technologies, accords, meshes of net	Connecting, communicating, trusting, adjusting

Depending to which city a situation refers, modes of coordination can be very different. Our societies, however, increasingly implies `composite situations', in which two or more cities or orders of justification can be called upon. People routinely deal with situations that pertain to various logics of justification, and they have to switch from one world to the other. Neither a person, nor a situation, is `attached' a priori to one particular city. This plurality of forms of legitimacy implies conflicts, disputes, and compromises.

A compromise, in this perspective, consists in a certain `mix' or a trade-off between the different forms of legitimacy. It will last in time through the mobilization of objects and/or the implementation of specific modes of coordination.

Referring to the above typology, firms and universities are composite organizations relying on several and differentiated cities. Turning more specifically to the pharmaceutical sector, three "basic" types of actors can be distinguished. The Big Pharmas can partly be viewed as a form of compromise between the industrial city, the merchant city and, to a lesser extent, the domestic city. New biotech firms combine the project-oriented city, the industrial city, the merchant city, and the inspired city, whereas the traditional university is based on a compromise between the inspired city, the civic city and the domestic city. Based on our interpretation of the literature, the hypothetical picture we are proposing here can be largely discussed, and obviously reduces reality. But it matches relatively well the result we get out from the first few interviews we have conducted within the BioValley Network, and constitutes a starting point for further research.

PPP are themselves composite objects and a response to the new imperatives of cooperation that feature the recent evolution of science and technology. They are supposed to embody compromises between science and market, hierarchy and autonomy, etc. These compromises, however, do not seem to have reached a durable character, and have not so far led to robust procedures and modes of coordination that can be used at large in PPP (Riley, 2001). This perspective allows us to take further distance from the dichotomic vision proposed by the new economy o science. First, we cannot attribute a unique logic to an organization. It means that, if in the worlds of science and technology for instance, some driving rules are significantly different, some others are common, or at least partially shared (Hamdouch and Depret, 2001). The academic scientist, as well as the private enterprise, discloses the results of its work in order to satisfy its own interests (reputation, financing, social status for the former, monopoly return or licensing revenues for the latter). Identically, the competition between research teams exists both in the field of research (run for patents and/or to standardization) or in the field of science (run for the earliest publication). Second, benefiting from interactions between the cities does not mean that one city has to be submitted to the rules of the other. In other words, a positive cross fertilization between market and science will not be obtained by pushing science toward the market: It can be obtain throughout non-conflicting objects or throughout coordination mechanisms producing compromises, on the basis of which the participant's action registers are really linked.

The capacity to recognise the cities at stake within collaboration is a necessary step for reaching agreement and finding compromises. One of the benefit of the city model is to study the "ways of possible compromises" (Boltanski and Thevenot, 1987 : 246) between different worlds and to see how, practically, theses compromises that "enable the linkage between people and resources that belong to different logics" (Derouet, 1989 : 12) are built and maintained.

6. Some leading forms of compromises

The previous section assumes that common interest in technical or market developments will not level the differences in the legitimate ways actors refer to, in conduct research. But it assumes also that collaboration neither implies a common perception. The co-ordination must be ensured by common principals and shared processes allowing the regulation of the collective decision. Those processes allow the stabilization of an association without calling to an ex-ante order, and allow implementing collaboration devices without the existence of a consensus upon the content. We try thus to push further the social network approach, in which collaboration and the quality of interactions basically rely on trust and the accumulation of "social capital".

Three situations can be distinguished. First, the situation can be confined within one particular city, in which case disputes can generally be solved by referring to the founding principles of the city. We believe this situation refers to most of inter-organization partnerships, such as partnerships with competitors or suppliers, which can fairly easily be confined within the merchant and the industrial cities, whose principles can be accommodated in numerous forms of compromises which have long been solidified.

The second case refers to situations that cannot be confined within a particular city or an established hybrid combination between two cities. These situations, however, do not necessarily lead to conflict. The juxtaposition of several cities can be managed smoothly if forms of coordination inside each city are found which do not meet each other or only meet through non-conflicting objects or subjects. This case applies, for example, to forms of industry / university alliances in which roles are clearly separated, and industry representatives do not intervene at all in the research process.

The third case corresponds to the situation in which the harmonious separation of situations cannot be achieved. The juxtaposition of several cities within the collaboration leads to confrontation and conflict. An agreement has to be found, which can be local and transitory, or take the form of a long lasting compromise. If the latter situation is certainly the most valuable, only few cases of stable and durable compromises exist. Concerning PPP in the pharmaceutical sector, they are mainly embodied in the implementation of intellectual property rights. But a lot of forms remain still to be "invented", by the development of objects and material tools such as proprietary contracts, research financing, research processes, commercialisation tests of product research, criterions of science significance and risk assessment, etc.

Concerning the conflicting situation, we will not review extensively all the forms of compromises existing in PPP. But we tackle three of them, which are in our view the most challenging to explore (FIG.3). The confrontation between the industrial and the inspired city generates conflicts, insofar as the production of fundamental knowledge is not used to deal with constraints like cost, prices, timing, or efficiency. But establishing a compromise issues on fruitful results, and improves performances of both scientific production and product design. The merchant and the inspired city are opposing immediate profitability to long run creation processes. Here again, finding' a compromise impacts heavily on the trajectory of the whole sector, by improving the sustainability and the quality of the cumulative innovation process. Bridging the inspired and the civic city is the third type of compromise we want to emphasize. Consequences of such a non-resolved conflict is clearly observable in the agro-food industry, where the reluctance of the public jeopardizes the potential of development opened by the introduction of GMO.

It is worthwhile to notice that the achievement of compromises will be favored by the existence of some over-lapping in the orders of legitimacy used by the actors.

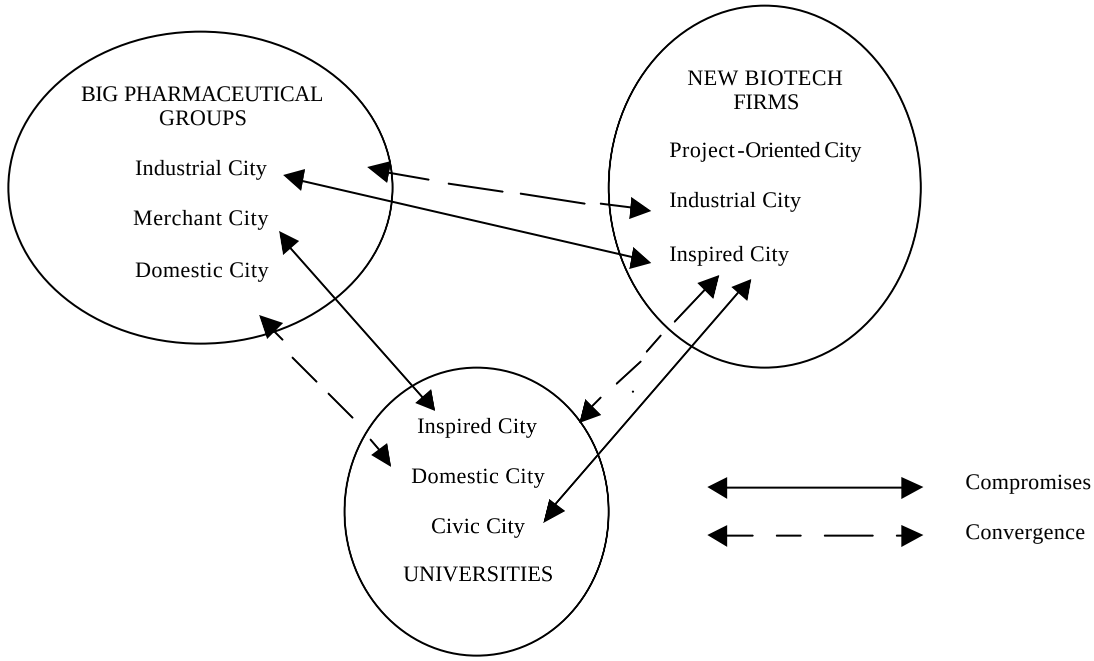

FIGURE 3 : THE CITIES DRIVING THE ACTORS OF THE PHARMACEUTICAL SECTOR

A first compromise at the base of the PPPs is the one that engages the inspired field and the industrial world (with the notion of learning) and that links the notion of efficiency with the promotion of creativity and energy. The scenario of passage from the discovery to efficient innovation depends on this form of compromise. The R&D processes in the field of biotechnology is greatly maintained by science, more precisely by the bringing out of general proprieties and the construct of theoretical models. It requires the participation of university researchers that are still the main sources of knowledge. The inspired logic, implying discoveries and risk, must be mobilized in the construct of these research processes. As such, in the PPP, research methods based on " discovery by serendipity " must be reconsidered.

The technological platforms developed by the biotechnology firms improve the research processes, by reducing costs and obtaining economies of scale (Nightingale, 2000), by limiting scientific dead ends, and more generally, by increasing the productivity of exploration processes. But all those scientific tools and research technics will support creativity depending on their users. Because the research in the field must simultaneously target practical applications and the understanding of fundamental mechanisms, there is a need of hybrid human capital, involving scientist aware of the market constraints.

We assume that a sustainable compromise depends from the mobility of the scientists from the academia to firms (mainly biotech firms) and vice versa. Dalpe (2003) shows very clearly that one of the strength of the US system is the possibility for scientists to enter in businesses without leaving the academic community. Our own interviews have confirmed that point: for instance, several interlocutors have underlined the need for an assessment, under academic criteria, of the scientific production done in small firms. The lack ot recognition by the academic community hinders the transfer of scientists in firms.

On the long run, it also implies to rethink the education process of the scientists, by introducing topics related to management.

There is also a compromise to be find between the inspired logic and the merchant world. It opens the discussion about the "creative market", and the favourable usage of the science's creative potential (even if risky) in order to create business deals, innovations, and to make profit (to deliver socio-economic profits and to get better positioning in the global market). This compromise derives from the recognition of the increasing costs of research, where no players can support alone the cost of project development. Within the research partnership, "business logic" must be combined with the world of inspiration, i.e. partners must achieve a business deal giving credit to creativity and discovery. Cassier (1997) well demonstrates that the integration of science and market raises the question of exclusive appropriation of data. The researchers must find different solutions of compromise to this problem using local partnership that they will establish with the industry.

Managing compromise thus implies to tackle the dilemma raised by the Intellectual Property Rights system. On the one hand, protection of intellectual property is a necessary condition to maintain incentives to invest in research. But on the other hand, the increase of property rights causes dangerous frictions and bottlenecks in a sector in which innovation relies, more than elsewhere, on collective processes of invention".

An extension of the practices of patenting seems necessary to preserve the sequenciality of the innovation processes. A first possible improvement is to clarify the distinction between the primary objective of the patent, the attribution of an invention, and the right to use that invention". Another possibility is to develop the protection by disclosing. The costs of the IPR system have led some small firms to publish their results on the Internet. The recognition of their innovation is granted by disclosing it as far as possible. A softening of the conditions of use of the patent can also be considered, by defining conditions of "fair-use", clubs of users or pools of patents (Cassier & Foray, 1999). Third the questions of patenting living organisms, methodologies and algorithms are still unresolved (Coriat & Orsi, 2001, Orsi & Moatti, 2001). Finally, there is a need to develop hybrid systems of public and private sponsorship (mixing grants or prizes and property rights), when they are dedicated to the production of "big science" (Maurer and Scotchmer, 2004).

Because of the width of the impact of pharmaceutical advances, in terms of risk, public health, economic development, the compromise between the inspired world and the civic world is necessary. The transition between these two logics is a matter of orchestrating the construction of the civic link by efficient methods of mobilization preserving however the multiplicity of the interests, the experience and the competencies of the principal concerned parties. In other terms, PPP must be equipped with co-operation devices where the sum of the interests and the views of all the concerned parties are represented allowing negotiation and conjoint construct of coordination objects.

Small technology firms often establish, for example, scientific advisory boards to evaluate the quality of research. In the case of PPPs, we have seen that the research must be assess against scientific criterions and also economic, social, ethic, and against the risks for public safety. It raises the question of the creation of councils able to gather and to preserve in their core, the multiplicity of the interests of all concerned parties by these major innovations.

Callon and al. (2001) get interested, for example, in the cooperation between profanes and scientist by studying "hybrid forums" aimed at solving conflicts about technological and scientific developments. For the authors, the success of hybrid forums depends on the development of tangible dialogic procedures that implies equity in the access to the debate, the transparency and the clarity of the rules that structure that debate. Such procedures imply a real openness, time and autonomy in order to forge local arrangements and ensure that each partner acknowledges the research and consider it as valid. These hybrid forums constitutes therefore networks of knowledge and action. They establish a collective expertise that is accomplished by the combination of a construct of scientific and technical knowledge. the consideration of sociologic and economic stakes, and at last, by the negotiation of work methodology (Lascoume, 2001).

Such expertise capabilities are crucial in our view. Because knowledge is very rapidly encapsulated in processes of economic creation, its management and assessment must include some ethical considerations, an appreciation of its related risks of misuse and of the conditions of distribution of its collective returns. Expertise does not only encompasses an objective validation of the quality of knowledge, but includes a prospective dimension and an assessment ability of the future consequences of potential developments. It modifies deeply the very nature of expertise, which is not anymore limited to an appreciation of the state of the art, but goes beyond that frontier to insure a type of mediation between the producers and the consumers/users of knowledge.

In that respect, the pharmaceutical sector is very peculiar. Because they rely on scientific discovery, innovative products arrive on the market following the technology-push mode. But because those products impact on the physical integrity of the consumers, the innovation process remains largely market pulled. Indeed, a new molecule, a new therapeutic protocol, and even a new research program must meet with social acceptance, from the financial, technical, cultural and ethical point of view. To adjust demand and supply is quite delicate, because of the ever-growing knowledge gap between producers and consumers. It follows that the management of innovation calls for experts able to attest the harmlessness of innovation. Expertise is not only a matter of technical capabilities (useful for the innovator), but relies also on the credibility and the independence of the expert, perceived by non-specialists. It raises the question of the status of academic public research centers. Their perceived and commonly admitted authority is liable to collapse because of their increasing involvement in market activities. The point is far from being marginal, as it can induce a contraction of the markets for the whole sector if potential consumers react negatively towards innovations.

Conclusion

The links between science and industry, and between science and technology have a long history which can be viewed as a process of gradual complexification. Behind the multiplication of PPP lies the intention of breaking away from a linear model of innovation in which the boundaries between science and society were clear and were based on powerful logics of justification. The analysis presented in this paper suggests that this rupture from a linear and bipolar model is not yet achieved. Hybrid conceptions of science and technology, the capacities to mix private and collective interests, the institutional, legal and physical devices mobilized for the management of PPP are still to be created. The recognition of the plurality of forms of legitimacy, upon which both academia and industry actors draw, induces a renewed conception of the relationship between science and industry that still is in a process of gestation and emergence. We have focussed on PPP as hybrid and composite organizations. It enabled us to question the broadly accepted view that firms on one side, and academic actors on the other, rely each on a peculiar logic, that tends to clash with the other. We assume that this dichotomy masks a plurality of logics or modes of legitimacy. The identification of those different logics, and the rules they embody, allows to locate the conflicts, but highlights also some grounds for compromises (that could not be apparent in the dichotomic view) and helps to identify the objects able to support governance mechanisms. Far from appearing only as a conflicts arena, the PPP are also described as important areas generating expertise capabilities obeying simultaneously to criteria of scientific quality, of economic efficiency and of independence. As such, grasping the diversity of the logics present in public-private partnerships is necessary to build suited modes of cooperation. Actors involved in PPP have to construct local arrangements, but have to do so in a global context, which tends to impose specific objects for the running of the collaboration. The management of composite situations requires not only the clarification of the different logic present but an attention to objects and material components that can sometimes look like unimportant details but that, in reality anchor the situation in a specific logic of action, sometimes against the will of the players. The traditional research methods of the pharmaceutical domain, the rules pertaining to intellectual properties or the evaluation criterions of the scientific quality of the research are just some examples of this fact. At this stage, it is already possible to suggest some recommendations to establish compromises. Procedures facilitating the mobility of the scientists from the academia to firms and vice versa, an extension of the practices of patenting or the modification of the expertise nature throughout the construction of hybrid forum are some possibilities that should be explored further. Formalizing the process for the conjoint development of coordination modes through procedures in the PPP seems to lead to better chances of success, as opposed to relying simply on player's initiatives. One must find a balance between directing principals that permit to move away from the conflicting terms at play and to set a frame for the collective decision, and the flexibility that favors contextual negotiation and local agreements. The conflict/disagreements generated within the PPP - and their resolution - can thus be seen as exploration and learning devices, supporting collective activities and giving birth to renewed organizational forms. The management and the valorization of the internal diversity of those partnerships are activities of governance (Lascousme, 2001), all the more important as the interaction between science and market within the pharmaceutical sector generates questions of general interest such as the public health.

End Notes

' a blockbuster is a drug generating more than one billion dollars of annual sales.

"" The pharmaceutical industry, the most likely candidate to commercialize biotechnology products, neither invested in genetics nor had molecular biologists on its research staff. Molecular biology and genetics were almost unknown in industry and, worse still, represented another sort of paradigm with respect to the chemical research large pharmaceutical firms conducted. " (Dalpe, 2003, p175)

"' . Their study is conducted in Canada, but the result should be similar in other countries.

'~ The fitness of the system is the degree to which the system and its context are mutually acceptable (Alexander, 1964, p19)
~ " A learning alliance differs from collaboration to share costs or spred risk across organizations, in that the primary motivation for joining a learning alliance is to gain new knowledge which can be processed and transformed into a competitive asset " (Carayannis et al., 2000,p480)
"' 'The available `windows' for effective public policy intervention at comparatively modest resource costs tend under natural conditions to be located towards the very beginnings of the dynamic process [of innovation]" (David, 1986, p5).
w "Public agencies are likely to be at their most powerful in exercising influence upon the future trajectory [of an innovation] when they know least" (David, 1986, p5).
v"' In the US, the 1980 Bayh-Dole and Stevenson-Wydler Acts can be seen as opportunities for public organizations to use their patents in order to disseminate knowledge rather than to extract rents. We do not mean that it was the first intention of the legislator - one objective was certainly to decrease the amount of direct public funding - but such a " side-effect " must be considered (see also Maurer and Scotchmer (2004) for a slightly different interpretation of the same effect).
"` "The problem, to which Dasgupta and David's (1993) recent analysis draws attention, is whether any single organization can function effectively in managing a truly equal partnership between members recruited from two quite different communities built around fundamentally antithetical sets of norms and cultural orientations and whether it is possible to contain the conflicts that are likely to arise from the disjonctures and lack of congruence between the goals sought by members who have been socialized in, and remain professionally commited to pursuing careers in the different research cultures" (David, P.A., Mowery, D.C. & W.E Steinmuller, " University-Industry Research Collaborations : Managing Missions in Conflict", unpublished paper , March 1994)
" "By conferring monopolies in discoveries, patents necessarily increase prices and restrict use -a cost society pays to motivate invention and disclosure. The tragedy of the anticommons refers to the more complex obstacles that arise when a user needs access to multiple patented input to create a single useful product. Each upstream patent allows its owner to set up another tollbooth on the road to product development, adding to the cost and slowing the pace of downstream biomedical innovation" (Heller & Eisenberg, 1998, p699).
XI’’ A patent gives its owner a right to prevent use of the patented invention by others, but it does not constitute approval for the patent owner to use the invention” (Binns, 2001)

The Challenge of Opportunity:
Small Business and their Websites – Evidence from New Zealand

Tim Beal
Victoria University of Wellington, New Zealand
Moha Asri Abdullah
Universiti Sains Malaysia, Malaysia

Abstract

One of the greatest challenges facing traditional Small and Medium Enterprises (SMEs) throughout the world is that posed by the Internet. In an environment where customers and competitors are moving online, SMEs have little choice but to do the same. However, whilst the Internet offers great potential to SMEs, from improving and cheapening production processes through to reaching global customers, in reality it also poses great problems. SMEs have usually, by definition, limited resources both financial and human. Given the decreasing costs of Information and Communications Technology (ICT) the financial constraints, at least in developed countries, are becoming less of a burden. However, human resource constraints are likely to increase as the technology changes rapidly.

This paper describes a survey conducted amongst small businesses in Wellington, New Zealand, on their use of websites. The research was a joint project between the School of Marketing and International Business at Victoria University of Wellington and the Wellington Regional Chamber of Commerce. The purpose was two-fold. Firstly to find out more about the achievements and challenges encountered by small businesses in the course of their actual business practice. Secondly, to learn what assistance and training they thought would be valuable in order to help them better realise the potential of websites for their business and to face up to and surmount the inevitable problems. It is part of a series of coordinated surveys on this issue, which are in the process of being carried out initially in South Africa and Malaysia.

Introduction

Information and communication technology (ICT) has entered the lexicon of business in many forms throughout the world. It has grown with overwhelming, sometime bewildering rapidity, hype and much confusion (Beal 2003). The rapid development of ICT affects the competitive environment of enterprises throughout the world, though the impact varies considerably by country. However, even in countries where general usage of ICT is low –say Cambodia or Laos, it is still possible for individual companies to participate in the global ICT environment. This means that ICT directly and indirectly affects all sizes of enterprises irrespective of size. Nonetheless, small and medium enterprises (SMEs) face more challenges in using ICT than their larger counterparts This is because they have relatively small and limited resources to understand and utilise the technology, they cannot afford in most cases specialist staff, they do not reap economies of scale and they are vulnerable major mistakes in their operations.

Nevertheless, the prosperity and development of SMEs within this new global ICT environment are becoming more important to the economy of many countries, developing and developed alike. SMEs need to face a number of issues and challenges, but are also presented with more opportunities and prospects by the development of global ICT, which is moving very fast through a number of interlocking modes and forms such as e-commerce, k-economy, website, email, dot.com, etc. An SME may participate in one or several of those forms without the other. Many, for instance, use email but not e-commerce.

The Internet is the main part of the communications aspect of ICT. From 1996, for instance, the number of users of the Internet doubled every nine months, and information flow and bandwidth increased greatly. From a report published by Neilsen/NetRatings recently, there are about 300 million users in just 20 countries (Moha 2003). Although the United States still has the largest number of Internet users (some 165 million) the larger East Asian and European countries now have very substantial numbers of users. The number of users in Pacific Asia, here defined as East and Southeast Asia, Australia, New Zealand and India, already exceeds that in the US, and will continue to outstrip it (CyberAtlas.com).

One important utilisation of ICT is e-commerce. The usage of e-commerce in businesses has also risen over the years. In 1998, for instance, it was recorded that retail income from e-commerce in the United States was US$8 billion and increased to US$18.6 billion in 1999. Based upon the trend, it is expected that the figure would reach something like US$80 billion by the end of 2003. In Europe, income from e-commerce businesses reached US$240 billion in 1999 (Zhonglu 2000).

The rapid increase in general Internet use, as well as the growth of e-commerce, raises the questions, how fast SMEs would and could adjust and adapt to these changes? The question is very relevant to New Zealand, when nearly 97 percent of all private enterprises are small and medium-sized enterprises, contributing for about 44.8 percent of private sector employment (Ministry of Economic Development 2001). New Zealand is predominantly a nation of SMEs. SMEs make a major contribution to job creation. Statistics show that the largest single contributor to job creation was new firms employing less than 5 full time workers, which created 194,000 new jobs between 1995 and 2002. Meanwhile, SMEs account for about 35.1 percent of total national output. SMEs by industrial sectors indicates that SMEs constitute over 98 percent of enterprises in several industries (Ministry of Economic Development 2001).

SMEs facing up to the challenges and opportunities presented by the Internet need to understand as fully as possible the Internet environment in which they operate. While it is known that the Internet as a mass phenomenon and is growing very fast, all enterprises including SMEs enter into businesses and other forms of usage with a rather confusion if not volatile. Internet and other forms of communications is growing steadily fast. The first survey given by Nua (subsequently taken over by CyberAtlas) dates from December 1995 and gave a figure of 16 million people. This consisted only 0.39 percent of the world's population. Some five years later, the number has grown to 407.1 million, representing 6.71 percent of the world's population (Beal 2003). The latest figures reported by CyberAtlas are estimates of 580 million (Nielsen//NetRatings) and 655 million by the International Telecommunications Union. The United States still has world's largest Internet population but now it is only a quarter of the global total. This share will naturally drop as connectivity to the Internet increases elsewhere. Europe and Asia Pacific have most of the rest, leaving the rest of the world, Africa, Middle and Latin America with about 6 percent (Beal 2002). The Asia Pacific countries share of global numbers on line has grown very rapidly. Other than Japan, South Korea is amongst world leaders in terms of ICT use and the percentage of the population with access to the Internet. South Koreans spend twice as much time on the Internet as others (SCMP 2001) and have the highest level of broadband penetration in the world (Korea Herald 2002).

Given the contribution of SMEs to the economy, their use of websites is of great importance and interest. This paper describes a survey on the use of web-site by SMEs in Wellington, New Zealand. It is hoped that the findings of the survey would help small and medium businesses in Wellington, and elsewhere in New Zealand, make better and more profitable use of the web. Since New Zealand is amongst the more advanced Internet countries – it ranks 14 in terms of the percentage of the population using the Internet – it will have more general applicability. The second part discusses the method of the research, while part four reveals some general findings of the survey and briefly discusses what the survey tells us about the training needs of SMEs as they attempt, with their limited respires and expertise, to capture the opportunities presented by websites.

NZ and Mexico in Cyberspace Geography

The use of the Internet varies considerably around the world. It is important there to get some idea of where New Zealand stands in 'cyberspace geography' to ascertain the relevance of this survey to other countries, and in particular, given this conference, to Mexico. We briefly present three sets of data:

1. Connectivity – the percentage of the population with access to the Internet
2. Internet market – the number of people in a country with access to the Internet
3. E-readiness

Connectivity – the percentage of the population with access to the Internet

The data here, and for the next graph, is from the Irish company Nua (subsequently taken over by CyberAtlas), which brought a number of surveys covering most countries in the world. The connectivity rate though, like all Internet data, subject to methodological uncertainties, does give a reasonable sense of the Internet environment. The higher the connectivity rate then the more likely it is that the firm's customers, competitors and supply chain partners, as well as government agencies, information sources etc. will be online and so the greater the pressure of the firm to utilise the Internet.

As Fig 1 shows, New Zealand is amongst the most-wired countries in the world, ranking 14, with just over half the population with access to the Internet. Mexico, on the other hand, comes in at 83, with just 3.4% of the population online.

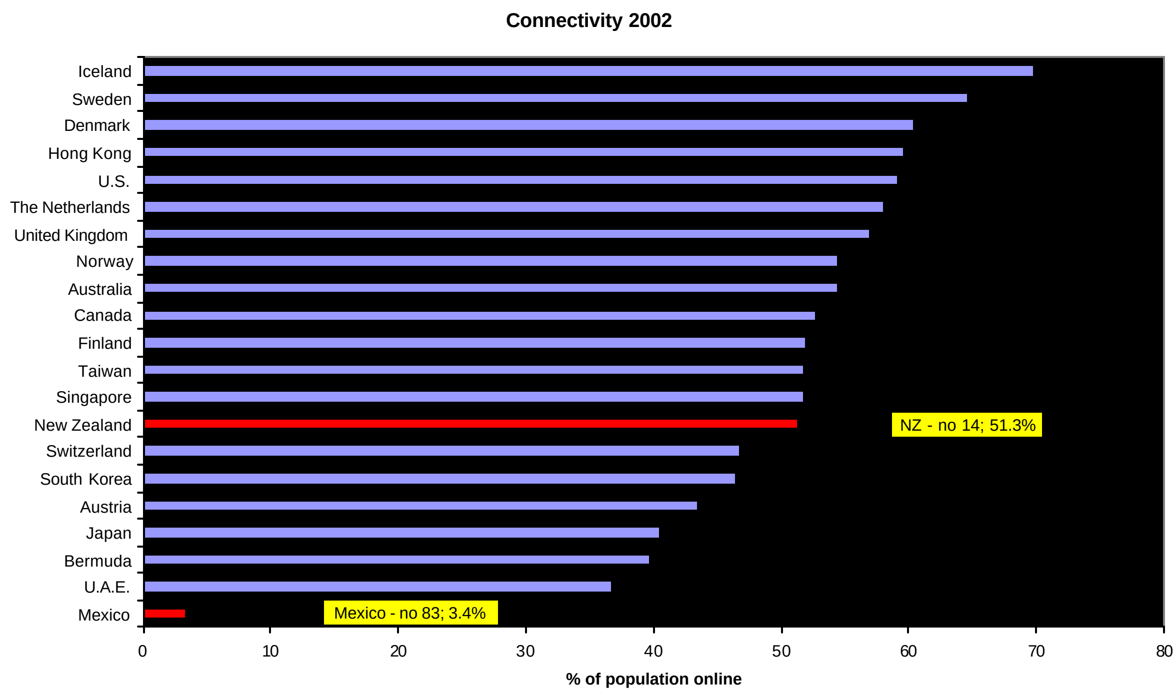

FIG 1: CONNECTIVITY 2002 – TOP 20 COUNTRIES PLUS MEXICO
Source: Calculated from data from Nua, May 2002

Internet market – the number of people in a country with access to the Internet

The size of the market is another motivating factor. In some large countries, with China being the classic example, the connectivity rate may be low but the Internet market still significant. As Fig 2 indicates, Mexico's Internet market is nearly twice the size of that of New Zealand. Moreover, the proximity to the huge United States online population (166 million) and specifically the Hispanic part of that, offers great incentives for Mexican firms to go online. It should be remembered that whilst the Internet itself is distance-neutral, most firms are dealing in physical goods and services so the old constraints still apply, and proximity to market is a valuable asset.

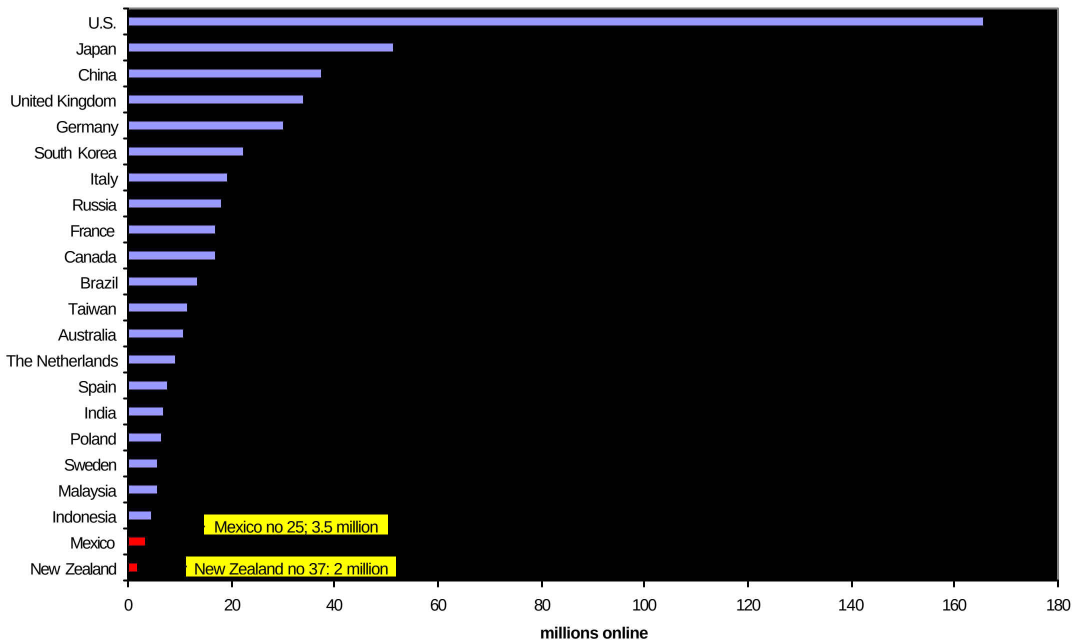

FIG 2 SIZE OF INTERNET MARKET, 2002
Source: Calculated from data from Nua, May 2002

E-readiness

A number of companies attempt to assess 'E-readiness', which may roughly be translated as the conduciveness of the national environment to use business use of the Internet. The survey used here is from the Economist Intelligence Unit and was conducted in March 2003. New Zealand comes out considerably better that Mexico, indicated that the barrier for New Zealand firms to use the Internet is lower than for their Mexican counterparts, and the Internet environment is generally more supportive.

Relevance of the Wellington survey

It is clear that for these and other reasons the business environment in which Wellington firms operate, and in which they decide upon and implement and Internet strategy, differs in many ways from that obtaining in Mexico, or elsewhere. On the other hand there is not reason to suppose that these differences are so marked that they make the experience of Wellington firms atypical. The differences should be borne in mind, and the particularities of the New Zealand situation noted, but it seems fair to say that the results of this survey have a general relevance beyond the confines of Wellington itself. How relevant they are for, say, Mexican firms, is perhaps something best left to Mexicans to judge.

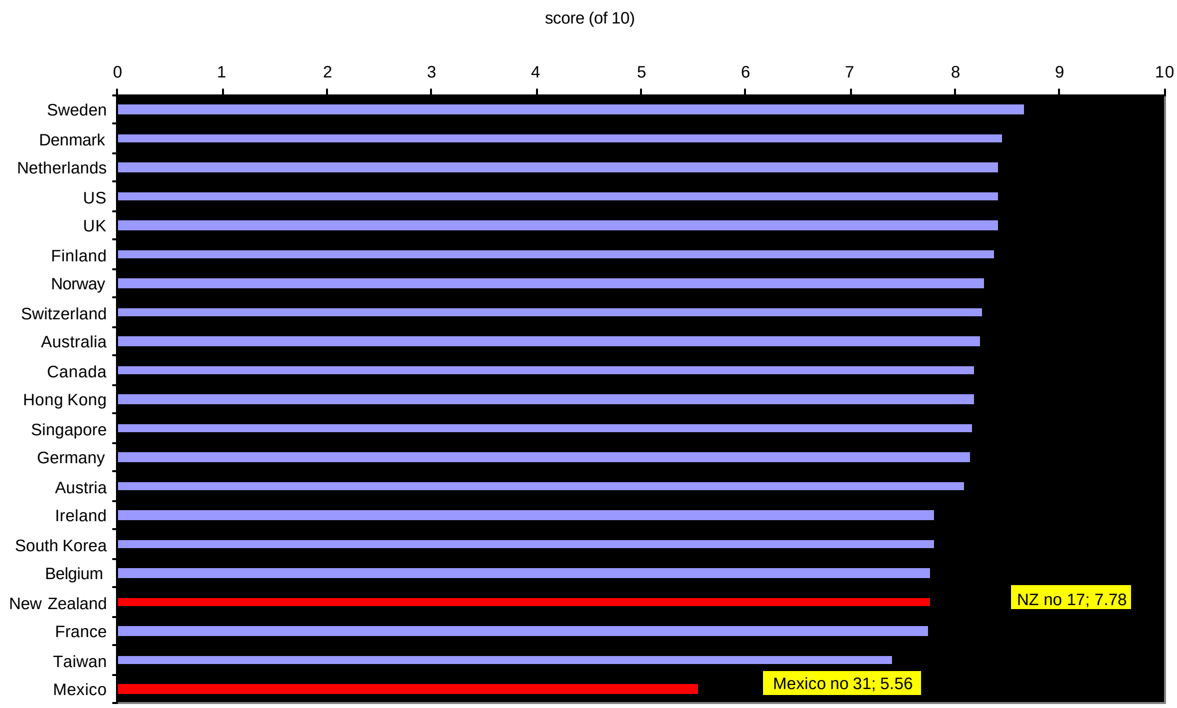

FIG 3 E-READINESS 2003

The research method

It is widely acknowledged that definitions of small and medium enterprises differ across countries and sectors. However, observation shows that there is a common pool of criteria, which is normally used in defining it. This includes number of full time employees, invested capital, personal ownership and management and total value sales or turnover or profit before tax. In many countries only one or a few of the above characteristics are typically chosen depending on the purpose of the study. In New Zealand SMEs are usually defined as enterprises employing 19 or fewer full time equivalent employees. Within SMEs, small enterprises are defined as those employing not more than 5 full time equivalent emp loyees and medium enterprises as those employing 6-19 full-time equivalent employees.

The study focuses on website use by members of Wellington Regional Chamber of Commerce (WRCC) whose email address was registered with the Chamber. The survey was carried out as a joint project with the School of Marketing and International Business of Victoria University of Wellington. The study did not formally confine itself to SMEs, because WRCC does not categorise its members it this way. However, the membership is predominately SME so the survey can be said to be SME-focused. The survey was carried out between late February and early March 2003. An email was sent to members who were requested to link to a secure website on which the questionnaire was posted. It should be stressed that all the members surveyed were thus, by definition, connected to the Internet. We cannot say how typical they are of SMEs in general. Out of 842 Chamber members surveyed, a total of 106 SMEs returned the questionnaire with a completed answers. The data was processed and analysed in the SPSS and some basic statistics were used in order to substantiate the findings.

General Findings

Out of 106 SMEs surveyed, over 40 percent or 43 enterprises have the turnover of less than $NZ500,000. Nonetheless, a significant percentage of the total sample, i.e. 32.1 percent has the turnover between $NZ10 and $NZ50 million, while another 4.7 percent with turnover more than NZ$50 million (see Table 1). The findings reflect that the size of SMEs in New Zealand is quite varied in nature, small and as well as medium sizes.

SMEs in the survey are currently quite inward looking as far as customer base is concerned. The findings show that about 28.3 percent of them market the products in the area of Wellington only, besides another 42.5 percent market the products nationally. Table 2 shows that those SMEs in the survey that market the products globally is only 20.8 percent, while another 8.5 percent restricted their markets to New Zealand and Australia only. To some extent this local focus reflects the nature of their business.

TABLE 1: TURNOVER OF THE ENTERPRISE ($NZ)

Turnover	Frequency	Percent
Less than 100,000	19	17.9
100,000 – 499,999	24	22.6
500,000 – 999,999	15	14.2
1 million – 9,999 million	34	32.1
10 million – 49,9999 million	9	8.5
50 million and above	5	4.7
TOTAL	106	100.0

TABLE 2: SMES BY THEIR CURRENT CUSTOMER BASE

Market Level	Frequency	Percent
Wellington only	30	28.3
National (New Zealand)	45	42.5
New Zealand & Australia only	9	8.5
Global	22	20.7
TOTAL	106	100.0

The findings of the use of computer in SMEs are revealed in Table 3. It shows that about 16.0 percent of the sample has more than 50 computers. Moreover, 37.7 percent of them used between one and five computers, while another 16.9 percent and 16.0 percent respectively used from six to ten and from 11 to 20 computers. Curiously one of the surveyed SMEs claimed not use a computer at all for business, but since the survey was conducted by email this is difficult to interpret. Based upon the findings, it seems that once Wellington SMEs move into ICT they do it with some gusto.

TABLE 3: SMES BY THE NUMBER OF COMPUTER USED

Number of computer used	Frequency	Percent
Nil	1	0.9
1-5	40	37.7
6-10	18	17.0
11-20	17	16.0
21-50	13	12.3
50 and above	17	16.0
TOTAL	106	100.0

The findings show that a total of 67.0 percent or 71 respondents have websites as compared to 33.0 percent of them that do not have any website. This suggests that a majority of SMEs in New Zealand who have Internet access currently have a website as a way of doing, operating and managing their businesses to some extent. It should be recognised that the sample is likely to be more enthusiastic about ICT than the norm. The very fact that they have answered an email survey on the subject reflects that.

Table 4 confirms, as expected, that the website established by the enterprises is relatively new with more than 80 percent have set up the website less than 5 year ago. Out of this, about 57.7 percent has set up the website between 2 and four years ago. Besides, only 4.2 percent has set up the website between eight and ten years ago, being the smallest percentage. The newness in setting up the website is very much correlated to the recent and rapid development of ICT industry in the country and global development.

TABLE 4: SMES BY STATUS OF WEBSITE AND ESTABLISHMENT OF WEBSITE

Status of Website	**Frequency**	**Percent**
SMEs with website	71	67.0
SMEs without website	35	33.0
TOTAL	106	100.0
Year of Setting up Website	**Frequency**	**Percent**
Less than 2 years ago	18	25.4
2 to 4 years ago	41	57.7
5 to 7 years ago	9	12.7
8 to 10 years ago	3	4.2
TOTAL	**71**	**100.0**

The principle aim of setting up a website should be to improve the business in some way. Table 5 shows that those who had established websites were broadly satisfied. 26.8 percent claimed that the setting up of the website had produced high and better performance for them, while another 46.5 percent said they had been moderately successful. Only 26.8 percent said that website had either not made much difference, or it was too early to judge the level of success. Thus, three quarters of the respondents who had websites found them worthwhile.

The findings are highly correlated to the objectives of the website perceived by SMEs in the survey. As illustrated in Table 6, the main objectives stated by SMEs in setting up the website, among others include; to enhance corporate image; to reach new market in New Zealand; to enable customer to check products; to communicate better with existing customer; to reach new market overseas; to compete with large companies and besides some other reasons.

TABLE 5: LEVEL OF SUCCESS WITH WEBSITE

Level of Success with Website	**Frequency**	**Percent**
Very successful	19	26.8
Moderately successful	33	46.5
Has not made much difference/Too early to measure	19	26.8
TOTAL	**71**	**100.0**

TABLE 6: THE OBJECTIVES OF SETTING UP WEBSITE

Objective of the Setting up Website	**Yes**	**Percent**
To enhance corporate image	56	78.87
To reach new markets in New Zealand	42	59.15
To Enable customer to check products	42	59.15
To communicate better with existing customer	41	57.75
To reach new markets overseas	31	43.66
To compete with larger companies	30	42.25
To grasp technology in business	28	39.44
To catch up with competitor	25	35.21
To enable to open all the time	23	32.39
To provide access to manuals, detailed product information etc	21	29.58
To replace the stocking or mailing of paper-based information	18	25.35
To provide means of customer to staff communication	16	22.54
To enable customer to order product	13	18.31
To provide saleable/subscriptions electronic material	11	15.49
To enable customer to pay for products	8	11.27
To provide an information resource for scattered staff	8	11.27

Note: The number and percentage of answers exceeded the total due to a respondent was allowed to select more than one answer.

As expected, the companies encountered a number of problems. Table 7 reveals that 22.5 percent of them acknowledge website took too much internal resource to maintain, another 21.1 percent said their staff who not have the required expertise, while another 18.1 percent revealed that the website generated no extra business to them. This last problem is not strictly incompatible with the most favourite objective of establishing a website, namely to improve corporate image. Whilst a better corporate image is intuitively presumed to be at least conducive to generating business it might not necessarily follow. In addition, a company might be happy with a better corporate image even though that had no discernable impact on business purely for reasons of self-esteem.

TABLE 7: PROBLEMS ENCOUNTERED BY SMES WITH WEBSITE

Problems encountered	Yes	Percent
Took too much internal resource to maintain	16	22.54
Staff did not have the required expertise	15	21.13
No extra business was generated	13	18.31
Took staff from more profitable duties	12	16.90
ISP performance was unsatisfactory	9	12.68
Set-up costs were too high	8	11.27
Consultants did not understand our business	7	9.86
It was difficult to find qualified and dependable consultants	7	9.86
Maintenance costs were too high	6	8.45
It created customer demands/expectations we couldn't cope with	4	5.63
Internet service provider (ISP) cost was excessive	4	5.63
There were security problems	1	1.41
Other	10	14.08

Note: The number and percentage of answer exceeded the total since a respondent was allowed to select more than one answer.

Further analysis is performed through SPSS to find out the level of relationship between a few main variables and the SMEs' status of website. The three main variables are analysed, i.e. number of computers that SMEs use, current customer base and turnover of SMEs. Those three variables are individually tested using normal cross tabulation (or cross tab) and then Chi-Square Test as well as Fisher's Exact Test, whichever is appropriate. The findings reveal very interesting and indicative results. Table 8 points out the relationship between the number of computers that SMEs use and whether or not they have a website. It clearly shows that the higher the number of computers in use, the more likely the company is to have a website. Fisher test result indicates that the relationship is very significant with probability of $P<0.008$. This means that SMEs with website tend to use more computers in their business operation.

TABLE 8: STATUS OF HAVING WEBSITE BY NUMBER OF COMPUTER USED BY SMES

Number of Computer Used	**Status of**	**Website**	**TOTAL**
	SMEs with Website	SMEs without Website	
None	1 (100)	-	1(9.4)
1-5	18 (45.0)	22(55.0)	40(37.7)
6-10	13 (72.2)	5(27.8)	18(17.0)
11-20	13(76.5)	4(23.5)	17(16.0)
21-50	11(84.6)	2(15.4)	13(12.3)
50 and above	15(88.2)	2(11.8)	17(16.0)
TOTAL	71 (67.0)	35 (33.0)	100.0

Note: Figure in bracket is percentage
Fisher Test = Value, 14.576; Exact Sig. .008; $P < 0.01$

The second relationship, i.e. between current customer base and the status of web site in SMEs is illustrated in Table 9. The finding is quite clear that SMEs with website tends to have broader customer base, while SMEs without website tends to concentrate their market around Wellington region and New Zealand only. The relationship is strong with the value of Chi-Square Test is 9.883 and exact significant level of 0.018.

TABLE 9: STATUS OF HAVING WEBSITE BY CURRENT CUSTOMER BASE OF SMES

Status of Customer Base	**Status of**	**Website**	**TOTAL**
	SMEs with Website	SMEs without Website	
Wellington Region only	14(46.7)	16(53.3)	20(18.9)
New Zealand only	31(68.9)	14(31.1)	33(31.1)
New Zealand and Australia only	7(77.8)	2(22.2)	17(16.0)
International	19(86.4)	3(13.6)	36(34.0)
TOTAL	71(67.0)	35 (33.0)	106(100.0)

Note: Figure in bracket is percentage
Chi-Square Test = Value, 9.883; df 3, Exact Sig. .018; $P < 0.05$

Table 10 shows a quite similar result, that is SMEs with website tend to have higher value of turnover. The result is validated by the Fisher's test, which indicates that the relationship is strong at the value result of 11.166 and exact Significant level of 0.039. This is consistent with the distance-neutrality of the web.

TABLE 10: STATUS OF HAVING WEBSITE BY SMES' TURNOVER

Turnover of SMEs (NZ$)	**Status of Website**		**TOTAL**
	SMEs with Website	SMEs without Website	
Less than 100,000	8(42.1)	11(57.8)	19(17.9)
100,000-499,999	14(58.3)	10(41.7)	24(22.6)
500,000-999,999	13(86.7)	2(13.3)	15(14.2)
1 million-9.999 million	25(73.5)	9(26.5)	34(32.1)
10 million-99,999 million	6(66.7)	3(33.3)	9(8.5)
10 million and above	5(100.0)	-	5(4.7)
TOTAL	71 (67.0)	35 (33.0)	106 (100.0)

Note: Figure in bracket is percentage
Fisher Test = Value, 11.166; Exact Sig. .039; $P < 0.05$

Training and Support Needs

Of great importance to the WRCC, and of particular relevance to this conference, was the final set of questions on training and support needs

The rubric read:

Whether you have a website or not, you want to make the best possible decision for your company. And if you have a website the decisions don't stop there. Are you getting value for money? Are you realising the potential of the technology? Could you be doing things better? Here are some possible ways the Chamber of Commerce could assist you in the web area. Please tick the ones you would find useful.

There were then two questions, each with a set of options and an opportunity to give an open-ended answer.

It should be remembered that these questions relate to service which members felt the WRCC might provide, so they do not necessarily reflect needs in general, that might be satisfied in other ways. In other words, respondent might perceive a pressing need for 'Accreditation of reputable commercial website developers' but not regard the WRCC as a suitable provider. However, since none of the respondents made this point in the open-ended section it seems likely that these answers do represent their perceptions about needs in general.

TABLE 11: WEB-BASED SERVICES

	no	%
Third party website verification service	40	37.7
Online business advice	48	45.3
Publications	48	45.3
Online booking/registration for WRCC events	53	50.0
Business information and statistics (e.g. web use data)	57	53.8
Directory of members and services	62	58.5
Accreditation of reputable commercial website developers	35	33.0

Curiously the only suggested service bearing directly on building a website, 'Accreditation of reputable commercial website developers' gets the lowest score. This may mean that most respondent were happy with designers, or their ability to chose the right one. On the other hand those who had already established a website might have felt this was now past history.

As is often the case, the open-ended answers gave hints that some companies at least found designers and IT specialists

- ?? Aligning web needs with developers, i.e. ensuring that low tech needs are matched with low tech providers and high need with high tech providers. Not every web site needs all bells and whistles and full suite of latest high tech ad-ons. A presence may suffice in many cases with add-ons coming later if needed.
- ?? A source to ask the simple (dumb) questions about computer use in general. presently this is done by phoning a friend who knows a bit about computers. Help pages always seem very complicated to navigate to and all I want to do is talk to someone and explain my problem. When I eventually get that opportunity often the solution is given very quickly.
- ?? Advice tailored to small corporate business services companies such as ours.

This is clearly an area that needs exploring further. It is hoped to use the results of this survey as a foundation for in-depth interviews.

The other question related to staff development.

TABLE 12: STAFF DEVELOPMENT (NOT NECESSARILY WEB-BASED):

General seminars on web marketing	52	49.1
User forum to network with other companies	27	25.5
Short training courses for non-specialists	56	52.8
In-depth courses - e.g. for particular web software	16	15.1

The results clearly indicate that the respondents felt the need for general, non-specialist training. This is consistent with what we know about SMEs in general; they are generally run by people who have to cope with a the whole gamut of business functions who need to interact with specialists such as accountants, lawyers and IT people, but do not have the time to develop specialist expertise in these areas themselves. It is noteworthy that the option with by far the lowest score (15%) was for specialist courses and the one with the highest (53%) was for non-specialist courses. General seminars on web marketing came a close second.

However, it is evident that although the scores varied, there was a high demand for all these suggested services. The respondents clearly felt there was a need for the WRCC to provide training and help for its members and they were conscious that their own utilisation of the web could be improved. In other words, they saw the web as a tool which they could use better to develop their business, but they did not want to be side-tracked into spending too much time and energy on the technology, and the mastering of it.

As one respondent put it:

Web marketing has to be understood in the wider marketing context. The web is not the only tool. In fact it is often over valued in marketing and has been since the beginning. Advice should be to look at marketing needs and methods including the web.

On the Business Model of a Biotechnology Venture in a Biotechnology Cluster of Sweden: The Case of Stockholm-Uppsala Area

Takao Fujiwara
Toyohashi University of Technology, Japan

Abstract?

As main purpose of here, by dealing with Sweden where the basic research level of life science is traditionally high as compared with the GNP or population, there are also some biotechnology clusters, some biotechnology ventures divide the work for each drug development stage with restructuring progress of the big pharmaceuticals firms, and both numbers of biotechnology venture and IPO biotechnology venture are relatively many, this article will examine the network of anti-entropy as a division-of-work network where the progressive biotechnology venture can be created. More specifically the article will, at first, discuss the network characteristics with the accumulation and feature of biotechnology ventures in main biotechnology clusters. Next, it will examine the possibility of the drug development by the ventures from the viewpoint of the autonomous division of work within pharmaceutical industry. And thirdly, it will investigate the drug development process and business model of a biotechnology venture which attained IPO.

Introduction

As a research background, some biotechnology ventures that are successful considering the scale, in spite of resources-restrictions of financial or human resources, with the high productivity of development based on innovative ideas exist. For example, according to Robbins-Roth (2000), as compared with Merck & Co of a large-scale pharmaceutical firm, the top 100 biotechnology ventures containing Genentech, Amgen, and Millennium excel in the productivity of per resources and of development for drug candidates.

However, as research questions, firstly, is it enough for the entrepreneur of a biotechnology venture to commercialize the original and creative ideas, with just the isolated and gifted talent? Secondly, why is the product development possible for biotechnology ventures with very few black-figures firms or being no product incomes for a long period of time, even if they succeed in IPO, while a high-risk project like drug development is characterized by a long-term equilibrium between supply and demand? And thirdly, how is it necessary to make evolve a business model, if the participation to drug development is possible also for biotechnology ventures, with progress of a drug development process?

A framework here is based on the network relevant to the business model of anti-entropy. That is, this framework will examine the autonomous mechanism which makes to occur and evolve the innovative idea produced by chance for business of high productivity, at three levels as a biotechnology cluster, a drug development value chain, and a business model of a biotechnology venture. And there are mainly two kinds of types of biotechnology ventures as the start-up from a university and the spin-off from a large firm. First, a university, VC, a technology transfer unit, and a large firm are contained, as the composition elements generating biotechnology ventures, in the biotechnology cluster as its accumulation. Next, there are the drug development stages and the drug developmental tool and service common to the each stage, within the drug development value chain as a division-of-work map in the middle between a university and a large pharmaceutical firm. And third, the evolutional mechanism of business model is required to enrich the development technology and the cash flow for promoting development further with progress of a drug development process, for a biotechnology venture. As main purpose of here, by dealing with Sweden where the basic research level of life science is traditionally high as compared with the GNP or population, there are also some biotechnology clusters, some biotechnology ventures divide the work for each drug development stage with restructuring progress of the big pharmaceuticals firms, and both numbers of biotechnology venture and IPO biotechnology venture are relatively many, this article will examine the network of anti-entropy as a division-of-work network where the progressive biotechnology venture can be created. More specifically the article will, at first, discuss the network characteristics with the accumulation and feature of biotechnology ventures in main biotechnology clusters. Next, it will examine the possibility of the drug development by the ventures from the viewpoint of the autonomous division of work within pharmaceutical industry. And thirdly, it will investigate the drug development process and business model of a biotechnology venture which attained IPO.

1. The Biotechnology Cluster

As the reasons that the country should attract attention in biotechnology industry, it is supposed, about the biotechnology cluster, that the number of biotechnology ventures is a top level also in Europe, there is a capability to analyze the relation between heredity and environment, the relation among the industry, the university, and the public medical institution is close, and there are VC funds and the capital market specialized in biotechnology (Invest in Sweden Agency, 2002).

1-1. The Number of Swedish Biotechnology Firms

In 2000, the number of biotechnology ventures of Sweden is the 4th place in Europe at 235 companies, subsequently to 504 companies of Germany, 448 companies of UK, and 342 companies of France. However, more than 100 companies were founded between 1996 and 2001 in Sweden, and its relative number size is the 1st place in Europe to the population and GDP (ISA, 2002). By the way, the number of the U.S. biotechnology ventures in 2000 is 1,273 companies (Ernst &Young, 2000), and that is about 300 companies in Japan in 2002 (JBA, 2003).

As the reasons of relatively many biotechnology companies of Sweden, the long history of the basic and clinical research of biotechnology, the cooperative industry-university atmosphere, the restructuring of the major pharmaceutical companies, and the present foundation boom are mentioned. According to Vinnova (Swedish Agency for Innovation), 93% of biotechnology ventures carries out the cooperative research with universities, and many biotechnology ventures are based on the research result in universities. Moreover, blockbuster drugs, such as Xylocain, Seloken, Losec, Prilosec, and Genotropin were developed by industry-university co-operation in the past. Furthermore, even in the pioneering medical device domain, a transplant pacemaker, an artificial kidney, a laser surgical unit, a titanium implant, a blood plasma substitute based on a polysaccharide, a separation method, a super-centrifuge, and an electrophoresis method are developed in this country.

Furthermore, many employees of biotechnology ventures are the skillful persons who changed their jobs into the ventures under the influences of the restructuring by former Pharmacia and AstraZeneca.

1-2. The Company Distribution of the Biotechnology Clusters around Universities and Big Firms

The representative features of the biotechnology clusters of Sweden include the proximity to universities and university hospitals, the support by VC, and the capability of founders who transform scientific discoveries into businesses. The biotechnology venture accumulation in the country mainly consists of three major clusters as Stockholm-Uppsala, Göteborg, and Malmö-Lund, and of two peripheral clusters as Linköping and Umeå.

Table 1: COMPANY COMPOSITION OF SWEDEN BIOTECHNOLOGY CLUSTERS IN 2001

REGION	RATIO
Stockholm-Uppsala	54%
Malmö-Lund	15%
Göteborg	14%
Umeö	2%
Other	15%

Source: Invest in Sweden Agency, Biotechnology, 2002.

1-2-1. Stockholm-Uppsala Area.

Capital Stockholm and a university town Uppsala are domestic core areas, and occupy the share of more than half of domestic biotechnology companies, with many resources of life science. Especially, the academic research tradition and the presence of big pharmaceutical firms like Pfizer (firmer Pharmacia) and AstraZeneca at both cities are the bases of biotechnology industrial formation of this area. First, five of eight domestic Nobel-prize winners in medicine and physiology area are KI (Karolinska Institute) related persons. KI covers about 40% of medical research in domestic universities including the medical institutes of Karolinska Hospital and Huddinge University

Hospital, and is the global research institute of medical science. And, Department of Biotechnology at Royal Institute of Technology is also one of the main fountainheads of entrepreneurial activities. The business foundation activities like spin-off or start-up are active at Uppsala where the head office of former Pharmacia was located. More than 100 biotechnology ventures have been founded here. As the reasons, the compactness of a town, the research resources including Uppsala University, the ease access to VC, and the availability of the skilled people from the restructuring of former Pharmacia are considerable. While many biotechnology companies of Uppsala are specializing in a remarkable degree in the tool and service business (examples: Biacore, Gyros, and Pyrosequencing), those of Stockholm are concentrating on the drug development value chain (examples: Affybody, Karo Bio, and Medivir). Industry-university interaction is supported by Karolinska Innovation AB as a technology-transfer company, Karolinska Investment Fund as an investment fund of a joint venture between the university and an insurance company, and Novum Science Park.

1-2-2. Göteborg Area.

Sahlgrenska Academy at Göteborg University is the medical research institute produced some Nobel-prize winners, and contributed to development of blockbuster drugs like Losec/Prolosec. As companies in the city, the research base for cardiovascular/gastrointestinal of AstraZeneca is located, and there are Arexis, Angiogenetics, Carlsson Reseaqrch, Cell Therpeutics Scandinavia, and Vitrolife as the biotechnology ventures of the drug discovery and development. For commercialization of technology, there are A-Plus Science Invest as a technology licensing company, Chalmers Innovation as an investment fund, and Sahlgrenska Science Park.

1-2-3. Malmo-Lund Area.

This biotechnology accumulation region including an adjoining Denmark-Copenhagen area is called Medicon Valley, and has the universities, about 100 biotechnology companies, science parks, and core facilities. Infrastructure development is made around Lund University or Ideon Science Park in this area of Sweden. Active Biotech, Biounvent, Biora, and Clinical Data Care are included in a bio-medical related industry.

1-3. Venture Capital

The number of Swedish VC companies increased from about 25 companies to 200 or more companies during 1995 to 2001. The amount of funds which could be used for VC also increased to 10 times as many SEK 2000 billion (Euro 22 billion) as in this period. Even in the amount of funds of VC industry, about half of investment by the member of Swedish Venture Capital Association was made to the domain of biotechnology, medical treatment, medical technology, and pharmaceuticals in the 3rd quarter in 2001. And 20% or more of capital is distributed to the early stages as seed or start-up phase. As the representative examples of VC companies which specialized in life science, the sophisticated investors such as HealthCap, Investor Growth Capital, Nordic Capital, and Karolinska Investment Fund attract attentions. International syndicate investments were also made. For example, 2nd round financing of SEK 309 million to Gyros by 3i, Investor Growth Capital, Karolinska Investment Fund and HealthCap in December, 2001, has attained the maximum scale of biotechnology VC financing in the country. Also with IPO, 16 biotechnology ventures, including Active Biotech, Karo Bio, Medivir, and Perbio Science achieved at going public to Stockholm Stock Exchange.

1-4. Technology-transfer Company

As the innovation of pharmaceutical industry inclines in biotechnology, the tendency to think the basic research in universities as important is arising. The technology licensing organizations and investment funds in universities are supporting the early stage of business foundation. First, as "teachers exemption", in case own invention is commercialized, unless the discovery has an exceptional relation with a university, the right which commercializes all is protected for the university researchers of the country. Moreover, while the technology licensing organizations (companies) are established in many universities of the country in order to pull out economical value from the research results of universities, in many cases, they are managed as the holding companies which maintain the rights to start ventures. As the technology-transfer companies, Karolinska Innovation AB in Stockholm, A-Plus Science in Göteborg, and Teknopol in Lund can be mentioned as representative examples. Those functions are to carry out also strategic and expertise advice about venture foundation and operation in addition to patent filing and licensing. And as a campus investment fund, for example, Karolinsk Investment Fund is established by KI and a Sweden insurance company Alecta in 1999, and is mainly carrying out the portfolio investment to 11 companies in the special domain of the medical science, biotechnology, and medical technology by the early 2002. Furthermore, a networking organization like Connect Sweden which is expected to introduce technical, financial, and business developmental resources to entrepreneurs also exists. Although an original and creative idea is emphasized not only with biotechnology but also with a venture, the fact that biotechnology ventures crowd and are unevenly distributed in specific areas as a biotechnology clusters is considered to be the proof which entrepreneurs tend to access to the specific location of or is building the original network on which information is crowdedly flowing, rather than that entrepreneurs are isolated and investigate original ideas.

2. The Medicine Development Value Chain

As one reason the biotechnology industry of Sweden attracts attention, the complement-division of work in drug development process by ventures is possible, because there are substantial ventures for all stages of the new drug development value chain and for the drug development support service as a clinical test service.

2-1. Genomic Drug Discovery

The main drivers of economical transformation of the R&D system of pharmaceuticals industry are the technological innovation of genomic analysis and its introduction to drug development. Thus, many ventures which specialize in each niches, such as drug discovery, biotechnology tool, and a clinical test, have come to cover the very drug development process by division of work against the large-scale pharmaceutical companies which had conventionally performed the whole drug development stages for themselves. Furthermore, some ventures exceed big firms by advanced development as functional genomics.

2-2. Full Value Chain Reorganization

2-2-1. Spin-off and M&A of Big Business.

The restructuring of big pharmaceutical firms and the increase in venture foundation in Sweden are reflecting the global trend which asks for the efficiency improvement of the drug development value chain. As former Pharmacia and former Astra which were the Swedish domestic companies changed themselves into the U.S. company Pfizer and the British company AstraZeneca, many large pharmaceutical firms have repeated M&A and its related restructuring, for the purpose of R&D budget procurement and the inclination for later stage of drug development. Consequently, many of skillful researchers of large pharmaceutical firms left for founding new ventures or becoming employees at ventures. Especially at Uppsala where the head office of former Pharmacia was located, many ventures started their businesses by utilizing unused resources, such as scientific people and VC. Such network-reorganization of drug development process meets the trend for the improvement in productivity as a whole.

2-2-2. Venture Niche Market.

With the improvement in prediction by genomics of the disease possibility and drug reaction, there are some ventures which are aiming at the identification of the disease targets and the drug candidates, and at the creation of new technologies, and also some more ambition-ventures which actually carry out to the conceptual proof of drug candidates are going to license out to the large-scale pharmaceutical firms responsible to later stage of drug development. For example, Karo Bio doing the drug target research in the core receptors, Melacure Therapeutics doing the drug discovery of the melanocortin receptor targets, and Medivir studying the medical treatment compounds in the infection and autoimmune diseases are included in this aggressive category.

And in genomics and proteomics research, there are attention attractive ventures as Aredxis, AngioGenetics, and Affibody which aim at the improvement in productivity of drug discovery by integration with high throughput technology and computer technology, and another ventures as Prevas Bioinformatics, Global Genomics, and Spotfire which correspond to the huge information produced by bioinformatcis as the fusion of biology and computer analysis. Moreover, in the domain of drug development support, there are Canag Diagnostics, IDL, Cellavision as the diagnostic drug ventures which contribute to the drug development by progress of the monoclonal antibody, Amersham Biosciences, Biacore, and Pyrosequencing as the development support tool ventures (bio med-tech suppliers), and Medical Products Agency, Scandinavian CRI, and Berzelius Clinical Research Center as the clinical research support ventures. The biotechnology ventures cover each special niche market through the whole value chain of drug development of the country. On the other hand, the drug development support systems, such as the schemes stimulating the industry-university cooperation, the foundations supporting the large-scale functional genomics research, the bio-banks, and the diseases management system are also established.

Table-2: SWEDEN BIOTECHNOLOGY RESEARCH TALENT'S DISTRIBUTION WITHIN VALUE CHAIN

Drug Development Stage	Ratio
Target Identification	29%
Target Proof	8%
Chemical Screening	16%
Chemical Optimization	8%
Pre-clinical Development	3%
Clinical Development	36%

Table-3: EXAMPLE OF BIOTECHNOLOGY VENTURE IN DRUG DEVELOPMENT VALUE CHAIN

Drug Development Stage	Company
Target Identification	Affibody, Biacore, Biovitrum, Carlsson Research, Global Genomics, Karo Bio, Pyrosequencing
Target Proof	Active Biotech, Esperion, Medivir, Melacure Therapeutics, Neuronova, Resistentia Pharmaceuticals
Pre-clinical Development	Amersham Biosciences, Bacterum, Bioinvent, Biophausia, Camurus, Diamyd Medical, Q-Med,
Clinical Development	Abigo Medical, Berzelius Clinical Research Center, Biora, Clinical Data Care, Conpharm, Elekta, Glycorex,

Source: Invest in Sweden Agency, op cit

2-3. Feature of Uppsala as a Biotechnology Tool Development Division-of-work Cluster

Stockholm and Uppsala are located across Arlanda Airport within a commuter region. While the biotechnology ventures of Stockholm concentrate on the drug development, those of Uppsala are specializing in development of the tool for drug development.

2-3-1. The Mechanism of Development Division-of-work Formation. In the domain of biochemistry, Sweden including Uppsala with Uppsala University of 500 years tradition has developed world's first technologies, such as the 1920s ultra centrifuge by Svedberg, the 1940s electrophoresis by Tiselius, and the 1960s chromatography for protein purification by former Pharmacia. As an example of a gatekeeper for the technology-transfer network from a university, Mathias Uhlén, Professor of Royal Institute of Technology and a member of National Research Council, applies for many patents in proteomics, supports many biotechnology venture foundations in Uppsala-Stockholm area, and has involved with many boards of directors and science adviser boards. In addition, about since the 1990s when global M&A of large pharmaceutical firms began to increase, in the biotechnology tool domain, about 135 companies as Biacore, Pyrosequencing, and Gyros have been founded around former Pharmacia and formed division of work of a biotechnology tool development in Uppsala rather than drug development.

As the formation factors of Uppsala as a tool development division-of-work cluster, first, the tradition of biochemistry exists in Uppsala. Next, pharmaceuticals industry is asking for the tool required for development of molecule medicine. And a large amount of risk capital is invested in the ventures of Uppsala from VC. Furthermore, the surplus of the human resources accompanying the restructuring by large pharmaceutical firms and of buildings from an army move exists, and R&D staff's labor cost is also estimated as about half of U.S..

2-3-2. Spin-off.

In Uppsala, former Pharmacia (the present Pfizer) after Pharmacia & Upjohn changed into specializing in the latter stage of drug development, unified Amersham Life Sciece which is the life science business of Amersham after Nycomed Amersham and Pharmacia Biotech, and made Amersham Pharmacia Biotech (the present Amersham Bioscieces). And former Pharmacia made also a drug development section of Stockholm spin-off as Biobitrum.

2-3-2-1. **Amersham Bioscieces**.

The Uppsala business unit of the comp any has been the core-existence of the Uppsala biotechnology cluster which has developed in the past ten years, and its sales are growing rapidly with the recent rise of the importance of protein research. Although former Pharmacia Biotech had a track record of the product development for separation/purification of the protein since the 1960s, Amersham Pharmacia Biotech (Amersham Bioscieces) was made by integration in 1997 of Amersham Life Sciences, a section of Britain Amersham, and Pharmacia Biotech, a section of Pharmacia. In the support tool offer strategy to all the drug development processes by the British head office, the chemical separation business unit of Uppsala is based on the former expertise of development and manufacturing of the product for protein purification/separation. Especially, since the focus of medicine research is concentrating on protein further with advance of the genome map, this business unit aims at supply of the advanced system which makes the protein analysis more quick and efficient.

2-3-2-2. Biacore.

In 1984, this company had been founded as Pharmacia Biosensor AB, by investment of SEK 550 million for initial development of a product system and of basic technology, and by integration of know-how and technical knowledge from former Pharmacia, Linköping Institute of Technology, and Swedish National Defense Research Institute. And in 1996, the company name was changed into Biacore AB before M&A of Pharmacia, and its independency was strengthened on the basis of Pharmacia's support. As of June, 2002, it had the employee number 316, the yearly turnover SEK 543.7 million, and the R&D cost SEK 105 million.

The company started the development of the biosensor technology which searches for and supervises the combination of the bio-molecules on the basis of SPR (Surface Plasmon Resonance) which consists of three component technologies of surface-chemistry, flow system, and optical detection in 1989. The company developed, manufactured and sold the first analysis apparatus in 1990, and attained black-figures and enforced its independency in 1994. And it realized the SPR array chip as breakthrough in the protein research in 2000. The present focus is put on the pharmaceuticals industry and on the discovery support of the new molecule as a drug candidate. As a latest innovative application example, there is a case of the drug candidate for kidney trouble treatment of the autoimmune disease patients by U.S. La Jolla Pharmaceutical. Although the third phase clinical test was stopped for serious side effects to some patients by US Federal Drug and Food Administration, a Biacore system allowed the drug candidate to get permission of test continuation from FDA, by the ability to identify the patients who can continue to receive the clinical tests without being influenced of side effects, and avoided serious technological and financial damages. The company attained at going public at both Stockholm Stock Exchange and U.S. Nasdaq in 1996. The latest development result caused the stock price rise more than 400% in 2000. In this way, also in a drug development value chain, if it specializes in a specific niche good at its company and divides the work, it can participate in a drug development business even with a venture business.

3. Drug development process and business model of biotechnology venture

KB (Karo Bio) was established in 1987, has placed the head office in Novum Research Park near Huddinge University Hospital in a Karolinska Institute south campus as a university start-up and achieved IPO at Stockholm Stock Exchange on April 3, 1998. After Karo Bio USA was purchased in May, 2000, this company enforced the ability to discover fundamental curative drugs specific in the receptor and biological organization for main illnesses, based on the research results in the domain of the core receptor biology and medicine chemistry in Karolinska Institute and U.S. Duke University. Of more in 100 scientists of 135 company employees, about half of scientists hold PhDs.

3-1. Business Strategy

As KB strategy, it aims at the development of precision drugs to main common diseases on the basis of the domain of the core receptor and protein science. To verify its own technology and business concept, it manages the project and financial risks mainly through the partnership with the large-scale pharmaceutical companies.

3-1-1. Business Concept.

The core receptors which are the R&D focus of KB control the activity of the gene of a cell and many organs in the living body, and form the group of the proteins which have close relations between structures and functions. The targeted markets are the treatment drugs for women's diseases, metabolism diseases (especially diabetes and obesity), cardiovascular diseases, cancers, skin diseases, and ophthalmology diseases. While the large pharmaceutical partners may need average five new products introduction into market in order to maintain 15% of annual growth rate, the company continuously focuses on the drug discovery stage to the pre-clinical test, enriches the drug pipeline, and proposes that the large partners can concentrate on the clinical development and the sales of final products. Moreover, this specialization strategy to the core receptor and drug discovery stage is also aiming at risk reduction against the volatility related to the specialization by the parallel management of some projects and targeting each project to each specific effect indicate. Although the down payment, research fund, and milestone are obtained with the drug development like clinical development after the drug discovery through the partnerships with large pharmaceutical companies, the main value construction is dependent on the long-term income based on the loyalty from future innovative drugs.

3-1-2. Platform Technology.

As the necessary factors for the drug discovery, there are the discovery of a drug target and the selection of drug discovery technology. Although a drug target is usually a protein, it has the physiological and metabolic effects in the state of the specific diseases. The proper technology to drug discovery is a means which enables selection of the compound most promising for quick discovery of a chemical substance peculiar to a target for verification, and for clinical development. The core receptors as the drug target are included in a group of functionally and structurally related proteins. In the composition of a core receptor, the domain which combines with ligands (hormone and drug substance) attracts most attentions for the drug discovery, since the domain is connected with control of gene expression. The drug discovery technology of KB is based on four bases as structure biology, pharmacological and calculation chemistry, HTS (high throughput screening), and lead compound selection system, by making "NucRecDB" as a core receptor discovery database into a core technology. In the domain of structure biology, a core receptor is protein, and since it combines selectively and specifically with hormones and drug substances, an understanding of the 3-dimensional structure is indispensable to the design of a new drug, or the optimization of a lead compound. The company's main element techniques have the receptor-ligand structure and the molecular braille information. A single compound, CADD (Computer-Aided Drug Design), and combi-chem are contained in the domain of pharmacological and calculation chemistry. The BioKey technology which is expected to significantly contribute to HTS utilizes the established technology which is called the phage display used to specify the molecule probe specifically combined with the biologically related pocket or surface on protein. The lead compound characteristic evaluation system is important to select the most promising compound for pre-clinical research and clinical development. This company uses the tissue profiling for specification of the compound of the low possibility of side effects, the Molecular Braille technology for quick recognition of the receptor conformity which reacts to the influence of organization specification, and the Cell Braille technology for specification of the influence of the compound on the receptor function of a cell.

3-1-3. Intellectual Property.

The IP (Intellectual Property) strategy includes the medicine substance discovered newly, process, method, technology, clinical use method, isolated gene in the protection objects of IP, and investigates the continual predominance in a market, and the long-term success and profitability. The compounds, technologies, and use methods are contained in the main candidates for patents. KB has applied for the patents which cover all the new and a series of compounds internally developed can be the protection foundation of new drugs. KB has 22 patent families in this domain as of December, 2001. Although technology is an important business tool, since it can be licensed as service, it is needed for the know-how protection of the company. KB has 25 patent families in this field. The patents about the clinical utility which uses some compounds for the medical treatment of the specific disease are based on the information which became clear in progress of research. KB has 15 patent families in this domain.

For example, in the patent area relevant to the receptor, it has the patents relevant to the specific rights about the estrogen receptor beta (ER beta), and the structural aspects of ER alpha and ER beta. And, in relation to the thyroid hormone receptors, it is applying both the patents about the drug compounds, and their use methods for the medical treatment of various illnesses like obesity, heart arrhythmia, hypercholesterolemia, and liver diseases, and the patents about the design methods of the thyroid hormone receptor ligands. Moreover, in order to prevent patent infringements in the main international markets of a medical product, and the domain of discovery and development, it has contracted with the patent lawyer's office in Europe and the U.S.

Table-4: KARO BIO’S PATENTS

Category	Drug Compounds	Use Patents	Enabling Technology	Total
Patent Families	22	15	25	62
Granted Patents	42	3	83	128
Number of Cases	178	45	196	419

3-2. Research and Development Process

The KB is focusing on the drug discovery aspect targeting on the core receptors, within the drug development aiming at the treatment for common diseases, and has strategic partnerships with pharmaceutical firms carrying out the clinical development and marketing. It has four sorts of project forms like the strategic partnerships aiming at the concrete clinical development by the partners, the internal projects which can search at each stage for partners, the exploratory projects which can be promoted to an internal project by the effects or validity verification of receptors, and the out licensing. The drug discovery process is started when a strong proof of the target protein having relationships with the specific illness exists. It means for KB to start the search for the compounds combined with a specific core receptor. Then, many of these lead compounds are chemically corrected by the test which acquires the optimal joint affinity in various cell and animal models, receptor selectivity, organization electivity, and effects. After that, the clinical test about validity and safety is performed.

3-3. Projects

As one of four sorts of project forms, firstly, it has 4 strategic partnerships with international pharmaceutical firms for development of the innovative medical treatment method for common diseases. Next, it has internal projects including clinical development, by focusing on the discovery stage of new drugs which uses the core receptors as targets. Thirdly, the drug candidates and technologies which are not suitable for internal projects may be out licensed. And fourthly, it has the exploratory projects in order to maintain the pipeline of the drug candidates in some new core receptor domain. Especially, in addition to the new effects of the existing receptors, at the exploratory projects, the discovery and characteristic inspection of new receptors are conducted. Since the drug development involves a high risk, the portfolio management with the project of four forms is performed.

3-3-1.Starategic Partnership.

Although the core receptors are important targets for metabolism diseases like diabetes, obesity, cancer, and atherosclerosis, and for women’s specific diseases, since the drug development accompanies high cost and risk, KB seeks the large pharmaceutical partners which undertake the clinical development in a specific domain, and is fundamentally specializing in the drug discovery from the strategic perspective. In many cases, a partnership is started from the drug discovery stage in a drug development process. In this time, while the scientists of a partner company provide for the selection of the optimal candidates of clinical development with important technical knowledge and resources, and the height of their devotion raises the success probability of a project. In addition, KB draws the strategy which raises the market introduction probability of projects, by running some partnership projects in parallel. As main recent occurrences, the new strategic partnership on the core receptors in atherosclerosis domain was formed with Wyeth (at that time American Home Products) in September, 2001. Among 4 partnership projects, the obesity project targeting the thyroid hormone receptor with Bristol-Myers Squibb carried firstly forward the compound to the clinical test phase I, then KB received a milestone payment. In addition, in February, 2001, this partnership was extended to include Molecular Braille technology, to specify the 2nd generation of the compound and to find additional effects. In the partnership for diabetes with Abbott, in spring of 2001, it succeeded in a world's first determination of the 3-dimensional crystal structure on the ligand joint domain of the glucocorticoid receptor, and could utilize now for the design of the compound which acts on a receptor selectively, and for the design of a compound with the anti-inflammation effect in internal project. And with Merck, it has kept the partnership on development of the innovative treatment drug to uncultivated clinical needs in the estrogen receptor domain for women's diseases since November, 1997.

3-3-2. Internal Project.

The KB maintains the portfolio of the internal projects which are in various preparation stages towards strategic partnerships. When the proof that a receptor is an important target for the specific disease exists, KB is sure of the competitive advantage, and there is a proof about the existence of the big potential market to medical drugs, the exploratory projects can be promoted to the internal projects. And when a monopolistic position is established and a clinical rationale is further supported with experiment data, marketing of the project to pharmaceutical industry is started. As the internal projects, each discovery and development project such as the project on an androgen receptor with a new male hormone (androgen) for hormone substitution treatment and with a new antagonist for prostatic cancer medical treatment, the project on a glucocorticoid receptor for anti-inflammation medicine with few metabolism system side effects, and the project on a thyroid hormone receptor for skin disease treatment medicine is proceeded. Among of them, the validity of thyroid hormone antagonist is already tested at clinical human skin research phase I-II.

3-3-3.Outlicensing.

Since the knowledge of each target function is required, the screening technology which depends on traditional biochemistry analysis obstructs the screening of a target with an unknown biological function, and consequently restricts the drug discovery. On the other hand, the foundation of the BioKey technological program for originally inside KB which enables the high throughput screening is proprietary BioKey molecule probe, even if it lacks the detailed functional knowledge about target protein. KB also develops towards the diversification of BioKey technology which is specialized in the use for GPCR. At each partnership, concerned people have succeeded by about 75% of probability at the specification of the BioKey molecule probe which has high affinity to the target chosen by the partner, and by about 85% at creation of the ligand substitution BioKey assay to the peptide specified as a target. As main license-out partners, it contains Aventis, Boehringer Ingelheim, GPC Biotech, NovImmune, and Serono International.

3-3-4. Exploratory Project.

Since the core receptor is mutually alike in the structure and function, it is easy for KB to develop the technology about an unexplored receptor quickly and to design a lead compound to it. The receptors treated by exploratory projects can be divided roughly into the traditional receptors like a thyroid hormone receptor or a mineralocorticoid receptor, and the orphan receptors. In the thyroid hormone receptor, it has projects about glaucoma, heart arrhythmia, and new effect. Although the receptors of which the natural hormones or vitamins are still unknown are called the orphan receptors, many of known core receptors are in such a state, and furthermore it is considered that there are also still the undiscovered receptors. Access to pioneering technology was indispensable to KB which is specializing in discovery and development of a new treatment drug. Then KB contacted the agreement that it can acquires the exclusive rights of many technologies including the Cellular Braille technology which the Duke university and Duke Univ. Medical Center of NC developed in May, 2001. Moreover, as its scientific network about basic research, Duke Univ., Karolinska Inst., Sahlgrenska Hospital, UNC, Univ. of Bochum, UCSF, and Univ. of York are contained. Although the net sales of the group in the 2001 fiscal year increased to SEK 136.9 million from SEK 100.6 million of the preceding year, the main reasons were caused from the down payment accompanying the new term research partnership with Wyeth (former AHP) and milestone payment from BMS. The increase SEK 146.9 million in expense was based on the costs relevant to the goodwill depreciation by the fiscal period change accompanying KB USA acquisition in 2000 and the new research partnership with Wyeth. The parent company made about one fourth of the debt total of the group to fill up in the stocks special liability reserve. As basically promising projects are included in the project pipeline of KB, and the importance of the drug development relevant to the core receptor is forecasted to increase in the future, the occurrence of new business opportunities will be expected with the progress of development. In the tendency of the shift of the large pharmaceutical firms into the clinical development stage within the industry, KB, as an individual company, by maintaining the relations with the academic network, adopts the evolution type of business model which screens and promotes each idea or project to exploratory project, internal project, out-license, or strategic partnership, responding to evolution of the project portfolio along the drug discovery/development process.

Conclusion

As a next-generation group of biotechnology ventures, the stem cell ventures and the nerve medicine ventures can be mentioned in Sweden. As, in the country, embryonic stem cell research is morally possible, and as it is considered as the research theme important also for healthy maintenance of the public, the stem cell ventures started in Stockholm or Göteborg are forming a unique position also in the world. For example, ventures such as Cell Therapeutics Scandinavia, Neuronova, and Ovacell were founded by the researchers of Sahlgrenska Acdemy or KI. Especially, Neuronova which is lead by Prof. Jonas Frisen of KI discovered first that an adult stem cell has the capability to produce other various organs. Carlsson Research was founded in Göteborg in 1998, based on the strategy which has evolved from research of Prof. Arvid Carlsson about CNS (central nervous system) or its disease relevant to his Nobel Prize in 2000. It is said that its original ISP (Integrative Screening Process) which functions through the completely new mechanism of the overlooked activity enables the innovative search of drug candidates. Although, for example, it is usually said for a High-throughput Screening process, to looking for one candidate from millions of compounds, the search of a candidate is enabled by composition of 50 -100 compound containing 16 by the minimum record at ISP of the company. While energy consumption, such as investment and development, follows on innovation, the anti-entropy state of the creative performance or sophisticated mechanism which produces innovations may arise also on each level of a region, an industry, and an individual company. For instance, there are such examples of anti-entropy as the industrial metabolism in a region, the form generating of the technology and the product by the development division of work within an industry, and the evolution of the business model accompanying the progress of the drug development process in an individual company. n this way, in a cluster, the entrepreneur of an original idea places own body into a suitable information network rather than is isolated. Next, with the drug development value chain of the long-term and high risk, even if the company specializes in a specific niche area, the risk dispersion by specialization, partnership, and whole network is possible. And in the development portfolio of an individual company like KB, even if it does not have the product revenue for ten years, it can survive through the uncertainty reduction by the parallel management of projects and the milestone management in the drug development process. Especially in order to evolve a business model, by changing technical information and financial capability, the role of business development becomes important.

Spin-Out Business Model: A Strategic Tool for Innovative Growth, Entrepreneurship and Flexibility in the Service Sector

Désirée van Gorp
Pieter Klaas Jagersma
Universiteit Nyenrode, The Netherlands

Abstract

This paper explores the applicability and the current implementation of spin-out business models by global management consultancy firms (MCFs). The study is built on the notion that these service firms should continuously be prepared to innovate their business. Sometimes incrementally, but if necessary drastically. In order to survive and grow in a highly competitive environment they should use a business model that allows them to inject flexibility and leverage on their entrepreneurial and innovative capabilities on different levels. The theory of spin-out management and business models is used as a theoretical framework. In combination with an overview of developments in the management consulting sector, this framework provides the basis for analyzing the results of the empirical study.

Spin-out Management

Just like other forms of corporate entrepreneurship, spin-out management is an alternative way to growing via mergers and acquisitions, and joint ventures, to name a few growth vehicles [25] [50]. The motives for growing a business from the inside out include corporate profitability, generating strategic renewal, fostering innovation and gaining knowledge that may lead to future revenue streams [58]. Researchers have acknowledged the importance of corporate entrepreneurship as a growth vehicle and addressed it from various perspectives e.g., the relationship between parent and venture, performance of ventures [58] etc. However, on spin-out management - as a variation of corporate entrepreneurship - in the service sector little research has been done. The spin-out process has been discussed though with regard to high-tech companies, universities, laboratories e.g., as a mechanism to transfer technology [20] [27] [51].

Spin-out management is a growth strategy by which a company decides to mainly grow through spin-outs i.e., by separating a new or an existing activity from the core business while profiting from the parent's assets [29]. It is a form of focused entrepreneurship [8] whereby spin-outs are placed outside the core business as separate ventures and involve a specially formed team of people. The spin-out is supported by the parent through infrastructure, existing network, reputation and distribution channels. The parent is coordinating a portfolio of relatively independent ventures with their own budget, strategy, assets and balance sheet and do not fall under established norms and guidelines of a parent. This type of smaller but complete venture is appealing to organizations seeking continual innovation [30]. The challenge of managing them is providing them autonomy while at the same time maintaining damage control [50]. This way spin-outs may contribute to renewal or even to changes in the competitive game in an incremental or radical way. Spin-out management can occur in a company next to other forms of corporate entrepreneurship [54] and facilitates an opportunity to grow with new ventures outside the core business that operate autonomously but yet are part of a large company. It is only in the past few years that this new variation of corporate entrepreneurship has become increasingly popular [29]. The implementation of spin-out management brings at least three strategic advantages: growth, entrepreneurship and flexibility [46] [53] and can lead to a new business model responding to the call for companies to operate close on the market and to minimalise bureaucracy [45]. This type of business model allows entrepreneurial firm-level behavior that can be a path to sustained competitiveness among established firms [17] operating in a highly competitive environment.

In this paper a distinction is made between spin-out management and ad hoc spin-out activities. In the case of spin-out management, spin-outs are part of a company's growth strategy and therefore a continuous process of initiating new activities in stead of single events. Making it a continuous process facilitates for example learning

from disappointments that characterize venture activities [23] [37]. Furthermore, it enhances experience in venturing that may result in improvement of the performance of ventures [35].
There are two different forms of spin-outs: 'start-up spin-outs' and 'going concern spin-out's'. Start-up spin-outs are new business initiatives initiated by a parent. Going concern spin-outs are activities which were initiated by a parent company in the past and subsequently positioned independently from other activities. In other words, these new ventures initiatives can be internally focused towards a rationalization of existing activities or the promotion of new ones [8]. For a spin-out is required that the parent company owns a minimum of 51% of the shares and has a final say in the management of a spin-out [29].

As spin-outs are placed outside the hierarchic structure, it is possible to operate closely on the market [29]. This is precisely the reason why spin-outs are a medium for competing within a dynamic sector dominated by technology [51] and why it is argued in this article that spin-out management is an interesting growth vehicle for companies in other sectors operating in a dynamic environment [29].

Business model

Towards the end of the last century, competition took place in an increasingly competitive business environment by some referred to as the technological revolution [6]. This period was characterised by an economic environment subjected to fast and dramatic changes [12]. Moreover, together with globalisation, technological developments have increased the scope as well as the dynamics of the relevant environment for companies [5]. It is these developments in the external environment that have caused a revolution in the business world on all levels of a company and through all sectors of the business community namely vertical linkages between businesses and their customers, suppliers and employees and horizontal linkages between firms within or between industries [1] [6]. To adapt to rapid changes in the environment is both demanding for the hardware[1] and the software[2] of a company [40] i.e., managers must develop new tools, new concepts, new organizations, and new mindsets [6]. Managers (software) must for example develop a mindset that allows cooperation with competitors as well as traditional economic competition [6]. Structures (hardware) must for example shift from vertical traditional hierarchical organizational structures [15] to horizontal structures with decentralized decision making processes and cross functional teams [6] [36]. What is a business model? Especially in the non-academic literature reference is made to business models in what seems to be a fashionable way, sometimes even without a clear idea of what the term stands for (e.g., [19] [31] [43]). According to Amit and Zott [3] the business model depicts the design of transaction content, structure and governance so as to create value through exploitation of business opportunities. In this paper a business model is referred to as an organizational model oriented towards adding value to stakeholders by combining tangible and intangible assets[3] in a unique way. In this definition a business model is not refrained to a single company's boundaries and stakeholders refer to the network of the firm i.e., the network of suppliers, investors, customers etc. is included in the business model [26] [48]. The changes in the environmental context of large established corporations and the shift in their focus from tangible to intangible assets demand for different and more dynamic business models than the traditional ones [5]. They should be able to meet the demands of a dynamic environment and sometimes even allow different dynamic levels within a company. For example, whereas an extreme traditional corporation is hierarchical in nature prohibiting new venture creation, a strong intrapreneurial firm has a flat organizational structure with networking, teamwork, sponsors and mentors abounding [26]. It is in alignment with scholars reasoning that strategic analysis of business ventures have to move beyond the traditional conception of the firm as the unit of analysis [3]. Whereas Amit and Zott [3] suggest that this is the case for e-business ventures, it is assumed here that it should be applied for analysis of any kind of business ventures as the new competitive landscape applies for all organizations [6].

This new concept of the firm changed the competition game and may according to Penrose even "call for a new 'theory of the firm' in economics and changed views about the behaviour of markets and the effect of 'free market' competition" [45]. Her line of thinking has been supported by studies emphasizing that developments in the business environment e.g., deregulation, global competition, technological discontinuities, have changed the base for competition [6] [40] [47] [62]. In this paper it is argued that a firm's business model is an important locus of innovation and a crucial source of value creation for the firm and its suppliers, partners and customers [3]. This is the case on the level of the parent as well as on the level of its individual spin-outs, for which a business model proves to be a key-success factor [37]. Moreover, business models are not only a source for innovation, but are or should be subjected to innovation themselves [6]. They have a life cycle and should be adjusted at a certain point in time. This applies not only for high-tech companies [33], but for all companies operating in highly competitive markets [6] [29]. Furthermore, research studies in the past show that the most successful companies are those that maintain a workable equilibrium for several years or perhaps decades and are at the same time able to initiate and implement dramatic changes when the environment is changing [59]. Especially incumbents have difficulties in (radically) changing their business models in response to developments in their business environment. The reason is that they frequently lack capabilities of creating or adapting to innovations that require substantial changes in their organization [13] [33]. In other words, success formulas of the past may become the reason for failure in the future. With existing capabilities that have become obsolete and perhaps even a handicap, they may, for example, not be able to change their boundaries [1].

While spin-outs can enable incumbents to leverage the innovative and entrepreneurial potential of their dispersed assets [8] they, at the same time, create tension between managing existing activities to ensure continuation and focusing on creating something new [30] [56]. This especially is the case for spin-outs as they are part of the parent company [29]. Entrepreneurial management is different from traditional management [53] because it requires for example different control mechanism [50] and reward systems [10]. In addition to a flexible structure, it requires a delicate balance between managing existing activities (administrative management) and new activities (entrepreneurial management) [30]. Therefore, it involves both the hard- and software of a business model.

It is assumed in this paper that it is not the size, the life-cycle or the sector of incumbents that determine their competitiveness, but their business model allowing to inject their hard- and software with features like innovation, entrepreneurship and flexibility to survive and to revitalize them [9]. It is furthermore assumed that spin-out management can be a tool to do so [38]. In fact spin-out management combines the competitive advantages of incumbents and new entrants by allowing flexibility and leveraging on innovative and entrepreneurial capabilities. At the same time it provides the ability to profit from the advantages of the parent e.g., established network and financial resources etc. [41] without suffering from the potential inertia of incumbents. Furthermore, if implemented this way spin-outs can enhance team learning as an essential factor for continuous innovation because it enables managers to explore new growth opportunities without being frozen into existing ones that may limit progress [54].

Management Consulting Business

In this paper strategy consulting is referred to as a part of management consulting. Management consulting is defined as the provision to management of objective advice and assistance relating to the strategy, structure, management and operations of an organization in pursuit of its long-term purposes and objectives [28].

In time the added value of the service sector on the overall economic activity has increased. By 1999 the value of cross-border trade in services was about 20% of total cross-border trade [61]. It is the largest and fastest-growing sector of the world economy and providing more than 60% of global output [61]. In the year 2000, corporate strategy services had the highest growth rate of all European management consulting services and strategic planning was the most important consulting service in this section [22]. Paradoxical little research has been done for example on the growth and internationalisation of service firms [11] [32] [16].

The transfer of knowledge across national borders was facilitated in the post World-War II period by new types of organizations and organizational forms [24]. From the eighties of the last century on, international expansion was primarily driven by 'follow the client' strategy. Service firms followed their multinational clients abroad [16] as opposed to market seeking entries that involve more risk because there is less knowledge about (potential) customers [32]. However, both entries are common in the management consulting business.

Some scholars assume that service firms internationalise and become multinational enterprises for the same reasons that the manufacturing companies do [11]. Others focus on differences e.g., the fact that the manufacturing industry has more internationalised than the service sector and that even the largest service firms may have a relatively low degree of multinationality compared to manufacturing companies [16]. Both schools emphasize the need to further research the (international) service sector to keep pace with the size and the growth of this sector [11] [16]. In line with Contractor, Kundu and Hsu [16] it is assumed here that also within the service sector there are substantial differences between the various categories -e.g., capital or knowledge intensity- that may produce different results when executing research studies. For example the creation of new ventures may be easier when there is no need for large amounts of capital and 'only' involves skilled people. Management consultancy is a people-based [11] and knowledge-based [16] service category. Contrary to capital-intensive service categories, it is more driven by intangible assets and has a much lower fixed costs burden [16]. The barriers to enter in this knowledge intensive part of the service sector is low as it is not capital intensive. New entrants need skilled professionals rather than large amount of capital [34]. Notwithstanding its rapid growth in the past, as an important contributor to the overall economic activity, the forecast for the future of MCFs seems to be less bright. Despite early predictions of increased activity, the Institute of Management Consultancy reports that 2002 has been a difficult year for the sector [28]. The Institute further reports that there were perhaps 15% fewer practicing management consultants and a significant change in offering to deliver as the market changed. The decline in the market came after the Internet boom [22]. The industry is suffering from a decrease in corporate spending on consultants, large global top-tier firms are downsizing by cutting their staff and strategy consultants no longer dominate the information channels on the latest thinking regarding strategies, management models etc. MCFs' management ideas, models and methodologies are increasingly available to their clients through business schools graduates and top strategy firms' alumni working for them. At the same time the Internet has an important impact on strategy consultants' global playing field as well. It decreases, for example, the cost of searching for, collecting, and communicating information [1] [4].

Since the Internet is an information technology and strategy consulting business has a large information content, it can be assumed to have an impact on global MCFs' boundaries [1]. Technology while creating new consulting markets (e.g., e-business) encourages at the same time the obsolescence of professional services that can be easily commoditized [34]. Some argue that because of the blurring of traditional boundaries professional service firms, once defined by specialty, are surging into new businesses [34]. Others conclude from this that there has been a shift form general analysis to specialist insights and knowledge [18].

It is argued in this paper that developments in the business environment of MCFs can involve either expansion or shrinking of their boundaries depending on the business model that is chosen [6]. This line of thinking supports the development of large multipurpose organizations being replaced by networks of specialized organizations and competition taking increasingly place among networks in stead of atomistic firms [6]. This also means that a service firm can create a network of spin-outs around the core that are specialized in different kind of services and products to obtain competitive advantage vis-à-vis its competitors.

It seems that not only the content (e.g., specialized versus general) of services, but also the way they are provided to clients (e.g., big teams versus software program) have to be -sometimes drastically- adapted and changed according to clients' demand. This new demand from clients forces consultancy firms to reinvent themselves with new business models, skills, profiles etc. [22]. This may prove to be a difficult task for global service firms because -although the overall economy is increasingly dependent on services- the innovation processes in general remained oriented towards products [57]. Furthermore, professional service firms that are people based are extra vulnerable because their strategic obsolescence may not be fully apparent for years and only occur when it is too late [34].

Research methodology

The aim of this paper is to provide insight in the spin-out business model as a strategic tool for growth, entrepreneurship and innovation for global MCFs and this way to contribute to the limited research on services [e.g.,16]. Given the fact that the theory regarding spin-out management, related to a low-tech sector like the services, is an early stage, a case based approach is chosen as a research strategy along the lines as suggested by Eisenhardt [21] and Yin [60]. This type of research is especially appropriate in new topic areas as it has the likelihood of generating novel theory and creative insights arising from contradictory or paradoxical evidence [21]. This research study involves multiple cases –with the parent as unit of analysis- of management consultancy firms, which may enhance extending the theory to a broader range of organizations in this sector. A priori specification of constructs is used to help shape the initial design of the research study. From the literature two potentially important constructs are identified: (1) spin-out management as a growth strategy for global MCFs (2) the business model as an important locus for innovation of firms. The research is based on a combination of multiple data collection methods as it provides stronger substantiation of the constructs used [21] and acknowledges the fact that to add to theory building in the service sector requires not only facts and figures (hard data) but also soft data i.e., rich description for example form anecdotes to explain them [42]. Data was gathered from a literature study on corporate entrepreneurship in general and spin-out management more specific in relation to the construct of business models. Furthermore this data was applied in professional service sector, namely well established global strategy consultancy firms (incumbents) here referred to as global MCFs. Six global MCFs were interviewed in the years 2002 and 2003. The conducted six interviews were semi structured, two to three hours length, with partners and senior consultants involved in corporate entrepreneurship in general and spin-out management more specific. Tape recordings of the interview were made and transcribed verbatim. To what extent did management consulting sector make this research on corporate entrepreneurship a special case? First of all the service sector at large deserves to be more researched. As explained earlier global MCFs is an important category in this sector. The management consulting setting is especially interesting in relation to spin-out management as many firms of this category have contributed to the development of theory and practice of spin-out management, they should be able to draw from a wealth of experience for example with respect to translating theory into implementation of the spin-out concept (e.g., [2] [55]) into their own firms. Furthermore, the perceived threat of new entrants and decline of demand for services of these incumbents could be a trigger for innovation of a category of firms that provided their services in the same way for many years. The study has a number of limitations. First, a limited number (six) of MCFs was interviewed. Secondly, there has been only one unit of analysis. An important step in building knowledge about spin-out management in global MCFs would be subsequent research in other firms and researching the spin-out perspective in addition to the parent perspective [8].

Analysis of results

Six dimensions of spin-out activities

In exploring the implementation of the phenomenon of the spin-out business model, as a strategic tool for innovative growth for MCFs, this paper focuses on the following six dimensions of implementing spin-out activities:

- ?? Do MCFs innovate their business models?
- ?? What is the status quo on implementing spin-out activities by MCFs as part of growth strategy and business model versus on an ad hoc basis as single events?
- ?? What are the advantages of spin-out activities?
- ?? What are the disadvantages of these activities?
- ?? What are the key-success factors for implementing spin-out activities?
- ?? What are the lessons learned from implementing these activities?

Table 1 shows the main advantages, disadvantages, key-success factors and lessons learned mentioned by the six interviewed MCFs. With regard to all dimensions a distinction is made between firms implementing spin-out activities on an ad hoc basis as single events versus firms implementing spin-out management. The reason is that this is an important distinction in this paper with regard to the implementation of spin-out activities. After elaborating on the innovation of business models and the status quo of implementing spin-out activities by MCFs in the next two paragraphs, the other four dimensions of table 1 will be discussed.

TABLE 1: ADVANTAGES, DISADVANATGES, KEY-SUCCESS FACTORS AND LESSONS LEARNED FROM IMPLEMENTING SPIN-OUT ACTIVITIES BY MCFs

Spin-out activities	**Single events on ad hoc basis**	**Spin-out management**
Advantages	Professional development of people.	Recruit, retain and develop first league human assets.
	Retain talent.	Package knowledge in different ways.
	Develop and commercialize new business ideas.	Establish wealth creating pillar separate from income generating business.
Disadvantages	Cultural clash between parent and spin-out.	Complexity of managing spin-outs.
	Many failures, few successes (sometimes even just failures).	Danger of loosing mass and control.
	Conflict of interest between new activities and consultancy services to existing clients.	Decrease in motivation of consultants not involved in entrepreneurial activities.
Key-success factors	Selecting manager(s) with an entrepreneurial mentality and skills to manage a spin-out.	Team of people inside the parent committed to establish a spin-out.
	Relatedness to the core business.	Relatedness i.e., possibility of sharing resources.
	(Lack of) structuring spin-outs.	Perception of customers that spin-out is valuable and their willingness to buy product or service.
Lessons learned	Spin-outs should be part of growth strategy otherwise they risk being abandoned after a failure.	The bigger and more established units are, the more they end up killing off new activities.
	Innovation and corporate venturing activities suffer unrightfully under economic downturn.	The challenge is being serious about running spin-outs as venture activities versus treating each new venture as some kind of new department.
	Due to cultural differences between consultants and people with a more entrepreneurial mindset, spin-outs in the service sector will rarely succeed.	The need to run ventures with discipline regarding investments (rather fewer strong investments than many dispersed), commitment of senior management time (for counseling and coaching) and timeframes for performance evaluation (e.g., getting out to the customers as soon as possible).
	Relatedness to core business will increase success rate of spin-out activities.	Allowing time for a spin-out to become profitable with a minimum of a couple of years.

Innovation of business models

Based on an analysis of the literature on business models, it is concluded here that business models are an important locus of innovation [3] for all firms operating in a dynamic environment. Furthermore, from the analysis of the management consulting business it is concluded that firms in this sector are operating in such dynamic environment and therefore may need to innovate their business models to survive and to grow. It is assumed that spin-out management may be a strategic tool to do so by injecting these established firms with characteristics like flexibility, innovation and entrepreneurship. Although form the interviews can be concluded that flexibility applies both to their hard- and software (e.g., low hierarchical structure and flexible mentality of their consultants), four out of the six interviewed firms have a low degree or lack of the two other characteristics of corporate entrepreneurship namely entrepreneurship and innovative growth.

The innovation process is built on knowledge-intensive features and relying on individual human knowledge [30]. Both characteristics are highly valued and available in MCFs. But when referring to their innovative activities, a majority of interviewed firms (five out of six) mention entering new countries and developing new practices and not renewing their organization by changing their business models. Moreover, these models have been in place since their foundation. Although MCFs develop concepts to advise their clients on innovative processes by introducing spin-outs and other venture activities, the interviewed firms do not translate it -or only to a limited extent- into their own firms. It seems that their partnership structure and fee-based system are much more geared towards consensus and low risk behavior being a barrier for entrepreneurial behavior and initiating spin-outs [30].

As far as the hardware is concerned, the six interviewed MCFs have a non-hierarchical structure compared to incumbents operating in other sectors. Their corporate center and the rest of the company is one and the same, because in their partnership structure, all partners are simultaneously owner, seller of services to clients and leaders of the firm [34]. The difference and distinguishing characteristic of the business model of these firms is that they rely first and foremost on skilled and motivated professionals [34]. As far as the software is concerned, the firms perceive themselves as creative and innovative inherent to the type of people they hire ‘people constantly thinking about and analyzing for example business models while at the same time being used to applying it to their own firm’ as one interviewee words it. Although it is relatively easy for consultants –whether partner or not- to develop new activities in the form of new practices or starting a new satellite office, most of them (four out of six) nevertheless experience difficulties or lack interest in innovating their business models.

Two firms out of six have introduced distinct business models compared to their competitors. One of them is different in the sense that it has a distinct remuneration system i.e., performance in stead of the traditional fee-based system. The software in this firm has a more entrepreneurial mindset than the software of traditional firms. People in the firm refer to themselves as ‘business people’ in stead of ‘consultants’. However, the potential benefits of an entrepreneurial style are not fully explored, because the firm is convinced that it should profit more from its core activities and, therefore, engages only to a limited extend in spin-out activities that potentially could expand or change the firm’s boundaries. Consequently, the focus of its entrepreneurial activities is on advising clients rather than on stimulating consultants to take risks, to innovate and to be proactive with regard to activities affecting the firm’s boundaries.

Only one firm introduced a business model that facilitates continuous innovation also on the level of spin-outs and their respective business models. It has both a wealth creating and fee-based system within the same business model. The firm adopted spin-out management as its main growth strategy, which is incorporated in its overall business model. The firm treats its boundaries as porous in stead of solid. It introduced a network model of different companies (main pillars) and spin-outs providing its consultants with opportunities to initiate and to implement entrepreneurial projects continuously testing the firm’s boundaries. There is one important lesson that serves as major input for the design of its business model.

When the firm was designing its overall business model about twenty years ago, it analyzed competitors. In the 1980s some competitive MCFs were growing rapidly. All these firms had one particular problem namely that they could not convert into wealth creating entities. More than anything else they were income creators. Every ten or twenty years they end up the same way, namely one generation selling to the next. The first generation would take the money and the next generation would leave, the firms would subsequently fall down. Based on its analysis of these developments in the past, the aforementioned firm implemented spin-out management.

It created a business model built on both an income and a wealth creating pillar. Establishing its wealth creating investment business provides the opportunity to sell off subsidiaries in case the firm decides to cash on its wealth. However, it is never prepared to sell its core business, because 'it would destroy the firm's whole engine'. This way it manages the tension between wealth creating and keeping the community together. The firm is convinced that clients are 'increasingly frustrated with traditional consulting models'. Rather than injecting the firm in a later stage of its life cycle with spin-out activities to survive or to revitalize, a reason for most incumbents to engage in venture activities [9], the firm implemented spin-out management since its foundation in the 1980s.

In conclusion a majority of interviewed MCFs have, just like incumbents operating in other sectors, a lack of interest and/or experience difficulties in revitalizing themselves. They remain inert to changes in the environment i.e., changes in the competitive landscape are not a trigger for revitalizing their business models. Furthermore, for a majority of interviewed firms, innovation is seen as entering new countries or developing new practices and remains within the boundaries of their existing business models. Both firms that introduced a different business model from their competitors were stimulated to do so by opportunity to differentiate themselves from competitors and meeting client demands rather than by threat due to developments in the global external environment.

Status quo of implementation spin-out activities

Five out of the six interviewed firms implement(ed) spin-out activities on an ad hoc basis as single events. Two of these firms withdrew completely from spin-out activities after bad experiences in the past. One of them developed a number of spin-outs, already early in its existence, which turned out to be all failures. The other firm started its spin-out activities only during the Internet era and ceased to do so after the burst of the Internet bubble. The remaining three firms have developed on a limited scale spin-outs that still exist as separate companies after they were spun off. The economic downturn seems to be an important factor for a decrease in the spin-out activities of these firms. This is a remarkable outcome since a majority of them states that especially in the current economic environment, an increase of competition in combination with an economic downturn, companies in general should invest more rather than less in spin-out activities.

Only one firm implemented spin-out management as defined in this paper meaning that spin-out activities are mirrored in its business model and growth strategy. The firm groups them in a separate unit 'the new enterprise group', which task is to hide the new enterprises from the rest of the organization because its experience is that the bigger more established units are, the more often they end up killing off new things. The reason for this behavior is that established units are suspicious of the activities of spin-outs and try to control them, because some of these new activities may cannibalise existing ones. Spin-outs are separate entities and the parent company will deliver a non-executive chairman who will leave after a while. This firm allows spin-out development to take place at different levels both as official decisions of highest level and from spontaneous creativity of those below. It refers to spin-out management as a fairly informal process that involves an informal testing of activities by a senior management committee, which authorizes some activities to become new enterprises. This committee also tries to keep the new enterprise focused on getting out on the market place.

In conclusion, although all interviewed firms mention that spin-out activities can be an effective strategy for growth that companies should implement more often in the current economic environment, only one out of six currently applies spin-out management as an integral part of its growth strategy and business model versus single events and ad hoc activities. Despite their flexible structure, a majority of interviewed MCFs have a low level or lack of entrepreneurship and innovation, the two other characteristics of corporate entrepreneurship. The higher degree of entrepreneurship and innovation are the distinct characteristics of the two firms that implemented different business models form their competitors. One of these two firms introduced a spin-out business model allowing a continuous flow of entrepreneurship and innovation throughout the company that allows it to build attributes of corporate entrepreneurship [54], to increase venture performance that is the case after several venture attempts [35] and to learn from disappointments [37].

Advantages and disadvantages

As far as the advantages are concerned, authors often refer to 'revitalization of incumbents' (e.g., [9] [13] [37]), 'growth, flexibility and innovation' (e.g., [30] [44] [53]) as advantages of implementing different types of corporate entrepreneurship. However, a majority of interviewed firms mention advantages related to their human assets -i.e., recruiting, retaining and developing human assets- as the most important ones and therefore in many cases a prominent reason for engaging or having been engaged in spin-out activities whether on an ad hoc basis or as part of growth strategy and business model. The advantages mentioned by the interviewed firms in fact all require long term commitment to spin-out activities as they involve changes to existing resource configurations and routines [38]. This is in line with the firm implementing spin-out management but in contrast with those firms that engage in spin-out activities as single events.

As far as the disadvantages are concerned there is a clear difference between those mentioned by the five firms implementing spin-out activities on an ad hoc basis versus the firm implementing spin-out management. In contrast to the first category firms mentioning the cultural clash between parent and spin-out as a disadvantage, the firm that implements spin-out management views the clash as a positive element: 'Companies are always full of tensions and frictions, it is not whether they are there or not but whether you use them for creative purposes or not'. In addition this firm does not experience the clash between new and existing activities as a disadvantage, because most of its spin-outs are not as much cannibalization of existing units, but compliments for their existing services.

With regard to the record of failures and successes of spin-out activities of the interviewed MCFs there are two extremes. One extreme is the firm with experience in establishing spin-outs in the past aiming to use them as a source of revenue and technology transfer mechanism [51]. Their performance record is extremely bad in the sense that none of these spin-outs have become successful in the end. As the main reason for these failures, the firm mentions a cultural clash between the consultants from the parent and the more entrepreneurial people in the spin-out who are forced to cooperate. The other extreme is the firm implementing spin-out management with a continuous flow of spin-outs growing around the core. Most of the firm's spin-outs became successful in a relative short period of time. Where the literature refers sometimes to eight years (e.g., [14]) this firm has a record of spin-outs that become successful after a maximum of five years and signs for success appear already in the second and third year of their existence when they pass three critical tests of (1) knowing whether it is a valuable entity for customers, (2) people staying motivated doing a spin-out and (3) creating new knowledge. The reason for this success may be due to the fact that the firm is focusing on obtaining market share in an early phase, which may reduce the time it takes to reach profitability [7].

In general the disadvantage of 'large losses' and 'high failure costs' referred to in the literature (e.g., [7] [9]) may be limited in the service sector, and therefore not mentioned by the interviewed MCFs. The reason may be that it is perceived to be relatively easy in a knowledge environment to establish spin-outs, because it involves skilled people rather than large amounts of capital. This is in contrast with high tech firms where the need for capital is the most important barrier to establish spin-outs [51].

Key-success factors and lessons learned

All interviewed firms mention the key-success factor related to the software of their business models as most prominent. For the firm implementing spin-out management, the availability of a team of people inside the parent is a requirement for starting a spin-out. This does not mean that the entire team has to be recruited from inside, there may be a need to recruit people externally, but not a whole team.

The issue of relatedness, referring to how close to a firm's current activities spin-outs should be, also is a key-success factor mentioned by all interviewed MCFs, but the degree varies for the different firms. For the firms implementing spin-out activities as single events, the ventures' activities should be as close as possible to the core business and may not or only to a limited extent expand (and not change) the firms' boundaries. The firm implementing spin-out management specified this key-success factor to the extent that the desirability for it varies over the long run. The firm will not start anything that has zero relatedness, but in time the requirement of relatedness may be less prominent than in the beginning.

The literature is not conclusive on the relation between venture performance and high and low levels of relatedness between spin-out and parent [52]. Although Sorrentino and Williams [52] argue that in general there is no relationship between relatedness and the success at venture level, they at the same time confirm that when combined with intangible assets held by the parent, relatedness may determine venture success. Further research would have to be executed in order to find out to what extent this is the case for MCFs' spin-outs.

With regard to the relationship between parent and spin-outs, the six interviewed firms have different views. Whereas some firms argue that high degree of autonomy and distance between parent and spin-out is needed for the success of spin-out activities, another firm explicitly warns against physical distance as it will lead to emotional distance and finally results in lack of commitment from parent to support spin-out activities. Others refer to a 'dark hole' meaning that a parent looses control over spin-outs when they are put at distance.

The firm implementing spin-out management has gained experience over the years and seems to have found a balance in the relationship between parent and spin-outs. While maintaining a high degree of autonomy, there is a strong commitment to counsel and to coach (rather than to control) management of spin-outs if needed.

Also the literature is not conclusive about the relationship between parent and spin-out. Some authors argue that a close relationship between the two is threatening the venture's performance [25] [39] [49]. More recently authors argue that a close relationship between parent and spin-out is positively related to a venture's performance while confirming that the relationship evolves as the venture matures [58] and the importance of managing the extremes providing autonomy and maintaining damage control at the same time [51].

The main lessons learned are drawn from the two extremes i.e., the firm implementing spin-out activities on an ad hoc basis and a high record of failures respectively the firm implementing spin-out management with a record of almost exclusively successful spin-outs. These firms are the most experienced firms of all interviewed MCFs. Both categories of firms confirm that corporate entrepreneurship are long drawn processes [54]. It is in contrast with firms suggesting that a continuous flow of spin-outs would be self-defeating and that there should be no structure at all.

Conclusions

There is a difference between the interviewed MCFs in their advisory role on strategic issues, being at the forefront of latest thinking on and implementation of strategic issues such as corporate entrepreneurship, and their own venturing activities. While all interviewed firms underline the importance of spin-out management as a strategic tool for growth, innovation and entrepreneurship for incumbents operating in a dynamic environment, a majority of interviewed MCFs do not apply it to their own organization.

Just like other incumbents, or perhaps even more because the interviewed global MCFs have been successful for so many years without an urgent reason to change their traditional models, they remain inert to changes in their environment and have difficulties or lack of interest in adapting their business models. For the time being they seem to prefer building on their past of long-standing client relationship, reputation permitting them to charge premium fees and their partnership structure forcing consensus decision making rather than looking at new ways of responding to clients demands in a changing environment.

This attitude may lead to a lag between current and future performance and result in that they do too little and too late [34]. The most important reason for their inertia is not the hardware of their business model, but their software lacking entrepreneurial and innovative characteristics. This paper suggests that introducing the phenomenon of the spin-out business model for global MCFs may be worthwhile, and perhaps even necessary, for the survival and growth of these service firms. Additional research should further develop the concept of the spin-out business model tailored to the specific characteristics of this category of knowledge intensive and people-based firms.

FDI & Financial Markets

Global and Regional Trends in FDI: “Myths” and Reality

Dusan Soltes
Comenius University in Bratislava, Slovak Republic

Abstract

The paper deals with the global and regional trends in the foreign direct investments (FDI) especially from the point of view of some potential benefits expected from them mainly by the recipient countries. In connection with individual benefits from FDI inflows, the paper tries to demonstrate that in order the particular benefits could become a reality it is necessary that the host country will prepare for the incoming investors among others also such conditions that the particular expectations could become a reality. Hence the success in achieving expected benefits from FDI inflows does not depend only upon their volume but also and mainly upon their quality that as a rule corresponds to the quality of conditions prepared by a host country for their inflows.

Introduction

It is already an undisputed fact that one of the main expected and desired outcomes of the whole ongoing globalization and regional integration has been an increased FDI inflows into the countries of their need practically all over the world. In this respect especially developing countries and countries in transition like those from the Central and Eastern Europe (CEE) have been among those who have often seen in FDI almost a “miraculous medicine” that could “cure” all deficiencies but also inefficiencies of their often very seriously undercapitalized and not the best handled national economies and thus to solve all related problems. As in various other similar cases also the whole area of FDI and their potential benefits have been accompanied by various “myths” and totally or at least partially justified beliefs that not always correspond to the particular reality of the potential FDI benefits.

In the next parts of this paper we will try to deal with some of the basic expected benefits from FDI in a more general context and will try also to justify what has to be done in order the particular FDI could bring the benefits as expected. In this respect, the main conclusions and recommendations as presented in this paper are drawn from the ongoing joint research project of the University of Bratislava and University of Pittsburgh on FDI in the Central and Eastern European Countries under the framework of the NISPA/NASPAA Program and being funded by the USAID.

Main Benefits Expected from FDI and What is the Reality

In this connection we have to stress that FDI inflows not always bring all the benefits as expected from their presence in the particular country. It is also important to realize that also in the area of FDI not always their quantity and/or volumes are the most important indicators on the success in FDI inflows. In most the cases much more important is rather their quality, development and innovation potential. In summary especially it is their value adding character. Some FDI apologetics would argue that FDI mean a long-term relation and thus also the benefits are not always seen immediately or not so soon. That is in principle true but equally it is also true that some FDI by their nature and their “value adding” potential just simply cannot bring the same benefits as some other kind of FDI. There is a lot of empirical evidence especially from the CEE countries that we just cannot expect the same benefits from the FDI coming e.g. through privatization of banks or coming into other similar sectors as e.g. from the so-called "green field" investments and/or investments into modern high tech and/or export oriented production, etc.

If from this wider point of view we assess the FDI inflows then we could come to the following main conclusions and/or recommendations.

FDI as a Source of the Readily Available Capital

The first potential benefit expected from FDI is that they are bringing into the country a readily available capital. In principle it is true, but if FDI comes to the country through the privatization of banks that before their sale to the foreign investors had to be "revitalized", their portfolio had to be cleaned of the so-called bad loans that are often higher than the FDI themselves. Then from the macroeconomic point of view there is not possible to speak about any readily available capital. If the re-vitalization of a bank has required e.g. over 30 billion SK and the incoming FDI was only about half of that amount then one could hardly speak about any readily capital. It is like to buy a foreign currency for the double of the official exchange rate, what under normal circumstances cannot bring to the buyer any of the expected benefits. Unless there would be a very beneficial purchase and/or import of some components or raw materials that could help to produce a highly profitable new export oriented production, but definitely the “revitalization” of relatively small national banks does not have any such an export oriented potential at all. Another important aspect of "readily available capital" is related to that important economic concept of " a capital" as such. Its substance is that those funds acquired through FDI have to be used as a capital i.e. for further investments into business, trade, production, etc. where it could be further accumulated, re-invested, etc. But if funds from FDI inflows are used as an extra source for various kinds of social programs, reforms, cleaning from debts, etc. then it is evident that in such a case FDI just simply cannot bring any of those benefits as generally expected.

FDI as a source of new technologies

The second potential and much expected benefit from FDI is that they will bring into the recipient country new modern technologies. Unfortunately we have again to state that in the countries with very low costs of labor and/or in the other words with the very cheap labor there is no specific incentive for foreign investors bringing in any new modern technology. As a rule the latest technology is a rather expensive component within the overall incurred costs for foreign investors thus they are rather conscious regarding the investment into new technologies as in addition they have to take into account also various other considerations. For example it is evident that with the new technology as a part of FDI there are related also various other extra costs that could make their overall investment a rather more costly and thus also less efficient. Such extra costs are related to the costs of: purchasing or hiring a modern technology or its production, its transport and insurance, preparation of the installation site, installation itself, testing and verification, training of the local workforce, etc.

The more sophisticated is the new technology the more expensive is also the training of the local workforce but also the costs of such a more qualified labor. In addition, it requires also a system of more complex and demanding system of maintenance, a supply of spare parts, quality requirements for the whole operation and utilization, etc. In addition, such a complex process of bringing in a modern technology means that the foreign investor has really to be convinced on the good and long-term perspective of the particular investment.

FDI and the R&D

With the previous benefit i.e. new technologies as a part of FDI inflows is very closely related also an another potential benefit and that is the so called R&D - research and development or FDI into the research and development facilities where in mutual cooperation foreign and domestic researchers would be preparing new technologies, new products, services, etc. and thus making the local production more competitive on the global or regional markets.. The investment into R&D are usually an qualitative addition to the particular modern innovative production so for the foreign investor it is quite logical that will try to place also the particular research and development as close to the actual needs of production as it is possible and desirable for their mutual efficient interaction. It is clear that the most of R&D facilities are not oriented towards some kind of sophisticated theoretical research but rather to very practical and pragmatic needs of the particular modern innovative production. The examples not only from the USA, the EU but also from various other parts of the world clearly demonstrate that combination of the foreign capital coming into the country through FDI and its combination with the local universities know how have been one of the most efficient ways how to get full benefits from FDI and also from local universities.

For example in the Czech Republic in Brno there has been the Czech Technological Park as one of the oldest and most successful of such enterprises in the country established directly in the compound of the Technical University of Brno and has been conducting its value adding R&D oriented activities in the close cooperation with the staff and the graduates of the particular University. The same example it is possible to find also in the Gyor Business Park that again is one of the oldest, largest and most successful parks in its category not only in Hungary but also in the whole CEE region. This innovation and development oriented Park has been from its inception closely cooperating on various R&D oriented investment activities with the local University of Gyor. And in order to have the good regional examples complete we add one also from Poland. The Katowice Special Economic Zone has also been - from its foundation in 1996 - very closely cooperating with 11 local Universities and higher education institutions based not only directly in Katowice but also in other major cities in the Province of Silesia. Hence, if the investment sites for FDI are too far or not linked directly with the local universities it is not possible to expect that the particular FDI would bring also anything from the area of R&D and thus also a possibility for utilization of the local research cadres. First of all it is again up to the recipient country to prepare such conditions and investment sites and opportunities that for a foreign investor it will be quite a logical step to establish there also its R&D facilities. It is clear that to offer for incoming FDI an industrial park somewhere in a “terra incognita”, far from any reasonable communication, transport and local research institutions is definitely not the way how to become attractive for R&D related FDI.

FDI and New, Especially Foreign Markets

Another important benefit expected from FDI inflows has been that they have to contribute to the opening of new markets especially for production being produced locally in the FDI sites. But in brief we could state that such a benefit is again not available automatically. It is possible to achieve it mostly only if and when the FDI are coming into new, perspective and innovative productions. It is more than clear that e.g. FDI coming through privatization into banks and other financial institutions have of course no evident potential regarding new foreign markets whatsoever. The same is also regarding some traditional industrial sites – so called brown field investments – as again if it is sector producing some products that has been difficult to place on the global markets like various iron and steel products, but also textile, footwear, etc. then even the FDI cannot help much in reversing such a situation. In this connection as the most illustrative example could serve the example of the Slovak Republic. Although in the last 2-3 years the country has received the record high FDI inflows at the same time it has achieved also the historically highest deficits in the annual foreign trade balances especially for the last two years 2001-2002. It is evident that if this benefit regarding new foreign market has to be achieved then it is necessary to support inflows of FDI into such prospective sectors like electronics, some kinds of consumer goods, recreational facilities etc. that as a rule could help to open foreign markets.

FDI and Integration into the TNCs

With the previous potential benefit of new markets is very closely related also an another important benefit and that being that FDI are an important vehicle also for bringing into the country the TNC i.e. transnational corporations as one of the most important symbols and actual dominators of the whole contemporary globalization. For example in this case the Slovak Republic is again among the least successful the V4 countries in attracting the TNCs. In order to be fair we have to state that especially during the last 5-6 years also into the Slovak Republic have entered numerous TNCs especially in the form of large chains of department stores. In most cases they really met expectations on the "green field" investments as in general they have built a new shopping malls mostly on real green fields on the outskirts of cities with new jobs, etc. But on the other hand it has also to be added that the opening of these big modern shopping malls have also to the large extent contributed to the liquidation of many small shopping outlets that just could not withstand the fierce price competition from their much bigger and stronger competitors hence in many cases they have just increased the numbers of unemployed people. In addition these chains of departments stores have except some positives brought in also some other negative factors as they to the large extent increased also import of cheap foreign goods that in many cases make the domestic production redundant and thus also increasing unemployment, etc. and/or they are forcing local suppliers into not the most favorable conditions in their business relations. Hence in many cases TNC are not creating new jobs but rather reducing them in potential competitors and/or local suppliers and local partners become a part of TNC but on the less beneficial side i.e. not as suppliers/exporters but mostly as importers of foreign goods that in many cases could be produced also locally.

FDI as a Vehicle for Clustering, Concentration, Matching and Various Other Programs with Local Businesses

Another important potential benefit expected from FDI closely related to the previous one has been the area of various matching, clustering, spill-over, integration oriented programs and/or processes between the foreign investors on the one side and local businesses on the other hand. One of the main positives of all these various programs and processes are first of all seen in positive effects of foreign investors and their business entities on the local partners who in general are supposed to serve for them as either suppliers or contractors, distributors, etc.

In this connection it is very important to have a good national strategy with various forms of matching programs that would help foreign investors to find their new local partners. In this case as a positive example we could bring the Czech Republic and its National Pro-Invest Agency Czechinvest Prague with its database of various categories of local suppliers, services, advisors, etc. It is again about the same. Foreign investors are used to some comfort in services for them and accordingly to that they make also their investment decisions. One cannot just expect that foreign investors will be main initiators of the matching programs; they are mostly their primary users. As a consequence, if such matching programs do not exist or not offered in the particular country then foreign investors rather avoid such a country or in the better case to the large extent they then prefer as suppliers or various other partners their former partners from abroad. That again is one of the cases where FDI are not providing otherwise an important potential benefit i.e. a gradual equalization in the overall standard of foreign and domestic businesses.

FDI and an Increase in the Quality of Locally Produced Goods and Services

Another important potential benefit from the FDI is their contribution to the higher quality of the locally produced products, services, etc. Thus also better opportunities are crated for acquiring new markets and that again leads to expanded production, more jobs, higher employment, higher and more stable incomes in the particular region and thus a higher domestic demand and again expended production, new jobs, etc.

Under normal circumstance it is almost an automatically achievable benefit as foreign investors bring into the host country their brand names, production standards, know how and thus also the required quality standards corresponding to the particular products on the global markets. But again in order to achieve this kind of benefits it is necessary to create also some necessary preconditions regarding availability of the necessary technology, qualification of the workforce, technological discipline, quality of the row materials, etc In view of this it is of utmost importance to prepare for foreign investors locally reliable suppliers, subcontractors, partners whose services would meet necessary quality standards according international standards like ISO 9002, etc. as otherwise, FDI will seek their suppliers from the outside of the particular region or country, etc. An increased quality of production has again a very positive impact not only on the volume of production and thus sales and exports but last and not least also on an increased employment. But again it is up to the local partners to create the particular conditions for achieving such an important benefit.

FDI and Respect for Intellectual Property Rights and Protection of Environment

In general, foreign investors with their know how, new technologies are bringing into the host country also a higher standard and respect for the protection of these i.e. their intellectual property rights. However, in most developing countries and countries in transition the general respect and legal protection and enforcement of laws are still rather low. One of the reasons has been that this kind of rights did not have a long history in these countries. Only after the demise of socialism and beginning of the transition to the modem market economy also this new phenomenon has come to fore. However, this area has still been rather underdeveloped and especially the respect for intellectual rights in such areas as music, video, software, games and their carriers like DVD, CD, etc. but also protection of brand names and trade marks in textile, garments, sport clothing and shoes, etc. have very often been violated. That of course has also impact on the foreign investors who in many cases just hesitate to bring with their FDI also their latest know how either related to the particular technologies or products. Hence, as a consequence, in many cases, FDI are hesitant and are not bringing into many host countries the latest technologies, productions, products that could upgrade and innovate the general standard of production, make it also more environmentally "friendly" and thus also creating for the country of origin a better position on the world markets and finally again an important impetus for growing production and new jobs. Hence it is again up to the host country to prepare such a legal environment for FDI that foreign investors will not be afraid to bring into the country the latest technologies but on the other hand also a technology that could be potentially environmentally hazardous.

FDI and New Modern Management Style and Business Ethics

New modern management style and business culture and ethics are another potential benefits from FDI inflows. The more FDI flows into the particular country, the more positive effects from the foreign investment sites are becoming available not only for the particular sites but also for the whole country. It is proved, that even one solid foreign investor in a particular region could positively affect the business culture and management style in the whole region. Of course all that only in case that the particular region has created good favorable business conditions for foreign investors. If that is the case then that foreign business entity can positively effect all its partners on the vertical as well as horizontal levels. First of all on the vertical level it means all suppliers on the side of inputs and all customers on the side of outputs. Among the most common methods in this respect are such methods and standards as Just-In-Time, TQM, ISO9002, etc. On the horizontal level the potential positives are also quite evident in case that there is created a healthy business environment with the fair market competition without clientelism, favoritism, corruption, etc. However, as in every problem area also in this one there is a potential danger – especially if there is again a lack of law and law enforcement policies in such important business areas like preventing domination on the market, monopolistic market power, price fixing - that this potential benefit turns to become a real threat to all above mentioned partners and competitors on the vertical as well as horizontal levels and finally the main victim of all these unfair business practices has been that one being most innocent and powerless - a final customer, client, user i.e. we all.

FDI as a Tool for "Physical Integration" of the Host Country into Ongoing Globalization and Regional Economic Integration

As we already know, FDI is one of the most efficient ways and means how to integrate host country into the processes of ongoing globalization and regional integration e.g. through TNC. Especially it is true as far as the so called "physical integration" is concerned. In general FDI is one of the most efficient ways and means how to achieve so called "physical" dimension of integration. The materialized FDI (i.e. according to the particular definition: a long-term relations and interests) coming from e.g. the EU to the host country are the best guaranty that there will be from the particular investors also a lot of interest in mutual integration of both countries. Big important (especially TNC) investors are able to lobby successfully not only towards their own national governments but also with the institutions of the EU and in particular at the Commission in order their FDI would be not only the most efficient and one of the ways is of course also integration of the particular host country into the same regional integration block without internal borders and with free flows of goods, investments, etc.

FDI and the Cross-Border Cooperation and Integration

One of the most important aspects related to FDI is also the so-called cross-border cooperation. From the world of FDI we could bring a lot of positive examples how important for a country's sustainable development is this kind of cooperation. For example Mexico's experiences how to lure FDI from the USA and also those from the thirds countries destined for the USA into its "maquiladoras" i.e. special economic zones on their common border is one of the most positive examples how to properly utilize the concept of cross-border cooperation. From that one we could learn also that such installations manage to lure both types of FDI. It means e.g. those from Hong Kong or Japan or South Korea but also from the EU that prefer entering an almost unlimited US internal market from more favorable production conditions existing on the Mexican side of the common border with the USA. And by a certain paradox the same side of border has been equally attractive also for FDI from the USA for about the same reasons as those of investors from Japan or the EU i.e. many comparative advantages that they could not acquire from operating directly on the US soil. And as mentioned also already, there has been at presence existing a serious spill over effect and FDI from the "overcrowded" areas on the Mexico-USA border have been moving further to the south of Mexico.

As we know FDI nowadays need also a little bit more than just rely on the strategically good location of the country. Perhaps it is still true in the terms of geography. However, as far as the FDI inflows are concerned in addition to the good geography it is needed to add something more tangible as special economic zones (similar to those in Poland or China), or industrial and other types of parks similar to those as in Mexico, Indonesia, Malaysia, China but also Hungary, Poland or the Czech Republic and so on and so forth.

FDI as the Most Important Vehicle for Regional Development

In general, regional development is considered as one of the main potential benefits from FDI inflows. Again as in the previous case, foreign investors have to be advised in due time on individual regions where and under what conditions they could place their FDI. According to many foreign investors as a rule they are mostly not coming to the particular region and even not to a specific country. Only on the availability of various sources of information they finally make their decision regarding the selection of the particular country and a region for their FDI inflows.

What is needed it is mainly to prepare a kind of regional development strategy and then also a suitable and efficient system of information for foreign investors in order they could learn all necessary information as they need for their investment decisions. First of all, foreign investors must be convinced by the host country or its regions that it would be worth for their business goals to invest right in this particular country and its regions. As a rule foreign investors are not behaving as business explorers, researchers or discovers of “terra incognita”. As one foreign investor put it quite clearly, they are also not a kind of charity. On the contrary they are businessmen who need to be navigated to the best investment opportunities for their capital and as a rule better ones than those in their home countries.

FDI and Creation of New Jobs

One of the weakest parts of many pro-investment strategies has been its insufficient orientation towards one of the most important potential benefits of FDI i.e. regarding the job creation. Unfortunately, again we have to repeat that if the growth in FDI inflows has been mainly through privatization and/or various forms of sale and acquisitions of the former state properties by foreign investors then the expected benefits in job creation is very hard to achieve. Especially in the case of the so-called "brown field" investments i.e. investments into existing facilities this kind of benefit is almost not existing. As a rule in such cases after the particular change of ownership, one of the first steps of the new foreign owners has usually been "rationalization" of the over-employment through reduction of the so-called redundant jobs. Due to this development then, FDI not only are not creating jobs but in many cases are on the contrary substantially reducing their numbers and thus directly contributing to the growing unemployment. As we have illustrated it also in connection with some of the previous potential benefits, many of them if not properly prepared and handled could in fact lead to the reduction even in the existing jobs. It is again a clear consequence of the low quality FDI coming into a country as simply only so-called "green-field" investments i.e. investments into new production facilities in fact have had a full potential for achieving the particular benefit in job creation.

However, in case if there are through the economic diplomacy opened sufficiently prospective foreign markets for the export then even so-called "brown field" investment are not leading towards any reductions in the so-called redundant jobs. For the small country like e.g. the Slovak Republic it is of utmost importance of having large enough foreign markets for the potentially growing industrial production, etc. as the domestic market is just too small for any more significant FDI. In view of this development it is an imperative to promote export as the main driving force also for production and through that attract also FDI that could contribute also to the creation of new jobs.

FDI is an Important Source for Higher Standard of Living, but Again…

Undoubtedly, FDI is an important source for achieving a higher standard of living. After all achieving this benefit should express the very purpose of all social activities and processes i.e. helping people in improving the quality of their life. After all, this last benefit in principle has been synthesizing if not all then at least many of the previous benefits.

Although, as we have demonstrated also in the particular parts regarding these and other benefits from FDI inflows, they all are first of all potential benefits only and not always and under any circumstances they turn also to become the real benefits. The same is true also regarding their synthesis into the higher standard of living of people as the result of FDI inflows into the particular region, country, etc. In general, nobody could deny such a positive impact of FDI on the standard of living of the local people. Without any specific research we could bring a lot of examples from all various parts of the world where thanks right to FDI inflows the standard of living has substantially improved. The standard of living in the Republic of Ireland, Portugal, and in Spain have been improved mainly thanks to massive inflows of FDI. The same is true also regarding Mexico, where the whole process of improved standard of living has started on the northern border with the USA and as the FDI inflows have been penetrating lower and lower to the south of the country thus also the standard of living has been gradually improving in the same direction. The standard of living in the large parts of the People’s Republic of China has been much higher in and around the special economic zones on the south of the country than in other parts of that enormous country. Singapore after the end of the colonial rule was destined to become a pariah among its neighbors with much more favorable natural conditions and resources. And just within two decades of its ability to attract record high inflows of FDI, the city-state has become not only the country with the highest standard of living but also a model for its otherwise in terms of natural resources much more luckier neighbors.

Therefore, with the full justification, the same positive effect of FDI could be expected also in any other part or region in the world including the region of V4 countries in general and the Slovak Republic in particular. It just requires having a sound national pro-investment strategy that will be not so much focused on the quantitative volume of FDI inflows but rather on their quality and potential for achieving a sustainable development.

Conclusion

In the previous parts of this paper we have focused on some more systematic approach towards FDI and their potential regarding a positive impact on various aspects of the overall socio-economic development. All these potential benefits could turn into reality only if and when the particular government administration will properly define its macroeconomic priorities and will create corresponding conditions for foreign investors. We have to realize that under the current ongoing globalization, the global market for FDI inflows has been – among others – characterized by a very though competition when more than 150 countries have been offering various kinds of incentives for foreign investors. Moreover, there have existed also more than 120 of various regional integration groupings of countries and of smaller regions. Hence if a country wants to succeed in such a global competition in attracting FDI inflows then one of the best ways to achieve that, it is to become a part of some regional/sub regional integration grouping of states. That is also one of the most efficient ways that also a small country could become a more attractive destination for FDI inflows. But again, only a membership itself even in the EU is not automatically securing that the FDI will start to flow to the particular countries as it is not also in case of a membership in the NATO, OECD or any other otherwise prestigious international integration blocks or organizations.

Refocusing and Internationalization of Multinationals in the Wines and Spirits Industry

Alfredo Manuel Coelho
ERFI – University of Montpellier I & UMR MOISA Agro Montpellier, France
Victor Manuel Castillo Giron
CUCEA – INESER Universidad de Guadalajara, Mexico

Abstract

This research focuses on the governance restructuring strategies of the 10 top world multinational firms in the wines and spirits industry, over the last decade (1991-2000). Specific assets involved in all the restructuring operations led us to identify and explain the dominant forms of governance and corporate strategies in the industry.

Introduction

During the 20th century, an increasing number of wines and spirits firms broke the boundaries of their regional markets and created brands for the national market. However, it was only in the last two decades when the top multinational enterprises (MNEs) truly expanded throughout the five continents. Yet, most of the top world MNEs is still located in the Triad (Europe, United States and Japan). More recently, giant companies with sizeable capital resources penetrated international markets through subsidiaries, joint-ventures and licensing agreements. Therefore, since the 1970s, concentration in the wines and spirits industry became more conspicuous than in other alcoholic beverage industry. This change was engendered by rapid metamorphosis in output (via expanding economies of scale) and marketing technology (Wilson and Gourvish, 1998). Many of MNEs are vertically integrated from raw material processing through wine production, brand ownership and marketing (e.g. Ernest & Julio Gallo).

The metamorphosis operated in the competitive forms lead MNEs to adopt more flexible modes of organizing with simplified structures in order to become more reactive to the demand for F&B. This industry is a mass consumption industry and its increasing power induces a progressive disappearing of the auto-consumption productions and the decline of the agricultural activity in modern Societies. Moreover, a great diversity of F&B consumption patterns persists across the countries, depending on cultural traditions and the local production potentialities. However, if globally the F&B consumption increases slowly, significant differences exist among products. Thus, in the last few years, one sees an increasing in the convergence of world consumption patterns, amplified by the development of eateries and, simultaneously, strongly resisting to local specificities (Rastoin, 2000).

This work is structured as follows. In part 1, we present the competitive environment of the wines and spirits industry and the 10 top world MNEs. In part 2, based on the works of Williamson (1975, 1985) and Dunning (1993), we build a typology of the internationalization and governance strategies of the MNEs. Finally, we discuss the factors constraining the emerging of the hybrid forms of governance.

1. Emerging of new "hybrid" forms in the wines and spirits industry: between financial constraints and reactivity

The years following the World War II were characterized by the emerging of big industrial and financial conglomerates which held steady relationships with the competitive environment (customers, suppliers, etc). Following the progressive liberalization of the markets, le rise of new information technologies (IT) (intranet, EDI Electronic Data Interchange, ECR Efficiency Consumer Response,…) and the incapacity of the Fordist model to produce the desired outcomes, firms started questioning about the nature of their procedures – basically the strategic planning – and to pay more attention to the process, i.e. "to the chains of finalized actions" which looked to change the conditions of insertion of the firm in the competitive environment (Lorino, 1998; Tarondeau, 1999).

This new environment imposes two new main constraints to the firm: a financial constraint and an innovation constraint. The first one is mainly related to the minimal thresholds to reach in the value creation process. The pressure exerted by the financial lenders (banks, insurance companies, pension and mutual funds…) motivates the firm the rethink its modes of governance and financing.

1.1. Restructuring and oligopolistic rivalry in the global alcoholic beverages industry

A high concentration level combined with a strong market power and a closed oligopolistic structure characterized for many decades the oil and non-iron metal industries (e.g. aluminium, nickel). The main feature of the actual phase of capital globalization is the extension of the supply side with high levels of concentration in most industries of "high technology" or mass production (Chesnais, 1997). Following a trend of simultaneous crossing international investment and mergers and acquisitions, the concentration level of the world industries in the manufacturing industries is very high today (e.g. at the beginning of 2002, the top 10 MNEs in the brewing industry accounted for more than 39,4% of the world market). Therefore, a substantial part of the restructuring operations in the alcoholic beverage industries mobilize more and more high level funds (thus, the joint acquisition of the Seagram's assets by Diageo and Pernod Ricard reached 8,15 billion $US), and from other side new strategic formulas are used by firms to avoid entering under the law abuse of dominant position (technological or commercial agreements) and of too expensive purchases of assets (share exchanges).

The existence of oligopolistic situations cannot be apprehended by simply analyzing the high level of concentration rate in the industry. The most general assumption, and also the most prolific, of the oligopoly is based on the interdependence that exists among firms. Thus, most often, some mimetic effects arise among firms because "*firms do not react to the impersonal forces issued from the market but personally and directly to their competitors*" (Pickering, 1972). That is the reason why some authors consider that the world oligopoly is like a "*rivalry space*" in which the boundaries are delimited by some mutual (inter)dependent relationships that interconnect a small number of big firms. These firms get, in an industry (or in a complex setting of industries with a common "generic" technology), to buy the status of effective competitor in a world basis.

The oligopoly involves simultaneously competition and co-operation among MNEs. These firms recognize their mutual interdependence through all kinds of contractual agreements (technical co-operation or setting joint technical standards and rules) and most of them avoid entering into conflict with the anti-trust legislation[1]. By its nature the oligopoly is an "excluding" entity. Of course, the firms that are the most affected by its effects are those from the most vulnerable countries – with the exception of those firms becoming attractive by the specific technological knowledge they hold. Many small firms survive, the only way to survive is to the "adhesion" to a network organization that means the transformation of their status in sub-contractors.

One generally agrees that the process consists of a "decomposition and re-composition of the oligopolies", as it was described by Delapierre and Mytelka (1988). It is a permanently combined process. The decomposition follows the impact of technical change whose rhythm and trajectories are also very strong and fast. Most often, the oligopoly combines both dimensions of competition and co-operation (e.g. the case of the distribution network Maximum following an agreement between Fortune Brands and Highland Distillers or, also, Triodis in France – Bacardi Martini, William Grant & Sons and Rémy Cointreau). Those are very strong means of oligopolistic rivalry having important consequences over some MNE. The agreements and partnerships among firms almost equal or those concluded by smaller firms that fight to get the access to oligopolistic markets dominated by firms very well established in those markets should be perceived as "an extension of the competition but by using other means". By opposition to the traditional joint-ventures, strategic alliances are not necessarily built to last a long time. Motivation of the partners can be aggressive or defensive – protecting the core business – (Hagedoorn and Dysters, 2002).

The strategic map of the alcoholic beverages industry, as most F&B industries, is structured in an oligopoly with "fringes" that is progressively reinforced. For e.g., in the wines and spirits industry, several mergers and acquisitions changed the structure of the industry:

- Constellation Brands (USA) buys BRL Hardy (AUS) assets (2003) ;
- Diageo (GBR) and Pernod Ricard (France) spin-off the assets of Seagram (Can) (2001) ;
- Merger between Guinness (GBR) and Grand-Metropolitan (GBR), giving birth to a new entity named Diageo (1997);
- Merger between the assets of Allied Lyons (GBR) and Pedro Domecq of Spain (1994) (now Allied Domecq);
- Merger between Bols and Wessanen (Netherlands) (1993);
- Merger between Bacardi (Bahamas) and Martini & Rossi Spa (Italy) (1992).

Taking into account the recent trends in the industry it seems that this movement is yet far from its end. These restructuring operations have major consequences in terms of corporate governance implications, namely in terms of the iterations between managerial strategies and the constraints derived issued from governance structures. That could be established at two different levels: upstream and downstream. At the upstream level, these operations have a major strategic impact and the question of managers' discretional behaviour – the role of incentive and control mechanisms – to achieve those major projects seem essential. At the downstream level, because these operations lead to new adjustments of the corporate governance structures in the MNEs involved in such operations. Mergers involving big firms from different countries raise the question of the pertinence of national borders in the determination of the discretional managers' discretional behaviour (Boissin et al., 2001).

1.2. Is nationality a discriminating criterion of the strategies followed by MNEs?

Based on the analysis of the externalization strategies and on the specificity of the assets used by the top 10 MNEs in the wines and spirits industry, we tried to assess the differences/similarities of the different "worlds" of MNEs (see table 1)[2].

TABLE 1: TOP WORLD 10 MNES IN THE BREWING INDUSTRY

USA	Europe	Japan
Bacardi-Martini	Diageo (GBR)	Suntory (USA)
Fortune Brands	Allied Domecq (GBR)	
Constellation Brands	Pernod Ricard (France)	
Brown-Forman Corp.	Rémy-Cointreau (France)	
	LVMH (France)	

Note: Our criteria took into account only the weight of the dominant activity (wines and spirits).

The alcoholic beverages industry is largely dominated by MNEs from the Triad countries, even if new actors appeared in the last decade (e.g. in 1998 the merger between Brazilian Brahma and Companhia Cervejeira Antarctica created Ambev, the main beverage company in South America) or at the beginning of this decade (at the beginning of 2002, the Canadian Molson acquires the second Brazilian brewery Kaiser and, more recently, South African Breweries buys Miller Brewing transforming itself in the second world brewing company). Some other MNEs decided to divest their assets in the brewing industry: Bass Plc sold in 2001 its brewing activities and the group was renamed "Six Continents" (hotel chains). The acquisition of wine firms Beringer (USA) and Mildara Blass (Australia) led Foster's Brewing Group to be renamed Foster's Group Ltd (specialized in the alcoholic beverages industry) (2001) (see table 2).

With the exceptions of Bacardi-Martini and of Suntory, all these MNEs are public companies. The need to increase its size and the need to stay attractive to corporate investors are, most often, the two main arguments to go public. Therefore, those firms are subject to shareholders' pressures

TABLE 2: TOP WORLD LEADERS IN THE WINES AND SPIRITS INDUSTRY AND ITS DYNAMICS OF RESTRUCTURING (1991-2000)

MNE leaders	Characteristics			Number of restructuring operations			
	Country	Zone	Sales 2002 (consolidated millions $)	1991-1995	1996-2000	Total	Tot. alcohol
Diageo	USA	NA	17 276	46	72	118	40
LVMH	FRA	EU	13 304	26	135	161	27

TOTAL				283	478	761	253

Source: annual reports, business magazines.

The last decade was also characterized by a new reorientation in the restructuring operations of the alcoholic beverages industry. First of all, we noticed a strong increase in the operations of external internalization ("hybrid" forms), which means a new search for more strategic flexibility because, as a consequence of the specific strategic assets involved, these operations are less restrictive in terms of the irreversibility of the investments carried out.

A previous comparative analysis of the strategies of the top MNEs in wines and spirits industry led us to identify two strategic trends: specialization (Bacardi-Martini, Pernod Ricard, Rémy-Cointreau, Brown-Forman Corp.), diversification (Diageo, Allied Domecq, Fortune Brands, Suntory and LVMH). Seagram could be considered as a specific case and finally this MNE sold its assets to Diageo/Pernod Ricard. However, at the beginning of the new century, one notice that Pernod Ricard develops a new strategic intention (divestment of non-alcoholic assets) and of Diageo (divestment of Pillsbury) (Coelho and Sousa, 2000).

The international expansion is followed by a new trend in geographical restructuring, leading MNEs to invest more and more in countries where the demand for alcoholic beverages is strong (essentially, it concerns South America and Asian countries).This new geographical restructuring is closely linked to the deceleration of the consumption of alcoholic beverages in low income countries and also to the changing of habits consumption (new patters of consumption are emerging with a special interest to the new market niches like the long drinks, low-alcohol beverages, functional beverages,…).

Finally, the (premium and super premium) brands and distribution networks are also two new keys in building of competitive advantage. Essentially, the top brands in the alcoholic beverages industry (wines, beers and spirits) are controlled by a short number of MNEs. In this specific case, the MNEs try to acquire and /or control a portfolio of international key brands, covering almost all market segments for each one of the beverages (e.g. draft beers, light segments, pale ale,….). At the world level, competition among MNEs is driven by a small number of international brands, having a strong market share or dominating several market niches (a strong position in a specific market segment).

The building of some distribution networks at the world level is also another essential factor of competitive advantage to approach the different markets. Two basic factors explain the interest of the network activities. From one side, the search for synergies between production and distribution activities (distribution networks allow to MNEs to benefit from the synergies common to a wide range of beverages). From other side, MNEs avoid to be dependent of other entities to distribute their own beverages because the unexpected lost of an independent distributor in a country could imply the lost of the entire market). Distribution networks are characterized by a specific phenomenon leading MNEs competitors to co-operate (see examples above).

2. Internationalization and governance forms of MNEs in the wines and spirits industry

By comparing the characteristics of the restructuring operations – degree of international orientation (in/out) versus the governance forms (hierarchy/hybrid) – the purpose of our analysis was to build a first typology describing the trends of these MNEs to adopt a "network" form (see Table 3). This typology is an adaptation of the "eclectic paradigm" (or "OLI" paradigm), described by Dunning (1993), and explains the main alternative firms have to enter in foreign markets. Dunning considers that firms have three main advantages to become a MNE: the specific advantage related to intangible assets (O for Ownership Advantages), location in foreign markets (L for location advantages) and the advantage related to the internalization (I for internalization advantages). Each type of advantages is linked to a level of analysis: O to the market structures, L to the comparative advantage of the foreign country, basically in terms of production, distribution and transport costs. Finally, I am linked to the organizational behaviour of the firm.

Therefore, the variables OLI will be influenced by the structural characteristics of the foreign country, of each industry and of MNEs. Several interactions among these three variables are possible. This approach is based on the implicit hypothesis of a strong dichotomy between the hierarchy and the market. The complementarities with the work of Williamson, allows us to model the process by integration the intermediary forms of governance ("hybrid forms").

TABLE 3: INTERNATIONALIZATION AND GOVERNANCE FORMS (1991-2000)

	Hy > Hi	Hy < Hi
In > Out	3	Allied Domecq LVMH Rémy-Cointreau Constellation Brands Fortune Brands
In = Out 1	Suntory	
In < Out 2	Bacardi-Martini 4	Diageo Pernod Ricard Brown-Forman

Legend: number of operations « in » = inside the zone and «out » = outside the zone; « Hy » = hybrid forms and « Hi » = hierarchic forms.

Note: The degree of internationalization is measured by the number of restructuring operations outside the "domestic" zone of each MNE, i.e. the domestic market enlarged. For e.g. for Pernod Ricard it would be the European Union and for Suntory Southern Asia.

All the restructuring operations were classed for the period 1991-2000, for each one of MNEs, by taking into account the criteria of the nature of the "specific assets" involved (see Williamson, 1985) and the location of the operations. Based on these two criteria we built a typology of the organizational and geographical frontiers of MNEs.

"Network"-based MNEs [Type 1 (In = Out; Hy > Hi); Type 2 (In < Out; Hy > Hi)].

The first results show that Suntory and Bacardi-Martini in the alcoholic beverages industry practice further the strategies of external internalization. In fact, Japanese MNEs tend to favour the "hybrid" forms of growth, even if these firms follow strategies of diversification outside the alcoholic beverages industry (functional foods). Historically inserted into organizational forms very specific – *keiretsu* – and dependent of the domestic and/or regional market, these MNEs have considerably increased their internationalization during the 1990s: Suntory became of the major actors in the bottled water industry in the United States and its Japanese direct competitors invested mostly in strategies of regional expansion in the Chinese and Indian markets. However, foreign direct investment in the Chinese market is greatly conditioned by the joint presence of local partners in the ownership structures.

Bacardi-Martini sustains its international development through the signature of license agreements.

"Hierarchy"-based MNEs [Type 3 (In > Out; Hy<Hi); Type 4 (In < Out; Hy < Hi)].

European MNEs have a dominant orientation toward the hierarchical modes of governance. These forms of investment are less reversible as a consequence of the presence of sunk costs. However, this analysis should take into account the level of concentration of the various sub-industries (in Europe, in the high-yield countries, the brewing industry is still in a phase of consolidation and rationalization).

MNEs of "type 4" follow their international expansion through the realization of very specific investments: the acquisition of production activities in foreign countries is the main mode of development.

These results are confirmed by the analysis of Figure 1. As in table 3, the same type of strategies can be identified and a clear opposition between "network-oriented" and "hierarchy-oriented" MNEs.

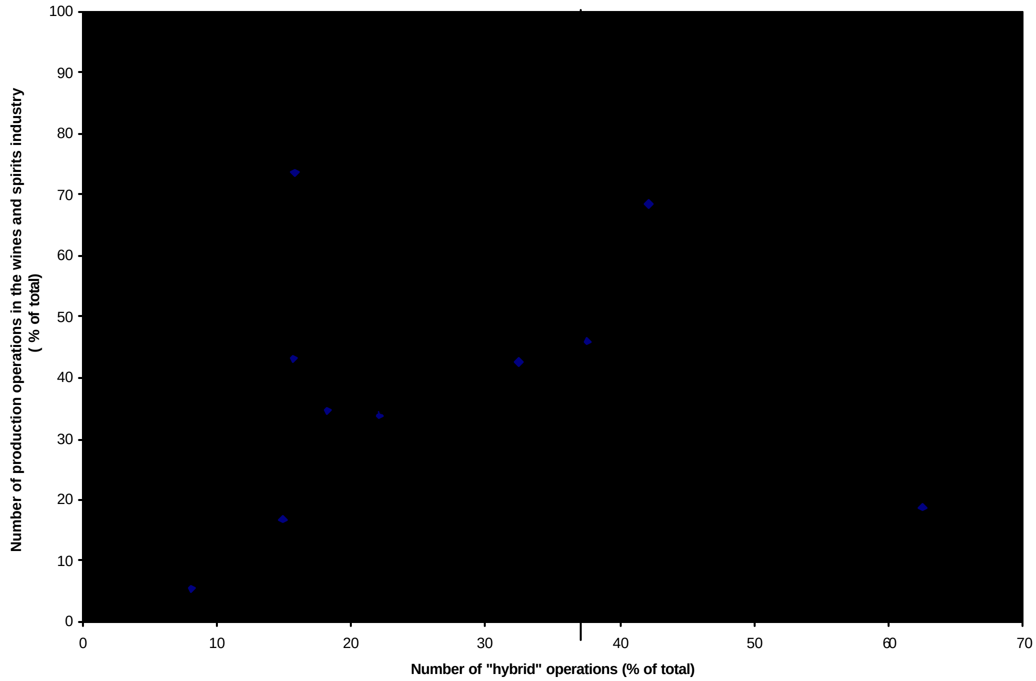

Figure 1: RESTRUCTURING OPERATIONS IN THE WINES AND SPIRITS INDUSTRY AND THE RELATIVE IMPORTANCE OF “HYBRID” GOVERNANCE FORMS (1991-2000)

Note: the full range of « production » operations comprises also plant closures and the disposal of assets.

The choice of network forms it is not insignificant: the main goals remain a greater internal and external flexibility and an increase in reactivity to the demand for alcoholic beverages. MNEs in the Japanese brewing industry are a good example of this trend. Between the Second World War and the end of the 70s these firms competed in an oligopolistic environment, stable and much protected by entry barriers in which competition was not based in prices. Since the mid 80s the competitive environment changed – hyper-competition phase – and, more and more, these MNEs move toward network forms of organization (D’Aveni, 1944; Craig, 1996). Therefore, these MNEs develop new organizational competencies in order to initiate or react to the new forms of competition. Also, the specificity of “network-oriented” MNEs is the coexisting of competition and co-operation strategies in the same industry.

In short, one could say that the external coherence modes of governance (Cohendet and Llerena, 1999) of MNEs in the alcoholic beverages industry vary significantly across MNE, depending on their geographic origin (for e.g., in the example, the strategies of European and Japanese MNEs are quite different). This idea should be considered with precaution as the destabilization of economic structures in some countries, whereas Japan is the most obvious recent example, lead to big metamorphosis in MNEs co-ordination modes with their competitive environment. Therefore, the liberalization of the Japanese market in the context of the World Trade Organization (WTO) should influence the coherence modes of governance in this market.

Network-organizations are characterized by a centralization of some activities of the value chain (financial reporting, computer services, HRM, R&D). Several other activities are managed directly by subsidiaries (e.g. marketing services). The adoption of a global information system allow to the different plants/services to communicate the information in real time to the holding company or to the strategic subsidiaries. The coherence of the global system is ensured by several “strategic points” that take into account the core competencies of the organization. The pertinence of the mode of organization is consequently verified by an increased efficiency of management.

The difficulties of putting networks to function are explained by the intensity of competition among MNEs. This could be explained by two main reasons. First, results show that in the industry exist less hybrid forms than hierarchical. Therefore, competition intensity will remain high because hybrid forms should constrain or reduce competition among firms. Thus, more MNEs are integrated more competition is intense because MNE tend to dominate the entire beverages chain (e.g. production and bottling operations, distribution networks). Secondly, concentration in the industry increases. This leads us to the question to know whether competition is more intense in an oligopoly (with "boundaries") than in an atomized structure. We agree to answer positively to the question because market pressures and more and more important and investors' activism have an influence at the "meso-economy".

2.1. Factors constraining the emerging of the network -organization in the beverages industry

Several factors explain the difficulties of MNEs in this industry to converge toward network-organizations. First of all, this is a mass consumption industry in which the demand is more and more volatile and in which a great number of goods have short term duration. Most often, raw materials are biological in the essence and thus difficult to standardize and industrialize (the all range of activities is more or less "cyclical").

"Psychological" factors play an important role in guiding firms' behaviour because firms are in general very individualist. The psychological profile of managers is also an important barrier (e.g. as far as we know the network of peer managers does not exist in this industry).

Also, the own nature of distribution networks, through the hyper-competition verified in the downstream of the value chain, hinders the emerging of truly co-operative organizational forms among firms.

Traditionally, this is a low-tech industry (low ratio R&D/sales). Generally speaking, the progressive introduction of biotechnologies, the pressures motivated by globalization lead MNEs to better control the processes and to exploit appropriately scale economies, to ensure food safety and a minimum of nutritional guarantees, to provide a new generation of functional beverages and to respond to the demand of consumers looking for convenience foods, variety and quality. All these elements will unquestionably conduct firms to intensify their R&D efforts.

At the same time, the changing of demand and food and drinks life styles led to increasing market segmentation (hyper-segmentation) increased the turnover of products and the development of transnational segments of food and beverages consumers. The reactions provided by firms were not only the introduction of new products but also a better focus in national and foreign consumers' expectations. All of these imply necessarily an improvement in the market and R&D competencies of MNE (Traill and Meuleberg, 2002).

Contrary to other industries, the food and beverages industries are characterized by a stable and cumulative technological process in which past innovation determines strongly the future path of innovation. At the same time, the pattern of innovation varies inside this industry. The learning experience curb of the "design" function is quite important in high manufacturing industries but has low significance in the basic food products. Firms' size is not very important in this process (Alfranca et al., 2002).

Most often, the introduction of new information technologies in this industry tries to improve the effectiveness of the global supply chain – basically it concerns the relationships with the downstream activities and to a less extent the integration of the various upstream and downstream functions (Craig and Hill, 2002). Finally, Gereffi and Korzeniewicz (1994) consider that the structure of the industry is determined by the type of goods or services produced as a consequence of the diversity of existing commodity chains, giving the possibility to a large number of firms to enter and to improve their positioning in the global division of labor.

Conclusion

The great economic and industrial transformations motivated the emerging of new schemes of value creation that distance more and more from the "productivist system" and in which the substitution of networks to the hierarchies is more than a management fashion. The emerging network organization can be positioned in this movement.

One of the central questions is that to know if this "new" morphology of organizations will substitute the big managerial integrated and hierarchizied firm. The answer to this question is not easy because several archetypes of network-organization exist. For example, Veltz (2000) considers that at least "six key-types" of network-organizations and that all of these forms could be combined.

Results show a reorientation of the world alcoholic beverages industry, characterized by a stronger concentration and specialization (Coelho and Sousa, 2000) and, also, an increasing quest for internal and external flexibility, typical of network organizations. Therefore, these various factors intensify competition among firms.

The slow emerging of network-organization in some zones of the world, like Continental and Southern Europe, could be explained by the less favourable cultural environment to this evolution. At the opposite, are positioned the Japanese MNEs in the food and beverages industry in which one could identify some key values like the team working and consensus. Hence, further research work should try to assess the "denaturing" process of organizational models, i.e. the converging pressures toward a unique "multicultural" model or the relative stability of national models.

Our approach has several limitations. First of all, the definition of "asset specificity" worth an in depth analysis. Boissin (1999) distinguishes between the "specific assets constructed" (creating and endogenous specificity) and the "pre-existing specific assets" (traditional view of transaction costs economics). Moreover, at a more analytical level the definition of what is a "network" contains several imperfections and thus should be refined. This is a consequence of the complexity and the variety of "intermediary" forms of governance but the same applies to the markets and hierarchies – the need of a more accurate typology of networks and of the environments in which they operate in function of the various combinations among the three modes of coordination is also an important key issue. Finally, the approach should take into account path dependencies and more particularly the life cycle phases of the industry and of each one of MNEs.

In a configuration in which the food and beverages MNEs tend to reinforce its dominant position (oligopoly), stroke by profound changing in the relationships between suppliers (industry) and customers (hypermarkets) and by the geo-strategies of MNEs in the whole food system, the future agenda for MNEs concerns the co-ordination of activities (identification of the "heads" of each network and the main processes) and the stabilization of each organization. In fact, optimizing the functioning of a network-organization requires not only the use of an effective technical device (hardware, software, common rules) but also minima of relational learning and of accumulation of shared knowledge. All of this needs time. When compared with other industries, the present restructuring trend in the food and beverages industry is relatively new and that is why one should expect that the emerging network-organization forms will take some time to be achieved, even if consumer pressures will accelerate the process (quality, traceability).

End Notes

[1] However, in the case of major restructuring operations - when the assets or the market shares of the firms are too important - the intervention of the regulation authorities is justified. Thus, lately in the alcoholic beverages industry the divestiture of Seagram (Canada) led Pernod Ricard (France) and Diageo (Great-Britain) to get the approval of the Competition authorities of the European Union and from Canada and from the Federal and Trade Commission in the US.

[1] For each one of the 10 MNE selected we identified all the restructuring operations done by these firms during the period 1991-2000. Data was collected from annual reports, Lexis-Nexis database and other specialized publications. All the restructuring operations were classified following the nature of asset specificities.

Characteristics of South-North Investments and Its Implications

Bindu Vyas
King's College, USA

Abstract

The country of origin and the stage of economic development play a major role in determining the characteristics of the multinational firms and their investments. This paper deals with the verification of characteristics of investments from developing countries of Asia and Latin America to the USA, industrially developed country and provides comparisons. Based on theoretical and empirical research the characteristics are expected to be different. The characteristics evaluated are average size of investment, capital intensity, level of exports from the USA, level of imports to the USA, profitability, extent of R&D in the U.S. , level of intra-firm trade, and the proportion of majority owned affiliates.

Introduction

This paper examines the characteristics of foreign-owned U.S. investments on the basis of Department of Commerce, BEA data. Based on the literature survey and the research questions hypotheses are formulated for analysis of the characteristics of FDI. Because of late industrialization and liberalization of their economies, the competitive advantages and characteristics ascribed to leading companies of developing countries are not same as developed countries and hence the characteristics of the developing country firms will tend to be different than those of developed and industrialized country firms. Due to industrial and structural differences between developing countries, the characteristics of developing Asian and Latin American country's outward Foreign Direct Investments (FDIs) are expected to exhibit different characteristics than those from other developing countries.

Characteristics of Developing Country Firms

In many ways Multinational Enterprises (MNEs) from newly industrialized countries are different from MNEs from industrialized nations. Our question is, are MNEs from Developing Countries (DCs) different from MNEs from Industrially Developed Countries (IDCs) countries and if so, how different? What characteristics enable DCMNEs to survive in the competition from IDCMNEs and from host country firms?

In the literature on the FDI from developing world, the important works of Kumar and McLeod [1981], Wells [1983] and Lall [1984] have studied the characteristics of Third World FDI. According to Lecraw [1981] and Monkkeiwicz [1986], Third World firms use small scale, more labor intensive and more flexible technology than MNEs from industrialized countries. They employ man rather than machine insertion of components in assembly lines. Their flexibility comes from switching labor from task to task and from product to product, and not from employing expensive multifunctional machinery as do MNEs. Third World MNEs depend more often on purchased production technology from abroad than on domestically developed technology. Their products contain a high proportion of components and parts bought from outside the organization.

It is argued that third DCMNEs' outputs are generally of a lower quality than that of other MNEs and compete in the low price end of the market [Wells, 1983]. Third World MNEs tend to export less of their output from their foreign subsidiaries. Their exports are more often to markets other than those in their home countries [Lecraw, 1992]. They tend to import a lower proportion of their inputs than do other MNEs, resulting in greater linkages with the host economies. Based on theoretical and empirical research as discussed above and in the chapter two on characteristics of FDI following propositions related to the characteristics of developing country firms in the USA are developed.

As a result of these characteristics, DCMNEs' market shares are usually small. They do not normally dominate a country's market, but they do dominate the low price end of the market, as Korean MNEs do in the UK and US personal computer markets.

Proposition 1: Because of structural differences in their home country economy, host economy and industrial differences, the characteristics of DC MNEs are likely to be different from those of MNEs from IDCs.

The rationale for country of ownership differences: Foreign investors are more likely to be active in industries with particular attributes, and, in a given host country, the characteristics of plants owned by investors from one foreign country tend to be different from those owned by investors from other foreign countries. The proposition is supported in general.

1.1 Size of the Investment

Proposition 1.1**:** The average size of MNEs from DCs is likely to be smaller than that of the IDCs.

The study of manufacturing establishments [Howenstine and Zelle, 1994 and Howenstine and Shannon 1996] suggests that the establishments of six industrialized countries and major investors in the US economy tend to be significantly larger than even the US owned establishments in the same industry. In the case of developing country firms we expect them to be of a smaller size than average industrialized investments due to structural differences in home country economy, development of markets and industry in home country. Table 1 confirms this proposition. The size of the firm is calculated by dividing the total investment by the number of firms. Asian average investments have increased from 50.24 million in 1992 to 80.35 million in 1997, and that is comparable to the Latin American average investment of 34.19 million in 1992 to 75.63 in 1997. But that still is much smaller than developed country investments of 161.04 million and 357.33 million in 1992 and 1997 respectively and hence the proposition is supported.

1.2 Capital intensity

Proposition 1.2**:** DC MNEs are likely to be less capital intensive than the MNEs from IDCs.

Due to labor surplus and labor-intensive manufacturing in the home countryDC MNEs are expected to be more labor intensive and less capital intensive. The verification of capital intensity by gross property to total assets suggests that developing countries are more capital intensive than the developed country firms. Capital intensity increased as ratio of gross property to total assets changed, from being 0.47 in 1992 to 0.60 in 1997. Compared to that the capital intensity of Latin American as well as other developed country investments decreased. For developed country firms ratio changed from .37 to .27 from 1992 to 1997 and is comparable to the capital intensity of all the foreign firms operating in USA.

1.3 Exports from USA

Proposition 1.3**:** DC MNEs are likely to record a lower export propensity than the MNEs from IDCs.

DC investments are market seeking investments. Based on assumption that DC investments are market seeking we expect DC MNEs to export less than the firms from IDC MNEs. Exports from developing countries as a percentage of total sales was 10.21 percent in 1992 and has increased since to 12.75 percent in 1997. Latin American firms exported 11.42 percent of its sales in 1992. In the case of developed countries, exports have been 8.92 percent in 1992 and have slightly decreased to 8.56 percent in 1997, matching the overall trend of decreasing exports as a percentage of sales. But the exports as a percent of sales of Asian exports were at 20.24 percent in 1992 and reduced to 17.22 percent that too is higher than the Latin American exports.

DC investments are market seeking as well as asset seeking. One of the major reasons for investing in IDC is to seek technical assets and hence it is likely that DC MNEs produce technology intensive products in IDC and export it to home country or near by regions. The proposition was rejected.

1.4 Imports to USA

Proposition 1.4: The import propensity of DC MNEs compared with IDC MNEs is likely to be higher.

As DC MNEs invest in USA to replace exports to USA, they are expected to import raw materials and labor intensive intermediate products from home country and/or near by countries with cheaper raw material and labor. The import propensity of DC MNEs compared to IDC MNEs is likely to be higher. Imports as a percentage of sales have been on he rise for all countries. DCs have a higher percentage of imports at 31.56 in 1992. Which has decreased to 27.06 percent in 1997. At the same time, developed countries' imports increased marginally less than a percentage point from 15.89 percent in 1992 to 16.28 in 1997. Latin American imports have been more or less leveled at 24 percent but this is much higher than developed country imports. The proposition is supported.

1.5 Profits

Proposition 1.5: The levels of profitability of DC MNEs are likely to be lower compared to IDC MNEs.

Due to lack of operational experience in the USA and related concerns, profitability of DC MNEs is likely to be lower compared to IDC MNEs operating in the USA. The verification of operating profits to sales suggests an increase in profits as a percentage of sales for both the groups, but the difference in the percentage of profits is remarkable. Developing countries have increased profits as a percentage of sales from 0.28 percent in 1992 to 1.33 percent in 1997. In comparison to that, operating profits as a percentage of sales for developed countries have increased from 1.74 percent in 1992 to 4.78 percent in 1997. The proposition is supported.

The verification of profits of Latin American and Asian developing country investments suggest that Latin American firms have increased their profits as a percentage of sales from 3.10 percent in 1992 to 3.71 percent in 1997. There have been negative profits in the case of Asian investments from developing countries, but that has decreased from –2.72 percent in 1992 to –1.63 percent in 1997.

The comparison as per Table 1 provides following observations:

1. The total (All countries) and the developed countries have reasonable dependence on their parents and affiliates for their overseas business. But in the case of developed countries,' exports to affiliates and to parent company has reduced from 60.25 percent in 1992 to 56.26 percent in 1997. In contrast, Asian developing countries' exports have increased from 47.46 percent in 1992 to 65.78 percent in 1997 as a percentage of the total exports.

2. The firms of the developing countries have somewhat more dependence in terms of imports, but the figures between the groups are comparable. Developing country imports have increased from 75.34 percent in 1992 to 78.71 percent in 1997. Developed country imports have increased from 78.91 percent to 79.52 percent, i.e. less than a percentage point.

Here the trend suggests that over the period of five years, these firms have had a remarkable increase in dependence on their parents group and affiliates for their imports from overseas.

3. The breakup of exports to sales and the imports to sales of the developed country firms is more or less constant over the period. However, though the exports as a percentage of sales are fluctuating, imports have increased less than a percentage point. Asian developing country exports as a percentage of sales have increased from 9.61 percent in 1992 to 11.32 percent in 1997 and imports as a percentage of sales have decreased from 24.90 percent in 1992 to 17.66 percent in 1997.

4. As is the case with overseas business, it is observed that the firms of developing countries depend more on their parents and affiliates for their overall supply/sales. Thus, observing the readings a trend/characteristic emerges which demarks the origin of the firm.

TABLE 1
CHARACTERISTICS OF THE INVESTMENTS FROM DEVELOPED vs DEVELOPING COUNTRIES

Characteristics	Variable		Total (All Countries)		Developed Countries		Asian Developing Countries		Latin American Countries		Source

Notes
1. Developed Countries include the EU + Japan while the Developing Countries include Asia Pacific & Latin American countries
2. Operating profit is arrived at by deducting the COGS and selling and admin expenses from the Sales.
3. Due to unavailability of R&D data on the Latin American companies for 1992, only Asia Pacific figures have been provided, and they are comparable, as it's a ratio.
4. For measuring the intrafirm trade, total quantum of Exim to and from Parent and Affiliates to the Total is taken
5. The mean of the number of affiliates is taken for the group of Developed and Developing Countries.
6. Created based on Department of Commerce, BEA Data.

1.6 Extent of R&D in the USA

Proposition 1.6: DC MNEs likely to be involved less in R&D related activities compared to MNEs from IDC.

DC MNEs do not have resources to undertake R&D activities and hence they are expected to be less involved in R&D activities compared to MNEs from IDCs. Significant differences exist between foreign firms from developed countries and developing countries, but in developing countries differences within the group also exist in terms of R&D: (1) establishment, (2) expenditure, (3) employment.

The level of R&D has been looked at from two angles, R&D expenses as a percentage of sales as per Table 1, and employment in R&D as a percentage of total employment in Table 2. The verification of level of R&D through both ways confirms our hypothesis that developing country firms are involved less in R&D related activities, i.e. they spend less on R&D as a percentage of sales and they employ less engineers and scientists as a percentage of total employment.

TABLE 2

1.7 Intra-firm trade

Proposition 1.7**:** Intra-firm trade by DC MNEs is expected to be less than intra-firm trade by IDC MNEs.

The typical characteristics of global MNEs from IDC is that they have global networks of affiliates facilitating intra-firm trade. DC MNC lack the networks of affiliates and hence intra-firm trade by MNEs from DC is expected to be less than intra-firm trade by IDC MNEs. It is the endeavor here to check whether the intra-firm trade, taking place amongst the units under consideration is a point that differentiates the origin of the firm. As a measuring tool, the firm's business (import or export) with either its parent firm or the parent group together, with the affiliate firms across the international borders is taken. The export of the affiliate firm to its parent group together with its export to its foreign affiliates (either of the same lineage or association) is matched with the firms total exports as well as to the firms total sales to acquire an understanding of the export behavior of the firm.

The corresponding comparison for the imports from the related firms, parent or cross border affiliates, to the total imports and the sales is also taken. Imports are also compared to Sales (instead of cost of goods sold) to give us a sales break-down. This comparison is done for 1992 & 1997 to give us movement of the said characteristic in that time frame.

1.8 Majority owned affiliates

Proposition 1.8: The percentage of majority owned affiliates of the total number of firms is expected to be less for DCs than for IDCs.

Due to capital intensive nature of investment in the IDC, lack of experience and organizational capabilities the DC MNEs are expected to have less percent of majority owned affiliates. The overall trend suggests that the percentage of majority-owned affiliates are more than 80 percent and less than 88 percent for all the countries, and it has not changed much over a period of time although it has slightly decreased in all groups. For all the countries, majority-owned affiliates have changed from 86.18 percent of the total to 85.19 percent; for developed countries it has changed from 86.20 to 85.23. In the case of subsidiaries in the USA from Asian and Latin American developing countries, the percentage of majority owned affiliates has decreased from 86.52 to 84.93 and 87.69 to 86.52 percentage from 1992 to 1997.

2 Mode of Entry

Proposition 2.1: There are likely to be significant differences between foreign firms from Group I, Group II, Group III countries in terms of the proportion of each of the four types of direct investment they have used in the USA: (1) green field investment, building new factories, (2) acquiring existing firms, acquisition, (3) investing in existing firms with a portion of ownership, joint ventures and (4) establishing a brand new joint venture, alliances.

There are significant differences between international firms from developed country firms and developing countries. Within group differences exist in terms of: (1) their original amount of investment in the United States; (2) the percentage ownership; (3) their total gross investment; (4) years involved in their foreign direct investment in the United States; and (5) the percentage of their total investment spent in (a) building new factories, (b) acquiring existing firms in the U.S. and (c) establishing joint ventures[1]. The proposition is supported by evaluations from Table 3[2].

Different current theoretical considerations explain the reasons why firms from NICs and the DC firms expand via FDI and why they often share equity with local or other foreign partners in establishing overseas subsidiaries.

Proposition 2.2**:** DC entry investments tend to be through acquisitions or cooperative alliances, and prefer JV or local collaboration than through the green-field mode.

Above proposition is supported by the data analysis and Asian developing countries do use mergers and acquisitions as mode entry.

Conclusions

Earlier studies suggest that the pattern of FDI by TWMNEs is changing when evaluated in the context of present theories of TWMNEs and IDP. In this chapter, characteristics of investments from the developing world are studied in light of earlier discussed major theoretical strands that provide the explanation of the outward direct investments from the developing world.

In conclusion our findings suggest that characteristics of DC MNEs are different from IDC MNEs as hypothesized. The average size of investment is smaller. We expected DC firms to be less capital intensive but their investment in the USA seems to be more capital intensive. The export propensity of DC firms was expected to be lower, but this proposition was not supported. The probable reason could be that the DC MNEs are market seeking as well as asset seeking and asset seeking MNEs export their products to their home country or near by region. Import propensity of DC MNEs is higher, the level of profitability is lower, and they are less involved in R&D related activities. They are much dependent on their parent firms for imports and hence intra-firm trade is higher. The DCs have less percentage of majority owned affiliates to the total number of firms.

The difference in characteristics of South-North FDI implies that the OLI (Ownership, Locational and Internalization) advantages suggested by Dunning differ for the MNE's from the south. In view of the North American Economic Integration and increasing trend of mergers and acquisitions suggests that the complimentary nature of advantages lead to greater gains for cross border business partners.

TABLE 3
ENTRY MODE SELECTED BY FIRMS INVESTING IN THE US FROM 1989 to 1994

Type of Investment	TOTAL		DC Total		Latin America Total	China CH	Hong Kong HK	South Korea KS	Malaysia MY	Singapore SN	Taiwan TW	Asia Total		Developing Countries Total

Developed countries include Belgium, Canada, England, France, the Netherlands, Sweden and Switzerland
Latin America includes firms from Argentina, Brazil and Mexico.
Table based on DOC, BEA data.

End Notes

1. Explanations and definitions of entry modes are based on the Department of Commerce description: An acquisition is a transaction in which title to stock or assets of the U.S. entity is secured by another person or enterprise. The substantive result is that one party obtains ownership of another. An equity increase is a gain in percentage of equity securities held, or an equivalent gain in the percentage of ownership, by a foreign investor. A joint venture is a transaction in which two or more parties establish a new business enterprise to which each contributes, and in which ownership and control is shared. A merger is a transaction which results in the dissolution of the acquired business enterprise, into either another already existing or into a reorganized (but not always renamed) company. A new plant is a new operating facility, established either in conjunction with an existing foreign-owned productive enterprise or as a completely new venture. The other entry mode includes new companies, headquarters, subsidiaries, branches, agencies, representative offices, stores, outlets, warehouses, and unidentified transactions. A plant expansion is an addition to the production capacity of an existing foreign-owned operating facility. Real Estate includes real property, excluding agricultural land and individual residential units for personal use.
2. Entry mode data is taken from Department of Commerce transaction data for the years 1989 to 1994; data for later years is not published and not available from the Department of Commerce.

FDI, International Financial & Capital Markets

Marco Chartuni
Universidad del Valle de Puebla, Mexico

Abstract

Considering the present and future scene, the financial activity is organized in large measure by Multinational Corporations. Their pre-eminence in world output, financial markets, trade, investment and technology transfer is unprecedented. In the 90´s the international movements of capital and several financial crises on international scale have taken place. Even when Multinational Corporations have a clear national base, their interest is in global profitability above all for the economies of the underdeveloped countries. The International Community has adopted political destined to attract foreign capitals. Multinational Corporations have grown from national firms to global concerns using Foreign Direct Investment to exploit their competitive advantages. Increasingly, however, they are using joint ventures, legal security to investors and strategic alliances-multilateral and bilateral agreements of protection and promotion of investments have subscribed- to develop and exploit those advantages or to share the costs of technological innovation. But the growing global financial market of production is not limited to Multinational Corporation activity, for over the last three decades there has been a significant growth in producer-driven and buyer-driven global production and distribution networks. The globalization of Foreign Direct Investment-business- is thus no longer confined to the Multinational Corporation but also embraces small and medium sized enterprises.

Firms engage in Foreign Direct Investment because they possess a specific competitive advantage that is best exploited in this way. The advantage may be a patented product or technique, but may also include management techniques and intangible assets in the skills and expertise of the firm of its personnel. But even so, firms do not have to produce abroad even with such advantages: Foreign Direct Investment markets can be served by exports or by licensing the technology to overseas producers; or the production process can be subcontracted to independent companies, possibly licensed to use the firms technology. However, the development of global financial networks necessarily involves the strategic organization of transnational transactions within the firm or among groups of firms rather than trough the market mechanism. The Direct Foreign Investment at the moment constitute more important volatile part of the dependent and interdependent components of the capital flows towards underdeveloped economies in the world. Although financial globalization is often understood simply as the spread of global markets, the growth of Foreign Direct Investment and global production networks represents something rather: the growing transnational organization of production and distribution within and among firms instead of through markets. International markets are not, therefore, perfect: if they were, Multinational Corporations and global production networks would not exist. As a consequence the costs of doing business for Multinational Corporations are significantly lower if they organize economic activity within the firm, or through networks of firms, rather then through market relationship.

Multinational Corporations, however, are the linchpins of the contemporary world economy. Despite regional concentrations of production, transnational business networks span the three core regions of the world economy, linking the fortunes of disparate communities and Nation-States in complex webs of interconnectedness (national firms with international operations). The Foreign Direct Investment play a much more central role in the operation of the world economy than in the past and they figure prominently in organizing extensive and intensive trasnational networks of coordinated production and distribution that are historically unique. Foreign Direct Investment and global production networks are critical to the organization, location and distribution of productive power in the contemporary world economy. This is reflected too in shifting patterns of global speculative markets of capital and migration of people on the move.

Finally, to be able to construct an efficient financial system, it is possible to mention that these measures-regulation of the international movements of capital- are possible with a good supervision and regulation of all international system.

Introduction

Foreign investment is one of the primary engines of development worldwide. Indeed, for those countries with low domestic rates of savings, and poor access to international credit, foreign investment is one of the only vehicles for development of any kind.

Neo-liberal globalization is a process that began in the 1980s with deregulation and trade liberalization. Globalization is a complex phenomenon that covers three dimensions: the international mobility of goods and services, the mobility of productive capacities through FDI, and the mobility of financial capital. Neo-liberal globalization involves a new regime of accumulation, with financial domination [2], which has increased the financial fragility of both internal financial systems and the international monetary and financial system. Capital markets become more prominent than banking credit in financing enterprises.

This new regime of accumulation radically changes the way corporations are managed. These large companies follow a fundamentally financial logic. Their profitability and the incomes derived from stock options do not depend so much on the productive and internal strength of the firm, but on its increased value on the stock market. Mergers and acquisitions, that were popular over the last decade, were decided not only on the basis of productive or trade potential, but more importantly on their repercussions on market share value. These mergers were a powerful lever that propelled stock market boom of the 1990s. I will begin with the hypothesis that changes to the productive systems of Capital Markets and International Direct Investment, in addition to the structure, composition, and geopolitical orientation of foreign trade flows; have been determined fundamentally by the movement of foreign capital.

This project examines whether policies to promote Foreign Direct Investment (FDI) make economic sense. The discussion focuses on whether existing academic research suggests that the benefits of FDI are sufficient to justify the kind of policy interventions seen in practice. For open economies, efficient taxation of foreign and domestic capital depends on their relative mobility. Also the role of business and capital markets networks in international financial by the Foreign Direct Investment (FDI) in the world economy. This study finds a significant positive role in inward FDI of networks by world investment system.

FDI, Financial Markets & Entrepreneurship: FDI, International Financial & Capital Markets

Since the trade liberalization of both countries, and mainly since the signing of the free agreement trade, the strategies of the primary transnational corporations were as follows Global corporations that follow a global logic focused on the world market and international market, combining this with the restructuring of internal private groups in the world system in order to adapt themselves to globalization process determine changes in asset ownership, the sector and geopolitical location of investment and the geo-strategies destination of produced goods, I mean, foreign market vs. domestic market is like to say FDI vs. world market. Foreign Direct Investment (FDI) has, in this way, contributed to strengthening transnational regions around the world.

Profound changes have taken place in the area of international direct investments and technology transfers over the past two decades. Foreign Direct Investment has emerged as the most important source of international resource transfers to developing countries since the mid-1980s. The trend of rising importance of arm's length licensing as an alternative channel of technology transfer has also been reversed since the middle of 1980s. Japan, for example, has emerged as an important source of FDI in this period as Japanese corporations were forced to move production abroad in order to stay competitive in the face of rising wages and appreciating yen since 1985. [3]

Nevertheless, the trend of rapid rise in magnitude of FDI inflows in developing countries tends to be a cause of optimism among them of prospects of receiving greater volumes of FDI inflows and associated multiple benefits such as technology transfer, market access and organizational skills as FDI is perceived to be transfer of a package of capital and these resources. The recent growth in magnitudes of FDI inflows to developing countries has, however, benefited only a few countries. The least developed countries continue to receive a negligible share of FDI inflows despite liberalization of policies.

The North America Free Trade Agreement (NAFTA) is a good example of this kind of integration, as it has been the main field of experimentation for Neo-liberal globalization, whose operating rules are established by US financial capital with the support of dominating groups and the Canadian and Mexican governments. In the trade agreement between Canada and the United States, and subsequently, NAFTA, a series of rules were approved for foreign investors granting unlimited freedom, as well as a series of privileges. For the United States, the trading area of North America is transcendent, not only in outlining the rules of future continental integration in the context of the Free Trade Area of the Americas, but also in the size of its investments, as well as its trade in Canada and Mexico. 13 percent of US direct investment is in these two countries and a total of 65 percent of its investments in the American continent. [4]

These rules allow the signatory nations to keep a Neo-liberal course of trade liberalization and eliminate all restrictions of foreign capital operations. Their application greatly limits the possibility of establishing an active and independent industrial policy or to protect determined sectors and economic activity. Since the 1980s, both Canada and Mexico have abandoned their former nationalist and regulatory foreign investment policies. Intellectual property rights, although attempt to guarantee the protection of innovation and fight piracy, are an obstacle that conserve the advantages enjoyed by oligopolies. This triggers high prices and incredible profits for transnational corporations.

Furthermore, Foreign Direct Investment inflows also vary greatly in terms of bringing associated benefits such as technology and market access. All FDI inflows do not benefit their host countries in the same manner. Some FDI inflows in high technology sectors or those of export-oriented type may benefit their host countries more than those in soft technology consumer goods sectors oriented to local markets. Therefore, the quality of FDI inflows may vary widely. The high quality FDI inflows which can directly contribute to improved competitiveness of developing countries are even more unevenly distributed across countries.

Foreign Direct Investment (FDI) has become an increasingly important factor in the global economy, but much less research has been undertaken on the causes, consequences, and policy implications of FDI than on international trade. This network has redressed the balance through a programme of research and training, bringing together eight leading institutions from seven EU countries. It has extended the analysis of Multinational Corporations (MNCs), examined the economic impact of MNCs and FDI on the home and the host countries, and explored both national and international policy implications. The starting point has been research on the determinants of multinational activity at the level of the firm, and on the relationship between foreign trade and multinational activity.

By other way, if foreign and domestic capital is equally mobile internationally, it will be optimal for countries to subject both types of capital to equal tax treatment. If foreign capital is more mobile internationally, it will be optimal to have lower taxes on capital owned by foreign residents than on capital owned by domestic residents. Absent market failure, there is no justification for favouring FDI over foreign portfolio investment. In practice, countries appear to tax income from foreign capital at rates lower than those for domestic capital and to subject different forms of foreign investment to very different tax treatment. FDI appears to be sensitive to host country characteristics. Higher taxes deter foreign investment, while a more educated work force and larger goods markets attract FDI. There is also some evidence that multinationals tend to agglomerate in a manner consistent with location specific externalities. There is weak evidence that FDI generates positive spillovers for host economies. [5]

While multinationals are attracted to high-productivity countries, and to high-productivity industries within these countries, there is little evidence at the firm or plant level that FDI raises the productivity of domestic enterprises. Indeed, it appears that plants in industries with a larger multinational presence tend to enjoy lower rates of productivity growth over time. Research thus provides little support for the idea that promoting FDI is warranted on welfare grounds. Subsidies to FDI are more likely to be warranted where multinationals are intensive in the use of elastically supplied factors, where the arrival of multinationals to a market does not lower the market share of domestic firms, and where FDI generates strong positive productivity spillovers for domestic agents.

By this way, the liberalization of emerging financial markets and increasing global financial integration over the last two decades have set the stage for a new, frightening kind of implosion, where a nation's currency and banks both collapse, leading to capital flight, soaring interest rates and a depreciation of the real economy. For example, since then, Russia, Mexico, Thailand, Indonesia, Malaysia and other nations have faced economic disaster when a currency crisis combines with a banking collapse.

Besides a formal devaluation, factors such as actual or rumored political instability, interest rate hikes, a spectacular company failure or unexpected declines in the economy can all lead anxious investors to move their money elsewhere. As this happens, people sell more of the local currency, flooding the market and further reducing its value. To maintain the peg, the government needs to raise the value of the currency, usually by selling its reserves of foreign currency and buying its own. When it becomes obvious that the government has insufficient reserves-or willpower-to meet its obligations to finance imports, debt and still support its currency, that triggers a currency crisis. When this occurs, governments, banks and companies that have taken out debt denominated in dollars, marks or other strong currency, but whose income is in the local currency face danger as debt becomes increasingly unmanageable: it takes more and more local currency to meet payment schedules. At the same time, real interest rates tend to rise after a currency crises to make up for risk of increases in future inflation to levels of 20% to 50%-levels that are generally considered unsustainable.[6]

However the arguments for capital account liberalization and against financial capital markets can be summarized thus; the first, flows of foreign capital into a country can help improve productivity and this, in turn, brings about a major increase in living standards. It also promotes integration of economies into the world financial system; the increased availability of capital and diversity of its source is good for growth. Second factor, open capital accounts promote good policies: countries which have stable governments, fair and consistent regulations, and attractive investment climates will attract more funds. Capital market liberalization provides both a carrot and a stick; countries that pursue such policies will find that they can attract more capital; those that do not will find capital rapidly leaving.

Third factor, capital markets are micro-economically inefficient in that they hinder the optimal allocation of resources, money isn’t allowed to naturally flow to the most efficient or successful companies, or investments. Control markets also have large administrative costs, are widely evaded, and give rise to corruption. But the downside of the process proved to be painful, and a series of global financial crises beginning in the late 1990s helped to start the reversal in the trend of rapid capital market liberalization.

The heavy inflow of capital into developing countries that liberalized their capital accounts had pushed the value of those countries currencies upwards against the United States (U.S.) dollar or euros. But when foreign investors lost confidence in the economies of these countries, they began to pull their money out. The value of the currencies then fell sharply against the U.S. dollar, making it ever more difficult for the developing countries to pay back their debts and causing foreign investors to lose even more confidence. The years after capital market liberalization spread were punctuated by a series of financial crises, including the Asian crisis in 1997, the Russian crisis in 1998, the Brazilian crisis in 1999, the crises in Turkey and Argentina in 2001. Over a hundred countries have faced crises in the past 30 years. While a number of different factors have contributed to each, capital market liberalization has usually been an important factor: Most of the crises have been precipitated by the rapid flow of money out of the country, and in some cases, such as Thailand, the country’s problems prior to the crisis had been exacerbated by rapid flows of money into the country.

In 1997 the Asian crisis began when foreign exchange speculators began selling off Asian currencies. The countries were stuck in a tight place. The way to stop money going out of a country is to raise interest rates, but developing countries found that raising interest rates was terrible for their banking sector. Higher interest rates mean that people and companies who have borrowed money find it harder to pay it back. When they stop repaying, banks go out of business and stop lending. Less developed countries don’t have strong stock markets and so rely far more on bank finance to grow the economy and create jobs. Bank closures can mean the economy stops growing. After currencies collapsed in Thailand, South Korea and Indonesia, so did their banking systems. As things got worse, commercial banks with long-term relations with many of the affected countries also reduced their credit lines. The end result was massive bankruptcies and an increase in unemployment. Ultimately some 12%-15% of Gross Domestic Product left these countries [7]as capital flowed out. Thailand, South Korea, and Indonesia did not have perfect economies and there were problems with some of their companies and banks, including shaky lending practices; over investment in bubble assets, such as real estate; lack of regulation and oversight-all of which contributed to the weakness in the region's banks. But despite these flaws, the crisis itself was triggered by the massive outflows of capital.

A separate problem concerns liquidity, or having enough access to cash when it is needed. Liquidity shortages typically occur as a result of one of two interrelated factors. The first has to do with the sudden cessation of capital inflows, which means that companies so far reliant on foreign flows for their financial survival now find it difficult to refinance their debt. The second factor has to do with the Central Bank, which, while trying to defend a currency peg, drains liquidity from the local system. By doing so, it can cause real sectors of the economy to contract, and even induce banking failures. Ironically, it is the strongest and most promising countries (for example Mexico in 1994 and East Asian nations in 1997) that are often subject to liquidity cris es. As the ones that attract the strongest capital inflows, these countries are sometimes likely to over borrow and are thus most affected by capital flight when things start financial crises.

Much depends, as noted above, on the currency in which revenues and debts are denominated and if there is currency mismatch, for example when revenues are in the local currency and debt is in hard currency. It also matters whether the private sector is exposed to risks from changing interest rates. Britain's sudden exit from the European Monetary System in 1992, accompanied by a sudden devaluation of sterling against other countries, seemed like a national humiliation at the time[8]. But, the domestic economy in retrospect, appears to have benefited from the sudden imp rovement in competitiveness and lower interest rates leading to an impressive economic recovery. While the devaluation of the Mexican peso in 1994 led to more than 50 per cent of the nation's bank loans being written off, the healthier Brazilian banks survived with no greater write-offs than usual after the Brazilian real was devalued in 1999. It is like to cite four prerequisites for financial collapse: a)Financial liberalization; b) a fixed currency value; c) large capital inflows; d) underlying weakness in banks and firms.[9]

Of course, any one of these factors can start the vicious cycle, but all must be present for a currency crisis to cause an economic disaster. For that situation the currencies lose value when the inflation means the currency buys less real goods and services within a nation. Measures the rate that prices increase. Inflation and Exchange Rate Depreciation are closely related over the long term, but can vary widely over the short term. For example, if a country expands the money supply faster than the economy itself is growing, the currency would be worth less both inside and outside the nation, causing both inflation and a devaluation. Exchange rates take into account not only current inflation, but anticipated increases. Devaluation can also lead to inflation by forcing up the price which locals must pay for imported goods.

However, the critics of rapid capital account liberalization market say, there is a difference between Foreign Direct Investment (FDI), (that is, investment in factories, businesses, and things that produce goods and services) and portfolio investment in stocks and bonds, which tends to be more speculative. FDI is money that is sunk into ownership of companies and property that can not be pulled out of a country overnight. Early supporters of capital account liberalization did not really think about the differences between these two kinds of capital flows, but now while pretty much everyone agrees that FDI is important, they worry about unregulated portfolio investment and the effect it has on developing countries.[10]

The FDI is a significant source of development finance for all its potential, there is far greater awareness of the complex nature of FDI and the possible negative impacts of rapid and large growth for least developed countries. A crucial question is how FDI might be better applied to support more sustainable forms of development, particularly in those countries with burgeoning debts and widening income disparity to the rest of the world. Attraction of FDI is becoming increasingly important for developing countries. However this is often based on the implicit assumption that greater inflows of FDI will bring certain benefits to the country's economy. FDI, like to Official Development Aid (ODA) or any other flow of capital, is simply that, a source of capital. However the impact of FDI is dependant on what form it takes.

With a stimulation of national economy, Foreign Direct Investment (FDI) is thought to bring certain benefits to national economies. It can contribute to Gross Domestic Product (GDP), Gross Fixed Capital Formation (total investment in a host economy) and balance of payments. There have been support indicating a positive link between higher GDP and FDI inflows, however the link does not hold for all regions over the last ten years FDI has increased in Central Europe whilst GDP has dropped. FDI can also contribute toward debt servicing repayments, stimulate export markets and produce foreign exchange revenue. Subsidiaries of Trans-National Corporations

(TNCs), which bring the vast portion of FDI, are estimated to produce around a third of total global exports. However, levels of FDI do not necessarily give any indication of the domestic gain. Corporate strategies protective tariffs and transfer pricing can reduce the level of corporate tax received by host governments[10-2].

Also, importation of intermediate goods, management fees, royalties, profit repatriation, capital flight and interest repayments on loans can limit the economic gain to host economy. Therefore the impact of FDI will largely depend on the conditions of the host economy, the level of domestic investment/savings, the mode of entry and the sector involved, as well as a country's ability to regulate foreign investment. By this way, the stability of FDI inflows can be less affected by change in national exchange rates as compared to other private sources (portfolio investments or loans). This is partly because currency devaluation means a drop in the relative cost of production and assets (capital, goods and services) for foreign companies and thereby increases the relative attraction of a host country. FDI can stimulate product diversification through investments into new businesses, so reducing market reliance on a limited number of sectors or products.

However, if international flows of trade and investment fall globally and for lengthy periods, then stability is less certain. New inflows of FDI are especially affected by these global trends, because it is harder for a foreign company to de-invest or reverse from foreign affiliates as compared to portfolio investment. Companies are therefore more likely to be careful to ensure they will accrue benefits before making any new investments. Examples of regional stability are mixed, whilst FDI growth continued in some Asian countries, Korea and Thailand, during the 1996/97 crisis. During Latin America's financial crisis in the 90's many Latin American countries experienced a sharp fall in FDI, suggesting that investment sensitivity varies according to a country's particular circumstances. Many advocates of capital market liberalization claim that without capital market liberalization, countries will not be able to attract foreign direct investment but there is little evidence to support that conclusion. China, for example, is the largest FDI recipient in the world and has a closed capital account (The Chinese government has made verbal commitments to liberalize, but few measures have yet been taken).[11]

Nevertheless, free capital mobility makes macro-economic management difficult, in good times, as well as bad. In good times, the rush of money into a country can lead to an overvalued exchange rate. That swells the country's liquidity which, in turn, fuels inflation. To avoid inflation, countries often raise interest rates, but this simply makes matters worse, as more capital is attracted into the country. While many countries have had problems implementing capital controls, some have done so with remarkable success, such as Latin and Asian countries.

Changes in technology have exacerbated the increase in volatility associated with capital market liberalization. When capital movements were first liberalized, foreign exchange trading was far less developed and communications were slower, so it was hard to imagine that it would be possible for speculators and banks to take hundreds of millions of dollars out of a country overnight. The situation over FDI, capital markets has remained highly contentious, but even mainstream economists have began to say that capital market liberalization should be done slowly and only after certain conditions had been met such as: the first development of a strong banking sector that is able to handle large inflows and channel them into productive investments.

Second factor, a restructured and efficient corporate sector that can use inflows effectively and not throw good money after bad. The third, a strong regulatory and legal regime that restricts monopolistic practices, ensures prudential banking practices, and, when needed, regulates bankruptcy of debt-burdened corporations. Fourth, a sound macroeconomic environment that avoids large fiscal deficits, which exacerbates the overheating associated with capital inflows, and inflexible exchange rate regimes, which can not handle the volatility of capital flows. Fifth factor, a strong system of prudential regulation, and laws that mandate proper accounting, auditing, and reporting. Finally, no implicit government guarantees that encourage excessive inflows of short term capital.

Without forgetting that, it is necessary to consider, the Cross-Border capital flows generally take one of three basic forms, Official Development Aid (ODA), debt, or equity investments. Therefore, Foreign Direct Investment is defined as any equity holding across national borders that provides the owner substantial control over the entity. This is generally defined as a 10% holding or greater. Most foreign direct investment ends up being 100% ownership by a Multi-National Corporation (MNC), though certain countries like to promote joint ventures with local entities. Cross-border investments providing less than 10% ownership of a foreign entity are referred to as portfolio equity investment.[12]

Likewise, there are two fundamentally different types of FDI, sometimes called modes of entry. The MNC can either buy an existing foreign company, or it can create a new company. The latter is often referred to as build vs. buy. Investment can create additional productive capacity in a country, but it may also create new competition for existing local companies. The important distinction is the difference between the FDI inflow and FDI stock. Inflow measures the amount of FDI entering a country during a given period. The FDI stock is the total amount of productive capacity owned by foreigners. FDI stock grows over time, and is defined to include all retained earnings of foreign-owned firms, which can be held in cash and or investments by the company.

The majority of FDI does go to the developed economies (Japanese automakers opening plants in the US and UK), but FDI to developing countries is still large and has increased substantially. Inward FDI to developing countries increased from $8.4 billion in 1980 to $37.6 billion in 1990, to $204.8 billion in 2001. This growth across regions masks the high concentration of FDI to developing nations. In 2001, about 62% of inward FDI to developing countries went to five countries: China, Mexico, Brazil, Hong Kong, and Poland. Least developed economies, including many in Africa, continue to receive very little FDI.[13] These tend to be shunned by MNCs, which prefer to invest in countries known to be safe, with relatively high levels of political stability, infrastructure, education, well enforced property rights, etc. The factors contributing to the growth of FDI starting in the early nineties a number of factors converged to make FDI increase dramatically. The first is the increased perception of risk associated with cross-border debt. The Latin American debt crisis in the 80's and the Asian capital crisis in 1997-1998 made lenders much less eager to lend across borders.

Perhaps the most important factor contributing to the growth of FDI since the late 1990s has been globalization, or the internationalization of production and the introduction of the so called global supply chain by MNCs. Technological change, especially lower transportation and communication costs, has enabled MNCs to locate specific stages of production in different locations, taking advantage of favorable local conditions to minimize costs and improve sales. Another substantial contribution to the growth of FDI has been change in government policy, as countries have begun actively courting investment from overseas. Many countries have changed policies to allow investments that earlier might have been prohibited or been otherwise difficult.

For what, the advantages of Foreign Direct Investment to help evaluate the merits of particular investments, or a particular country's inward FDI portfolio, look for some of the key benefits of FDI to a developing country that are listed here. The first can contribute to growth, higher incomes, and reduced poverty - perhaps the most it could hope for any economic activity in a developing country is that it contributes to economic growth. This is the heart of the matter, but as with many economic phenomena, there is not conclusive evidence here one way or another. But the empirical evidence is good that FDI often, though definitely not always, contributes to economic growth. To the extent that FDI contributes to economic growth, the evidence is indeed good than economic growth usually leads to reduced poverty, though not necessarily to a more equitable distribution of income.

Likewise, the second point, incentive structure leads to productive investment because Foreign Direct Investment is generally done by Multi-National Corporations; those companies are usually concerned with making investments that will create profits. Therefore, the investments are usually well-targeted towards setting up a business that will make money and create jobs. This contrasts especially with aid and loans to governments, which have often been squandered through corruption or spent inefficiently on unneeded infrastructure or other vanity projects.

Nevertheless, in third place, less volatile than other capital flows -because FDI is generally spent on hard assets such as plant and equipment, the capital embodied in FDI cannot flee a country in times of crisis as easily as debt capital. A company can not sell off a factory and pull out of the country as quickly as a bank can sell off the country’s bonds, or refuse to roll over short term loans. Even in instances where the FDI is in a service-related industry such as banking or advertising, substantial effort and time is spent to develop an ongoing business, and owners will not easily pull the plug. Thus FDI is said to be much less likely than debt capital to exacerbate a crisis situation, as happened in the Asian crisis in the late 90's. Experience through the nineties showed FDI to be much less variable than debt flows.

In consideration, fourth point, can lead to increased tax revenues -a successful foreign-owned firm should generate profits, and hence generate tax revenue for the host country. Those taxes can then be spent on needed infrastructure, social programs, education, etc. This is a strong incentive for government encouragement of FDI.

However, in some cases the tax benefits can be disappointing. One risk is that the government may provide too great a tax amnesty as an incentive. Also, if the foreign-owned entity produces an intermediate good purchased by its parent company, such as car parts that are shipped to an assembly plant in another country, then profits can be affected by transfer price manipulation. That is what happens when the subsidiary sells its product at an artificially cheap price to the parent company, so that it can pay lower taxes.

The fifth, can lead to technology transfer and management skills transfer - these are components of positive spillover, or the positive effect on local firms that is often cited as a key advantage of FDI. Because MNCs typically have greater technological and management expertise than local firms, such expertise can be transferred to other parts of the economy. This appears to happen most clearly when the MNC has close ties to local partners, suppliers and customers. But even in cases where the MNC is not tightly integrated with local firms, there is evidence that technology and skill transfer takes place, most likely through labor mobility, professional contacts, or a general raising of competitive pressure.

In this way, in sixth place, can improve skill and wages of labor force, FDI is often encouraged because MNCs are thought to provide training and better employment opportunities for development of the labor force. Evidence is strong that MNCs pay better and train employees more thoroughly than domestic firms in developing economies. It is also claimed that the presence of MNCs in the labor market provides incentive to local firms to improve conditions and wages of workers. However, that from the perspective of local firms this can be a negative if MNCs skim the local workforce of skilled workers, labor costs for local firms can increase.

Next point, may improve access to export markets, Multi National Corporations almost by definition require substantial skill in importing and exporting. Many economists and policy makers believe that a key benefit of FDI is that the presence of export oriented foreign firms in a country can help improve efforts by local firms to sell overseas. There is good evidence that this is the case. One way this happens is through improvements in shipping and logistics infrastructure increased presence of international shipping firms. There is probably also some knowledge transfer, where managers of local firms learn from the example of the MNC how to open new export markets.

However, the eighth, can provide additional demand for output of local producers - another key component of positive spillover is the increased demand for inputs from local suppliers that a new MNC can create, which can lead to increased revenue and profits for local firms. Some studies have suggested that a key determinant of the benefits to national income from FDI is the extent to which the foreign enterprise sources locally, rather than importing its inputs. Ninth, can provide lower-cost inputs for local suppliers - Similar to the previous benefit, if the MNC creates a product previously imported by local producers or otherwise in short supply, the FDI can lead to a decrease in production costs for local firms and correspondingly higher productivity and profits.

Finally, can improve the balance of payments and capital account - because exports will typically bring in hard currency, an export-oriented foreign-owned entity can improve the balance of payments and capital account of a nation. This balance of payment benefit is reduced, however, by the extent to which the firm imports its production inputs. In addition, the initial FDI investment itself can also be an important source of hard currency, since the MNCs will typically need to convert hard currency to the local currency to either purchase a local entity or contract for work and equipment in setting up a new entity. Note also that MNCs will eventually repatriate profits and retained earnings periodically, which causes a reduction in hard currency reserves.

Nevertheless, we need to consider, the social development in FDI, where it generates and expands businesses, can help stimulate employment, raise wages and replace declining market sectors. However, the benefits may only be felt by small portion of the population, where employment and training is given to more educated, typically wealthy elites or there is an urban emphasis, wage differentials or dual economies between income groups will be exacerbated. Cultural and social impacts may occur with investment directed at non-traditional goods. For example, if financial resources are diverted away from food and subsistence production towards more sophisticated products and encouraging a culture of consumerism can also have negative environmental impacts. Within local economies, small scale and rural businesses of FDI host countries there is less capacity to attract foreign investment and bank credit or loans, and as a result certain domestic businesses may either be forced out of business or to use more informal sources of finance.[14]

Despite, the risks of Foreign Direct Investment exist if foreign ownership becomes too extensive, decapitalization can occur as foreign owned firms become established and profitable, they begin to repatriate earnings to the home country of the owner. In so doing, local currency is converted to the home country currency, and capital leaves the country. If the base of foreign owned companies is large enough, this can lead to a serious capital drain. This is especially a concern if in times of crisis foreign-owned companies repatriate retained earnings suddenly. The effect of this can be similar to the effect of foreign lenders refusing to roll over short term loans - the country can be starved of capital, and a bad economic situation can be made dramatically worse. This is sometimes cited as one of the primary risks of a country becoming too reliant on FDI.

If FDI is to take a greater role in building developing country economies, further assessment of the factors which influence and are influenced by FDI flows is necessary. Foreign companies are thought to be attracted to recipient countries for a whole range of factors, political stability, market potential and accessibility, repatriation of profits, infrastructure of currency conversion. Privatisation and deregulation of markets are seen as central means to attract FDI, however this can leave the poorest or most indebted countries open to destabilising market speculation. National legislation can support better investment security for local markets, fair competition and corporate responsibility through defining equitable, secure, non-discriminatory, transparent investment practices. Whilst there is concern that increased regulation could detect new foreign investors, there is evidence, such as in Eastern Europe, that tighter regulation of corporate, environmental and labour standards has not affected FDI growth.[15]

Where low income and developing economies are successful in attracting FDI, they require considerable support to ensure that they can adapt to rapid and large inflows of FDI, and that these flows positively benefit domestic economic stability. This means developing strategies which encourage greater and longer term domestic investment and saving, as well as higher returns on investment capital. The development of an international multi-lateral rule based trading and investment system has been advocated widely. However, whilst the abandoned Multilateral Agreement on Investment would have provided greater rights for companies and investors, it gave limited support for the social, economic and environmental concerns of host countries. Furthermore, regulation of investment is only as effective as a country's ability to enforce it. The cost of implementation may be prohibitive for many countries, bilateral and multilateral support, along side multi-stakeholder participation, is vital for the formulation of such agreements.

The FDI can be better targeted toward the advancement of developing and heavily indebted countries, whilst ensuring the global security of coming generations. Consider the mobilise domestic resources, intemational private financial flows, international financial cooperation, trade, debt, new financial mechanisms and governance, in the context of increasing globalization, as well as the use of economic instruments and incentives to support long term private investment. And it is a crucial opportunity to take a closer look at institutional processes and the linkages between Foreign Direct Investment, trade and financial mechanisms, so that all of these can be better targeted toward meeting sustainable development targets. However, it will need to provide a good opportunity to create their implications making for a more economic sustainable future.

Conclusion

Today, generally agree that rapid liberalization of capital markets can be dangerous for developing countries unless they have strong banking sectors and developed ways of overseeing the financial sector.

The idea of controls on short term borrowing has also economy increasingly accepted, even if the idea of imposing controls during a crisis is still controversial. However, it is unlikely that the past trend of liberalization will be reversed. Countries that have liberalized will find it difficult to go back to the old system, but it seems likely that countries that have not fully liberalized will not rush to do so.

The new technologies, managerial practices and financing techniques of business operations have considerably changed the environment and decision-making process for international investment. At the same time, larger FDI flows also create new challenges to policy makers in host countries, in particular to preserve the capacity to pursue- in a non-protectionist and non-discriminatory way its own social and environmental objectives.

As a first conclusion, it should be repeated that external foreign investment is one of the fundamental elements in the development of the region. For it to be properly assessed various crucial factors must be taken into account, such as its form, amount, influence on the productive system and the effective contribution made to the investment. Its influence does not only concern the effective functioning of the economy but also transcends it and affects both the economic power and the political power structures. It is not merely a commercial problem or even a production problem. Rather, it transcends and defines the basic lines of economic development, which in turn, transcend political considerations. A parallelism may be drawn between investments that predominate in the basic economic sectors and hegemonic political power. In synthesis, Foreign Direct Investment encourages important productive process and simultaneously builds one part of power elite.

A second point for reflection concerns the nature of investments: whether they are carried out with the aim of tapping the internal market of the host country or of boosting exports; whether the foreign investor is being financed in his country of origin or through international funding or whether the investor resorts to sources in the country in which it is establishing itself.

A third consideration has to do with economic policy: for Foreign Direct Investment activities to be beneficial to the country involved, they must be effectively coordinated with local economies and integrated in the overall economic policy. At the legal level, the conditions governing the implementation and functioning of Foreign Direct Investments were liberalized, and certain crucial incentives were offered, particularly tax incentives. Making these investments consistent with the interest of the nation will require the establishment of regulatory standards.

Fourth, there is also a clear need to avoid risks that may lower the contribution of these investments to national development: excessive imports, the substitution of internal savings for external savings, excessive remittances of profits and obstacles to technological research.

There is no doubt that foreign direct investments must be placed within a long-term framework and must be viewed from the perspective of a national development project. They should be committed to the development of the host country, a fact that tends not to be consistent with their aspirations to increase markets and to raise profits.

Today, the globalization on Foreign Investments, capital markets and international financial are organized in large measure by Multi National Corporations. Their pre- eminence in world output, trade, investment and technology transfer is unprecedented. Even when MNCs have a clear national base, their interest is in global profitability above all. MNCs have grown from national firms to global concerns using international investments to exploit their competitive advantages. Increasingly, however, they are using joint ventures and strategic alliances to develop and exploit those advantages or to share the costs of technological innovation. But the growing globalization of production is not limited to MNC activity, for over the last three decades there has been a significant growth in producer - driven and buyen – driven global production and distribution networks. The globalization of business is thus no longer confined to the MNC but also embraces Small and Medium-sized Enterprises (SMEs).

Rather MNCs play a much more central role in the operation of the world economy than is the past and they figure prominently in organizing extensive and intensive transnational networks of coordinated production and distribution that are historically unique. MNCs and global production networks are cirtical to the organization, location and distribution of productive power in the contemporary world economy.

Foreign direct investment (FDI) can provide benefits to host countries and regions through new jobs and the possibility for technology transfer and productivity improvements in domestic firms. However, these benefits may not always be realized, and there may be offsetting costs in terms of reduced employment and market share among domestic firms.

The relevant modern technology has changed the management of financial transactions investment in ways that have expanded international capital flows. It is also financial technology that has encouraged and increased the international flow of investment. Derivative markets allow investors to separate cross-border equity or interest rate risk from cross-border currency risk by hedging the currencies associated with equity or bond positions. This hedging may help to explain the an important but still inadequately understood feature of the international capital market, it is mean the contrast between the very large volume of gross flows and the very small volume of net flows.[16]

The most obvious contribution of Foreign Direct Investment and international capital flows to host countries is to augment the supply of domestic saving in countries with unusually rich investment opportunities. The high marginal product of capital means that capital importing countries can benefit even when the interest rates and the equity yields to the foreign providers of capital are high.

Despite the importance of this contribution, it is important to note that the magnitude of the capital inflows is still small relative to the volume of domestic saving. Most of the investment in plant and equipment-technologies-and in real estate in every country is financed by domestic saving. This reflects the limited size of the current account deficits and the associated capital inflows that the international capital market will support.[18]

Direct foreign investment means much more than additions to the stock of capital. It brings with it better technology, modern management, and an expanded access to global markets. Portfolio equity investments also help in a different way by exposing local companies to the scrutiny of the international capital markets, requiring greater accounting transparency and more effective international corporate governance. Money goes where it wants, and stays where it is well treated.[19]

Whither Foreign Direct Investment in Malaysia in a Volatile Global Business Environment?

Dawood M. Mithani
Universiti Utara Malaysia, Malaysia

Abstract

This paper examines the growth trend, sector-wise inflows and economic impacts of FDI in Malaysia. The results show an increasing trend of foreign investment inflows during the period 1985 to 1996. A declining trend emerged in the post 1997 Asian Crisis period. The macroeconomic variables such as GDP, exports and employment are found to be positively influenced by the growth of FDI in Malaysia. To enhance the positive effect of FDI on the growth process in the country the flow of FDI into export-oriented sector and use of domestic inputs by the foreign-oriented firms need to be encouraged. It is suggested that for sustained flow of FDI, price stability, macroeconomic balances- both monetary and fiscal, good governance and continuation of economic liberalization are crucially important in Malaysia In the event of declining inflows of FDI, Malaysia has to shift towards inward looking policies and search other alternatives to sustain its growth and economic prosperity in the emerging modes of global trade and investment in a volatile business environment.

Introduction

Over the years in most developing countries foreign direct investment (FDI) as an effective source of foreign capital, has assumed a significant role in their development and industrial growth process. Especially, in the Asia-Pacific region high levels of foreign capital investment including FDI, predominance of multinational companies and export-led growth strategy and the market-oriented economic integration across the region largely comprise its business and economic growth model. By and large, in most developing countries FDI is regarded as an engine of growth.

In the Asia –Pacific belt among ASEAN countries, however, Malaysia has acquired a unique position of rapidly growing newly industrialized open economy in the past two decades. As such, it is worthwhile to examine its growth characteristics in the light of FDI inflows in its development process, performance and prospects.

Rationale for the Study

A plethora of studies on the issues of FDI is available in the context of developed and developing countries. Since the present study is confined to the Malaysian case, it is needless to go through the wilderness of all these studies.

In the post-Asian 1997 Crisis era, the growth scenario of the ASEAN countries has a different story about the flows of FDI. Besides, international business environments are rapidly changing in the accelerated pace and processes of globalisation, growth of economic imperialism of the super powers-possessed by the countries and corporations, and emerging new great markets like China and India. In this regard, a fresh look and discussion is warranted on the issues of FDI in developing countries to serve as guidelines for the policy-makers in determining their future course of direction. Malaysia, however, provides on example of one of the most successful cases of the newly industrialized country (NIC) to attract large quantum of FDI in the pre-Asian Crisis years. Indeed, despite the 1977 economic crisis, the Malaysian policy makers never marginalise the importance of FDI as a growth propelling force. The Government of Malaysia did recognise the varying impact of different investment inflows by offering multinational corporations (MNCs) several incentives including liberal ownership rights and taxations allowances. Looking to the pragmatic approach and efforts of her policy-makers, thus, Malaysia serves as an interesting case to analyse the issue pertaining to foreign direct investment flows that might provide some useful lessons for other developing countries in Asia and Africa.

Incidentally, available studies on FDI in Malaysian context have tackled various issues in segregation and most of them have been descriptive in approach. Some (Ariff 1992, Aware and Metussin 1999, and Bhatt 2000, for instant) have focused on the ASEN region and made a peripheral reference to Malaysian situation. Fry M.J (1994) observed an inverse saving-investment correlation in Malaysia over the period 1979-91. This is attributed to public sector investment and FDI. Hill (1990) provides an explanation to this by saying that Malaysian authorities might have preferred FDI to local non-indigenous (non-Bumiputras) investment to check the racial economic imbalance in the country. Comprehensive study of recent Malaysian experience is yet unavailable. An attempt is made in this paper to fill up the gap to an extent.

In particular, this paper has three-fold objective. Firstly, to review the trend and pattern of foreign direct investment (FDI) inflows in Malaysia, secondly to examine the impact of the FDI inflows on Malaysian economy and finally to discuss the interface of the country with the AFTA (the Association for Free Trade Area) and make inferences towards its future prospects.

FDI: Growth Trends in the ASEAN and Malaysia

Globally, FDI has increased dramatically over the years. (Refer to Table 1 for details). The inflows of FDI, however, have largely been channelised towards industrial contries. Even by 2001, developed countries remain the prime destination of FDI, accounting for mare than 75 percent of global inflows. In the developing countries, FDI has grossly concentrated among a few natins. In 1990,over 90 percent of FDI hads flown to eighteen developing countries, and half of which was claimed by eight South-east Asian countries (Hong Kong, Indonesia, Korea, Malaysia, Philippines, Singapore, Taiwan and Thailand), on accunt of their growing market economies, competitive capacities of domestic business groups, economic imperatives, such as a deteriorating current account over a period, and increasingly open and receptive policy providing superlative investment climates (see Fry, 1991,1993 and Hill,1990).

TABLE 1: WORLD FDI INFLOWS AND OUTFLOWS

(USD Billion)

	FDI Inflows	FDI Outflows
1970	12.59	14.11
1980	54.95	53.67
1984	60.18	52.77

By and large, FDI has played a key role in development process of the major ASEAN countries including Indonesia, Malaysia, Philippines, Singapore and Thailand. Mid-Eighties onwards till the Asian Crisis of 1997, the ASEAN region has been highly successful in attracting large inflows of foreign direct investments in the developing Asia. During 1985, for instance, the world FDI inflows amounted to USD 576 billion of which the ASEAN received

USD 2.2 billion thus claiming just 3.8 percent share. There has been a quantum jump in 1995,when the ASEAN claimed USD 25.3 billion from the total world FDI inflows amounting to USD 330.5 billion, which implied nearly doubling of its share (at 7.7 percent). In 1997, the world FDI inflows increased to USD 478.1 billion of which the ASEAN received 30.4 billion, claiming 6.3 percent share in the total.

Data in Table 2 suggest that in the post-1997 Crisis period, the ASEAN experienced a declining trend of FDI inflows from 18.5 billion in 1998 to 11.1 in 2000, as against the rising trend of the world FDI inflows from 694.5 billion to 1491.9 billion in the same period. This is attributed to a diversification of the world FDI inflows towards other channels – the new emerging markets such as China, India and African countries.

Malaysia, on the whole, represents a rising trend of FDI inflows over the years since 1970.During seventies and eighties, from the bottom of 94 million FDI inflows in 1970, the Malaysian economy had received a peak level of 1397 million FDI inflows in 1982.Its share in the ASEAN FDI inflows, thus increased from 25 percent to 41 percent.

During 1985-2001, the compound annual rate of growth (CARG) of the FDI inflows in Malaysia estimated to be 12.4 percent as against that of 10.6 percent in the case of ASEAN.

During 1986-91, the annual average FDI inflows estimated to be USD 1605 million in Malaysia, which constituted around 20 percentage share in the annual average flows amounting to USD 7908 million in the ASEAN region. During nineties, prior to the crisis year 1997,the Malaysian economy witnessed an increasing trend of FDI inflows from 695 million in 1985 to 2611 million in 1990 to the peak level of 7296 million in 1996.

The rising trend in the inflows of FDI in the country may be attributed to the policy shift and growing market orientation of the country. The other important determinant of FDI inward flows to Malaysia during this period is the successful industrial and technological upgrading acquired in achieving a competitive edge in the export markets.

A setback is, however noticed in the post-1997 Crisis period. The FDI inflows in the country shrinked to 2714 million in 1998.In the recovery period 1999 onwards again the rising trend is noticed. The FDI inflows in the country increased to 3895 million in 1999.The FDI inflows, however, marginally declined to 3788 million in 2000.

Sector- wise Pattern of FDI in Malaysia

Malaysia attracted foreign direct investment even in the British regime prior to her independence in 1957.In the beginning the multinational companies were concerned with seeking raw materials such as rubber and tins from the country. Gradually, as an impact of the country's new economic policy of 1970, there was a marked diversification of the FDI inflows towards manufacturing sector; (basically a large channels in the electronics and textiles). The FDI inflows also went into wood, wood products, fixtures, paper, printing and publishing, plastics, machinery and equipments and measuring equipment industries of the country. In recent years, high-tech and such other industries requiring extensive R & D has received a greater attention of the MNCs in Malaysia. Over the years the manufacturing sector received the largest share of foreign direct investment in the country in 1986, this sector receives 93.33 per cent of non-oil sector FDI. (Refer to IMF, 1987).

In 1991, however, the share of manufacturing investments dropped almost 10 per cent on the average. This is partly due to expansion of the property sector from 2 percent in 1989 to 13 percent in 1992. Ironically, the drop in manufacturing is partly due to the challenges faced in Malaysian labour market. The rapid decline of 'low-technology' and labour-intensive industries implied that the labour markets in the country have become increasingly tight. Malaysia should uplift the workforce to develop more skill- and technology-intensive industries. During 1995-1997, the agriculture, manufacturing and property sectors claimed 2 percentages, 78 percentages and 20 percentages respectively in the total inflows of FDI in the country.

Current scenario

FDI inflows in major ASEAN countries are least affected by the 1997 economic crisis. In the case of Malaysia and Thailand with a marginal set back in the investment applications in 1997, soon there has been an upturn in FDI activity in 1998 onwards. Malaysia has successfully attracted FDI in the manufacturing and electronic sectors to a large scale.

Recovery measures undertaken by the Government in Malaysia has shown some positive results. The country had speedy recovery form the 1997 crisis is evident by the fact that its economy depicted a strong 11.7 percent growth in the first quarter of 2000. In 1999, real GDP increased by 5.6 percent, rebounding form the recession (7.4 percent economic contraction) in 1998. Consequently, foreign investor sentiments towards Malaysia supposed to have improved. Yet, the amount of foreign applications for manufacturing projects dropped 16.4 percent to RM2.5 billion during January –May 2000, compared to RM3.0 billion during January –May 1999. This compares very unfavorably against the amount of RM6.0 billion during same period in 1998 and RM 5.6 billion 1997. Malaysia now ranks fifth form previously number one before the crisis within ASEAN as a recipient of Japanese FDI, next to Singapore, Indonesia, Thailand and Philippines. An official research is needed to find the reasons involved and the government should try to improve upon the situations. Perhaps, one of the reasons may be assumed to be the phenomenon of the exchange/ capital control and imposition of exit tax. In the ASEAN region Malaysia is unique in this regard; hence, it might have become less attractive venue for FDI inflows in comparison to many other competitive developing nations. For an effective control of short-term capital flows, thus, we side with the MIER view that foreign capital should better be regulated at the entry rather than at the exit point. Mechanism may be devised to make it compulsory for inflowed funds to be deposited in the central bank (Bank Negara Malaysia) interest free and should be charged with a penalty (say 10 percent) when it is out-flowed within a period of less than one year; at the same time, provision for a reasonable interest payments is justified for funds retained for longer period. (See, MIER, 2000).

In recent years, across border Merger and Acquisition (M&A) activity caused increasing share of a country in the expanding global FDI inflows. Data in the Table 3 relate to the cross border M&A purchased by Malaysia during 1990-2000. It shows that from the bottom of USD 144 million in 1990 the amount of the cross border M&A purchase of the country had gone up to a peak level at USD 9635 million in 1996. A declining trend is, however, noticed in the post crisis period since 1997. It has decline to USD 761 million in 2000. As per of the World Investment Report 2002, the world FDI inflows declined to USD 735 billion in 2001, as against that of 1492 billion in 2000. This is attributed to slow down of the world economy and weakening of business confidence and prolonged recession in the global economy. Nevertheless, the expansion of international production continued at a slower pace. In comparison to the lower level of inflows to Asia, Malaysia's record at FDI inflows in the post 1997-Asia crisis period is not very discouraging. In the ASEAN region, however there is an increase in the FDI inflows to USD 13, 240 million in 2001 as against that of USD 11,055 million in the previous year. In Malaysia, the FDI inflows substantially decrease to USD 554 million in 2001 as against that of USD 2026 million in 2000.

The Impact of FDI in Malaysia

Below an attempt is made to trace the impact (time-trend effect) of FDI on the country's Gross Domestic Product (GDP), exports and employment has been traced. In empirical measures we have worked out the time-trends of FDI relating to the concerned variables, for tracing the income effect, export effect and employment effect of the FDI inflows in the Malaysian economy during 1985-2000.We have used the SAS Programme software for the least square regression analysis of the data and our results are discussed below.

The Income Effect

In a developing open economy, the inflows of FDI considered to be an important source of capital formation and expanding business activities that stimulates a rise in the domestic output and income of the country. The inward FDI flows as a percentage of gross fixed capital formation (GFCF) in the Malaysian economy is estimated to be 14.7 per annum on an average from 1986-1991. In 1992, it was at the peak of 26.0 percent and declined drastically to 11.0 percent in 1995 (See Table 4 for details).

Table 4: INWARD FDI FLOWS AS A PERCENTAGE OF GROSS FIXED CAPITAL FORMATION (GFCF) IN MALAYSIA AND ASEAN (1986-2000)

(Percentage)

	Malaysia	ASEAN
1986-91 (Annual average)	14.7	-
1992	26.0	-
1993	20.3	-
1994	14.9	-
1995	15.0	11.0
1996	17.0	11.0
1997	15.0	12.0
1998	14.0	12.0
1999	22.0	12.0
2000	17.0	6.0

Source: UNCTAD, World Investment Report, 2001

The following double log linear lagged model is estimated to capture the direct elasticity of FDI on GDP:

$$Ln\ GDP\ (t) = b_0 + b_1\ ln\ FDI\ (t) + b3\ ln\ FDI\ (t-1) \quad (1)$$

Where,

GDP = Gross Domestic Product
FDI = inflow of FDI in the country
t = time in the period of year
t-1 = previous year.

For the Malaysian case, our estimate is stated, thus:

$$Ln\ GDP\ (t) = 8.561 - 0.142 \ln \text{FDI (t)} + 0.586 \ln \text{FDI (t-1)} \quad (2)$$
$$(-1.144) \qquad (4.574)$$

R^2 = 0.733

(Parentheses represent t values)

The model is a good fit explaining 73% of the variations. It suggests that FDI in the previous year causing a positive effect on rise in GDP in the current year. Over the years, a large part of growth in Malaysia's national income can be rightly attributed to the positive income effect of the FDI inflows.

The Export Effect

From host country's view point, FDI is warranted owing to its certain positive effect such as it leads to increase in the volume of trade, (especially, exports) improvement in the production functions due to transfer of technologies and managerial know-how resulting to into enhancement of economic efficiency as a whole. Much of the growth in Malaysian grew in the range of only 2 percent prior to 1975. By 1980, Malaysia had become an important producer and exporter of finished manufactured and semi-manufactured product, thus setting out the foundation for rapid and balance growth in the export sector.

TABLE 5: MACROECONOMIC INDICATORS OF MALAYSIA
(million)

	GDP MARKET PRICE	EXPORT	EMPLOYMENT
1985	77470	37576	5.6246
1986	75194	37976	5.7065
1987	79625	44733	5.8808
1988	90861	54607	6.0875
1989	101463	66727	6.3508
1990	115201	77458	6.621
1991	129381	92226	6.891
1992	148357	100910	7.096
1993	165206	118383	7.396
1994	190274	148506	7.618
1995	218726	179491	7.915
1996	249784	193363	8.161
1997	281795	217712	8.391
1998	283243	281947	8.572
1999	300764	319568	8.869
2000	342157	374033	9.271
2001	334589	334326	9.535
2002	355493	349471	9.843

Source: Ministry Of Finance, Economic Report, Various issues.

As can be seen from data in Table 5, the Malaysian exports amounted to RM425.43 billion in 1985. After a slight drop in 1986, experts grew steadily to RM901 billion at an average growth of 16 percent. This was the outcome of the 1986 Industrial Master Plan (IMP) that aimed to further diversify the value added manufacturing product for the export base.
The country exports grew rapidly to reach the peak of RM3632 billion in 1999. It has been observed that the growth rate was at 22 percent in average during 1991 until 1999.For capturing the impact of FDI on Malaysian exports; we used the following double log linear lagged model for regression analysis.

$$Ln\ EXP\ (t) = bo + b1\ ln\ FDI\ (t) + b2\ lnFDI\ (t\text{-}1) \qquad (3)$$

Where,
EXP = Exports
FDI = inflow of FDI
t = current year time in the period
t-1 = preceding year time in the period.

Our result is stated as under:

$$Ln\ EXP\ (t) = 6.951 - 0.190\ ln\ FDI\ (t) + 0.801\ \ln\ FDI\ (t\text{-}1) \qquad (4)$$
$$(-\ 0.969) \qquad\qquad (3.977)$$

$R^2 = 0.677$
(Parentheses represent t-values)
It is seen that the lagged determinant (FDI (t-1)) is highly significant, thus, implying that exports tend to rise only in the subsequent years of initial FDI inflows. It follows that the country's export-led growth strategy has succeeded on account of the positive export effect of the FDI inflows over the years.

The Employment Effect

Foreign Direct Investment is assumed to generate employment in a developing host country. To capture the employment effect of FDI in Malaysia, we worked out the following double log linear lagged, model:

$$Ln\ N(t) = b0 + b1\ ln\ (FDI\ (t) + b\ 2\ ln\ FDI\ (t\text{-}1 \qquad (5)$$

Our result is stated thus:

$$\text{Ln N (t)} = 0.944 - 0.054 \text{ ln FDI (t)} + 0.188 \text{ ln FDI (t - 1)} \qquad (6)$$

$$\qquad\qquad (-1.303) \qquad\qquad (4.431)$$

$$R^2 = 0.706$$

. (Parentheses represent t-values)

The result indicates the inflows of FDI in the proceeding years have been much significant in generating employment in the current years. This is obvious since time lags are functionally involved in the process of production and job creation in real terms. Indeed, the Manufacturing Census data of 1968, 1973 and 1981 revealed that of the total number of jobs created in the manufacturing sector (400,000), 30 percent was on account of FDI inflows.

The aforementioned discussion implies that the inflows of foreign direct investment in Malaysian economy tend to have a favorable impact on exports, employment and income generation.

Malaysia's Propensity to Attract FDI

The relative performance of a country in attracting FDI can broadly be examined with consideration of its relative economic size and strength on position in the global economy. A new measure called the Inward FDI Index (IFI) suggested by the world Investment Report 2001 in this regard. The Inward FDI Index (IFI) is measured as follows:

$$IFI = \frac{(FDI/WFDI).}{\left[\frac{CGDP}{WGDP} + \frac{CN}{WN} + \frac{CX}{WX}\right]}$$

Where,

CFDI = the country FDI inflows
WFDI = World FDI inflows
CGDP = the country domestic product
WGDP = the aggregate world GDP
CN = the country employment
WN = the world employment total
CX = the country export
WX = the world export total

The inward FDI Index (IFI) reflects a country's propensity to attract FDI after adjusting for its relative's economic size and strength (international exposure/position) in the global economy. It's a measure for the policy makers to compare how well their country performs in attracting FDI relatives to others.

Interestingly enough, according to the World Investment Report (2001), Malaysia with IFI >1 was placed 17^{th} in the rank among top 30 high performance nations during 1988-1990. In 1998-2000, however, Malaysia turned up as a "balanced" country (other balanced countries include Costa Rica, El Salvador, Hungary and Slovenia) with the Inward FDI Index of one with their share of FDI inflows exactly matching their average shares of worlds GDP, employment and export. There are 53 country with IFI > 1 and 79 with IFI <1. Majority of the developed countries, also Hong Kong, China and Singapore with IFI >1 regarded as the "over performance" nations. While Japan, Italy, Greece, Taiwan, Turkey, and Saudi Arabia and low income countries with IFI<1 are classified as "under performance" nations. Incidentally, Singapore has slipped from the first rank in the high-performance group in the end-eighties to the thirteenth position in the end-nineties. Apparently, the slippage of the Singapore as well as Malaysia is attributed to the Asian Financial Crisis in 1997. Besides, Malaysia's competitive strength is remarkably good among the developing nations. As per the World Competitive, on the strength of the competitiveness, Malaysia was ranked 9^{th} among the 53-selected country and 2^{nd} (next to Singapore) among the ASEAN country.

Towards New Paradigms and Strategies

In the global context, Asia (ASEAN too) is facing currently a great pressure of economic slow down owing to external driven and trade oriented recessions, cocurrent problems in many parts of the world, structural transitions and financial constraints. Future prospects of FDI in the ASEAN countries, and particularly n Malaysia, need to be examined in the context of AFTA (the Association for Free Trade Area) in the Southeast region. Besides, emergence of new big markets China and India plus increasing openness of Viet Nam and African countries in the wake of the 21st Century has posed new challenges. Time and again, global business environment is becoming more volatile due to unexpected events and uncertainties. Recently, the world will gloom by the disasters of two US-led wars and epidemic such as SARS (Severe Acute Respiratory Syndrome).

Below an attempt is made to discuss some such challenges as well as opportunities juxtaposed to the future course of FDI in the Malaysian context.

Interface between AFTA and Malaysia

The AFTA was established in January 1992 with a view to enhancing economic development, growth and linkage of economic cooperation among the ASEAN countries through creation of a free trade and investment regime in the region. It aims at creating an integrated regional market and strengthening member countries' competitive advantage in the global arena. The AFTA is to position the ASEAN as regional investment avenue to continually attract FDI inflows under the situation of volatility that may be caused by the emerging competitive great market such as China and India. The AFTA is intended to be complementary to the forward and outward-looking ASEAN countries in their export- led and investment –oriented growth strategies. Essentially, the objectives of AFTA are to be realized through a tariff reduction scheme – called the Common Effective Preferential Tariff (CEPT) Scheme – for manufactured goods as well as processed and unprocessed agricultural products. The scheme is to effectively reduce tariff rates for all relevant products at the level 0-5 percent by 2002/2003. By now, 96.6 percent of Malaysian products are covered in the CEPT scheme of which 91.7 percent are subject to tariff rates between 0-5 percent. Almost 60 percent of the products have zero tariffs. In the year 2000, the average CEPT tariff rate for Malaysia's products were 2.8 percent, which is expected to decline further to around 2 percent in 2003. However, automotive products, unprocessed agriculture products in the sensitive list and products in the General Exception list are yet to be included into the CEPT Scheme.

TABLE 6: INTRA-ASEAN TRADE, 1993-2000

	1993	**1994**	**1995**	**1996**	**1997**	**1998**	**1999**	**2000**
Intra-ASEAN trade (US billion)	89.7	115.7	132.5	155.2	131.1	138.5	141.0	179.7
Total global trade of ASEAN country (US billion)	432.0	545.0	651.0	706.6	623.2	624.4	646.6	782.7
% of Intra-ASEAN trade of ASEAN's global trade	20.76	21.23	20.35	21.96	21.04	22.18	21.81	22.96

Source: ASEAN Secretariate

With reduction of tariffs and trade barriers envisaged under the AFTA, it is expected that the infra-regional trade and investment will increase and integrated markets will tend to improve resource allocation within the region. Data in Table 6 suggests that infra-ASEAN trade has steadily rising trend, from USD 89.7 billion in 1993 to USD 179.7 billion in 2000. The compound Annual Rate of Growth (CARG) is measured to be 10.4 percent. On the other hand, the percentage of the infra-ASEAN trade to ASEAN's global trade over the years has remained stable at around 21 percent.

The AFTA as a single regional market constitutes a high potentiality for business, owning to estimate population of 513 million and a combined national income of USD 580.2 billion and per capital income of USD 1,121 in 2000. Collectively, the ASEAN stands a better chance of competing against the mighty China.The ASEAN economy can be treated as a big integrated market caused by the removal of trade barrier and infrastructure linkages transport, energy and telecommunication systems. The emergence of China's big consumer market should be considered as growing opportunities through supply chain alliance "AFTA-China" Business Strategy – that constitutes the world's largest regional trade bloc with a market containing 1.8 billion people clubbed with over USD 2 trillion GDP, and total two-way trade of USD 1.2 trillion. As a matter of fact,"AFTA-China"has created a new business environment that should provide fresh impetus to the ASEAN members for growth and prosperity.

Malaysia has a potential to grab the economic opportunity, as the AFTA facilitates specialization on the basis of comparative and competitive advantage, technology transfer among businesses, improved resource pricing and better management. Malaysia's economic policies are conducive in this context. The New Economic Policy (NEP) of 2001 has the common goals towards the country's economic development aspirations. Essentially, the Malaysian approach is a strong exponent of trade liberalization and multi lateral trading system.

Among the ASEAN nation, Malaysia enjoys the relative competitive and comparative advantages in certain industries, such as in terms of low import taxes on chemicals, electronics and ICT, raw materials coming from industries outside ASEAN, relatively trained and educated workforce, market-friendly government policies-initiatives and support, and political stability.

Due to the Information Technology (IT) sector advancement, Malaysia has a comparative advantage in the development of knowledge-based economy. Multimedia Super Corridor (MSC) has provided the further impetus to the growth of the information and communication technology (ICT) industry in Malaysia. By March-end 2002, there are 657 MSC-status companies, of which 30 percent are world class and 32 percent are foreign owned, with many doing their business in the regional and global markets. With a focus on this area it can accelerate it the nation growth process even with declining FDI flows in the near future.

Malaysia should evolve a mix of outward and inward looking growth strategy. With the e-ASEAN initiative, Malaysia can exploit the situation of growing opportunities as supplies of ICT products and technology through domestic output as well as outsourcing. Malaysia should search the potential for outflow of its direct investment in the promising ASEAN countries such as Vietnam, Thailand, and Philippines. The country can also assume leadership role of IT sector development in the promising Muslim countries and African nations. Even Iran and Iraq (in future) can be the host country for the Malaysian direct investment. Through cooperation and economic ties with countries such as India and Sri Lanka, there is enormous potential for the economic prosperity of Malaysia. Malaysia should try to come out as the leading suppliers of ICT products, knowledge and technology management and center for higher education and training for uplifting the base of knowledge in the emerging markets in Asia and Africa.

Currently, Malaysian economy is skewed with a greater reliance on the US economy. The country needs to balance out its global economic position by improving its trade and investment relationship with the European Union. Its foreign reserves composition should scale up with equal proportion of 'Euro' with 'US Dollar in due course of time.

Of course, Malaysia need to evolve new paradigms (such as six-sigma system, IS 14,000, total ICT-orientation as norms-improvement system) as productivity and quality will be the hallmarks in gaining strong foothold and seizing the emerging opportunities in the regional pockets of the global economy. Serious efforts are required on productivity aspects and quality improvement and competitive pricing for an increased level of Malaysian exports in years to follow. It is possible with integration, dedication and techno-economic cooperation of the ASEAN countries.

Furthermore, Malaysia needs to re-evaluate its existing manufacturing-centered economic model. There is a need to build it towards higher-value activities of service industry and knowledge based ICT industry, so that it becomes a more attractive investment venue for foreigners. Malaysia has this potential which is yet untapped adequately in proper direction. The Malaysian Government needs to chalk out the necessary incentives through appropriate policy measures in this regard.

The IMP2 and FDI

Incidentally, the Second Industrial Master Plan (IMP2) leads the strategy to attract investment with high value-added industries against the phasing of labour-intensive industries. It promotes the 'Manufacturing Plus Plus' concepts and chances for better and greater industrialisation. The plan envisages the qualitative trend of FDI; strengthen global competitiveness and productivity on the prime motivation for the future course of direction and development

The country needs to increase its domestic investment level. It has the potential, with its saving ratio being 38 percent and there are untapped natural resources and knowledge-human-technical resources. The Malaysian policy makers ought to improve the share of domestic investment to make up 60 percent of total investment in long term. In 1996, however, the ratios of domestic investment to foreign investor stand at 50.1 percent as against total of 56.2 percent in 1995.The decline is attributed to the higher inflow of foreign capital in the year. But the 1997 crisis, and emerging uncertainties due to wars and epidemics in the current year (2003), the situation has become more alarming. The major problem is of declining investment efficiency. As seen through incremental capital-output ratio that has gone up from 3.0 in 1988 to 6.5 in 1997 in the Malaysian economy, it critically warrants two things: Firstly, improvement in overall factor productivity and enhancement of efficient use of capital to lower down the incremental capital-output ratio. Secondly, the need to increase domestic investments to compensate for the declining flows of the FDI. The distress of 1997 reaffirm that the country also needs to structure to make it strong and stable, with an effective intermediary function, mobilisation of saving and productive allocations of the resources.

By and large, Malaysia's future depends on mitigating threats and converting the opportunities and building its strength, overcoming weaknesses through implementation of various strategies and initiatives at the local, national, regional and multilateral levels. There is also a need to revitalize and redesign management practices by evolving a Malaysian-centric style of management to motivate the Malaysian workers towards both 'hard-work' and 'smart-work' with greater devotion and sincerity for the betterment of self and society together. Imperatively, being an economy in the global setting, Malaysia has to maintain a stable, balanced macroeconomic environment through a 'mix' of prudent monetary exchange rate, fiscal and trade policies contributing to its expert-led growth strategy centered around the attracting foreign direct investment with due diversification, and to further reform and development of its banking and financial system. The country should tighten its linkages with China, Japan, ASEAN, USA, and with the European Nation as well as India, Sri Lanka, Africa, Egypt, Iran and Iraq in due course of time. It can gain trough 'Give and Take' Policy with the emerging markets of Asia and Africa.

In the first and second quarter of the year 2003, many Asian Countries including Malaysia have been subject to business drifts and slow down of their economies due to the war in Iraq and SARS. To promote growth and investments, Malaysia needs to deal immediately with certain issues such as implementation of the productivity-linked wage system, the abolition of the Automatic Pricing Mechanism, scrapping the (AP) Approved Permit (AP) control on steel products and cut on EPF contributions (Navaratnam, 2003).

The American Malaysian Chamber of Commerce (AMCHAM) observed that several investment projects have been missed by Malaysia on account of the failure of the Government Agencies in attracting large companies. Foreign investors have been frustrated over the many outstanding issues such as immigration hurdles, need for greater flexibility in equity structure requirement, reduction and simplification of the application and processing time for application for pioneer status. In this context, the Government should set up one-stop Foreign Direct Investment Center. (See Navratnam, 2003). The policy makers should endeavor to increase transparency, quick decision making, reduce bureaucracy, improve administrative efficiencies, and provide greater facilitation of business and foreign investment. If the public officials are not ready to change their attitudes and policy norms, the country will have to bear the fate of declining FDI in these days of stiff competition in the global economy. Though the country's economic fundamentals are supposed to be strong enough, the nation must gear up to meet the emerging challenges and uncertainties time to time.

Summing Up and Concluding Comments

This paper examined the major impacts of foreign direct investment (FDI) in Malaysia economy, following the review of growth trend of FDI during 1985 to 2001.

The flows of FDI have contributed substantially to the Malaysian economy's path on the emerging as a newly industrialized country within a short span of time. The country has provided a cost-competitive and growth potential environment for foreign investors. The Malaysian Government and its policy approach has always remained business-prone and market-friendly, by stressing on creation of necessary infrastructure, provision of incentives and administrative support for evolving a conducive environment for trade and investments

The results of empirical analysis in our study confirm the following hypothesises that:

- ?? GDP is positively related to FDI
- ?? Export volume has a positive trend in tandem with the flow of FDI
- ?? The FDI inflows have contributed positively in increasing the employment level in the country.

A number of policy implications follow form the study's findings. First, since FDI plays a positive role in Malaysia economic expansion, the government should continue to pursue the policies that encourage the inflow of foreign investment. Malaysian government should remain committed to its attributes of monetary and fiscal discipline essential towards macro balancing Regional integration will be a major explanatory factor of future patterns of FDI. Economic and political stability in Malaysia and its neighboring region is of the utmost importance if the region wants to attract FDI. Positive action should be taken to improve the country's eco-political risk rating to make it more attractive to foreign investors. This includes a wide range of policy options such as a reduction in crime, good governance and continued macroeconomic stability, besides the remarkable racial and social harmony of the country.

Stable economic environment is a pr-requisite for inducing FDI. Malaysia should continue to follow its course of fiscal, monetary, exchange rate and financial policies that has helped the country in macro balancing and creation of stable domestic economic and financial market conditions. Indeed, maximum benefit from FDI can be yielded in developing countries, which are free of domestic distortions such as financial depression and trade control. (Fry, 1993).

The policy-makers should encourage foreign -owned firms (F0Fs) to use locally produced inputs/materials a far as possible. Tax incentives may be given for using domestic inputs. Secondly export- led growth strategy of the country has shown positive results; therefore, activity of export-oriented F0Fs should be encouraged. Furthermore, for transformation of Malaysia's K-economy it is essential that F0Fs should be encouraged to participate in high-tech industries. The government should continue to follow its first wisdom and increase the share of expenditure on educational and labour training programme with a focus on human knowledge development in the country.

The Malaysian economy needs greater diversification in order to make it more resilient to the vagaries of the global trade cycles and the emerging and growing uncertainties of the world economic-political-social order. In the emerging knowledge-based economy, the flows of FDI will tend to be rising faster with a focus on the expanding service sector. Indeed, Malaysia has successfully marketed its services including construction, healthcare, education and tourism internationally. A further move in this direction will pay handsome rewards. Malaysia needs to revive its agricultural sector 5 as a move towards self-reliance and to check its food imports bills6. Malaysian agricultural sector can be upgraded and revolutionised through biotechnology. Malaysia needs to pose a long-term "Agrarian Policy Vision" to achieve self-sufficiency in food and other agricultural products through import substitution and thereafter creating surplus for export targeting. Indeed, the Malaysian Government has introduced the new agricultural policy[NAP](1998-2010) in this direction to improve agricultural productivity and output by dealing with problems of labour shortage, high labour cost, low productivity, need for modenisation of farming, production technology, storage, distribution network and marketing expertise and system. The country is aspiring to develop and exploit the potential as an international 'halal food-hub', pharmaceuticals, cosmetics and toiletries, and to utilise the rich biodiversity in due course of time.

In the Malaysia economy, time and again, the evolutionary process of FDI has excessively focused on production without bargaining much for transformation of technology. Alike other developing counties, the present kind of channelisation of FDI inflows in Malaysia is the least effective in preparing the Malaysian workers and entrepreneurs to meet the challenge of the new world of technological innovations. In the course of global FDI inflows a new trend is developing that the motivation of FDI is shifting from resource seeking to new advantages such as international alliances and innovation. Malaysia and other developing countries, therefore, have to change their policy strategies towards benefiting through such advantages. Investors also look towards more open and stabilization policies, simpler rules and regulations, transparencies and lesser government intervention in the market plays – unless inevitable for the preventive checks and positive results.

In Asia, Malaysia can be regarded as an attractive place to invest for her government has managed macro economic fundamentals commendably, She possesses a high level of skills, excellent infrastructure, improved corporate law enforcement, fewer and bigger banks, good governance of the financial institutions, harmonious, balanced and civilized multi-ethnic society, besides her exposure to lesser legal and political risks in comparison to several other counter-parts in the region. Malaysia should improve its Government public relations in exposing and justifying its policies and decisions containing hidden values to the prospective foreign investors from the West and elsewhere.

Chasing the Dragon: Accounting for the Under Performance of India by Comparison with China in Attracting Foreign Direct Investment

John S. Henley
University of Edinburgh, United Kingdom

Abstract

This paper compares and contrasts the performance of India and China in attracting foreign direct investment (FDI). Both economies are large emerging markets that had rather similar profiles in 1978. Today, China ranks number one as the world's preferred foreign investment destination. Closer examination of the FDI statistics suggests that India's performance has been significantly understated while China's performance continues to be overstated. However India still lags for a number of reasons. These include a high tariff regime, poor infrastructure (power, ports, roads and railways), a regulatory system that is too often not business-friendly, a policy of reservation of many potentially export-oriented sectors for small businesses and inflexible labour laws. The government's large budget deficit is preventing investment in necessary physical infrastructure yet India needs to increase the rate of private investment to enhance the economic growth rate and reduce poverty. The paper concludes that based on China's experience of promoting FDI, further economic devolution to state level is the best way forward. While this is likely to exacerbate inter-state income inequality in the short term, it does offer the possibility of redistribution in the longer term.

Introduction

Over the last two decades the policy stance of governments in emerging markets towards foreign direct investment (FDI) has changed dramatically. This has been brought about by the mounting evidence of the positive association of FDI with increased growth rates and in improvements in total factor productivity (TFP) [see, for example, 8, 12, and 13]. Notwithstanding calls for a nuanced assessment of the spillover benefits of FDI from some observers,[i] FDI is much sought after by governments seeking a catalysing boost to economic growth through technology transfers, employment generation, improved access to managerial expertise, global capital and product markets, marketing and distribution networks. Multinational enterprises (MNE) seeking a global rate of profit are generally unsentimental about where it is achieved. A concomitant of the global trend towards increasingly liberal trade and investment regimes and fierce competition to attract investors is the need for serious investment and leadership by governments and their agents at many levels, to create and maintain the necessary business-friendly policy environment.

This paper will examine why India and China that represent examples of very large emerging markets perform so markedly differently in attracting FDI despite the increase in the importance of global drivers behind FDI. Explanation will be sought in the way in which national and sub-national governments have gone about the task of promoting inward foreign direct investment. It will also consider how the governments of the two countries have faced the challenge of reconciling the many, often contradictory, interests of groups affected by economic liberalisation and foreign investment in the domestic economy.

Attracting FDI

Conventional analysis of the drivers behind FDI focuses on the distinction between horizontal market-seeking investment and vertical cost-minimising investment seeking a low cost production location [see 26 and 44]. A large and growing market that permits economies of scale is particularly attractive to market-seeking investment. Market servicing costs that favour foreign direct investment over exporting include the presence of import tariffs, non-tariff barriers, transport costs and local competition offering customer responsiveness.

The strategic logic behind production cost minimising through overseas location is based on segmenting the value chain and relocating those parts that can benefit from inexpensive inputs whether they are raw materials, intermediates or a lower unit-cost of labour. In general, since this type of overseas production rarely includes the entire value chain, but is part of a geographically distributed production network, it is invariably export-oriented. As the key drivers behind the investment are cost differentials between locations, there is sensitivity both to changes in technology and wage rates impacting on unit costs and to overhead costs and incentives associated with particular policy regimes. Although evidence is ambiguous as to whether fiscal incentives directly influence FDI because of the political risk attached, tangible benefits such as provision of cheap land and appropriate pre-start infrastructure are often considered to be necessary if not sufficient conditions for FDI of this type [38]. A competitive fiscal regime is, at the very least, interpreted as reflecting a positive official attitude to the needs of business.

Recent work [3] suggests that global factors have increased in importance in explaining FDI flows. Using a large cross-country time-series data set, they model the significance of worldwide sources of risk that drive FDI across several countries. They conclude that in recent years, developing countries' exposure to global factors driving FDI has increased steadily and is now approaching that of developed countries.[ii] They identify capital market liberalisation and integration as the key driver. While [3] argue global drivers are increasing in importance, domestic drivers (growth in local productivity, trade openness, financial depth, low government burden and macroeconomic stability) still account for a sizeable amount of inter-country variation in foreign direct investment.

The impact of FDI on growth is complex. First, growth occurs through capital accumulation and the introduction of newer technology, management systems and innovative products associated with FDI.[iii] Second, FDI improves the efficiency of locally-owned firms through contact and demonstration effects and exposure to increased competition. Third, FDI under the right economic conditions leads to technological progress through the introduction of new varieties of knowledge-based capital equipment. Fourth, the FDI 'package' proceeds through specific productivity-enhancing management development and skills training programmes. Fifth, just as local firms learn from contact with FDI so do governments, institutions and public service providers. MNEs bring certain expectations about the quality of the business environment and the cost of doing business in a particular location to the bargaining table with host governments. They are often in a stronger bargaining position than domestic firms from which to persuade the authorities to introduce the necessary reforms. Last, preconditions in recipient economies – a liberal and efficient business environment including infrastructure, quality of human capital stock and the complementarity of existing firms – improve the conversion of FDI into higher levels of output.

Comparing the economic performance of India and China

China is a natural comparator for India for obvious geopolitical, economic and demographic reasons (Table 1). They both have populations in excess of one billion – China at 1.27 billion and India with 1.03 billion people in 2001. According to the World Bank [53], on a purchasing power parity (PPP) basis, they are respectively the second and fourth largest economies in the world. In A T Kearney's September 2002 survey of the leaders of the world's 1000 largest corporations anticipated FDI intentions and preferences; China was ranked first, ahead of the USA for the first time, as the most attractive investment destination in the world. India was ranked fifteenth, down from seventh in 2001.

It is when changes in the participation of India and China in world trade are compared that one of the sharpest differences between the two countries is apparent. In 1978 external trade represented around 12 per cent of GDP for India and 10 per cent for China (Table 1). By 2001, India's merchandise trade amounted to 19.7 per cent of GDP and China's trade had expanded to 44 per cent of GDP reflecting China's emergence as one of the world's major trading powers. In 2000, China generated 4 per cent of world merchandise exports compared to 0.7 per cent from India (Table 3).[iv] In terms of merchandise trade, China ranked as the seventh largest exporter and eighth largest importer in the world in 2002.

A major difference in the composition of the output of each country is the relative importance of the contribution of the service sector, particularly computer software, in India. When trade in services is included, India's relative openness to trade improves significantly. Trade in goods and services amounted to 28.6 per cent of

GDP in the case of India and 47.1 per cent of GDP in China. Even so, in 2001, China was a bigger exporter of commercial services ranking as the world's twelfth largest exporter while India was nineteenth.

One of the most obvious differences in the trade regimes of the two countries is the tariff regime. The average Most Favoured Nation (MFN) tariff rate in China has fallen from well over 50 per cent in the early 1980s to 15.3 per cent in 2001 [45]. India's standard applied MFN tariff averaged 32.3 per cent in 2001/2002 and is amongst the highest in the world [57, p.31].[v] In addition, there is a Special Additional Duty (SAD) which is estimated to raise the unweighted average customs duty on all goods to 35 per cent in 2002/03 [53, p.53]. The government's stated aim is to reduce the simple average applied MFN tariff rate to ASEAN country levels of less than 15 per cent [57, p.5].[vi] However this poses a major problem for the government because of its heavy reliance on customs tariffs for tax revenue – 30 per cent of net tax revenue was derived from import tariffs in 2001/2002. By contrast, the Chinese central government only raised around 7.4 per cent of its revenue from import duties in the period 1995-98 (IMF, 2002). The potential benefits for India of liberalising trade in manufactures are clear. Wood and Calandrino [52] estimate, using China as a benchmark, that were India to reduce its existing barriers to trade, especially to exports, to Chinese levels it could double its per capita income and increase exports five fold within two decades.

Tariff reform would be a lot easier to implement in India were it not for the size and continuing deterioration of the fiscal deficit. The Central Government's deficit has risen from 4.2 per cent of GDP in 1995/96 to 5.7 per cent of GDP in 2001/2002, while the overall public sector deficit (which includes the deficits of the Centre, of States, central public sector enterprises and the oil pool account) was 10.6 per cent of GDP in 2001/2002. The overall revenue deficit was estimated at 6.9 per cent of GDP in 2002/03 [53, p.16]. This is larger than the crisis level of 1991 and is projected to go higher still in 2003/04. Partly this is because agriculture and the services sector, which make up more than three-quarters of Indian GDP go virtually untaxed unlike in China.

FDI Flows

One of the major drivers behind China's trade expansion has been foreign direct investment (FDI) so that by 2000, China's stock of FDI as a percentage of GDP amounted to 32.3 per cent compared to India's stock equivalent to 4.1 per cent of GDP, [47].[vii] Even if allowance is made for some inflation of Chinese FDI statistics, and some estimates suggest the figures may be inflated by as much as 30-50 per cent by "round tripping", there can no doubt about the significance of foreign direct investment for Chinese economic performance (Table 2 and Figure 1).[viii] According to Tseng and Zebregs [45], FDI flows to China have raised annual GDP growth by nearly 3 percentage points per year during the 1990s. In 1992, foreign affiliates contributed 6 per cent of total industrial output, 20 per cent of exports and 6 per cent of tax revenues. By 2001, they were generating some 23 per cent of total industrial value added, 48 per cent of China's total exports and 18 per cent of tax revenues [32]. Significantly, reinvested earnings constituted nearly one third of total FDI inflows in 2000-2001.

India's FDI statistics, prepared by the Reserve Bank of India (RBI), until July 2003 only recorded flows in the form of foreign investors' direct equity investments.[ix] There has thus been significant downward bias in Indian FDI statistics. An International Finance Corporation (IFC) estimate suggests that India's actual FDI inflow in 2001 was between US$5 billion and US$8 billion.[x] The Planning Commission Report [40, p.16-17] argues that if allowance is made for round tripping of FDI in China and under-estimation in India, then China's FDI inflow/GDP ratio at 1.8 per cent is *only* double the adjusted FDI inflow/GDP ratio for India. The provisional estimates released by the RBI in July 2003 indicate that FDI flows to India stood at about 1.3 per cent of GDP in 2001/202 declining to 0.9 per cent in 2002/03 compared with 4 per cent of GDP to China [53, p.49]. When disparities in the per capita GDP of China and India are factored in the volume gap widens much further.[xi]

Overall then, India's performance in attracting FDI is still modest in aggregate. Aspects of the business environment continue to discourage FDI flows on a scale commensurate with the size of the Indian economy despite all the liberalisation efforts since 1991. Perhaps it is India's misfortune to reach the mid-point of reforming national business legal and regulatory infrastructure at the end of a period of rapid world economic growth. Many observers believe that there is still much that needs to be done. Acharya [1] cites the anti-export bias of foreign trade policies, the rigidity of labour laws, the policy of reservations for the small-scale industry sector, the weakness of infrastructure (especially power, ports, roads and railways) and slow and cumbersome administrative procedures (especially customs and excise) as factors contributing to a sluggish industrial economy. Wei [51] estimates that if India reduced its level of bureaucracy and corruption to Singaporean levels, it could expect FDI 348 per cent higher than present levels (and in China, if the authorities could do likewise, FDI would be 218 per cent higher than current levels). Clearly if Wei's estimates are reasonably accurate, China also has some way to go in improving its business environment to Singaporean standards.

Sources of FDI

Table 3 reports sources of FDI flows to India and China in 1999. The information has to be interpreted with a degree of caution. Firstly, country of origin is as declared to the authorities in each country yet much of the investment goes through a process of 'two-stage round-tripping' making it very difficult for the authorities to collect meaningful country of origin statistics. Investment, which can originate anywhere in the world (Europe, Japan, US, etc. including India and China), may first go through a registered company in an offshore tax haven such as the British Virgin Islands or the Cayman Islands. It then passes through a subsidiary registered in Mauritius (for India) or Hong Kong (for China) or direct into the country concerned. For example, Mehta [28] reports that Enron's Dabhol Power Company in Maharashtra was controlled through six different companies registered in various offshore locations. Indeed, UNCTAD [47, p.25] estimates that as much as 40 per cent of total FDI inflows into Hong Kong in 1998 was 'Hong Kong-tax haven routing' and the British Virgin Islands became the fourth largest source of FDI in China during 1999-2000. Meanwhile, Hong Kong's FDI in the mainland has apparently been decreasing since 1998.

A second source of difficulty in making comparisons is that the Reserve Bank of India only publishes statistics relating to country of origin of FDI by RBI approvals. The conversion rate of RBI approvals to actual investment varies from year to year but appears to be rising. In 2000 it was just under fifty per cent compared to a 1991-99 average of around one-third, although this may be a function of a slowdown in the number of applications to the RBI for approval of new projects [34][xii]. In China, the Ministry of Foreign Trade and Economic Co-operation (MOFTEC) compiles FDI statistics. MOFTEC statistics inevitably exaggerate the significance of Hong Kong as the ultimate source of foreign investment because of the much greater significance of 'round tripping' of domestic capital and what Zhan, [58] describes as 'transit FDI' from elsewhere through Hong Kong.

Looking at Table 3, it is clear that Hong Kong plays a very important role in the financing of FDI in China. Whether this is as a transit centre for FDI or as an independent centre for mobilising finance capital is much less clear-cut. Mauritius plays a more limited role in relation to FDI into India functioning essentially as a tax haven. This is because India's capital market is much more developed than that of China and India's foreign investment regime provides 'national treatment' to all investors. There are corporate income tax advantages established in 1982 for Mauritius-registered companies operating in India but these are not dependent on specific policy instruments of the Indian government. A second feature is the importance of European Union FDI for India and the Asian Pacific Rim countries for China. Japan and Korea are also becoming increasingly important for India. Both India and China receive significant volumes of FDI from the USA. However as noted above it is difficult to establish whether country of origin statistics merely reflect the changing tax advantages of offshore registration. As China extends its policy of "national treatment" of FDI as part of the WTO accession agreement it is expected that round tripping of domestic capital will have all but disappeared by 2005. This, of course, does not mean that foreign investors will stop seeking to minimise their global corporate tax rate through judicious use of tax havens.

Sectoral distribution

When the sectoral distribution of FDI is examined, major differences between the two countries are apparent. Between 1991 and 2000, a quarter of approved FDI in India was for power generation, 18.5 per cent for mobile phone companies, and electrical equipment - mainly software - attracted 10 per cent by value. Manufacturing attracted 12 per cent of FDI approvals and, within that total, labour intensive textiles received only 1.4 per cent of approvals. In China, the majority of FDI went into the manufacturing sector – 60 per cent of total contracted FDI –

while real estate attracted 24 per cent. Within the manufacturing sector, according to Tseng and Zebregs [45], half was directed towards labour-intensive manufacture (textiles and clothing, food processing, furniture).

What is striking about the statistics is the impact of government investment regimes on FDI sectoral flows. India opened up the power and telecommunications sector in the 1990s to FDI while China has only recently begun taking tentative steps to allow FDI in these sectors. By contrast, India maintained a policy of reserving real estate development and the textile industry up until 2000, before introducing a gradual process of liberalisation. The retail sector remains closed to FDI in India, while China began permitting international retail investment after 1992.

Sectoral trends suggest that China's policy of opening up the manufacturing sector virtually without reservation has been effective in attracting FDI to the sector to take advantage of the low unit cost of labour, while preceding cautiously with liberalising the service sector (telecommunications, power, retail and distribution and financial services). This cautiousness as exemplified by the policy of only granting licences to foreign investors in restricted sectors in designated cities, has been tempered by a willingness to ignore infractions of the FDI regulations by powerful municipalities when it has been thought politically expedient to do so.[xiii]

In India, the private sector is much more developed and politically active than in China. Liberalisation of FDI equity caps has tended to proceed first in central government-controlled infrastructure sectors where the authorities are manifestly unable to finance the requisite investment (power, telecommunications, transportation infrastructure and large-scale urban development). The policy of reserving industrial sub-sectors for small-scale industries (SSI) particularly textiles, garments and leather is taking a long time to roll back because of political opposition and the threat to the livelihoods of millions of small producers.[xiv] Unel's [49] analysis reveals that the productivity of Indian manufacturing after the 1991 reforms increased sharply in the chemical, metal, machinery and transport sectors, while productivity in all the traditional sectors remained static or declined. He suggests that it is no accident that the sectors experiencing significant productivity growth have also been subject to competition from imports and FDI.

The list of SSI reservations contained over 800 items in 1991 and still contained 674 in 2003, although as a concession to large-scale exporters, a license can be obtained for manufacturing SSI-reserved products provided all output is exported. Perhaps the most crippling element of SSI policy is the cap on investment by SSI firms at Rs. 10 million for 610 reserved categories and Rs. 50 million for 64 reserved items.[xv] This has stunted the natural growth path of successful domestic SSI sector firms and deterred expansion of domestic operations and venturing into exports. Of course, many Indian entrepreneurs have built up their operations by artificially sub-dividing business units to fit under the capital cap but this inevitably adds to business costs. It also inhibits subcontracting and joint venturing relationships with foreign partners because of the limit it puts on scale efficiencies in the SSI sectors.

Indian retailing remains totally protected from FDI apart from very limited franchising, because of fears of the political consequences of retail consolidation. As the Planning Commission Report on Foreign Direct Investment (August, 2002) observed; 'The retail sector in India is dispersed, widespread, labour intensive and disorganised. In the light of this it is not thought desirable to lift the ban on FDI in retail trade' [40, p.46].

By contrast with their Indian counterparts, local government officials in China are incentivised by the central government to expand the penetration of FDI at provincial and city level and across selected sectors. The incentive comes in two main forms. First, provincial and city governments are under considerable competitive pressure from the central government and their peers to produce FDI statistics that demonstrate they are expanding inward foreign investment year on year. For example, local government officials have been known to court potential investors by offering to lobby central government for a licence on their behalf. Foreign-owned banks and insurance companies are currently only granted full licenses to operate in a small number of major coastal cities. Yet behind the scenes, provincial governors and city mayors elsewhere are campaigning hard to gain licences for foreign financial institutions in anticipation of greater liberalisation that is part of China's WTO accession timetable.

Second, foreign invested enterprises (FIEs) are an important source of local tax revenue. Local government officials derive their authority directly from central government but have delegated powers to enact laws "according to concrete local conditions and actual needs". Because central government has increasingly devolved spending responsibilities to local governments, while reducing their share of central government revenues, they have had to raise business taxes to meet the shortfall[xvi].

Local officials have been forcing private Chinese businesses, since the beginning of the introduction of economic reforms after 1978, to make ad hoc contributions to local infrastructure and social development. Officials expect FIEs to behave in a similar way [7]. Local Chinese bureaucrats have both administrative and legislative power so local taxes are subject to negotiation within the "sprit of applicable law and the Constitution" and many of the regulations are intentionally vague. As a result local taxes are not imposed on all enterprises at a standard, centrally set rate but are administered on an informal quota system. This lack of transparency can give rise to corruption and complaints from investors. However the fierce competition for FDI at municipality level seems to keep the worst excesses under control. For example, the mayor of Chengdu, the provincial capital of Sichuan in western China, has a monthly meeting with all foreign investors in the city. Before the meeting officials from city hall routinely telephone investors to ask if they have any complaints to make about the business environment.

In India, there is sensitivity to political opposition from large-scale domestic business interests. This is hardly surprising given the high concentration of ownership in the private sector. Bardhan [6] estimates that in 1996, the top 50 Indian business houses controlled 44 per cent of private sector assets. The great majority of the most valuable companies are family businesses. For example, Harriss [19] reports that in Chennai, of the 31 companies represented in the list of the top 500 Indian companies only five are not family businesses, while seven belong to a single family group. Up until 1991 and the beginning of liberalisation, big business houses rarely faced much competition in the highly protected industrial economy, did not need to be customer-oriented and invested little in product development. Joint ventures with foreign companies could be used to reap monopoly profits in the domestic market. Since 1991, many of the big family-controlled business groups are in crisis as a result of growing competitive pressure from MNEs. Harris reports sharp declines in capitalisation of the big family groups relative to MNEs operating in India.[xvii]

Big business groups are well represented at the highest level by trade associations such as the Confederation of Indian Industries (CII) and the Federation of Indian Chambers of Commerce and Industry (FICCI). Many industrial groups have extensive connections with the political elite, some dating back to support for the independence movement. As Encarnation [15] observed in his pre-economic liberalisation study of Indian business houses, many maintained what he styles 'industrial embassies' in Delhi to co-ordinate lobbying efforts. Domestic small-scale business interests impact more directly through political parties at State level. The BJP, the leading party in the ruling coalition, is well known for its small business connections in many northern states. The democratic political process has continued to constrain the authorities' capacity to develop policies to capitalise on India's comparative advantage in labour-intensive manufacturing and repeal totemic policies dating back to pledges rooted in the struggle for independence [4].

The power of China's industrial oligarchs is of more recent vintage than in India. It was recently recognised by the election of the chief executive (CEO) of the Haier Group, Zhang Ruimin, to become an alternate member of the Chinese Communist Party Central Committee in 2002. Most Chinese CEOs direct diversified conglomerates with many business units: some units may be joint ventures with foreign partners, some may be partially privatised (up to a maximum free float of 35 per cent of equity), while other units may be entirely state or municipal government-owned. Overall ownership control of these often extremely complex conglomerates remains vested in the state or a local government authority. Thus representation of Chinese domestic industrial interests in the political system is exercised, if at all, directly through the state apparatus. Where protection and support is provided, it is dispensed through that apparatus, typically through favourable treatment in the allocation of state resources such as land or access to credit from state-owned banks or a light touch by the regulatory authorities. This process is usually opaque which is difficult for foreign investors to challenge and the outcome has only a tenuous connection with considerations of economic efficiency.

Geographical Distribution of FDI

The geographical distribution of FDI in China is notoriously skewed towards the coastal provinces and Shanghai and Beijing municipalities. According to the OECD [37], the coastal provinces plus Beijing accounting for 64 per cent of GDP, attracted nearly 88 per cent of total FDI inflows between 1983 and 1998, while the central provinces attracted 9 per cent (21 per cent of GDP) and Western China received only 3 per cent of FDI inflows (15 percent of GDP).

The central government's policy since the early 1980s has been to selectively channel investment into infrastructure in support of inward FDI promotion, initially in the coastal region, while at the same time experimenting with new policy instruments in a limited number of locations before adopting them more widely. The first step was taken in 1980 to establish four Special Economic Zones along the coast, which offered potential foreign investors significant tax holidays, low tax rates and flexible administrative arrangements. In 1984, 14 coastal cities were declared open foreign investment areas. Since then the central government has gradually devolved power to allow provincial governments and municipalities to establish a wide variety of different 'special' investment zones across the country to attract FDI. China now has 49 national zones, complemented by hundreds of export processing zones, development zones, industrial parks and science and technology zones at municipality level [46]. After 1996, the central government began to relax restrictions on access to the domestic market and started to implement a policy of "national treatment" for FDI that will be completed by 2005 as part of the WTO accession agreement. A concomitant of this policy of introducing "national treatment" for FDI is the phasing out of tax concessions.

The outstanding success of this strategy in the coastal region and resulting disparities in quality of infrastructure and distribution of FDI from east to west is also reflected in widely differing levels of economic development. The Ninth Five-Year Plan (1996-2000) committed the government to introduce measures to redress regional economic imbalances. The Western Regional Development Programme launched in 1997 explicitly recognised that the remarkable development of eastern China in the 1990s now permitted the central government to redistribute resources from the east to develop the west through heavy investment in human capital and physical infrastructure. The policy initiative to develop Western China was again reiterated in the Tenth Five-Year Plan (2001-5).

Work by Buckley et al. [8] confirms that the significance of the growth effect of both domestic and foreign investment increases from the western region of China to the coastal region. Furthermore the relative growth impact of FDI rises from west to east. In the less developed western region of China, domestic investment is of primary importance, while in the coastal provinces it is the interaction of domestic and foreign investment that produces growth-promoting effects. They conclude that FDI favours growth in the economically stronger provinces of China and those endowed with superior infrastructure. The contribution of domestic investment to growth is important at all levels of provincial development. Dayal-Gulati et al. [11] are less sanguine about the role of domestic investment pointing out that the loan-deposit ratio by province has a negative impact on growth. They interpret this relationship as reflecting state-owned banks being required to lend to inefficient state-owned enterprises. By comparison with coastal provinces, central and western provinces have a disproportionate share of state-owned enterprises in their economies as a result of state industry dispersal policies adopted in the 1960s and as a consequence of the overwhelming concentration of FDI in coastal provinces.

Graham and Wada [17] suggest a more finely nuanced view of foreign investment patterns in the coastal region. They distinguish between non-Japanese Asian-controlled FDI (owned by the ethnic Chinese diaspora from countries around the South China Sea) that is primarily concentrated in labour-intensive, export-oriented activities and FDI from Europe, Japan and North America which tends to be concentrated in more capital-intensive activities targeted at the domestic market. They conclude that while total factor productivity has accelerated in the coastal region relative to other regions, if China is to optimise the potential benefits from FDI it is necessary to differentiate between the policy regime for export-processing FDI and import-substituting FDI. In so far as export-oriented FDI in China is routinely tested in the global marketplace for competitiveness the policy regime may generally be assumed to be satisfactory. The more problematic policy regime is that operating in the import substitution sectors which is famously opaque and unequal in its treatment of investors once they have established themselves in China. This topic will be returned to below.

Unfortunately there is no comprehensive record of Indian FDI stocks or flows at state level so that it is not possible to carry out conventional statistical and econometric analysis of determinants.[xviii] However RBI statistics do provide information on the declared location of approved FDI by state. As in China distribution of FDI in India is also skewed. Some 45 per cent of approved new FDI investment by value between August 1991 and May 2002 was destined for four southern states of Maharashtra (17.4 per cent), Tamil Nadu (8.3 per cent), Karnataka (7.7 per cent), and Andhra Pradesh (4.7 per cent) and Gujarat on the west coast (6.6 per cent). Delhi attracted a further 12.2 per cent of approved FDI. Only 16 per cent went to the remaining states.[xix]

Ahluwalia [2] presents data to demonstrate rising regional inequality in India as measured by an increase in the inter-state Gini-coefficient from 1986-7 to 1997-98. The main driver behind differences in growth rate at state level is private investment, which has a strong and significant positive correlation with growth. Public investment and plan investment had no discernible impact on growth. The high growth states identified by Ahluwalia are, unsurprisingly, the states that have been most successful in attracting FDI (with the exception of West Bengal, which paradoxically has experienced agriculture driven growth and private industrial capital flight).

Unlike in China there is no central government policy in India to direct infrastructure investment in favour of particular states or regions in order to promote inward FDI, though at central government level there is a general budgetary redistribution mechanism that operates between the wealthier and poorer states. Since the economic liberalisation programme began in 1991, the power to attract FDI has been devolved to states. This has been taken up with varying degrees of energy and success.

In 1997, the World Bank [55] could write enthusiastically about the complementarity of state-level development spending in support of attracting private capital investment. By 2003, the situation had deteriorated significantly. Revenue deficits have averaged more than 6 per cent of GDP over the last six years reflecting falling revenues and rising expenditures on interest payment, subsidies, civil services salaries and pensions. This has inevitably crowded out development spending. High real interest rates necessary to sustain the funding of rising government debt have also constrained private investment. Indian banks in 2003 had one of the highest ratios of government debt to deposits in the world [53, p. v].

In this situation, state governments find they have very limited capacity to fund the quality of physical infrastructure necessary to attract large volumes of FDI even though there is evidence of strong positive complementarities between public investment in infrastructure and private investment. For example, Oman [38] cites a study by Venkatsen of the correlation between the incentives offered by states and their ability to attract FDI, which concludes that the major determinant of investors' decisions in India is the availability of good quality infrastructure. A state's provision of incentives can "play a significant role in attracting private investment if, and only if, the state has a certain level of infrastructure available to support investors' activities"(p.46).

Despite the fact that India was a pioneer in creating one of the world's first export processing zones (EPZs) at Kandla in 1965, they have never had much impact on India's export performance. Tariff exemption schemes have tended to be excessively complex and encourage a 'licence raj' mentality at the operational level. The Central Government introduced a policy promoting fifteen Agricultural Export Zones (AEZs) and the enhancement of Special Economic Zones (SEZs) in April 2000.

Unlike the previous EPZ policy and reflecting the current reality of acute shortage of development funds, the private sector is expected to play the lead development role in the zones.

Work by Lall et al.[25], on the economic geography of industry location in India, concludes that the local presence of a mix of industries at district level is the only economic geography variable that has a significant, consistent and substantial positive effect for firms. This factor is significant for all sizes and sectors of manufacturing industry. The implication of this finding for India is clear. With the very modest public investment in industrial infrastructure that is possible given the size of current budgetary deficits, industrial growth is likely to continue to occur where a diverse manufacturing base has already become established, and where all kinds of private investment – foreign and domestic – is growing vigorously. This in turn is likely to have a positive impact on state-level capacity to invest in infrastructure, both because of the positive impact of growth on state revenues, and because various forms of private-public funding partnerships to develop infrastructure are likely to become more feasible. Nevertheless, any improvements in infrastructure investment are likely to be modest in comparison with, for example, even 'remote' western Chinese provinces such as Sichuan, which in 2001 alone invested US$ 20 billion in infrastructure. Sichuan's GDP is ranked tenth in China.

The critical importance of efficient physical infrastructure was recognised early on in the 1980s in the process of establishing special economic zones (SEZs) in the coastal region of China for foreign, export-oriented investors. By contrast in India, the share of infrastructure in fixed capital formation has declined sharply for nearly one and a half decades, [34], p. 1709.

Business climates compared

One of the paradoxes of India's FDI policy regime is that few restrictions apply to foreign-owned enterprises that do not apply to Indian-owned entities, yet the perception remains that business activity is over regulated and foreign investors are viewed with some suspicion, [40], pp.21-3. Apart from equity limits on a relatively small number of sectors, India extends National Treatment to foreign investors and so there is no specific statute to regulate foreign direct investment [57], p.22. However, it is a common complaint effectively orchestrated by organisations such as the Confederation of Indian Industries (CII) that one of the major barriers to investment in India, domestic or foreign, is excessive regulation of entry and exit. In surveys carried out by the World Bank Group, of a sample of firms in India and China [54 and 56], it was found that it takes 10 permits compared to 6 in China, and 90 days in India relative to 30 days in China, to start up a new business (see Table 5). [xx] When it came to a foreign-invested power plant in India, the survey [56] reports that it took 43 clearances at the central government level and 57 at the state level.[xxi] LaFarge apparently required 75 permissions to take over an existing cement business.

Widespread criticism of the Indian licensing system for business start-ups has sparked off reform in many states where the introduction of the so-called single window system of investment approval has been adopted and seems to be working well. For example both Tamil Nadu and Andhra Pradesh have adopted such a scheme and actively proclaim the involvement of the Chief Minister in monitoring the progress of large projects (more than Rs. 25 crores[xxii]). The Chief Secretary is responsible for tracking even quite modest new investment proposals (up to Rs. 25 crores). The state government of Orissa is committed to introducing a single window system in its new Industrial Policy [16], paragraph 5 and 6.

Once the deal has been done and the investor attempts to open for business in India, the 'inspector raj' is liable to move into action. While this may be a minor irritant for a large international company with good political connections, the management time that has to be devoted to dealing with an endless stream of inspectors can be a significant cost burden for smaller companies. The World Bank surveys estimate that in India it takes on average 16 per cent of senior manager's time to deal with government officials compared with 9.9 per cent of management time in China. Foreign investors do not seem to find this as burdensome as domestic investors because they rely on their local joint venture partners to deal with these intrusions or, in the case of a wholly-foreign owned subsidiary, a specially selected local manager to liase with officials. Nevertheless interview data suggest that foreign investors are also annoyed by visits from too many inspectors from different government department making surprise inspections and sometimes pulling up management on frivolous grounds. In its worst form, it is often little more than blatant 'rent collecting'.

Conclusions

The Indian authorities are beginning to actively promote an investor-friendly policy stance to the outside world. This rather belated policy response is driven by concern for the sustainability of growth rates of sufficient magnitude to lower poverty rates. When current levels of GDP growth of 5-6 per cent per annum are combined with a population growth rate of 1.8 per cent per annum, the Planning Commission estimates poverty will begin to increase, that is unless real GDP growth rises above 7-8 per cent per annum. Facing a government budget deficit of over 10 per cent of GDP, the authorities have very limited capacity to invest in growth. Additional growth can only come from increased private foreign and domestic investment. Unfortunately, private domestic investment is being squeezed by the government's high interest rate policy necessary to fund the budget deficit. This is forcing the authorities to look towards foreign direct investors. India's previous economic policy tradition of *swadeshi* (self-reliance) adopted after Independence in 1947 does not fit easily with current economic realities. Vested political interests continue to fight a rearguard action against the expansion of FDI in India. This is forcing the Union Government to proceed with extreme caution in opening up the Indian economy to FDI.

The best prospects for significant growth of FDI is occurring at state level where local accommodation to the realities of economic development is much easier in some states than others. For example, Andhra Pradesh, Tamil Nadu and Karnataka have been very successful in attracting FDI, particularly into the IT sector, by judicious investment in appropriate infrastructure and focused investment promotion and support activity through the state political and administrative system. The situation in traditional manufacturing is also beginning to improve but as indicated above many barriers to growth of FDI remain.

Whether India can catch up with China in terms of GDP growth rate, share of world trade or FDI seems rather problematic. However, in 1982, when China first began to actively seek FDI few would have expected it to be playing host to over $400 billion of FDI by 2002. Chinese infrastructure was then very backward and the authorities were still deeply suspicious of foreign investors. Few were certain that China would never return to the autarky of the past. Through a process of policy experimentation and encouraging economic devolution to provincial and municipal level, the authorities developed a mutually reinforcing system of incentives for state bureaucrats and foreign investors. Opposition to economic liberalisation was dealt with by sharing the benefits first with the urban population of the coastal provinces and then some 150 million economic migrants from the interior as growth accelerated in the 1990s.

India needs to further open up its economy to trade and foreign investment so the benefits of growth extend beyond the urban middle class beneficiaries of India's world class software and IT industries and beyond the highly protected workers in traditional manufacturing industry. Reform has to be seen to work at state and district level and this requires political leadership to drive an efficient state-level bureaucracy. There are a few Chief Ministers in India today who are providing that leadership. It remains to be seen whether their example becomes the dominant role model or whether caste-based politics focused on dividing up public sector jobs amongst supporters takes over from pragmatic pursuit of economic growth as the priority

End Notes

[i] For example, [43] argues that the effect of FDI on economic growth tends to be weak or even that much of the superior economic performance is driven by favourable domestic factors to which foreign investors respond.
[ii] [3] estimate the share of explained variance accounted for by their globalisation measure as 60 per cent for developing countries and 78 per cent for industrial countries.
[iii] The extent to which new products and technology are introduced is related to the motive behind FDI. Where there is only limited competition and the motive behind FDI is primarily market-seeking then the incentive for technology transfer is likely to be lower.
[iv] Indian industrial products amounted to 0.55 per cent of world exports in 2002/3 up from 0.5 per cent in 1990/91 [53].
[v] The average collected tariff rate was 21 per cent in 2000/01 down from 31 per cent in 1996/7. The collected tariff rate does not bear any direct relationship with the "marginal" tariff rate, which may even deter all imports under a particular category. It does include various exemptions. As a consequence collected rates do not reliably capture the distorting effects of the overall tariff structure.
[vi] China has already announced that its import duties are expected to average 9 per cent by 2005.
[vii] If flows of FDI are considered the gap between China and India narrows. According to UNCTAD, FDI as a percentage of gross fixed capital formation was 2.4 per cent for India and 11.3 per cent for China in 1999. It should be noted that FDI flow statistics are much more prone to volatility than stock statistics.
[viii] Wei [51] estimates that China's FDI stock figures should be reduced by 60 per cent and flows by 50 per cent, to take account of the Hong Kong effect and "round tripping".
[ix] Until July 2003, the RBI did not follow the standard IMF definition and excluded reinvested earnings, royalty payments, inter-company debt transactions and commercial borrowing by foreign direct investors. For example, BG plc announced in 2002 investments of £500 million in the oil and gas sector using loan financing but this investment would not have appeared in the Reserve Bank of India's FDI statistics. The equity capital of unincorporated entities such as foreign bank branches were also excluded.
[x] Estimate attributed to Guy Pfeffermann, Chief Economist of the IFC, in the Planning Commission FDI Report [40, p.16].
[xi] India's GDP per capita was $467 and China's was $855 in 2000, [45].
[xii] As Nagaraj [34] observes, 'Apparently, even the concerned official agency does not seem to know - let alone monitor - how actual inflows are translated in capital formation, transfer of assets or change in managerial control' (p. 1702).
[xiii] For example, in 1992, China agreed to allow FDI in retailing in 14 designated cities but by the late 1990s city authorities were openly flouting the regulations in a dash to attract FDI to the sector [5].
[xiv] For example, it is estimated that there are 12 million handloom weavers working in the State of Andhra Pradesh whose livelihoods would be put at risk if the weaving sector were fully opened to investment in integrated textile mills and a non-discriminatory tax regime for domestic and foreign investment.
[xv] US$1 = Rs. 47.3 as at May 2003.

[xvi] Blackman [7] reports that in the early 1980s expenditure by local governments was about equal to that of central government. By 2000, local government was spending at more than twice the central government rate and yet its share of central government revenue had fallen from 67 per cent to 50 per cent.
[xvii] Khanna and Palepu [24] suggest that the performance of Indian business groups initially declines with group diversification and subsequently increases once group diversification exceeds a certain level. Affiliates of the most diversified business groups outperform unaffiliated firms.

[xviii] Some might argue that the lack of visibility of FDI in state-level economic statistics reflects a deep-rooted ambivalence. However there is a general absence of reliable data at state level covering both domestic private and foreign investment. The Centre for Monitoring the Indian Economy (CMIE) does maintain a capex database but that has a number of weaknesses (see [2], pp. 11-12.).
[xix] 26.8 per cent of approved FDI is not allocated to particular states in official statistics though it seems reasonable to assume a similar geographical distribution to that for FDI where location is declared. (http://iic.nic.in/iic2_c03.htm)
[xx] Both the India and China studies are based on surveys of firms located in state or provincial capitals, ten in Indian states and five in Chinese provinces. There is no distinction made between foreign and domestic firms in the Indian sample.
[xxi] A more charitable interpretation of the licensing requirements for power plants might be that the authorities are trying hard to avoid the mistakes made over the Enron investment in the Dhabol power plant in Maharashtra which had a damaging impact on India's reputation as an FDI destination.
[xxii] Rs. 25 crores is approximately US$5 million.

Corruption, Trade and Foreign Direct Investment

Mohsin Habib
Leon Zurawicki
University of Massachusetts, USA

Abstract

The paper examines the effects of corruption on import, export and foreign direct investment (FDI). Countries are usually keen on attracting FDI for economic development. However, corruption can raise operational (and strategic) concerns for potential investors and sway their decision in favor of a less corrupt country over a more corrupt country. With regard to exporting to a country, corruption-induced operational issues can also have a similar effect. Importing from a country that is corrupt can lead to questions regarding overall productivity and commitment to product quality, delivery schedules, etc. Importers may view this as problematic if it starts affecting their relationships with distributors, wholesalers and retailers. The findings confirmed a negative relationship in all three cases. Corruption affected import and FDI the most followed by export. The existence of a high level of corruption in a country will hurt its chances of competing in the global market place. Policy makers in these countries must address the issue of corruption and attempt to allay the concerns of international companies and investors alike. The fact that corruption does not equally affect different modes of international business operations offers an important insight into the managerial decisions.

Introduction

Corruption is an endemic disease distorting international business. While not always illegal; corrupt acts reflect improbity—the breakup of sound, virtuous rules, and procedures applicable to social and economic life. It can take on different forms. While bribery and extortion can be the most common, such manifestations as dishonesty, misrepresentation, reneging on the commitments, passing on confidential information, nepotism, cronyism belong to the same category. Corruption manifests itself in the "petty" format but also reaches big dimensions—individual cases where large amounts of money are involved. It can be associated with mere "grease" activities aimed at easing the burden of bureaucracy as well as with operations that break the law. Corruption may occur at the points of contact between public administration and business and thus relate to the nature of regulatory environment, authorization procedures and the degree of public scrutiny. But corrupt practices thrive within the business world as well. All the facets of corruption make transacting international business more cumbersome, confusing and, ultimately, less efficient. The only beneficiaries are unscrupulous individuals or groups, who due to their position of control and power are able to extract private rents in the shadow of actual contracts. [1, 2, & 3]

Unfortunately, despite the resolutions by the international organizations such as the United Nations, the OECD, the International Chamber of Commerce and good will demonstrated by many MNCs in their codes of conduct, the malaise persists. Transparency International has been monitoring corruption since 1995 and the number of countries for which the corresponding indices have deteriorated does exceed the scores of nations where the indices improved. [4]

Literature Review and Hypotheses

The impact of corruption per se on international business did not emerge as a separate topic for empirical studies until the early 90-ties of the past century. Earlier, corruption was implicitly lumped together with other factors in the composite index of political stability. Following theoretical arguments pointing to the damage corruption inflicts on the economy; several studies looked at the impact of corruption on the inflows of foreign direct investment. [5] Findings corroborated the assumption that corruption is a detriment to FDI and hence a liability to the host economy. [6, 7, 8, & 9]

While it can be posited that corruption can also adversely affect the international trade (exports and imports), the subject has been hardly studied. The scarce empirical work published underscored a generally negative impact on trade. [10] Lambsdorff offers a more nuance approach in that out of the 19 exporting countries studied by him, some respond in relative terms better to corruption than others do. [11] The specification of his model –relative shares—does not allow for testing the overall impact of corruption on exports.

We believe that it is inconceivable to expect that corruption would across a wide array of cases prove an incentive to international business contracts regardless of its format. As a matter of fact we posit the opposite is true: corruption discourages international business transactions. Hence, the present work attempts to test the following hypotheses:

Hypothesis 1. Imports from the country of origin to the world are negatively affected by the level of corruption in that country.

Hypothesis 2. Exports from the world to the destination country are negatively affected by the level of corruption in that country.

Hypothesis 3. Foreign Direct Investment from the world to the host country is negatively affected by the level of corruption in that country.

At the same time, it seems logical that the adverse effects of corruption are the function of the riskiness of the type of the transaction itself. Hence we propose the following hierarchy:

1. FDI as the most complex and long term business commitment is by its nature and the capital involved the riskiest of international contracts—in any event certainly riskier than the export-import transactions. [12]
2. Import transaction is riskier (for the importer) than exporting. It involves much conditionality such as the quality of goods/services ordered, timely delivery, adequate insurance coverage, handling the warranty, maintenance and service. In a corrupt environment, all of these become a cause for potential problems with additional costs to resolve them. As far as exporting to the country characterized by corruption is concerned, the above concerns are handled in the country of the exporter and not directly affected by the characteristics of the importing country. Compared to the import transaction, exporting involves two additional concerns: 1/ securing payments, 2/ obtaining the import license (whenever applicable). Any problems in those areas with corrupt partner or respective administration may act as a deterrent. However, they can be alleviated when shifted upon other parties: financial institutions, the importing company itself. After all, the license needs to be obtained **prior** to the shipment of goods and the payment against the documents can be effected by the banks. Finally, in the buyer's market, the exporter needs to be prepared to accept higher risks while eventually attempting to beef up the price accordingly. Also, ever since Transparency International started compiling the Bribe Payers Index there is evidence of exporters using the tools of corruption to their advantage. [13] Except for sporadic cases of bribes paid to obtain contracts for limited raw materials, far less documentation exists with respect to the importers.

The above considerations lead us to formulation of the following two hypotheses:

Hypothesis 4. Corruption is a relatively stronger deterrent to FDI than to the international trade.

Hypothesis 5. Corruption is a relatively stronger deterrent to imports from a corrupt country than to the exports to such country.

Methodology

The sample of countries is chosen from the International Financial Statistics data set published by the International Monetary Fund (IMF). The data set is an annual publication. The country-specific data are updated regularly but usually lags a year or two due to the enormity of the task. Five years of data covering the period 1996-2000 is chosen for the study. This ensured fairly recent and comprehensive data for 89 countries. These countries represent a wide spectrum covering the developed, developing and transition economies of the world.

Trying to measure corruption is a serious challenge. First, objective measures are hard to come by and do not always fully capture the corruption phenomenon. For example, the magnitude and the frequency of corruption are not always found and presented in a single variable. Also, given that there are different forms of corruption, bribe and otherwise, it is difficult to find one source of data that can represent the whole range of corruption. These problems have reduced the application of objective measures in empirical studies.

Subjective measures have become a good alternative for researchers to analyze corruption. Questionnaire-based surveys are widely used for corruption. Transparency International (TI), the non-profit organization which vows to fight corruption worldwide, publishes the Corruption Perception Index (CPI) for countries around the world. This index is updated annually and is proven to be a reliable indicator of corruption. Its validity has been established when researchers found a high positive correlation between it and other subjective corruption measures. [14] The CPI index ranks countries on a 0 to 10 scale, with ten being the least corrupt. It has been used extensively by researchers and is adopted as the corruption variable in this study as well. For further details and a critique of the measure, see Husted. [15]

Data on country specific FDI are collected from the UNCTAD Foreign Direct Investment Online and measured in the US dollars (billion). [16] FDI is the annual inflow of foreign direct investment to the host country. Data on Import and Export are also collected from the International Financial Statistics Yearbook. Data for import, export and FDI are reported in US dollars (billion). Log transformation of all three variables are done and used in the analysis to make the distributions nearly normal and the error term homoscedastic.

Based on the international business literature, there are several macro determinants of foreign direct investment and trade. These macro factors are incorporated in the analytical model to extract the specific effects of corruption on trade and investment. A brief discussion of these factors is presented here. FDI and trade are positively influenced by the size of the host country's economy as measured by its population or GDP. [17, 18, 19, 20, & 21] For this study, country size is measured as the log of population. [22] GDP per capita is another significant explanatory variable for FDI and import representing the purchasing power of the host country. [23, 24] Log of GDP per capita is used here as a measure of a country's purchasing power.

Country-level unemployment figures have been considered a proxy for labor availability. [25] Under high unemployment, workers value their current job higher and are willing to accept lower wages to keep the jobs. Thus, a high unemployment would positively affect FDI. The same argument will also positively affect export from the target country. The unemployment data (percentage of population unemployed) is collected from the International Labor Organization. [26]

It has been shown that the duration of diplomatic and economic ties between the home and host country increases the likelihood of FDI. Greater interactions should promote understanding between the home and host country that is conducive to trade and FDI. Economic ties reflecting the home and the host country participation in the same common market areas (EU, MERCOSUR, NAFTA, and ASEAN) are included as a (dummy) variable in this study. Data was collected from the official membership lists of the regional blocs.

Geographic distance affects trade and FDI. Geographic proximity exerts a multifaceted impact, facilitating contact with target country and reducing the transportation costs. Also, in case of large geographic distance, the transportation costs encourage substitution of exports by market-oriented FDI. [27] The three prominent centers of trade and investment, USA, Western Europe and China are used to measure geographic distance. Three distance variables are included in this study. They are the distances between the target country and the USA, France (a middle point for Western Europe), and China respectively. The distances were obtained from Hengeveld. [28]

Finally, the presence of the corporate watchdogs in the host country is included as a variable affecting trade and FDI. It is expected that the presence of organizations such as Transparency International (TI) will improve the overall business and investment climate. Representation of TI in the host country was included as a dummy variable in the study. [29]

The five-year, cross-sectional data on 89 countries are pooled together for statistical analysis. A maximum of 445 observations for the variables was expected applying this method. However, missing values related to a country or a particular year resulted in less total observation for analysis.

An OLS (ordinary least squares) multiple regression model is adopted for the analysis since continuous variables are used in the study. A test conducted for multicollinearity among independent variables using the variance-inflation factor (VIF) did not suggest any serious problem. Table 1 reports the correlation coefficients.

Results

Three separate regression analyses are done for the three dependent variables. The dependent variables are log Import, log Export, and log FDI. The independent variables for all three regressions are the same. This provided an opportunity to compare the effect of corruption and other independent variables across the three models. Table 2 shows the results of the regression analyses. In column one the findings for the dependent variable log Import is shown. Column two shows the findings for the dependent variable log Export. And finally, in column three, the log FDI results are reported.

For log Import, the overall model is highly significant (F=146.87, p<.001). The adjusted R-square is 0.87, which is very high suggesting that the independent variables explain most of the variance in the dependent variable. The log Export model also is statistically highly significant (F=204.09, p<.001) with an adjusted R-square of above 0.90. Again, this suggests a good explanatory power. The last model, with log FDI as the dependent variable, is statistically significant too (F=39.28, p<.001). The adjusted R-square is not as high as the other two models but is quite good (0.64).

In all three models, the corruption variable CPI is statistically significant (at the p<.01 level or higher). This supports hypotheses 1, 2 and 3. Corruption negatively affects the FDI inflow as well as import to and export from a country. In addition, the findings further point to a difference in the magnitude of the impact of corruption across the three dependent variables. Looking at the standardized coefficients of corruption in the three regression models, it can be concluded that the impact of corruption is the highest for import (coefficient =0.233) and FDI (coefficient=0.228) followed by export (coefficient = 0.190). The findings that FDI is more influenced by corruption than export, partially supports hypothesis 4. The stronger effect of corruption on import than exports supports hypothesis 5.

Besides corruption some other independent variables showed significant results. As expected, market size (log population) and purchasing power (log GDP/capita) positively affected trade and FDI. These two variables are

* p < .05 , ** p < .01

well established in the literature and this study is no exception. Geographic distance from China is the only distance variable of the three which is statistically significant and in the right direction. Distance (from China) negatively affected trade and FDI. However, given that the other two distance variables failed to show significance, not much should be made of this finding. Economic ties showed positive significant results for both import and export but not for FDI. Trade, it seems is influenced by regional cooperation and economic development. FDI motives, on the other hand, seem to be far more complex and not bounded by regional economic agreements. Actually, it has been long emphasized in the literature that FDI is an instrument to overcome the investors' disadvantage of being from outside the regional economic blocs—the so called "tariff jumping." This factor might still play a role. Finally, the TI Chapter variable is shown to be significant for trade and FDI. A corporate watchdog such as the TI has a positive impact on businesses in general.

Discussion and Conclusion

This study tested corruption's impact on trade and FDI. The large number of countries in the sample provided diversity to generalize the relationships found. Specifically, the findings show that corruption in the target country negatively affects FDI. The higher the level of corruption is, the less the FDI coming into the country. Similar relationship exists for exporting and corruption. Countries targeted for export can expect less if the corruption level is high. Exporters do not view these countries favorably and would like to stay away from the hassles of dealing in a corrupt environment.

Also, the magnitude of the corruption coefficient for FDI is higher than the corruption coefficient for exporting. This implies that, ceteris paribus, the impact of corruption on FDI is greater that that on exporting. Companies from home countries view FDI as an entry mode requiring greater level of commitment and investment than exporting. This increased level of involvement translates into a higher level of risk (and uncertainty) for the concerned companies. As a result, various effects of corruption on strategic and operational decision making are taken much more seriously in case of FDI than exporting. For exporting, in comparative terms, there is less need for direct control. Once the goods reach the target country it is usually the importer's or an agent's responsibility. This typically relieves the exporter from further involvement. Also, exporting as an entry mode provides more flexibility (in strategic and operational matters) than FDI. Given that it requires less overall investment in the target country, a need to change can be made relatively easily. Exporting companies can adjust their market focus according to the corruption level of the target countries and in extreme situations can completely pull out of a highly corrupt country. Such decisions are much more difficult for companies involved in FDI. Also, our results suggest that dealing with corruption is an easier and less costly a task for the exporters than for the foreign investors. Considering that (some) exporters do offer bribes, it follows that doing the same regarding FDI is a more complex and cumbersome job. [30]

The study also tested corruption and its impact on importing from a target country. The results confirmed a negative effect between the two. Companies interested in importing from a target country are cautious about the corruption level that exist there because they want to ensure consistency with respect to the quality, pricing, delivery and other terms for the goods and services. Without having any direct control over the individuals and companies in the target country, it is quite difficult for importers to maintain standards for goods and services. A corrupt environment which raises the uncertainty level for importers and makes it difficult to pursue legal recourse or any other action (short of canceling the order and taking a hit) is a matter of serious concern. Companies are careful in pursuing any kind of importing relationship with a corrupt target country. A related finding in our study is that the magnitude of the corruption coefficient for importing is higher than the corruption coefficients for exporting and FDI. It seems that companies when buying from a country are far more concerned about the corruption and its impact than when they are selling or investing in that country. The fact that being on the one side of trade relation than on the other affects the sensitivity to corruption needs to be further explored and empirically tested.

The findings of this study have obvious implications for policy makers in the target country. At a minimum, policy makers in charge of developing trade and investment must understand the debilitating effect of corruption on the country's prospect. Business dealings can only flourish in a transparent and open market where the rules of the law are firmly established and trust can take hold. Corruption can destroy any hopes of building trust among business partners and the lack of proper regulatory institutions can further discourage potential investors. Policy makers must take strong measures against corruption. The development of trade processing zones with special procedures to combat unintended interference and corruption can be a fruitful approach. Providing incentives to rule enforcers for getting rid of corruption can be another option. At the country level, developing a good international image for business is essential to attract new partners and investors. Above all, strong leadership that can set good ethical standards is crucial in this respect.

Modeling Volatility and Forecasting the Mexican Stock Market Price Index

Francisco López Herrera
Universidad Nacional Autónoma de México, Mexico

Abstract

ARCH models have become increasingly popular on financial literature. This paper shows a study of performance of some ARCH models. First an AR model, allowing to accommodate time-varying volatility through ARCH effects, is used to capture the main stochastic features of historical returns of the Mexican Stock Exchange with two third of data in our sample. The time-varying volatility is accommodated by GARCH (1,1), TARCH(1,1), and EGARCH(1,1) models. Then a k-step forecast of the Mexican Stock Index is conducted with the remaining data. We find all the ARCH models succesful on reproducing the features of the index prices probability distribution. We conclude that models accommodating time varying volatility are a promising field of research.

I. Introduction

Is widely known that financial markets time series exhibit some stylized facts such as clusters of volatility, leptokurtosis, and "leverage effect". The clusters of volatility suggest significant temporal correlation of the volatility, i.e., the volatility observed on time t depends on volatility on time t-i. Leptokurtosis implies departures of the normal distribution that alters the probability density, in such a way that extreme values are observed with a higher frequency than that corresponding to a gaussian distribution. On the other hand, by the leverage effect, in financial markets is observed that a negative shock produces a higher level of volatility and a more pronounced fall in returns that the level of volatility and rise of returns when a positive shock occurs.

The ARCH model, introduced by Engle in 1982, was designed to model a process exhibing autorregresive conditional heteroskedasticity, so being an *ad hoc* mean to deal with the temporal dependence observed in the volatility of many assets returns. Nevertheless, as pointed by Peters [2001], a high-order ARCH model is required to capture the volatility's dynamic. To solve this, in 1986 Bollerslev introduced the generalized ARCH (GARCH) model. Despite the capability of ARCH and GARCH models to cope with the heteroskedasticity and leptokurtosis, both fail to capture the leverage effect, so, other models of conditional volatility were introduced, e.g., the Treshold ARCH (TARCH) and the exponential GARCH (EGARCH). This is not a exhaustive list, but only a sample of the several models included in the ARCH family.

The purpose of this paper is to present our first step on the evaluation of the capability of ARCH models to capture the main stochastic features of the volatility present in the returns of the Mexican stock market, and their usefulness to forecast the level of the main price index of this market.

This paper is organized as follows. In section II a conceptual model of the supposed data generating process is presented. Section III deals with the empirical study and shows the modeling results. Section IV concludes.

II. The Model

Assume that the price of an asset follows the discret process $P_t\ ?\ P_0 e^{?r_t\,,?\,t?}$, ? ?1; with a changing rate of growth, i.e., be the rate of return, r_t, a function of time. So, the relevant information available to any market agent is the set of past realizations of the process, and the conditional expected value of the rate of return can be expressed as $E[r_t \mid ?_{t-1}] = ?_t$, whose conditional variance is $E[(r_t - ?_t)^2 \mid ?_{t-1}] = ?^2_t$.

Some financial modelists represent the rate of growth as stochastic processes, sometimes with a member of the familiy of stationary ARMA models. If this is the case, the rate of return is made to depend on its past values and, or, the past forecast errors; i.e., r_t = $?_t + ?_t$, $?_t\ ?\ ?_0\ ?\ \sum_{i?1}^{p} ?_i r_{t?i}\ ?\ \sum_{j?1}^{q} ?_i ?_{t?j}$, p,q ? 0??As a result, $?_t^2$ = Var(r_t | $?_{t-1}$) = Var($?_t$ | $?_{t-1}$).

Turning the attention on the dynamics for one period, making ? t = 1, and taking natural logs in the original expression for the assumed process generating the prices data, we can obtain logP_t–logP_{t-1}= $?_0\ ?\ \sum_{i?1}^{p} ?_i r_{t?i}\ ?\ \sum_{j?1}^{q} ?_i ?_{t?j}\ ?\ ?_t$.

Under an ARCH process, we have $?_t$ = $?_t ?_t$, and $?_t^2\ ?\ ?_0\ ?\ ?_1 ?_{t?1}^2\ ??\ \ ??_m ?_{t?m}^2$, $?_0$?? ?, $?_I$?? ???I=1,2,…,m, and {$?_t$}?iid(0,1). The GARCH model of volatility is $?_t^2\ ?\ ?_0\ ?\ \sum_{i?1}^{m} ?_i ?_{t?i}^2\ ?\ \sum_{j?1}^{s} ?_j ?_{t?j}^2$, the effect of past volatility also accounts for the present volatility, not only the past shocks as in a ARCH model. Furthermore, now is required $?_0$?? ???$_I$?? ???$_j$?? ??and $\sum_{i?1}^{\max(m,s)} (?_i\ ?\ ?_i)\ ?\ 1$.

The ARCH asymmetric models allow for accommodating the asymmetry in volatility induced by the stronger effects of negative shocks (“the leverage effect”). For instance, Tarch model is $?_t^2\ ?\ ?_0\ ?\ \sum_{i?1}^{m} ?_i ?_{t?i}^2\ ?\ \sum_{i?1}^{m} ?_i ?_{t?i}^2 d_{t?i}\ ?\ \sum_{j?1}^{s} ?_j ?_{t?j}^2$, where d_{t-I} is a dummy variable equals 1 if $?_{t-I} < 0$, and 0 otherwise. The EGARCH model is $\log ?_t^2\ ?\ ?_0\ ?\ \sum_{i?1}^{m} ?_i \left|\frac{?_{t?i}}{?_{t?i}}\right|\ ?\ ?_i \frac{?_{t?i}}{?_{t?i}}\ ?\ \sum_{j?1}^{s} ?_j \log ?_{t?j}^2$.

Once completed the conceptual framework, next section is devoted to the empirical analysis.

III Empirical Study and Results

The series analyzed is the Mexican stock market prices index, known shortly as IPC, the main indicator of the Mexican stock exchange performance. The daily closing values of the index (from April 19, 1990 until February 10, 2003) were obtained from Banco de México website (www.banxico.org.mx). Not accounting for days in which the market exchange was closed, we have 3204 observations. Fig. 1 shows the index time path, which clearly suggests a nonstationary time series.

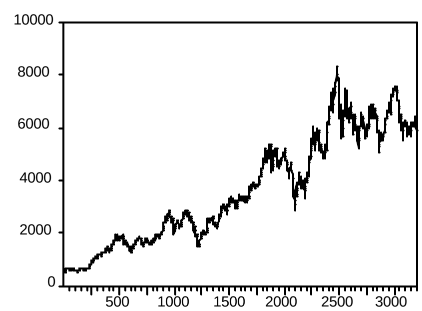

FIGURE 1. IPC TIME PATH

The correlogram for the first 200 lags sugessts a process with long memory effects, because the estimates of the autocorrelation function (acf) and the partial autocorrelation function (pacf) coefficients are 0.999 at the first lag, and at the lag 200 the acf coefficient is 0.782, although the pacf coefficient is only 0.008. The high and significant coefficients at the first lag show a high probability of a unit root process governing the series. So a formal test is at order. The modified Dickey-Fuller test, especified with five lags, an intercept and a deterministic trend, does not allow rejecting the nule hypothesis of a unit root process.

Transforming the series in natural logs first differences, *logIPC (t)-logIPC (t-1),* is a common design to get a stationary series, and, in a very conveniently way, we get an approximation to the rate of return. Fig 2 shows the new series obtained.

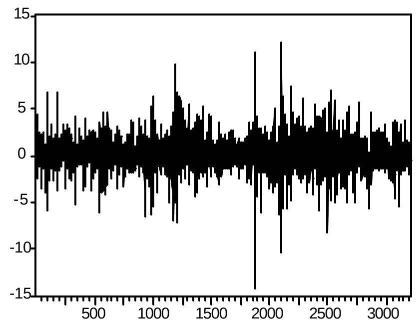

FIGURE 2. *logIPC(t)-logIPC(t-1)*

Now, the Dickey-Fuller test can reject an unit root process on the logs differences, inclusive at less than 1% of marginal level of significance (probability of Type-I error) the existence of a unit root test is rejected. The correlogram of this new series suggests an ARMA process, not being clear the *ad hoc* process to fit the series.

After estimation of several ARMA models with the first 2136 observations (two thirds of the total available sample), a model with significative AR parameters on the first and fourth lags is attained. It is worth to say that the fourth lag estimated coefficient results only significative at a 10%, but its inclusion to continue in our analysis was decided because it produces apparently white noise distributed residuals, as shown by the corresponding correlogram and Ljung-Box test. On the other hand, the correlogram of the squared residuals exhibits some signals of dependence, as shown by the high significant Ljung-Box tests, although acf and pacf with a relatively small absolute value are observed. This dependence is confirmed by a strongly significative Lagrange multiplier test failing to reject the nule of non-existence of ARCH effects, inclusive at a less than 1% marginal significance level (m.l.s.).

The evidence at this point is that ARCH models can be natural prospects to model the volatility of the Mexican stock market returns. An estimation of a GARCH(1,1) model, with Bollerslev-Wooldridge consistent covariance matrix to get homoskedastic errors and right estimated standard errors, shows significative coefficients on the variance equation but an insignificant fourth lag AR parameter in the mean equation, being significative the remainder parameters in the latter. The estimated ARCH and GARCH effects parameters (0.177315 and 0.773657, respectively) are higly significative (less than 1% of m.l.s.), and their sum equals 0.950972, suggesting persistent volatility on the estimation time horizon. Removing the non-significant coefficient the results are essencially the same, suggesting that a robust estimation has been made. Both the inspection of the correlogram and Ljung-Box test shows white noise residuals. The Lagrange multiplier test fails now to reject non ARCH effects.

A joint test, intended to discern if exists dependence of the fitted models squared error on their own past values and if the bias of such errors induced by the sign of past values is significative, was conducted. The evidence drawn from an auxiliar regression points out that it does not matter the sign of the past errors but a higher weight and significance in the case of negative past errors. Thus, two additional models of conditional volatility are specified and fitted: a TARCH (1,1) and an EGARCH (1,1) models, both incluiding an AR(1) specification on the mean equation.

It is worth to note that the main results are the same as in GARCH estimation but the intercept is now weakly significative in TARCH model and it is not in EGARCH model. Both models exhibit evidence in favour of asymmetric effects. Particularly, the EGARCH model coefficient capturing the “leverage effect” is highly significative. Removing the intercept in the EGARCH model mean equation keeps the results unchanged for practical uses. On the other hand, the persistence of volatility in the Mexican stock market returns is shown again. Test of the null $\{?_t\}$?iid(0,1) were conducted (t and z tests for mean; chi-squared test for variance), not being able to reject it for any of the three ARCH models.

The fitted models in-sample forecasting capability was evaluated (see Table 1). Being too similar, is convenient to point out that the EGARCH model shows a better adequacy in terms of the decomposition of the mean squared error, but only in a marginal sense.

TABLE 1. FORECASTING PERFORMANCE MEASURES

	GARCH	*TARCH*	*EGARCH*
ROOT MEAN SQUARED ERROR *	104.7493	104.5301	104.5653
MEAN ABSOLUTE ERROR	78.51273	78.24245	78.2202
MEAN ABSOLUTE PERCENTAGE ERROR	1.3112219	1.307541	1.307102
THEIL INEQUALITY COEFFICIENT	0.0085444	0.008529	0.008535
BIAS PROPORTION	0.004779	0.001103	0.000065
VARIANCE PROPORTION	0.001450	0.001084	0.000768
COVARIANCE PROPORTION	0.993771	0.997814	0.999166
**FORECASTING STANDARD ERROR*			

Then, using the remaining 1068 observations, *ex-post* k-steps forecasts of the level of the Mexican stock exchange index were made. In accordance with the interval forecasts, at 95% of confidence, less than 5% of each model predicted values lies out of the limits stated at two standard deviations, as expected if probability of making Type-I error is fixed equals or less than 5%. Sligthly, asymmetric (TARCH and EGARCH) models are the best performers.

Comparison of some statistiscal measures describing features of the IPC observed values against the predicted level index values by the ARCH models deserves some commentaries. Seemingly, the probability distribution of observed values on the market is reproduced fairly well by forecasts based on ARCH models. Table 2 shows figures of some statistical sample features.

TABLE 2. IPC, AND FORECASTED GARCH, TARCH AND EGARCH SERIES: SOME STATISTICAL MEASURES

	IPC	GARCH	TARCH	EGARCH
Mean	6057.621	6064.862	6061.092	6056.777

Minimum	3300.420	3272.661	3270.085	3265.123
Standard deviation.	912.7699	916.7604	916.2126	915.6699
Skewness	-0.588678	-0.582731	-0.582631	-0.582142
Kurtosis	3.544881	3.529189	3.529168	3.529066
Jarque-Bera normality test	74.89625	72.90613	72.88463	72.77844
(J-B) Probability	< 1%	< 1%	< 1%	< 1%
Observations	1068	1068	1068	1068

As Table 2 shows, at forecast horizon, mean, median and standard deviations of EGARCH forecasted index values are closer to observed values than the other two models. In this sense TARCH outperforms GARCH. Nevertheless, the latter works better in describing skewness and kurtosis of the values observed on the market. The F tests of means do not let us reject equality of the observed and predicted values. Similar conclusions were reached on tests of equality on medians (chi-squared, van der Waerden, and Kruskal-Wallis tests) and variances (Bartlett, Leven, and Brown-Forsythe). In general, the three models behave fairly well in the attempt to reproduce the main statistical features of the observed stock indexvalues sample distribution. Nevertheless, note that, as shown in table 2, all three models overestimate the maximum and minimum values, i.e., they show a trend to forecast more extreme values than observed.

IV. Concluding Remarks

ARCH family models have received a lot of attention by reasearchers and practicioners. Suggested uses go from academic finance research to applications intended to quantify the assets market risk through the measurement of a changing volatility.

Over twelve years of daily closing values of the Mexican stock exchange prices index were studied. It is found that analyzed ARCH models offer a good description of the index series when time-varying volatility estimated with such models is accommodated in the rate of growth (return) according to a theoretical growth equation.

In a very optimistic view ARCH models seem good candidates to study the main stochastic features of the Mexican stock exchange prices index. In short, they could be a good option to represent the unknown data generating process governing the realizations of some financial series. Thus, more reasearch on the ARCH familiy models is warranted, especially since some features of these models are not well known yet.

The Bargaining Gap: Explaining the Stability of Domestic Foreign Investment Regimes and the Limitations on State-MNE Bargaining in a Globalized Economy

Paul Alexander Haslam
Canadian Foundation for the Americas (FOCAL), Canada

Abstract

The 1990s have been characterized by a remarkable lack of state-MNE bargaining and overall stability and further liberalization of foreign investment regimes at the national and international level - a state of affairs that is poorly explained by the liberal bargaining model. The paper considers two cases of state-firm bargaining that occurred in Chile and Argentina in the late 1990s in the mining sector in order to assess the limits to the liberal bargaining model, and the explanatory relevance of recent attempts to re-conceptualize it. This paper develops the concept of the "bargaining gap" to represent the shortcomings of the obsolescing bargaining model. It suggests that host countries determine their bargaining preferences with reference to expectations regarding future FDI inflows, not the single investment in question.

Introduction

Over the last thirty years the rules and regulations which govern foreign direct investment in most developing economies (and in the developed world too) have become increasingly liberal and fixed - regardless of the combination of assets (or lack thereof) held, and strategies pursued by the foreign investor. This is a global trend which began with Chile's unilateral adoption of its foreign investment statute in 1974, and subsequently has been promoted on a global level by the United States in bilateral investment treaties (BITs) and international organizations such as the World Bank's Multilateral Investment Guarantee Agency (MIGA), the Organization for Economic Cooperation and Development (OECD), and the General Agreement on Tariffs and Trade (GATT). Such fixed rules have liberalized the investment climate to the extent that there are very few restrictions on foreign direct investors and even less opportunity for host country-multinational enterprise (MNE) bargaining as governments are increasingly tied into a web of international commitments. The global reality is that government policy towards MNEs is now as liberal as it was during the 1950s.[1]

However, these changes have only been reflected in the bargaining literature to a limited extent. This paper examines two case studies of host country-MNE bargaining in the mining sector in Chile and Argentina in the late 1990s. Contrary to the expectations of the obsolescing bargain, attempts to renegotiate the investment bargain were frustrated by the central governments in both countries, which preferred to demonstrate their commitment to the stability of the "rules of the game" than extract more surplus from the foreign firms. Building on the insights gleaned from the case studies, the paper proposes the concept of the "bargaining gap" as a way to understand the limited nature of host country-MNE bargaining in the 1990s.

Wither the Obsolescing Bargain?

The liberal bargaining model pioneered by Raymond Vernon (1971) and Theodore Moran (1974) saw the inevitable conflict between the national interest of the host country and the global interests of the multinational enterprise as resulting in state-firm bargaining over the terms of investment at the entry, operational, and exit stage of the investment (how they would share the expected economic rent).[2]

The bargaining model assumes that there is a potential economic rent (both profits and non-tangible benefits called externalities) from any individual investment by a foreign firm. The TNC and the state determine how they will share the expected rent by bargaining over the terms of the investment. Each determines its bargaining position by assessing what it wants from the other party. Bargaining power is conferred by having some asset that the other party wants, and for which it cannot easily find a substitute. For example the firm may possess capital, technology, managerial expertise, proven access to export markets, while the state may possess human capital, internal market, or unique natural resources. The bargaining outcome that results should be a compromise based on strategy (wants) and structure (power resources and constraints) of the actors.[3] Moran assumed that the original bargain granting the firm access to the country would favour the firm, which received a risk and scarcity premium for its investment. With the passage of time, once the firm had sunk its investment, and the government progressively improved its ability to regulate and even run the industry, the pressures to renegotiate the investment terms in favour of the government increased.[4]

The Resourceful Enterprise

Since this thesis was articulated, however, there has been considerable doubt as to whether the bargaining model accurately described the state-firm relationship. There is little doubt that the original view expressed by Moran and others, that the bargain inevitably obsolesced in favour of the state could not be generalized to any industry beyond the mining sector, or the temporal period of Moran's study which ended in the early 1970s.[5] A series of studies conducted in the 1980s showed that MNEs were particularly innovative in avoiding attempts to renegotiate the original investment bargain.[6] Manufacturing firms, in particular, had a greater range of policy options than extractive industries when faced with government pressure, including manufacturing new products, adding more value, incorporating more technology and even changing the product.[7] Furthermore, firms could avoid an effective loss of control, even if forced to become minority shareholders, through a variety of strategies, including retaining control of strategic functions of the firm.[8] The formation of alliances or links with domestic business groups and government departments or elites could also be an important source of defensive power.[9]

The empirical evidence from the 1990s has further undermined the claims of the liberal bargaining model – the decade was characterized by a remarkable lack of state-MNE bargaining and the further liberalization of foreign investment rules. One the one hand, new research has proven that the period of expropriations was limited both in time and geographically. The "mass" expropriations, which had characterized the 1960s and 1970s, were in fact limited to a small number of regimes (28) and by the 1990s it was possible to claim, without hyperbole, that expropriation was no longer a serious threat to the multinational enterprise.[10] The United Nations *World Development Report* confirmed these observations in its overview of trends in foreign direct investment legislation. Of the 1035 regulatory changes to national legislation governing FDI that occurred between 1991 and 1999 only 5.9% were in the direction of greater restriction on foreign investment.[11] The signing of bilateral investment treaties between countries in the 1990s (96 countries signed BITs in 1999 alone) also extended the legal protection enjoyed by MNEs.[12]

To Bargain or Not to Bargain?

The change in state-firm relations and decline in the relevance of the liberal bargaining model has been addressed in the literature through what may be categorized as three major currents which, in terms of their approach to bargaining in state-firm interactions, may be categorized as asserting the irrelevance of bargaining; the displacement of bargaining; and the maximization of bargaining power.

Many theorists assert that bargaining no longer defines the MNE-host country relationship, and that the (relative) irrelevance of bargaining is reflected in a shift from a conflictive relationship to a more cooperative one.[13] Governments and firms are viewed as increasingly interdependent in realizing wealth and competitiveness in the global marketplace.[14] Recent research has also demonstrated that reducing the restrictions on MNEs can help better integrate them into the global competitive strategy of their parent companies. When this occurs, local subsidiaries are more likely to employ the latest technology and managerial techniques – which have greater spillover effects on the local economy.[15] The central argument is that the strategy of both the the government, has changed since the era of "mass expropriations." Edward Safarian writes, "The key to the new [liberal] approach to TNCs [MNEs] is that policy on FDI and policy on endogenous growth have converged. TNCs are regarded as central to the creation and diffusion of knowledge, within and between firms, and in cooperation with Governments."[16] That is to say that firms have shifted from resource and domestic-market seeking strategies – contentious with nationalists everywhere - to efficiency (or strategic-asset seeking) strategies, at the same time that countries have rejected the import-substitution model in favour of a more liberal and export-oriented approach.[17]

Secondly, the apparent absence of state-firm bargaining in the 1990s may be due to *displacement of bargaining* to other arenas. Ravi Ramamurti argues for a "two-tier" model that takes account of the bargaining which occurs between states in the bilateral and multilateral arena. He suggests that state-state bargaining shapes international investment regimes in such a way that it limits the range of state-firm bargaining options. In this conceptualization, strong states (in the international system) enhance the bargaining power of their firms everywhere.[18] It is true that the aggressive promotion of liberal international rules on foreign direct investment by the United States, and such dominant international agencies as the the IMF, WTO, World Bank's Multilateral Investment Guarantee Agency (MIGA), and the would-be Multilateral Agreement on Investment (MAI), has been accompanied by the adoption of such rules by developing countries.[19]

Furthermore, while national investment rules may be stable, there still exists considerable flexibility in some other areas. Privatization frameworks may be separate from FDI legislation and can demand the fulfilment of specific obligations which vary according to the firm being privatized.[20] In addition, the wave of foreign investment in public services since the mid-1980s has meant the government must play a larger regulatory role than when these industries were state-owned firms. Regulation also offers the possibility of significant discretion (and therefore bargaining) over key issues such as pricing policy.[21] Likewise, other areas of legitimate governmental intervention, such as labour legislation, tariff rates, R&D policy, and subsidies may also be bargaining opportunities.

The third approach explains the failure of bargains to obsolesce through the *dominant bargaining power* of the MNE. In this scenario, either the MNE enjoys greater power resources than the state, or there are constraints which limit the state's ability to act, or both. In mining and other extractive industries, for example, MNEs have reduced the likelihood of obsolescence through project financing their investments and using "prominent victims" such as international banks or multilateral institutions as financial contributors or guarantors. In such cases, expropriation of property, or renegotiation of contracts would be a "crime" not only against the particular firm involved, but also heavy hitting backers such as the World Bank's International Finance Corporation.[22] The use of cross-fault provisions in project financing mean that a host-country default on a IFC loan or guarantee could put other World Bank disbursements at risk, as well as a loss of reputation in other institutions which share directors with the IFC.[23]

Certain structural characteristics of the TNC organization and its particular insertion in the host country economy also strengthen the power of the firm relative to the state. It is a unique source of high technology and knowledge. Global integration of activities may mean that any given investment is an insignificant part of the TNC's overall structure. Production for export may make the firm more "footloose" and willing to close its operations if the terms of its investment are revised. At the same time the host-country is subject to an expanding web of commitments at the international level, which constrain its domestic actions. As a signatory to sovereignty limiting treaties such as the WTO and MIGA it must abide by certain rules regarding foreign investment. If it runs a deficit which requires stand-by loans, or seeks to renegotiate outstanding debts with creditor banks and countries, it must abide by IMF conditionality. Interestingly, much of the anti-globalization movement, arguing that the state is increasingly hostage to international capital in the era of globalization, accords with this position.

A Tale of Two Bargains

The limits on state-firm bargaining in a context of globalization, and the explanatory relevance of the approaches identified above will be examined through a comparative study of the obsolescing bargain in the mining sector in Chile and Argentina in the late 1990s. The mining sector, a long-standing nationalist lightning rod with enormous sunk investments has, since the early work of Theodore Moran, been considered the paradigmatic example of the obsolescing bargain. Mining, and natural resource extraction for export in general, is also likely to be least sensitive to many of the factors identified above as limiting the bargaining power of the state. As the sector in which, according to theory, the obsolescing bargain is most likely to continue to exist, it is an ideal empirical test of its continued relevance.

With the advent of the military governments in 1973 and 1976 in Chile and Argentina, came newly liberalized foreign investment rules. Both Chile's DL600 and Argentina's Law 21, 382 have set the basic rules for foreign direct investment up until the present day. Although the Argentine legislation went through some modifications in the 1980s and 1990s, the stability of Chile's legislation has been unrivalled in the world. It has frozen the rules and regulations regarding foreign investment in Chile for over 26 years. Such fixed rules have liberalized the investment climate to the extent that there are very few restrictions on FDI and fewer opportunities for bargaining. This is even true in mining, which has been the classic example of the obsolescing bargain in state-firm relations.

Nonetheless, there have been occasional attempts to challenge the existing division of economic rent between the state and multinational mining companies. This section discusses two of these attempts: the 1997 tax reform proposal in Chile; and the 1997-2000 royalty dispute between Minera Alumbrera and the provincial government of Catamarca in Argentina. In both cases, renegotiation of the original bargain failed despite an objective increase in the bargaining power of the state since the original contracts were signed. The principal reason in the two countries, was the state's fear of damaging its reputation by changing the "rules of the game."

The Villarzú Tax Reform Proposal

In late 1997, in Chile, there were some indications that the ruling *Concertación* government intended to renegotiate the terms of its investment bargain with foreign firms in the mining sector. The initiative originated with a respected member of the government. In October of 1997, former president of the state-owned copper company, CODELCO, and then Secretary to the President (the second ranked position in the government), Juan Villarzú proposed that a special tax be levied on the "exploitation of non-renewable resources" in Chile.[24] This initiative, known as the Villarzú proposal, was a response to a popularly held view that the foreign mining companies operating in the country were not paying sufficient tax on profits to the government. The government's interest in pursuing this matter was later confirmed by the then-Minister of Mining César Díaz Muñoz. Villarzú broached the subject once again in February of 1998 while attending the World Economic Forum in Davos, Switzerland. Nonetheless, the contours of the legislation remained fairly vague, and the government only committed itself to conduct a study into the implications of a new tax, which included an assessment of some of the means used by mining companies to reduce their tax burden (accelerated depreciation, and use of the mining claim fees – *patente*- as a credit against taxes).[25] The proposed tax was to be applied only to new investments in Chile, not firms which had already established operations.

The debate around the Villarzú proposal was more than a debate about the suitability or legitimacy of certain kinds of taxes on the mining sector. At its core, it was about the nature of the foreign investment strategy. Was it necessary to channel FDI through instruments such as extra taxes, in order to increase the contribution of mining to economic development (as was believed in Chile prior to the dictatorship)? Or was it more important to establish the basic legal conditions to attract foreign investment? Party for Democracy (PPD) Senator, Sergio Bitar underlined this problem in a debate on the subject organized by the local mining magazine, *Minería Chilena*: "It will be difficult to repeat this mining boom, so the question is how do we transform mining into a lever for economic development which goes further."[26] Although some industry leaders recognized the need to increase the contribution of mining to development, mining executives as a whole unambiguously decried the government initiative as uninformed, discriminatory and negative for the industry. Hernán Hochschild, President of the National Mining Society (SONAMI), the association representing privately-owned mining companies, characterized the Villarú proposal as "the most negative fact of the decade for SONAMI."[27]

As previously indicated, the logic behind the Villarzú proposal was the need to compensate for the supposed failure of foreign firms to pay profits taxes to the government. This argument emphasized the contribution of state-owned CODELCO to national development, and simultaneously cast great doubt on the current and future contributions of the private mining industry. In the mid 1990s, CODELCO was contributing more than $US 1000 million per year to the national treasury, while the private sector contributed much less, approximately $US 300-350 million (despite producing almost twice as much mineral).[28]

The mining sector, due to its historical importance in the Chilean economy, and the staggering sums of money invested in the country, had attracted much nationalist attention, and criticism for not meeting the developmental needs of the country. Examples such as Exxon=s Disputada de Las Condes, widely understood in media, government and business circles as not having reported profits in a single year between its initial investment in 1978 and 1998 fuelled this resentment.[29] Suspicion of foreign firms was also enhanced by the failure of most TNCs to publish their annual financial results. Most mining firms in Chile were not publicly listed companies, and consequently were not required to make their finances public. Mining executives tended to view this criticism as the result of misunderstanding the nature of the industry. One mining executive put it this way:

This industry is not as high margin as people think, but it moves massive amounts of money...verything is enormous, contracts, etc, and that mesmerizes people, they forget how much you invest, and that sometimes copper is at $1.20 and sometimes 70¢, which makes a big difference on the return.[30]

The Villarzú proposal faced an immediate reaction the mining sector. Representatives from the largest companies organized a powerful lobby group with the assistance of Senator Ignacio Pérez Walker, a member of the congressional Mining Commission and the right-wing party, Renovación Nacional (RN). A three-pronged strategy was designed in which separate efforts targeted the internal fractures between the parties composing the governing *Concertación* including Ricardo Lagos, leader of the Party for Democracy (PPD); the highest ranking members of the Christian Democrats including the Minister of Economy Eduardo Aninat and then-President Eduardo Frei; and consensus was sought among mining firms and the regional centres of mining activity. Mining firms also agreed among themselves (once checking that the numbers supported their argument) to open their accounts to public scrutiny. This was a key element in making the technical argument that extra taxes were unnecessary and inadvisable. The lobbying effort culminated in a personal meeting between Ignacio Pérez Walker and President Eduardo Frei on December 29, 1998.[31]

The Villarzú proposal was opposed by all the mining executives interviewed for this study on 2 bases: a technical argument, that payment of the profits tax had only been differed until amortization payments were completed; and secondly, a philosophical argument, that the refom "changed the rules of the game" and threatened to undermine Chile's reputation as a good investment climate.

On the first point, the Chilean legislation permitted accelerated depreciation of the amount invested. Only when enough financial profits had been earned to pay down the investment will real (taxable) profits be generated. Such accelerated amortization rules are common to many countries including Canada and Argentina, and are intended to act as an incentive for investors. When combined with taxation rules that specify a higher rate for repatriated profits (in Chile it is 15% on tax base, and an additional 20% on repatriated profits), it is a strong incentive for companies to reinvest in the country (instead of taking profits out). Thus, in Chile, mining companies were simply responding to the investment incentives created by the government - although admittedly, the military one. Since most mining investment in Chile was relatively new (within the last five to ten years), many companies were still amortizing their investments. With huge investments such as Escondida at $US 2050 million, Collahuasi at $US 1860 million, or Los Pelambres at $US 1300 million, it would obviously take some time to pay down the debt and amortize the initial investment.[32]

According to mining executives, comparison with the revenue generated by CODELCO, was also unfair. Taxation on CODELCO is significantly higher than on the rest of the industry in Chile (as it includes both profits tax and the special military tax on sales for a total of 55%) In addition to a higher rate of taxation, the state collects the rest of the surplus due to its ownership of the company. Furthermore, CODELCO had already amortized most of its assets, and was thus unable to use the principal deduction against profits used by other companies.[33] SONAMI commissioned and circulated a paper on taxation in the mining industry. It suggested that there was likely to be a significant increase in profits tax collected by the national treasury between 2000 and 2008.[34]

However, perhaps the most compelling argument from the point of view of the government was the claim that the Villarzú proposal changed the "rules of the game."[35] Opponents of the Villarzú proposal argued that it would seriously damage the reputation of the country, and the foreign investment flows upon which it depended. Over the 1990s, Chile had developed a well-earned reputation as the most stable and professional business climate in Latin America. This reputation had been fundamental in attracting foreign investment in the mining sector, but also in other sectors of the economy. The extent to which Chilean development in the 1990s was based on huge FDI flows made changing the rules of the game a risky proposition.

Furthermore, the international context was not propitious for following up the proposal. The Asian crisis and its effects on the price of metals, especially copper which fell below US 70¢ a pound in 1998, threw the entire mining sector into crisis, and the country into recession. Many firms, including foreign MNEs had to close unprofitable mines (such as Barrick Gold's El Indio, and Phelps-Dodge's Ojos del Salar). In this context, Chile's bargaining strength was low, and government efforts were focussed on maintaining existing employment levels in the industry.

The government abandoned the project due to a number of reasons: political opposition (within and outside the PDC); the lobbying efforts of the mining firms and Ignacio Pérez Walker in the Chamber of Deputies, Senate, and Congressional Mining Commission; and the low price of copper in 1998.[36] On February 18, 1998, President Eduardo Frei publicly reprimanded Juan Villarzú for his proposal, and stated that the government had no plans to increase the taxation rate on the private sector and was committed to stable rules of the game.[37]

Minera Alumbrera Royalty Dispute

At $US 1.2 billion, the Minera Alumbrera mining project was the largest single mining investment in Argentine history. Many considered it to be the test case for mining in Argentina. It was a test, above all, of whether the revision of Argentina's mining legislation in 1993 had really changed the investment conditions and attitudes of provincial governments in such a way as to make the country an attractive destination for foreign investors. Enrique Loncan, President of Barrick Explorations expressed it as follows,

Bajo la Alumbrera is the first megaproject established under the new mining legislation, and as a result puts to the test the consistency of the legal and fiscal framework that will determine its feasibility. As a consequence, the international community considers this investment to be a reference point.[38]

However, the Bajo de la Alumbrera project became a "reference point" for the first major round of state-firm bargaining in Argentine mining. In this case, the Radical government of the province of Catamarca under Governor Arnoldo Castillo, where the mine was located, sought to increase the value of royalties paid by the foreign company. Unlike the Villarzú proposal, which never really got off the ground, the royalty dispute pitted both the federal government and Minera Alumbrera against the province of Catamarca. However, the principal argument against the changes was the same as that used in Chile - changing the rules of the game undermined the country's reputation as a good business climate.

Shortly after Minera Alumbrera had sunk half of its $1.2 billion dollar investment, the government of Catamarca announced that it would be charging the company a royalty of 3% on the mine-head value of its production. However, unlike the firm's definition of "mine-head value" which included a deduction of all costs incurred between the extraction of the mineral and the first stage at which it was priced, Catamarca would not allow any deductions. This added significantly to the value of the royalty. Firm executives calculated that it effectively doubled the royalty to 6%, or an extra $US 8-9 million per year.[39]

However, the government of Catamarca found itself opposed by both Minera Alumbrera and the national executive.[40] From the viewpoint of the Nation, Catamarca's royalty stance undermined the rule of law, and put in jeopardy the entire structure of stable rules which was to make possible the development of Argentina's mining potential. It was an attitude emphasized by the President of Minera Alumbrera,

The uncertainty that exists as a result of the current situation, presents other entry barriers to those who wish to invest, not only in Catamarca, but also in Argentina... If the consensus falls apart at the first opportunity, independent of who is correct and who is mistaken, the victim is the confidence of those who contribute the capital and financing.[41]

The royalty issue was thus part of a larger problem faced by Argentina, the problem of the "rule of law" – and the fact that foreign investors (and local investors for that matter) perceived that they could not count on the impartial, effective rule of law.[42]

The dispute had emerged out of the federal division of powers, which allowed the federal government to define national mining policy and legislation, but which gave the provinces the right to apply and enforce it. In May 1993, as part of its renovation of the national mining legislation, the federal govemment passed the Mining Investment Law 24,196, which limited the royalties that could be charged by the provinces to 3% of the mine-head value (*valor boca mina*). The Federal Mining Accord Law 24,228 then secured provincial agreement for these changes. Since Argentine legislation is made effective through its later regulation, it was assumed that "mine-head" value would be defined in more detail when the law was regulated. Mining executives claimed that the term was widely recognized in international mining circles, as meaning the value of the mineral at its first stage of commercialization (first stage at which a price can be attributed to it) minus the costs incurred between its extraction and that stage, including amortization.

However, Catamarca adhered to the federal legislation regarding royalties, on 17 November 1993, but not before passing its own law on royalties in October. The Catamarcan law accepted the 3% royalty, but failed to define the calculation of mine-head value - thus leaving space for its own interpretation of the formula. On December 28, 1993, the federal government issued Decree 2686 which regulated the Mining Investment Law, and defined *valor boca mina* as the price of the mineral at the first stage of commercialization with the deduction of costs incurred between extraction and sale. However, Catamarca's regulation of its own royalty law did not accord with the federal definition, and neglected to add the deductions to the calculation of mine-head value.[43] According to the Catamarcan authorities, the fact that its royalty law predated its adherence to the federal law, and that it had the constitutional right to regulate its own laws, meant that its own interpretation of the *valor boca-mina* took precedence.[44] Since Catamarca had previously accepted the federal definition of "mine-head value" in its 1994 contract with another foreign company operating in the province (FMC Lithium), its stance seemed particularly opportunistic.

Catamarca was following a traditional bargaining strategy. Once the investment was sunk, it changed the rules of the game to extract more rent from the firm. From the province's point of view, the firm would have little choice but to pay the relatively paltry surcharge demanded by the province. Interviews revealed that the government of Catamarca made the move because it thought its bargaining power was strong, and it could get away with it. Catamarca was the province with the hottest prospects for new mining development, with dozens of foreign exploration companies (juniors) operating in the region, and many deposits already identified and owned by the province. The province viewed the payment of royalties as legitimate compensation for the extraction of a non-renewable resource. In addition, it believed there was extra surplus to be gained at the Bajo de la Alumbrera site, which unlike many other sites, had a high mineral grade and relatively easy conditions of access (low altitude), and was therefore assumed to be highly profitable. At the core of the argument was the assumption that there were profitable opportunities in the province, and a little extra bargaining by the province would not change those fundamentals.[45]

There were also political calculations behind the conflict. Catamarca had one of the highest unemployment rates among all the Argentine provinces, and by the start of operations in mid-1997 the development at the Alumbrera site had already frustrated high local expectations regarding its economic impact on the surrounding regions. Facing gubernatorial elections in March 1999 the governing party (a provincial variant of the Radical party, the Unión Frente Cívico) found it useful to portray Minera Alumbrera, the federal government, and the Peronist party governing at the federal level, as deliberately preventing Catamarcans from cashing-in on their birthright.

The national executive, Minera Alumbrera, and the government of Catamarca entered into negotiations to resolve the issue. All parties rejected taking the issue to the Supreme Court, although it clearly fell within the Court's competence. The firm thought a political solution would offer more enduring stability, while the province recognized that a lengthy court battle would delay its ability to collect its royalty payments - if it could win in a court dominated by the appointees loyal to the President. The national executive on the other hand feared the damage to Argentina's reputation that the publicity surrounding a court case might cause.[46]

Negotiations took place through the Federal Mining Council at which all the provinces were represented, and the Bicameral Commission on Mining (of the Argentine Congress). The Commission consulted with the private sector, the Council, and the province of Catamarca. As a result of these consultations, it proposed a definition of *mine-head value* which was to allow all deductions except amortization.[47] The new deal was to cost Minera Alumbrera 25-30% more than the original royalty law.[48]

In addition, a Compensation Fund For Development was to be established. Paid for by federal monies, the fund was intended to compensate the province for the income lost from adopting the new definition of mine head value. The changes required modifications to the original Mining Investment Law, which had to be passed by both houses of Congress, and the provincial governments. The project law was passed by the Senate in June 1998, but without the support of the Catamarcan representative.[49] The final version of this law, sanctioned in November 1999 also failed to get the necessary provincial approval. By mid-2000 the conflict remained unsolved.[50]

Interestingly, the solution to the royalty issue was not pursued through state-firm bargaining, but rather inter-governmental bargaining, in which the federal government of Argentina took the side of a *foreign* firm against a recalcitrant provincial government. The fundamental argument which motivated the federal government to move decisively against the actions taken by the province of Catamarca, was the fear that changing the rules of the game would negatively impact foreign investment flows if investors thought that their investments were vulnerable due to political and judicial insecurity. This was confirmed by the efforts made by the political authorities (both federal and provincial – other than Catamarca) to underline their commitment to the rules of the game, and condemn Catamarca for breaking them.

Is There A "Bargaining Gap?"

The "bargaining" experiences of both the Bajo de la Alumbrera royalty dispute, and the Villarzú proposal reveal the extremely limited nature of bargaining in the epoch of neoliberalism. Not only was the bargaining in those cases limited to relatively insignificant issues, but in both cases the attempt to extract more surplus out of the foreign firms failed (in significant part) because the central government realized that the country's reputation as a good investment climate was worth more than what it would gain from the bargaining.

Curiously, the explanations for the apparent lack of bargaining in the 1990s summarized in the literature review do not seem to explain well the outcome in Chile and Argentina. On the one hand it is clear, that the liberal bargaining model does not adequately explain these truncated bargaining experiences. The Chilean case is perhaps more striking. In 1974, the military government in Chile promulgated a new statute on foreign direct investment, Decree Law 600. At the time, DL 600 was almost unique in the developing world for its liberal and permissive approach to foreign investment. It also marked a radical shift in Chilean policy. Under democratic governments since the mid 1960s, investment policies had become increasingly restrictive towards MNEs, culminating in Chile's adherence to the Andean Pact's FDI regime (Decision 24) and nationalization of the foreign copper companies under Salvador Allende.

What is particularly interesting about DL 600, however, is that (apart from some very minor adjustments) it froze the rules and regulations regarding foreign investment in Chile for 26 years. That is to say that changes in the relative bargaining power of the state and MNEs (which must have fluctuated over the last quarter century) have apparently not been reflected in the legal norms that govern foreign investment (which have remained constant). This defies all expectations of the liberal bargaining model. When Chile promulgated DL 600 in 1974 the country was in a deep recession, the government was running a large deficit and desperately needed foreign exchange, and foreign direct investment had all but dried up following the nationalization policy pursued by the Allende government between 1970 and 1973. In this context, it was reasonable to expect that Chile's bargaining power was at an all-time low, and that the massive liberalization envisioned by DL 600 reflected these circumstances. By 2000 however, Chile had experienced fifteen years of solid growth, persistent balance of payments surpluses, and huge inflows of foreign direct investment. It would be pure nonsense to suggest that Chile in 2000 had the same or less bargaining power than Chile in 1974 - and yet DL 600 remained basically unaltered. Contracts signed in the 1970s did not obsolesce – even in the mining sector, the classic example of the obsolescing bargaining literature.

But it is not clear that the three alternative views, the irrelevance of bargaining, the displacement of bargaining, and the maximization of bargaining power offer much more compelling explanations for the stories of the Villarzú proposal and the Minera Alumbrera dispute. In terms of the irrelevance of bargaining – the strategy of host country may be more in tune with that of the firm (at least in terms of encouraging larger FDI flows) but in the natural resource sector where mines often operate as enclaves, we should not exaggerate the spillover effects (beyond employment multipliers). The host will never have the kind of strategic symbiosis in this sector than it would in high-technology manufacturing for export. Therefore we cannot explain the failure of bargaining in terms of such a synergy. While it is true that the general relationship between host country and MNE is vastly improved over the 1970s, we also see that conflict and the desire to extract a greater share of the rent from the investment persists.

In this case, we cannot say that bargaining had been displaced to the international level. Taking Ramamurti's hypothesis as an example, that weak firms with the backing of strong states will triumph over host governments (and strong firms backed by weak governments will fail) – because of the influence of these home countries at the international level – we find it is falsified. Minera Alumbrera is an example of a weak firm (because of its sectoral location) backed by relatively weak governments – at that time it was owned by Australian and Canadian companies. Minera Alumbrera should have been the paradigmatic example of a bargaining player that would lose, instead, it lost very little. Nonetheless, a curious and unexpected displacement of bargaining did occur when the government of Argentina took the side of the firm against its own provincial government. This is probably explained by the executive's concern that the Catamarca-Minera Alumbrera conflict had implications far beyond the single firm itself. It was this concern that caused the displacement of bargaining and ultimately the relatively favourable outcome for the firm, not the displacement itself that was causal – as in Ramamurti's thesis.

Nor does it appear that the mining firms in both stories triumphed because their bargaining power was maximized. With the low price of copper in 1998, and the overall dependence of the Chilean economy on mining, there is little doubt that the bargaining power of the government was not at its highest point. Nonetheless, as the history of the foreign investment statute indicates, it was much improved over the time when DL 600 was promulgated. Perhaps most importantly however, the ability to tax (the issue of the Villarzú proposal) is not usually restricted by foreign investment regimes at the international or bilateral level. In Chile's case, the Foreign Investment Committee signs contracts with foreign firms committing the government to a certain tax rate for a certain period of time. But even this was not violated by the Villarzú proposal, which envisaged a tax on future investments. In this respect, neither the maximization of firm bargaining power, nor the web of international investment treaties, which may have constrained Chile's actions, can be viewed as explanatory.

Learning from the Case Studies

The two case studies of host country – MNE bargaining discussed in this article shed some light on the reasons behind the limitations on state-firm bargaining in the 1990s. In terms of the examples often provided in the literature, they are unique for three principal reasons:

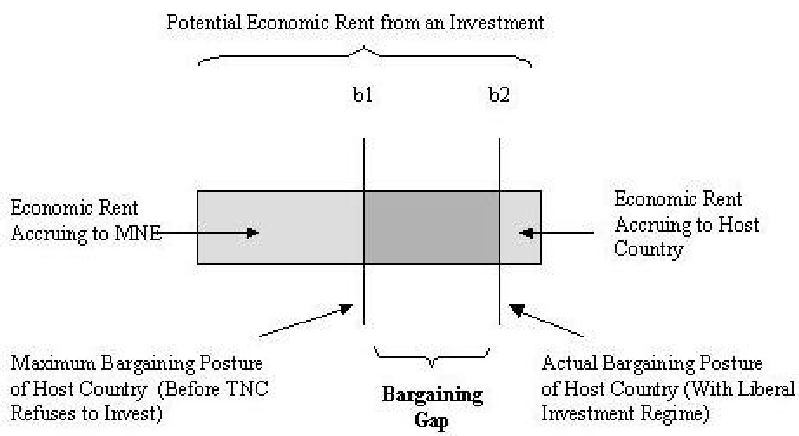
1) They demonstrate both bargaining attempts and the failure of those attempts in liberal economies with a history of openness towards foreign investors.
2) They show the importance of political factors in bargaining attempts and outcomes – particularly that firm-specific advantages (such as technology, changing product mix, etc.) usually considered to be determining in bargaining outcomes due to their effect on firm bargaining power were less important than political factors ostensibly unrelated to the firm. In Chile, the political strength of the right and its determination to resist regulatory encroachment was fundamental to the outcome. In Argentina, the federal-provincial division of powers and responsibilities played an important role.
3) The importance of the national strategy for economic development to bargaining. In particular, the dependence of both the Chilean and Argentine economy on large FDI inflows made both governments wary of doing anything to prejudice those flows.

Modeling the Limits to Host Country-MNE Bargaining

This section represents the limits on bargaining graphically in Fig.1 and uses the observations above to seek a theoretical explanation – that may be used to supplement the liberal bargaining model. The core of the problem is viewed as the state's unwillingness to push its bargaining advantage in any one particular investment. When investment terms for a particular foreign investment are agreed upon, most bargaining theory assumes that both the state and the firm make an assessment of the advantages it wants from the other. Based on this assessment, the two parties bargain over the division of economic surplus, or rent, the parties expect will be generated by the investment. The entire theory is contradicted by the existence of fixed investment rules in countries like Chile and Argentina. This stability means that the host country does not make any assessment of the advantages brought by a single MNE or change its bargaining posture from one MNE to another.

If the host country makes no attempt to extract the maximum benefits from a foreign investment, then the its actual bargaining posture (none) falls significantly short of the maximum position it could hold before the MNE decides it is no longer profitable to invest. The difference between the potential bargaining position of the state (b1) - up to the maximum point where the MNE determines the investment is no longer profitable - and the actual posture (b2), I call the "bargaining gap." It is illustrated by Fig. 1.

Fig. 1: The Bargaining Gap - the Potential and Actual Division of Economic Rent between MNE and Host Country



Proposition 1: thus we can conceptualize the absence of (or limits on) host-MNE bargaining, as the difference between the maximum and actual bargain, or the value of b1-b2.

The two case studies also revealed the importance of political factors. This is not a new observation, for example, Moran's 1974 classic suggested that the 1954 *Nuevo Trato* in Chile (the first major liberalization of mining legislation) was part of a broader political deal to strengthen the political right. At this time the government traded lost economic rent (extra taxation on the foreign mining firms) for other political objectives. Other theorists have noted the general failure to consider political factors in bargaining models, Rhys Jenkins observed, "What is common to these [both liberal and dependency] approaches is an inadequate theorization of the state, and a tendency to view the state as unproblematic."[51] In contrast, we assert that the state has both political and economic interests (it is never wholly autonomous from domestic social forces).

Proposition 2: economic rent may be traded for political goals.

The case studies also identified the principal motivation behind the host county's decision to fight against the bargaining efforts of its subnational jurisdiction in Argentina, and to abandon a controversial tax proposal in Chile, as fear of changing the "rules of game" and the impact that would have on future foreign investment inflows. It seems clear then, that a host-country does not define its bargaining posture towards a particular foreign firm, without considering the effect of that posture on other (yet imaginary) foreign investors. When the development strategy of the country is dependent on FDI inflows and when there are few alternatives, it is hypothesized that the host country will give even greater consideration to its present decisions on imaginary future investors.

Proposition 3: host country bargaining posture is not only determined by reference to a particular state-firm relationship but also to the value (both economic and political) of a hypothetical future-projected series of bargains (fut-b).

Proposition 4: the host country also considers the value of a hypothetical future-projected series of second-best alternatives (fut-alt).

Based on these propositions, we can come to some conclusions regarding what conditions increase or decrease the limits on host country –MNE bargaining. As the value of the future-projected series of second-best alternatives (fut-alt) approaches the value of the future projected series of bargains (fut-b) the host country will strike a harder bargain and its actual bargaining posture (b2) will approach its maximum bargaining posture (b1). When the value of alternatives is equal or more than the value of future bargains, the bargaining gap will be zero, and the host country will maximize its bargaining power. When the the bargaining gap equals zero, the calculation of the host country's bargaining posture will follow the normal logic of the liberal model. In contrast, the bargaining gap will approach its maximum size when there are almost no second-best alternatives (fut-alt=0).

It must be remembered that political factors are integrated into the determination of the state's bargaining posture. Political factors are therefore included in the calculation of value that can be attributed to a series of investments. Some vested economic interests with influence over the government may be willing to trade a lot of the potential economic rent from future foreign investment flows if more liberalized flows will damage their opponents politically and economically. Political factors may be more or less important depending on the context and perceptions of value associated with the hypothetical investment flows and hypothetical second-best alternatives. A neoliberal government supported by the country's largest conglomerates – as was the case in Argentina, and to a lesser extent Chile in 1998, would find the second-best alternative of increased state involvement in the economy as having very little value – thus tending to increase the size of the bargaining gap.

This means that the objective assessment of whether certain MNE or host country characteristics increase or decrease bargaining power or likelihood of regulation of a particular investment - indeed a table of such assets and powers is *de rigeur* in most books on bargaining - is influenced by other concerns: namely the calculations made by the government regarding the hypothetical future value of all FDI flows, and the alternatives which exist to those flows.

Conclusion

As economic crisis and declining FDI inflows have gripped Latin America over the last two-three years, and new left-leaning governments such as Argentina's Néstor Kirchner, Brazil's Luiz Inacio "Lula" da Silva. Ecuador's Lucio Gutiérrez, and Venezuela's Hugo Chávez seem to herald a new era in state-firm confrontation, it may be asked what the implications of the "bargaining gap" model are for predicting how the pendulum of host country-MNE bargaining will swing – towards more liberalization of foreign investment rules, or towards less?

One the one hand, declining FDI flows to the region, and the new-left ideology of many of Latin America's new leaders have undoubtedly reduced the hypothetical future value that governments attribute to these inflows. However, as a result of the crisis, the alternatives are also greatly reduced. It is unlikely that inflows of portfolio capital will reach 1998 levels for many years, and the ongoing fiscal crisis of the state, and completed privatization of many state-owned enterprises has not left governments in any position to re-start a nationalization process. As a result, the balance continues to weigh in the favour of less regulation, not more.

[34] Tomás Flores and Carlos Williamson (September 1998), "Contribución de la minería a la recaudación fiscal en el mediano plazo," Santiago: Catholic University of Chile, Economics Institute, 15, 17-18. The study identified two possible scenarios for

2008-2020 depending on the price of copper. It suggested that the state should expect to collect $US 1000 million per year based on a price of $US 1 per metric tonne of copper. Under current taxation laws (and a $US 1 price), it claimed that the state would collect 41% of the net value of the investment, amounting to some $US 5.8 billion. Modification of the tax law to allow a 5% tax on sales, would allow the state to capture 56% of the net value. Nonetheless, the study warned against such changes which would put some marginal mines out of business, and possibly affect future capital inflows, thus undermining tax collection in the long run.

Cost of Capital: The Factor Influencing Economic Value Added

Drahomíra Pavelková
Adriana Knápková
Kishor Goswami
Tomas Bata University in Zlin, Czech Republic

Abstract

Economic Value Added (EVA), an indicator of newly created value for the owners of a company, is an important tools for measuring companies' performance. Costs of capital play a very crucial role among the major factors that influence EVA. This paper attempts to:

- **Explain the nature of influence of costs of capital in creating economic value added,**
- **Introduce different methods for the calculation of cost of capital and difficulties involve in each method,**
- **Explain the importance of selecting suitable sources for companies' financial stability.**

1. Economic Value Added

Efficient capital management is one of the important areas of a competitive market. The basic aim of companies' activities in countries with advanced market economy is to use their equity as well as debt in a productive way that maximizes the market value of the company in a sustained way. Thus the general aim of a company is to maximize the market value for its owners [1], [2], [4], [5], [8], etc. To measure the creation of economic value for different companies and to compare their performance we need a common tool. Economic Value Added (EVA) checks the companies' value creation and evaluates companies' effectiveness and managerial performance.

Economic Value Added (EVA), the registered trade mark of Stern Stewart & Co., is one of the highly discussed topics in today's financial world. It is because EVA can define the amount a business generates through the measurement of rate of return over cost of invested capital. Economic value added is a financial performance measure that helps to reduce capital costs and improve profits, which in turn increase shareholder's value.

According to Tully, 1998 [7], EVA is a simple measure that provides information about shareholder's real wealth creation. As maximizing shareholder's wealth is the main motive of most privately held for-profit companies, application of EVA is becoming increasingly popular in today's business world.

Calculating EVA involves a few pre-requisites steps like i) Calculation of Net Operating Profit After Tax (NOPAT), ii) Identification of Company's Capital, and iii) Determination of Cost of Capital. All the above steps are important and involve certain crucial calculation. Creation of economic value can be calculated as follows:

$$\boldsymbol{EVA} \ ? \ \boldsymbol{NOPAT} \ ? \ \boldsymbol{Capital} \ ? \ \boldsymbol{WACC} \tag{1}$$

Where, NOPAT = Net Operating Profit After Tax
WACC = Weighed Average Cost of Capital

Thus economic value added is influenced by profit, amount of capital (bearing the cost) necessary to finance the assets, and amount of cost of capital (Figure 1).

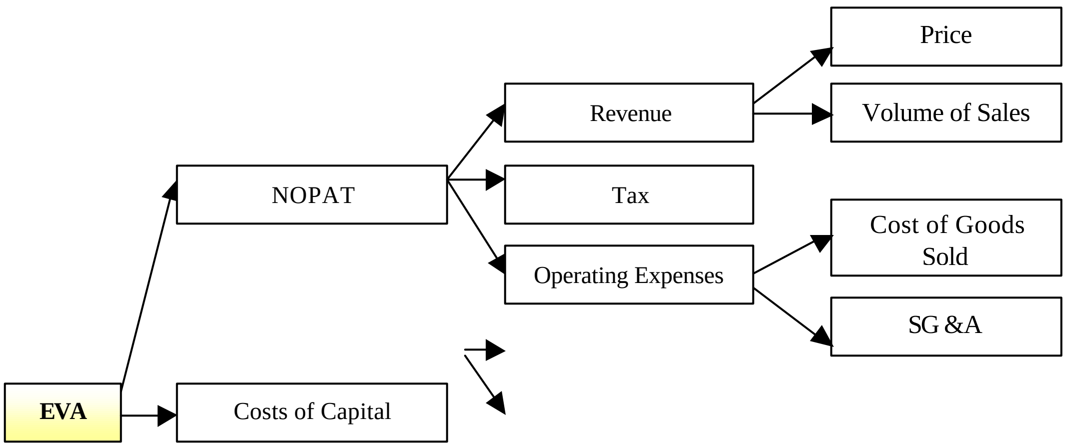

FIGURE 1: USING VALUE TREE ANALYSIS TO ASSESS SENSITIVITY OF EVA TO VALUE DRIVERS [13]

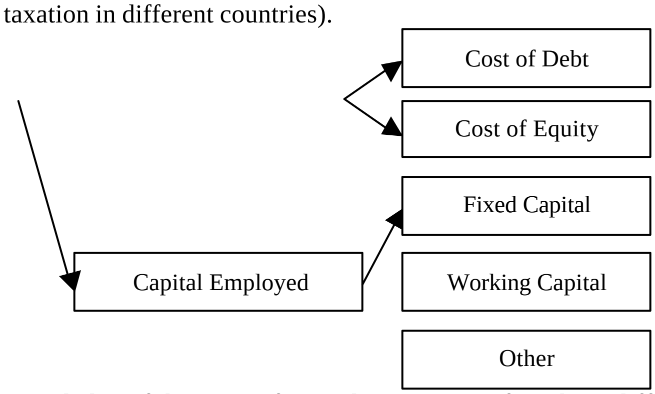
The required profit can be realized by good structure and adequate value of assets. However this should be connected with effective investment in projects with a required rate of retum. These projects should be financed in such a way that the price of these sources does not exceed the investment effects.

The amount of capital expenses available to a company depends on the structure of this capital i.e. on the ratio of the equity and debt. The amount of capital expenses depends on the effectiveness and the risk of business activities of individual companies. Companies with high rating usually obtain capital at lower costs or can obtain it easily and at lower cost at international financial markets (it is even possible to take advantage of different interest rates and taxation in different countries).



Knowledge of the costs of capital is important for taking different financial decisions, especially those with strategic character (e.g. investment plans realization, selection of the source of finance, company evaluation etc.). In addition, all these spheres of financial management are closely interconnected. Therefore, it is always important to study the problems of calculating the costs of capital.

2. Costs of Capital

Calculation of costs of capital is one of the difficult tasks in companies' financial management**.** Cost of individual capital is the cost borne by a company in connection with obtaining and utilization of a particular types of capital (e.g. share capital, credits, bonds etc.). The average cost of capital of a company is a weighed average of cost of individual types of capital.

2.1 Cost of Debt

Cost of debt can be expressed, as the income required by the creditors (investors). The real cost of debt is the cost that takes into account taxes, and cost connected with possible issue of securities (2). If the interest is variable i.e., tied to one of declared bank rates with a fixed percentage surcharge then it is important to know the rating of the company and prognosis of basic macroeconomic values. Cost of debt can be calculated as:

$$r_d \ ? \ i ? 1 ? T ? \qquad (2)$$

Where, r_d ? cost of debt in percentage

i ? interest rate (bonds) in percentage

T = company´s tax rate (tax on profit in percentage / 100)

2.2 Cost of Equity

For the calculation of cost of equity the Anglo-Saxon countries have adopted a concept based on the theories of capital market. It is because, in Anglo-Saxon countries the capital is obtained mostly from capital markets. These theories are quite simple. The cost of equity can be determined with the help of the share prices that reflect the condition and prospects of the company on liquid (flexible) markets. Because of well-operated financial markets in the USA and in the Great Britain, the banks have remained weak. On the other hand, in most of the European countries, the financial institutions, especially universal banks and insurance companies showed higher growth than financial markets. Formation of liquid and stable market is a long journey in a small country. For this reason, historically, the task of capital allocation has been taken over by banks in most of the European countries. This is also a reason why sometimes the relatively simple Anglo-Saxon models cannot be applied fully in today's European practice. For this reason new models have emerged in Europe.

2.2.1 Models Used for Determination of Cost of Equity

There is lot of approaches to determination of cost of equity. The basic approaches are referred in Figure 2.

Capital Asset Pricing Model (CAPM)

The model that determines the cost of equity makes use of the data from the capital market. Efficiency of market is important here. For this reason it is used in Anglo-Saxon countries in particular. In Germany and other West-European countries this model wins recognition in theory rather than in the corporate practice.

The aim of CAPM is to explain the relation between the level of exchange rate and the security risk. The cost of equity capital can be calculated by adding the rate of return of risk-free investment and the risk premium set with the help of information obtained from the capital market. Cost of equity capital can be calculated by the following formula.

$$r_e \ ? \ r_f \ ? \ ß_i \ ? (r_m \ ? \ r_f) \qquad (3)$$

Where, r_f = risk-free rate

$r_m - r_f$ = risk premium of the capital market (equity risk premium)

$ß_i$ = change in rate of return of shares of a certain company in dependence on the change in rate of return of the capital market (stock beta)

If we want to use this model, we must be able to determine the risk-free interest rate, risk premium and the level of ?.

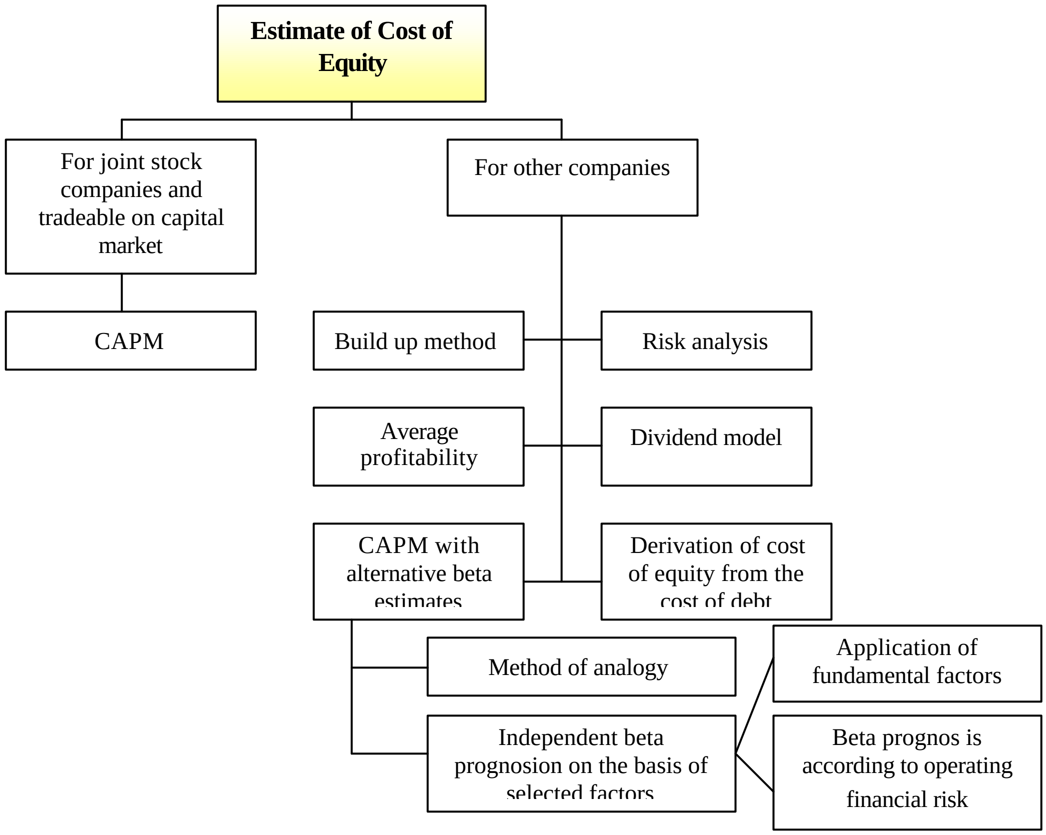


FIGURE 2: BASIC APPROACHES TO ESTIMATE THE COST OF EQUITY [3]

Although there are no risk-free assets in general, state treasury notes or state bonds are considered as very little risky (interest rate of ten-year state bonds is usually recommended to consider as a risk-free interest rate). Risk-free rate reflects development of the macroeconomic environment. Even this rate, although considered risk-free, includes inflation and a surcharge for the decreased liquidity in it.

Risk premium can be determined by the rate of return of assets on the local capital market, and on the basis of calculation of the average rate of return of state bonds. The risk premium is then derived as a difference of the two values. Market yield is set mostly by means of exchange indices. But this does not correspond to the theoretical prerequisite of this model, where all tradable assets should be considered.

The basic procedure to estimate the coefficient ? is to find out regression dependence between the stock yields and market yield. The slope of the straight line is the value of the parameter ?. Source of data in the time series data of share prices and value of global indices. Consideration of a long period enables to use more data, but older data lose their sense. In the USA a period of 2-5 years is generally used.

Companies that are not tradable in public markets, the cost of equity capital can be estimated using the CAPM model with alternative estimates of ?. This maybe by using analogy or independent prognosis of ? on the basis of selected factors.

The CAPM model is blamed for variability of beta coefficients and thus for big differences in the calculated cost of equity. Since the model has several prerequisites on risk-free borrowing and lending rates, possibilities of trading all assets, etc., practical application of the model is complicated. Many of these prerequisites are not met even in the most developed countries, not to say in transitive economies like the Czech Republic with little developed capital market.

The latest empirical researches refer that other risks are decisive for the determination of capital cost on the capital market than the fluctuation of yields (i.e. identification of the risk and ? coefficient). For companies whose market value does not exceed the book value, higher risk is usually considered.

Build up Model

The basic principle of build up models is to add a certain surcharge on risk to the risk-free interest rate. An example of the build up model used for calculation of the cost of capital in the Czech Republic is the INFA model [4]. The model uses the following procedure for the calculation of the cost of equity capital (altemative cost).

$$r_e = r_f + r_{size} + r_{entrepreneurial} + r_{FinStab} + r_{FinStr} \tag{4}$$

Where, r_f = risk-free rate
r_{size} = function characterizing size of the company
$r_{entrepreneurial}$ = function characterizing earning power
$r_{FinStab}$ = function characterizing the relation between assets and liabilities
r_{FinStr} = function characterizing capital structure

Dividend Model

The main idea of this model is that the value of the share is given by the present value of revenues, which can be expected from this share (dividend, selling price).

For the assumption of an infinite share holding, it can be expressed as:

$$r_e = \frac{D}{P} + g \tag{5}$$

Where, D = dividend paid,
P = market value of share,
g = annual growth of dividend

Dividend model is very simple and easy to calculate for the companies those pay dividends and have adopted stable dividend policy.

Average Profitability in the Sector

Another possibility to determine the cost of equity capital is using the data of average profitability of the equity capital in the sector. The main advantage here is that the data on profitability are better accessible than the other data. Problem arises when the sector is in critical situation, and when too low or even negative profitability is reached. This model is not advisable in a situation of higher profitability in the sector.

Derivation of the Cost of Equity Capital from the Cost of Debt

This procedure presupposes that the cost of equity capital is higher than the cost of debt. Since the owner bears higher risk than the creditor, owners usually call for higher yield. This can be estimate by the following procedure:

- Find out a real level of cost of debt
- Add some percentage to the cost of debt, which give a certain estimate of cost of equity capital.

2.3 Weighted Average Cost of Capital (WACC)

The weights at WACC calculation are the share of debt and the share of equity capital on whole capital (in market values) (6).

$$WACC = \frac{Debt}{Capital} \times (Cost\ of\ debt) \times (1 - T) + \frac{Equity}{Capital} \times (Cost\ of\ equity) \tag{6}$$

Where: Capital = sum of the market value of debt and equity finance
T = company´s tax rate

When determining the structure of capital in market values, either the present structure of capital or the target structure of capital or structure of capital common at comparable companies can be used. If change in structure of capital is a part of strategic decisions, then it is necessary to start with the target structure of capital [2]. But in many cases, it is very problematic to determine the market value of capital particularly for companies non-tradable in capital markets. To calculate the value of capital through yield-making methods, it is again necessary to know the cost of capital. Thus we can see ourselves in a vicious circle.

Economists such as Sweeneye *et al*. 1997 [6] refers to the fact that empirical studies that deal with the average cost of capital or use it often, rely on book value of the debt, even if the theory promotes market value application. This procedure can have a negative influence upon the calculation of indebtedness rates and the cost of capital. Differences in book and market capital structure are determined by changes in the level of interest rate. (Market value can be influenced by the fact that indebtedness can influence the value of the previous debt. This applies in the case when further indebtedness is motivated by unexpected fallout of the cash flow). Especially bonds show different book and market values.

2.4 Case of Granitol, a.s. Company

Each model (especially models for calculation of cost of equity capital) has its own problems in obtaining the required input data or in accuracy starting from subjective approach to their estimation. The example of Granitol is demonstrated here to show the individual procedures used for calculation of the cost of capital. The company is a joint stock company employing 420 people and at present the biggest manufacturer of polyethylene foils in the Czech Republic. The basic data used in this example have been taken from the annual reports of Granitol, a.s. company [12].

Determination of Cost of Debt

The cost of capital that the company obtains as debt is expressed as an interest that the company has to pay. Granitol, a.s. uses only one outside source for its long-term financing i.e., bank credit. If we consider the income tax as 35 per cent in 1999 and 31 per cent in 2000 and 2001, the cost of debt will be as follows [1].

$\mathbf{r_{d1999} = 8.85\% \times (1-0{,}35) = 5.75\%}$

$\mathbf{r_{d2000} = 12.11\% \times (1-0{,}31) = 8.36\%}$

$\mathbf{r_{d2001} = 10.81\% \times (1-0{,}31) = 7.46\%}$

Determination of Cost of Equity

Capital Assets Pricing Model (CAPM)

As Czech capital market is not developed sufficiently, the CAPM model cannot be used for determination of the cost of equity capital. However, there is a possibility to use the CAPM model with alternative estimates of ß. Another way to determine the coefficient ß is by using the method of analogy. The idea of this method is very simple. Here average ß of similar companies is used. This method also considers the influence of capital structure and ß is adapted according to the relation:

$$ß_D = ß_E \times \left[1 + (1 - T) \times \frac{D}{E}\right] \qquad (7)$$

$ß_D$ = ß of equity capital with the company in debt

$ß_E$ = ß of equity capital at zero indebtedness

T = income tax rate

$$\mathbf{ß_{1999} = 0.81 \times \left[1 + (1 - 0.35) \times \frac{154770}{316044}\right] = 1.07}$$

$$\mathbf{ß_{2000} = 0.55 \times \left[1 + (1 - 0.31) \times \frac{134105}{333952}\right] = 0.70}$$

$$\mathbf{ß_{2001} = 0.59 \times \left[1 + (1 - 0.31) \times \frac{112605}{339270}\right] = 0.73}$$

The risk premium of 5.5 per cent that is valid in the USA was used for the calculation in the analyzed years. A surcharge of 1.5 per cent was added to it, allocated for the Czech Republic on the basis of a rating (for detail see http://pages.stern.nyu.edu/~adamodar/). The "risk-free" premium is considered as 7.6 per cent, 6.5 per cent and 6.3 per cent in the Czech Republic for the individual years (for detail see http://www.mpo.cz/). Substituting it in the original relation (3) the cost of equity capital is calculated out.

$r_{e1999} = 7.6\% + 1.07 \times 7\% = 15.07\%$
$r_{e2000} = 6.5\% + 0.70 \times 7\% = 11.42\%$
$r_{e2001} = 6.3\% + 0.73 \times 7\% = 11.38\%$

Build up Model – Using INFA Model

The cost of capital is calculated here by using the relation (4). Every year the risk-free surcharge was the highest. Cost of capital was considerably influenced by the surcharge in small size company, which, in the case of INFA model (2), is characterized by the amount of equity capital. The surcharge for trading risk was the highest in the year 2000 when a low ROA was reached. The surcharge for financial stability was zero thanks to high liquidity of the company. The decreasing indebtedness contributed to gradual decrease of the surcharge for financial structure.

$r_{e1999} = 7.6\ \% + 4.28\ \% + 1.38\ \% + 0\ \% + 3.51\ \% = 16.77\ \%$
$r_{e2000} = 6.5\ \% + 4.23\ \% + 4.08\ \% + 0\ \% + 2.59\ \% = 17.40\ \%$
$r_{e2001} = 6.3\ \% + 4.21\ \% + 2.20\ \% + 0\ \% + 1.74\ \% = 14.45\ \%$

Calculation on the Basis of Risk Analysis

For the purpose of this calculation we estimate the trade risk at 6 per cent. This is because, the company operates in a branch of industry with relatively stable sales so far, but it has got problems in realizing satisfactory rate of return [3]. Financial risk is low (2%), the company uses mainly its own equity sources for its finance and its financial situation is good. The premium for trade and financial risk is added to the risk-free interest rate, and thus the cost of equity capital is obtained.

$r_{e1999} = 7.6\% + 6\ \% + 2\% = 15.6\%$
$r_{e2000} = 6.5\% + 6\ \% + 2\% = 14.5\%$
$r_{e2001} = 6.3\% + 6\ \% + 2\% = 14.3\%$

Dividend Model

Granitol company does not pay dividends every year, and for this reason this method cannot be used.

Average Profitability in the Branch of the Industry

The joint stock company ranks among companies working in rubber and plastics industry. Information on average profitability in this branch of industry can be obtained from http://www.mpo.cz/.

$r_{e1999} = 12.62\%$
$r_{e2000} = 12.61\%$
$r_{e2001} = 8.55\%$

Derivation of the Cost of Equity Capital from the Cost of Debt

In case of the analysed company the real cost of debt can be found out as a ratio between the cost interests and the amount of bank credits in individual years, to which a surcharge of 2.5 per cent is added [3]. The resultant value of the cost of equity capital is mentioned below.

$r_{e1999} = 8.85\% + 2.5\% = 11.35\%$
$r_{e2000} = 12.11\% + 2.5\ \% = 14.61\%$
$r_{e2001} = 10.81\% + 2.5\% = 13.31\%$

As different results are obtained in different methods, it is either possible to choose a method most suitable to fulfil the objective or to calculate arithmetic average or weighed arithmetic average where certain weights will be matched to the results of individual methods. It is also evident that the method in use influences the calculated cost of capital and thus the EVA (see **Tables 1** and **2**). In spite of the different EVA, which was influenced by the different methods of calculation of cost of equity capital, it can be said that Granitol a.s. did not create economic value in any of the years observed. The most suitable method for the conditions of the Czech Republic (owing to insufficiently liquid capital market) seems to be the build up method. Stressing the risks connected with the concrete company (size of the company, its financial stability, etc.) Another suitable method that can be used in practice is the CAPM with alternative estimates of beta. The other methods should be used only as complementary criteria.

3 Capital Structure and Economic Value Added

The growth of debt increases the owners' risk, as their demands are satisfied only after all the other liabilities have been paid. The growth of the debt burden increases the risk of insolvency. At the same time, increasing the debt in capital structure, the financial leverage can be used. For this reason, changes in the ratio between the debt and the equity capital influences the cost of individual sources of capital and WACC and thus the reached amount of the economic value added.

3.1 Possible Alternatives of Financing – Example of Granitol, a.s Company.

The data from Granitol were used again to evaluate the influence of the financial leverage upon EVA. Here we came out from the real situation of the company. Moreover another three alternatives for financing the company were simulated. In the first two alternatives, we gradually replaced most of the bank credits with equity capital. However, in the third alternative, we replaced a part of equity capital with bank credits in such an amount that the company could be able to pay cost interest from its EBIT and thus the increased indebtedness would not threaten its existence.

From **Table 3** it is found that, in the existing situation of the company as well as at other three alternatives of financing, negative value of economic value added is reached.

Let's have a look at how individual elementary factors (NOPAT, WACC, C) influenced the value of EVA at individual alternative financing.

3.2 Change of Elementary Factors Influencing EVA at Individual Alternatives of Financing

A: WACC

The most useful method related to objective was used to calculate the cost of equity (r_e) - build up method. The lowest average costs of capital is reached in the case when the value of the equity capital increases to 90% of all capital. Contrary to that the highest average cost of capital is reached at higher indebtedness. The higher cost at higher indebtedness was resulted by higher surcharge for the increased trade risk and financial structure.

There was only a change in WACC due to the different capital structure. The change in this elementary factor influences the amount of Economic Value Added. As we can see on the Figure 3, the increasing indebtedness from 0 to 10 per cent (decreasing WACC) resulted in positive influence upon EVA. Futher increase of the indebtness resulted in WACC increasing and had negative influence upon the EVA.

TABLE 3: CALCULATION OF EVA FOR POSSIBLE ALTERNATIVES OF FINANCING

		Build-up Method		For EVA = 0
Real Situation	**Indebtedness (debt/capital)**	**WACC**	**EVA**	**NOPAT**
1999	33%	13.15%	-42 831	61 912
2000	29%	14.81%	-47 823	69 319
2001	25%	12.71%	-42 505	57 433

1999	39%	14.40%	-48 716	67 797
2000	35%	15.06%	-48 993	70 489
2001	31%	13.10%	-44 268	59 196

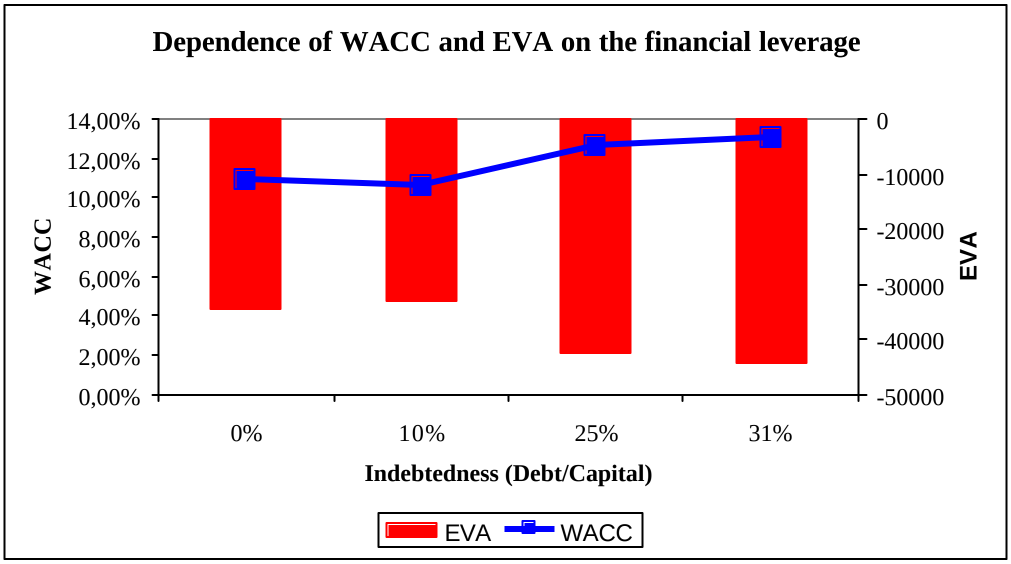

FIGURE 3: DEPENDENCE OF EVA ON THE FINANCIAL LEVERAGE IN 2001

B: NOPAT and Capital

Change in capital structure does not influence either the value of NOPAT or the amount of capital (C) on which interest is paid.

However, it is interesting to note that, for the analyzed company, the priority should be to increase the efficiency. If NOPAT is insufficient (as it is in the case of the analyzed company), even good capital structure will not save anything. A considerable increase in NOPAT is the main prerequisite for successful performance of the company. We calculated the amount of NOPAT for individual alternatives of financing which should have been achieved by company´s activities to reach EVA=0 (see **Table 3**).

End Notes

Cost of capital, as a measure of company effectiveness, influences the amount of Economic Value Added in a considerable way. Determination of the cost of equity capital is linked with many problems. In countries where the capital market is developed, CAPM can be used. Under conditions of non-liquid capital market, the most suitable method seems to be the build up method. Another applicable model could be CAPM with alternative estimation of beta. The results also show, using a concrete example, how the capital structure influences the cost of capital. In spite of the fact that the capital structure plays an important role in financial management of the company, even a suitably chosen capital structure will not help when the profitability of the company is insufficient.

Location Advantages of the Mid-West China and Types of Foreign Direct Investment Targeted

Xiaoling Huang
University of International Business & Economics (UIBE), China

Abstract

The positive effects of FDI on the economic development of the hosting country are not generated automatically with the arrival of FDI. Instead, the realization of the potential positive effects is determined to a large extent by the types of foreign direct investment and the matching of domestic investment environment. This paper briefly reviews theories on the effect of technology disparity between the hosting country and the investing country on FDI, discusses types of FDI that Mid-west China should target based on its location comparative advantage, and proposes specific measurements for promoting targeted FDI.

Introduction

The mainstream research on multi-national investment has always focused on the behavior of multi-national companies since S. Hymer's innovative study on FDI (Foreign Direct Investment) in 1960. The location advantage of a hosting country is considered only as a constraining factor in cross-national investment from prospect of transnational corporations.

The benefit that the hosting country seeks in cross-national investment may be quite different from that of multi-national companies; therefore their explanations of "Location Advantage" may be different as well. The location advantage of the hosting country needs to be constructed such that it attracts foreign investment and maximizes the benefits of foreign investment on the hosting country. In another words, the positive effects of FDI on the economic development of the hosting country are not generated automatically with the arrival of FDI. Instead, the realization of the potential positive effects is determined to a large extent by the types of foreign direct investment and the matching of domestic investment environment.

Introducing FDI is expected to be of great importance in China's "Great Western Development Strategy". However, the positive effects and the magnitude of the effects of FDI on the economic development of the region are closely related to the matching of FDI and local investment environment including government policies. While it is important to have government policies that attract and encourage FDI, it is as important that we analyze types of FDI according to local comparative advantage and development vision and ping down those that can help develop regional economy the most. This paper analyzes in theory the effect of technology disparity between the hosting country and the investing country on FDI, discusses types of FDI that can be attracted to the Mid-west China based on its location comparative advantage, and proposes specific measurements for promoting FDI.

I. The Impact of Technology Disparity between the Hosting and Investing Countries on Technology Advancement of the Hosting Country

Many researchers show the effect of technology spillover of FDI, which promotes technology advancement of the hosting country (Caves, 1974; Globerman, 1979; Blomstrom & Persson, 1983). However, the effect of technology spillover of FDI is not materialized automatically. Its realization depends on many economic and technological factors. Findlay (1978) built a model of transferring technology from developed countries to developing countries, suggesting that the technology disparity between the hosting country and the investing country is positively related to economic growth brought by technology spillover. That is, the bigger the technology disparity, the larger the potential space for the imitation of technology by the hosting country, thus faster economic growth. In contrast, Lapan and Bradhan (1973) argued that if the technology disparity between the hosting country and the investing country is too big, it may very well become an obstacle to technology disperse, reducing the potential benefits of FDI to the hosting country. Large disparity in technology suggests large differences in economic development, income level and consumption level. The technology of developed countries may not be appropriate for developing countries at their stages of economic development, obstructing the transfer and disperse of advance technology.

Luiz (1999) argued that the effect of FDI on technological advancement and economic growth is not directly dependent on the absolute disparity in technology between the hosting country and the investing country. The technology brought by FDI affects technological advancement and economic growth in hosting countries through different venues in different countries. For example, investment between OECD countries usually brings in new technology that substitutes the old one. Technology is dispersed and promoted through substituting less efficient technology with more efficient technology. Instead, FDI by OECD countries in non-OECD countries usually brings in technology that coexists and complements with local existing technology. There are two explanations for the above difference. One is that developing hosting countries usually lack the capacity to digest and absorb advance technology brought by FDI, which integrates slowly with or even becomes independent of local technology. As a result, developing hosting countries cannot take full advantage of the new technology brought by FDI. In worse cases, it may lead to reinforcement of "duality" in developing hosting countries. Another explanation is that multi-national companies do not provide advance technology on the bases of the hosting country's trade protection and the stages of life cycle of local industries. Instead, aiming at industries that have a limited production capacity but a rapid increase in demand, parallel technology is provided to rapidly increase production and take over market shares, which coexists and complements with the local technology. In fact, factor endowment of the hosting country is one of the factors that determine FDI. Thus the complementarities between foreign technology and local technology are indeed one of the important factors that attract FDI, at least in the short run. Because of the complementarities, local technology is able to continue to survive and even becomes more profitable due to the cooperation of technology brought by FDI. The co-movement and integration of foreign technology and local technology will be able to accelerate technological advancement and extend production possibility frontier in the hosting country.

Based on the above analyses, we can infer that: if FDI brings along technology that is much more advanced than that in the developing hosting country, it is possible for the hosting country to skip over some stages of technological development and adopt advance technology directly. However, since the technology brought by FDI is much higher than the average technology in the hosting country, which means it lacks the necessary support of exterior technology, foreign investment with high technology may be separated from the local technological system and contribute little to the local technological progress. If FDI brings along technology that complements, coexists, and integrates with the local technology, it is probably more reliable to produce positive effects on local technological development. Therefore the hosting country needs to choose FDI with different levels of technology according to an industry's developmental stage and its need for technology.

II. The Analysis of Regional Conditions of the Mid-West for FDI

Industrial development and regional conditions of the Mid-West of China is markedly different from those of the East coastal region. The successful story of the East in attracting FDI cannot be copied directly by the Mid-West. In addition, the Mid-west covers a vast amount of area with large differences in many respects within the region. Therefore, the Mid-west region needs to exam its specific industrial and other regional conditions and chooses FDI with different level of technology that forms differential co-movement with local technology and enterprises. The developmental stages of industries and technological structure of industries in the Mid-west region could be characterized as follows:

Sparsely industrialized, the Mid-west region will continue to target FDI that invests in the manufacturing sectors.

On average, China has entered the accelerated stage of industrialization. However, the degree of industrialization is uneven, decreasing gradually from the East region to the West region. The economic reform has led to speedy development of manufacturing industries in the East region, widening the disparity in industrialization between the East and the Mid-west region. The tertiary Industry is in the high mode of development in the East region, while the Mid-west region is still in the accelerated stage of manufacturing industry development. Continued industrialization and structural changes in manufacturing sectors will be the driving force in the economic development of the Mid-west. Absorbing investment, especially FDI, needs to target the manufacturing sectors, accelerating industrialization by increasing the amount of investment and by adjusting sectoral structure. In addition, the Mid-west has a rich endowment of agricultural resources. The primary industry, which has a hefty presentation in its economy, can realize its huge potential by introducing FDI and adopting advance technology.

Similarity in industrial structure has reduced in the Mid-west, with increased differences in sub-regional advantages.

Similarity in industrial structure has been reduced in China since 1990. Structural changes in industries have led to increases in specialization and decreases in the similarity in industrial structure.

According to calculations of specialization indices[i] on the total production value of the 31 industries of all provinces/cities in the Mid-west China (table 1), specialization indices on industrial structure increase in all provinces except for Chongqing, Shangxi and Tibet, where the data for Tibet were unavailable. Some have also improved their rankings nation-wide.

The overall structure of the three industries (primary, secondary, tertiary industries) has improved and the similarity in secondary industry structure has gradually reduced among different regions with the reduction most noticeable in the Mid-west region. During the years of 1992-1997, the index that measures the similarity in industrial structure[ii] declined in 18 provinces/cities in China, among which were all provinces with data available in the Mid-west region. Yunnan and Shangxi provinces experienced relatively bigger decline in the similarity index, with 5% and 3.36% respectively.

Source: calculated based on data in "China's Input & Output Table"1992, 1997, data for Hainan and Tibet are not available. The increases in specialization in the Mid-west region suggest the increases in the differences of location comparative advantage and competitive advantage among sub-regional areas. To develop specialized economy in sub-regions, it is important to attract FDI that targets different industries and FDI with different investment vehicles.

There is a relative over-supply of traditional industries in the Mid-west.

The Mid-west region is much more richly endowed with natural resources than the East region. Traditional industries primarily focus on exploring and processing of natural resources, such as mineral processing, and machinery manufacturing. Traditional technology accounts for a large percentage in the structure of production technology with a small percentage of advance technology. The Mid-west region is also richly endowed with agricultural resources. It needs to emphasize FDI that will help the region's specialized agricultural products and processed high value-added agriculture products.

The resource-intensive industries gradually lose their traditional advantage with products over-supplied during changes of economic structure and changes in supply-demand relationship that come along with economic growth. Such traditional industries lose their steam in propelling the growth of the economy, leading to greater disparity in economic growth between the Mid-west region and the East coastal region. As China's manufacturing industry becomes more and more balanced between heavy industries and consumer industries, self-sufficiency within the heavy industries has been corrected (which were the dominant feature of China's industrial development pattern).

In addition, since the opening of China's markets, prices of many resource-intensive products begin to reflect those of the international markets, which make supply greater than demand in primary industries in the Mid-west such as coal, steel, petroleum. Primary industries in the Mid-west have gradually reduced their impact on economic growth. According to Sun Jiuwen's calculations (1999) of the impact of industries with strong comparative advantages on economic growth in 1986-1990, and 1991-1995, the index that measured the impact grew rapidly for the three provinces in the East region (Jianshu, Shandong and Guandong provinces), indicating strong propelling effect of the industries which enjoy comparative advantages on economic growth. However, the index for the four provinces in the Mid-west (Hunan, Shangxi, Guazhou, and Shangxi provinces) for the same periods declined gradually, indicating that the weakening of their primary industries was hindering the growth of the region.

The adjustment of economic structure in the Mid-west is badly needed. To revitalize old primary industries, the Mid-west region needs to take advantage of advance technology and develop in-depth processing of resource-intensive products with high added values. In addition, new primary industries should be identified and developed according to the trend of development of industries and technology in the world. In both cases, FDI that brings in advance and appropriate technology will be indispensable.

The adjustment of ownership structure in the Mid-west is lagging behind relative to the East region.

Due to both historical reasons and the delay of economic reform, the structure of ownership in the Mid-west is vastly different from the East coastal areas. State-owned enterprises account for a much larger percentage in the economy in the Mid-west than in the East region. In general, non state-owned enterprises in the Mid-west also have a smaller scale than those in the East.

The relative delay in the development of non state-owned economy has constrained the progress in market economy, technological innovation, and structural adjustment in the Mid-west. Introducing FDI to the Mid-west will accelerate the adjustment of ownership structure and help develop enterprises with different technology needs through competition and collaboration.

Foreign Funded Enterprises can form strategic coalition with state-owned enterprises of mid to large size. Instead, mid to small size state-owned enterprises can be reshaped by FDI through acquisition and merger. Therefore, some state-owned enterprises can compete and coexist with the foreign enterprises, while some others can become local suppliers of foreign enterprises, benefiting from the so-called backward linkage of FDI.

III. What types of FDI to attract in the Mid-west?

The analyses above show the impact of technology disparity between the investing country and the hosting country on technology advancement and economic growth of the hosting country, and the regional conditions for industrial development in the Mid-west. Based on these analyses, in addition to encourage investment in the much needed infrastructure, the Mid-west region needs to attract FDI to traditional and related industries that have a large amount of existing enterprises, and to new industries with high technology that can promote leap-frogging growth of the Mid-west.

Attracting FDI to traditional and related industries.

Traditional industries in the Mid-west are resource-intensive industries such as mineral processing,, and machinery manufacturing, resource intensive chemical industry, etc.. The similarity in industrial structure within the region has observably reduced since 1990. Specialization is enhanced, resulting in increased differences in industries with comparative advantage in different provinces/areas. A 1997 study (Lu Zhongyuan) shows that agriculture is one of the industries with top comparative advantage in all 12 provinces/cities in the West

With limited industrialization, agriculture weights heavily in the economy of the Mid-west. It has heterogeneous geography with large variance in climate, which provides potential advantages for specialized agriculture. However, with lagging production technology, productivity in agriculture is low. Therefore, to develop specialized agriculture, the Mid-west should actively attract FDI and adopt modern production technology and processing technology in agriculture.

In addition, production line should be extended to processing industries in an effort to increase added values to products and industrialize traditional agriculture.In the same study, the second industry was also analyzed for comparative advantage in the Mid-west. Each province proved to hold its own comparative advantage in different sectors. Such that each province/city should attract FDI of different types based on its specific resource advantages and industries with comparative advantage.

FDI that uses resource intensively and FDI that refines resources

The Mid-west needs to attract users of local specialized resources to build production site near local resource sites. This can reduce transportation costs due to insufficient transportation infrastructure in the Mid-west. This can also form supply linkage with local resource suppliers, so-called backward-linkage, so as to help develop local enterprises that produce resources. The Mid-west also needs to attract foreign direct investment of in-depth processing of resources that are specific to the local and that have comparative advantage. It can choose products whose technology is easily transferable and products that have large domestic market demand and can substitute imports directly, such as high-quality dairy food, organic agricultural products that are specific to local, flowers, fruits, herbs, … etc. Because of its low capital demand, this type of FDI is easier to attract; because its technology is easily transferable, such FDI can take advantage of local conditions faster and set up standards of products similar to the international market; most importantly, this type of investment can meet different demands for the domestic market and the international market and increase exports by using foreign investors' existing marketing venue.

This type of resource-oriented FDI can form strong complementarity with local production capacity, which can survive and grow due to the larger market brought by foreign investment. The local production technology can also be improved by inflow of visible or invisible assets transferred from the foreign-invested enterprises. For example, in order to acquire important resources with high quality, some foreign-invested enterprises are willing to provide technical help to some local suppliers to up grade their production.

This type of FDI will help traditional industries to survive and construct new industries with comparative advantage in the Mid-west. In addition, strengthening of supply linkage between foreign-invested enterprises and local enterprises will help tighten the integration of foreign economy and local economy.

FDI that invests on up-stream industries, which provide inputs for industries with comparative advantage.

FDI can also positively affect local production and technology through forward linkage. That is to attract FDI on up-stream industries, especially those for industries with comparative advantage, such that input supply can be improved both qualitatively and quantitatively for industries with comparative advantage. The localization of input production can reduce production costs and increase market competition for the industries with comparative advantage. Direct investment and local production and marketing can also help foreign investors to take up market shares and keep up their competitive advantage. For example, the development of specialized agriculture in the Mid-west will create a strong demand for high-quality animal food, fertilizer and other agriculture backup products.

Encouraging foreign investment on industries with potential market demands and industries that affect economy widely and deeply will help develop local down-stream industries with comparative advantage and enhance the quality of their products. Due to its characteristic of large production scale and its position on the production chain, this kind of up-stream industries need to attract big foreign investment with strong backup for capital and technology. Such FDI should provide production technology much higher than domestic technology and have strong R&D capacity such that production technology can be improved and innovated and such FDI can affect down-stream industries through backward linkage and spill over effect.This type of FDI can also help reorganize and develop local small and medium size enterprises.

More and more multi-national companies have tried to focus on enhancing their main production capacity while subcontracting exterior products and processing, so called outsourcing, to reduce burden and increase flexibility. Large-scale FDI on up-stream industries is likely to partnership with local reputable small and medium enterprises and provide needed technological support with or without cost. These local enterprises will become alliance with multi-national companies.

FDI on high-tech industries.

In addition to attracting FDI on industries with comparative advantage, the Mid-west needs to create competitive advantage to realize "late-comer advantages". Although technology development in the Mid-west is on the week side in general, some metropolitans such as Xian, Chengdo, Chongqing and their neighboring areas are among the front-runners of technology development.

With many colleges, universities and research centers, these metropolitan areas have better supply of human resources than other areas and have started to become focus areas for knowledge-intensive and technology-intensive industries such as electronic information, airplane and air-space, electronic machines, pharmaceutical industry, and gene engineering. Based on the developmental trend of high-tech industries, the Mid-west should attract FDI on such industries to effectively increase the chance for leap-frogging development.

The specialization between the East region and the Mid-west region should focus not only on orthogonal or ladder but more on parallel specialization such that the disparity in economic growth between the West and the East can be shortened and more balanced development between the two regions can be achieved. The Mid-west region should attract FDI on industries that bring in technology that is much more advanced than local technology.

This can strengthen the propelling effect on local technological development, help develop pillar industries that promote economic growth in the Mid-west, and reduce its technological disparity with advance technology in the world, taking full advantages of late comers'.

Conclusion

Introducing FDI is expected to be of great importance in China's "Great Western Development Strategy". But the realization of the potential positive effects of FDI is determined to a large extent by the types of foreign direct investment and the matching of domestic investment environment. If FDI brings along technology that is much more advanced than that in the developing hosting country, it is possible for the hosting country to skip over some stages of technological development and adopt advance technology directly.

However, since the technology brought by FDI is much higher than the average technology in the hosting country, which means it lacks the necessary support of exterior technology, foreign investment with high technology may be separated from the local technological system and contribute little to the local technological progress. If FDI brings along technology that complements, coexists, and integrates with the local technology, it is probably more reliable to produce positive effects on local technological development.

Therefore the hosting country needs to choose FDI with different levels of technology according to an industry's developmental stage and its need for technology. Based on the above judgments and brief investigation of local advantages in Mid-west china, two types of FDI should be targeted to serve development needs from different perspective: Attracting FDI to traditional and related industries FDI to high-tech industries.

The former aims to materialize strengthen and renew local comparative advantage, while the later focuses on technology leap-frogging development. To promote FDI of targeted types, local governments are supposed to pursue at least two measures: Firstly, to specify regional and sub-regional comparative advantages, thus to clarify specific industries and sectors which by inflow of FDI are most likely to spur local development; Secondly, to help establishing linkages between local and foreign invested enterprises. The positive effects of FDI in the end have to be realized through either "spill over" effect or "following the leader" effects, both require the integration of local economy and foreign invested activities. The integration could be in many different forms such as competing, complementing, collaborating, alliance, etc.

End Notes

1.

$$H = 100 \times \left(1 + \frac{\sum_i s_{i*} \ln s_i}{h_{\max}}\right)$$

H is specialization Index, which takes value from 0 to 100, S_i refers to Similarity index. H takes value of 0 when sectors are evenly distributed, when there is one sector in the economy, H takes value of 100. The higher the index, the higher the specialization is.

2. Similarity Index reveals the degree of similarity between a region's industrial structure and the national industrial structure.

$$\mathbf{Si} = \sum X_{ij} \overline{X}_j / \left(\sum X_{ij}^2 \sum \overline{X}_j^2\right)^{(1/2)}$$

Si refers to the similarity index of region i, X_{ij} refers to the share of industry j in region i, $\overline{X}_j$ refers to the national share of industry j.

Are Global Equity Markets Becoming More Correlated?

Yunke He
Okanagan University College, Canada

Abstract

This paper examines the correlation coefficients between the US and other eight equity markets over a 30 year time period. The time series of yearly correlation coefficients based on the monthly data shows no statistical evidence that the global equity markets were becoming more correlated over time, either among developed markets or between developed and emerging markets. The findings contradict some of the recent empirical studies. There are two important implications of the findings. First, international diversification is still beneficial despite an increasing amount of literature suggesting more integrated world equity markets. Second, the market rotation is the key to diversification.

Introduction

In recent years, an increasing amount of literature has suggested that the benefits of international diversification have diminished. Specifically, two factors generally have increased the correlation among the various markets, particularly among the equity markets. One factor is so called crisis mentality, which drives investors bearish almost simultaneously [Faboozi & Modigliani, 2003]. The second factor is that the global sectors tend to follow the global market for their goods and services rather than their local economy. This is also referred to as the industry factor [Cavagia, Brightman & Akid, 2000] or sector effects [Baca, Garbe, & Weiss, 2000]. Some empirical studies illustrate the increasing correlation in the world equity markets. Harrinton [2003] uses 3-year, 5-year, 10-year, 14-year, and 30-year time periods and shows an increasing correlation between S&P 500 and MSCI EAFE, and S&P500 and IFCI Emerging Composite.

There are three research questions we need to answer. First, the correlation coefficients between various equity markets are increasing or decreasing over time? Or they are simply unstable and trendless? Second, do developed vs. developed and developed vs. emerging markets behave any differently? Finally, what are the implications of these empirical results?

Methodology

The correlation coefficients of the US and eight equity markets are examined over the time period between 1973–2002 (subject to the data availability of some markets). The eight markets are UK, Germany, France, Canada, Australia, Japan, Korea, and Mexico. These markets cover four major continents, and both developed and emerging markets.

First, the yearly correlation coefficients are derived from the monthly data by using the Share Price Index of the International Financial Statistics. These data are in local currency, which effectively isolates the equity market performance from the currency performance. The results are eight sets of time series. Then each time series is plotted in a scatter, which provides an intuitive result. Finally, the trends are analyzed based on the scatters, and the statistical interpretations help us to conclude the study.

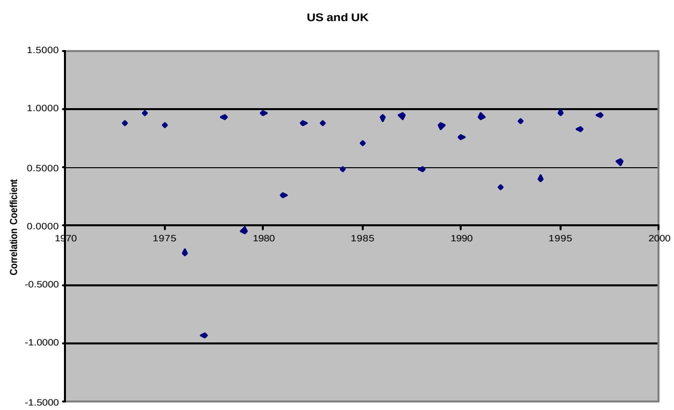
Major Findings

In general, there is no statistical evidence to support the hypothesis that the correlation coefficients between the studied equity markets are increasing, decreasing, or stable over time. In fact, no obvious patterns of these time series are observed. Each pair of the equity markets is examined as follows.

US and UK

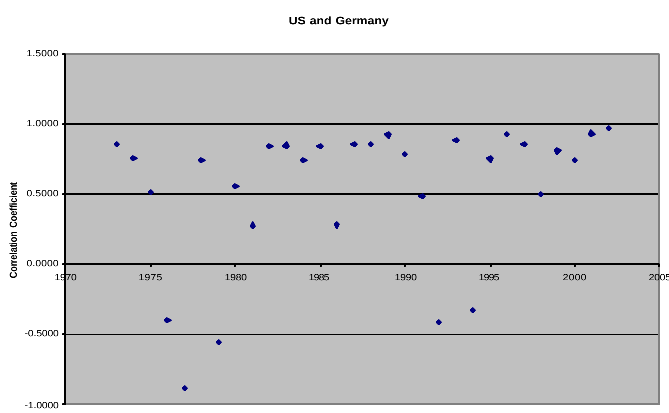
Intuitively, this is the only time series that shows a slightly increasing linear pattern. There are three negative coefficients occurring in 1976, 1977 and 1979. For most years, two markets are highly correlated. Unfortunately, for some reason the UK share price index data for 1999-2002 are missing in the database.Using the ordinary least squares (OLS) method, the fitted trend line has a positive slope of 0.015. P-value for the slope coefficient is 0.215 and R^2 is 0.06. P-value indicates the exact significance level associated with a particular testing result. In our testing, the null hypothesis states that the coefficient or slope is zero. Therefore, the probability of committing Type I error is 21.5%. Type I error occurs when we reject the null hypothesis which in fact is correct. At the commonly used significance level 5%, we certainly do not reject the null hypothesis, i.e. statistically speaking, the coefficient is zero. R^2 = 0.06 indicates that the explained variance of the correlation coefficients by this regression is only 6%, which is extremely low.

Therefore we have no statistical evidence that the correlation between the US and UK equity markets has been increasing over time.



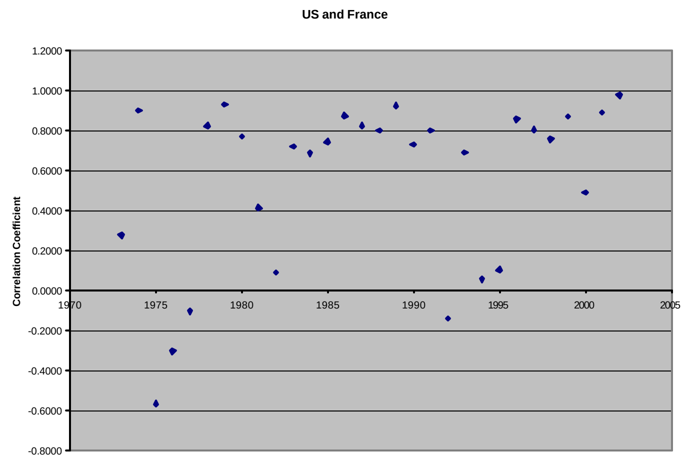
US and Germany

The linear pattern is not observed unless excluding all five negative correlation coefficients in 1970s and 1990s. An OLS trend line has a positive slope of 0.018 with a P-value of 0.094 and an R^2 of 0.097, which suggest a very weak fit. Therefore we have no statistical evidence that the correlation between the US and UK equity markets has been increasing over time.



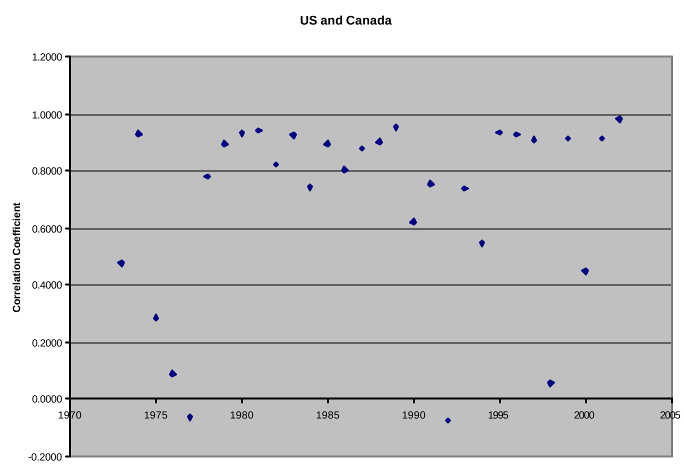
US and France

The linear pattern does not exist. An OLS trend line has a positive slope of 0.016 with a P-value of 0.061 and an R^2 of 0.12, which suggest a very weak fit. Therefore we have no statistical evidence that the correlation between the US and France equity markets has been increasing over time.



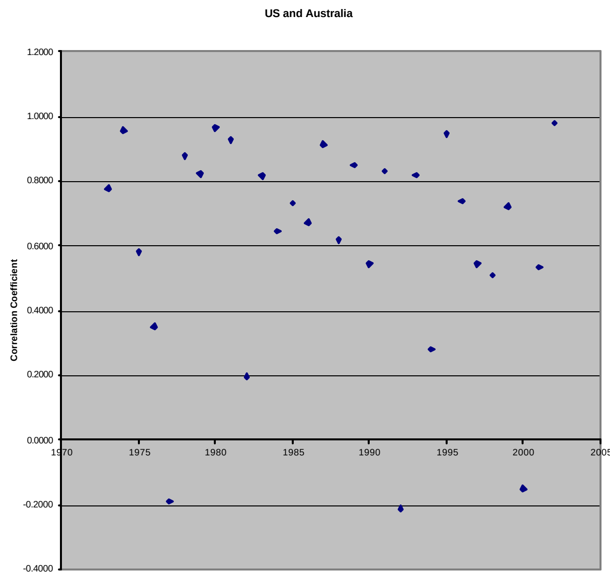
US and Canada

It is interesting to see that, Canada, as a very close trading partner with the US, does not show an increasing correlation with the US. An OLS trend line has a slope of 0.006 with a P-value of 0.392 and an R^2 of 0.026, which suggest a very weak fit. Therefore we have no statistical evidence that the correlation between the US and Canada equity markets has been increasing over time.



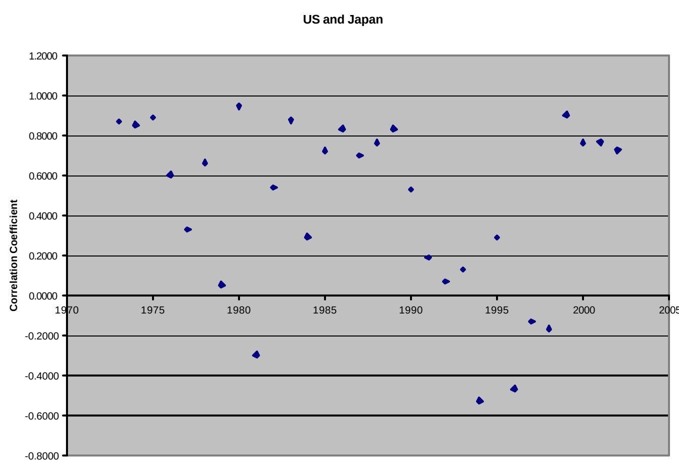
US and Australia

The linear pattern is not observed. Negative and low positive correlation occurred in 1970s, 1980s and 1990s. An OLS trend line has a negative slope of 0.004 with a P-value of 0.566 and an R^2 of 0.012, which suggest a very weak fit. Therefore we have no statistical evidence that the correlation between the US and Australia equity markets has been increasing over time.



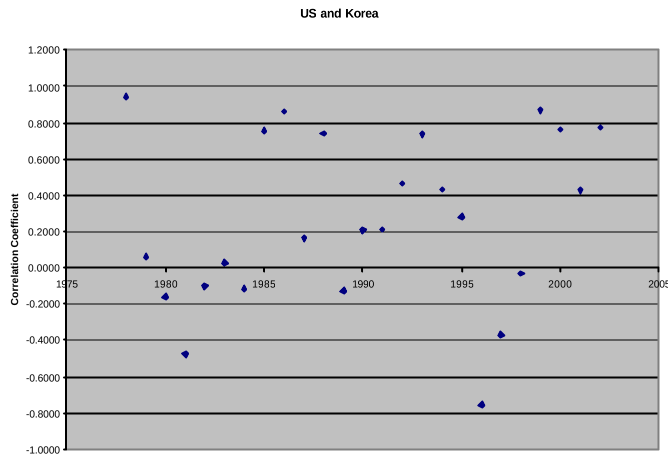
US and Japan

The linear pattern is not observed. There are four negative and four low positive correlation coefficients through 1990s. An OLS trend line has a negative slope of 0.014 with a P-value of 0.132 and an R^2 of 0.079, which suggest a very weak fit. Therefore we have no statistical evidence that the correlation between the US and Japan equity markets has been increasing over time.



US and Korea

Korea, as an emerging market, has shown its very positive, very negative and low correlation with the US market over time. A linear pattern is not observed. An OLS trend line has a positive slope of 0.011 with a P-value of 0.395 and an R^2 of 0.032, which suggest a very weak fit. Therefore we have no statistical evidence that the correlation between the US and Korea equity markets has been increasing over time. The Korea share price index data are not available between 1973-1977 in the database.



US and Mexico

Mexico, as an emerging market and a close trading partner with the US, shows a fairly stable positive correlation with the US equity market if excluding those three low correlation coefficients in 1990, 1992 and 1998. An OLS trend line has a slope of 0.0003 with a P-value of 0.981 and an R^2 of 0.00003, which suggest a weak fit. Therefore we have no statistical evidence that the correlation between the US and Mexico equity markets has been increasing over time. The Mexico share price index data are not available between 1973-1983 in the database.

To compare the eight sets of time series, the study time period is divided into three sub-periods: 1973-1982, 1983-1992, and 1993-2002. Further, the correlation coefficients (r) are categorized in four groups: 1 ? r ? 0.5 (positive), 0.5 > r ? 0 (weak positive), 0 > r ? -0.5 (weak negative), and -0.5 > r ? -1 (negative). The following table records the occurrence of each category of correlation coefficients for each pair of markets in each sub-period. For example, the cell (6, 1, 2, 1) indicates that there is a positive correlation for 6 years, weak positive for 1 year, weak negative for 2 years and negative for 1 year between the US and UK equity markets during the sub-period of 1973-1982.

	US &UK	US & Germany	US & France	US & Canada	US & Australia	US & Japan	US & Korea	US & Mexico
1973-1982	6, 1, 2, 1	6, 1, 1, 2	4, 3, 2, 1	6, 3, 1, 0	7, 2, 1, 0	7, 2, 1, 0	1, 1, 3, 0	n/a
1983-1992	7, 3, 0, 0	7, 2, 1, 0	9, 0 1, 0	9, 0, 1, 0	9, 0, 1, 0	7, 3, 0, 0	3, 5, 2, 0	7, 2, 0, 0
1993-2002	5, 1, 0, 0	8, 1, 1, 0	7, 3, 0, 0	8, 2, 0, 0	8, 1, 1, 0	4, 2, 3, 1	4, 3, 2, 1	9, 0 , 1, 0

All pairs have positive or weak positive correlation in most years. But whether the correlation coefficients are increasing over time is ambiguous. Furthermore, positive correlation does not occur simultaneously for all markets if individual yearly coefficients are compared. For example, in 1981 the correlation coefficients are 0.94 with Canada and 0.93 with Australia; but –0.30 with Japan, -0.48 with Korea, and 0.26 with UK. Similar situations exist in other years.

We may also want to compare the average correlation coefficients for each sub-period. They are compiled in the following table:

	US & UK	US & Germany	US & France	US & Canada	US & Australia	US & Japan	US & Korea	US & Mexico
1973-1982	0.4551	0.2700	0.3231	0.6090	0.6262	0.5476	0.0537	n/a
1983-1992	0.7298	0.6187	0.6979	0.7408	0.6408	0.5838	0.3185	0.6200
1993-2002	0.7662	0.7027	0.6501	0.7373	0.5917	0.2295	0.3128	0.7113

It is evident that the average correlation coefficients have increased for all pairs from 1973-1982 to 1983-1992. However, the results are mixed from 1983-1992 to 1993-2002. The UK, Germany and Mexico show increased average correlation coefficients with the US, while other five markets show decreased correlation, particularly Japan. The popular argument that the global economy is becoming more integrated does not justify that the global equity markets are becoming more correlated.

In addition, the compiled data show the six developed markets behave differently with the US market and so do the two emerging markets.

Conclusions

The correlation coefficients between the US equity market and other eight equity markets have been examined over a 30-year time period. The time series of yearly correlation coefficients based on the monthly data shows no statistical evidence that the global equity markets were becoming more correlated over time, either among developed markets or between developed and emerging markets.

As mentioned in the introduction section, some empirical studies illustrate the increasing correlation in the world equity markets and the proponents use industry factor or sector effects to explain the results. Interestingly, we may also use the same explanation for the different empirical results shown in this paper.

It is a well-known fact that each country's equity market has its own distinguished composition of industries or sectors. For example, the resource sectors such as metals and forest products in the Canadian equity market weigh much more compared to the US equity market. The industry or sector differences among countries will not necessarily diminish as the world economy becomes more integrated. Instead, specialization and comparative advantage may widen these differences in the future. As a result, the world equity markets may become less correlated. Of course, this is not to say that the equity market composition is the only underlying factor that will affect the correlation of the world equity markets. Identifying all relevant factors and examining their effects/interactions are not conducted in this paper.

There are two important implications of the findings. First, international diversification is still beneficial despite an increasing amount of literature suggesting a more integrated world economy. Indeed, the rapid growth in international trade and economic cooperation are integrating the world economy; cross-border listing/trading and other market activities are also integrating the world equity markets. However, the integration is a very long process and so far we have no evidence to conclude that it has resulted in an increasing correlation over time. Moreover, an increasing integration does not guarantee an increasing correlation among equity markets. Therefore the ample opportunities for diversification are still existing and will continue to exist for a very long time.

Second, the market rotation is the key to diversification. We have observed that positive correlation does not always occur simultaneously for all markets, despite sometime it does. This is also true for those markets with very close economic ties. Then the strategy is not simply a passive diversification. It is essential to identify the markets with weak or negative correlation within a certain time period. As a result, we need an active diversification strategy, particularly in the more dynamic future.

Private Equity as a Driver for Growth in Central and Eastern Europe

Jozef Komornik
Comenius University in Bratislava, Slovak Republic
Marian Herman
Williams de Broë PLC, United Kingdom

Abstract

Venture Capital and Private Equity have become a main driver of financing in mature capital markets. Making their way from the US to the UK in the first step, they are now widely used all over Europe and have rapidly found acceptance as an interesting alternative to debt financing.

Both equity instruments allow the investor to participate in the shareholding of the company, which results in a more active involvement in the day-to-day business or at least the main decisions.

Private equity provides equity capital to enterprises not quoted on a stock market. Private equity can be used to develop new products and technologies, to expand working capital, to make acquisitions, or to strengthen a company's balance sheet. It can also resolve ownership and management issues – a succession in family-owned companies, or the buyout or buy-in of a business by experienced managers may be achieved using private equity.

Venture capital is, strictly speaking, a subset of private equity and refers to equity investments made for the launch and early development of a business. Among different countries, there are variations in what is meant by venture capital and private equity. During the last years, the term venture capital is generally used for early stage investments, especially in the technology industry. However, for this paper we will use both terms interchangeably.

European private equity

The European venture capital industry can trace its roots back 50 years but growth started in earnest in the 1980s. It now provides the European private corporate sector with permanent access to professional sources of growth capital.

Key European market data

?? Since the emergence of private equity in Europe in the early '80s, a cumulative total of more than €160 billion of capital has been raised for investment in Europe's most promising growth companies

?? 41% of all investments are to provide expansion finance

?? Venture-backed MBOs and MBIs are contributing significantly to Europe's corporate restructuring effort and helping to create new entrepreneurial businesses

?? In the UK, the private equity fund's long-term performance outperformed most of the principal stock market indices over three, five and ten years, including FTSE All-Share and FTSE 100. It yielded a 13% return over 3 years, a 15.7% return over 5 years and 17.4% return over 10 years respectively

?? Private equity investors are active partners providing more than finance. According to managers of investee companies, the three main contributions made by venture capital investors, other than finance, were financial advice, assistance on corporate strategy and acting as a sounding board for ideas.

?? Private equity backed management buy-outs led to greater competitiveness, increased employment and better pay.

?? 81% of managers of investee companies believed that their company would not have existed or would have grown less rapidly without venture capital.

Since the opening of former communist countries in the early 90, these countries have experienced a lot of interest of all foreign direct investment (FDI), investments via private equity and venture capital funds.

The last years have shown that investments in the technology sector have almost levelled to western standards, both in pricing as well as quality of the ventures. It seems, the CEE region jumped over some market stages by adopting the lessons learned from the western neighbours.

We feel that the difference between the new economy in the CEE region and its western counterparts became almost negligible and is more driven by stock prices and peer group evaluation than anything else. Venture capital does a lot for the CEE region in respect to growth, but the impact of venture capital does not differ from its influence in western hemispheres.

The same is only partially true for the old economy, where evaluation patterns differ substantially from comparable companies in the west. It is obviously far easier for new and emerging ventures to mimic the recent trends in the west than for bricks and mortar businesses to change the actual patterns.

Introduction

Over the course of the last four years, making the case for investing in private equity in Central Europe has sometimes been difficult. Returns on local equity markets have been volatile and have often fallen short of expectations. Returns have also suffered from contagion effects from events in other emerging markets.

The fundamentals are now changing. The Central European states of the Czech Republic, Hungary and Poland are entering a period of rapid, sustained growth in GDP. Inflation is down sharply from the double-digit rates of only a few years ago. Future membership in the EU from 1st of May 2004 is already contributing to convergence in inflation and interest rates towards West European levels. Membership in NATO and OECD and the existence of strong, healthy democracies are sharply reducing country risk premiums, a development that is unique to Central Europe among emerging markets.

In addition, emerging market contagion effects are working in reverse. Most of Southeast Asia is experiencing strong economic growth again and GDP in Russia and Ukraine is finally rising. Although still sizeable, some of the economic instability that has characterised Russia and the other successor states of the former Soviet Union has diminished. Finally, the U.S. equity valuations have also adjusted to more realistic levels. For these reasons, Central Europe promises to provide some of the most attractive investment opportunities among emerging markets in the coming years.

This paper will make the case for investing in Central European equities, in particular, private equity. In the medium-term, this asset class is projected to outperform other classes not only in the region but also in comparison with other emerging markets. The paper will first assess prospects for strong GDP growth in the region and for the convergence of inflation and interest rates towards EU levels. It will then evaluate prospects for equity markets in the region and the impact of Private Equity investment on the region. It will conclude with a discussion of the advantages of making private equity investments in the region.

The paper will concentrate on the Central European states of Poland, Hungary and the Czech Republic, the leading countries in the transition process. While the analysis also applies to other countries in transition, in particular Slovakia, Slovenia and the Baltic states, because of the size of the three Central European economies and the importance of their equity markets, the focus is on these three countries.

Economic rationale behind CEE convergence

The CEE countries are undoubtedly going down the convergence way towards the European Union. The economies of the CEE countries have experienced so far one of their most dynamic period in history and will continue going through a period of great convergence towards their western counterparts. This is where the biggest excitement for private equity investors entering the region comes from, as the gap between the EU and CEE countries' economies is still significant, thus offering a reasonable upside as this gap narrows in the future.

The CEE economies have more or less gone through privatisation and restructuring and are now entering a period of rapid sustained growth. The Inflation is under control and with the gradual price liberalisation seen in the region there are no threats of turbulence. Steady decline in unemployment in the region is supported mainly by direct investments and “greenfield projects”. With the strong inflow of foreign investments into the region coupled with incomes from tourism sector, the mounting C/A deficit poses a manageable challenge to the national banks of Eastern European countries. The external (current account) convertibility in some CEE currencies have been restricted before, but the full convertibility of those has been arranged according to IMF regulations already, even though in some countries the internal convertibility remains limited for local citizens. Some of the CEE currencies remain pegged (those of the Baltic countries) and some are freely convertible (CZK, SKK, HUF). But most of the currencies in the CEE should experience a stable period over the course of the next few years, before converting to the Euro. Thus, the region is marked as relatively safe in terms of FX risk for foreign investors in general.

All the macroeconomic fundamentals create a sound environment for GDP growth and wealth creation – a solid base for all investors in general.

Equity valuation assumptions and characteristics

The private equity market worldwide has experienced a strong growth (in funds) during last 10 years with the cumulative average growth rate at almost 40%. Demand for these instruments has been driven mainly by a history of superior private equity returns and distributions. A number of new institutions opening private equity/venture capital funds has been steadily increasing, building a broader portfolio of financial products. Pension and other long-term funds have increased their percentage allocations in the private equity funds, viewing them as a mean of deploying excess capital. As such, private equity investments have gradually started appearing on the radar screen of investors from Western Europe too. Investors seem to intend to reduce the number of managerial levels, having their investment managers tightened closer to the actual investments.

In the CEE region, we could have clearly seen a sectoral approach to private equity investment. While most of the investors rushed to invest to the "fancy" technology area across the borders, other areas remained virtually untouched as of yet. This obviously caused huge differences in the equity valuations across the sectors in the CEE markets. Especially in the area of internet and technology investments, similar valuations could have been seen as those in the US and Western Europe. The valuations in the technology sector have first gone through the roof and since early 1999 started declining. With the US equity valuation declining to more realistic levels, funds investing in the CEE region start broadening their investment horizon and start looking on other sectors too. The rationale behind is that technology and telecommunication sectors no longer provide such rosy upside potentials in terms of the old "sky-high" valuations. However, the US and Western European equity valuations remain the basic assumptions for valuations of the respective sectors in the CEE countries. The threat of long-term economic recession in the western universe would obviously affect not only the CEE economies and their growth, but also their respective equity valuations.

CEE private equity/venture capital markets

Overall, the private equity market in general (not only in the CEE region) is characterised by lower level of transparency and higher information imbalance than other parts of the capital markets. The non-existence of standardised investment tools and secondary markets creates a potential liquidity problem, should the private equity investor wish to exit the investment prematurely. It also burdens the information base that is generally available on private equity deals to outsiders. The private equity/venture capital market in contrast to the capital market is not regulated by an official body. This virtually removes any possibility for market supervision, performance presentation and disclosure standards. As most of the private equity/venture capital deals are intended to last for a period of several years, with no secondary markets available, questions can be raised on how to value the private equity portfolio before an actual exit is achieved.

A typical private equity fund investing in the CEE region is looking for the IRR of approximately 25-30% pa, which implies slight risk premium of roughly 5-10% for the location of the investment in the Emerging Markets area. However, the actual level of risk the Venture Capital investors are willing to undergo varies across the types of Venture Capital investments. The Internal Rate of Return is subsequently a derived function of the risk associated with higher return required for riskier investments.

The most risk-averse funds are those with mainly governmental sources of funds. They usually focus on handful of non-cyclical sectors like consumer goods, telecommunication etc. Such Venture Capital funds tend to invest for 3-5 years horizon and generally require 20-30%pa Internal Rate of Return on investments. Their main investment patterns are straightforward deals, providing development capital.

Private investors (including pension funds) in contrast to that are more risk-prone and thus are more flexible to search for less rigid-structured investments, including bridge financing, mezzanine financing, pre-IPO investments, distress situations, mergers and take-over investments, management buy-outs and buy-ins and special situations investments. Investment period can also vary from 1 year (in case of pre-IPO, mezzanine and bridge financing) to as much as 5-8 years (in special situations and management buy-outs). As these investments carry much greater risk, the required Internal Rate of Return on investments is in the range of 25%-40%pa. The more complicated transactions often include special risk-reducing features, enhancing the safety cushion for Venture Capital investor. To mention a few:

?? downside risk protection – turning the investment into a convertible bond effectively

?? earn-out / drag-along and tag-along clauses – giving the investor the right to exercise additional control if company targets are no achieved, including the right to initiate or participate in an eventual trade sale process

The highest demand amongst the Private Equity investors investing in CEE has traditionally been for investments in the information technology, telecommunication, internet, chemical, service and manufacturing industries in this respective order. As mentioned above, the focus is expected to shift slightly towards the "old economy" sectors for the reason of global equity valuation change. Several segments, for example military and tobacco industries have always remained outside the radar screen of private equity investors and this is projected not to change, as the main investors (mainly multinational non-private organisations) should hardly change their investment mandate in the "social" respect.

In the case of MBOs and MBIs financed by the private equity investor a strict management commitment is obviously sought. The empirical evidence shows that such management team had all co-invest their 1-year income in the initial phase. In later stages, even higher participation has been quite common.

Average intended investment period sought by private equity investors in the CEE has been 6 years with the range of 3-8 years, very seldom more or less. It is worth to mention that so far very little (almost none) private equity investments have reached their intended maturity in the CEE region. Nevertheless, some investments have been exited by trade sales to strategic investors, but most of them prematurely. Crucial point, thus for every private equity investor is the mean of exiting the investment.

The process of private equity investing in the CEE countries requires perhaps even deeper attention, as several of the investment patterns not necessarily automatically work in the region, compared to the situation in Western Europe and the USA. There are certain specifics in the private equity Investment Cycle (Fig. 1) typical in the CEE region:

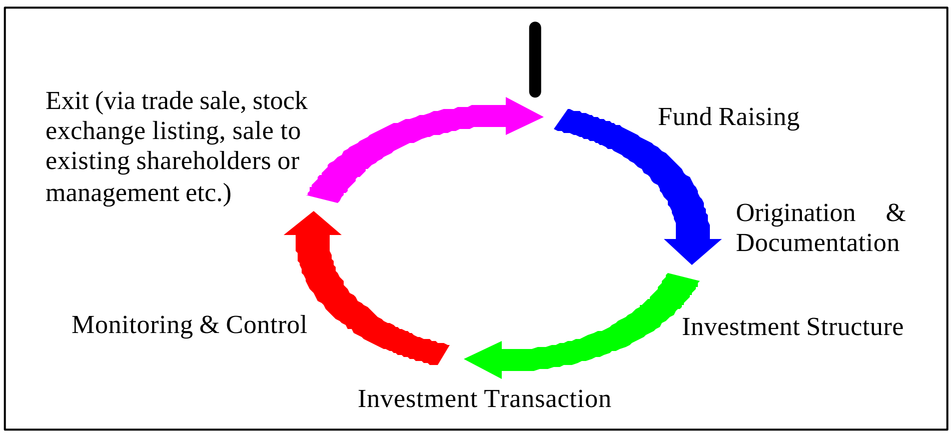

FIG. 1: PRIVATE EQUITY INVESTMENT CYCLE

?? Fund Raising – predominant investors in private equity/venture capital funds investing in the CEE region are governmental organisations and multinational non-private banks (EBRD, EIB, World Bank etc.) unlike in the USA and the UK, where the main contributors are companies from private sector like banks, pension funds and insurance companies accompanied by private individuals.

?? Origination & Documentation – as a result of smaller potential market size in the CEE countries, some burdens are placed on private equity funds investment managers in terms of the size and structure of potential deals, as there usually is only a limited number of potential sizeable deals. The potential deal-size is a hurdle, as an average private equity fund operating in the CEE region is looking for single investment of approximately $10m and it may be sometimes difficult to find suitable investment opportunity, compared to more mature and larger Western European and US markets. The lower level of corporate governance also makes it rare situation for a small and medium developing company to have an acceptable financial audit from a reputable international company (the so called big 5). As private equity funds can hardly make any investment without a thorough due diligence on the target company, the non-existence of the basic reliable financial audit poses a serious complication from time and financial point of view.

?? Investment Structure – this is where there are almost no differences in comparing private equity investments in the CEE region and their western peers.

?? Investment Transaction – itself also contains only minor differences to the process in Western Europe and the USA.

?? Monitoring & Control – requires perhaps the biggest personal involvement of the investment managers of the private equity/venture capital funds. Since the corporate governance and business culture usually do not reach the levels seen in western countries, some of the highest valued contributions of private equity investors are the new financial and business advice and the creation of corporate strategy. Nevertheless, the private equity investor's role has mainly been limited to the supervisory board membership in the investee company.

?? Exit – with very weak local equity capital markets in the CEE, the main hope for the investors must have been company trade sales to a strategic partner or some version of management buyout. Potential capital market listing has to be approached cautiously and with the view to list the investee company in the broader pan-European capital markets platform should this be suitable (LSE Alternative Investment Market etc.). Strategic investors trade sales are therefore more appropriate and enable to search for the investor on world-wide reach basis.

Among the private equity/venture capital companies investing in the CEE region, the main players are: Advent International, GE Capital, Warburg Pincus, Dresdner Kleinwort Capital, Barings Private Equity, Doughty Hanson, Emerging Market Partnership, AIG, RZB Private Equity, Bancroft UK, Renaissance Partners, EPIC, CSFB Private Equity, CVC Partners etc.

As the impact of private equity investments on the CEE region is concerned, the following table (Fig. 2) is self-explanatory. The main impacts are depicted on the level they most closely affect.

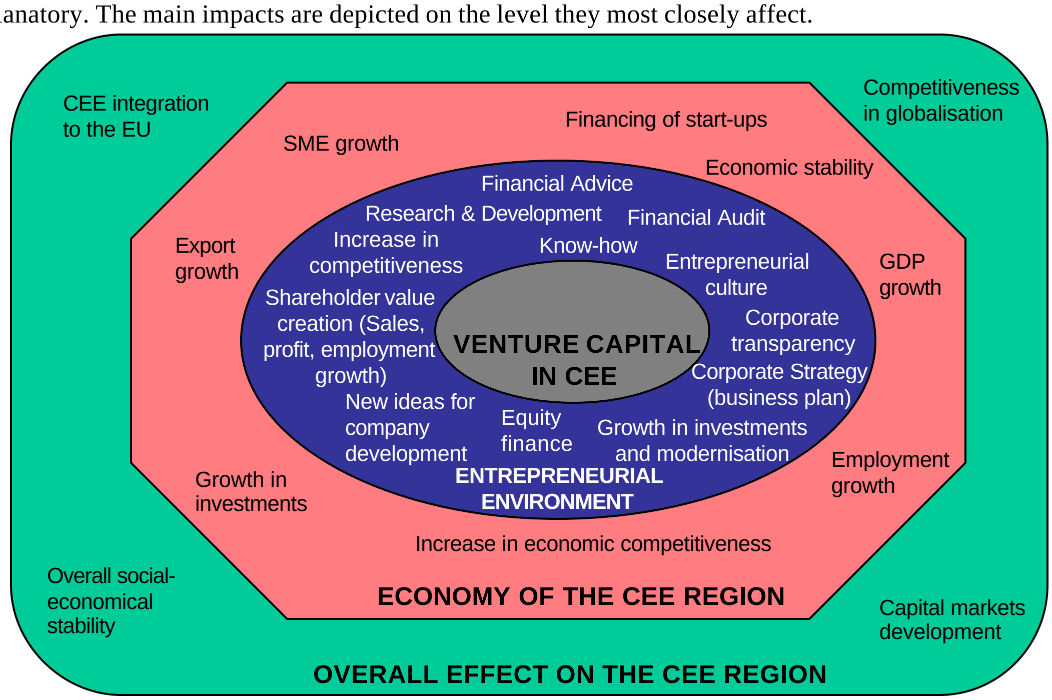

FIG. 2: THE IMPACT OF VENTURE CAPITAL/ PRIVATE EQUITY ON THE CEE REGION

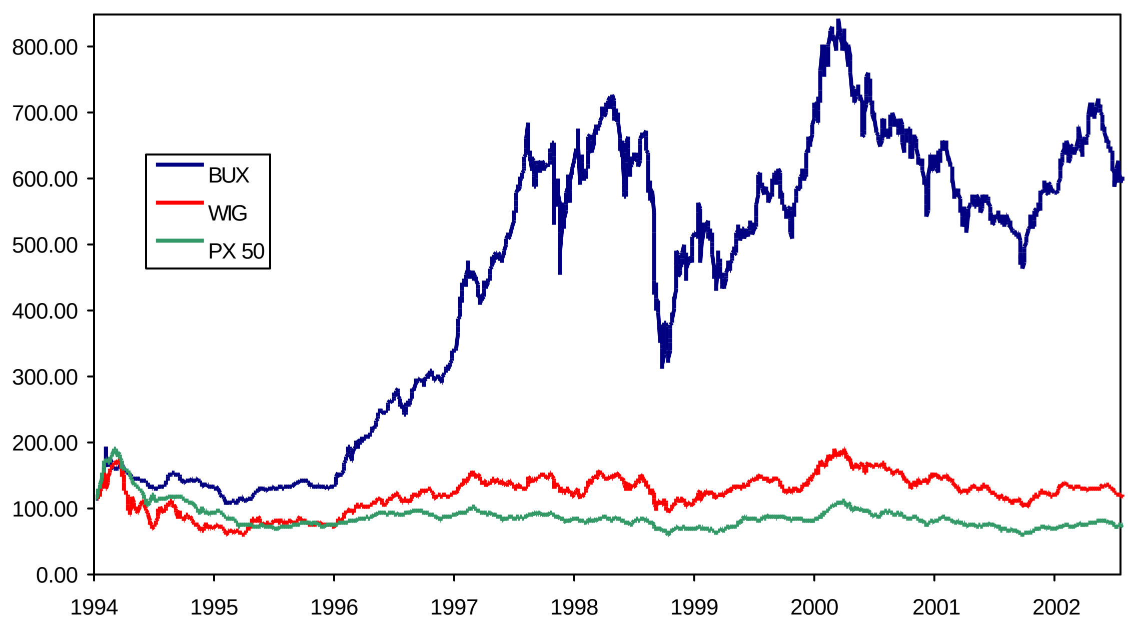
EU/CEE equity markets outlook, impact on CEE private equity

In early 1991 in Hungary, 1992 in Poland and 1994 in the Czech Republic, equity capital markets were born. Many investors rushed into the CEE region to take advantage of new, fast developing markets, which offered attractive investment opportunities in terms of very low asset valuations. Major US and European Asset Management firms contested to open dedicated CEE equity funds to attract investors. In the early stages all the CEE capital markets performed really well and most of the investors booked hefty gains in their portfolios. However, the lack of corporate governance, slow structural reforms and huge political influence over the transforming Eastern European economies caused that many of the investors "burned their fingers". The devastating effect had a special magnitude in the smaller markets (for example: foreign investment restrictions imposed in Slovenia, privatisation scandals in Slovakia etc.) or during the Russian crisis in 1998.

Looking back at the equity markets performance in major CEE countries (Fig. 3) implies that of the three main capital markets, only that of Hungary actually produced any sensible return. This implies that the typical USD-benchmarked foreign portfolio investor investing into CEE equities would be hardly posting any sensible returns on the portfolio, but perhaps breaking even in the best case.



Source: Reuters

Fig. 3: CEE EQUITY MARKETS PERFORMANCE [RE-BASED AS OF 3/JAN/1994 TO 100 POINTS]

Originally it seemed to be a brilliant idea to exit venture capital investments via equity capital markets, as most of the CEE markets did well. Unfortunately, because of the later performance the importance of the local equity capital markets has been declining. As a response to the weakening CEE markets during the last 2-3 years, some of the companies from the CEE region (mainly the early stage ones) sought listings and IPOs directly on the Western European and US bourses. Examples of that include Hungarian Graphisoft (Neuer Markt), Polish Netia (NASDAQ, LSE), Russian MTS (NYSE) and Golden Telecom (NASDAQ) etc. The recent consolidation and merger activities of western stock exchanges seem to indicate that in the future there will be a pan-European platform with special segments for trading respective industry sector based shares. As with many other things in life – size does matter – and the smaller markets (especially those of the CEE) will face a difficult challenge to survive. And with diminishing number of instruments – shares to trade – with prevailing lack of new issues and finishing privatisation activities, their independent survival might prove a major hurdle. At the end of the day the CEE stock exchanges will have to give up and integrate into broader pan-European market structure, enabling investors to enter all the European markets at once.

Important factor worth mentioning is the planned pension reform in the CEE countries and emergence of local pension fund investors base that these reforms will create. Poland has pioneered this field in the last years and with its pension reform created local investors base with assets well over $12bn as of 2003. Of this amount, nearly $2.5bn was invested in local equities, helping the Polish bourse to perform better. In future, the newly created pension funds could prove a vital driver for local stock exchanges, helping create a platform enabling private equity investors exit their investments.

Outlook for private equity investments into CEE markets

The outlook for private equity/venture capital investments in the CEE region has to be considered in the light of:

?? The European integration process – as the CEE countries converge towards the EU, not only their political systems will equalize with the EU standards, but also their economies will grow to match the levels of their western counterparts. With ill-functional or almost non-functional (in some countries) equity capital markets, one of the best opportunities for investors to bet on this convergence play seems to be the private equity business.

?? Increased financial valuations in the CEE – in certain sectors (such as the new economy), asset valuations in the CEE have already levelled out to the western rank. Nevertheless, a big gap in asset valuation remains in the field of old economy. This disparity has been caused partly by sky-high valuations in the new economy sector, partly by the difficulty to restructure the old economy to adapt to market practices and be competitive. It is this valuation gap that creates the upside potential for investors to profit on supplies of finance for the growth.

?? Globalisation and ownership centralization – as in the other parts of the world, also in the CEE, huge interest from (mainly foreign) strategic investors can be seen to take over the smaller CEE peers and to integrate them. The strong strategic investor can not only help restructure the target company, but also create savings from the economies of scale and finally, the target company profits from being a part of large conglomerate. This process started in the CEE already in early 90s, since the privatisation program began. Gradually we are witnessing a shift more towards the corporate sphere, where domestic and foreign companies integrate local CEE companies in order to maximize the synergy effects (e.g. Hungarian MOL and Slovakian Slovnaft). Private equity investors can view these globalisation and integration trends as a favourable way to exit their investment.

Private equity investment in the CEE offers opportunity whereby investors could both take advantage of very low asset valuation and look forward to rapidly developing economies. Private equity investments enable investors to more directly interact with the investee company, supervise their investments and avoid any potential problems with weak corporate governance or entrepreneurial culture, such as portfolio investors often have to face in the CEE region. Thus, private equity seems to be the best proxy to the economic growth potential of the region while maintaining certain investment protection degree. This asset class definitely seems to be poised for take-off in the CEE region. Have you got your seatbelts fastened?

Europe's ETF Market: Emerging Trend or Imminent Shake Out?

A. Seddik Meziani
Montclair State University, USA

Abstract

With over 100 product offerings in just over three years, the exchange-traded funds (ETF) market in Europe has grown remarkably in recent years. The rise of ETFs coincides with increased investor interest in (relatively cheaper) passive investing. However, doubts remain as to its potential to match the U.S. in terms of assets under management anytime soon. The European market is persistently fragmented due to multiple regulatory agencies and taxing authorities, numerous products on the same underlying benchmark, and the existence of many subscale exchanges.

Introduction

With the arrival of ETFs in Europe in April 2000, a whole new panorama of investment opportunities was opened up for both private and institutional investors. Their phenomenal growth since their introduction confirms that they are indubitably gathering momentum. So, what makes them so unique that the gap between the number of US and European ETFs has been closed in a matter of just over three years?

Demand from investors facing the dynamics of an ever-changing market has certainly been the engine behind their development and as this demand increases more esoteric ETFs are launched. But before analyzing their growth in Europe, we must first examine the environment in relation to that in the US where these investment vehicles are seemingly thriving. This could shed some light on whether European ETFs are capable of bridging the gap with their US counterparts in terms of assets under management (AUM.) as well.

Indeed, in the face of the ongoing inconsistency of the financial markets and persistent fragmentation of the regulatory markets, several experts have doubted their ability to truly match the success they have experienced in the US. These experts are, nevertheless, well aware that in addition to their phenomenal proliferation, European ETFs reached in just over two years, the same AUM level that it took the US over four years to reach.

The Two Markets Have Common Features But Also Quite A Few Differences

In a broad comparison of the US and European ETF markets, one might start by saying that the most popular ETFs in both continents have more or less the following common features: liquidity, low costs, full index replication, transparency, and simplicity. In themselves, these commonalities should logically ensure to European ETFs a degree of success similar to the one experienced in the US.

It is generally agreed that the single most important ETF characteristic is liquidity. With live prices on the exchanges and the ability to continually make bid and offer prices, dealers help generate the narrow spreads and sizes that yield a liquid product. Although an ETF's net asset value (NAV) can theoretically be different from the exchange price, arbitrage opportunities during the trading process keep both premiums and discounts at a minimum.

Spreads are also kept narrow thanks to the products' transparency. Investors know exactly what the fund is holding, which helps generate an indicative NAV at any moment in time. This allows for a continual comparison between the ETF quoted price and its so-called fair value. As to replication, in spite of all the talk regarding European integration, ETFs that fully replicate individual country indices are still among the most actively traded. In comparison, the most actively traded ETF in the US, but no means the largest, is the QQQ, which tracks the Nasdaq-100, an index that includes some of the biggest information technology companies with household names such as Microsoft, Cisco, and Dell.

Finally, one of the main benefits of ETFs is that they have cheaper management fees, compared to other investment alternatives. From this perspective, however, ETF expense ratios in Europe remain much higher than those of their counterparts in the US. For example, at the time of their launch, the Stoxx 50 LDRS (EUNF) and the FTSE 100 (ISF) products, both underlined by core benchmarks, had expense ratios of 0.35% and 0.50%, respectively, compared to only 0.12% for the Standard & Poor's 500 Depositary Receipts (SPDR) or 0.09% for the iShares S&P 500 (IVV). To their credit, total expense ratios have been gradually declining in Europe since their introduction in March 2000.

Europe's Regulatory Markets Are Still Fragmented

In spite of the many common features European offered ETFs have with US ETFs, doubts remain as to their ability to mirror US ETFs' success. Critics believe that it is one thing to rival the US in terms of the number of traded ETFs but quite another to match its success in terms of AUM. For now, total ETF assets in Europe are only a sliver of that in the US. Many reasons are being advanced as to why the two figures will not be the same any time soon including competition from the futures market and market fragmentation.

European investors are generally considered more comfortable with futures than their American counterparts. For example, it is only recently that the ban on trading single stock futures has been lifted in the US. Regulators justified the ban arguing that, just as individual securities are open to manipulation, derivatives constructed around them could also be manipulated to influence the price of the underlying stock. Given that several successful liquid futures already exist on many of the popular indices tracked by European ETFs, experts have doubted the mass appeal of these funds in Europe. Not only are European investors more familiar with futures, but also many believe that the latter carry lower transaction costs than ETFs.[i] Of course, just as in the US, increased competition could push costs significantly lower once the market has reached sufficient depth. This is not to say that buying futures is easier in Europe. Just as in the US, one has to have an established relationship with a broker as well as considerable financial resources since, contrary to ETFs, futures cannot be bought in small denominations.

Market fragmentation is another argument advanced against the success of European ETFs matching that of US ETFs. For all the talk of a united Europe, doubters point at the eurozone as still a collection of individual countries. They rightly claim that its still uncoordinated regulatory framework as shown by the existence of multiple regulatory agencies and taxing authorities keep the marketplace very fragmented. For example, considering that the widely accepted tax efficiency of ETFs has been instrumental to its growth in the US, they can hardly imagine a parallel success in an environment where unsynchronized tax regimes could turn the marketplace into a minefield for the unsuspecting investor.

Furthermore, Europe still has multiple regulatory agencies. Ceteris paribus, every individual regulatory authority must be approached separately because each has different concerns and issues that affect the product and its marketing, distribution, and trading, not to mention registration that must be enacted in different languages. For example, in Spain, deemed by ETF providers as the most difficult country along with Italy, the country's financial-services regulatory agency requires the use of government-approved translators, contrary to Sweden where the documents don't have to be translated from English. ETF approval can also take a longer time in Spain, especially if the application form isn't filed correctly.

Last but not the least**,** multiple clearing and settlement systems along with multiple product listings add extra layers of difficulties to the viability of ETFs. In the US, on the other hand, a single regulator, the SEC, controls all ETFs. They also trade mostly on one exchange, the American Stock Exchange (Amex), and in one single currency.

The European Commission, the eurozone's executive arm that is supposed to enforce single-market rules, admits that it has been slow to fix the problems. Its efforts to create a single market for financial services across the 15-nation European Union (EU) have been understandably hampered by a multitude of barriers, including dealing with a separate regulator in each country and 11 official languages.

Europe's ETF Market Is Experiencing An Explosion Of New Products

In Europe, ETFs are a relatively new industry, with the first product launched just over three years ago. Despite falling stock markets and fears that this might deter Europeans from investing, ETFs have proliferated to such an extent that Europe now has more listed ETFs than the US (122 versus 114 as of June 2003) where the first product was launched on the Amex in 1993. Table 1 illustrates the development of listed ETF offering in both areas since April 2000, with the launch by Barclays Global Investors of their iShares products in the US and Merrill Lynch of their Listed Diversified Returns Securities (LDRS) in Europe.

Table 1: LISTED ETF GROWTH: USA VERSUS EUROPE

	Assets in $US (Billions)		Number of Funds	
Date	USA	Europe	USA	Europe
Apr-00	$38.12	$0.43	30	3
Jun-00	$46.15	$0.50	56	3
Sep-00	$49.70	$0.51	76	3
Dec-00	$65.59	$0.68	80	6
Mar-01	$66.00	$1.84	83	16
Jun-01	$75.56	$2.63	85	33
Sep-01	$64.35	$3.54	92	43
Mar-02	$88.20	$6.90	102	92
Jun-02	$88.95	$8.50	102	92
Sep-02	$82.26	$7.70	106	111
Dec-02	$102.14	$10.69	113	118
Mar-03	$102.28	$11.86	114	116
Jun-03	$121.20	$15.78	114	122

Source: Morgan Stanley, Investment Company Institute, Bloomberg, and SSGA.
As of June 30, 2003.

The total assets under management for European ETFs stand at $15.78 billion (13.52 billion euros at 1.1674 US dollar to the euro) as of June 2003. This represents approximately 13% of the US market. The US therefore clearly remains the leading market for ETFs even if Europe has made huge strides illustrated by a significant growth of about 86 percent over the June 2002 figure and a remarkable 232 percent since April 2000. Also worth noting is the fact that European ETFs have reached the $10.7 billion mark in just over two years, the same level that it took the US over four years to reach.

It Is Also Experiencing A Proliferation Of ETF Managers

Europe's ETF market is quite open as shown in Table 2. It leads the rest of the world with 14 managers, followed by the US with 7 managers, then Japan and Korea with 4 managers each. In the US the ETF market remains dominated by a few players such as Barclays Global Investors (BGI), State Street Global Advisors (SSGA), and the Bank of New York (BONY). Europe's three main issuers share around 58% of the market compared to a much higher percentage for the aforementioned US managers. With 24 percent market share and 32 ETFs listed on the Deutsche Borse, IndEXchange is now the largest manager of ETFs in Europe. Set up by HypoVereins Bank, it is based and distributes mainly in Germany. This is quite a change from 2000, when US-based companies such as BGI and Merrill Lynch had the market for themselves. With 15.3 percent and 13.7 percent, respectively, these two companies have slipped to third and fourth in terms of market share, behind the surging Lyxor. Lyxor is the asset management subsidiary of Societé Generale, another European-based ETF provider. Relatively speaking, it is a brand new player, which has hit the ground running with the Master Share CAC 40 (CAC FP). Targeting the institutional market, Lyxor quickly grabbed 18.8% of the market, which translates into $US2.98 billion in managed assets. Although a dominant player in the US ETF market, SSGA ranks only sixth in Europe with 6.8% market share. To its credit, however, SSGA joined the crowd with its streetTracks sector funds much later than the two aforementioned American companies. The dominance of banks on the European ETF market underscores another major difference between it and the US market. Usually, this is a function of better distribution channels. Because they seem to benefit from the trust of European private investors who are more accustomed to dealing with banks than with money managers, they can effectively use their existing channels to educate and facilitate the acceptance of ETFs by the general public. In the US, on the other hand, money managers predominantly run the ETF market. Here, the focus is on brand recognition of not only the sponsoring institution but more importantly the underlying index. As a case in point, SSGA is the manager of the SPDR which is based on the S&P 500 and is the largest ETF in the world; despite this, the SSGA streetTracks ETFs, based on lesser known Dow Jones indexes have gathered very few assets and some were even discontinued.

Table 2: MANAGERS OF EUROPEAN LISTED ETFs

Managers	Number of ETF Li	Assets	Market
stings	(Billions)	Share (%)	
AXA Gestion	12	0.39	2.5
BGI	15	2.42	15.3
Credit Lyonnais	2	0.51	3.2
Credit Suisse	5	1.59	10.0
IndEXchange AG	32	3.80	24.0
Merrill Lynch LDRs	15	2.33	14.7
Societe Generale (Lyxor)	5	2.98	18.8
SSGA	15	1.08	6.8
UBS Asset Management	11	0.48	3.0
Others	5	0.29	1.8
Total	117	15.80	100.0

Europe Has Many ETF Exchanges

Unlike the US, which still has one dominant exchange for the listing of ETFs (the Amex), Europe has several exchanges competing for ETF activity (see Table 3). Whether there are too many exchanges or just enough to keep the competition healthy is, of course, a matter of opinion.

Despite the existence of UCITS rules established to facilitate the marketing and distribution of ETFs in Europe, a still fragmented marketplace has forced issuers in Europe to go through the time and expense of obtaining multiple listings on these exchanges. However, even as European investors seek to diversify their ETF holdings, they still buy the funds primarily on the Deutsche Borse, the first exchange to list ETFs in 2000.

Table 3: ETF TRADING VOLUME IN EUROPE

Exchange	Average Daily USD Volume	Share Daily Volume (%)
Berlin Stock Exchange	$19,501	0.0%
Borsa Italiana	$6,4343,306	2.0%
Deutsche Borse	$140,751,718	44.2%
Euronext	$70,573,466	22.2%
London Stock Exchange	$59,079,960	18.6%
Swedish Stock Exchange	$17,335,661	5.4%
Swiss Stock Exchange	$20,791,629	6.5%
Virt-x	$3,140,413	1.0%
Total	$318,330,227	100.0%

Source: Morgan Stanley. As of June 30, 2003

According to data obtained from Morgan Stanley, the Deutsche Borse garnered nearly 44% of the volume of Europe's ETF business. Euronext, the only pan-European exchange follows with 22.2% of the trading volume.[ii] With 57 and 56 ETF listings, respectively, these two exchanges are considered the most assertive and successful of the group and have emerged as the main centers of ETF activity in Europe. With far fewer listings (16) but 18.6% of the trading volume, the London Stock Exchange is not far behind Euronext. Virt-x, one of the smallest of these exchanges, is known as the pan European blue chip electronic exchange. Until the beginning of 2003, Virt-x was jointly owned by a consortium of ten banks and the SWX Swiss Exchange. SWX has since bought out the banks and now owns about 95% of the equity capital and voting rights of Virt-x. According to the exchange's web site (www.swx.com), SWX is the only exchange that offers ETFs in multiple currencies.

Certainly there are subscale exchanges in Europe that would not have survived in a more homogeneous setting such as the one characterizing the US financial markets. Because fragmentation seldom generates market efficiency, these markets are not expected to disappear as long as the former persists. Also, fragmentation has made it hardly possible to find one source where all ETF data is deposited on a timely and regular fashion. As a result, information important to investors such as closing prices is sometimes hard to find.[iii]

Asset Allocation In Europe's ETF Markets

The flexibility and lower expense ratios of ETFs when compared to other financial products has fueled their growth in Europe just as it has in the US and elsewhere. Compared to their underlying securities, they provide a level of diversification that would otherwise be time consuming and expensive. They also provide a more efficient investment alternative for settlement and administrative purposes.

Table 4: ETF BY INDEX CATEGORY

	Market Share (%)	AUM ($US)	Market Share (%)
Eurozone	32%	$4,834,110,212	31%
Regional Europe	12%	$1,551,703,802	10%
Eurozone Sectors	2%	$529,168,740	3%
Europe Sectors	6%	$689,020,480	4%
Global Sectors	2%	$155,018,991	1%
European Country Benchmarks	38%	$5,948,387,739	38%
International	8%	$1,844,444,306	12%
Fixed Income	0%	$206,069,950	1%
Total	100%	$15,757,924,220	100%

Source: Numbers compiled from Morgan Stanley Equity Research Europe Data

In setting their investment objectives, European investors seem to consider their fragmented markets as temporary. Indeed, in spite of the continuing volatility of the financial markets, on most measures Europeans seem to have more or less maintained the level of their investments in European-listed ETFs.

Beyond issuer or exchange differences, it is telling to look at ETF growth broken down by investment coverage. In table 4, ETF AUM is divided into eight distinct investment categories reflecting the dynamics underlying Europe's current business environment. The difference between regional Europe and the eurozone is that the constituents in the latter comprise only those countries in the EU that have joined the euro, whereas the former can be made up of ETFs from any country located in Europe regardless of its monetary denomination.[iv] Country benchmarks are based on established local indices such as the CAC 40 in France, Germany's DAX or England's FTSE 100.

Country indices are the most familiar indices to European investors and have a long history as the basis for investment. Unsurprisingly, with 38% of ETF AUM (a portion that remains little changed since December 2002) country-based ETFs still command most of European investors' attention. This is followed by regional ETFs such as those tracking the eurozone (31%) and regional Europe (10%).

As to sector investing, in theory it should appeal to investors who seek the performance potential that individual stocks in a sector may offer but do not want to take the responsibility of researching individual companies. It should also attract investors who want to target a strategic opportunity and believe that a particular sector is about to enter a period of strong performance.

In practice, however, sector investing does not seem to have picked up in Europe, in spite of allegations to the contrary from the financial press.[v] According to Morgan Stanley's data (see table 4), the market share of both global and Europe's sectors decreased over a sixth-month period starting December 2002, whereas that of the eurozone sectors increased a modest 1%. This trend or lack of may explain recent announcements by Merrill Lynch, BGI, and UBS to discontinue a total of 26 sector ETFs in Europe.

Clearly, there is a lack of interest in sector investing on the part of European investors in spite of its theoretical groundings. In an effort to explain it, one might suggest that they have perhaps come to realize that the establishment of a single European market is not a simple matter after all and will take sometime to implement. As to the ETF providers, some of the main players may have decided that these products are too costly to maintain given their low asset base although launching these sector ETFs seemed logical given Europe's move toward integration. Perhaps, they have realized that they have simultaneously jumped into a still shallow market creating a crowding out effect. Whether this is a shakeout from which fewer but more economically viable products will emerge remains to be seen.

Conclusion

While the European market for ETFs has developed significantly on most measures over the past few years, certain changes to the environment in which these investment vehicles continue to operate remain necessary for sustained growth. These changes should lead to a true pan-European single market that eliminates the need for individual country registration. By facilitating ETF access to both institutional and retail investors and significantly lowering their costs, such a market would allow the ETF trend in Europe to truly mirror that of the US.

In the meantime, ETF exchanges, such as Euronext, which provide a single point of entry for issuers instead of approaching each country's regulatory authority separately for permission to be listed, might be a partial answer to the regulatory challenges still beleaguering Europe's ETF market.[vi] Under the Euronext market format, trading fees become uniform because the same electronic platform facilitates the listing, clearing processes, and the trading of the product. However, other serious issues such as taxes remain unresolved as they continue to depend on the investor's country of residence.

End notes

[i] Although many experts advise to carefully weigh up the difference in costs. For example, Massoud Mussavian, director of equity derivatives and Jacques Hirsh, equity derivatives analysts, both at Goldman Sachs, advise investors to carefully assess the initial costs and holding costs associated with the two investment alternatives. For more detail, see M. Mussavian and J. Hirsh in "Counting the Costs: ETFs versus Futures," *Financial Times Mandate* (June 3, 2002).

[ii] Euronext was created in September 2000 by the merger of the Paris, Amsterdam, and Brussels exchanges.

[iii] For detail, see "A Future Replacement," the theme of a round table organized by *Global Pensions* (July, 2002).

[iv] The member countries are Austria, Belgium, Finland, France, Germany, Greece, Ireland, Italy, Luxembourg, the Netherlands, Portugal and Spain. Collectively these countries are known by their official name of the 'euro area' or more formally the 'eurozone'. Denmark, Sweden, and the United Kingdom are the three remaining members of the EU who have yet to join. Note that Sweden overwhelmingly rejected the euro in a recent vote.

[v] For example, see "European and Global Sector Products," the theme of a round table in the *Financial News*, December 17, 2001 or more recently, an article by Eelco Ubbels "Stock Picking is Old Economy: Sector Picking Will be the Future," in *International Fund Management*, March-April, 2003.

[vi] Currently, issuers gain access to trade on the three exchanges comprising Euronext simply by choosing one as their home market and jurisdiction. This means that they are subject to only one regulatory authority, that of the country in which they are granted permission to list.

Test of Weak Form Market Efficiency: Evidence from Dhaka Stock Exchange

Ainul Islam
Massey University, New Zealand
Mohammed Khaled
Victoria University of Wellington, New Zealand

Abstract

The Dhaka Stock Market appears to be weak-form efficient. Stock prices have a unit root. Predictability of returns arising from auto correlated errors is also ruled out by variance ratio tests. Although a heteroscedasticity-robust Box-Pierce test was used by Lo and MacKinlay (1989) in their Monte Carlo experiments, our study appears to be the first one to apply this test to stock prices. By this test, we have resolved the conflicting results reported by two recent studies of the Dhaka market. Autocorrelation tests typically reject weak-form market efficiency. Given our results, we suspect that previous findings, based on the usual autocorrelation tests, may be reversed by using a heteroscedasticity-robust test.

1. Introduction

The securities market is a crucial institution in the financial system of any country. The activities of buying and selling of shares on the securities market are extremely important for efficient allocation of capital through proper pricing of capital and risk. An active securities market contributes to economic growth by increasing the funds available to finance industries and other productive enterprises, and by channelling the funds into the appropriate industries and other productive activities. In a capital starved country like Bangladesh, efficient allocation of scarce resources and encouragement of foreign private investment are both of vital importance. Success of an increasing privatisation of the economy now under way in Bangladesh will depend crucially on the presence of an active share market. The role of stock markets in harnessing domestic saving takes on an extra dimension in a country like Bangladesh with a predominantly Muslim population. According to the Islamic faith, usury (*riba*) is prohibited. The correct interpretation of *riba* is a highly contested matter in Islamic economic discussions, but there are many Muslims who consider any fixed interest saving instruments as unacceptable. For such people, a well functioning stock market can provide an ideal alternative saving/investment mechanism. At present, there are two stock exchanges in Bangladesh, namely, the Dhaka Stock Exchange (henceforth DSE) and the Chittagong Stock Exchange (CSE).[1] For the purpose of this study we will concentrate on the DSE, as this is the country's oldest stock exchange, and according to Standard & Poor's "Emerging Stock Markets Fact book 2000", the DSE is one of the frontier emerging markets of South Asia.

Compared to the stock markets in developed countries, the emerging stock markets are in many cases characterised by a lower volume and frequency of trading ('thin trading'), ease of manipulation by a few large traders, weaker disclosure and accounting requirements, settlement delays, and a generally less than smooth transmission of financial information. If correct information on business performance and prospects fail to be quickly and fully reflected in the stock prices, those who are privy to such information can benefit by anticipating the course of such prices. Stock markets are said to be efficient when all available relevant information is reflected in the stock prices. Any abnormal price changes should not be predictable in an efficient market. When any random components in the changes of a share price are not correlated, unpredictability (or efficiency) of such a price is also known as a 'random walk'. Emerging stock markets may not be efficient in this sense owing to imperfections like those mentioned above. By failing to price capital and risk correctly, an inefficient stock market is not likely to be able to make its full possible contribution to economic development of a country.

A stock market is said to be inefficient in the weak form if stock prices and/or returns are predictable based on past information on them. The findings of market efficiency tests (mostly weak-form efficiency tests) on emerging markets are rather varied. Some researchers find evidence in favour of weak-form efficiency, as they cannot reject the hypothesis of a random walk in emerging markets (Chan, Gup and Pan, 1992; Dockery and Vergari, 1997; Ojah and Karemera, 1999; Alam, Hasan and Kadapakkam, 1999; Cheung and Coutts 2001; and

Abrosimova and Linowski, 2002). On the other hand, some researchers are able to reject the hypothesis of random walk, and therefore find evidence of predictability of stock prices in the emerging markets (Ko and Lee, 1991; Claessens, Dasgupta and Glen, 1993; Cheung, Wong and Ho, 1993; Urrutia, 1995; Poshakwale, 1996; Lee, Chen and Rui, 2001; Smith, Jefferies and Ryoo, 2002; and Mobarek and Keasey, 2002).

There have been only two studies so far (Alam, Hasan and Kadapakkam, 1999; and Mobarek and Keasey, 2002) testing the market efficiency of DSE. The results are conflicting. Applying a variance ratio test, Alam, Hasan and Kadapakkam found that the monthly stock price index series of the DSE (during 1986 to 1995) followed a random walk, which implies the existence of weak-form efficiency in the market. However, by applying runs and autocorrelation tests, Mobarek and Keasey concluded that the daily price index series of the DSE (for the period of 1988 to 1997) did not follow a random walk. In addition to the aggregate DSE index, Mobarek and Keasey also considered 30 randomly selected companies which had shares actively traded during their study period. Their results for these individual shares also suggested that the Dhaka Stock Market was not weak form efficient.

However, Mobarek and Keasey concluded that one should interpret their findings cautiously because of some limitations in their study, e.g. they used daily data, which may not allow a reliable test of stock market efficiency in a country like Bangladesh where thin or infrequent trading is a problem for some individual components of the share price index. Other limitations of their study are that, in their individual company tests, they used data that were not adjusted for dividend, bonus and rights issues; prices not adjusted for these factors might not reflect the real forces driving the market.

Besides making a contribution to the literature on the assessment of efficiency of an emerging stock market with more recent information, the aim of this paper is to revisit the Dhaka Stock Market data to determine if the conflicting results reported by the only two studies on this market to date stem from different test methods employed and/or from the use of monthly versus daily data. We carry out a more comprehensive study by considering data at all of the three intervals – daily, weekly and monthly. The DSE index and the individual indices for the top 95 companies listed on the DSE – those with market capitalisation above the median level – are examined for the period January 1990 to November 2001. The rest of our discussion begins by outlining the various methods typically employed in testing for stock market efficiency in section 2. A brief summary of results of such tests in developed and emerging stock markets are then presented in section 3. A short history of the DSE and description of data on the DSE share prices used in our tests are included in section 4; this is followed by a presentation and discussion of efficiency test results in section 5. Our conclusions are finally stated in section 6.

2. Methodology

Efficiency in financial markets is generally represented as lack of predictability of market returns in excess of normal returns. According to the weak form of the efficient market hypothesis (EMH), the current rate of return cannot be predicted by past rates of return. If P_t is a share price, rate of return $R_t = \ln P_t - \ln P_{t-1}$. Consider the multiple regression:

$$R_t = ?_0 + ?_1 R_{t-1} + ?_2 R_{t-2} + \ldots + ?_k R_{t-k} + ?_t \qquad (1)$$

Where $?_t$ is a random error. Here, the weak EMH is the hypothesis that H_0: $?_1=0, ?_2=0, \ldots, ?_k=0$. Under this hypothesis, $R_t = ?_0 + ?_t$, that is,

$$\ln P_t = ?_0 + \ln P_{t-1} + ?_t \qquad (2)$$

Which is known as a ‘random walk’ or a ‘unit root’ process. Thus, weak EMH can be tested in two alternative ways, either by testing H_0: $?_1=0, ?_2=0, \ldots, ?_k=0$ in (1), or by testing for a unit root in (2). An F-test could be used for the former if R_t satisfied stationarity, i.e. it didn’t have a unit root. An alternative to this test used by many investigators of the EMH is the Box-Pierce test of autocorrelations. Let correlation between R_t and R_{t-h} = $?_h$. Under weak EMH, $?_h = 0$ for any h. In this case, the statistic

$$Q = T\sum_{j=1}^{h} \hat{\rho}_j^2 \qquad (3)$$

Where T is the number of observations, is asymptotically distributed as chi-square with h degrees of freedom.[2]

Unit roots are usually tested by an augmented Dickey-Fuller (ADF) or a Phillips-Perron (PP) test, but a more commonly used test in financial economics is the variance ratio (VR) test developed by Lo and MacKinlay (1988). This test is based on the fact that the variance of the q^{th} difference of a random walk increases linearly with q. Let $\Delta \ln P_t = \ln P_t - \ln P_{t-1}$ be the first difference, and $\Delta_q \ln P_t = \ln P_t - \ln P_{t-q}$ be the qth difference. The variance ratio $[var(\Delta_q \ln P_t)]/[q(var(\Delta \ln P_t)]$ will equal 1 for a random walk process. Using this ratio, Lo and MacKinlay define another measure:

$$M(q) = [var(\Delta_q \ln P_t)]/[q(var(\Delta \ln P_t)] - 1 = \sum_{j=1}^{q-1} \frac{2(q-j)}{q} \hat{\rho}_j \qquad (4)$$

Where $\hat{\rho}_j$ is the sample autocorrelation coefficient of order j of the $\Delta \ln P$ series. A significant departure of this value from 0 would indicate absence of a random walk. In particular, significant negative values would indicate the variance of the qth difference increasing less than linearly with q. This situation, known as 'mean reversion', occurs when stock price changes are negatively correlated. This can arise in the presence of a zero-mean stationary component in the stock prices representing transitory deviations from the efficient market prices owing to "irrational bubbles in prices" and/or "large rational swings in expected returns" (Fama, 1991). According to the story told by Bagehot (1971) and Kyle (1985), dealers lose when trading with the informed investors, but recoup the losses by trading with the uninformed "noise" investors. Mean reversion can occur as the private information of the informed investors is gradually reflected in market prices.

Given a total of T observations, a test statistic using (4) is given by:

$$z(q) = \frac{(\sqrt{T-1})M(q)}{\sqrt{\theta(q)}} \qquad (5)$$

where $\theta(q) = \sum_{j=1}^{q-1} \left[\frac{2(q-j)}{q}\right]^2 \hat{\delta}_j$, $\hat{\delta}_j = \dfrac{(T-1)\sum_{k=j+2}^{T} (\Delta \ln P_k - \hat{\mu}_0)^2 (\Delta \ln P_{k-j} - \hat{\mu}_0)^2}{\left[\sum_{k=2}^{T} (\Delta \ln P_k - \hat{\mu}_0)^2\right]^2}$, and $\hat{\mu}_0$ is the sample mean of the first differences. Under the null hypothesis of a random walk, statistic (5) is asymptotically standard normal for any q, and is robust to both heteroscedasticity and non-normality. VR tests are typically carried out using this statistic.

The hypothesis of random walk cannot be rejected by the VR test if it is not rejected for *all* the selected q's. For a test at the 5% level, if we compared each |z(q)| with 1.96, the overall significance of the test would not be 5% as multiple variance ratios are involved in this comparison. Chow and Denning (1993) proposed a multiple variance ratio test by which the random walk hypothesis can be rejected at 5% significance only if $\underset{q}{Max}|z(q)| >$ SMM(0.05, m, v), the latter being the critical value with a 5% upper tail area of the

Studentised Maximum Modulus (SMM) distribution with m = k(k-1)/2 where k is the number of q's selected, and v = degrees of freedom (= T-k).[3]

Lo and MacKinlay (1989, p. 210-211) pointed out that a heteroscedasticity-robust Box-Pierce test could also be constructed using $\hat{?}_j$. In this case, the test statistic

$$Q = ?_{j?1}^{h} \frac{\hat{?}_j^{2}}{\hat{?}_j} \tag{6}$$

With an asymptotic chi-square distribution with h degrees of freedom could be used in the case of large samples.?

Stock prices and/or returns are typically found to be non-normal in distribution. This is not really a problem for our tests above if the sample is large as these tests are valid asymptotically even with non-normal errors. In the case of small samples, predictability of returns can also be checked by using the runs test of independence, which is a non-parametric test free of the normality assumption.

3. A Review of Empirical Evidence on Weak-Form Efficiency Tests

We will begin by looking at a few studies of developed stock markets. Campbell, Lo and Mackinlay (1997*)* used weekly stock returns data from 1962 to 1994 for the USA (NYSE-AMEX returns). The results of their VR tests show that the random walk model is rejected for the equal-weighted index, but not for the value-weighted index, suggesting that market capitalization or size can make a difference in these tests. Their results for the individual stocks on average tend to support the random walk hypothesis, company-specific noise being the likely reason for unpredictability of the individual returns relative to the aggregate portfolios.

Since mean-reverting behavior can lead to a rejection of the random walk hypothesis, investigations have also been carried out with returns data on stocks held for periods long enough to allow such behavior. For example, Poterba and Summers (1988) investigated monthly data on NYSE returns from 1926 to 1985, as well as annual returns data for the years 1871 to 1985. Results of their VR tests suggest that returns at long-horizons show negative serial correlation, i.e. mean reversion.

In contrast to the significant negative serial correlation that Poterba and Summers found for longer horizon returns, Lo and MacKinlay (1988) found no evidence against the random walk model in the four-weekly NYSE-AMEX returns for the years 1962 to 1985. Even the Poterba and Summers (1988) data do not really contradict the random walk hypothesis for long horizon returns as Chow and Denning (1993) demonstrated by applying a multiple VR test, which is the appropriate VR test to use.

Daily stock returns data can also be used to study market efficiency if data do not suffer from non-trading and spurious autocorrelation that can be induced by it. Groenewold (1997) examined share market efficiency of Australia and New Zealand using daily, weekly and monthly share price indices for the period 1975-92. Presence of a unit root was not rejected by the ADF and PP tests, but weak EMH was not supported by the VR test owing to correlated errors.

Chan, Gup and Pan (1992) used unit root and cointegration tests to examine the daily and weekly stock market indices in Hong Kong, South Korea, Singapore, Taiwan, Japan and the United States. They found unit roots in stock prices, but there was no evidence of co-integration among stock prices across countries. Hence, they concluded that the stock prices in major established Asian markets and the United States were weak form efficient individually and collectively in long run.

More recently, Cheung and Coutts (2001) failed to reject the random walk hypothesis for the Hong Kong Hang Seng Index with daily data over the period of January 1985 through June 1997, hence concluding that the Hang Seng Index is weak-form efficient.

Thus, developed stock markets generally appear to be weak form efficient, but the evidence summarized below for emerging stock markets – including the fairly new and the relatively older ones – are rather mixed.

Urrutia (1995) examined monthly stock price indices for four Latin American countries (Argentina, Brazil, Chile and Mexico) from December 1975 to March 1991 to test for the presence of random walk. Weak form efficiency was supported by runs tests, but variance ratio tests led to rejection of the random walk hypothesis for Brazil, Chile, and Mexico.

Ojah & Karemera (1999) revisited the study of Urrutia on the four Latin American emerging equity markets using both single and multiple VR tests. Monthly stock price indices expressed in US dollars for the period December 1987 to May 1997 were used. Results of single VR tests were like those of Urrutia, but the multiple VR tests led them to conclude that all four equity series followed random walk and that the markets were weak form efficient.

Smith, Jefferis and Ryoo (2002) used multiple variance ratio tests of random walk on eight African stock markets including the largest market (South Africa), five medium size markets (Egypt, Kenya, Morocco, Nigeria and Zimbabwe) and two small new markets (Botswana and Mauritius). They used weekly data for January 1990 to August 1998 except for Egypt and Nigeria, for which the series start in the first week of January 1993, and 1994 respectively. Their results show that only the price index of the Johannesburg stock exchange of South Africa followed a random walk.

Dockery & Vergari (1997) examined the random walk hypothesis for the Budapest Stock Exchange (BSE). They used weekly observations for the BSE share price index covering the period January 1991 to May 1995. Their VR test results indicated that the Budapest Stock Exchange was efficient in the weak form.

The existence of weak form efficiency in the Russian Stock Market was examined by Abrosimova and Linowski (2002) using daily, weekly and monthly Russian Trading System (RTS) index series covering the period from 1/9/95 to 1/5/2001. They conducted unit root tests and variance ratio tests to assess the predictability of the RTS index. ADF tests indicated presence of a unit root, but autocorrelation and VR tests supported weak form efficiency only in the case of the monthly index.

Empirical studies in testing of market efficiency of Asian emerging markets is not very extensive. The findings of the studies undertaken so far are also conflicting. Poshakwale (1996) investigated weak-form efficiency in India using the daily price index of the Bombay Stock Exchange over the period of 1987-94. Evidence based on runs test and serial correlation test suggested that the Bombay Stock Exchange was not efficient in the weak form.

Alam, Hasan and Kadapakkam (1999) applied variance ratio test to five Asian stock markets: Bangladesh, Hong Kong, Malaysia, Sri Lanka and Taiwan to test if these markets were efficient in the weak form. They used monthly value-weighted market indices from November 1986 through December 1995. Results of VR tests indicated that the index return series for Bangladesh, Hong Kong, Malaysia and Taiwan followed random walk, implying the existence of weak-form efficiency in those markets. The authors suggested that rejection of the hypothesis of random walk in the case of Sri Lanka might be due to a serious infrequent trading problem in that market rather than market inefficiency.

Lee, Chen and Rui (2001) examined daily returns for the Chinese stock indices, Shanghai A & B and Shenzhen A & B, for the period 1990 to 1997. The random walk hypothesis was rejected by both ADF and VR tests.

Mobarek and Keasey (2002) wanted to find out if the Dhaka Stock Exchange (DSE) was weak form efficient. Their sample included the daily indices of 30 of the listed securities on the DSE as well as the all-share index for the period 1988 to 1997. The indices were not adjusted for dividend, bonus and rights issues. Using a non-parametric test (the runs test of independence) as well as autocorrelation (Ljung-Box Q test) and auto regression tests, they concluded that the market index as well as an overwhelming majority of the individual indices did not follow a random walk.

4. A Brief History of the Dhaka Stock Exchange (DSE) and Data

The DSE was incorporated on April 28, 1954 under the name of East Pakistan Stock Exchange Ltd., but formal trading started later in 1956. On June 26, 1962, it was renamed as the Dhaka Stock Exchange Ltd. After separation of Bangladesh from Pakistan as an independent country in 1971, the activities of the Exchange were suspended in pursuance of the economic policy of the government at that time. Trading activities resumed in 1976 with only nine listed companies with a total paid up capital of Taka 137.54 millions (equivalent to US$ 2.75 millions approximately) on the board.

Since August 1998, the DSE has been providing automated screen-based trading facilities for its members, and all the buy or sell orders are now processed by a computerized trading system every day except Friday – the weekly holiday in Bangladesh – and the other government holidays. Normally, a client who wants to buy or sell shares opens an account with a broker. The system is designed to match the best buy and sell orders, and to confirm the deal automatically. After the trade, the broker sends a contract note called '*Howla*' giving details of the transaction to the client for settlement. Although DSE turnover has increased rapidly since automation, the trading system and facilities prior to that time were primitive by international standards.

The size of a country's security market is usually measured by market capitalization, and its liquidity by turnover and turnover ratio. Unlike other Asian countries, the size of the DSE market in terms of market capitalization and number of listed securities is relatively small, but the turnover ratio is fairly high. The position of Bangladesh in terms of these measures compared to other emerging markets in Asia in 1999 is shown in table 1.

TABLE 1: NUMBER OF LISTED COMPANIES MARKET CAPITALIZATION, TURNOVER AND TURNOVER RATIO IN SELECTED EMERGING STOCK MARKETS 1999

Country	No. of Listed Companies	Market Capitalization (US$ Million)	Turnover (US$ Million)	Turnover Ratio (%)
Bangladesh	211	865	789	83.0
Sri Lanka	239	1,584	209	12.7
Philippines	226	48,105	19,673	47.2
Thailand	392	58,365	41,604	89.2
Indonesia	277	64,087	19,903	39.8
Malaysia	757	145,445	48,512	30.9
India	5,863	184,605	122,247	84.4

Sources: Emerging Stock Markets Fact book: 2000, IFC, Washington.

The DSE has been growing rapidly since 1999. As of October 2002, there were 258 securities listed on the stock exchange consisting of 239 shares, 10 mutual funds and 9 debentures. Total market capitalization of all listed securities was approximately US$ 1.2 billions.

After the stock market crash in 1996, the policy makers took various steps to reorganize the capital market and to regain the confidence of investors in the market. The market is now comparatively more transparent due to self-regulation of the Exchange and close monitoring by the Securities & Exchange Commission (SEC). The Dhaka Stock Exchange is now being considered as one of the frontier emerging markets of South Asia.

DSE Price Indices and Returns

This study uses daily, weekly and monthly market prices and returns of the Dhaka Stock Exchange during the years 1990 to 2001. Starting from January 1990, the daily market price data cover the period up to 23 November 2001, while the weekly and monthly price data cover the period up to 21 November 2001 and 31 October 2001 respectively. The price indices for the period 1992 to 2001 were collected from Data Stream Advanced Version 3.5 developed by Data Stream International Limited. Data for the period 1990 to 1991 were taken from the daily price quotations (after adjustment for bonus and right issues) of the Dhaka Stock Exchange.

A plot of the monthly indices in figure 1 gives an idea of how the prices changed during the sample period. The market peaked in November 1996 (month 83 in graph).

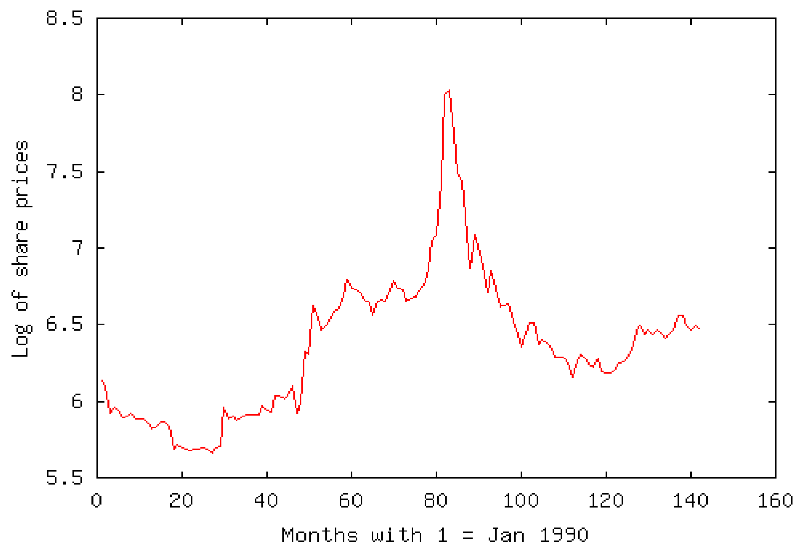

Figure 1 : Log of Monthly Share Prices, Jan 1990 – Oct 2001

Some summary statistics for market returns calculated as first differences of log prices appear in table 2.

TABLE 2: SUMMARY STATISTICS FOR DAILY, WEEKLY, AND MONTHLY MARKET RETURNS

	Total # of Observations	Mean	St. Dev.	Minimum	Maximum	Skewness	Kurtosis
Daily Returns Jan 90 - 23 Nov 01	3104	0.00009	0.0188	-0.3464	0.3264	0.472	105.123
Weekly Returns Jan 90 - 21 Nov 01	617	0.00045	0.0459	-0.3369	0.4604	1.040	29.137
Monthly Returns Jan 90 - Oct 01	141	0.00236	0.1070	-0.3508	0.5692	1.221	7.427

Weekly return is computed as the return from Wednesday's closing price index to the following Wednesday's close. If the following Wednesday's price is missing, then Thursday's price (or Tuesday's price if Thursday's is missing too) is used. The monthly return is computed as the return from the month end index. If the last day of the month is a holiday, then the following day's closing price is taken. If the following day's price is also missing, the index of the day before the month end day is taken.

Average stock returns in table 2 are all positive, but the distributions of returns are leptokurtic, i.e. more sharply peaked about the mean than a normal distribution, and positively skewed in all the cases. Non-normality of stock returns is a common feature of most stock prices, e.g. Poshakwale (1996) for the Indian market, and Smith, Jefferies and Ryoo (2002) for African stock markets.

5. Results and Analysis

Unit Root Tests

The daily, weekly and monthly Index series of Dhaka Stock Exchange are first tested for the presence of unit root in the log of the index using Augmented Dickey-Fuller (ADF) and Phillips-Perron (PP) tests as formulated in SHAZAM (Whistler, White, Wong and Bates, 2001). In both tests, a linear trend term is included. The null hypothesis for each series is that it is generated by a difference-stationary model against the alternative of a trend-stationary model. The lag length in the ADF test and the truncation lag in the PP test were chosen by SHAZAM as the highest significant lag order from either the autocorrelation function or the partial autocorrelation function of the first differences (i.e. the returns in this paper). The unit root hypothesis can be rejected if the t- test statistic is smaller than the critical value.

The results of the unit root tests reported in table 3 indicate that we cannot reject the null hypothesis of a unit root for any of the series by either test at the 5% level of significance; in each case the test statistic is not smaller than the critical value.

TABLE 3: TESTS OF UNIT ROOT IN THE DSE ALL-SHARE PRICE INDICES

	Total # of Observations	**ADF**	**PP**	**Critical Value @ 5%**
Log Daily Index	3105	-1.849	-1.262	-3.41
Log Weekly Index	618	-1.504	-1.332	-3.41
Log Monthly Index	142	-1.741	-1.683	-3.41

The presence of a unit root supports the weak efficient market hypothesis in the absence of autocorrelation in errors. Since the presence of a unit root is a necessary, but not a sufficient condition for a random walk process, we now proceed to a more definitive test of return predictability.

Variance Ratio Tests

Results of variance ratio tests are shown in table 4. Variance ratios were calculated at lags up to 128 for the daily index, up to lag 64 for the weekly index, and up to lag 32 for the monthly index. The variance ratios are reported in the main rows, with heteroscedasticity-robust test statistics, to test if the variance ratios differ from 1, given in parentheses immediately below each estimated variance ratio.

TABLE 4: VARIANCE RATIO TESTS OF DSE ALL-SHARE PRICE INDICES

	# of observations	At lag 2	At lag 4	At lag 8	At lag 16	At lag 32	At lag 64	At lag 128
Daily Index	3105	1.068* (2.884)	1.052 (0.425)	1.093 (0.489)	1.236 (0.961)	1.466 (1.397)	1.739 (1.722)	1.924 (1.718)
Weekly Index	618	0.991 (-0.085)	1.050 (0.230)	1.257 (0.765)	1.488 (1.099)	1.547 (0.976)	1.475 (0.686)	
Monthly Index	142	1.208 (1.382)	1.323 (1.124)	1.279 (0.632)	1.192 (0.323)	1.083 (0.113)		

*indicates significantly different from 1 at the 5% level

Under the null hypothesis that the variance ratios equal 1, the test statistics have a standard normal distribution. Test of any single variance ratio at the 5% level can be carried out by comparing the test statistic with critical value ± 1.96, but the appropriate critical values for a multiple variance ratio test are ± 2.69 for 7 variance ratios (the daily index), ± 2.64 for 6 variance ratios (the weekly index) and ± 2.57 for 5 variance ratios (the monthly index) from the table of critical values in Miller (1981, p.239).

Thus, the results in table 4 show that the null hypothesis of random walk cannot be rejected at the 5% significance level for the weekly and monthly indices, all the test statistics being inside the respective critical ranges. For daily data, the test statistic is outside the critical range for only the smallest (lag 2) of the seven lags. This is clearly a result of error autocorrelation at a lag of a day or two since we found previously that the daily index also had a unit root. In the presence of transaction costs, any error predictability over just a day or two is highly unlikely to offer profit opportunities to any investors.

Given the overall evidence above then, it is likely that the Dhaka stock market is weak form efficient. This result agrees with that of the VR test of the Dhaka market by Alam, Hasan and Kadapakkam (1999), but differs from that of Mobarek and Keasey (2002) who used daily data and relied on the Box-Pierce-Ljung test, which is a less powerful test of autocorrelations when errors are heteroscedastic.

Autocorrelation Tests Robust to Heteroscedasticity

To check the robustness of findings based on a Box-Pierce test of autocorrelations, we applied this test with and without heteroscedasticity adjustment to the daily Dhaka stock index. The results displayed in table 5 indicate that the null hypothesis of zero autocorrelations (i.e. weak form efficiency) could be rejected at any of the lags if the Box-Pierce tests weren't adjusted for heteroscedasticity, but not if the tests were made robust to this problem.

TABLE 5: BOX-PIERCE TESTS OF DSE ALL-SHARE DAILY PRICE INDEX
(Numbers within parentheses are the p-values)

	# of observations	At lag 2	At lag 4	At lag 8	At lag 16	At lag 32	At lag 64	At lag 128
Test not robust to heteroscedasticity	3105	14.196 (?0)	33.764 (?0)	37.351 (?0)	102.193 (?0)	164.156 (?0)	255.159 (?0)	429.337 (?0)
Test robust to heteroscedasticity	3105	0.003 (0.959)	0.003 (?1)	0.004 (?1)	0.008 (?1)	0.012 (?1)	0.020 (?1)	0.037 (?1)

Although a heteroscedasticity-robust Box-Pierce test was suggested by Lo and MacKinlay (1989) in the context of their Monte Carlo experiments, our study appears to be the first one to apply this test to stock market data. Results based on autocorrelation tests not corrected for heteroscedasticity typically result in rejection of the hypothesis of weak form market efficiency, e.g. Claessens, Dasgupta and Glen (1995), Poshakwale (1996) and Groenewold (1997). Given our results for the Dhaka market, we suspect that previous results based solely on autocorrelation tests not adjusted for heteroscedasticity may be reversed by the use of a heteroscedasticity-robust test.

Results for Individual Securities

In addition to the overall market indices, we tested the EMH also by using individual stock prices of the top 95 companies listed on the DSE, these being the companies with market capitalization above the median level for all the listed companies. Since thin or infrequent trading is a very common scenario of some individual shares on the DSE, we used monthly data to alleviate any bias in test results that thin trading can cause when using daily or even weekly data for individual companies (Lo & Mackinlay, 1988). Multiple VR tests were carried out for each of the companies individually. Weak form efficiency couldn't be rejected at the 5% level for all but one of them.

Cross-sectional means, standard deviations, minimum and maximum values of variance ratios for lags up to 32 are reported in table 6. For 13 of the companies, variance ratios were calculated only up to a lag of 16 as they had fewer than 64 observations.[4]

TABLE 6: SUMMARY STATISTICS FOR VARIANCE RATIOS OF INDIVIDUAL COMPANY MONTHLY INDICES

Variance ratios at	Number of companies	Mean	Standard deviation	Minimum	Maximum
lag 2	95	1.031	0.159	0.654	1.590
lag 4	95	0.984	0.268	0.306	1.733
lag 8	95	0.922	0.303	0.224	1.650
lag 16	95	0.811	0.367	0.160	1.729
lag 32	82	0.694	0.442	0.105	2.339

Although the sample standard deviations in table 6 cannot be used for any hypothesis tests, it is interesting to note that the sample means of the variance ratios at each of the lags differs from 1 by less than one standard deviation. This is a reflection of our previous result that variance ratios do not differ significantly from 1 for all but one of the companies.

Runs Tests

We also conducted runs test of independence between successive returns for the 13 companies with fewer than 64 observations. The standard normal runs test statistics ranged from –1.34 to 1.22, all within ?1.96 indicating that the null hypothesis of independence of returns (or weak form efficiency) cannot be rejected at the 5% level of significance for any of these companies.

6. Conclusions

Evidence in favor of weak form efficiency of the Dhaka Stock Market seems to be overwhelming from our investigations above using data for the years 1990 to 2001. All-share stock price indices at all the commonly used intervals – daily, weekly and monthly – are shown to have a unit root by the Augmented Dickey-Fuller and Phillips-Perron tests. Any predictability of returns arising from auto correlated errors is also ruled out by further Lo-MacKinlay variance ratio tests.

Individual share prices of all companies with market capitalization above the median level – 95 companies in all – were also examined. Company data at monthly interval were used in order to avoid any spurious autocorrelation arising from thin trading. The hypothesis of random walk or weak form efficiency again failed to be rejected for all but one of the companies. Share prices of 13 companies with relatively small sample sizes (63 or fewer observations) were also subjected to a non-parametric test of independence of returns (the runs test). The results of these tests confirm the presence of weak form efficiency.

Although a heteroscedasticity-robust Box-Pierce test was suggested by Lo and MacKinlay (1989) in the context of their Monte Carlo experiments, our study appears to be the first one to apply this test to stock market data. By applying this test, we have been able to resolve the apparently conflicting results reported by the only two studies of the Dhaka Stock Market carried out so far. Results based on autocorrelation tests not corrected for heteroscedasticity typically involve rejection of the hypothesis of weak form market efficiency. Given our results for the Dhaka market, we suspect that previous results based solely on autocorrelation tests not adjusted for heteroscedasticity may be reversed by the use of a heteroscedasticity-robust test.

End Notes

[1] Dual listings of companies are allowed. For example, most of the companies listed at Dhaka Stock Exchange are also listed at Chittagong Stock Exchange.

[2] In the case of a small sample, it is typical to use the Box-Pierce-Ljung statistic Q = T(T+2) $\sum_{j=1}^{h} (T - j)^{-1} \hat{\rho}_j^2$ with the same asymptotic distribution.

[3] SMM critical values for v = ? can be read off the standard normal z table. For example, the 5% SMM critical value is the z value leaving an upper tail area of $0.5[1-(1-0.05)^{1/k}]$. Miller (1981, p.239) provides 5% SMM critical values for v ? 120.

[4] When lag is large relative to the sample size, a variance ratio test may have little power (Lo and MacKinlay, 1989, p.224). In their Monte Carlo experiments, Lo and MacKinlay chose the maximum lag size to be no more than half of the sample size.

Section 4
Global Trade and Trade Policies

Indicators Supporting Trade Policy Implementation in New EU Members

Andrej Kumar
Faculty of Economics Ljubljana , Slovenia

Abstract

Slovenia as EU member will have to change foreign trade policy. Changes will be on two levels:

- **Adjustments of national trade policy objectives and instruments to obligatory EU trade policy framework,**
- **Utilization of the EU trade policy in helping domestic companies to increase trade with non-traditional markets outside the EU.**

Adequate trade policy requires supporting sustainable growth of national business sectors' competitiveness. Countries with similar characteristics of production have similar trade patterns and vice versa. Identifying similar trade patterns may suggest the country's characteristics most important in determining trade patterns and by those elements of their competitiveness relevant to trade policy implementation.

Reviled Comparative Advantage index indicates goods in which Slovenia presumably has pre-trade comparative advantage. Grubel-Lloyd index indicates industries with high level of intra-industry trade; assumingly they present industries with higher competitive ability. Calculated indicators help to effective adjustment of Slovenian trade policy within the EU.

Introduction

Slovenia as the new EU member (May 1, 2004) will have to focus on elaborating and implementing adequate and sizable changes in its foreign trade policy. Changes are to be on two levels:

- Adjustment of national trade policy in relation between Slovenian national trade policy priorities/objectives and the EU trade policy becoming its obligatory implementation framework,
- Utilization of the new EU trade policy environment (instruments like the EU bilateral, multilateral trade agreements, the EU trade financial supportive measures, the EU market protective measures like anti-dumping, anti-subsidy, etc.) to help Slovenian companies to expand trade with their non-traditional markets outside the EU.

To develop and continuously apply effective and allowed national trade policy within the EU integration's policy for a small country predominantly require ability and efficiency in supporting sustainable growth of the national business sectors' competitiveness. To follow such orientation firstly the trade policy implementation authorities have to have ability to assess, which national business sectors have a good potential to be growingly competitive internationally ?7?. Secondly creators of national trade policy in a small country within the EU must skillfully and consistently utilize all and every possibility (organized, and focused participation in all formal procedures, searching for supporters and partners within the decision making process, …) to voice and to integrate their policy objectives into the applied forms of the EU actual trade policy. Joining the EU will expose Slovenian national market and domestic producers to substantially increased competition coming from the third countries, provided that the EU foreign trade protection is applied on substantially lover levels than Slovenian before its joining of the EU. As known the trade briers are among the lowest between the WTO members, approaching applied tariff level of 0% for a number of manufactured products, and being on average applied level of 3,6%, compared by pre-joining applied tariff average level in Slovenia at 8,1%. The average applied tariff protection level for all products in pre-accessing Slovenia is at 9% and in the EU at 6,3%. Interestingly applied tariff protection in some sectors in Slovenia is lover as in the EU at present; agriculture in Slovenia 13,7%, the EU 16,2% and fishery applied tariff in Slovenia 5,9% and in the EU 12,4%. Beside such differences in applied tariff protection levels between Slovenia and the EU there will be other changes after the EU joining in relation to the foreign market access. Free trade agreements (FTA) concluded between Slovenia and other non-EU countries will cease to be effective due to acceptance of the EU trade policy. The change will be important for Slovenian companies and its trade especially in the cases where export is high and the respected countries have in force certain import trade barriers towards the EU. Such case is for instant Croatia where present FTA allows free exports to Slovenian companies but not to companies from the EU. Croatia is for years among most important trade partners for companies from Slovenia, it was the third largest market for exports in 2002. After May 2004 Slovenian exports as of a member of the EU to Croatia will be levied again by import tariffs. Similar effects but on smaller scale will happen with FYROM and B&H and some other countries. That is why the question of effective trade policy adjustment and especially of export promotion after joining the EU is such vital interest to Slovenia. Further we will concentrate mostly on the question on how a government can decide which industries could be successful in future, which could experience potential problems due to market opening and due to increased market entry barriers after joining of the EU. And above all which industries have potential to growth fast and steady in the new integrated environment especially by utilizing trade policy implemented by the EU. For those industries the national trade policy will have to elaborate arguments and ways, which will be suggested in the process of developing or applying the EU trade measures. On the other hand for those industries eventually applied specific promotion measures could be introduced on national level (as allowed within the EU general framework), together with information network supporting the companies seeking the information of the best applicable elements of the actual trade policy implemented by the EU.

To focus national trade policy in the EU framework properly, to avoid its negative impacts and to stimulate the positive once, specific objective measurement criteria/indicators could be of important value. Such indicators should group industries in above-mentioned groups, helping national trade policy to act most properly on the level of the EU trade policy during its preparation and during its implementation. On the level of specific allowed level of "internal" national trade policy such indicators cold help to optimize its results by directing eventual supports to the most promising export segments of national industries. Further we give some theoretical background to idea of selecting proper indicators, and some evidence of their analytical use in the case of Slovenian.

Theoretical background

Countries with business sector being more internationally competitive have higher potential to have positive and sustainable economic growth. International trade theory defines on different backgrounds the bases for business international competitiveness, creating as an aggregated value as well the over all national international competitiveness. A substantial part of nation's international competitiveness is based on factors deciding national comparative advantages. On the other side competitiveness of different national business sectors is based on comparative advantages derived from differences in supply side characteristics of a country. Then countries with similar characteristics of production[?] should have similar trade patterns. Conversely, countries with similar trade patterns should have similar characteristics. Hence, observing which countries have similar trade patterns may suggest the country's characteristics (e.g. factor prices, technology levels, location, etc.) most important in determining trade patterns ?1? and by that their competitiveness.

Expected positive effects of integration into the EU for all 10 new members in great deal depend on adequate utilization of the country's competitiveness derived from supply side characteristics of a country. Trade policies in real world tend to support or protect different industries with the intention to utilize comparative advantages by supporting the growth of partial and general increase of competitiveness. By using index of reviled comparative advantage (RCA= (Xij/Xwj)/(Xi/Xw))[2] we have searched for those goods in which Slovenia presumably have a pre-trade ("original" or "basic") comparative advantage. Trade policy in Slovenia must see to eliminate barriers or to support (in lines with the EU and WTO rules) industries with indicated RCA comparative advantages.

On the bases of intra-industry trade theory we studied a second approach to adequate selection of national industries, which could have low, high, growing or decreasing level of indirectly expressed competitiveness. We calculated the values of the Gruel-Lloyd index (G-L index)[3], measuring the degree of trade overlapping – trade between countries in the same or similar products ?8?. Taking in account methodological limitations (dilemmas about justifiable level of data aggregation ?3? by using STIC[4] which is product based, not an industry based, classification) and often suggested danger of subjective results interpretation, we will indicated industries with high level, or importantly changing level of intra-industry trade, measured by IIT index. Changes in the level of IIT are indirectly reflecting the changes in the industries' competitiveness provided that we assume that higher levels of intra-industry in open economy environment show the industry's ability to compete successfully on domestic and international markets.

Analytical results in relation to the used indexes for detection of industries with potentially high or strongly changing level of pre trade or intra-industry trade competitiveness could be useful to Slovenian foreign trade adjustments.

The same can be utilized in other accessing countries.

Pre trade competitiveness of Slovenian industries

We have calculated pre trade competitive advantage for all product groups on the level of two digits of the SITC for Slovenia in 2002. As the logic of the RCA index suggests the production groups with index level above 100 have a pre trade comparative advantage and by that companies related to such product groups are potentially more competitive internationally. The following table shows all products traded by Slovenia, which reviled in year 2002 trade comparative advantage, by having RCA index above the value of 100.

Table 1: PRODUCT GROUPS IN SLOVENIA TRADE WITH RCA INDEX OVER 100 IN YEAR 2002

SMTK no.	**SMTK description**	**RCA Index**
2	**1. Crude materials, inedible, except fuels**	
21	Hides, skins and fur skins, raw	274,6
24	Cork and wood	305,5
25	Pulp and waste paper	101,5
28	Metalliferous ores and metal scrap	174,1
3	**2. Mineral fuels, lubricants and related materials**	
35	Electric current	365,3
5	**Chemicals and related products, n.e.s.**	
52	Inorganic chemicals	113,0
6	**3. Manufactured goods classified by material**	
61	Leather, leather manufactures,	126,0
62	Rubber manufactures, n.e.s.	430,0
63	Cork and wood manufactures (excluding furniture)	467,0
64	Paper, paperboard and articles of paper pulp, of paper or of paperboard	156,7

The largest number of products showing comparative advantage in Slovenian trade is the group 6, containing products classified by the material. Further calculations on the three digits SCTI levels disclose that most important products in this group are; car tires (SITC 625), other products from wood (SITC 635) and aluminum products (SITC 684). Wood products are logical choice due to high natural supply of wood in Slovenia. Aluminum as a product having comparative advantage in trade is less obvious choice on the bases of RCA index use. Namely aluminum is energy intensive product and Slovenia is not energy reach country. On the other side energy cost for large manufacturing consumers was in past years extremely low, while it was not market decided. Buy the privatization of parts of the electrical system in Slovenia and by introducing market environment on supply and demand side one could reasonably expect that comparative advantage of aluminum could be reduced in coming years. Car tires are expressing comparative advantage not due to the abundance of key needed inputs, which are not available in Slovenia, but most probably due to high productivity related to FDI made into the only Slovenian car tires producer.

To generalize according to different theoretical analyses ?2? and to our data in Table 1, comparative advantages are in small countries found mostly in products having standardized demand. Often these are semi- finished products where the tastes on the small domestic market have no impact on their production. In line with such assumptions are as well our indicated products in section SITC 2 and to large extend as well in section SITC 8. In section SITC 7 we can see the effects of high production specialization of one only producer.

Use of RCA index calculation to indicate product groups and by that indirectly industries with higher competitiveness potential to support trade policy implementation seem reasonable especially when some specifics of the economy and industry sectors are taken in to account too. In case of Slovenia such additional evaluation of the RCA results for the trade policy implementation is no doubt possible.

Intra Industry Trade and Slovenian Trade Policy

To investigate the usefulness of the theory of intra-industry trade by use of Grubel-Lloyd index (IIT index) calculations for the better focusing of the national trade policy some explanations must be given. The absolute level of IIT for the same year and same group of products is changing while we change the definition of a products group let says from two SITC digits to three or more. For total Slovenian trade in 1998 the IIT index on the level of two SITC digits was 76,15 but on the level of three digits was lower reaching only value of 61,06, calculation on level of 5 digits as expected further decreased IIT index to the value of 44,77.

The reasonable (de)aggregation of products in relation to SITC digits level maters for our intend. Not due to needed objectivity of the calculated level of the intra- industry trade on the bases of IIT index, but due to the need that product group defined by SCTI level resembles as much as possible the typical national industry. The tradition – first calculations made by Grubel and Lloyd and further tests ?4?, including our ?6?, suggest that for most of the objectives related to calculations of IIT index can be best suited by the use of three digits SITC level. Our calculations were made on that level of three digits. We may add that for the indication of product groups with potentially higher level of competitiveness, and what we need for focusing of trade policy, more than absolute level of IIT index matters its change through time. Growing level of IIT indexes indicates more intra-industry trade and by that more direct and not pre trade type of products group/industry competitiveness. Comparison of IIT index data for 1999-2002 and 1993-1998 give some insights into transitional structural changes in Slovenian production on one hand and on the other indicates product sectors with stable, increasing or decreasing level of intra-industry trade, hence of competitiveness change.

Table 2: IIT INDEX FOR SLOVENIA ON THREE DIGITS SITC LEVEL, 1999-2002

Sector / Year	1999	2000	2001	2002
0 Food and live animals	42,095	39,640	37,919	38,907
1 Beverages and tobacco	63,876	55,915	53,485	45,446
2 Crude materials, inedible, except fuels	43,787	38,848	44,674	43,843

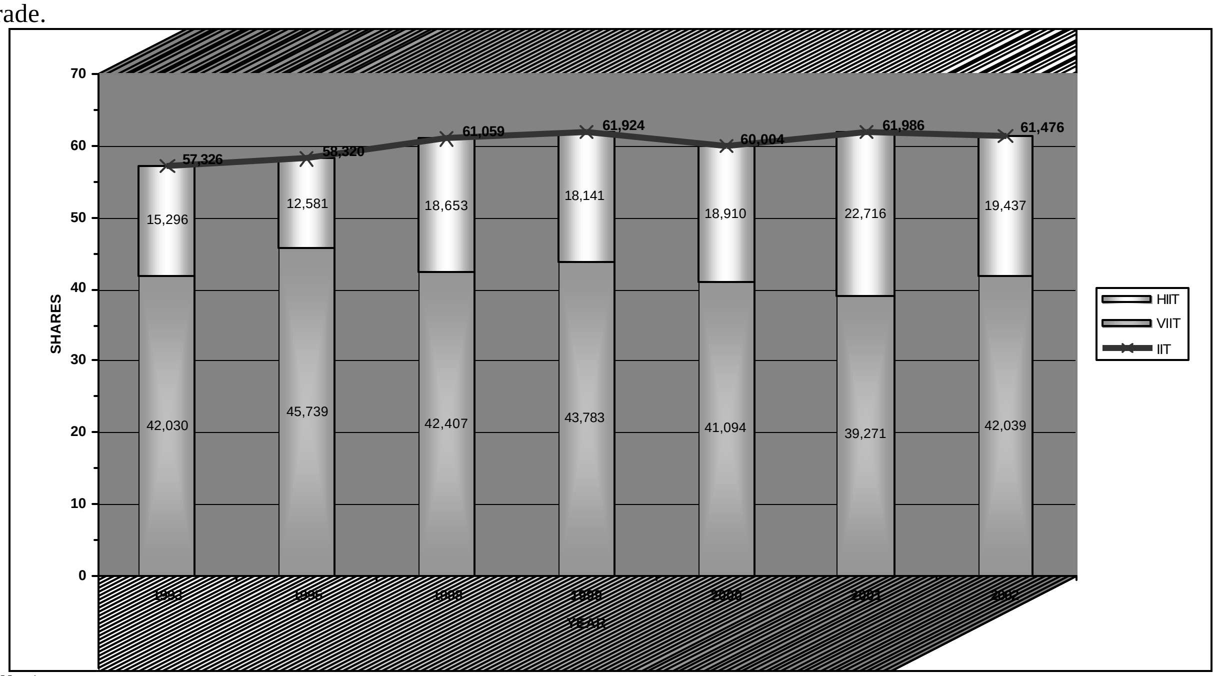
Source: *Boršic, 2000, p. 41.*

Values in table 2 for SITC 0-4 suggest that the intra-industry trade with these products is more or less decreasing. It could be interpreted that products in these groups are loosing their competitiveness in trade. Such results are not a surprise. For beverages and food products produced in Slovenia is for instance known that they have not have successfully introduce internationally – in Europe at least - recognized brand names. Intra-industry trade as a result of market differentiation of products and by that as specific element of their competitiveness is not really possible. Intra-industry trade based on non-differentiated product – as a result of seasonal differences in production is mostly not possible due to the same climate of Slovenia and markets in Europe. There are eventually some exceptions, like strawberries where natural environment in Slovenia allows them to be rape approximately 14 days before that happens in more northern European parts. For other products in SITC 0-4 shoving decreasing tendency of intra-industry trade the explanation is that form many there are no real natural potential available to be effectively produced in Slovenia. Growing openness of Slovenia and countries in Europe affects these product groups by decreasing of their intra-industry trade. From the trade policy view these groups of products are not future leaders in Slovenian trade on the other hand there further restructuring may cause increases in unemployment (coal mines are already closing down,..) and problems in the areas where farming is major activity. SITC 5-8 product group show in last years and in long ran (table 3 and table 2) some signs of increasing value of intra-industry trade. In last years (2001 to 2002) often as well some stagnation or stability. Anyhow in this broad product groups one would expect by de-aggregation to find groups of product with stable and dynamic growth of intra-industry trade. That could help to really better focus the adjusted trade policy in Slovenia. The strongest intra-industry development is observed in sectors SITC 6 (Manufactured goods classified by material) and in sector 8 (Miscellaneous manufactured articles). Companies producing products in these segments are potentially competitive and could be successfully included into the new trade policy environment of the EU.

We mentioned already different reasons for intra-industry trade and by that as well the basic explanation of the elements deciding about the higher or lover level of their competitiveness on international markets ?5,6?. These two basic aspects generate intra-industry trade by exchanging of two types of products;

- Differentiated products: similar products of the same sector who are different by quality elements (like more functions, higher speed, better known brand name,…etc.) and
- Non-differentiated products: similar products of the same sector with some functional specifics (like fresh fruit during winter, and similar).

First group of specifics creates so-called vertical type of intra-industry trade (VIIT) and the second the so-called horizontal intra-industry trade (HIIT)[5]. For Slovenia more important in the future will be vertical intra-industry trade.



* Note: For calcualtion the interval decided by *d=0,15 is used.*
Source: *Boršic, 2000, p. 44, and own calculation.*

Fig 1: SHARES OF HORISONTAL AND VERTICAL INTRA-INDUSTRY TRADE FOR SLOVENIA, 1993-2002*

For the past years – after 1993 - dominant part of Slovenian intra-industry trade was in its horizontal form. To the year 2001 vertical part in Slovenian intra-industry trade was gradually growing till 2002 when was slightly decreased. Growth of vertical intra-industry trade in general is a good sign indirectly suggesting that in general trade competitiveness was improving. Further analyses of horizontal and vertical intra-industry trade on level of 3 SITC digits could revile more closely product groups and indirectly businesses who succeeded to improve vertical part the most and who are by that potentially the most competitive part in the past Slovenian trade development. The decrease vertical of intra-industry trade at the end of the period analyzed could lead to different conclusions. One reason for the decline in vertical intra-industry trade in 2002 could be a result of introduced total openness for Slovenian trade for manufactured products towards the EU from January 1, 2001 onwards. Or decline in 2002 could suggest changes in production structure and by that a need to adjust the trade policy in the future, to help future growth in the share of vertical intra-industry trade.

However besides calculating the general IIT index to help the national trade policy to its effective orientation additional calculations of veridical and horizontal intra-industry trade indicators could further help to understand changes in trade competitiveness and by that directions for the national trade policy adjustments within the overall trade policy of the EU.

Marginal intra-industry trade and trade policy implications

Broad groups (SITC level of one digit) of products showing potential to be internationally competitive followed their growing or relative high level of intra-industry trade has to be broken into smaller groups for two reasons. By de-aggregating our IIT index expresses competitiveness of more and more similar products, and by that products structure is to reasonable extend approaching the business structure of the country. The second reason is related to already observe difficulties to interpret changes in vertical and horizontal intra –industry trade on the level of on SITC digit. We will combine this two reasons for intra-industry indicators calculation on the level of more SITC digits with additional need to understand better the dynamic change in the competitiveness measured by year to year change in intra-industry trade. We can follow such objective and additionally we can neutralize mentioned problem in relation between the level of IIT calculated and the change in the balance of payments. Calculation of so-called marginal index of intra-industry trade (MIIT)[6] is based on changes of export and import for product group in a selected period of time. The SITC 8 group of products has a high level of IIT index (tables 2 and 3), we were interested to see which products groups within this broad category have higher or lover levels of IIT on three digits level of SITC. Such calculation could help to more closely define product groups and indirectly businesses with potentially higher levels of competitiveness. In next table we add as well calculated values of MIIT to test how the indirectly measured competitiveness level of product groups was changed over a period of time – from 1999 to 2002.

Table 4: MARGINAL INDEX OF INTRA-INDUSTRY TRADE (MIIT) FOR SLOVENIA , 1999/2002

Sector		IIT 1999	IIT 2002	MIITB02/99
811	Prefabricated buildings	16,012	17,680	35,6
812	Sanitary, plumbing and heating fixtures and fittings, n.e.s.	50,448	87,239	27,8
813	Lighting fixtures and fittings, n.e.s.	84,357	86,798	90,6

892	Printed matter	78,933	82,548	89,8
893	Articles, n.e.s., of plastics	97,603	93,375	80,9
894	Baby carriages, toys, games and sporting goods	98,928	82,948	56,3
895	Office and stationery supplies, n.e.s.	84,946	75,861	50,0
896	Works of art, collectors' pieces and antiques	97,622	52,423	0,0
897	Jewellery, goldsmiths' and silversmiths' wares, and other articles of precious or semiprecious materials, n.e.s.	54,590	51,049	0,0
898	Musical instruments and parts	33,045	54,148	94,1
899	Miscellaneous manufactured articles, n.e.s.	55,211	56,858	60,0

Source: Calculated on data from Statistical Office of R. Slovenia.

For trade policy use data in table 4 add some additional insights into the search for those industry groups and indirectly business sectors, which show potentially, the most promising production potential related to their competitiveness to focus-selected instrument of national trade policy adequately. The growing or high value of the IIT as we noted already expresses potential for higher competitiveness level of production producing the specific group of products. Adding to that information as well the values of MIIT we can more securely judge which product groups in time effectively increase intra –industry and by that indirectly had grooving competitive potential in the time. To put it simply, high level of IIT is indication of competitiveness, if at the same time MIIT is high it shows that intra-industry trade in time was growing and by that indirectly as well the group of products competitiveness. If we take group of products 871- optical instruments, we notice high level of IIT in 1999 and its increase for 2002. While the MIIT for the same group of products is 0, explaining that for 871 products competitiveness on the bases of intra-industry trade was not achieved in fact. Increase of IIT in such case was caused by inter-industry trade changes, so not by increase of intra-industry trade which we relate indirectly to competitiveness, mostly by product differentiation.

Conclusions

Calculations of RCA index and of different forms of IIT index for Slovenian trade helped to detect sectors of production, defined by product groups on SITC bases, with some elements of high indirect competitiveness. Adjustment of trade policy in Slovenia will have to be substantial due to joining the common EU trade policy after May 1, 2004. It could be formally correct and if possible as well effective, so that Slovenian companies will be able to utilize positive elements of the EU trade policy on one side and to restructure most effectively following additional market openness. Calculated RCA indexes and IIT indexes in our paper suggest that they may be used to help national trade policy adjustments within the EU trade policy. Deciding about product groups relevant to get allowed support from the national trade policy based on calculated indexes need as well some caution and eventually introduction of some additional indicators to check relevance of the suggestions given by the calculated values of the used indexes. How-ever we are convinced that use of suggested indexes could at least narrow the areas of search where – on which product groups - to direct the part of activities included in the future Slovenian trade policy adjustments and implementation.

End notes

[?] We will limit our actual analytical effort to merchandise goods only. We assume that the same logic as for merchandised goods is valid for services in relations to conclusions explaining ways of enhancing competitiveness of a nation. Services are not analysed partially due to "tradition" generally used in other similar analyses and partly due to the problems with proper interpretation and availability of trade data on services.

[2] Xij country i's exports of commodity j, Xwj world export of commodity j, Xi country i's total export and Xw total world export.

[3] Intra Industry Trade (IIT) index or GLI index for the industry (i), with export X and import M has the form: $IIT = \left(1 - \frac{|X_i - M_i|}{X_i + M_i}\right) * 100$.

Index value is between 0 and 100, the last value denotes total level of intra-industry trade. When the index has the value of 0 trade is not within the analyzed industry but it is performed entirely between different industries – inter-industry trade. If the national level of intra-industry trade is calculated the calculation is made by:

$$IIT_{ag} = \left(1 - \frac{\sum_{i=1}^{n} |X_i - M_i|}{\sum_{i=1}^{n} (X_i + M_i)}\right) * 100$$

In the case of IITag results interpretation the problem is how to explain its value changes based on balance of payments change. We will not elaborate solution of the problem while we are interested only on specifying individual industries with growing, relative high or decreasing levels of the IIT.

[4] SITC – Standard International Trade Classification.

[5] Calculation of horizontal intra industry trade follows the assumption of transport and other costs, in our case assumed on the level of 15%=α. Intra industry trade is horizontal (HIIT) when coefficient value between sector's export and import is within the following interval: $1 - \alpha \le \frac{UVx_i}{UVm_i} \le 1 + \alpha$. *UVx* and *UVm* are unit export and import values for products of sector *i*. When the value of the export import coefficient is out of the specified interval the intra-industry trade has its vertical form (VIIT).

[6] Calculation of marginal intra-industry trade index is based on change of export ΔX and import ΔM in given time (two years for instance), ad follows the equitation: $MIIT = \left(1 - \frac{|\Delta X - \Delta M|}{|\Delta X| + |\Delta M|}\right) * 100$. The value of MIIT is 0 when marginal trade change is base exclusively on inter-industry trade and is 100 when the change is caused entirely by intra-industry trade.

Development of Foreign Trade Structure of Central European Countries to EU (Mainly German) Dominance

Jozef Komornik
Robert Bohynik
Comenius University in Bratislava, Slovak Republic

Abstract

The fall of communistic regimes in Central Europe after 1989 started process of dramatic changes that had impact not only from geopolitical point of view (creation of new countries) but also on overall economic development of respective countries. These are currently on the way from centrally planned economies towards free market or liberal economies. This paper examines and describes significant structural changes in trade balance of central European countries in last decade, their natural orientation towards western European countries.

Introduction

The list of events that impacted the Central European countries after 1989 are as follows:

1. Germany took over leading role of major trade partner for central European countries from Russia and its share on exports as well as imports of these countries is rising. Another interesting fact is that except of Slovenia there is no significant second partner in international trade of CE countries.
2. The size of bilateral trade between Czech and Slovak Republic is very low and has tendency to decline.
3. There can be observed positive change in the structure of exports and imports among respective CE countries with an increase of exports and imports of machinery &transport equipment that means strengthening the position of these countries in the field with higher than average added value.
4. Food products exports of Poland and Hungary are continuously declining and thus reaching the role these countries are expected to play in the near future. (after joining the EU)
5. Imports of natural resources (natural gas, oil) from Russia stayed at the same level as before the change, which suggests crucial role of Russia in supply of these resources in the whole region.

Germany as a prime trade partner for Central Europe

Opening of economies significantly influenced the structure of trade partners of all CE countries. This was driven by two major factors at the same time. CE countries were loosing their position at important Russian market thanks to: i) worsening economic situation that culminated during the crisis in 1997 ii) requirement of mutual payments in hard currencies (DEM or USD) and iii) aggressive arising of new (western) competitors that had constrained access to the market before.

Germany became prime trade partner for the whole central Europe and its position is driven by following factors: i) its geographical location close to the CE region (common border with Czech Republic and Poland) ii) huge direct investments of German companies in respective countries, that generate increasing flow of semiproducts and final products between CE subsidiaries and their parent companies located in Germany. iii) bilateral trade and investment relations are not oversensitive to changes of political situation in respective countries as Germans concentrate their attention to the business questions and do not pay too much attention to political nuances.

Czech and Slovak Republic

Development of international trade structure of Czech and Slovak Republic has similar patterns due to the common history and very close relations from previous times. Tables 1 and 2 show significant growth of German share of both republics' exports as well as imports. Secondly, mutual trade between Czech and Slovak republic is still declining. This is due to: i) interruption of traditional production chains between Czech and Slovak companies ii) arising of the new and substitute producers &products at domestic market and iii) mutual loss of the advantages of internal market (i.e. duties, tax, quotas)

German's share on export of Czech Republic is significantly higher than the one on Slovakian. This may be caused (apart from other reasons such geographic location or amount of direct investments mentioned above) by the fact that semiproducts exported to Czech Republic from Slovakia are used in production and later on exported to Germany as parts of Czech final products.

TAB. 1: CZECH REPUBLIC – MAJOR EXPORT AND IMPORT PARTNERS

Hungary

Stable macroeconomics with manageable fiscal and current account deficits, environment open to competition and unproblematic political conditions offered by Hungary attracted high and fast foreign direct investments and these became major driver of trade structure changes. Russian importance as trade partner declined and reaches 1/3 of 1993 share only, while the one of Italy is growing.

TAB. 3: HUNGARY – MAJOR EXPORT AND IMPORT PARTNERS

	Exports				Imports

Poland

While in other CE countries the significant changes of trade structure started only in 90-ties, Poland (and to some extend Hungary) is an exception to the rule. Its structural changes started as early as in 80-ies after the different political development. As a result of these differences trade relations of Poland with USSR weakened and to some extend were replaced by its orientation towards Germany and other western European countries.

Tab. 4 shows that during last years considerably high trade share of Germany on Polish exports and imports stayed flat in recent years.

TAB. 4: POLAND – MAJOR EXPORT AND IMPORT PARTNERS

Slovenia

The situation of Slovenia is unique compared to the rest of CE countries. It did not have significant trade contacts with Russia and thus it was not hurt by Russian crisis. After the separation from Yugoslavia, Slovenia very quickly oriented itself to western European countries. Slovenia is the only CE country that has another strong EU neighbour (Italy). The trade share of Italy is naturally increasing after some original mutual political conflicts had been removed.

TAB. 5: SLOVENIA – MAJOR EXPORT AND IMPORT PARTNERS

	Exports				Imports

Change in the structure of exports and imports

Structural changes of exports and imports of CE countries are also dependent on forces behind them. The tendency of respective economies to change their production structure is driven by: i) an attempt to produce products with higher added value and ii) foreign direct investments that created new capacities and provide local subsidies international marketing channels and thus assured demand for products manufactured in CE.

Looking at structure of exports, “Manufactured goods classified chiefly by materials” was the dominant commodity group exported from all CE countries except Hungary. The outcome of the shift in the exports structure was steadily growing share of machinery and transport equipment on total exports in the whole region, while share of all the other commodity groups on total exports was falling. The shift has different intensity in respective countries. Tab. 6 shows that the portion of this commodity group on total exports in Hungary and Slovakia more than doubled in last 8 years; while in Slovenia it grew only slightly. This is due to fact that the structure of Slovenian exports had from the beginning healthy structure.

TAB. 6: SHARE OF MACHINERY AND TRANSPORT EQUIPMENT ON TOTAL EXPORTS (IN%)

Country	1994	1995	1996	1997	1998	1999	2000	2001	2002	Index 2002 vs.1994
Czech Rep.	**25.9**	**30.4**	**32.7**	**37.7**	**41.3**	**42.4**	**43.5**	**47,3**	**48.6**	**187**

Source: CESTAT Statistical Bulletin, 2001

The same shift can be observed in the structure of imports within the region. However, the shift was not that strong as it was in the structure of exports. Tab. 7 shows that the share of machinery and transport equipment grew most significantly in Hungary while in Czech Republic and Poland it grew only slightly. Growing positive difference between the export and import shares of machinery and transport equipment means growth of added value created in respective countries and this has also positive impact on development of respective industry.

TAB. 7: SHARE OF MACHINERY AND TRANSPORT EQUIPMENT ON TOTAL IMPORTS (IN%)

Country	1994	1995	1996	1997	1998	1999	2000	2001	2002	Index 2002 vs.1994

Food production of Poland and Hungary

Tab. 8 suggests another important pattern. We can observe continuous decline of "food and beverages" commodity group share on total exports of Poland and Hungary. In last 7 years it fell nearly 35% in case of Poland and reaches only 40% in case of Hungary. Thus the structure of both Poland as well as Hungary converges to the average of their neighbor countries. Major forces behind this dramatic decline of food products exports are: i) quotas posed on food products by EU and ii) loss of comparative advantage of extremely low prices due to overall increase of inputs prices. Thus food products are becoming less attractive for foreign markets.

TAB. 8: SHARE OF FOOD &BEVERAGES ON TOTAL EXPORTS (IN%)

Russian natural resources imports to CE

Due to instability caused by weakening economy the share of Russian imports from CE declined significantly in last years. However, Russia preserved its position in exports of natural resources to all CE countries. Attempts of CE countries to increase their exports to Russia and thus pay at least part of their natural resources imports failed and partly success of Poland to increase exports turned against Polish companies after the 1997 crisis when these ended up with unpaid receivables.

The dependency on Russian natural resources imports to CE creates high exchange rate risk. This is due to the fact that all payments for natural resources are in USD while majority of CE revenues are in Euro as they come from trade with Eurozone.

Conclusion

Despite recent changes in CE exports and imports and strong position of Germany that thanks to its location and other reasons mentioned above achieved superior position in bilateral trade, the future is not as clear as it seems to be. Now the question is whether other countries will follow the way Germany pioneered, or not. There is one very interesting fact; cumulative capacity of economies of France, Italy and Great Britain is 2 times higher than the one of Germany however their cumulative share on CE exports and imports reaches barely half of the German's one. Are these countries able to overcome their mental barrier that prevents them from trade and investments in CE or it is just geographical location of Germany that gives comparative advantage to it?

Close look at trade partners of respective CE countries reveals that bilateral trade among these countries is very low. If geographical location is comparative advantage, there are probably other barriers to the trade. One of them is probably very similar structure of the industry that produces variety of supplementary products but a lack of complementary products that could strengthen basis for bilateral trade.

Generally, the industry structure of CE countries has successfully undergone positive changes that can continue in case accession process will proceed smoothly. Spontaneous integration of CE economies to EU structures already started. Via FDI and increasing exports and imports CE economies are naturally becoming part of "New Europe" despite official date of EU enlargement even hasn't been announced.

Despite significant decline in exports and imports of Hungarian and Polish food products due to reasons mentioned above these countries have good prerequisites and tradition to stay strong in this industry. Moreover, joining EU will remove artificial barriers to their exports and after modernisation, reorganisation and capital influx to agriculture both countries can play important role in this industry in the future.

Russia plays and will play even more important role in supplying CE countries with natural resources (oil, natural gas/. It will even strengthen its position after new gas pipeline is completed. This means persisting threat of exchange rate risk mentioned above.

Currently the substitution of Russian natural resources supply is not economically advantageous. In spite of this fact CE countries should consider diversification of their demand in the future. After stabilisation of Russian economy should all CE countries try to cover at least part of their imports by exports to Russia. As Germany has very good position at Russian market part of the export can be incorporated in exports of German companies.

Is there Convergence between North America Free Trade Agreement Partners?

Alicia Puyana
Flacso, Mexico
José Romero
Colmex, Mexico

Abstract

Mexico has already gone through two decades of macroeconomic reforms. Among these, the liberation of the economy and its opening has been essential. They were accompanied by political and institutional reforms as well, and these were equally important. All of them were undertaken with the same final goal: speeding up sustained growth, reducing internal gaps and strengthening political democracy. The NAFTA agreement included the specific goal of reducing migration toward the United States, an objective that could be achieved if the convergence between these two economies were under way. The convergence process was to be invigorated by both foreign trade liberalization and structural reforms.

Introduction

This work is part of a more extensive one, an analytical effort exploring the impact of trade reforms on the absorption of domestic factors, productivity and growth. An increment in exports presupposed a more intensive use of the abundant labor factor, in other words, unqualified labor force. As export rates expanded, the demand for this resource would increase and wages would also rise. Moreover, if workers augmented their productivity as a result of being transferred to activities enclosing more comparative advantages, and due to educational improvement, workers' remuneration would increase as well. However, remunerations to capital would not grow to the same extent. The gap dividing Mexico and the United States would be reduced, and migration would lose incentives. In the Mexican scenario, these effects are not clearly settled down.

This work analyses the convergence between Mexico and the United States within the NAFTA framework. It is organized and divided into the following sections: In the second section, convergence issues are discussed. The third section provides several definitions of convergence, and presents quantification methods. In the fourth section, the evolution achieved by the NAFTA region is shown through a long term perspective including pre-opening and pre-NAFTA experiences. Having found the presence of convergence between 1945 and 1982, as well as a gap amplification during the 1983 –2001 period, the fifth section poses a growth model for the three economies, with the aim of explaining the causes for divergence. In the sixth section, the very sources of Mexican economic growth are explored. Finally, the seventh section comes up with a conclusion.

I. Convergence as the Goal of Economic Growth

When any given country introduces reforms to its development model, or when it starts negotiating multilateral or bilateral trade or integration agreements, the aim is to overcome the obstacles to its economic growth and advance toward the more developed ones. To speed up growth and shorten distances between member countries, preferential treatment needs to be granted to the less developed economies (GATT and WTO). In multilateral negotiations, as well as in regional integration, preferential treatment has been conceived to create mechanisms of convergence and to stabilize the agreements.

Concerns about the different dynamics attached to per capita incomes between countries have been a constant discussion-matter of growth theories, and they have been synthesized into multiple growth models. Smith, Malthus and Ricardo have looked into the causes that allow population to increase welfare, and ever since, these have constituted an essential part of the economic thinking. Recently, analyses on the correlation between the changes in trade policies, the regional integration programs, and convergence rates, have been studied in depth. It has been assumed, without much theoretical nor empirical foundation, that economic liberalization, and a more intensive trade integration among countries, should raise trade volume, affect rates of growth, and reduce income unevenness. Supposedly, there is a direct rapport between trade liberalization and convergence rates. This conclusion can be discussed when observing that convergence can occur in "sufficiently similar regions, of the same country, and less clearly, among nations integrated through commerce", Bergg and Krueger (2003). Nonetheless, these authors conclude that poor countries and regions may grow faster than the rich if their economies are sufficiently open and integrated. For OECD countries, several authors conclude that convergence has actually shown up since World War II. When it comes to the European Union, convergence was clearly revealed when the Treaty of Rome took place in 1958 (Ben-David, 1993; Olivera et al, 2003). Other authors suggest that convergence goes back to the end of the 19th century, and also covers countries not being part of the EU nor of the European Free Trade Association EFTA (Quah, D.1995; Slaughter 1998; Rodríguez and Rodrik, 1998). Trade has not come into view as the main catalyst for the convergence registered between EU countries. More than that, the process slowed down soon after the Treaty came into effect, and trade could enhance more divergence (Slaughter 1998 y 1987).

According to Rodríguez and Rodrik (1998), the direct rapport between the opening of an economy, foreign trade, and the cut down in the dispersion of countries trading with each other (subject-matter of many theses), is based on the postulates that countries open to external exchange speed up their growth. Since it has been taken for granted that poorer countries have preserved severe restrictions to external exchange, it is possible to conclude that their opening has to induce higher growth when they are compared to those that had previously undergone an opening-like process. In that sense, increasing exchange and opening economies to international competition has an important influence over convergence rates, affecting them with the very same devices that accelerate economic growth: the increase in investment efficiency, growth with constant return-rates due to major market access, higher domestic savings and external flow of capital rates, and strict domestic discipline when handling macroeconomic policies (Bergg and Krueger, 2003).

Measuring convergence has not been a serious methodological problem, nor has it entered into debate. This controversy emerges from the very sources of convergence and from the possibility of isolating the effects of each variable in the per capita GDP dispersion and its swiftness to grow. Slaughter (1997) provides an approach different from that presented by Barro and Sala-i-Martin (1992) and all the research work based on the Solow Model. According to Solow and his supporters, the convergence of growth of *per capita* GDP is a result of the differences in capital accumulation rates financed by domestic savings. Therefore, the effects produced by the accumulation of capital in international trade and rates of growth are put aside.

Barro and Sala-i-Martin (1995) studied the convergence process designed for American Union States, regions of Europe, prefectures in Japan, and OECD countries from 1952 up to 1960. Their results suggest the existence of an absolute convergence rising up from per capita GDP rates of growth, being the rates of poor countries and regions higher than those of the rich. This happens only when the economies are sufficiently integrated into each other.

Sachs and Warner (1995) graphed the GDP/worker rhythm of growth and the per capita GDP logarithm of 1965 for two countries classified in accordance with the opening degree defined by them. They found evidence showing that increments in convergence rates and products increase due to commercial opening impacts. These pieces of work, as well as the analysis of both authors, are intended to demonstrate that trade opening increases convergence and speeds up product growth in the countries involved. Quah (1995) raises doubts about the 2 % uniformity in convergence rates that can be proved through several analyses. Likewise, he reveals that this quasi-absolute 2 percent convergence law was brought about by the estimation method, having very little to do with economic growth dynamics and getting closer to the unitary root in time series. Using a theoretical model based on dynamic balances, he points out all problems attached to cross section convergence estimations and panel-type analyses. Moreover, he finds polarisation emerging from the convergence of rich and poor countries, and the disappearance of the middle-income group of countries. These statements explain why he has doubts about the existence and interpretation of the ?-convergence.

In the same study line, Arora & Vamvakidis (2001) explore the impact made by the American GDP growth on other economies. Convergence is used as an independent variable in the growth model. The per capita GDP logarithm shown in the first year is a part of other series of explanatory variables of economic growth (e.g. population growth, investments in fixed capital, high school registration, inflation, governmental consume, international trade share of GDP, rates of growth in the United States, rates of growth in the rest of the world, among others). The transmission mechanisms of the multiplying effects of growth in the American economy are synthesized in trade, in exporting-importing effects, financial flows, technological spillovers, and the impact on sectors non-directly related to trade.

Olivera Herrera's work applies the classical Solow growth model and does not presume any opening or international trade impact on economic growth. He analyses economic convergence considering internal factors, and ponders these results considering trade effects and opening process. Among the inner determinants of growth, we can highlight the presence of investments in physical capital, population rates of growth, human capital stock, the existence of a technological mechanism of convergence, labor markets evolution and the stability of nominal inflation, public budget deficit, interest rates, and so forth.

Berg & Krueger (2003) have looked into a series of articles[i], focusing their analysis on demonstrating that trade opening constitutes an economic source of growth and has very positive side effects because it diminishes poverty. Without going too deep into this matter, they mention a debate over the measuring problems attached to commercial opening levels and the causality between trade opening and economic growth. Throughout their work, they tend to overestimate the effects produced by trade, since trade policies are just a part of a more extensive package of measures related to macroeconomic stability, direct foreign investment, internal markets liberalization, solid institutional market, corruption, bureaucratic quality, expropriation risks, etc. Nevertheless, to Berg & Krueger, poor regions and countries tend to grow faster than the rich if the first group of countries is well integrated into the second. This statement contradicts Slaughter's results (2001), since he did not find any forceful evidence demonstrating that trade liberalization has positive effects on the speed of convergence shown by countries. From their revision, Bregg and Krueger also conclude that poor countries may grow and reduce poverty levels if they are open enough to foreign commerce. However, this conclusion is rather forced, since none of these studies reveals the opening effects and trade expansion over poverty, nor do they prove the existence of free trade mechanisms diminishing the number of poor people.

Another analytical review on several articles discussing the correlation between trade, reforms, opening and growth was made by Rodríguez and Rodrik (1999). These authors question methodological problems, and the consistency of the statistical results used to assure that trade opening is closely related to economic growth. Likewise, they strongly point out that economists must be extremely cautious when it comes to presuming a direct connection between trade, growth and welfare.

In their original specifications, and applied to different or modified cases ?designed to unmistakably assert the strength of their results, Rodríguez and Rodrik prove Dollar's (1992), Sachs and Warner's (1995), Ben-David's (1993) and Edwards' (1998) models. This way, Rodríguez and Rodrik questioned this so-believed connection linking trade and growth, that is, the bond that these authors have been testing in some of their articles. In other words, they doubt the restrictive measures to trade, the effective exchange rate distortion index, and the real exchange rate variability index applied by Dollar. Due to its restrictive assumption and its high degree of sensitivity to any alteration in the model or index, the effective exchange rate variability index is of very little use. They specially focus on Sachs and Warner's work, and the five indicators which have helped them assemble their renowned opening index. According to Rodríguez & Rodrik, the fact that there are only two state exporting monopoly indicators and that the prize to black-market dollar does not exceed a 20%, settle on the opening index behavior. At the same time, the first indicator generates bias on estimations. The second, on the other hand, is not really a good trade policy measure, since it is also a proxy of other variables non related to trade policies. With regard to the positive correlation between opening, productivity growth and GDP stated by Edwards, Rodríguez & Rodrik demonstrated that this does not constitute a statistically absolute result, at least not in the case of a countries' cross section.

Baldwin (199?), in his review on this literature, confers significant weight to the critics made by Rodríguez & Rodrik. Nonetheless, in general he concludes that the opening of an economy is more favorable to economic growth than the economies orientated toward their inside or the autarchies. He inverts the correlation of causation and underlines that the increment in exports is more likely to be a consequence of economic growth rather than its cause.

II. What does Convergence Mean?

There are several definitions and menstruations on convergence. All of them aim the reduction in the differences of welfare levels, or in rates of growth between countries or regions within a State. In every case, convergence has to do with growth sources and the conditions and policies that trigger them.

Absolute convergence, or type-ß convergence (Barro, 1991 and Sala -i- Martin, 2000), indicates the process according to which the economies having lower income levels register rates of growth superior to those having higher per capita incomes. This implies, on one hand, that there is a negative correspondence between rates of growth of income from the starting year and the following years.

The sigma d convergence, a concept that must not be mixed up with the previous one, indicates that per capita rent dispersion between groups of economies tends to be reduced in time, and it is expressed as the reduction of the differences in GDP/C levels between countries or groups of countries (convergence clubs). This calculation is based on the standard deviation of natural logarithms of the per capita incomes of countries or regions. The existence of a reduction in the deviation, that is, when the deviation trend sign is negative, suggests the presence of convergence, the opposite to divergence. This concept involves that countries having a lower GDP/C will register rates of growth superior to those experimented by more developed countries. This study is usually prepared for a period of time which is long enough to allow the detection of movements toward convergence or divergence, and so as to determine whether these changes in trend are related to any particular incident. A good example could be found in trade liberalisation or in the instrumentation of an integration agreement (Arora and Vamvakidis (2001); Sala – i - Maritn (2000); Quah (1995); Quah (1995).

Another basic concept is conditioned convergence, as it incorporates the structural conditions of the stationary state of each economy. These requirements are essential for the poor economies to speed up their growth more rapidly than rich countries. To figure it out, it is necessary to define equations of growth, with different variables, according to each school.

IV. Are the NAFTA gaps getting narrower?

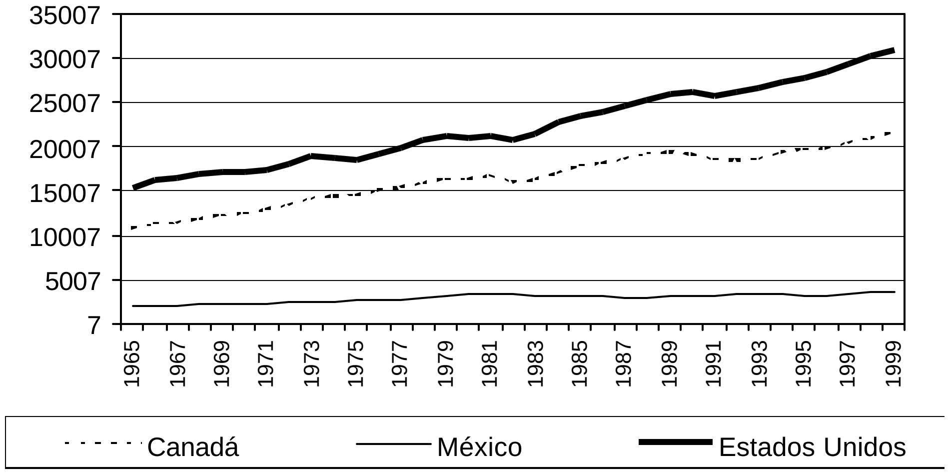
In this section, we will examine whether the NAFTA member countries have reached convergence after this agreement came into effect. We will also calculate absolute and sigma convergence and we will look deeply into the variables affecting the rates of growth of the three economies being part of the agreement. The path of growth of the per capita product in the three countries will be analyzed as well, during a sufficiently long period of time, so as to detect the historical trend and determine when and why there were changes in this path.

Even though there are a small number of countries, this analysis is important because of several reasons. These three economies were closely related to each other long before the NAFTA came into effect. In addition to a very intensive commercial exchange, investments and technological transfers, ?not to mention that migration has consolidated purely commercial relations even more, the links connecting these economies are of great importance, as suggested in the studies made by Krueger, and therefore convergence should appear as evident. Other than that, this analysis allows to test the suppositions stating that trade flows going from small countries (or less developed) to the rich are catalysts of convergence, as acknowledged by Arora & Vamvakidis (2001) and Krueger (2003).Given the great importance of the Mexican human capital investment, that has considerably elevated university labor supply (Romero and Puyana, 2003), it is possible to prove whether this factor promotes convergence in accordance with Ben-David & Kimhi's results(2000). It is also feasible to verify whether there is a positive correlation between opening and changes in trade policies of foreign investments and convergence.

To analyze the path of the member countries' GDP/C, first we would have to measure the sigma convergence for the 1930 – 2000 period, having Madisson's data (1998) on the 1930–1986 period as a base, as well as our calculations to complete the series up to the year 2000, all of them based on the World Bank's World Development Indicators (2002). After having found positive values to sigma convergence, that is, detecting divergence in a 56-year period of time, we will figure an equation of growth for the economies of the three countries, so as to identify the factors explaining the lack or the presence of beta convergence.

Graph 1 indicates the GDP/C trajectory for all three NAFTA member countries. At first sight, it is clear that the income gap registered in 1965 has been enlarged. It is possible to settle how much wider and when this amplification started by calculating sigma convergence.

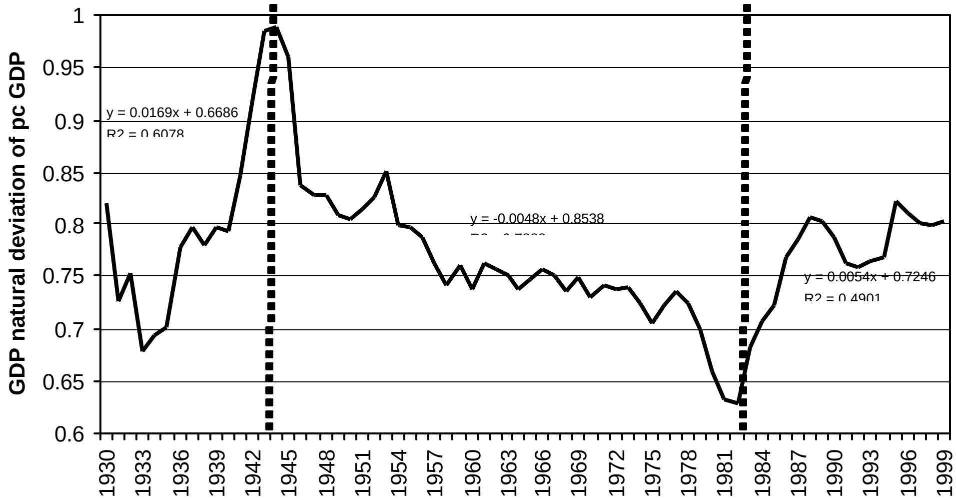
Graph 1
Per capita GDP of NAFTA countries (1995 dollars)



Source: Puyana and Romero's calculations based on World Bank, World *Development Indicators, 2002* CDR

As previously settled, sigma convergence suggests the rhythm speed of approaching or distancing of per capita incomes. Graph 2 presents sigma convergence for the 1930–2000 period of time, that is, the trajectory of the standard deviation value of the GDP/C natural logarithms belonging to the three countries. It is possible to distinguish three periods: 1930–44, when the prevalent trend was the augmentation of dispersion. During these years, the entire world was undergoing deep perturbations related to the 1929 crisis and the Second World War. The second stage, 1945–1982, includes the reconstruction efforts made by the Japanese and European economies, and the world economy reconversion from war to civil. During this period, the world economy grew like never before. This period is also known as the "golden age of Capitalism", (Scott, 1991). These have been the only years when the standard deviation value has been actually negative, that is, that these three economies expanded at a much accelerated rate. As a consequence, by 1982, they reached a point where the distance separating them was the smallest ever registered. The third stage, 1982–200, started with the debt-crisis outbreak and the reforms, and it ended with the 20th century, when these changes had been already established, the opening process had been settled down, and seven years after the NAFTA and the privatization process had been set in motion. During these years, the standard deviation augmented, and the three economies grew distant from each other. Neither the export push nor the NAFTA effects could change the sign in this trend.

Graph 2
Per capita GDP dispersion in NAFTA, and trends according to periods, 1930-1999



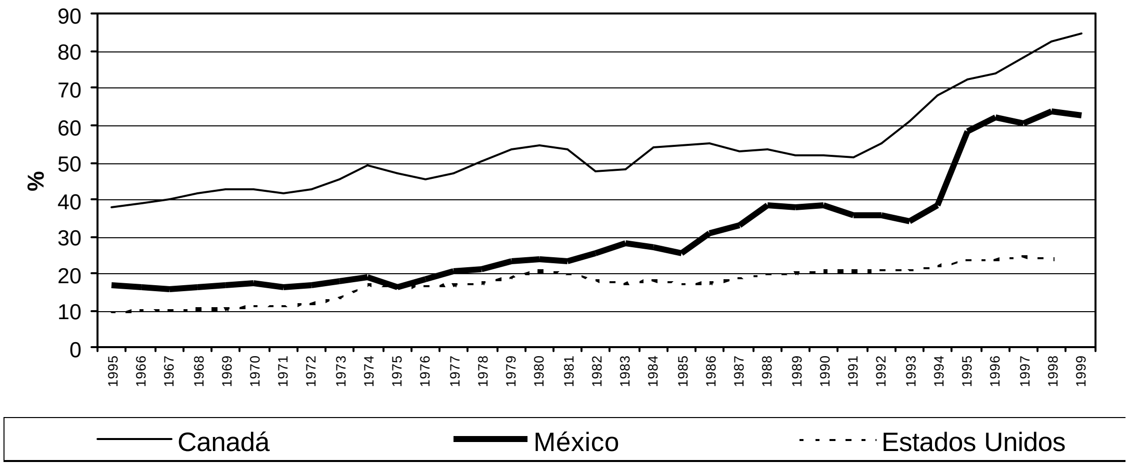
Source: Puyana and Romero's calculations based on Madisson (1999) and World Bank (2002)

Based on this exercise and given the sigma convergence values, it is possible to assert that convergence was shown exclusively during the fast growth period of these economies. This process took place throughout a stage marked by the second post-war reconstruction, when the world order was kept relatively closed (Promfett, 1999) and most of the developing countries, including those of Latin America, were applying with emphasis variations, import substitution (Krugman 2002), and there was convergence in Southeast Asian countries and developed countries, when the first still kept the most essential elements of their intervened economy model (Rodrik, 2003). To NAFTA members, convergence slowed down and started reverting in 1982, the year when the three countries, especially Mexico, liberated their economies. This turnabout in the course of events did not restrain this gap amplification, and results looked as if they could coincide with Quah's conclusions (1995) on the European Union case, –in this sense, growth and convergence precede the opening, and growth cannot accelerate convergence.

To go deeper in the analysis on NAFTA convergence, and due to the importance given to the opening in designing policies, and the argument sustaining the unmistakable existence of a positive correspondence between trade and sustained growth, we will explore the opening rate for these economies and their correlation with GDP growth. Our results reinforce the previous conclusions about the gap amplification between NAFTA member countries, especially between Mexico and the United States, from 1982 to 2000. These conclusions also provide Rodríguez and Rodrik's discussion with argumentation. For NAFTA countries, and particularly for Mexico, we found a very small or a non-existent correlation between the opening rate and the GDP growth. To come to this conclusion, we took as an opening measure the external rate of GDP[ii]. This indicator points out the opening degree of an economy, and ultimately that of productivity. It must be assumed that a successful procedure of trade liberalization, "to put prices right", should generate the sustained growth of the export-import rate with regard to GDP. If the export sector showed productivity higher than that of the rest of the economy, it would be logical for those countries to relocate the productive factors toward exports, revealing raises in the external rate of GDP, and higher rates of productivity and economic growth.

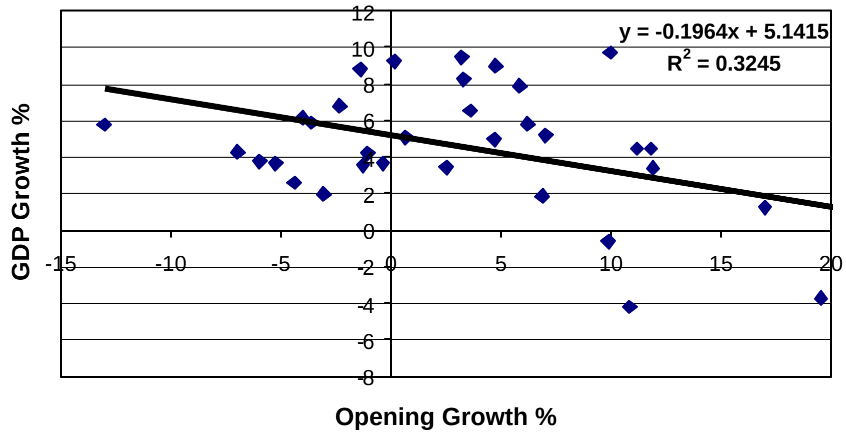
We will start out by mentioning that the American economy is less open than the Canadian and the Mexican (Graph 3). This statement, however, does not imply that the American economy is being more protected by tariff or non-tariff barriers. It only suggests that the American domestic market is wider, that Americans export a lesser amount of products, and that the external content of their economy is smaller, –due to a larger productivity, among other factors.

Graph 3
Trends in the opening coefficient of NAFTA countries



It is possible to detect a negative correlation between the high rhythm of growth of the GDP external rate shown by Mexico, and the expansion rate of its economy. Graph 4 presents the two-variable value of simple correlation results from 1960 to 2000. The trend sign is negative, and in the Mexican case, it suggests that the bigger the opening degree, the smaller the growth. There is no causation rapport between the variables, so it is necessary to go deeper into the elements explaining Mexican economic growth. The interesting thing, and therefore worrying, is that we did obtain a positive and significant correlation between the two variables in the Canadian case, and we actually observed a positive correlation (to a lesser extent) in the American case (Graph 1 and 2 of Appendix). Consequently, it is essential to explore Mexican economy's sources of growth and think of the causes explaining why this opening has not included higher rates of growth and convergence, as it was expected. Our results are in line with those of Slaughter y Quah (1995).

Graph 4
México: Correlation between GDP growth and opening growth



V. NAFTA SOURCES OF CONVERGENCE

Once it has been recognized that there was no convergence between NAFTA countries during the 1982-2000 period, we will establish the convergence sources in NAFTA countries. The first step is to calculate Beta convergence for the 1960-2000 periods. To do so, we include data on the variables of growth, and not exclusively on the per capita income of the three nations, shown in the previous exercise. Beta convergence suggests whether the less developed country in the starting year grows more rapidly in the following years. Beta convergence is calculated according to the following expression:

$\mathbf{GY_{Ti} = Co - ?\, LNY_{t-1} + U_t}$**.**

Where $\mathbf{GY_{Ti} = LN\ Y_t - LNY_{t-1}}$ is the difference of the natural logarithm of the per capita income of the i country in the t and t-1 periods of time, **Co** is the constant, and the ? parameter estimates absolute convergence. $\mathbf{LNY_{t-1}}$ is the logarithm of the per capita product in the initial year for each i country, and the std. error is represented by $\mathbf{U_t}$**.** The result goes as follows:

Beta Coefficient = -0.001390132. The beta coefficient sign is negative. As a result, there is divergence.

The results suggest that the initial GDP/C level does not determine convergence between NAFTA countries. Thus, it is essential to explore the variables explaining the trajectory of product growth in this region. That is why we estimated the per capita GDP growth for Canada, Mexico and the United States by defining an equation that integrates variables generally accepted by the specialists[iii].

Variables in the equation represent the values registered to each one of the three countries CRECY=C(1)+C(2)*YPCT+C(3)*INV+C(4)*GOB+C(5)*COM+C(6)*POB+C(7)*INF+?

Where:

CRECY	Rate of growth of the per capita GDP of each country,
YPCT	Logarithm of the per capita income in 1960 for the three countries
INV	Gross formation of tax expenditure in product for the three countries.
GOB	Tax expenditure share in product in the three countries. All expenses included, but investments. This is considered to be positive.
COM	Opening degree for the three countries.
POB	Population rates of growth for the three countries.
INF	Inflation rate for the three countries.
?	Std. Error

The results were the following:
Dependent Variable: **CRECY**

	Coefficient	Std. Error	T-Statistic	Prob.
C(1)	-5.210200	7.561826	-0.689014	0.4922
C(2)	0.458987	0.812938	0.564603	0.5734
C(3)	**0.591213**	**0.121737**	**4.856494**	**0.0000**
C(4)	**-0.389847**	**0.121795**	**-3.200844**	**0.0018**
C(5)	0.007223	0.020115	0.359077	0.7202
C(6)	**-0.953812**	**0.679500**	**-1.403697**	**0.1631**
C(7)	-0.068860	0.013614	-5.058015	0.0000

R-squared 0.302075

Convergence coefficient C(2), the per capita initial GDP, even though positive, is not statistically significant, which is consistent with the results obtained in absolute convergence.

The inversion C (3) is a significant element to countries' growth, this is caused by countries augmenting their participation at 1 percentage point in the product and it is likely to expect a 0.6 raise in the per capita income. Meanwhile government consume C(4) negatively affects the rate of growth[iv]. Commercial opening C(5) maintains a positive though not significant correlation[v]. This non significant effect is partly due to permanent deficits in balance of trade and the limited added value of exports, that is, the restricted usage of domestic factors, which triggers the coefficient and not the added value. In this sense, population growth C(6) keeps an inverse correlation with product growth, however it is not significant. Finally, the change in price levels C(7) is inversely related to the product rate of growth.

VI. Some Factors of Growth in Mexico

To determine the variables of growth of the Mexican economy, we selected the most common ones: demographic growth, physical capital investment, macroeconomic policies, trade opening, and the effect produced by Mexico's most important trade partner.
The equation to calculate Mexican GDP within the studied period is explained as follows:

$$YG = C(1) + C(3)*YGUS + C(4)*GOB + C(5)*INF + C(6)*INV + C(7)*COM + C(8)*POB + ?$$

Where:

YG is the per capita income rate of growth in Mexico,
YGUS is defined as economic growth in the United States,
GOB represents Mexican government consumption, in GDP,
INV is the percentage that gross fixed capital formation represents in Mexican GDP,
COM is the correlation of exports plus imports divided into the product,
POB is the rate of population growth, and last
? Std. Error

Results
The interrelation degree C(3) between the rhythm of growth of the United States and Mexico is positive and significant. Nonetheless, the positive effects of North American growth are attenuated by an inverse correlation, not significant though, between the opening degree C(7) and the variation of Mexican GDP, given than the export level has been constantly bigger than the Mexican exports.

	Coefficient	Std. Error	T-Statistic	Prob.
C(1)	**-4.732378**	**8.765193**	**-0.539906**	**0.5928**
C(3)	0.582804	0.208366	2.797023	0.0084
C(4)	-0.958338	0.410303	-2.335684	0.0255
C(5)	-0.062201	0.015491	-4.015276	0.0003
C(6)	1.058073	0.256400	4.126647	0.0002
C(7)	**-0.019830**	**0.069807**	**-0.284074**	**0.7781**
C(8)	**-1.650799**	**2.001186**	**-0.824910**	**0.4152**
	R-squared		**0.554937**	

To a considerable extent, if governmental consumption C(4) increases in one percentage point in the gross domestic product, the inhabitant product growth will be reduced in one percentage point, approximately. This way, governmental consumption has negative effects more intensive than those registered by price variation C(5).

Gross fixed capital formation C(6) notably preserves the greater expansive effects on Mexican growth. In the Mexican case it is alarming that this has not presented a tendency increasing in the entire period.

Education has been mentioned among the variables that supposedly have a positive impact on growth. According to Romer-type models of growth (1990), efficiency in human capital investment is one of the most important variables to determining the factors of growth. Even when it is true that there has been a remarkable improvement in the educational level of manpower, the outstanding thing about the Mexican case is the lack of a positive correlation between educational levels and growth, as shown in graph 5. A credible explanation to this phenomenon states that given the current Mexican labor market conditions of employers, education has turned out to be a mechanism to compete. Workers must accept low salaries and be in charge of activities inferior to their qualification. Attributable to these conditions, most of human capital investments are neither translated into higher productivity nor into better income levels (Romero y Puyana, 2003).

The per worker capital endowment is another variable that has impacted growth, and it is related to raises in productivity and economic growth. Even when it was not integrated into the equations, it is interesting to point out that, in the Mexican case, there has been a strongly negative trend during the 19809-2000 period of time (graph 6). This negative trend contributes to explain the inverse relationship between the educational level improvement of labor force and economic growth. Therefore, it suggests that better qualified human resources have been given access to less equipment and technology, both means to productivity and income growth.

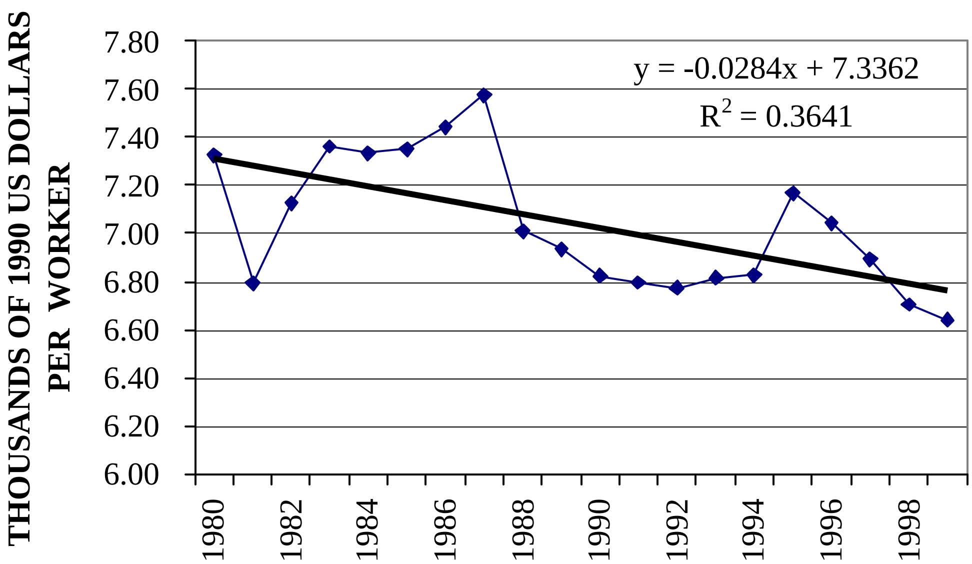
VII. CONCLUSIONS



After more than fifteen years of economic reforms, and ten since the NAFTA was set in motion, the effects announcing a change in the model and the integration with the United States' economy have not yet crystallized. Even though it is true that there have been periods of growth for the Mexican GDP, these have only been sporadic, and have not been fully shown as a sustained approach to the income and welfare levels of Mexican NAFTA partners. To detect whether there is a trend toward convergence in per capita income of NAFTA members is the goal of this analysis.

The convergence registered from 1946 to 1980 has not been recovered, and today these economies are as distant as they were 20 years ago. It is important then to explore the determiners to this behavior, which was by no means expected neither by theoretical enlightenment, nor by those who had set their minds on demonstrating that convergence should have arisen once these economies had been integrated into the international market and more prosperous economies.

Our results provide those who have questioned the mechanical correlation between opening, foreign commerce and higher rates of growth with a standpoint. They also side with those who remained skeptical in the face of this positive and undeniable correlation between integration and convergence.

One of the causes for this lack of convergence between Mexico and its NAFTA partners lays on the fact that Mexican investments, measured by the GKF, have not been energized to an appropriate extent. For Mexican investments to be a convergence factor, they should have raised a much greater growth, and the GKF Coefficient of GDP should have grown notably distant from the values registered for the United States and Canada.

This analysis detected a very restricted or non-existent correlation between the opening of an economy and growth, in the Mexican case, and a positive relationship for Canada and the United States. It is essential to look into the causes for this phenomenon. One of the most likely explanations, –not explored in this work, is the weight of the imported content in Mexican exports, approximately a 60 per cent. Given these conditions, the multiplier factor of exports is reduced. Besides, when the income elasticity of imports is elevated, the external restrictions to growth are worsened.

End Notes

[i] The authors are Hall y Jones(1999), Sachs y Warner(1995), Dollar y Kraay (2001), Alcalá y Gicoone (2001). Besides the opening effects, Hall and Jones have come up with a social infrastructure index, which refers to governmental management in the presence of corruption, expropriation risks , etc., as well as data concerning to territorial extension of common language, distance to the Equator, the GDP international share of the international market, demographic and geopolitical characteristics. There is a positive correlation between this index and per capita GDP logarithm.

[ii] The external rate of GDP is calculated as follows: [(Exports + Imports) / GDP]. It has been suggested that the external rate of GDP is a good and impartial measure for the opening. (Sheeby, 1992; Easterly et al 2001; Berg and Krueger 2003; Dollar et al 1995).

[iii] Just like Dollar and Kray (2001), and because the variables are measured in rates of growth, it is not necessary to test unitary roots and co-integration. In Arora & Vamvakidis(2001), per capita GDP in the first year is the approximation of convergence, which is part of a set of explanatory variables: population growth, fixed capital investment, inflation, government consume, international trade share in GDP.

[iv] The signs of governmental investment and consume coefficients are equal to those found by Arora & Vamvakidis (2001). When using Dollar's direct foreign investment (1992) we found that this foretells the growth in the very same way that it does with the opening degree. Both variables are correlated.

[v] This non significant result is a part of a debate over de causation between economic growth and commercial opening. In relation to the hypothesis of trade opening as a source of economic growth and convergence, see: Ventura (1997), Grossman & Helpman (1991), Edwards (1998), Frankel & Romer(1998), Lucas (1988), Young(1991), Barro & Sala-i-Martin (1995), Dollar(1992), Sachs and Warner(1995), Ben-David(1993). Neither Slaughter (2001) nor Rodríguez & Rodrik (1999) found evidence showing that trade liberalisation has positive effects on countries' speed of convergence.

Causal Analyses between Foreign Trade and Economic Growth in China

Kun Wang
Renmin University of China, China

Abstract

This paper uses cointegration and error-correction model to analyze the causal relationship between foreign trade and economic growth in China using annual data from 1978-2001.The empirical results show evidence for unidirectional causality running from export growth to economic growth. There is also evidence that bi-directional causality exits between import growth and economic growth, and export growth significantly causes economic growth.

1. Introduction

The relationship between foreign trade and economic growth has long been a subject of much interest. The economists of Classical theories and endogenous economic growth theories demonstrate from different aspects that foreign trade is a positive-sum game and a driving force of economic growth. Foreign trade makes for a better allocation of resources and a greater utilization of the productive capacity; makes it possible to obtain economies of scale, resulting in the direct proceeds for countries involving in foreign trade; allows access to a wider base of technological knowledge; makes technological diffusion easier; motivates research and avoids redundancies; all these will accelerate the long-run growth of economy. These theories provide import academic foundation for expanding foreign trade.

Some development economists (Singer, 1950; Prebisch, 1962) argue that foreign trade brings on negative consequence in the long run for the Less Developed Countries. The Less Developed Countries specialize in products with low demand income elasticity for foreign trade. Therefore, with a weak perspective of exports growth, their trade terms have a tendency to constant deterioration. Furthermore, this specialization entailed significant economic and social costs of adaptation to the evolution of the chain of foreign trade. Some countries put into practice the introverted and protectionism development strategies in response to the protectionism trade policy reasoned by development economists after World War II.

Owing to the failure of introverted growth experiments and to the association of quick economic growth with the opening of foreign trade and the consequent international specialization in several countries, empirical pursuers have exhibited increased interest in undertaking the research on trade and growth to find sources of growth from the 1970's on. These studies focused on the export-led growth hypothesis can be categorized into two groups: those based on cross-country data and those based on time series data.

Early researches employ cross-country data to investigate the role of exports on economic growth through regressing real growth on contemporaneous real export growth. They generally conclud that highly significant positive correlation exists between export growth and economic growth, supporting for export-led growth hypothesis (See, for example, Michaely,1977; Balassa,1978; Tyler,1981; Feder,1983; Kavoussi,1984; Balassa,1985; Moschos,1989).There are some main weaknesses of these studies. Cross-country studies assume a convergent economic structure and similar production technology. These rigorous assumptions are most likely not true in reality. On the other hand, the researches suppose that export growth causes economic growth without considering the causal direction between the variable. In fact, while export growth speeds economic growth, aggregate economic growth resulting in scale economy can enhance the competitive advantage of export section and then promote export expansion. Simple correlation analysis cannot reveal the relationship adequately.

Time series analyses based on causality concept have been taken in a number of recent studies followed the pioneering study of Jung and Marshall,1985; (See, for example, Chow,1987;Darratt, 1987; Kunst and Marin, 1989; Salvatore and Hatcher, 1991; Ghartey,1993; Sengupta and Espana, 1994). The causality testing approach is designed to assess whether or not causality relationship exists between exports and economic growth and the causality direction if there is such relationship. The conclusions of these studies are different from those in cross-country data analyses. Some researches cast doubt on validity of export-led growth hypothesis (see, for example, Jung and Marshall, 1985; Darratt, 1987; Kunst and Marin, 1989; Ghartey, 1993). It should be pointed out that most macroeconomic variables are not stationary. In order to avoid the spurious regression problem that arises when statistical inferences are drawn from non-stationary time series, the time series properties of the data have to be investigated before employing causality test.

Testing for causality in multiple time series has been the subject of considerable recent researches. Vector autoregressive (VAR) model was applied in some of the researches (see, for example, Kunst and Marin, 1989; Jin, 1995; Jin and Yu, 1996; Jordan Shan and Fiona Sun,1998). VAR model need not to distinguish between exogenous variables and endogenous variables. Therefore it can avoid some specification bias of model. Whereas, no matter whether or not the variables are stationary, this unrestricted VAR system cannot abstain from over-parameter and multicollinearity problems that prevalently exit in multiple regression. Besides, these studies use F-test for Granger causality, but standard tests (such as t-test, F-test, Wald test) for causality originally designed for stationary variables are not valid if there exists cointegration (Granger, 1988). Engle and Granger (1987) provide a more comprehensive procedure for causality test for variables that are found to be cointegrated. This procedure is known as 'error-correction model' (ECM). ECM has many advantages. First of all, the variables involved in the ECM have the stationary property, ensuring the validity of causality test. Next, ECM has solved the spurious regression problem that puzzled econometrician for a long time. Furthermore, ECM compartmentalizes parameters of model into long-run parameters and short-run parameters, incorporates information from the cointegrated properties of time series and allows for a causal linkage between two (or more) variables stemming from an cointegrated relationship, consequently changing the complexion that previous empirical researches economic theory only discuss the causal linkage from the short-run adjustment of individual variables. Engle and Granger (1987) have proved that ECM is a restricted VAR model under cointegration restriction. This restriction has dealt with the over-parameter and multicollinearity system problems generally occurred in unrestricted VAR model.

Since the open door policy in 1978, China, the largest developing country in the world, has undergone far-ranging reforms of trade system that have steadily reduced the role of planning and increased the importance of market forces. This condition is likely to influence the relationship between foreign trade and economic growth. Several empirical studies have been undertaken to investigate the relationship between exports and economic growth in the case of China. These include, among others, Kwan and Cotsomitis (1991), Lee (1994), Zuo (1994), Xue (1995), Jordan Shan and Fiona Sun,1998; Shuanglin Lin(2000). They find that export growth has a positive impact on Chinese economic growth. However, except Jordan Shan and Fiona Sun,1998, they have not considered the properties of the original time series and consequently their inferences may suffer from the spurious regression problem. Zuo (1994), Lee (1994), Xue (1995), Shuanglin Lin(2000) make a assumption that export growth causes economic growth and do not consider the direction of the causal relation. Kwan and Cotsomitis (1991) have based their studies on a simple two-variable framework in the causality, while a simple two-variable framework may be subject to a possible specification bias. Jordan Shan and Fiona Sun,1998 have applied a six-variable VAR system to test the causality link between exports and economic growth. This unrestricted VAR system may suffer from serious over-parameter and multicollinearity problems that prevalently exit in multiple regressions.

The focus of the paper is to test the causal relationship between foreign trade and economic growth in China for the period from 1978-2001.This paper examines the direction of causality between foreign trade and economic growth by utilizing a cointegration and error-correction modeling framework, which provides a more comprehensive test of causality than the standard Granger causality test.

The remainder of this paper is organized as follows. Section II sketches the econometric model employed in this paper. Section III uses unit roots test to examine properties of the univariate time series. Given the nonstationarity nature to each of the univariate series, cointegration analysis is employed. The evidence supports for cointegration relationship among variables, so causality relationship is examined through error-correction model. Section IV provides conclusions. All operations are finished by EVIEWS3.1.

2. Econometric methodology and data

To undertake the analysis, this paper uses Chinese annual time series data over the period 1978-2001. The economic growth is measured by GDP, and the trade growth is denoted by export growth and import growth. All annual data are collected in logarithm and deflated using CPI index, for GDP (LPGD), exports (LPEX) and imports (LPIM). The data source is China Statistical Yearbook published by China Statistical Bureau.

In this paper, the relationship between trade and economic is empirically tested for Granger causality with error-correction model. Since it is essential to check for the cointegrating properties of the original real exports, imports and GDP series before applying the standard Granger test, cointegration analysis is applied first. Granger(1986) and Engle and Granger(1987) define a nonstationary time series X_t to be integrated of order d , $I(d)$, if it achieves stationary after being differenced d times. For $d ? 0$, X_t is stationary in levels and no differencing is necessary. If the time-series variables are found to be nonstationary and integrated of the same order, tests can be performed to see if the variables are cointegrated. An identified cointegrating relationship among variables implies there exists a long-term equilibriating relationship among those variables. Generally, a set of variables are side to be cointegrated of a linear combination of their individual integrated series, which are $I(d)$, a regression is run, such as:

$$Y_t ? ?X_t ? ?_t \quad (1)$$

If the residuals ($?_t$) from the regression are $I(0)$, then X_t and Y_t are said to be cointegrated. The constant and trend values can be included in equation (1) as needed.

The main methods for cointegration analysis are Engle-Granger(1987) cointegration analysis and multivariate maximum likelihood testing procedure (Johansen ,1988; Johansen and Juselius,1990; Johansen,1995). Engle-Granger (1987) cointegration analysis assumes uniqueness of the cointegrating vector. However, in a multivariate context, the number of cointegrating vectors could be more than one. Furthermore, Engle-Granger mothod cannot make sensible judgement about the significance of the parameters on account of non-normality of the distribution of the estimators of the cointegrating vector. Johansen (1988), Johansen and Juselius (1990) and Johansen (1995) have developed a multivariate maximum likelihood testing procedure on the number of cointegrating vectors that also includes testing procedures for linear restriction on the cointegrating parameters. In this paper, multivariate maximum likelihood testing procedure is used to make judgements.

In order to determine the integration level and the possible cointegration among variables, this paper employs the Augmented Dickey-Fuller(ADF hereafter) test which is based on estimating the following regression:

$$?X_t ? ?_0 ? ?_1 t ? ?_2 X_{t?1} ? \overset{k}{\underset{i?1}{?}} c_i ?X_{t?i} ? ?_i \quad (2)$$

Where $?X_t ? X_t ? X_{t?1}$ and X is the variable under consideration, k is the number of lags in the dependent variable, $?_t$ is the stochastic error term. The null hypothesis is $H_0 : ?_2 ? 0$. If the null hypothesis cannot be rejected, it implies that the time series is nonstationary at the level and therefore it requires taking first or higher order differencing of the level data to establish stationarity. The optimum lag length k is selected using the Akaike Information Criterion (AIC) and Schwarz Criterion (SC).

Granger(1969) has brought forward a test of causation, a variable X is said to cause another variable Y , concerning a given information set that includes X and Y , if current Y can be predicted better by using past values of X than by not doing so, given that all other past information in the information set is used. In view of the properties of time series, Engle and Granger(1987) provide a more comprehensive procedure for causality test for variables that are found to be cointegrated. They have shown that if variables are integrated of order one, that is $I(1)$, and are cointegrated then either unidirectional or bi-directional Granger causality must exist in at least the

$I(0)$ variables. If the variables are cointegrated, there must exist an error-correction representation. A vector ECM can be established as follows:

$$? LPGD_t \; ? \; \mathop{?}\limits_{i?1}^{k} \; ?? _{1i} ? LPGD_{t?i} \; ? \; ?_{1i} ? LPEX_{t?i} \; ? \; ?_{1i} ? LPIM_{t?i} ?? \; ?_1 EC_{t?1} \; ? \; ?_1 \quad \text{(3a)}$$

$$? LPEX_t \; ? \; \mathop{?}\limits_{i?1}^{k} \; ?? _{2i} ? LPGD_{t?i} \; ? \; ?_{2i} ? LPEX_{t?i} \; ? \; ?_{2i} ? LPIM_{t?i} ?? \; ?_2 EC_{t?1} \; ? \; ?_2 \quad \text{(3b)}$$

$$? LPIM_t \; ? \; \mathop{?}\limits_{i?1}^{k} \; ?? _{3i} ? LPGD_{t?i} \; ? \; ?_{3i} ? LPEX_{t?i} \; ? \; ?_{3i} ? LPIM_{t?i} ?? \; ?_3 EC_{t?1} \; ? \; ?_3 \quad \text{(3c)}$$

Where $EC^{i?1}_{t?1}$ is the error-correction term obtained from the cointegrating regression equation, ? represents first-differences. If the series are cointegrated, then the error-correction models are valid and the coefficients $?_1$, $?_2$ and $?_3$ are expected to capture the adjustments of $?LPGD_t$, $?LPEX_t$ and $?LPIM_t$ towards long-run equilibrium. $?_{1i}, ?_{1i}, ?_{1i}$ are coefficients that describe the effects of k current and past values of $?LPGD_t$, $?LPEX_t$ and $?LPIM_t$ on $?LPGD_t$ respectively in equation (3a), $?_{2i}, ?_{2i}, ?_{2i}$ describe the effects of k current and past values of $?LPGD_t$, $?LPEX_t$ and $?LPIM_t$ on $?LPEX_t$ respectively in equation (3b), $?_{3i}, ?_{3i}, ?_{3i}$ describe the effects of k current and past values of $?LPGD_t$, $?LPEX_t$ and $?LPIM_t$ on $?LPIM_t$ respectively in equation (3c). The $?_1, ?_2$ and $?_3$ are mutually uncorrelated white noise series.

The Granger causality can be tested through the null hypotheses that $?_{1i} \; ? \; 0, ?_{1i} \; ? \; 0$ in equation (3a) , $?_{2i} \; ? \; 0, ?_{2i} \; ? \; 0$ in equation (3b) and $?_{3i} \; ? \; 0, ?_{3i} \; ? \; 0$ in equation (3c) for all i respectively, which can be done using standard tests. If null hypotheses are accepted, then there is no causality. If some $?_{1i} \; ? \; 0$ or some $?_{1i} \; ? \; 0$, for instance, focusing on equation (3a), then $?LPGD_t$ is said to be caused by $?LPEX_t$ or $?LPIM_t$. If both $?_{1i} \; ? \; 0$ in equation (3a) and $?_{2i} \; ? \; 0$ in equation (3b), then there is bi-directional causality between $?LPGD_t$ and $?LPEX_t$. The relationship between other variables such as $?LPGD_t$ and $?LPIM_t$, $?LPEX_t$ and $?LPIM_t$ can be determined in light of the same way.

The inclusion of $EC_{t?1}$ in the Error-correction model gives an extra channel through which the effects of causality can occur. It incorporates information from the cointegrated properties of time series and allows for—in addition to the causal linkage from the short-rum adjustment of individual variables—a causal linkage among variables stemming from a cointegrated relationship. The long-run relationship among variables can be tested on the null hypotheses that $?_1 \; ? \; 0$ in equation (3a), $?_2 \; ? \; 0$ in equation (3b) and $?_3 \; ? \; 0$ in equation (3c). If the null hypotheses cannot be rejected, there is no causality from $EC_{t?1}$, if the null hypothesis is rejected, causality is inferred.

For the sake of avoiding arbitrary lag-length k specification, a statistical procedure is used for choosing the lag length.

3. Empirical results

Test results for unit root

Each time series are first tested for their orders of integration by using ADF test (Table 1). The tests show that

LPGD, LPEX and LPIM achieve stationarity after being differenced one time, so they are integrated of order one, or $I(1)$, at the 5% level of significance.

TABLE 1. ADF TEST RESULTS FOR UNIT ROOTS

Variables	ADF	Critical Values (5%)	Lag	Conclusions
LPGD	-3.630362(a)	-3.6920	5	Nonstationary
LPEX	-1.926379(a)	-3.6330	1	Nonstationary
LPIM	-2.484682(a)	-3.6330	1	Nonstationary
? LPGD	-3.309674(b)	-3.0114	1	Stationary
? LPIM	-3.395153(b)	-3.0114	1	Stationary
? LPEX	-4.776046(b)	-3.0114	1	Stationary

Note: (1) The critical values for the ADF tests are taken from EVIEWS3.1 ; (2) The optimum lag length is selected using the AIC and SC;(a) The ADF test includes constant and trend; (b) The ADF test includes constant but no trend.

Test results for cointegration

Since the time series of LPGD, LPEX and LPIM are found to be integrated of the same order (i.e, order one), a cointegration test can be conducted to determine whether a long-run equilibriating relationship exists between them. Johanson multivariate maximum likelihood testing procedure is performed.

Before applying cointegration test, this paper determines the structure of Vector Autoregressive (VAR) Models first because Johanson cointegration test is a method based on VAR Models. To determine the order of VAR used in Johanson cointegration test, the order of a unrestricted VAR should be confirmed first. This paper has therefore built the following three-variable unrestricted VAR(k) system:

$$\begin{bmatrix} LPGD \\ LPEX \\ LPIM \end{bmatrix}_t ? ?_1 \begin{bmatrix} LPGD \\ LPEX \\ LPIM \end{bmatrix}_{t?1} ? ?_2 \begin{bmatrix} LPGD \\ LPEX \\ LPIM \end{bmatrix}_{t?2} ? \ldots ? ?_k \begin{bmatrix} LPGD \\ LPEX \\ LPIM \end{bmatrix}_{t?k} ? C ? ?_t$$

$$t ? 1,2,\ldots,T \quad (4)$$

where $?_1, ?_2, \ldots, ?_p$ are coefficient matrix, C is intercept vector, $?_t$ is error term, k is the order of VAR system.

With a view to balancing between ensuring approximately white-noise errors and allowing for enough degrees of freedom in estimation, the optimum VAR order is estimated from 3 to 1 in turn with the AIC and SC, and confirmed by LR tests. The results show that the VAR order is optimum when it is 3 according to the AIC while it is 1 by the SC. LR test is used to determine the optimum VAR order between lag length 1 and lag length 3. The LR test null hypothesis H_0 : k=1,

$$LR ? ?2*(l_1 ? l_3) ? ?2*(87.6035 ? 101.9032) ? 28.5994$$

where l_1 and l_3 denote the log likelihood value when VAR order k is 1 and 3, respectively ; $LR \sim\ ?^2(18)$.

The result rejects the null hypothesis at significance level of 5.35% , so the optimum unrestricted VAR order is 3.

Because Johanson cointegration test is applied to VAR Models under cointegration restriction, the order of the restricted VAR system is the lag length of first differencing variables in unrestricted VAR system. Accordingly, VAR(2) system for Johanson cointegration test is used to determine the number of cointegration equation (r), based on eigenvalues of the stochastic matrix.

The result of Johanson cointegration test (Table 2) indicates that one can reject the null $r\ ?\ 0$ against the alternative $r\ ?\ 1$, but cannot reject the null $r\ ?\ 1$ against the alternative $r\ ?\ 2$, that is, there exists a 'unique' cointegrating equation among LPGD, LPEX and LPIM at 5% significance level.

TABLE 2. RESULT OF JOHANSON COINTEGRATION TEST

Eigenvalue	Likelihood Ratio	Critical Value at 5%	Critical Value at 1%	Null hypothesis No. of CE(s)	Alternative hypothesis No. of CE(s)
0.699995	44.60768	34.91	41.07	r=0 **	r=1
0.434188	19.32459	19.96	24.60	r=1	r=2
0.295823	7.365222	9.24	12.97	r=2	r=3

Note: (1) *(**) denotes rejection of the hypothesis at 5%(1%) significance level.
L.R. test indicates 1 cointegrating equation(s) at 5% significance level.
(2) The length of the lag is estimated with AIC and SC.

The cointegrating equation is represented as follows:

$$EC\ ?\ LPGD\ ?\ \underset{(?6.35)}{0.8615}LPEX\ ?\ \underset{(2.62)}{0.3889}LPIM\ ?\ \underset{(?33.28)}{6.0199} \qquad (5)$$

Note: The number in parentheses represents t statistics.

The result of the ADF test applied to residual of the cointegration equation denotes the cointegrating equation is stationary at 5% significance level (Table 3), supporting that cointegration exists among the variable vectors.

TABLE 3. RESULT OF THE RESIDUAL-BASED ADF TEST FOR COINTEGRATION

ADF Test Statistic	5% Critical Value	10% Critical Value
-3.146120	-3.0038	-2.6417

Test results for causality

Having confirmed the existence of a 'unique' cointegragion relationship for real GDP, exports and imports over the long run, this paper conducts Granger causality test in the context of a vector ECM by estimating a restricted VAR model under cointegration restriction to determine whether the causality relationship exists among the data series. Because vector ECM is a restricted VAR model under cointegration restriction, the optimum order of the unrestricted VAR system determined is 3, so a VAR(2) system is used for vector ECM. Various mis-specification tests of the VECM are reported in Table 4. No problem is revealed at 5% significance level in these tests, the validity of the system can therefore be taken with confidence.

TABLE 4. PROPERTIES OF VECTOR ECM RESIDUALS

	?LPGD	?LPEX	?LPIM
White statistics	0.9841	1.5450	0.3788
P value	0.55	0.31	0.94
ARCH(1) LM statistics	0.3295	1.9704	0.5471
P value	0.57	0.16	0.46
ARCH(2) LM statistics	0.5839	2.2484	4.9743
P value	0.75	0.32	0.08
JB Normality statistics	2.0713	0.6574	0.7679
P value	0.35	0.72	0.68

Note: ? represents first-differences.

The empirical results of causality test on the estimated vector ECM are presented in Table 5.

TABLE 5. CAUSALITY TEST BASES ON VECM

$$?LPGD_t ? \underset{i?1}{\overset{2}{?}} ?? _{1i} ?LPGD_{t?i} ? ?_{1i} ?LPEX_{t?i} ? ?_{1i} ?LPIM_{t?i} ?? ?_1 EC_{t?1} ? ?_1 \quad \text{(6a)}$$

	Test for $? \; ?_{1i} ?LPEX$	Test for $? \; ?_{1i} ?LPIM$	Joint test	Test for $EC_{t?1}$
H_0	$?_{1i} ? 0, ? i$	$?_{1i} ? 0, ? i$	$?_{1i} ? ?_{1i} ? 0, ? i$	$?_1 ? 0$
Wald Statistics	7.189492	5.640480	3.653262	28.80221
P -value	0.007111	0.015971	0.030714	0.000099

$$?LPEX_t ? \underset{i?1}{\overset{2}{?}} ?? _{2i} ?LPGD_{t?i} ? ?_{2i} ?LPEX_{t?i} ? ?_{2i} ?LPIM_{t?i} ?? ?_2 EC_{t?1} ? ?_2 \quad \text{(6b)}$$

	Test for $? \; ?_{1i} ?LPGD$	Test for $? \; ?_{1i} ?LPIM$	Joint test	Test for $EC_{t?1}$
H_0	$?_{2i} ? 0, ? i$	$?_{2i} ? 0, ?_i$	$?_{2i} ? ?_{2i} ? 0, ? i$	$?_2 ? 0$
Wald Statistics	0.140891	2.915549	3.669299	7.891816
P -value	0.869800	0.087391	0.030287	0.013925

$$?LPIM_t ? \underset{i?1}{\overset{2}{?}} ?? _{3i} ?LPGD_{t?i} ? ?_{3i} ?LPEX_{t?i} ? ?_{3i} ?LPIM_{t?i} ?? ?_3 EC_{t?1} ? ?_3 \quad \text{(6c)}$$

	Test for $? \; ?_{1i} ?LPGD$	Test for $? \; ?_{1i} ?LPEX$	Joint test	Test for $EC_{t?1}$
H_0	$?_{3i} ? 0, ? i$	$?_{3i} ? 0, ? i$	$?_{3i} ? ?_{3i} ? 0, ? i$	$?_3 ? 0$
Wald Statistics	3.588567	2.404312	3.146996	2.389850
P -value	0.055186	0.126589	0.048416	0.144426

Note: $EC_{t?1}$ is equivalent to EC in equation (5).

The error-correction term $EC_{t?1}$ represents the long-run impact of variables on other variable. Statically significant non-zero $?_1$ and $?_2$ suggest that in the long-run real trade growth (including real export growth and import growth) Granger causes real GDP growth at 0.01% significance level, and real imports and GDP growth Granger cause real exports growth at 1.4% significance level.

Turning to the short-run Granger causality, the results indicate that unidirectional causalities exist from real export growth to real GDP growth at 0.8% significance level and from real import growth to real export growth at 8.8% significance level. Bi-directional causality exists between real GDP growth and real import growth, while the causality from real import growth to real GDP growth (with the 1.6% significance level) is stronger than the causality from real GDP growth to real import growth (with the 5.6% significance level). Moreover, results of joint test show that in the short run real trade growth (including real export growth and import growth) Granger causes real GDP growth at 3.1% significance level; real import and GDP growth Granger cause real export growth at 3.1% significance level; real GDP and export growth Granger cause real import growth at 4.9% significance level.

It is important to note that negative signs for the corresponding error-correction terms (Table 6) accord with the reverse modification mechanism of ECM. The estimated parameters on $?_1$, $?_2$ and $?_3$ give an indication of how fast $?LPGD_t$ and $?LPEX_t$ adjust themselves toward the long-run equilibrium level. For $?LPGD_t$, the adjustment was made at a speed of around 2.8 years (a coefficient of around 0.36 on annual data). For $?LPEX_t$, the adjustment was about one year (a coefficient of around 1.04 on annual data).

Table 6. Coefficient for $EC_{t?1}$ from vector ECM

Error Correction:	$?LPGD$	$?LPEX$	$?LPIM$
Coefficient for $EC_{t?1}$	-0.358579	-1.039937	-0.551153
t-statistic for $EC_{t?1}$	(-5.36677)	(-2.80924)	(-1.54591)

4. Conclusions

This paper has analyzed China annual data for real GDP, exports and imports over the period 1978-2001. The empirical results indicate that level data series are integrated of order one and a 'unique' long-run equilibrating relationship exits among the data series, namely, the series are cointegrated. In order to avoid multicollinearity and simultaneity bias problems, a VECM system is applied to investigate the causality relationship among these cointegrated time series. The causality test by estimated VECM reveals a bi-directional causality between the growth of foreign trade and real GDP not only in the short run but also in the long run. It can be maintained that trade expansion and economic growth are two interactive processes of economic development. In addition, this study has also investigated the effects of export growth and import growth on GDP growth in China respectively. It has been shown that export growth significantly causes economic growth, and bi-directional causality exists between import growth and GDP growth while the causality from import growth to GDP growth is stronger. The Chinese experience confirms that trade expansion play an important role in accelerating economic growth. These findings are virtually consistent with the theoretical hypothesis presented by classical economic theories and endogenous economic growth theories.

The Open Chinese Capital Account:
Principles, Prerequisites and Procedures

Ming Men
University of International Business & Economics (UIBE), China

Abstract

The most important issue of an economy is to allocate resources efficiently. The efficiency of the capital market is critical in the process of converting residents' savings into investments. To open a nation's capital market to the outside world means that the restrictions on the types of financial services are provided by different financial institutions will be removed and the restrictions on cash flows will be removed. An open capital market will benefit the growth of the economy. It could also induce unexpected risks and even financial crises.

This paper will investigate the relationship between capital liquidity and economic growth, analyze Chinese capital market efficiency under the framework of WTO, and suggest suitable solutions to enhance Chinese capital market efficiency. It will discuss the potential problems and risks of an open capital market and the suitable policy reactions in a more volatile financial environment.

I. Introduction

The increasing volatility of financial market is one of the main economic phenomena of the past quarter century. Since the World War II, the world economy has been integrated to such a degree that not only end products are traded globally, but production factors, such as capitals, materials and production equipment, are moving around the world also. The new global economic environment posts great challenges to not only corporations that are operating internationally, but also governments that are striving to enhance the political and economic competitiveness of their countries. Although volatile financial market may increase business risk, they also create profitable investment opportunities for both firms and investors, given a proper understanding of financial risk management. In the process of economic globalization, the integration of financial markets is one of the most difficult issues. Government officials, industry leaders and financial experts have been discussing the issue of opening capital account intensively for a number of years. As a matter of fact, it is one of the most difficult, most controversial and most risky problems in the economic globalization process for the developing countries. The pros and cons of opening capital account are so ambiguous that the decision makers may often do things right in one aspect but do things wrongly in others.

If we look at the recent financial crises around the world, it is not difficult at all to find out how risky to open a country's capital account to the outside word is. The Latin America countries' crises in the 1970s and 1980s, the Mexico crisis in 1994 and the Southeast Asia crisis in 1997 are all related with the improper opening of the capital account in someway. Although this inductive reasoning may not be totally reliable due to the small size of the sample, it would be beneficial for us to fully consider the potential financial, economic and even political uncertainties imbedded in the opening process of Chinese capital account. There are several important questions we need to consider before we go further to the next step of China's financial system reform. Is it necessary for a country, say as large as China to open its capital account? If yes, how to open the capital account properly? What is the right procedure to open the capital account? How to maximize the benefit of globalization while avoiding the unexpected financial risk and crisis? These are important issues that the decision makers of developing countries are facing when considering to open the capital account.

Let's take a brief look at the latest history of the development of China's financial market. Since the seventies of last century, China's financial system reform has roughly fallen into the following three phases:

(1) The first phase started from 1978 and ended in 1996, which was the initial formation period of Chinese financial system.
(2) The second phase started from 1996 and ended in 2001, which was the reform period of Chinese financial system.

(3) The third phase started from 2001 and lasted till present, which is the period of opening Chinese financial market according to the WTO agreement.

At present, how and when to open of Chinese capital account draws significant attention from financial practitioners, government officials and theorists all over the world. This is probably because that the scope and the procedure of the open of Chinese capital account will have significant impact not only on the direct returns of the investors both inside and outside China, but also on the way of participating and managing their financial risks in the long run for the major financial market players.

The timing of opining China's capital account is the crucial part of the decision. If China's capital account opens too early, it will induce the expected risks for Chinese financial institutions and investors. The ill-prepared opening may put them into unfavorable competitive positions of the market. On the other hand, however, if Chinese capital account opens too late, it will undermine the development of Chinese financial market and impair the competitiveness of Chinese financial institutions even further. Therefore, the issue of open Chinese capital account constitutes a real dilemma for Chinese decision makers.

Let's analyze the issue a little bit further by looking at the underlying forces of the opening capital account. Based on the fundamental methodology of the economic analysis, there are two underlying forces determining the openness of the capital account. One underlying force is the demand for capital market efficiency; the other one is the desire for financial stability. The conceptual relationship between the market efficiency and the degree of capital market openness is that the more the capital market openness, the larger the capital market efficiency. On the other hand, the conceptual relationship between the financial market stability and the openness of the capital market is that the more the capital market openness, the less the financial stability. The art to deal with the open of capital account needs a well-designed combination of these two underlying forces. Fig. 1 depicts these conceptual relationships in the following page.

The goal of open capital account is to increase the liquidity of the capital asset so that the resources can be allocated more efficiently. As a matter of fact, to open capital account is an important step to enhance the efficiency of the capital market. An efficient capital market allows the transfer of financial assets with little loss of wealth. Capital market efficiency results from market prices reflecting all available information so that prices are fair to all market participants. But how can prices in the capital market reflect all available information?

It is generally believed that an efficient market should posses the following features.

(1) There are no barriers to entry in the financial market. This is one of the key aspects of perfect market competition.
(2) The market competition is perfect, which means all participants in the financial market are price-takers.
(3) Financial assets are infinitely divisible. This will enable the buyers and sellers to trade any amount of the financial asset they agree upon.
(4) No transaction costs, no bankruptcy costs. This feature will make the law of value additivity hold in the financial market. Value additivity means that the value of the whole exactly equals the sum of the values of the parts. If value additivity holds, the law of value conservation holds.
(5) All existing information is fully available without charge. This feature will make it possible for all market participants obtain the information instantly.
(6) No government or other restrictions on financial assets trading. This will allow the financial market participants to take any position they want, no matter long position or short position. In other words, there is no penalty to take short position.
(7) Market participants are rational in making their financial decisions. This feature means that all the investors are so knowledgeable that they can understand and interpret the market information properly and take correct actions based on the newly receiving the information.

The above features are the assumptions of the Efficient Market Hypothesis (EMH). If we compare these assumptions of EMH with the financial market in the real world, we find that these conditions are not fulfilled in the real financial market. Usually, there is a big gap between the two. But the assumptions of EMH have extremely important implications for us to improve the efficiency of the capital market. These assumptions could serve at least as the guidelines to improve the efficiency of the capital market.

Capital asset's liquidity plays an important role in an efficient market. The more liquid the capital assets are, the more efficient the capital market. Money allows for the easy transfer of resources, much as liquids can flow through a tube better than solids. The rate at which a liquid flows depends on how thick the liquid is. Therefore, to improve capital market's liquidity becomes one of the key approaches to enhance economic growth of a nation.

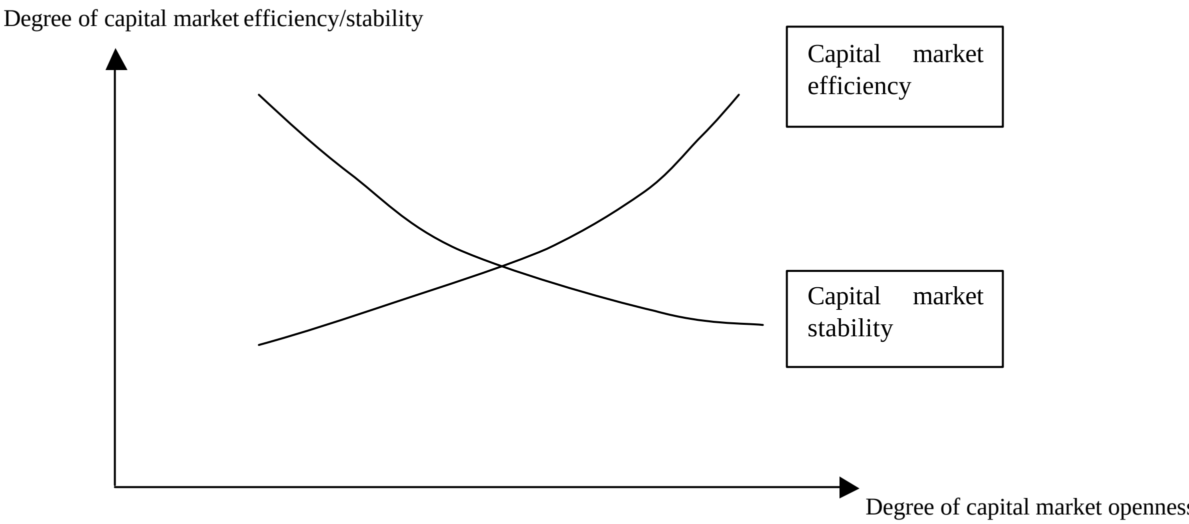

Fig.1: RELATIONSHIPS AMONG CAPITAL MARKET EFFICIENCY, STABILITY AND DEGREE OF CAPITAL MARKET OPENNESS

For several centuries, economists have used the classical economic theory of comparative advantage to explain trade movements between nations. Springing from the writings of Adam Smith and David Ricardo in the eighteenth and nineteenth centuries, the theory, in simple terms, states that everyone gains if each nation specializes in the production of those goods that it produces relatively most efficiently and imports those goods that other countries produce relatively most efficiently. In other words, every country, small or large, in the world will benefit from international trade as long as it produces goods according to its comparative advantage. Up till now, the world economy has internationalized, globalized, multinationally integrated, whether individuals in specific countries or specific forms recognize or acknowledge it. As firms expand their sales of products and services, their input sourcing, their management structures, their very profits across borders, the problems of financial management become more important and more complex. Nowadays, Chinese government is undertaking the policy of sustainable economic growth, which is one of the fundamental and far-reaching economic policies. To achieve this objective, Chinese government needs to set its economic goals compatible with the goal of the conservation of the natural environment in the long run. To enhance the capital market efficiency is definitely one of the important subsets of the sustainable growth policy. To achieve this objective, it is necessary to remove or eliminate capital market imperfections, which include transactions cost, information asymmetry and government tax. There is no doubt that to open Chinese capital account is in the line of the world trend of globalization.

The subsequent issues in dealing with the opening capital account are:

(1) What are the fundamental principles of opening Chinese capital account?
(2) What are the major contents of the open of Chinese capital account?
(3) What is the appropriate procedure of open Chinese Capital account?

This paper will focus on the solutions of these questions. Nevertheless, the aim of this paper is not to depict a clear picture of the path of the open of Chinese capital account will probably follow in the next ten or twenty years, but rather to provide some basic ideas and clues to start with this significant program. Moreover, I would like to stress that the decision making of the opening of Chinese capital account should be a dynamic continuum. The right way to deal with this issue is to incorporate new information into the decision-making system whenever possible and react to that information properly. The flexibility to react to the new environment is of great value, especially in dealing with such an important issue. Before we move on to discuss these important issues, let's take a look at the practice of the open of Chinese capital account.

II. An Overview of the Practice of the Opening Process of Chinese Capital Account

China is the biggest developing country in the world. The fast growing of China's economy makes it one of the driving forces for the world economy in recent years. The growth of Chinese economy has significant impact on the world economy as a whole and the Asia countries surrounding China in particular. China's capital market is one of the largest emerging capital markets in the world. It provides higher-return investment opportunities for investors both inside and outside China. It is necessary to notice that Chinese economy is in its transition period from planned economy to market economy at the time being. A market economy with Chinese characteristics has been formed in the past twenty years. The capital market is by all means the core subset of the total market because of the close relationship existed between financial sectors and other industries. .

During this transition period, there are two basic objectives for Chinese government to pursue in controlling its capital account.

(1) To avoid domestic capital escape out of China. A well-known analogy is that the capital is the blood of the economy. This simple analogy illustrates the dominant role capital plays in economic growth of a country. Since capital escape may undermine the sustainable economic development, the central government needs to take actions to avoid capital escape from happening.

(2) To avoid massive speculative short-term capital inflow. The basic principle of finance tells us that there is a trade-off between risk and expected returns. If some investors obtain huge returns while taking little risk for the financial transaction, we would like to say that the financial market is not quite efficient. The arbitrage opportunity may result in unbalance of the domestic capital market. Therefore, the regulators need to make effort to eliminate the risk-free arbitrage opportunities and encourage long-term capital flows to Chinese capital market.

Next, let's review the capital account regulations of some of the major economies in the world. Table 1 provides us with some critical information about International Monetary Fund member countries' current account and capital flow supervision framework.

Table 1[i]: IMF MEMBER COUNTRIES CURRENT ACCOUNT AND CAPITAL FLOW SUPERVISION FRAMEWORK

Items	# of Countries	PRC	U.S.	U.K.	France	Germany	Japan
Open current account	150	·	·	·	·	·	·
Restrictions on capital account transaction							
Capital market security transaction	133	·	·				
Money market security transaction	115	·	·		·		
Collective investment security	103	·	·		·		
Derivatives and other securities	87	·					
Commercial credit	105	·					
Financial Credit	112	·					
	88	·					
Direct investment	149	·	·	·	·		·
Direct investment clearing transaction	52						
Real estate	134	·					
Individual capital flow	82	·					
Specific clauses on commercial bank and other credit institutions	155	·		·			·
Specific clauses on institutional investors	82	·			·	·	·

Based on the information provided by the table above, it is fairly easy for us to get the first impression that China has been put relatively strict restrictions on its capital account compared with other major economies. This conclusion makes sense because China has restrictions on 12 of the 13 items while U.S., U.K, France, Germany and Japan only have 4, 2,4,1and 3 items respectively. But wait a minute, we need to investigate the fact with more details before we draw our conclusion.

First of all, China's capital account restriction is not as strict as it seems to be. In practice, many items of Chinese capital account have been opened to a certain degree, even though they are restricted nominally. For example, in the 28 items under the capital account, China only puts relatively strict restrictions on 5 of them, which is 17.86% in 1999[ii]. These strict restricted items include cash outflow of the direct investment, residents' foreign equity investment, residents' foreign debt security investment, and residents' purchasing securities in foreign countries and residents borrowing of foreign securities.

Secondly, China has been put relatively loose restriction on 11 items of the capital account, which constitute 39.29% of the total. These loosely controlled items include foreign direct investment, residents' issuing equity in foreign countries, residents' returning principals of investment back to their foreign lenders, inflows of trade credits, etc.

Thirdly, China has been put almost no restriction on 12 items, 42.85 % of the total. Outflow of foreign direct investment, flow of non-residents equity investment (the B share), and cash inflow and some other items are fallen into this category.

Finally, statistical figures from the authority may provide us with additional message about Chinese capital account control. According to Mr. Dai Xianglong, the former president of the People's Bank of China, there are 43 items under the capital account according to the IMF classification, China realized convertible in 12 of them, which constitutes 28% of the total. China has only restrictions on 16 items, which is 37%of the total[iii].

Up till now, China has been making significant progress along the way of opening capital account. For example, a number of foreign financial institutions have established their business branches in the fastest growing areas in China, such as Beijing, Shanghai, and Shenzhen. The business scope of foreign financial institutions has been broadened significantly. Some foreign financial institutions have even been authorized to deal with Chinese RMB business. In the spring of the year 2003, QFII s (qualified foreign institutional investors) are allowed to purchase Chinese listing corporations' shares. In addition, the QDII (qualified domestic institutional investors) system is under consideration of Chinese financial decision makers at the time Being.

Based on the analysis above, it is reasonable to conclude that although China has restrictions for the capital account, it is not as strict as it seams to be. Moreover, China is making effort to open its capital account to a larger extend. An open Chinese capital market will benefit not only Chinese firms and investors, but world economic growth as well. The essence of the issue is how to avoid the unexpected risks in the process of opening Chinese capital account.

III. The Fundamental Principle of the Open of Chinese Capital Account

To open capital account is by all means a far-reaching decision in the process of a country moving from a closed economy towards an open society. To open capital account fully means a country's economy and financial market are integrated into international society to a larger extend. Chinese domestic corporations will have more opportunities to seek cheaper fund to finance their profitable investment projects. In addition, investors will have more chances to get a higher return because there will be more successful corporations playing in the capital market. On the other hand, however, open capital account also means there would be more chances for financial speculators and arbitragers to utilize market imperfections (transaction cost, information asymmetries and government tax, etc.) to get risk-free returns by taking advantage of the opportunities of mis-priced financial assets often appear in a newly freed financial market. The decision of whether or not to open the capital account is not only a strategic economic decision, but also a political decision. It will have immense impact on the future economic operation both in the short run and long run. To make a sound decision, the decision makers need to put this decision issue into a big picture of international relationships among various countries. The decision makers should not only have a good command of knowledge about economics, finance and politics, but also have a deep understanding of the evolution of international political in economic relationships and the their development trend. The fundamental question is to understand where we are at present and where we want to go in the future. The following points can be served as the basic guidelines when dealing with the issue of China's opening capital account. The fundamental principle is to strengthen Chinese economic power and contribute to the growth of the world economy. First of all, there are no mandatory clauses to open the capital account either in the IMF agreement or the WTO agreement. Therefore, when and how to open the capital account is totally depending on Chinese decision makers' own judgment. In other wards, China has the option to decide whether to open its capital account. Secondly, many developed countries open their capital accounts in and after the eighties of last century. Some immerging financial market opened their capital account even in the nineties of last century. In fact, some of them opened their capital account so hastily that they cannot control the rash cash flow risk properly and resulted in financial crises. Confucius once said: "Preparation ensures success. People can not expect success without proper preparation"[iv]. I personally have no doubt that we will benefit from the wisdom of ancient Chinese philosopher if we lesson to him carefully even in dealing with the modern affair as complex as capital account opening. One important fact is that China is not under the time pressure to open its capital account. China has enough time to make a sound decision on the open of its capital account. The bottom line of this issue is that it should enhance Chinese economic sovereignty. The criterion to judge whether it is a sound decision should be whether it would enhance the ability of Chinese government to control the financial market stability and improve its macroeconomic performance in the long run.

IV. The Prerequisites of the Open of Chinese Capital Account

In order to allocate the resources efficiently, we need to enhance the development of the efficient capital market. If there is not an efficient capital market in place, financial investors would have to incur higher transaction costs— extra time, effort and money. To smoothen the opening process of Chinese capital account, it is imperative for the Chinese top-level decision maker to understand the conditions on which the opening policies are based. It is widely believed that for the capital inflow, to open long-term capital account (E.g. long-term direct investment, long-term security investment and long-term government bond investment) will benefit the operation of domestic financial system and economic growth as well. It would be better to open the capital account along with the path of Chinese foreign trade system reform. Hence, there are no preliminary conditions for opening capital account for the long-term cash inflow to a country.

For the short-term cash inflow, however, there are some preliminary conditions that must be fulfilled. These conditions include the following.

(1) Free trade system has been established at least two year when capital movement limit is removed. We know that China's economy is in its transition period from planned economy to market economy. The market economy has been playing more important role for the growth of Chinese GDP. Well-developed commodity market, factor market, labor market and financial market are the basis to open Chinese capital account.

(2) In the first three years after the removal of capital movement limit, the average deficit to GDP ratio should not exceed 5%. Central government's fiscal policy is one of the most effective policies for Chinese government. The government should be extremely careful as far as financial deficit is concerned. Although Chinese government has good reputation in dealing its debt obligations in the history, it would be highly recommendable to control the deficit ratio fewer than 5% each year. The realization of this objective will allow the central government to control the speed of macroeconomic growth without incurring unnecessary financial distress.

(3) The financial system has opened to its domestic market for at least two years. An efficient domestic financial market is the foundation for the open financial system. This is because in an open domestic financial market, the financial assets' prices are set by the equilibrium of demand and supply. The participants of the financial trades have to get information about the financial market and obtain valuable knowledge to understand the market information in order to make a sound decision on buying and selling the assets. In this trading process, the market participants will become more and more rational so that their behavior will enable them to maximize their financial welfare.

(4) The entry limit for the banks (both domestic and international banks) has been removed for at least two years. Banks are the most powerful financial institutions in China. The increase of Chinese financial market efficiency is relying heavily on the banks' ability to eliminate the non-systematic risks, reduce their bad debts, and deal with their credit loan properly. Furthermore, Chinese banks, the state-owed banks in particular, need to improve their ability to innovate new financial instruments and management to cope with the new financial environment.

(5) The asset ratio of state owned banks has been bellow 40% of the total for at least two years. Nowadays, the non-state owned enterprises are playing more and more important roles in the growth of Chinese economy. The growing market share of the non-state owned business contributes to the growth of imp ort and export, the growth of GDP and the national employment. The decrease of the share of the state-owned banks indicates the improvement of the capital market efficiency.

(6) A market-oriented financial supervision system has been established. In the process of the transition from planned economy to the market economy, the role of the central government has been changed dramatically. The major economic management obligation of the central government has been shifted from direct management of the large state-owned enterprises to controlling the macro-economic performance indirectly. To make sound decisions and regulations, the officials of the government should have a good command of both the world economic development trend and domestic business practices. The ability of decision-making and economic management of the government ought to be improved in the process of economic development.

(7) Further reform of domestic enterprises. A large number of well-managed and operated enterprises are the foundations for a highly efficient capital market. The enterprises are the micro-basis of the economy to utilize the resources efficiently. At the time being, Chinese enterprises are still facing many difficulties in modernizing the management skills, production facility and technology.

In addition, the open of the cash outflow of a country, regardless of the term of the capital is long or short, relies on the following conditions:

(1) The domestic interest rate is liberalized. Domestic interest rate liberalization is a higher stage of preparation for the open of capital account. A liberalized interest rate regime will allow the natural resources to be distributed efficiently in a competitive environment. In addition, market competition experience will also educate investors to be more rational in dealing with their financial assets.

(2) Government economic policies are stable. A stable policy environment is the key aspect to reduce unexpected financial volatility as far as the capital account is open. It is the government's responsibility to make its financial policy relatively stable and foreseeable in order to build up the investors' confidence.

(3) The taxation system is effective. After the open of Chinese capital account, there will be more financial innovations coming up in the financial market. There are certainly advantages of these financial innovations, such as making the financial market more liquid and enlarging the financial market scale. In the down side of the financial innovation, however, it would be possible for some financial institutions and organizations to get the risk-less returns by taking part in taxation arbitrage if the taxation system is not modernized in time to cope with the complicated financial innovations.

(4) Chinese government controls enough foreign exchange reserves. Foreign exchange reserve in the central bank is one of the most effective financial tools of the central government to deal with the financial crises. Open Chinese capital account will require more foreign exchange reserves to meet the need of handling the unexpected capital movement and changes in financial exchange rates and interest rates.

V. The Procedures of the Open of Chinese Capital Account

Opening Chinese capital account should be a long-term process, rather than a one-shot task. We know that there is an inherent contradiction between the efficiency of the capital market and the safety of the market operation. The implication of this inherent contradiction is that China's opening capital account strategy should based on such a sound principle that it will balance the two sides of the consequences of an open capital market. Therefore, to make a sound decision on the right opening procedure is the essential part of the success of the opening of China's capital account. A well-designed capital account opening procedure will enable us to do the right things in the right direction.

Based on the analysis above, I would like to suggest the following strategies in opening the capital account to embrace the new globalization era. There are should be three steps to further open Chinese capital account

In the first phase, which should start from now on and end in 2004, there are four major items need to be open.

(1) To remove the restrictions on foreign financial institution's security brokering business in China gradually;
(2) To loosen the requirements on domestic enterprises' issuing equity securities abroad (Hong Kong in particular);
(3) To loosen the requirements of on foreign corporations' (both in China and abroad) issuing equity securities in Chinese capital market;
(4) To loosen the requirements on foreign corporations' and financial institutions' issuing bond securities in Chinese financial market.

Up till now, the first two steps of these are already finished. The decision makers are considering the last two of these.

In the second phase, which will start from 2004 and end in 2006, there are six major items need to be open.

(1) To loosen requirements on Chinese financial institutions' setting up branches (including fund management organization) abroad gradually;
(2) To loosen the restrictions on Chinese financial institutional investors trading securities abroad (e.g. QDII);
(3) To loosen the requirements on foreign financial institutions and institutional investors' setting up wholly owned organizations; remove the limit on the maximum shares of 49% of the foreign partners in the joint-ventures in China;
(4) To loosen restrictions on Chinese financial institutions' and enterprises' issuing corporate bond in foreign countries;
(5) To loosen the restrictions on foreign financial institutions' trading securities in Chinese financial market;
(6) To remove the restriction on Chinese enterprises' direct investment in foreign countries and remove the restrictions on Chinese individuals' direct investment in foreign countries.

In the third phase, which will start from 2007, there are four major items need to be open to the foreign investors and financial institutions.

(1) To remove the restrictions on foreign individuals' investment in Chinese security market gradually;
(2) To remove the restrictions on foreign financial institutions' and institutional investors' trading financial derivatives in Chinese capital market gradually;
(3) To remove the restrictions on Chinese financial institutions, institutional investors and enterprises' issuing and trading securities in foreign financial market Completely;
(4) To further the process of foreign exchange rate system reform and make RMB convertible in the capital account.

Financial management, even in a domestic environment, is one of those curious combinations of mathematical precision with the prime source of all random behavior--human behavior. When financial management activities must stretch across geographic, cultural, political, and jurisdictional boundaries, the attention paid to organization and goals becomes critical. In conclusion, it is worth to mention that the procedure of opening Chinese capital account is a continuum rather than something uncorrelated. It would be wise to interpret them not in absolute terms. Moreover, these steps of opening capital account are "conditional". In other words, there are some preliminary conditions. If the preliminary conditions are not matched, a rash open of the capital account will probably result in unexpected financial and economic disasters and even social turmoil. Furthermore, the steps of opening capital account constitute a "gradual" process. Here the word "gradual" means that it is a complex one. We can neither unreasonably accelerate this process to reach the target, nor miss the opportunity without noticing it.

Is Barter Still Relevant in The New Millennium?

Nadeem M. Firoz
Montclair State University, USA

Abstract

Barter is the direct exchange of goods between two parties in a transaction. Barter is often regarded, as an old fashioned idea that enables business to buy some needed products and services in exchange. It involves the exchange of goods or commodities without the use of currency. For example, all members of our society have participated in some form of bartering, from our children trading baseball cards and video games, to some of the world's largest corporations exchanging unsold inventory for other goods. Businesses of all sizes are trading goods and services through such commercial operations as the Barter Business Exchange and in the process are solving cash flow problems, increasing sales, and getting rid of excess inventory. Barter allows you to buy what you need to pay for it with unsold products and services---without the use of cash (Healy 1996, p38). A leading barter company executive, when asked, "How big is the barter business?" responded by saying "No one really knows how big it is because companies won't talk about it." "They're not advertising it," he said. "They don't want their competitors to know about bartering." Whatever it is— surplus or seasonal inventory, a discontinued line, canceled orders, store returns—-you can trade it, rather than liquidate it, and recover the value that has been lost," says an executive of one of the oldest bartering companies in America (www.barterworks.com).

Introduction

Most people regard bartering as a primitive form of trade best suited to the Dark Ages, when beads could be exchanged for food. But it has ridden into the 21st century on the back of the Internet: Now it allows businesses to trade unsold inventory for goods that they need, without spending valuable cash. Hotels, for example, can trade vacant rooms to advertising agencies for free ad space. Barter networks like the one run by Barter card allow companies to expand through bartering one-to-one. United States based e-commerce site Asia4sale.com, which runs BarterAsia.com, says its new online exchange in China is already registering a modest number of commercial and industrial deals. The Thai government last month confirmed it was considering a deal with Malaysia to swap good for crude oil (International Business Asia, March 2, 1998). Business to business bartering is flourishing on the back of online banking technology. The International Reciprocal Trade Association, a U.S. based organization that represents 180 barter networks, says more than 500,000 companies' worldwide barter, and it expects the industry to grow 15% a year over the next decade. That is great for the founder and managing director of Barter card, Andrew Federowksy. Federowsky claims that it is the world's busiest barter site and he expects its annual worldwide turnover to top billion this year (Eastern Economic Review May 10, 2001).

Many companies are involved with barter. Nationally and internationally, over 250,000 businesses are involved in barter. It is estimated that 65% of the fortune 500 companies engage in barter to one degree or another. Included in the 65% are PepsiCo, Pizza Hut, Casio, General Electric, IBM, Amoco, Caterpillar, 3 M, Goodyear, Xerox, Pan-Am, Chrysler, and Hilton (www.barterworks.com). A recent innovation is bartering goods and services for excess office space. The many products that are bartered are trading advertising time, hotel rooms, or office equipment. Barter is making new roads in commercial real estate by bridging the gap between the book and market value of surplus building and leases. In exchange for the sale and lease of a surplus space, a barter firm issues trade credits at Permian of an asset's market value. An owner or tenant for advertising, travel, telecommunications, computer equipment, or the like subsequently uses the credits. According to Michael Bell, Vice President of barter company, The Intrac Group, "…barter provides enhanced value for excess inventory" (Ciandella 68). Barter allows firms to use excess inventory in order to finance the cost of operations and conserve cash.

According to the International Reciprocal Trade Association, 250,000 firms worldwide made $6.5 billion in barter deals in 1992, up from 180,000 firms and $4 billion in 1991(Ciandella 68). New data shows that there are over 400,000 firms worldwide today. Netscape Communications Corporation is the top vendor of the World Wide Web advertising and the fifth largest purchaser of the Web ads, has built its dynasty with the help from barter deals. The firm has recently renewed its contracts with their four search engines: Yahoo, Excite, Info seek Corp., and Lycos. Unlike its 1996 deals, in which search engines agreed to pay $5 million each to be premier providers on the search area of Netscape, each engine this year is paying on a cost-per-thousand impression basis. However, the overall investment should be fairly equivalent, according to Jennifer Bailley, vice-president of electronic marketing at Netscape. She says that the search engine contracts are heavily weighted on the "real cash" side but do involve barter. She adds that most of Netscape's advertising on search engines comes from barter agreements (Krause 30-2). Publishers and broadcasters have barter ads for a long time. Meanwhile, the Internet is shaping up as one of the most promising media for ad sales. Television networks are now exchanging airtime for equity stakes in start-up Internet companies. CBS Corp. and NBC have traded millions of exchange for stakes. CBS barters for stakes in Medscape and Sports line USA, while NBC trade for stake in iVilliage and Talk City. The networks hope the ad swaps will sell the charms of network-TV advertising to other Internet companies who would pay cash (Beatty b1-2).

Bartering is also a viable and attractive option for restaurant proprietors. By offering meals through barter, eateries can fill up vacant seats. Although there may not be instant return, each dollar given away is a dollar off the cost of a needed service. Using trade dollars instead of cash saves money and provides necessary working capital, reserve that is needed for more difficult times. Moreover, the word of mouth and advertising generated by these non-cash customers will entice both trade and cash customers to try out to eat (Meharg 28). Barter is a great way for growing or stable companies to conserve cash, reduce payable accounts, collect on old receivable, and get rid of excess inventory. The only companies that are not appropriate for a barter situation are those that have very specialized products and services that few people would need. Any company considering joining a barter exchange should visit the trade exchange to talk to the people who will service the account and secure a list of clients and the various products and services that they offer. It is important that barter exchanges clientele and have products and services that they exchange by contacting the National Association of Trade Exchanges. Lastly, a company should remember that every time they trade, they are taking inventory off the shelves or committing production time, or unless they have enough incoming cash to replace their inventory. And finally, they need to cover bills that they normally pay on a daily basis (www.bartertrust.com). In the U.S., approximately 100 corporate barter exchanges help large manufacturers, wholesalers, and distributors trade excess inventory. Unlike retail exchanges, which primarily serve the small-business market, corporate barter companies typically take ownership of customers' excess inventory as well as broker large-scale company-to-company deals. Corporate barter dollar volume in North America exceeded $9.27 billion in 1999, according to the Corporate Barter Council (CBC), a not-for-profit U.S. trade association (Linnett 2001 p59).

Reasons to Countertrade

Countertrade can be defined as a reciprocal exchange involving limited or no transfer funds. In its simplest form, it is trade without money (Kwabena & Harvey 1995). It also describes a multitude of trade arrangements, both domestic and international, in which goods, services, and technologies are exchanged in addition to or in place of money. Countertrade began as a simple barter. Although barter declined drastically with the invention of currency, it has resurfaced periodically, especially during times of economic stress. Given the political and economic pressures of many countries and the competitive world market, it is no surprise that countertrade represents a substantial and increasing part of global trade today (Kwabena & Harvey 1995).

There are many reasons why countries may consider to countertrade. They may want to preserve hard currency, improve their balance of trade, gain access to new markets, upgrade manufacturing capabilities, and maintain prices of export goods (Cateora 2001 p573). Countertrade is broken up into several components, one of them being barter. Barter is the simplest and oldest form of countertrade. It is a one-time, direct exchange of goods at equal value. Although money isn't usually exchanged, it isn't excluded. Letters of credit, performance bonds and similar instruments are sometimes used to secure delivery obligations. Pure barter, or trade without cash, is relatively rare in contemporary international trade (Kwabena & Harvey 1995). There are many advantages to countertrade and many good reasons why it should be used. The most popular reasons include a shortage of foreign exchange, restrictions on import license and as a devaluation hedge. Foreign exchange shortage can be further divided into three categories: blocked profit repatriation, blocked funds for trade debt and the availability of more favorable exchange rates (Cateora 2001 p570). By engaging in countertrade, countries are able to preserve hard currency by exchanging products for products. Countertrade makes possible sales that otherwise would not have been made and helps improve the balance of trade. Countertrade, if used creatively, is a way to expand sales to new markets, as it offers more flexibility in enhancing exports. One aspect companies do not think of in the early stage of a countertrade transaction is the accessibility of raw materials. One of the easiest ways for a company to move the countertraded products is to get a product that it needs, either as a raw material or as a finished product. Countertrading also broadens the accessibility to a new source of raw materials that may have a better price or quality.

At times, broader supply base works to the advantage of the company. It can also be used to establish and improve the company's relationship with the foreign government. With the exchange of products, the foreign government can have imported goods without using its reserve of hard currency. The other benefits that countertrading associates with is the fact that they are expanding the global market by gaining access to new markets; improving the quality and distribution of a country's products; and improving a method to manage exchange rate risk, clean up bad debt, repatriate blocked funds, and solve liquidity problems. In the coming years, the proportion of countertrade as a share of world trade is not likely to deviate very much from present levels barring a substantial decrease in the volume of world commerce. One of the best reasons to engage in countertrade is to combat the devaluation of a foreign currency. Companies lose billions of dollars to exchange rate fluctuations. Why waste time, money, and effort when countertrade is available? A company can protect itself against currency devaluation by accepting the customer's product as payment, rather than a soft currency that can devaluate drastically overnight. From a countertrader's perspective, the abovementioned obstacles are not problems but opportunities for increased sales (Business Credit April 2001).

Forms of Countertrade

Compensation Deal

This involves the payment in goods and in cash. The advantage of having a compensation deal over barter is that there is an immediate cash settlement of a portion of the bill; the cash that is leftover is generated after the sales of the goods are received. If the company has a use for the goods received, the process is very simple. Then again, if the seller has to rely on the third party to locate the buyer, the cost drawn in must be anticipated in the original compensation compromise if the net proceeds to the seller are to be equal to the market price (Cateora 2001 p571).

Counter purchase, or Offset Trade

This is probably the most frequently used form of countertrade, of which the seller agrees to sell a product at a set price to a buyer and receives payments in cash. Two contracts are then negotiated. The first is an agreement by the original seller to buy goods from the buyer for the total monetary amount involved in the first contract or for a set percentage of that price. This arrangement provides more of a time period in between deals and more flexibility. There is about 6-12 months to finish the second contract. During this time, the seller has received full payment for the original sale. Then, the goods that will be purchased in the second contract are by and large of greater variety than those presented in a compensation deal. Another way that makes the second contract to last even longer, is when the second contract is named as nonspecific. For example, books on sales and purchases need to be cleared only at certain periods. The seller is then required to produce enough purchases to keep the books stable or obvious between purchases and sales that are involved (Cateora 2001 p571).

The Product Buy-Back Agreement

This type of agreement is made when the sale involves goods or services that produce other goods and services, like, production plants, production equipment, or technology. The buy-back agreement usually involves one of two situations:

(1) The seller agrees to accept as partial payment a certain portion of the production,

(2) The seller receives full price originally but agrees to buy back a certain share of the output.

The only major downside to product buy-back agreements comes when the seller finds that the products bought back are in competition with its own produced goods.

Clearing Account Barter

In clearing account barter, clearing accounts are made to track debits and credits of trades. They only signify the purchasing power, but cannot be withdrawn right away. Each party can then be in agreement with a single contract to purchase goods or services.

Offset

An offset requires that portions of a product be produced or assembled in a buying country. For example, a country purchasing aircraft from the United States might require that certain portions of the aircraft be produced and assembled in the purchasing country. A newly formed kind of countertrade, which is used as a financial tool, is called debt swaps. These swaps are carried out with less developed countries in which governments face large debt (Czinkota 2001 p522).

The Effects of Currency Devaluation on Barter

Currency devaluation is usually the depreciation of a nation's currency implemented through a government action. When a nation's government notices a trend that it will be losing markets in the world market, it devalues its currency by lowering prices relative to other currencies without any changes on its domestic prices. One key effect of currency devaluation is that it makes the domestic currency cheaper when compared to those of other currencies. It also makes a country's exports relatively inexpensive for foreigners. On the other hand, it makes foreign products more expensive and beyond reach for domestic consumers thereby discouraging imports and encouraging exports. Therefore when a country exports more, they can ask for the hard currency. Exporting more means sending more goods or selling more while accepting needed products in return if they don't have hard currency. So, devaluation can stimulate the economy.

A country can barter more goods for goods. This can also help to reduce the current account deficit of a nation. Devaluation of a currency has its negative and positive impact and untold financial burdens on the poorest nations of the world. When a nation can no longer depend much on its export earnings as a result of the inexpensiveness and the trickle funds coming into it's treasury, the economy suffers (Aschkenasy 1996 p10). When a government devalues its currency, it is often because of interaction of market forces and policy decisions that has made the currency fixed exchange rate untenable. For a country to be able to sustain a fixed exchange rate, it must have sufficient foreign exchange reserves, often dollars and be willing to spend them to procure all offers of its currency at an established exchange rate. When a country is unable to do so then it must devalue its currency to a level that it is able and willing to support with its foreign exchange reserves. Rather than implementing unpopular fiscal spending policies, a government might try to use devaluation to boost aggregate demand in the economy in an effort to fight unemployment
(Goff 2000 p233).

Barter and Weak Money

Over the last three decades, several companies have been gaining a superior profit achievement through the recognition of opportunities in foreign markets. At the beginning, companies were only aware of the advantages of the international trade by exporting to and importing from overseas markets. The possible cost advantages from producing in foreign countries and the possible revenue opportunities from demand by foreign markets have encouraged firms to consider international business as a major concern to secure a profitable growth. A great example of this innovation is the Coca Cola Company, which is selling its products to over 160 countries and using 40 different currencies (Business Week, Sept.10, 1994). Many countries have money that is weak therefore they know they will bring back goods home via Barter techniques. Many times a weak country's money is not used in the world's Financial Markets such as China's "Yuan" and Russia's "Ruble." Pepsi sells Pepsi Syrup to Russia and gets Rubles. Then they spend Rubles back in Russia to buy vodka; sell vodka in the U.S. and Ahmad. Pepsi sells Pepsi Cola and buys back with Indian Rupees, rice, and spices.

Benefits of Bartering

Although barter and countertrade are an excellent way of exchange rather than the exchange of hard money, there could also be problems that come with that. Countertrade could pose some legal and financial concerns with the parties involved. Since countertrade involves more than a one-time deal, there could be some anti-trust issues that arise. In addition, companies must assess their tax liability amounts from all raw materials or other goods collected during these deals. Goods and services are considered taxable events under the tax code, however enforcement of this is often difficult since no actual currency is changing hands. Countertrade often conflicts with policy issues as well. It is viewed by many as an impediment to "free trade" since it can be coercive, anti-competitive and discriminatory. No tariffs are generally imposed on these transactions. It is also viewed as a way to "dump" undesirable products on an unsuspecting foreign entity (Business Credit, April 2001). Countertrade supporters believe that it is instrumental in accelerating the industrial development of the developing nations. There is also a major impact on the U.S. Economy.

United States labor groups have long argued that products imported through countertrade results into significant losses of jobs. During a recent congressional hearing, the topic of military related countertrade was discussed. The AFL-CIO testified that it deprived the United States industrial base of "essential capability and capacity". As more and more manufacturers are reaping the benefits of barter transactions, yet they should be aware of pitfalls involved. In a typical exchange, barter companies give a manufacturer trade credits that are redeemable for media in exchange for the manufacturer's obsolete or excess products. As the barter companies purchase products in bulk, they can negotiate favorable pricing for it. The barter company then sells the goods at a price that covers the cost of the product and provides for a profit. However, even as barter grows, it remains somewhat shrouded in secrecy, and many firms are reluctant to exchange such information (Business Credit, April 2001). There are many benefits that bartering conveys towards our society. A recent survey taken by AMR Research found that excess consumer goods inventory would exceed $60 billion in the U.S. and $120 billion globally by the end of this year. Until recently, businesses had few choices for disposing of excess assets. In most cases, they could either donate the products and take a tax deduction or turn the merchandise in for cash through a traditional liquidator or auction. Either way, businesses could expect to salvage only 5 percent to 30 percent of the product's original cost (Linnett 2001 p.59).

Barter in the New Age

Barter is back, but this time it has a new, more polished name: corporate trade. Whatever the name may be, the concept remains the same and it may have a new appeal to a tough economy. Marketers short on money that want to buy ad time and space use barter deals to trade unsold inventory for media credits (Advertising Age Feb 19,2001). Barters work in different ways. A barter company buys the excess inventory at full value from a company, and uses the trade credits and cash to help fill the needs of other barter customers. Barter exchanges (also referred to as networks), charge monthly maintenance fees ranging from $10 to $25, transaction fees from $5-$15, and membership fees from $100 to $700. It works very similar to a checking account. Although the actual trade is paid for in barter dollars, real currency must be used to pay fees, taxes, and any freight expenses. The barter exchanges report of their transactions to the Internal Revenue Service on form 1099B at year-end. A recent noted transaction was a graphic arts company who moved into new offices without spending cash. They paid for it with their printing services. According to the International Reciprocal Trade Association (IRTA), the number of clients for the barter exchange companies has increased from 17,000 to 300,000 since 1974. Included in these numbers are companies such as General Motors, 3M, AT&T, Fuji Film, and baseball teams such as the Chicago White Sox. Some major television networks including Fox have created bartering divisions within their organizations. In 1990, the Advertiser Syndicated Television Association expected bartering advertising revenues in excess of $1.25 billion (Financial Management 2001)

Something to Learn From Companies Associated With Barter

The many companies that are associated with bartering and show us the newest forms of bartering in our new millennium age are many. Euro Barter Business is a network that uses transferable credits to facilitate exchanges of goods and services. Bartercard is also a new and large international computerized bartering system that started in Australia (Fisher and Harte 1985). BarterNet is the Online Barter Association's website. Contranet is an Irish Barter Exchange system. LassoBucks is a barter network utilizing an alternative currency system so that businesses can trade excess time, inventory, or capacity for other goods or services that they might need (www.bartertrust.com). While barter has operated only in a few companies, several big players are now giving it a try. North Communications' KSL Media has launched a joint venture with barter company Corporate Trading Solutions, and Carat North America has set up Carat Exchange, a joint venture with an unidentified bartering company.

This year's softening of the U.S. economy has clearly played a role in barter's revival (Advertising Age Feb.19, 2001). KSL's model is to create barter deals through a third party, in this case, CTS. For example, if a computer company comes to KSL to buy ad time and doesn't have the budget to do it, but it does have unsold inventory to exchange, KSL brings in CTS. CTS will then take the inventory and convert that into media credits. Kal Liebowitz, CEO of KSL, admits that the arrangement is not at all like a typical one to one barter between a client and a media owner, brokered by a media agency, in which an airline will furnish plane tickets to a network in exchange for airtime. Instead, CTS takes a company's inventory and immediately converts it to cash credits, which it then turns over to KSL to buy media Liebowitz states that they are the only ones with this new way of bartering, and that they are a consulting firm that uses corporate trade as a marketing solution (Advertising Age Feb.19, 2001).

Airline Reservations Network in Orlando, Florida, sold $800,000 worth of airline tickets last year without receiving a dime. How? Company President Scott Bender says it is because of barter. They barter airline tickets for printing, advertising space, and employee benefits. He says bartering boosts their profitability by opening up a whole world of opportunity (Linnett 2001 p59).

Advantages of Bartering

Bartering is also advantageous for smaller business interested in saving money. A printing shop, for example, can finance the purchases of goods and services it needs by trading unused printing capacity (The Economist (US) Oct.21, 2000). It also helps in getting new businesses. "When someone joins an exchange, they're exposed to thousands of potential clients" says Tom McDowell, former director of the National Association of Trade Exchanges. Also, since few businesses run at full capacity, barter can help you squeeze extra profits from unsold or underused products and downtime (Home Office Computing Sept.2000). In addition, you can use your extra barter income to offset normal operating expenses or to cut costs. Jason Perry, President of Azavar Technologies in Chicago, uses barter for printing, restaurants, and employee rewards. "We provide employees with barter credits to spend as they wish," says Perry. "It's like an auction where employees don't spend any of their own cash, or mine" (Home Office Computing Sept.2000). Barter also gives home based businesses the chance to trade both nationally and internationally. "Internet bartering transcends geographic limitations," says BarterTrust.com CEO Mike Edelhart. "It puts companies in contact with good products and services in places they wouldn't otherwise know about" (Home Office Computing Sept.2000).

Tax Advantages Associated With Barter

There are also tax advantages that barter is included with, for example, barter income should be viewed as a company would as cash income. There are no inherent tax advantages or disadvantages just because a company uses a barter exchange. Barter is a marketing tool, not a tax tool. Generally speaking, as with cash income, barter purchases that are business-related are deductible, and conversely, barter purchases that are made for personal use are not deductible. Naturally, a company's barter income (sales) and business deductions (purchases) should be accounted or separately on a companies tax return. Although, as the commercial barter industry has matured, it has achieved recognition in the laws of the United States. Barter Exchanges are legally third party record keepers on a par with banks, credit card companies, and other custodians of taxpayers' financial records. Barter exchanges also have responsibility imposed by law to provide the IRS with the information on the barter income of each client (Healy 1996 P10).

Bartering on the Internet

The Internet offers a variety of changes for barter. The exchanges of goods and services remain mostly a local matter, but the Internet is taking barter to new heights. Exchangemall.com, the virtual marketplace for commerce without currency, sets the new standard for barter in the global economy. It is designed to meet the needs of everyone, from the largest of Fortune 500 companies to the individual consumer (Link-Up Jan.2001). Mark Savoy, CEO of Exchangemall.com, stated that in the electronic age, we are already moving towards a cashless society, and barter is simply taking it one step further. This web site unites people who seek to barter their products or services in a secure environment and enables them to make a trade with another person for his/her product or service. Users can trade goods for goods, goods for services, and services for services. They can create a personal "store" to barter their wares. After a product or service is listed and assigned a value, users wait as exchangmall.com barter dollars, as well as currencies from all other exchanges, to buy goods and services outright, or they may make a monetary transaction. Exchangemall.com credits a user's account after their product or service has been "purchased" by another user. This one-stop online barter system allows users to quantify their goods in monetary and non-monetary terms as well as to negotiate what products and services they want in return for them (Link-Up Jan.2001).

Many people feel that online bartering is not the best way to get what they need. These common consumer-to-consumer barter sites include MrSwap.com, WebSwap.com, Switchouse.com, and SwapVillage.com. These sites will most likely tell you to fill out a list of your "haves" and "wants" and you will be matched with people who have what you want, as well as people who want what you have. Items that are exchanged include anything and everything; books, CD's, games, DVD's, art, furniture, etc. However, finding a match can be difficult, and many times if a match is found, they may not respond to your email. No shows are a problem with many of these sites, but there are many other things to consider. If someone does respond to your email, you need to have something to send back to him/her, since that is the whole point of bartering. That is the main dilemma with these sites; it is rare that the person who has the item you want will also want any of the things you are offering them (Goff 2000).

Types of Barter Exchanges

There are two types of barter exchanges. Retail exchanges, of which there are over 400 in the United States today, allow mostly small businesses and individuals to trade with each other, with the exchange facilitating the trade, providing a common currency or "trade credits" and receiving a transaction fee for each trade. For example, let us say that the owner of a sign painting company needs some brochures printed. Instead of paying cash, he goes to a printer within his barter exchange and pays with trade dollars. The printer doesn't have to spend those with the sign painter. He may decide to eat at a restaurant or seek legal advice for his business (Linnett 2001 p59). The other type of barter exchange is corporate barter. It involves millions of dollars worth of goods, services, and raw materials. It is primarily conducted on behalf of large companies. The major goal is helping "sellers" obtain cost-of-goods value for their obsolete or excess goods. Corporate trade helps minimize loss from perishable goods, reduce inventory storage costs, extend geographical distribution and tap liquid assets. Income from barter is used to finance equipment and capital assets or to offset other business purchases (Linnett 2001, p 59).

Conclusion

The question that many people ask, "Is barter still relevant in the modern world?" Barter and money are not necessarily completely incompatible. One of the most important improvements over the simplest forms of early barter was first the tendency to select one or two particular items in preference to others so that the preferred barter items became partly accepted because of their qualities in acting as media of exchange although, they still could be used for their primary purpose of directly satisfying the wants of the traders concerned. Barter still often plays an important role in trade with countries whose currencies are not readily convertible, e.g. the communist countries during the cold war. At the retail level barter has become the main means of exchange on occasions when currencies have collapsed completely as a result of hyperinflation, e.g. in Germany after the two world wars.

There is a definite popularity barter has begun. It should be important to have an equal exchange of goods, but we all know that it is impossible. As long as firms are willing to sell their goods, others will buy goods in return. In conclusion, companies are selling and buying goods to their advantage.

Some Accounting and Technical Problems with Antidumping Trade Cases Involving Transition Economies: A Russian Case Study

Galina G. Preobragenskaya
Locia, Russia
Robert W. McGee
Barry University, USA

Abstract

Antidumping laws have been on the books for many years, but it has only been in the last few decades that they have taken on such a degree of importance. As World Trade Organization rules reduce the importance of tariffs and quotas, antidumping laws are rising to take their place as a major tool of protectionists. There is controversy about the methods used to calculate the cost of production. Calculation difficulties are compounded when the target country is labeled as a nonmarket economy, which was the case with Russia until April 2002, since cost figures of surrogate countries are used to estimate production costs and profit margins.

This paper reviews the literature on this subject and reports the results of the authors' review of public documents from dumping cases and interviews conducted in July and August 2003 with individuals experienced with Russian antidumping cases.

Introduction

Although this paper focuses on antidumping cases involving Russian products, the same administrative procedures, rules and principles apply to any antidumping case involving a nonmarket economy, and almost all of these same procedures, rules and principles apply to target companies located in countries that have market economies as well. Thus, the applicability of this study extends beyond Russia, Eastern Europe, China and other countries considered by investigating authorities to be non-market.

A foreign firm can be charged with dumping if it either sells its product on some foreign market for less than the cost of production or if it sells in the target market for a price that is lower than the price charged in the home market. Antidumping laws have been on the books of some countries for two or three generations but they were seldom used as a means of blocking trade until the 1970s. They have become more important since the advent of the World Trade Organization (WTO), for at least two reasons.

For one, the WTO has rules about dumping and WTO members that previously did not have antidumping laws are starting to adopt and use them. Secondly, with the decline in tariff rates and the liberalization of quotas, nations that want to resort to protectionism find tariffs and liberalized quotas less effective than before. Antidumping laws are being used to fill the gap that was formerly provided by tariffs and quotas, since they can be used as tools by domestic producers to thwart competition from foreign companies.

A Review of the Literature

Although much has been written about antidumping in both the economics and legal literature, practically no one has addressed accounting issues. One article that does focus on accounting issues in antidumping cases was written in 1990 by Bollom and Simons [5] and presents an overview. The authors of this article take a public policy perspective and call for further research. Davis and May [12] examine the way the Commerce Department computes the cost of production, but their study focuses only on how interest expense is treated in a Korean antidumping case involving sweaters. Kaplan, Kamarck and Parker [19] do a thorough job of analyzing the costing rules in antidumping cases, but the rules have changed since their article was published. A classic exchange of views on cost of production theories in general was published in the 1930s between Abramson [1, 2] and Neal [31] in the American Economic Review. Canning [10] wrote a classic article on the cost of production but did not apply it to antidumping cases.

A court case, NAR, S.p.A. v. U.S., 1989 [30] held that the use of average prices for comparison purposes was unfair in a case involving the importation of plastic tape from Italy. Yet this practice continues. This case also examined how transportation costs and exchange rate data can be used in computing the cost of production.

A few studies have addressed exchange rate issues and how exchange rates can affect the calculation of antidumping margins [32, 52]. The Commerce Department's use of best information available has also been examined by McInerney & Giesze [27] and criticized by Bovard [8].

Several studies have criticized antidumping laws in general, or how the rules are applied in certain cases [11, 13, 18, 48]. A 1979 study by the United States General Accounting Office criticized the antidumping laws for being too costly, time-consuming, complex and imprecise and also criticized the way cost comparisons are made by the Commerce Department [34]. It also criticized the Commerce Department's practice of ignoring sales at prices that were below average prices, since the effect was to increase dumping margins. More recently (2002), Kim [20] makes the same criticism.

Bovard criticizes antidumping laws for being unfair to producers in Eastern Europe in general [6] and Russia in particular [7]. Moore[29] found that the rules may be biased against developing countries. Applying special antidumping rules to a nonmarket economy has also been criticized by a number of authors over the years [4, 16, 17, 24, 49, 50, 51]. Meszaros [28] and Lantz [22] examined the application of these rules to cases involving Chinese and Russian companies.

McGee [26] and Caine [9] have called for the repeal of the antidumping laws because of their inherent unfairness. Other scholars have merely called for their reform [14, 21]. Several historical studies have also been made of the antidumping laws [15, 25].

Russian manufacturers of urea and ammonium nitrate have been the targets of prior antidumping investigations. In 2001 the European Union extended its antidumping measures against Russian companies out of the fear that failure to do so would result in continued dumping [3]. The U.S. Commerce Department has also investigated the dumping of ammonium nitrate by Russian firms in 1999 [45, 46] and 1998 [47]. The 1999 investigation calculated the dumping margin for both JSC Azot Nevinnomyssk and Russia-wide to be 253.98 percent. The 1998 study did not result in any antidumping penalties. Urea from Russia or the Soviet Union has been a target of antidumping actions for a long time. In a 1987 case, the Department of Commerce substituted U.K. natural gas prices for USSR prices to overcome the advantage that the much lower USSR prices would other wise enjoy [7].

Russian companies have been the targets of antidumping investigations for other products in recent years as well. Many of the other investigations involved steel products. The silicon metal investigation was concluded in 2003 [36, 41]. Investigations of cold-rolled steel products [37, 42], ferrosilicon [38] and structural steel beams [39, 43] were completed in 2002. The preliminary report on the ferrovanadium and nitrided vanadium case was issued in 2001 [44] but no further reports have been issued, which likely means that the case was settled before reaching the final investigation stage.

The authors note that Russia is not a member of the WTO and therefore does not have the protections of WTO antidumping rules. Russia is now negotiating its accession to the WTO and is expected to join in the coming years.

Accounting Issues

Although antidumping laws are primarily concerned with the theory and practice of international trade, there are a number of accounting issues involved, especially in the measurement of the cost of production and in the calculation of dumping margins. The way prices for product costs are computed and compared have been criticized. The Commerce Department often ignores individual selling prices that are below average cost while including individual prices that are above average cost, which tends to increase the dumping margin [8, 34]. This zeroing technique was found to violate WTO antidumping rules in a recent case brought against the EU by Indian manufacturers of bed linen but it continues to be used by the U.S. Commerce Department [53].

Price comparisons are sometimes made between products that are dissimilar without discounting for differences. Comparing prices from different periods can also distort results, especially if exchange rates have shifted or prices have either been increasing or decreasing rapidly [54]. In a Brazilian case involving steel wheels, the Commerce Department computed the U.S. selling price using the exchange rate in effect at the date of the sale but based the company's cost of production on the rate that existed when the product was exported, several months later. In another case, a fresh flower in Amsterdam and a wilted flower in New York were considered equivalent. No allowance or discount was made for the difference in quality [8].

The Commerce Department has been known to add 10 percent administrative overhead and tack on an 8 percent profit margin to the cost of production in a one-size-fits-all sort of way without considering either the industry involved in the investigation or the actual administrative overhead or profit margin of the particular company under investigation. The result of this kind of accounting is to penalize the more efficient companies and reward less efficient companies.

The way the Commerce Department computes the cost of production has also been criticized. In one case involving a Brazilian company, the Commerce Department computed the cost of production ten different ways [8]. Such flexibility makes it impossible for foreign producers to anticipate what the Commerce Department will do if the company is targeted for an audit.

The Commerce Department has also been criticized for comparing prices in dissimilar markets, comparing U.S. wholesale and foreign retail prices, disregarding volume discounts, and classifying costs as direct or indirect in an inconsistent manner. It has also been criticized for disregarding the cost information provided by the target company and verified by a Commerce Department audit and substituting information provided by the domestic producers who asked for the investigation, because such information is almost universally biased against the foreign company and is generally of a lower quality as well.

Urea Ammonium Nitrate

Introduction

Rather than merely presenting an overview of accounting issues involving several Russian cases it was thought that gathering some more specific information about just one case would serve to shed further light on the problems that Russian firms face when they become the target of an antidumping action. Interviewing individuals with practical experience in Russian antidumping cases was chosen as the means to gather this additional information. This methodology has not been used previously, as far as the authors could determine from their research of the literature.

The authors focused on the most recent Russian antidumping case involving a major Russian producer of urea ammonium nitrate solutions (UANS). Managers from Euro Chem, the holding company for Nevinka, were interviewed [www.eurochim.ru] There were a number of reasons why this firm was chosen. For one, it was involved in one of the more interesting antidumping cases. For another, and perhaps most importantly, the individuals who could provide the best information about the antidumping case were located in Moscow, a relatively convenient location. Most of the Russian firms involved in the other antidumping cases either could not be identified or located, or were located in cities that were not convenient to travel to for purposes of conducting interviews.

Several obstacles had to be faced and overcome to accomplish this task. For one, there are cultural biases that must somehow be circumvented if information is to be gathered. Russians and other East Europeans are extremely hesitant to discuss their business with outsiders. In addition, antidumping investigations concern very sensitive commercial information and companies fear that competitors might be able to profit from such information if disclosed.

The authors visited the Moscow office of the Russian company and interviewed employees who were involved with administrative, legal and accounting aspects of the case. The interviews proved to be very enlightening. The individuals who were involved in the antidumping case were quite knowledgeable and comfortable to discuss their antidumping experience. One official interviewed had an MBA from the University of

South Florida, a factor that enhanced the quality of the interviews considerably, since he was fluent in English and was familiar with American business.

One topic discussed that had relevance to many, if not all Russian antidumping cases was the cost of energy and the part it plays in the computation of the cost of production in Russian antidumping cases. One of the few comparative advantages Russia has is energy costs. Energy is substantially cheaper in Russia than in practically any other country in the world. That is because Russia has vast oil and natural gas deposits. Even though these resources might not be as efficiently exploited in Russia as in other countries, the fact that Russian companies have relatively low energy costs proved to be an important factor in their computation of production costs.

Another factor regarding energy costs is that natural gas prices are more volatile in the United States than in Russia. That has an effect on the demand for Russian fertilizer (urea ammonium nitrate). When natural gas prices are high in the United States, U.S. firms that sell natural gas decide to sell natural gas for heating rather than for agricultural purposes like the manufacture of fertilizer. The result is that the supply of natural gas available for the production of fertilizer in the U.S. is reduced, causing the U.S. agriculture industry to turn to Russia for its fertilizer needs. When the demand for Russian fertilizer (urea ammonium nitrate) increases, Russian firms that produce this kind of fertilizer operate at higher capacity levels, thus reducing the unit cost of production. If these production cost savings are passed on to their customers in the form of lower prices, the prices that U.S. and other foreign customers pay can be considerably less than the prices charged in the Russian domestic economy, thus triggering a charge of antidumping.

This energy cost advantage is not confined to fertilizer. It exists in any industry where energy costs comprise a material production cost. In the case of steel, for example, energy costs comprise between 60-70 percent of total processing costs. This comparative advantage works to the advantage of foreign consumers if energy costs are passed along in the form of lower prices. But foreign producers find that this Russian comparative advantage stiffens competition for them and causes them to lose sales and market share, thus providing ammunition for launching antidumping investigations.

The interviews produced new perspectives regarding the Commerce Department’s process not immediately apparent from the official public documents. While it cannot be said as a general rule that the U.S. Commerce Department’s staff that is involved in an antidumping dispute is highly professional and thorough, it could be said for this antidumping investigation (a sample size of one). The technical people the U.S. Commerce Department sent to review the Russian company books were fantastic, according to the Russian individuals interviewed. They knew the rules, knew what questions to ask and how to apply the accounting data to the rules. One woman spoke fluent Russian, thus dissolving any possible communication problems. These particular individuals were competent and professional. They were merely implementing bad policy.

Some Specifics of the Case

This investigation was launched as the result of a petition filed by the Nitrogen Solutions Fair Trade Committee, an ad hoc coalition of U.S. domestic producers that felt threatened by competition from urea ammonium nitrate solutions (UANS) producers from Belarus, Lithuania, Russia and Ukraine [40]. Lithuania was later dropped from the investigation because its exports to the United States were deemed to be negligible [35]. Coalition members included CF Industries, Inc., Long Grove, IL; Mississippi Chemical Corp., Yazoo City, MS; and Terra Industries, Inc., Sioux City, IA.

Natural gas is an important ingredient of UAN and accounted for 59 percent of the total cost of production of UAN for U.S. producers between January 1999 and September 2002, according to a questionnaire completed by U.S. producers that comprised 94.5 percent of total U.S. production [35]. As the price of natural gas fluctuates, this percentage also changes. Domestic producers purchase futures contracts to minimize the uncertainty of price changes. During the period under investigation, natural gas prices fluctuated, dramatically at times. Prices in the United States were less than $2 per MMBtu in early 1999 but rose sharply in late 2000 and early 2001, peaking at almost $10 per MMBtu, which was more than three times the historical price for natural gas [35]. As the price rose, U.S. producers of UAN curtailed production.

Transportation costs were also examined as part of the total cost of UAN. Average transportation costs varied between 24 percent and 49 percent of the cost of the imports, compared to domestic shipment costs of between 9.2 percent and 23.3 percent. The foreign producer share of the U.S. market also increased – from 2.7 percent of apparent U.S. consumption volume in 1999 to 8.8 percent in 2000 to 13.5 percent in 2001.

After all data had been examined, the Commerce Department calculated final antidumping margins to be:

226.82 % from Belarus,

193.57 % from Ukraine, and

between 106.98% and 239.14% from Russia.

The Russian company that cooperated in the investigation (Nevinka) received the lowest antidumping penalty. Russian companies that did not fully cooperate in the investigation received the highest penalty margins. Either rate would be prohibitive in a commercial sense, so in fact there was no practical difference between the two rates.

This differential penalty is in keeping with Commerce Department methodology, although its fairness is questionable. This procedure can be criticized on several counts. For one, the penalty should be based on the degree of dumping that has actually occurred. If that is the case, the fact that some targeted companies cooperated in the investigation while others did not should be irrelevant. Another criticism that could be made is that the data used to calculate the dumping margins for the Russian companies that did not furnish 100% of the data the Commerce Department demanded is almost always biased in favor of the domestic producers that requested the investigation. The Commerce Department could, but does not discount this data when it estimates the dumping margin. A less biased approach would be for the Commerce Department to make its own cost estimates, rather than use the data supplied by the petitioners.

The Surrogate Country Rule

Since Russia was, at the time of this investigation, classified as a "non-market economy," the Commerce Department felt justified in selecting costs and prices from a surrogate country. It considered Colombia, South Africa, the Philippines, Thailand, Tunisia and Egypt as possible surrogate countries because these countries were, according to the Commerce Department at least, operating at a similar level of economic development in terms of per capita Gross National Income (GNI). The petitioner asserted that South Africa was the most appropriate surrogate country and gave reasons why each of the other choices was not appropriate. As is usually the case, the Commerce Department agreed with the petitioner's choice, and South African prices were used as surrogates for Russian costs of production at the preliminary stage of the investigation (Fed. Reg. 67:97, p. 35495, 2002). However, the Commerce Department switched to Egypt at the final stage of the investigation because Egypt had recently become a huge producer of natural gas (Fed. Reg. 68:41, p. 9979, 2003).

Such a methodology has a number of weaknesses that any economist who does not work for the Commerce Department or for a petitioning company would quickly point out. Perhaps the most glaring weakness from the standpoint of economic methodology is that it is not appropriate to choose a surrogate based on general similarities, and then use actual data from some sub-part for comparison purposes. For example, if the Commerce Department wanted to calculate the cost of growing tomatoes in Arizona, it could very easily choose to use the cost of water in Iowa, where water is abundant and cheap, rather than the cost of water in Arizona, where water is scarce and has to be piped in. Such methodology is inherently flawed, as well as unnecessary in cases where the target company provides relevant information. Yet there are no procedural safeguards to prevent the Commerce Department from using such inappropriate methodology.

This methodology also violates generally accepted accounting principles. But the Commerce Department and the U.S. government in general, are not obligated to follow generally accepted accounting principles. They are free to set their own accounting principles, since there is no accounting standard setting body above them to prevent them from making their own rules. This fact results in a structural weakness in antidumping investigations, since the rules cannot be known in advance and since there are no safeguards to prevent the Commerce Department from choosing biased rules that work against the foreign producers (and thus also against U.S. consumers, who must pay higher prices as a result). The U.S. General Accounting Office criticized the Commerce Department's methodology as far back as 1979 [34], but the Commerce Department continues to use approaches that violate generally accepted accounting principles, not to mention general notions of fairness [8].

Facts Available

One could dispute the fairness of the rules [9, 21], or how the rules are applied in other cases [8, 25], but not how the accounting rules were applied in this case, at least in a sense. Unfortunately, the accounting rules are not the only rules that the Commerce Department applies in antidumping cases. The Commerce Department officials found that almost all of the Russian company's costs of production could be verified. But almost all is not enough for the Commerce Department.

The Commerce Department has a rule called facts available, formerly called best information available 27]. This rule allows the Commerce Department to totally disregard any information the target company provides if the information the Commerce Department obtains is anything less than 100 percent of what it demands. That is what happened in this case. Even though perhaps as much as 99 percent of the information demanded was supplied, and even though the accounting data was exactly as originally stated, the Commerce Department rejected it and substituted its own figures instead. The reason why the Commerce Department disregarded all of the information provided by Nevinka was because it thought that Nevinka did not answer some of the questions in the Commerce Department's questionnaire in sufficient detail. So even though the information furnished by Nevinka could have actually exceeded 99 percent of the information requested, all information supplied by Nevinka relating to the cost of production was rejected. As a result, all of the time and resources Nevinka spent to gather the information demanded by the Commerce Department was wasted, since none of the information was used by the Commerce Department.

A great deal of time and effort went into the compilation of information. When the Commerce Department came to Moscow and then Nevinnomyssk, the location of Nevinka, to inspect Nevinka's records, they used a room about twice the size of the 15' x 24' room used during the interview. The room was filled with tables that had documents stacked a foot high. Much of the information examined had been translated into English prior to the Department of Commerce visit. Other documents were translated into English on the spot, as needed.

When the Commerce Department chooses to reject the data the target company has provided, it has a choice of alternative sources of information. It can use the information provided by the domestic producers who asked for the investigation to be launched in the first place, which is almost always highly biased in favor of the domestic producers. Or it can use data from a surrogate country. In many cases the Commerce Department uses information from a surrogate country that is gathered and supplied by the petitioners, who often also suggest which surrogate country is appropriate.

The Commerce Department obtained its data for natural gas prices from an article published on the internet. That price was used by the petitioners. Nevinka officials argued that that price was not a realistic price and was not even close to the average market price in Egypt.

Eurochem did a detailed investigation of Egyptian natural gas prices, which included a calculation of the average price of natural gas in Egypt. The Commerce Department disregarded that study and used the internet article instead.

Price Comparisons

Some price comparisons were made at both the preliminary and final stages of the investigation. At the preliminary stage, 61 comparisons were made between the prices charged by domestic companies and the prices charged by exporters from Belarus, Russia and Ukraine. In the period between January 2000 and March 2002, Russian exporters sold their product for less than the domestic producers 19 times and sold for higher prices 8 times. The results for Russia and the other two countries under investigation are summarized in Table 1.

At the final stage of the investigation, 95 price comparisons were made covering the period January 2000 to September 2002. In this comparison, Russian companies sold for less than domestic firms in only 14 of 41 cases. Russian firms charged higher prices in 66 percent of the cases examined.

These results are summarized in Table 2.

TABLE 1
PRICE COMPARISONS BETWEEN DOMESTIC AND IMPORTED UAN
JANUARY 2000 – MARCH 2002

	Total	Lower than Domestic	Higher than Domestic
Belarus	14	3 (21%)	11(79%)
Russia	27	19 (70%)	8 (30%)
Ukraine	20	3 (15%)	17 (85%)
Totals	61	25 (41%)	36 (59%)

Source: USITC Pub. 3517, p. V-12 [40]

TABLE 2
PRICE COMPARISONS BETWEEN DOMESTIC AND IMPORTED UAN
JANUARY 2000 – SEPTEMBER 2002

	Total	Lower than Domestic	Higher than Domestic
Belarus	26	9 (35%)	17 (65%)
Russia	41	14 (34%)	27 (66%)
Ukraine	28	6 (21%)	22 (79%)
Totals	95	29 (31%)	66 (69%)

Source: USITC Pub. 3591, p. V-30 [35]

If an unbiased economist were to look at these statistics, the likely conclusion would be that there was no predatory pricing but merely price competition. It is difficult to conclude that predatory pricing exists when the Russian firms charged higher prices than domestic companies in 66 percent of the test cases. The Russian company that was the target of this investigation was not accused of predatory pricing, although one of the economic theories underlying the antidumping laws is the prevention of predatory pricing.

The antidumping rules in the United States operate under a bifurcated system, which has been criticized for its inefficiency as well as the uncertainty such a system produces [23]. The Commerce Department decides whether dumping has occurred and the United States International Trade Commission decides whether the U.S. domestic industry has been injured. In the case of Russian urea ammonium nitrate, the Commerce Department decided that dumping had occurred, but the USITC decided that there had been no injury to the domestic industry as a result of the dumping. Thus, the Russian firms won the case, but only at great cost. Smaller firms would not have been able to incur the costs of defense.

Costs of Defense

The cost of defending against an antidumping investigation can be staggering, especially for a smaller company. An American law firm with an office in Washington, DC must be retained, since the case must be argued in Washington. The law firms with the most expertise in this area are the large firms that charge high hourly rates. Some antidumping cases cost more than $1 million to defend. Others cost less. A mid-point might be around $500,000.

In all cases, the targeted firm must also expend resources locally. It might retain the services of a local accounting firm, and it definitely will use a great deal of internal man-hours to gather the information the Commerce Department demands. The firm's employees must work extra hours, sometimes for extra pay and sometimes without. But perhaps more importantly, they must be diverted away from their other activities, activities that could otherwise produce profits for the company. This diversion causes the company to operate less efficiently, although the amount of economic harm that results from the diversion of resources is difficult or impossible to estimate. A reasonable estimate of labor hours lost might be between 10,000 and 20,000. Monetary figures are difficult to estimate, since a number of employees are involved in gathering information and coordinating the effort, and they earn a wide range of salaries.

Nevinka also had to spend a great deal of effort, first to get the opportunity for the suspension agreement, and then to get acceptable terms. But the terms of the suspension agreement turned out not to be good at all. The suspension agreement prohibited it from making any sales in the United States for about a year. Since the United States is one of only two big markets for the firm's product (the other market is the EU), cutting off one of the two revenue spigots for such a long period resulted in major revenue losses. Prior to the antidumping investigation, Nevinka exported over 500,000 metric tons of UAN to the United States each year. At a selling price in the range of $100 per ton, that amounts to over $50,000,000 in annual sales. In 2002 it could only export one-third of the normal amount, which resulted in a substantial loss of sales, perhaps $34,000,000. In 2003 it was not allowed to export anything to the United States until the end of March, the time of the ITC's final determination, and then spent another three months striving to regenerate sales, which resulted in additional lost sales of perhaps $25,000,000 during the first half of the year.

But that is not the end of the story. Nevinka uses a process costing system because it processes raw materials to make several different products at the same time. Technologically, production of UANS at Nevinka is also interlinked with production of other fertilizers. Since the demand for UAN had shrunk drastically, it was forced to cut back on the production of the other fertilizers it made. Production cutbacks and the resulting lost sales for these other products was also substantial but difficult to estimate. If the lost sales from these other products were one-third of the lost UANS sales, then Nevinka lost additional sales of about $11,000,000 in 2002 and $8,000,000 in the first half of 2003.

TABLE 3
SUMMARY OF COSTS OF ANTIDUMPING DEFENSE

Legal and accounting fees	$500,000+
10,000 – 20,000 hours of employee time	???
Lost sales from:	
UANS in 2002	$34,000,000
UANS – 1st half of 2003	$25,000,000
Other products in 2002	$11,000,000
Other products – 1st half of 2003	$8,000,000

Concluding Comments

"Won" is perhaps not the best word to describe the result in the UAN case. While it is true that the USITC found that the U.S. domestic industry was not injured as a result of the dumping, the Russian company had to spend a great deal of financial and human resources to defend itself against the antidumping charge. It also lost nearly $100 million in sales during the period when it was not allowed to sell in the United States. Furthermore, being targeted for investigation produced a chilling effect on price competition. In order to avoid antidumping charges and further investigations in the future, the Russian firms have a tremendous incentive to raise their prices, thus making them less competitive in international markets. However, even raising their prices does not guarantee that they will not be targeted in the future, since domestic producers have little or no downside risk of asking the Commerce Department to launch further investigations. Luckily for Nevinka and the other Russian firms that were targeted, they won the case at the USITC level. If they had lost, the antidumping margins calculated by the Commerce Department would have forced them to raise their prices so high that no one would buy their products. They would have been shut out of the U.S. market. Consumers, including the agriculture industry in the United States and everyone who consumes food made in the United States, are also harmed as a result of this antidumping investigation. If the Russian firms that make urea ammonium nitrate feel compelled to charge higher prices in the future, the consumers of this product must also pay higher prices for it. The U.S. agriculture industry is one of the most easily identifiable victims of this investigation, but it is not the only victim. Any firm that uses urea ammonium nitrate will be faced with higher prices, as will consumers of any product that is made using urea ammonium nitrate. Thus, a secondary victim of this antidumping investigation will be anyone who consumes U.S. agricultural products, since the U.S. farmers will try to pass along the extra cost they incur in the form of higher prices for whatever product they sell.

In 2002 both the United States and the European Union reclassified Russia as a market economy. What this means is that the Commerce Department will no longer use surrogate countries to determine a target company's costs of production. However, Russian firms might still have to defend some of their costs.

For example, the EU continues to treat gas, electricity and transportation costs as those of a nonmarket economy, even though Russia itself is now classified as a market economy. Also, petitioners in future U.S. Commerce Department investigations might try to have some Russian company factor costs classified as those of a nonmarket economy. Natural gas prices comes to mind as one such price that might be challenged, since the price for natural gas in Russia is considerably lower than the price for natural gas in most other countries, including the United States. If this happens, Russia will be punished for trying to exploit one of its few comparative advantages.

In Russia's bid for WTO accession, there is a movement to have special rules such as the EU selective classification of Russia as a nonmarket economy. Russia would obviously prefer to have the same rules apply to it as to all the other WTO member states. It seems unfair to single out Russia for special treatment, especially when the treatment is likely to be adverse. So there is a fairness issue that needs to be resolved. The proposed two-tier treatment has been criticized in the literature [33].

Future investigations may target accounting differences. Russian Accounting Standards (RAS) are not identical to International Accounting Standards (IAS) or U.S. generally accepted accounting principles (GAAP). Inventory and depreciation are two areas that are somewhat different, and both of these areas involve items that affect the cost of production. These issues did not arise during the UAN investigation because the Commerce Department ignored Nevinka's cost figures and used Egyptian surrogate costs instead. But if surrogate country costs cannot be used in the future, more attention might be paid to Russian Accounting Standards and the differences between RAS and IAS or GAAP.

It is questionable whether it is fair or appropriate to apply U.S. GAAP to a Russian company's books. It is also somewhat hypocritical to do so, since the U.S. government does not use U.S. GAAP. It might be more appropriate to apply IAS, especially in cases initiated by the EU, since EU companies must adopt IAS by 2005. But even the forced application of IAS impinges on Russian sovereignty. Determining which set of accounting standards to apply is not easy, but such issues must be faced in the future, since Russia is no longer classified as a nonmarket economy and since RAS are not identical to IAS.

Financial Risk Issues in Intellectual Capital: A Study of the E-Commerce Sector

K. B. Oh

N. Billington
Victoria University, Australia

Abstract

This paper investigates the risk and return relationship of intellectual capital investments in relation to the informational efficiency of the security markets and predictability of stock prices. Both have been contentious issues in finance and predictability relates to what component of equity returns can be predicted give n specific information and the general awareness that in competitive markets there are no 'free lunches' to investors. In competitive security markets, the risk-return relationship explains the notion that higher expected returns come with the need to bear greater investment risk. The main focus in this paper is to identify the relevant risk factors and study how they should be measured to determine the appropriate risk premia and what should be the quantitative trade-off between risk and expected return for an investment that draws its value from predominantly intangible assets. The study of Australian high technology sectors in this paper provides an empirical identification and analysis of the economic factors that contribute to the value of intellectual property and draw from it the underlying issues of volatility and predictability in the capital markets.

1. Introduction

The dominance of intellectual capital as the basic element of wealth creation in all industries is highly evident today. The successful development and commercialisation of technological innovations depend, amid other qualities, on the ability to raise capital to fund the business process. It is from this perspective that it is crucial to understand the relevant capital markets pertaining to the funding of technological innovations and the role they play in ensuring the momentum of technological advance in the market is maintained. The decision whether to proceed with new product development should be based on an assessment of expected returns from the project against its risk exposure. Empirical evidence suggests that financial markets reward firms that embrace innovation (Cooper 1984). This tenet has since been compounded by the advent of financial deregulation and increased globalisation of capital markets where major equity markets around the world have witnessed increased upward trend in equity prices together with a heightened degree of idiosyncratic volatility in returns (Campbell et al. 2001; Oh 2002).

The central theme of this paper concerns the risk and return relation of intellectual capital investment and its implications for informational efficiency of the financial markets and equity price predictability. The risks associated with investment in intellectual capital are evaluated to account and explain investor's behaviour and to provide a rational framework for individual investors and firms in terms of the risks they are willing to bear and pay for.

The objectives of this paper are: firstly to highlight the emerging financial issues of risk and return pertaining to the development of intellectual capital, and secondly to explain the determinants, assumptions and implications of risk in equity valuation for intellectual capital and thirdly, the analysis of the financial markets relating to fund raising for intellectual capital investment. This paper provides both a literature review and an empirical analysis of some other important issues pertaining to risk and valuation in the intellectual capital financial markets and presents alternative hypotheses for intellectual capital pricing.

The paper is structured as follows: Section 1 summarises the risk-return issues pertaining to e-commerce. Section 2 provides a literature review of the financial theories, concepts, and models relating to financial risk and return, while Section 3 introduces the approach taken by this paper to evaluating risk and return for the e-commerce sector. Section 4 briefly explains the data collection and Section 5 presents the empirical evidence of the tests on the risk-return model developed in this paper and the portfolio analysis and implications. Section 6 presents the portfolio analysis of our study and Section 7 provides some conclusions to this study with particular emphasis on the implications of e-commerce stock risk-return on cost of capital and equity valuation.

2. Literature Review

This paper studies the role of risk in the valuation of intellectual capital by exploring the key elements of the discount rate and its calculation. This section provides an introduction to the use of the equity risk premium in business valuation and the underlying assumptions.

2.1 Risks and equity valuation

It is a common acceptance that all investments are made in an environment of uncertainty and the reward for holding onto an investment is the expected return. A fundamental principle of finance is that investors require a higher return to bear higher risk. The risk premium is used in the discount rate which ultimately determines the overall valuation of the investment. Arthur (1996) proposes the era of increasing returns in the intellectual capital-intensive sector (i.e. the new economy) where firms could achieve market capitalisations that took old economy firms much longer to achieve. This situation requires different investment evaluation techniques and management strategies (Bontis1996).

The theory of risk in investment underlies the consequences of undesirable outcomes and their implications to individual investors or firms. Thus when stock prices are volatile, this means that prices fluctuate widely and can be difficult to predict. The traditional approach used in estimating the equity risk premium is to use historical data implying past performance as representative of future events. However, Cowles (1944) and Kendall (1953) suggest that financial prices could not be predicted from either changes in the series themselves or from past price changes in other time series. This statement has more credence when applied to nascent firms, which possess relatively higher levels of intellectual capital and have less reliance on historical data for valuation. This paper adopts the historical approach in the absence of a more functional and general methodology for estimating equity risk. The relevant risk implications in this paper are the volatility risk associated with equity prices and the valuation of risk in the context of intellectual capital returns. Investment risk analysis involves studying the amount of uncertainty about future cash flows and risk from two perspectives, firstly the firm-specific or idiosyncratic risk and, secondly the portion of total risk that cannot be diversified away, the market or systematic risk. The price of risk in the equity capital market represents that part of total risk that cannot be diversified away or the concept of risk premium, the difference between expected returns and the risk-free interest rate.

To conduct risk evaluation, the process is to first measure the level of risk associated with a particular class of equity or market benchmark, in this case the Australian stock market index. The traditional measurement of risk in the financial literature is one that uses the mean-variance approach in financial asset pricing first proposed by Hicks (1946), Markowitz (1959) and Tobin (1958), who developed the portfolio theory that explains investment portfolios in terms of the mean-variance sphere. In this context, a well-diversified investor would choose mean variance efficient portfolios, being the portfolios with the highest mean return for a given level of variance. Therefore, the relevant risk that should be measured and compensated is only that an investment adds on to a diversified portfolio. This is followed by an attempt to capture the time variation in volatility using contemporary approaches such as those based on the parametric ARCH or stochastic-volatility models (see Campbell, Lo and MacKinlay 1997 for a review of these models).

The equity risk premium underlies the main cost of equity models such as the capital asset pricing model and Fama and French (1993) three-factor model. Both require an equity risk premium to estimate the cost of equity capital. The intangible nature and the phenomenon of increasing return make the estimation of the equity risk premium for intellectual capital more nebulous. The aggregate stock market is in general inherently volatile to varying degree over time and the complexities of valuation associated with intellectual capital will entail the development of more sophisticated statistical models in an attempt to discern the time variation in volatility.

The discount rate represents the inherent risk of the business in the discounted cash flow (DCF) approach. The fundamental principle of valuation by Miller and Modigliani (1961) under perfect competition is that the price of each share must be such that the rate of return, comprising of dividend plus capital gains per dollar invested, on every share will be the same throughout the market over any given interval of time. The value of all assets (in this case stocks*)* must comply with the law of economics where investors choose to allocate their scarce resources (capital*)* in order to satisfy wants (returns) according to personal circumstances (risk). The idea of the rational investor and the efficient markets hypothesis (discussed below) underpin stock prices and they reflect the true value of economic fundamentals and market efficiencies which will prevent attempts by investors to make excess profits. One of the fundamental principles of economics is that value is created by scarcity; in the late 90s the demand for ecommerce stocks appears to far exceed supply causing prices to escalate[i]. A proliferation of ecommerce stocks would likely satiate demand and cause stock prices to fall back into line with the general market (see Kindleberger 1989). As Porter (1980) emphasised, in a competitive market with free entry (the ecommerce sector has relatively low entry barriers), firms cannot earn sustainable supranormal profits indefinitely because that would encourage other firms to enter and drive down prices. This situation implicates the concept of efficient market hypothesis of an assumed world (Fama 1970, 1991). In such a market the share price will be an unbiased estimate of its intrinsic value, where investment value is the present value of the share's future cash flows as estimated by well-informed and capable investors.

2.2 Efficient markets hypothesis (EMH)

The recent e-commerce equity boom has been attributed to 'noise trading' (Black 1986) and this market situation implicates the concept of the efficient markets hypothesis (Fama 1970, 1991). Noise traders are not fully rational in their investment decisions and often overreact to fundamental news or are subject to systematic biases, such as positive feedback trading strategies, providing a reinforcing mechanism for market trends. The concept of EMH is that in such markets the share price will be an unbiased estimate of its intrinsic value, where investment value is the present value of the share's future cash flows as estimated by well-informed and capable investors. The EMH holds that the return of an investment is equal to its opportunity cost (allocative efficiency), stocks are always in equilibrium and it is impossible for an investor to consistently beat the market (information efficiency).

As EMH predicts that stock price fairly reflects all relevant information about the stock that has been fully revealed to the market, this price must represent its fair market value. Then stock price only moves in response to new information that, by definition, is unpredictable. Hence stock price should be random. Therefore, e-commerce stock prices must be fairly valued in market equilibrium situation. Information technology is interpreted as a fundamental factor transforming the real economy to high profit growth in the future (De Long 1996). In the context of EMH, this implies that the stock market reflects the future growth of the real economy because investors have incorporated this high growth expectation into their investment decisions and therefore fundamentally justifies the stock prices.

Schumpeter (1934) emphasised the important role played by the financial sector in economic growth and recently supported by King and Levine (1993). The benefits derived from the financial intermediation are through efficient capital mobilisation, risk management, project screening and monitoring and transaction cost reduction. These activities invariably contribute to market efficiency by addressing the problems of high transaction costs and information asymmetries (Pagano 1992). Therefore, information dissemination by the financial sectors about the real market factors influence economic growth and ultimately stock prices.

2.3 Applications of Equity Risk Premium

The discounted cash flow approach, capital asset pricing model and Fama and French (1993) three-factor model all relies on the equity risk premium to compute a cost of equity.

Discounted cash flow approach

The DCF method operates under the premise that the value of a firm is obtained by the sum of the discounted value of cash flows to be generated by the firm's existing assets and the present value of cash flows to be generated from future growth opportunities. While the financial performance of most e-commerce firms may not justify their market value (Bontis and Mill 2000), there is a need for a more profound understanding of the issues and a comprehensive valuation method to address the investment risk-return situation. This requires a clarification of the investment process and choices to help the investor overcome the ambiguity and identify the most appropriate valuation model to estimate the absolute investment value of an ecommerce firm and its common stock.

The two major elements in the valuation of e-commerce stocks, other than cash flow, are the potential growth and risk exposure of the firm. In the context of contemporary ecommerce stocks, the absence of positive cash flow poses a problem in adopting the DCF method for valuing an e-commerce firm. Even if positive cash flows can be reasonably estimated in the absence of historical earnings, the extrapolation of growth on earnings estimates might be based on weaker foundations. The Gordon Constant Growth model (below), which is a variation of the DCF method, create problems with valuation especially when the discount rate (k) and the assumed growth rate g are close, the result being highly sensitive to minor changes in the assumptions. For intellectual capital investment, this situation amplifies the importance of risk in determining the discount rate and the need to conduct an accurate estimate of growth. The discount factor in the DCF model provides for risk adjustment. When they are equal, the valuation is infinite.

$$V = \frac{D_1}{k - g}$$

where:
$V =$ the value of the firm;
$g =$ the growth rate;
$D_1 =$ the dividend in period 1; and
$k =$ the discount rate;

The DCF method is subject to manipulation and skewed results if the discount and growth rates are used without fully understanding the function and reflecting the underlying market conditions.

Capital asset pricing model (CAPM)

The CAPM is an economic model that predicts a trade-off between systematic risk, known as beta (?), and expected return under specific conditions stated as follows:

$$R_i = R_f + ?_i(R_m - R_f)$$

R_i = cost of equity for firm i;
R_f = risk-free rate;
$(R_m - R_f)$ = market risk premium;
$?_i$ = beta of firm i; and
R_m = market return.

The CAPM is an economic model that restricts the parameters of statistical models to provide a more constrained normal return. It proves that the relationship between prices of assets in a general equilibrium, where the investors select assets to maximise the mean-variance utility, is linear. Although the CAPM is widely used there are many criticisms (Roll 1977) against the CAPM. The evolving nature of the ecommerce sector creates a situation where information is dynamic with the constant introduction of unanticipated operating conditions in the industry, creating information surprises that may cause e-commerce stocks to move in a magnitude or direction not predicted by CAPM.

Fama and French three-factor model

The Fama and French (1993) model is an extension of the CAPM in which the cost of capital is estimated as follows:

$$E(R_i) = R_f + ?_{i1}(R_m - R_f) + ?_{i2}\,SMB + ?_{i3}HML \qquad \text{or}$$

$$E(R_i) - R_f = ?_{i1}(R_m - R_f) + ?_{i2}\,SMB + ?_{i3}HML$$

$E(R_i)$ = expected return for firm i;
$E(R_i) - R_f$ = risk premium for firm i;
$?_{i1}, ?_{i2}, ?_{i3}$ = regression coefficients for firm i;
$r_m - r_f$ = market risk premium;
SMB = size factor risk, i.e. difference between the expected return of a portfolio of small stocks and big stocks; and
HML = distress factor risk measured by book equity divided by market equity, i.e. difference between the expected return of high book-to-market stocks and low book-to-market stocks.

Unlike the CAPM, which uses a single factor – beta, the Fama-French model has three factors by adding the firm's size factor (*SMB*) and "distress" factor (*HML*) to the CAPM model. *SMB* – measures the difference in expected returns between small capitalisation and big capitalisation firms and *HML* – measures the historical excess returns of small capitalisation firms over the market and they represent the excess returns of "small-caps" and "value" firms over the market as a whole, respectively. The risk implication of the FF model is that high risk should be rewarded with high returns and that means that if returns increase with book-to-market ratio, the firms with high book-to-market must be more risky than the average firm. While a stock with high book-to-market may indicate a bargain stock, the EMH suggests that such a stock can only be a bargain because the market thinks it is risky. Unlike many traditional firms, intellectual-capital intensive firms are expected to have relatively low book value due to a high composition of intangibles in the asset base and high market value due to potential growth. They would normally be perceived as high-risk investments but EMH would dictate that such firms are priced because of their potentially high earnings and therefore should command moderate returns.

2.4 Valuation and risk issues of intellectual capital

A high proportion of investments in intellectual capital are made of start-up firms, which are in a nascent stage of business development and do not have the historical performance to list publicly. These firms are mainly funded by private equity such as venture capital and required returns for such capital are normally high. This is because intellectual capital investments carry more risk compared to most investments and the returns are expected to commensurate with the risk exposure. There is some degree of similarity in venture capital investments and listed small growth firms (Cochrane 2001) and this leads us to use the Australian ecommerce sector as the proxy to analyse the risk-return characteristics of the intellectual capital sector. There has been enormous growth in e-commerce on a global scale and not all this growth can be explained by the firm's financial fundamentals. The growth of e-commerce is largely a result of advances made in information communication technology (ICT) but the study of information as a key economic variable has been given much more attention by disciplines other than economics (Arrow 1996). The virtual world is one where many of the conventional constraints of physical economic processes (R&D, manufacturing, distribution and marketing) no longer apply and firms, big or small, can sell their products to anyone in the world just as easily. Arthur (1996) defines the criteria for firms subject to increasing returns as those having made high investments in information systems on their operations and are now using this information relatively cheaply. A parallel can be drawn between the present ecommerce firm and the neo-Schumpeter model of repeated innovation by a 'new theory' firm.

The development of intellectual capital for the foundation of market dominance and continuing profitability of firms has been driven by the rapid growth of intellectual capital. In spite of its growing importance, there is no absolute valuation method for intellectual capital (Dabek 1999). Introducing new intellectual products into the market has its fair share of risk, and may even be considered extremely risky in certain circumstances. Managing the project life cycle from beginning to successful commercialisation of the new product entails difficult decisions that involve risks and determine the future course of the program as well as the firm's future revenue and profitability. This means that it is far more difficult to estimate cash flows, growth and discount rates in the knowledge economy than in more traditional and stable industries.

The equity risk premium used in the discount rate should reflect what investors expect future risk premium for the business and is thus a forward looking concept. The concept of increasing returns from intellectual capital (Arthur 1996) complicates the calculation of the equity risk premium by the magnitude and timing of the increase.

2.5 Equity risk premium and valuation models: a critical review

The primary financial management function of the firm is about the optimal matching of uses and sources of corporate funds that will maximise the firm's market value: in essence, the value of the firm is estimated from the present value of its earnings over all future periods (Chew 1997). The central consideration of this postulate is the explicit recognition of the effects of all future periods. The effects include investment decisions in technology and industry and thus pose the question as to whether the principles the market adopt to valuing e-commerce stocks are appropriate and reflect all future period effects, including risk. The effects on an intellectual capital intensive business will depend on the performance of various critical success factors (Oh, Bose and Billington 2003) that decide the growth prospect of the firm.

2.6 Limitations of Current Models

The discounted cash flow models for stock valuation where future dividend are discounted at a constant rate poses three problems, the absence of historical earnings data in the vast majority of intellectual-capital intensive firms, the incidence of skewed results due to the uncertainty of the growth factor and the argument that stock prices are too volatile to be rational forecasts of future dividends discounted at a constant rate (Shiller 1981). The absence of the earnings data required by and the limitations of traditional valuation models make it imperative that alternative approaches be considered for determining the value of e-commerce stocks. Schumpeter's theory of economic development promotes the causal relation between the financial and the real sectors. The limitations of conventional approaches compel the use of real economic activities in this paper, in an integrated and analytical manner, to visualise the economic logic behind this recent development. This approach is consistent with Fama (1970, 1990, 1991), Huang and Kracaw (1984), Chen (1986, 1991) and Fama (1991), who conducted extensive study of the relation between stock market returns and fundamental economic activities.

2.7 Efficiency, Volatility and Predictability of the E-Commerce Sector

The development of intellectual capital is inherently riskier and involves commitment of valuable resources, failure could cost their investors substantial amounts of money. The implications of the EMH in ecommerce stocks relate to the efficient allocation of capital in the sense that under the EMH market financing conditions and the firm's cost of capital are optimal. The measure of volatility of the ecommerce stocks vis-à-vis other market benchmarks and statistical analysis is crucial as a further test of market efficiency for the allocation of financial resources. If the e-commerce prices do not reflect market fundamentals then resources might be misallocated and hence, volatility tests are joint test for informational efficiency. The predictability of e-commerce stock returns depends on the statistical analysis of the random walk hypothesis of the stock prices. If e-commerce stock prices were unpredictable, such test would support the rational expectation element of the EMH that forecast errors should be zero on average and uncorrelated with any information available at the time the forecast was made. The EMH emphasises that it is impossible for investors to persistently make supernormal profits.

3. A new method for estimating the risk premia in e-commerce stocks

The lack of historical data and the highly dynamic environment of the ecommerce sector make it prudent and imperative to evaluate the risk and return relation using a macro approach. Macroeconomic analysis generally focuses on changes in macroeconomic conditions as a result of changes in government policies, market structure, technology, culture and other reasons. As these factors change, expectations about the performance of a firm, industry or economy will change and affect the investment weighting given to a particular sector. The linear multifactor model (Sharpe 1964; Lintner 1965; Merton 1973; Ross 1976) developed in this study addresses the macroeconomic variables that are considered pervasive to e-commerce equity returns (Oh 2002) from an *ex post* perspective. There is a widely accepted view that the variations in expected returns are rational variations in response to market conditions (Chen 1991; Schwert 1990; Fama 1989, 1990), i.e. the expected return on a financial asset is a linear function of its betas or covariances with some systematic risk factors. The linear ecommerce multi-beta model discussed in this paper uses the method of ordinary least squares (OLS) for measuring the risk premium of e-commerce equity.

From a risk perspective, the multifactor model generalises the concept of risk under the traditional CAPM that market risk, risk that cannot be diversified away, underpins the returns of the ecommerce stocks. In this model, the market risk is measured using a series of risk factors that determine the behaviour of ecommerce returns, whilst the CAPM measures risk only relative to market return.

4. Data

The ecommerce firms in this study are selected from the population of pure-play ecommerce companies from a variety of sectors listed on the Australian Stock Exchange. The proxy for market return for the study period is calculated from the closing SP/ASX 200 index on the last trading day of the month in the period July 1999 to June 2000 obtained from the Australian Stock Exchange. The macroeconomic variables used are monthly data for the corresponding period as the stock market data, selected from various sources such as the Australian Bureau of Statistics and the Reserve Bank of Australia.

5. Econometric analysis and empirical findings

The following summarises the results obtained from our study of the e-commerce sector in Australia.

5.1 Risk-return profile of Australian e -commerce stocks

A comparison between the actual e-commerce market returns and risk (both beta and standard deviation) is presented in this section to highlight e-commerce volatility, and the results provide a characterisation of the empirical behaviour of the sampled e-commerce stocks (the market return for the period is 10.96%). The tendency of a stock to move up or down with the market is reflected in its beta coefficient -?. In Table 1, all the e-commerce sectors had positive returns except for the High Technology sector. Volatility measured against the market, represented by beta, is generally higher for most sectors with the exception of Miscellaneous Financial Services (0.57), Casino & Gaming (0.03) and High Technology sectors (-0.26). This indicates that the majority of e-commerce stock returns were more volatile than the market return in the study period. The Health & Medical Services sector had the highest beta of 19.86 and one of the lowest returns, whilst, Casino & Gaming sector had the second highest return but one of the lowest betas. From the perspective of risk-return relationship, the risk-return trade-off appears not to hold in the sample stocks in the study period.

TABLE 1 RELATIVE MARKET VOLATILITY OF SECTORS AND RISK-RETURN TRADE-OFF *

E-commerce sector	Sector beta	Sector return	Standard deviation
Health & Medical Services	19.86	0.39%	1105.33%
Miscellaneous Services	6.39	5.41%	47.04%
Retail/Retail Investment	5.22	4.20%	29.74%
Diversified Media	5.00	0.67%	28.99%
Computer & Office Services	4.93	0.07%	30.32%
Equipment & Services	4.25	26.97%	140.37%
Other Telecommunications	3.74	2.67%	21.38%
Miscellaneous Financial Services	0.57	0.44%	30.69%
Casino & Gaming	0.03	24.06%	56.33%
High Technology	-0.26	-1.26%	27.45%

Source: Oh 2002

*ranked in order of beta

Though e-commerce firms have a number of advantages over traditional firms such as lower operating costs, the global market consolidation[ii] of e-commerce stocks in early 2000 indicates a reaction to market risks and conditions faced by this sector and investors are constantly studying to see how changing technology will end up transforming the market. This confirms the general systematic risk level of the e-commerce stocks and that they move predominantly in a volatility sphere of their own, and relatively independent of the market.

The total risk associated with the e-commerce stocks is decomposed from the analysis of variance (ANOVA) of the stock return to market return regression by dissecting it into systematic and unsystematic risks. The systematic and unsystematic risk profile as measured by the market index, S&P/ASX 200 indicates that the e-commerce stocks were to a large degree subject to unsystematic risk (82%) rather than systematic risk (18%) in the study period (Oh 2002). This means that there was less of a tendency for the e-commerce stock prices to move together with the general market variability and unsystematic or firm-specific risk explains 82% of their variance. This situation can be explained by the higher return variability of the e-commerce stock portfolio; where monthly ? equals 49.82% (Appendix 1), compared to the general market; monthly ? of 3.13% (Appendix 2).

5.2 The Multivariate Regression Model - Results

This section presents the results of the tests done in estimating the e-commerce multi-beta model for Australian e-commerce stocks. The underlying hypothesis in this model is that this set of factors is important in determining and explaining the risk- return relation in e-commerce stocks. The set of factors include the relevant forces in the financial markets, international and the global financial systems the influence of which is proxied by the NASDAQ and foreign exchange rate. The limitations with this model are that time is not incorporated in the model and there may be an upward bias in the measure of expected returns (Cochrane 2001). However, the model is appropriate in that it assumes that investors are myopic (no systematic variations in the investment opportunity set) and the utility function of the investors is logarithmic. This multifactor model differs from the traditional CAPM and the market model in that both are single-factor models. The stationarity and cointegration tests conducted in this study help to detect the influence of time (i.e. the trend in the time series) and enable the study of the long-term effects of the explanatory variables on the dependent variable. On the basis of the criterion of goodness of fit, the following is estimated equation represents the e-commerce equity risk-return relationship:

$$stockret(?\overset{?}{PR})_t = -0.1900 + 0.0013?NAS_t + 0.0692?CC_t - 0.3287?FE_t$$
$$\qquad (-1.2772) \qquad (3.7657) \qquad (1.9345) \qquad (-2.1045)$$

R^2 = .6421

where:

$stockret(?\overset{?}{PR})_t$ = the returns for the e-commerce portfolio of order one in period t;
$?NAS_t$ = the risk factor - NASDAQ composite index of order one in period t;
$?CC_t$ = the risk factor - consumer confidence index of order one in period t; and
$?FE_t$ = the risk factor – AUD/US$ exchange rate of order one in period t.

All three risk factors in the estimated equation are statistically significant at the 10% significance level (t-statistics in parentheses) and indicate their pervasiveness on the e-commerce portfolio returns. While systematic risk measured by the *NAS*, *CC* and *FE* explains more than half of the variance (R^2 = 0.6421) of the e-commerce portfolio returns - PR, in the equation. Such systematic risk level is consistent with empirical study done by Drummen, Martin, Zimmermann and Heinz (1992) where systematic risk explains almost half of the variance of European stocks. The estimated model therefore provides a better measure of e-commerce portfolio return compared to the average 17% systematic risk level by the market model using the S&P/ASX 200 as the market index in this study. From an e-commerce portfolio perspective these three risk factors have the strongest influence on e-commerce stock return across all the stocks and sectors evaluated in this study. They remain statistically significant even when we use a more stringent significance level of 10% (c = 1.943). Of the three risk factors, *NAS* and *CC* have a positive correlation and *FE* has a negative correlation with the returns of the portfolio of e-commerce stocks.

5.3 Predictability

Consistent with the practice for testing market efficiency in the literature, an asymptotic analysis is used to test the weak-form EMH that information observable to the market prior to month t should not help to predict the return during the month t for the ecommerce sector return (the estimates for the EMH tests by sector are presented in Appendix 3). The weak-form EMH tests using the autocorrelation of returns data suggest the validity of the EMH for the returns of the e-commerce stocks in this study. The low R-squared of these tests supports the EMH. This indicates the tests based on (*ex-post*) real returns cannot be used to predict excess returns. De Bondt and Thaler (1985) find stocks with extreme price movements appear to have strong negative serial correlation of returns and are thus mean reverting. This would be contrary to the EMH in that it would be possible to make supernormal profits from predictability in stock prices. For the constructed e-commerce portfolio, there is no evidence of negative serial correlation except for some industry groups at the sector level. A longer time series data would be necessary to conduct a meaningful study of this volatility issue for the e-commerce stocks.

6. Portfolio Analysis

The portfolio evaluation is conducted under the Kuhn-Tucker conditions and analyses a constrained optimisation context within the context of a three-asset portfolio, being e-commerce stocks, S&P/ASX 200 (representing the market stock) and cash. The data used is from the study period. The *GAMS*[iii] portfolio evaluation program (Thompson et al. 1992) is used to test the data. The program selects the portfolios by solving a series of problems with different lambda (?), representing risk aversion, using the equation below (the risk parameter is denoted by ? and when ? is large, there is greater risk aversion).

Maximise:

$$19.95x_1 + 0.96x_2 + x_3 - ?(0.22x_1^2 + .0009x_1x_2 + .0019x_2x_1 + .0009x_2^2)$$

subject to:

$$14.66x_1 + 7.47x_2 + x_3 = \$1.394$$
$$x_1, x_2, x_3 = 0$$

The results of a series of parametric tests for various values of ? are shown in Table 3.

TABLE 3 OPTIMAL SOLUTION [iv]

??	e-Stock*	Mkt Stock*	Cash*	Expectation	Variance
0.0005	31.62	0	1,393,972	41.45	9,836
0.0006	26.34	0	1,393,978	34.54	6,831
0.0007	22.59	0	1,393,981	29.61	5,018
0.0008	19.76	0	1,393,984	25.91	3,842
0.0009	17.57	0	1,393,986	23.03	3,036
0.0010	15.81	0	1,393,988	20.73	2,459
0.0015	10.55	0	1,393,993	13.82	1,093
0.0020	7.91	0	1,393,996	10.36	615

Source: Oh 2002
*$'000.

The general conclusion about market stock drawn from this parametric test is that it would not be a portfolio choice for all risk levels. This is largely due to its insignificant impact, in a portfolio context, in terms of the stock's relatively small expected return (0.96%) in relation to its risk (standard deviation = 3%). When risk aversion is less (i.e. ? is small) there is a tendency to purchase more of the riskier e-commerce stocks. When risk aversion is high (i.e. ? is large), the preference would be to hold more cash rather than the less risky market-stock, as the trade-off between the risk-return of the market-stock would tend to favour holding cash. This optimisation test supports the degree of volatility, i.e. riskiness, of ecommerce stocks as manifested by the small amount allocated as an investment choice in this highly volatile asset. When risk aversion is at its lowest in the test (i.e. ? = 0.0005), the amount invested in e-commerce stocks is only $31,620 (or 0.000023%) out of the available investment sum of $1.394 billion during the study period. This suggests that the investor would rather choose to hold cash than to invest substantially in any of the two stocks when the e-commerce stock is too risky and volatile and the market-stock's return is too low for its risk level to be considered an advantage to holding cash. Conversely, the analysis suggests that the investor has to have relatively low risk aversion to remain invested in e-commerce stock.

In a three-asset portfolio selection scenario consisting of one risk-free asset, the e-commerce stock becomes a portfolio choice in preference to the market stock. The trade-off in portfolio choice is between the riskless asset and the highly volatile e-commerce stock. The relevant optimal portfolios would consist of a very small proportion in e-commerce stock and mainly in cash. From table 7.1, with increasing proportion of e-commerce stock in the optimal portfolios, from ? = 0.0020 to ? = 0.0005, we are able to see a four-fold increase in expected return but a sixteen-fold increase in portfolio risk. This confirms the earlier results that the inclusion of e-commerce stock in a portfolio leads to a disproportionate increase in portfolio risk.

7. Conclusion

The volatility of ecommerce stock returns appears to be consistent in terms of: the yield spreads, betas and standard deviations of the individual stocks; the systematic and unsystematic risk profile; and the EMH tests of the class of stocks examined in this study. Compared to the market, the yield spreads are excessively wide, while the standard deviations and betas are relatively higher. The high degree of unsystematic risk profile together with the weak form efficiency of the stocks suggests a higher level of industry-specific information turnover reflecting the evolving nature and nascent stage of the e-commerce industry. This infers that e-commerce prices (hence returns) that alter by large amounts in the months of this study reflect the rapid changes in fundamentals of the industry. These changes may represent the opportunity sets for ecommerce firms and industry or more general structural market reform in response to ICT related developments. It is probably difficult at this stage to gauge whether the e-commerce market is excessively volatile relative to the general market, due to the lack of comparative and long-horizon earnings performance data for e-commerce firms, which could provide a yardstick against which to compare volatilities. The following sets out the more discernible risk characteristics of Australian e-commerce stocks.

7.1 Risk and valuation of e-commerce equity

The multifactor modelling approach is used in this study to explain the return-generating mechanism of stocks consistent with the various theories that have been advanced (i.e. Sharpe 1964; Lintner 1965b; Mossin 1966; Ross 1976) and at the heart of these pricing theories is the notion that one or more pervasive factors are dominant source of covariation among asset returns. The systematic risk measured by the *?NAS*, *?CC* and *?FE* factors in the estimated AEMM model, explains more than half of the variance of the e-commerce portfolio return *?PR*. The parameters in our regression of e-commerce stock returns, based on a set of predictive variables, appear to be weak when described by usual statistical measures. This is first evidenced by the low estimated systematic risk for ecommerce stocks that suggests e-commerce stocks to be in a unique universe. The use of a higher significance level for testing the null hypothesis for correlation between the dependent and the explanatory variables is another example. This suggests a weaker predictive quality for the variables. Nevertheless the selected pervasive factors do tend to explain a substantial part of the e-commerce portfolio return with an R^2 of 64.2% for the estimated three-factor model using the first difference data of the time series.

7.2 Systematic and Unsystematic Risks

The excessive volatility against market return of the e-commerce stock returns is attributed to the high level of unsystematic risk (low R^2) in the stocks as discovered in the regression analyses using the market model. The low compliance of e-commerce return to the market return reflects emphasis on different economic fundamentals in stock valuation. It appears doubtful that information for equity valuation can be used consistently and therefore rationally in the absence of an agreement (or general understanding) on the economic fundamentals that determine e-commerce valuation –therefore suggesting a strong presence of event effects in e-commerce stock prices in the market.

As the business activity of e-commerce firms becomes more established and stabilised, the level of unsystematic risk is expected to decrease while the riskiness of the stock is expected to reflect more the systematic risk or market risk. This can be explained by the fact that a firm's earnings become more stable and predictable as its business matures and it carves itself a niche in the market. It is consequently able to set clear objectives and direction for future growth. What then happens is that ecommerce firms become more like the traditional firms in the market that are sensitive and subject to market fundamentals. This characteristic is consistent with the mean reverting behaviour of stock returns, that is, higher than average returns are followed by lower returns in the future (Fama and French 1988a; Poterba and Summers 1988). Initial above average e-commerce stocks could be due to the low information content of a relatively new class of stock in a euphoric new market which as time progresses, and more information about the ecommerce firm, industry and market becomes available and the industry establishes itself, the stock returns will adjust accordingly. In their studies, Fama and French (1988a) and Poterba and Summers (1988) find mean reversion in stock return over long horizons, in excess of 18 months. The 'normalisation' or mean reversion of the ecommerce stocks is probably going to take longer as e-commerce is still evolving with the Internet, and to become fully developed and universally accepted as an established market structure, may still be a while yet. The wide spread in actual return and the substantial difference compared to the required rate of return for the ecommerce stocks suggest the market for this class of stocks has not reached equilibrium.

7.3 Portfolio risk

The portfolio study suggests a high degree of risk aversion towards the highly volatile e-commerce stocks. The portfolio-choice analysis of the three-asset portfolio comprising of the e-commerce stock, market stock and cash, indicate that the efficient portfolios under different risk aversions would tend to minimise the holding of e-commerce stock. The study on financial optimisation here is confined strictly to the prevailing market conditions (i.e. pertaining to e-commerce stock return, risk-free rate and market index return) during the study period and within the context of the specified risk parameters. This portfolio position is not expected to remain static given the changing market conditions and investor's risk profile.

7.4 Risk and cost of capital

Our analysis highlights several important implications in relation to the cost of capital issue and e-commerce investments. First, the risk premia we have identified are extremely important for determining the hurdle rate on new e-commerce investments in that they represent the levels of compensation for the taking risk in ecommerce equity investment. These risk premia are estimates based on real economic factors and therefore fundamentally and explicitly incorporate the relevant market risks. Second, as investments in the e-commerce sector are riskier projects, they rely more on equity capital than debt financing and always face a higher cost of capital than debt financed investments. This implies that a greater emphasis is placed on the effective measurement of the cost of equity capital vis-à-vis e-commerce investment.

Global Strategy Against Financial Risk

Alfonso Merino
René Estrada Cervantes
Universidad Intercontinental, Mexico

Abstract

The aim of this highly polemical and current issue is to provide professionals with international vision on the new business culture. We propose that business ethics is the most important foundation of the business culture and requires professionals to commit themselves to the course of ethical actions. Under these conditions, not only are the business professionals expected to detect but also to reject illegal financial operations.

In the worldwide global environment new protagonists, such as new business, religions and highly organized criminal groups are appearing on stage. Therefore, it is clear that we are facing a rising rate of social unpredictability, which have the potential to lead to faradism and invention of new terrorism tactics for individuals and institutions. Thus, the concept of security, and security itself, must be reconsidered and reevaluated.

The Role of International Organizations

Financial stability and economic prosperity are threatened by money laundering and by finance for terrorism. All of which is aggravated by crimes committed in order to obtain such money.

When criminals or terrorists use an institution in an unnoticed manner, this harms the industry's image and reputation. And if some company managers are in collaboration with those criminals to launder funds or to send finance for terrorism, the harm can be even greater and can even draw the company to its closure.

After the September 11 attack, the scandals due to the ENRON and WorldCom bankruptcies as well as others, and to the detection in several countries of important money launderers, when general public senses that an institution is prone or vulnerable to become a money launderer company, it simply stops investing in it.

The most serious known consequences are those where a financial institution is controlled by criminals, since in these cases the whole integrity and operations of the financial system are engaged.

Money laundering consists in the operation of transforming illegal money from illicit activities into usable forms. This money is disguised from its illegal origins and introduced into the financial system and then hidden (or laundered) through a great variety of financial transactions and vehicles both domestic and international, which in the end will be invested in legal financial products and assets. All this procedure is aggravated by the speed of electronic transactions worldwide; in other words we can say that money laundering is intrinsically global.

Financial terrorism can be defined as the processing of a property of some source (maybe legitimate) to be used in the finance of terrorist activities that have been or will be committed, by using the same techniques as those for money laundering.

Several terrorist organizations are known to finance their activities with means that have no connection with criminal procedures. These organizations are much harder to detect than money launders. It may be possible that the only violation they could be accused of is that of a machination or a conspiracy to commit an act of terrorism.

The amount of money needed to finance terrorism is much less than the amounts of money laundered daily by drug dealers. According to some specialists, the amount of money required for the September 11 attack to the World Trade Center and on the Pentagon was approximately less than one million dollars.

The international community has been working to fight against money laundering and financing for terrorism. After the September 11 attack these efforts have doubled, countermeasures have focused on a better supervision, a better regulation has been proposed as well as a timely detection of critical information gaps through borders. The effectiveness of such battle relies on the creation of a reasonable countermeasure system in the global field. Several conventions and protocols (UN, OECD, ASO and APEC) have agreed to develop the following commitments at a global scale:

1. To penalize the laundering of money derived from illegal activities.
2. To design and establish regulations and surveillance for financial institutions and related organizations.
3. Exchanging of experts.
4. To use state of the art technology.
5. To develop instruments of international cooperation for the restrictive application of the law.
6. To guarantee information cooperation and exchange of such in the international field.
7. To establish financial intelligence organizations in each country, to perform the analysis and promotion of specialized information.
8. To supervise real and virtual trans-border movements.

Both the International Monetary Fund (IMF) as the World Bank (WB) in 2001 have evaluated the way in which actions have been taken to stop money laundering and finance for terrorism within their areas of specialization and responsibility, and have arrived to the conclusion that the greatest responsibility falls on governments, financial institutions and citizens of each and every country.

Since then, the IMF has focused on the integrity and stability of the international financial system and is working in close collaboration with the Financial Action Task Force (FACT) and together with the World Bank in the setting of international standards.

Financial World and Globalization

We Mexicans have not cleared anymore how to interpret the past, and much less what to expect from the future. Since the future is not necessarily related to the idea of progress. Under certain circumstances change can be interpreted as something with no direction, undetermined, because people feel uncertain not only because of the present crisis, but due to the rapidness of change itself and the complexity of the new globalize world. In times of turbulence, luck plays a key role in the determination of the future.

As States, individuals and groups become global actors, insecurity and vulnerability grow and two fundamental questions about globalization arise: What is it? And, is it inevitable?

To the first question we can answer that globalization is a whole formed by technical elements such as mobile telephones, Internet, satellites, personal computers, television, radio, cassettes, etc. which are available for States, individuals and groups. However, the behavior of such actors is guided by egoism and ideology, not by humanitarian reasons. Such behavior is opposite to that of a globalize vision based on an illustrated utopia (scientific, rational and universal) if not so; ask the millions of poor people, whose number is increasing day by day in our planet.

To the second question we can answer that the scope of globalization is still limited due to the fact that civil societies are international yet not globalize, thus, a trust towards the formation of a World State seems less possible each day. Globalization is both partial and fragile. If it is so, we should all ask ourselves how our global world could be made more inhabitable.

Globalization contains internal contradictions which we will briefly state: 1) International and transnational cooperation is necessary so that globalization cannot be undermined by inequalities. 2) States and actors must operate in an altruist manner in that concerning their long-term interests.

Globalize institutions are atomized and are not large enough, foreign investment grows according to bilateral agreements and there is very little improvement in environmental protection matters. Globalization forces us to decide between the competitions levels of economy of the level of protection of social security. We are living in a world joined by technology but separated from the perspective of collective solidarity and ethical behavior.

Criminal organizations have modernized themselves up to the point of becoming a global organized structure. In the past, their activities were very specific and focused in a particular location. Nowadays they have found a way to fragment their illicit products and services as well as to launder money by electronic means at an every day higher speeds, which in turn gives them the possibility of corrupting individuals and groups that belong to those institutions devoted to their combat.

We must add that the globalize world now has new actors such as: big enterprises, religions, criminal cartels and globalize criminal organizations. The only thing we know is that we are heading to a point of high unpredictability within the social field, of high uncertainty that will cause the finalization of some people and institutions and the birth of new forms of terrorism which will force us to rethink our concept about security.

These criminal organizations endanger the security of democratic institutions and the sole viable option to stand up against them in international cooperation. This means that each nation will be forced to make a coordinated effort to establish new legal frameworks, better and larger education and training programs as well as the needed tools to effectively prevent and combat the works of such criminal organizations.

Establishment of Business Ethics in Universities

In 1960 the business community of the USA started taking into consideration business ethics and companies began to establish their own ethics codes. In the nineties a great number of enterprises had their own codes. By 1991 the federal Penal Code of the USA stated that if a company accused of breaking regulations had indeed an ethics and conduct code, then any court verdict would be "softened" to a sentence and fines.

Most of the companies understood this and devoted themselves to the establishment of ethics and conduct codes and few were actually caught without a well elaborate ethics code. However many or these companies did not pay much attention to their codes or used it only to have good public relations, and only very few of them really stuck to and followed it.

In April 1995, The Economist published that according to a research 60% of companies in the USA had ethics codes, because they had discovered that is was useful to have an ethical behavior. The research mentioned the most of these companies had a specific department for ethics and some of them even had an ombudsman.

If this is true, why did the corporative cataclysm started by ENRON and WorldCom occur and was followed by a legion of frauds that caused the fall of the stock exchange market where loss was greater than that of the Black Tuesday in 1929?

What failed? For some, neo-liberalism and its markets know nothing about ethics and besides the objective of companies are to look for the maximization of the immediate profit and forget to praise impeccable conduct and ethical persons.

For others, the failure resides in the increase of the corruption rate in the world of big enterprises, as well as the severe deficiencies or absences in the supervision and control mechanisms on behalf of the State. The main question in that moment was to increase the efficiency of surveillance and control and the resetting and rewriting of ethics and transparency or in such a case, do nothing. From this point on, the international consultant enterprise Price Waterhouse Coopers developed three future scenarios about the different results for corruption and fraud treatment as follows:

Scenario No. 1: **Do Nothing.**

1. Nothing is done against corruption, and complete chaos overcomes.
2. Each country follows its own accounting principles.
3. No country adheres to global principles.
4. Nobody trusts anything.
5. Capital flow is paralyzed worldwide.
6. Auditing ceases to have relevance.

7. World becomes chaos.

Scenario No.2: **An Overreaction is caused.**

1. There is an overreaction in regulations: (As it is starting in the USA with the Sarbanes-Oxley Act).
2. Everything is extremely controlled by the governments.
3. Bureaucracy increases which delays taking of decisions.
4. Nobody is interested in auditing companies.
5. Government auditing offices abuse of their authority to submit companies under their control.
6. Bureaucracy grows in an exponential way creating social anomy.

Scenario No. 3: **Everybody Searches for Business Transparency.**

1. Principles and Tools are applied to seek for business transparency.
2. Everybody participates in its implementation.
3. Everybody feels responsible.
4. Companies have honorable staff.
5. Transparency is created within each one of the chain links of financial business information.

Reality gave us a double answer. On one hand scenario No. 3 was adopted, and on the other hand, regulations, domestic, and international principles to regulate and evaluate business systems were improved. Unfortunately short term vision, the search for immediate profits regardless of the means to attain such profits prevents an effective implementation of the necessary control and supervision to avoid frauds, hoax, and traps.

All of this forces us to re-elaborate the ethical systems through education and training at all levels within an organization. It is the only solution to prevent us from ending up in a chaotic scenario or under the influence of an Orwellian repressive bureaucratic apparatus.

Business ethics can be defined today as a business strategy in which compromises and responsibilities are adopted together with the key audience of a company (clients, employees, stockholders, suppliers, creditors, community and government), by obtaining at the same time economical benefits. It is necessary to clarify that a reasonable effort has to be done to stand apart from the tendency to justify business ethics just because they are useful, without understanding that ethics are inherent to all human activities. Now, considering it from the point of view of maturity as business methodology, we can say that it is now where quality was 20 years ago.

When faced to global competition, values, integrity, and ethics have become a very important patrimony. However, globalization affects the execution of ethics due to cultural differences and to work practices in the different business fields.

It is the task of our Universities to be the leaders of a movement where ethics are no longer an elective academic subject just because it is not a useful matter for the professional's performance. If social life has deteriorated so much, it is greatly because a lot of people regard and deal ethical and moral issues in a slanting, condescending, indifferent, and cowardly manner if not stupid. From now on ethics and integrity must be the basis to improve the performance of both companies and society. Social responsibility and ethics must be the axis of all business and social actions.

We need new programs, new courses, new diplomas, and postgraduate studies as well as the ethical intervention at all levels and in all university study programs. A great amount of new knowledge, new themes and new approaches are coming up that will enhance our university curricula. We can see some examples in Table No. 1.

TABLE 1

THEMES OF ETHICS	THEMES OF ETHICS	THEMES OF ETHICS
1. Business ethics and electronic	5. Ethics of the relations client-	9. Ethics and business

business ethics.	suppliers.	transparency models.
2. Theory of ethical decisions.	6. Ethic interaction with the communication media.	10. Compared Codes of professional ethics.
3. Ethical auditing in companies.	7. Social balance ethics of the companies.	11. Ethics and conduct codes.
4. Ethics, uncertainty and business risk.	8. Ethics, corporate conduct and professional conduct.	12. Ethics in the market and free competence.

We must teach our university student “that in the end we will always find ourselves with the ethical responsibility and that we must avoid moral hypocrisy and their representatives since they are the ones that cause social stagnation”.

To talk about ethics without having an idea of where things may lead is not only vane but useless, without the ability to know the possible future their can be is neither ethics nor progress. A concept of the world and of man that cannot be translated into a direction in life is inefficient. Every situation and condition, every institution and every action that affects quality of life and man’s possibilities for his development falls within the domain of ethics.

The ethical net consists of the individual’s capacity to see the contradictions between what he is and how he lives, and what he could become and how he could live. The core of ethics is the need for codes and norms that allow regulation of human relations and the assurance of a stability of society.

Universities are the keepers of knowledge and wisdom, they guard the future, and they are in charge of preparing men that can extend their ethical judgments to larger grounds of the human experience and conduct. I invite all of those present here to revalue ethics and give it a new impulse in your own Universities, to make it grow not only in a quantitative but in a qualitative way (in teaching and research), since adapting oneself to life’s changing conditions confers moral codes and ethical theories their biological and socially evolved value.

We are now at the moment in which we need to make an effort to create an ethical revolution that goes ahead of the rest of the world revolutions.

Towards a New Corporate Culture

All cultural activity is conscious and is bound to progress; therefore it has an ethical signification: man’s destiny is to become the creator of cultural values. Every cultural work must be good and every good action is a cultural realization; in this similarity we expose the relation of ethics and culture.

Culture can be defined as ways of living and creativity patterns. Every human organization has a culture, which in some cases is fragmented and in others, it is strong and cohesive. Be it strong or weak, culture exerts a powerful influence over organizational structure. Culture influences everything, from personal motivation and taking of decisions to social behavior.

We are heading towards a new culture, local and planet wide, a culture prone to legality, institutional transparency, personal integrity, ethical conduct, accounting for and high social responsibility if we wish to survive. It seems that we are entering a very dangerous world, where companies in order to survive and develop in a solid way, apart from being effective, have to be honest and transparent.

The Dangers of Money Laundering in Financial Institutions

Much has been said about the problems that every financial institution can face with its staff, executives, and directives when operations with resources of illicit origin are detected. However, the lack of consciousness of certain areas of such enterprises, do not have the sensitivity of the problems in which they may be involved in because they do not know the final objective of battles against illegal operations.

The issue we are presenting now has to do with High Risk because it affects the security and calm of the board of directors of many financial institutions who can in turn be affected in legal and economic ways, and with great moral harm for the owners of the money since they were not attentive enough to the money laundering problem.

This is a calling to the members and directors of universities to establish an approach through the knowledge of the money laundering issue, and to find different ways to participate in the conformation of specialty studies, diplomas, forum creation, and integration of expert committees to be part of the solutions that are required in the different areas of our public institutions for the battle against this crime.

It is also a calling to high level investors that trust their money to executives and high rank officials who are not trained in the Prevention and Detection of Money Laundering, who have no specialization studies or have no certification that may guarantee an institutional transparency as well as a personal and moral tranquility.

Globalization has allowed the Mexican financial System to increase its scope in international business, as well as the incorporation of new banking and financial services, granting in such a way the automatic handling of huge amounts of money made in a great number of direct (origin) and indirect (transit) operations. These operations are used by money laundering professionals to infiltrate within domestic and international investments, which in turn, because of their great volume cannot be identified by an executive, who on top of everything does not have a specialized training to do so.

Capital infiltrations may have several forms within the operation of money laundering. They can be infiltrated in small amounts with frequent and permanent quantities from enterprises established as *Laundering Fronts* that allow these professionals to have an economic and productive façade legally constituted for the development of its main illegal activity. However, in Mexico still, in spite of the efforts made in the fulfillment area, the view of our executives does not fully understand the Fundamental Principle of Financial Inconsistency as a vital tool to star specializing in this subject.

Another way to infiltrate great capitals for money laundering is administrative negligence, which resides in procedures made by staff lacking knowledge in financial prevention. These situations enable us to say that there is a large possibility that processes have enormous deficiencies and that these deficiencies are very well established, and the lack of integration of specific defense mechanisms that protect the institution's integrity of that of its stockholders in a permanent way by establishing a prevention and protection culture. All of this enables the attaining of financial and contra-analysis elements which may allow us to *identify investors with capitals of doubtful origin and who do not have a financial transparency* within the operations they perform.

The lack of accounting for financial statements on behalf of the directors is solely an honorable and corporate ethics compromise that must be stated in the organizational politics, systems, and procedures. High CEOs monthly inform of the institutional activities to the board of directors, yet there must be confidence about the kind of information, which stockholders receive through the establishment of quality in the information with elements such as opportunity, reality and depth which can guarantee transparency and tranquility for them. The Board, who in turn must determine the guidelines for institutional fulfillment and protection including some communication with the corresponding authorities, must set the norms for the truthfulness of the information.

The Board of Directors must emphasize in the incorporation of staff in their financial business, since the lack of filters of high selectivity in the hiring of personnel can only be an open door for the infiltration of illegal operations that can endanger the institution's integrity. This and the corruption of officials is one of the most successful activities for money laundering, hence prevention actions in this aspect must be increased.

Lack of Financial Transparency for Domestic and International Investors

Year plans of financial growth developed under a directive planning may be implemented, as part of an institutional compromise in fulfillment of the trust placed in them by the stockholder group. Yet this can also be violated by the breach of the established plans due to the director's lack of results. But part of this transparency becomes an obligation to present to the authorities, investors, and clients the goals achieved as well as the deviations from the purposes of good results.

The integration of politics in the corporate and financial report supply for the stockholders group, one of the tasks of the fulfillment area, will allow information to flow in a transparent way and with the integrity of those who develop this kind of information. The opportunity to establish in a very near future a manual of financial ethics in which quality and honesty of information are included must be pointed out.

One of the red alert points for stockholders is the constant reports, surveillance, and audits established by authorities, as well as the observations about operation practices in the institution. Attention must be set in all those parameters that point out to the surveillance organisms about the different dispositions, requirements and internal auditing results performed by the areas in charge.

Institutional Negligence

There are financial administrations that only develop general fulfillment procedures, which are intended to cover a minimum of the established dispositions arguing high costs of implementation of these kinds of programs. However, the development and setting of internal control procedures on fulfillment place in high-risk institutional survival just to please personal interests and no integrity. The development of plans with an institutional conservation and protection vision as a long-term permanent investment strategy allows the required and internationally established business transparency.

To delay the corporate and institutional setting of an ethics code may lead to huge voids of honesty, integrity, responsibility, and surveillance in the development of integral processes of financial operations, as well as to the lack of permanent commitment of executives and staff of the institution. Institutions are formed and directed by men, men who require action limits and truthfulness in their performance.

New rules, new regulations and dispositions will continue to be incorporated in a permanent way, and these will again cause a change in politics, procedures, and systems. Therefore it is necessary to establish in Mexico a validation system of the internal control processes which will allow the guarantee of the confidence in the implementation of the prevention systems which will operate within standard parameters but most of all, of the security of those who are undertaking such processes. Thus, it is important to stand out the Certification of Processes, which in other continents is providing confidence to the investors, financial stockholders, and institutions in general.

It is a top priority to create our own certification parameters in co-participation with authorities and regulation organisms. This is a vital and opportunely participation which can be chained to other areas of fulfillment.

It is clear that each financial organism trains its staff according to its resources and characteristics, and in some cases, the little or no supervision in the integration of training can only lead to institutional mistrust (for example in branch offices and/or sale force) to the point of inhibiting the sale of products and services because of the fear caused by the unawareness of their responsibilities. However, concerning money laundering, finance for terrorism and institutional transparency there is only one direction and all efforts must be joined to standardize specialized training, as well as the training and specialization of prevention and fulfillment units, all headed to a studies certification. Therefore, this specialized subject requires specialized consultants and counselors that will permit to order and reorient efforts to attain the confidence and guaranty of having highly prepared crews.

Collateral Effects

?? Vulnerability to financial tricks, frauds, scams, money laundering, infiltration of capitals of doubtful origin, and tax evasion.
?? Judicial investigation processes.
?? Total or partial loss of domestic and foreign investment.

- ?? Freezing of financial accounts and operational systems.
- ?? International public damage of the corporate and institutional group image.
- ?? Involvement and relation with illegal situations and felonies.
- ?? Companies ranked with low levels of corporate integrity by authorities and certain sectors.
- ?? Trust and credibility loss on behalf of clients, stockholders and future investors.
- ?? Total loss of international business opportunities.
- ?? Low or no level of repurchase or stock response from domestic and foreign investors.
- ?? Tendency to merging or disappearance from the domestic and foreign markets.

Strategies for Corporate Prevention

1. The passing from a restrictive system to a preventive one that will allow the financial anticipation and protection.
2. Integral collaboration with domestic and foreign authorities in accordance to their suggestions.
3. Establishment of a permanent program of institutional surveillance that will allow the validation of such supervision, the internal control processes with stockholders and authorities.
4. Institutional diagnosis over prevention internal control processes that will enable to measure and establish a level of financial risk.
5. Konklave 1. Support instrument for the corporate institution and authorities that enables the establishment and maintenance of politics, norms, processes, systems, fulfillment and training in virtue of the measurement of financial risk.
6. Verification of control processes for the prevention and detection of operations with illicit resources.
7. To count with specialized consulting firms with recognition from authorities in this subject, which will validate internal control processes of corporate protection.
8. Certification of internal control processes that will guarantee above all the tranquility of the corporation.
9. Periodical training in financial risk and institutional transparency for partners, stockholders, and investors of financial institutions.
10. Specialized training and qualification programs, which are registered in institutions, and ruling organisms that allow a confirmation of structures and reliable plans mainly for the prevention and fulfillment areas.
11. Permanent design and revision of the Ethics Code and its fulfillment at an institutional and corporate level.
12. Promotion of internal control audits from the ruling authorities with the application of sanctions in case of non-fulfillment and its recommendations.

Legal Framework about the Prevention of Money Laundering

The dangers of high financial risk are the practice of laundering of illicit resources that are generally developed by the triangulation of operations among different countries and continents, to make identification of real sources of such recycled resources more complicated. There we can see the relevance of forums like this one whose objective is to value the advances and challenges that must be faced regarding this subject in order to educate the next generations in the prevention culture of such crimes.

Mexico has subscribed international agreements and treaties to fight against this type of operations with resources of illicit origin and has a place as a permanent member with full rights acquired on June 21st, 2000, within the organism named FACT (Financial Action Task Force), which proposed 40 recommendations to which eight were added about finance for terrorism, related to money laundering which have been based on the following principles.

1. Qualify as a serious crime money laundering, i.e. the performance of any financial operation with the profit a crime;
2. To allow the confiscation of property;
3. Identify the clients and maintain the corresponding documentation;
4. Implement internal controls within financial institutions and make these report any suspicious activity to the authorities, and;
5. To maintain from the authorities a close supervision and control of financial institutions.

Mexican authorities have issued a series of legal dispositions to fight against the performing of financial operations with sources coming from crimes that include the making of activities with money, rights, or properties of any nature that come from or represent the product of an illicit activity, moreover, several normativities have been issued to implement the principles of FACT, such as the internal control and report of financial institutions regarding relevant unusual or concerning activities among others.

After Mexico became a member of the FACT, the Ministry of Treasury (SHCP) issued in November 2000, some modifications to the General Character Dispositions in which it established that credit institutions must identify persons that perform multiple or fragmented operations that added up are equal or exceed an amount of $10,000 US Dlls. In their equivalent in Mexican pesos or in any other legal currency, independent of the obligation of identifying their clients or third parties when they are performing individual operations in any monetary instrument starting from the above mentioned amount.

All of this is a consequence of the reforms passed to the dispositions referred to in article 115 of the Credit Institutions Law, which implies the necessary modifications in the corresponding Operation Manuals in order to customize its internal procedures and politics to prevent, detect, and report operations with resources of probable illicit origin that might be detected.

Proposals:

Significant Changes in Professional Information

Caused by the regrettable events in New York and Washington D.C. on September 11, 2001, the Mexican government has redoubled efforts to adhere to international normativity agreements and treaties regarding combat to terrorism, psychotropic substances and institutional transparency.

Present agreement define the actions that different governments must adopt to attack this problems, in the case of Mexico, the Ministry of Treasury (SHCP) is developing because it is the main governmental dependency that regulates financial and tax operations in the country.

From the events of September 11, the Security Council of United Nations established some resolutions that force country members to:

- ?? To secure and confiscate properties of persons directly related to terrorist acts.
- ?? To spread lists of members of terrorists groups currently operating in the world to determine the existence of these within our financial system.

In Mexico, money laundering is a crime considered serious in Mexican legislation and we must remember that it is originally born as a tax crime to be later transformed into a federal crime in accordance to the recommendation of the FACT.

We must state the difference between money laundering and tax evasion crimes according to that established by the FACT. Since the first one is derived from the performance of operations with resources of illicit activities, and the second one is derived from the non-fulfillment of obligations by taxpayers, they are punished on a separate basis. These are two different but related crimes; and strangely Money Laundering necessarily reunites all the elements of tax evasion.

Crimes such as money laundering and terrorism are considered in our Federal Penal Code as serious. However, the finance for terrorism crime has not yet been classified as serious but actions are being taken for its incorporation to such Code.

We can take a look at the following eight recommendations established by the FACT about finance for terrorism:

I. Ratification and execution of the United Nations;
II. Classification of finance for terrorism and money laundering;
III. Freezing and confiscation of terrorists assets;
IV. Report of suspicious transactions related to terrorism;
V. International cooperation;
VI. Alternative systems of fund sending;
VII. Cable transference; and
VIII. Non-profit organizations.

Future medium and long-term actions about regulation of non-financial institutions are currently in discussion on different international forums. In this sense, the role played by accountants, lawyers, notary publics, public brokers, real estate enterprises, and currency exchange centers are the main discussion point, since they are not regulated in the present moment. Therefore the intention is to look for an integral opinion among professionals and authorities to strengthen supervision and surveillance on financial operations that are made between institutions, countries, and continents.

Conclusions:

The Importance of the Participation of Universities

Participation of Universities in the themes we have talked about is very significant, because they represent the main vehicle in the achievement of an objective culture realization in these and other themes, as well as to overcome the deficiencies presented by our professional market at the time of problem solving. Such problems are not exclusive of a certain society group, but they touch and affect all the population of our great country, Mexico.

If we do not act within the academia field, we could loose the opportunities to establish mechanisms and strategies to give the young population in our country elements to solve specific problems. Indeed we could dangerously increase social, professional, governmental, and corporate chaos.

To end, I wish to express that what we have stated here it not something trivial but only the principles and norms to which we should submit ourselves to live our lives. This is not my saying Plato expressed it in his work The Republic more than 2,300 years ago.

Thank you very much.

Political Risks and Foreign Investment

Yolanda Cruz
Instituto Tecnológico y de Estudios Superiores de Monterrey Campus Guadalajara, Mexico

Abstract

This paper presents the impact of the political and economic environment of Mexico on the operations of the multinational corporations. The ideas presented here are the result of a research that was done using six major British multinationals operating in the food and beverages industry, namely, Allied Domecq, Cadbury Schweppes, Grand Metropolitan, Guinness, Tate & Lyle and Unilever. The particular events to which these companies were exposed are the political and economic risks that occurred in 1994. The findings show that politics and economics are intertwined and in Political Risk Analysis they have to be treated together. It is also clear that the characteristics of each company will shape the impact of these risks on their operations and on the design of their response. Multinationals are not interested in the politics of a country in which they are operating as long as the conditions exist for profitable operation.

Introduction

In this research, a single industry is chosen but the companies operate in different sub-industries within that sector; this will help to show the complexity and specificity of political-economic risk. All the companies were exposed to the same adversities but the impact of these events and the multinational corporations (MNCs) reactions might be different because of the characteristics of each company. This research analyses both the nature of the MNC and the environment of the country to find out why multinationals react the way they do. This study is concerned with the political-economic risks that took place in 1994 and attempts to provide a more exact explanation and a better understanding of the performance of these MNCs after 1994.

In this study the responses of the MNCs to that political-economic risk and the differences in the negative impact of the risk on their operations will also be studied. This study intends to look at the impact that the political and economic environment in Mexico has had on a group of companies operating in the same industry. The companies chosen are major British MNCs operating worldwide in the food and beverages industry. They are Allied Domecq, operating mainly in wines and spirits, through Casa Pedro Domecq; Cadbury Schweppes, which owns a soft drinks company, Cadbury Bebidas; Grand Metropolitan, with a share in a spirits and wine company, Casa Cuervo; Guinness, which has a wholly owned subsidiary, United Distillers de Mexico; Tate & Lyle, which has a large share in a sugar refining company, Azúcar Grupo Sáenz and Unilever, which has different companies in the fast consumer goods sector operating under the corporate entity of Unilever Mexico. It is important to stress that we are concerned only with their direct investments and not with other operations that they have in Mexico, such as franchises or joint ventures. It is not a unified sample of companies, since each one specialises in a different sub-industry. The differences among the companies will help us to understand the reactions of these companies to the same events.

This sample has several characteristics. First, with the exception of Unilever, all the Mexican companies were acquired by the British parent company after 1990. Second, not all the acquisitions were made with the objective of having a presence in the Mexican market; two of them resulted from the global strategy of the MNC. Third, the six companies have a different pattern of ownership and this will help us to see whether this ownership affects the impact of the events on the MNCs and on the design of their response.

The purpose of studying the period between 1990 and 1998 and using 1994 as the centre of the analysis is because, even if the neoliberalist reforms started in the middle of the 1980s, it was in 1988, with the arrival of President Carlos Salinas de Gortari, that measures were speeded up. Mexico began to be perceived by the outside world as a successful economy which was developing rapidly. It was during these years, 1990 to 1998, that most of the companies used in this study became interested in Mexico. The hope that Mexico was becoming a developed country was proved wrong in 1994. The events starting in January of that year, which culminated in the devaluation in December, reflected the inequalities of the Mexican society, the difficulties of its economy and the contradiction of a political system which did not seem to be responding to the new demands of the economic programme.

These events are going to be evaluated in a number of ways. First, we will look at the past performance of the MNCs and the way they have reacted to previous conditions at a global level. Here the objective is to disentangle their strategy in order to understand where they place their investments. Second, the study relies on the qualitative data obtained through interviews, both in Mexico and the UK. The fieldwork included a total of 22 personal interviews conducted with senior managers of the parent and subsidiary companies, with Mexican and British government officials and with two consultancy groups

Political-Economic Risk

A definition of political risk is: "Contingencies arising from the political environment, not political events and processes per se. Political events must be regarded as cause, not effect, and hence they are of concern only in so far as they affect managerial strategy." [1] Another author states: "Political risk in international business exists, 1) when discontinuities occur in the business environment, 2) when they are difficult to anticipate and 3) when they result from political change." [2] One consultant defines political risk as: "Any situation or development that can affect a business venture in any way." [3] The obvious examples are political instability, military *coup* and problems arising from elections. Political risk goes further; it is anything that can affect business, which could be an economic downturn or devaluation, as in 1994 in Mexico, but also operational obstacles, which can include corruption, bureaucracy or environmental legislation. Political risk is not an exclusive quality of developing countries but they are more common than in developed countries. From these definitions it is possible to consider that when a political or economic event affects an organisation in a significant, negative way, it is classified as a risk. It is not wise to make generalisations in this field because a particular event may not affect all MNCs in the same way.

Political risk is different for each company since the characteristics of the company will determine how susceptible it is to political risk. Some political changes will adversely affect the company while others will probably improve the firm's conditions. The characteristics, such as the goals of the firms, internal structure, share of ownership, product and position within the country are essential in determining the political risk it faces. As the case studies will show, even if the six companies are operating in the same sector and are exposed to the same environment, the events do not affect them equally. What is clear is that many authors separate risk from uncertainty. [4] The risk exists and is a fact but uncertainty, which is really doubt, causes managers to make preparations that may avert that risk.

Some risks might be classified as economic and they are identified just by origin, a currency devaluation. Other risks have a political source, they relate to power or authority relationships and here political instability is identified with either violent events, riots or assassinations. This differentiation causes a problem; where to draw a line between political and economic risk: "Although government decisions are always political, by definition, the forces dictating the decision may be purely economic." [5] In other words, changes in the business environment might be a result of an economic policy that does not have any politically motivated reason but which affects the activity of the company. This differentiation deserves some discussion because it seems that some authors insist on a separation between politics and economics, when in fact they can not be divorced. As Gilpin stated some time ago, economics and politics are distinct but they depend on one another. [6] To reinforce this idea, Susan Strange said that separating what is political from what is economic is an illusion, which does not apply to the real world. [7] Based on these statements, it will be argued that, in fact, politics and economics are two different disciplines and that politics, of its own nature, is more uncertain than economics but they have a direct relationship. Therefore, we will define political risk as any political or economic event whose outcome negatively disrupts the activities of an MNC. It is our belief that instead of using the term 'political risk' it would be better to use the term 'political-economic risk', which embraces all the non-commercial risks that impact on the MNCs.

Among the factors of political-economic risk are social unrest and disorder; these are not directed against foreign companies but may affect business activities. The causes of social unrest may range from extreme economic hardship to racial disorders. [8] Another source of political-economic risk is a change in the law which may put ownership in danger or directly affect the conditions of FDI. Finally, one of the causes that ought not to be underestimated is the political influence of local business. Governments tend to support and protect their own businessmen but this position may change because of the economic and political requirements of the nation; if national businesses feel threatened by the presence of FDI they will certainly react. In a later chapter the influence local businessmen have had on the actions of the Mexican government, concerning the participation of FDI in the economy, will be considered.

Stefan Robock and Kobrin agree in identifying two types of risks, those that are 'macro', that act on all firms in more or less the same way and are unanticipated and politically motivated, such as the Cuban or Iranian revolutions, and those that are 'micro' which impact on a specific industry, company or project. The latter types of risks are more prevalent. The micro risks do not normally involve political conflict; they are changes in the policy of the host country government such as ownership regulations, restriction on remittances and exchange rate controls. [9] Changes in the exchange rate are a risk when using foreign currency and their effect is reflected in the balance sheet of the parent company. It is important for the MNCs to have a reliable economic environment in the host country. The businesses vulnerable to this type of risk will vary from nation to nation; dominance of a foreign company in an industry and the capacity of nationals to operate a business in that same industry are factors that change the vulnerability of such an industry. A characteristic of political-economic risk is specificity. The political environments can alter both the security of assets and the viability of operations; the latter is the most common. This classification also confirms that political-economic risk is not only a quality of developing countries, since all political environments change.

Even if revolutions, military governments, *coups* and other events affect the performance of MNCs, the most important source of political uncertainty is the policy of the host government which will reflect the interests and power of the different social groups in the country: the government, labour, local businessmen, military and consumer groups. This research will be dealing with 'micro' risks as defined above.

The Dimensions of the 1994 Crisis

The 1994 Mexican crisis was not limited to the devaluation of the peso in December; in fact, the devaluation was a symptom of the crisis. The socio-political events that took place in 1994 put pressure on the economy of the country and the result was the devaluation of the peso. The purpose of this section is to present the events of 1994 and the way in which they impacted negatively on the economy, eroding even more the already devalued Mexican peso.

On January 1st, 1994, the Ejército Zapatista de Liberación Nacional, EZLN, or Zapatista National Liberation Army, declared war on the government in the name of the people of Chiapas; they demanded the removal of the national president and the governor of the state, to be followed by free and fair elections. The rebels called for the support of all Mexicans. The causes of the uprising were poverty, racism and social inequalities; the government argued that its economic reforms were part of the solution in Chiapas, not part of the problem. The signing of NAFTA and the changes in the Constitution concerning land tenure certainly affected the rural and ethnic population. [10] Some of the southern producers, many of whom were located in Chiapas would not be able to compete with cheaper US imports. They did not have access to credit, machinery or to irrigation.

The Zapatistas did not pose any military threat but the government is under pressure to solve the socio-economic problems that gave rise to the EZLN. Chiapas is a rich state; it has land for farming, forests, is a major producer of coffee and an important supplier of the nation's electricity and oil. The problem is that the wealth is concentrated in few hands and most of the 'Chiapanecos' live in extreme poverty. The movement has raised concerns about human rights and has attracted the attention of the international community; it has become a blot on the reputation of the government. [11] This uprising showed how limited was Mexico's incorporation into the first world. The movement claims that ethnic groups are being exploited by an oligarchy and that in Chiapas, as in other states, there are no free, democratic elections.

If the Zapatista movement threatened the viability of NAFTA and the success of the economic policies of President Salinas, the political murders in the following months brought to light the malfunctioning of the political system. During the presidential campaign of 1994, the candidate of the PRI, Luis Donaldo Colosio, was assassinated, on the 23rd of March. Both the national and international financial community reacted with panic and the demand for Mexican securities fell. Colosio's death further tarnished the image of modern Mexico.

A few months later, on the 28th of September, a second political assassination took place; the secretary general of the PRI, José Francisco Ruiz Massieu, was killed. Both murders remained unsolved but it is believed that Carlos Salinas was involved. In an attempt to restore both the confidence of the Mexican people and also that of foreign investors, the government accepted foreign observers to scrutinise the general elections of August 1994. It is important to stress that in the past this would have been seen as an affront to national sovereignty. The government, and more specifically the PRI, realised that observers would guarantee that there would be no electoral malpractice and the result would be accepted. [12]

The 1994 elections were a step towards a true democracy. These elections were closely scrutinised and there were reports of some irregularities that raise suspicions about the tactics of the PRI. The real test for a political system is the peaceful transfer of power from one government to another, even a government of a different political party. It was difficult to believe that the PRI would reform to permit a biparty system; this reform was characterised as a 'mission impossible.' [13] The result of the 1994 elections was a signal that politics had changed. The opposition gained almost 50% of the votes, which meant that the PRI had to listen to the demands of the electorate and that a three party system, the PRI, the PRD and the PAN, was developing. Both the PAN and the PRD increased their share of the vote.

In the congressional elections of 1997, a real opposition emerged and the voters were presented with an alternative. Previous elections had been a formality and this had given rise to 'popular cynicism' but the elections of 1997 proved to be different. For the first time in 70 years, the citizens of Mexico City voted to elect their mayor; previously this position had been a presidential appointment. In the mayoral election, Cuauhtémoc Cárdenas and the PRD achieved 48.6% of the votes, the PRI 25.9% and the PAN 15.7%. [14]

Investors hoped that this new pluralism would bring further change in economic policy. However, the crisis within the PRI gave cause for concern, because they were in control of the senate and the presidency. It was possible that the PRI might have pushed an agenda which could paralyse policy making and the passing of legislation.

The devaluation was not an overnight event. The brief economic recovery, which started with the administration of President Salinas, in 1988, was already showing signs of faltering by 1991. The various pacts which Salinas had instituted to curb inflation were having damaging effects and, by 1993, the Mexican economy was stagnant. The cost of the fight against inflation was becoming very high. The productive structure of the country was being weakened, economic activity was slowing down and the commercial deficit and the deficit on the balance of payments were increasing. In 1993, top government officials were discussing whether they should continue to try to bring down inflation to international levels or to relax the exchange rate, in order to reduce the deficit in the current account. The Central Bank of Mexico argued that the huge deficit in the current account was caused by the fact that foreign investment was high and internal saving was low. In spite of this, the government decided to continue the fight against inflation which was reduced to 6% in 1994. The Zapatista movement added to the political and economic uncertainty which was fuelling internal inflation; by February 1994 the peso had lost 8% of its value. This meant that the peso had reached the bottom of the exchange rate band established by the government. This depreciation threatened to grow after the assassination of Luis Donaldo Colosio and the Central Bank of Mexico had to use its reserves to prevent a currency collapse. [15] Uncertainty was intensified by the assassination of the secretary general of the PRI, José Francisco Ruiz Massieu, in September.

The recovery seemed to be working at the macro level and by 1996, Mexico was second after Brazil in the Latin American list as a choice for foreign direct investors. It is worth mentioning that Mexico had kept the first position as a recipient country for FDI in Latin America since 1990. [16] Investors had been encouraged by the stability of the Mexican peso. The prospect of declining inflation raised hopes that Mexico might be about to embark on a virtuous circle of lower interest rates, healthier economic activity and stronger stock market prices. The improvement in economic conditions continued to attract investors. In an article in 'Director', December 1996, the author summarised those factors in the Mexican economy which made it attractive to FDI. The article mentioned conditions such as the size of the local population, the membership of NAFTA which opened the US market for Mexican goods, the possibility of selling to the rest of Latin America, the competitive labour rates and the relaxed investment regulations. [17]

British Multinationals investing in Mexico

Allied Domecq

Pedro Domecq is one of the oldest sherry companies in Jerez, Spain. The business started in 1730 and was acquired by the Domecq family in 1816. In 1941, the family extended its interests to Mexico and Pedro Domecq Mexico was set up as a subsidiary in 1956. Further subsidiaries were established in Latin America and Domecq developed as one of the largest drinks distributors in the region. Among the reasons for Allied-Lyons acquisition of Pedro Domecq was that they could build a strong portfolio in the principal spirits categories. The ownership would give Allied-Lyons better distribution of its products and facilitate the broadening of Allied-Lyon's businesses in developing markets. The acquisition would give Allied-Lyons six of the world's top 100 spirits brands. [18] At the time of the acquisition, in 1994, Allied-Lyons was the world leader in brands, it was second in sales volume and the fifth largest distiller in the world. The ownership of Pedro Domecq in Spain and Mexico brought the benefit of a better distribution of Allied-Lyons products and enhanced access to the Hispanic and the US markets, which are considered to have a high potential for growth. Allied-Lyons would now control 94% of its own spirits distribution worldwide. [19] In September, 1994 Allied-Lyons plc changed its name to Allied Domecq plc and its two core businesses started operating under the names of Allied Domecq Spirits and Wine and Allied Domecq Retailing. As a result of the acquisition of Domecq, the group reorganised its structure in 1995. The Pedro Domecq group holds an 83% share in Pedro Domecq Mexico which was the largest spirits marketer in Mexico, by volume, in 1992 and, in 1993, reached annual sales of 9.3 million cases.

Cadbury Schweppes

In January 1969 Schweppes and Cadbury merged. Technically Schweppes bought Cadbury but the new company bore the name Cadbury Schweppes. In March 1992 Cadbury Schweppes paid £188 million to Valores Industriales, Mexico's beer and soft drink giant, through its Femsa subsidiary, for the sale of its mineral water division, Aguas Minerales. Aguas Minerales is the leader in bottled water, both plain and fruit-flavoured; it includes Peñafiel, Balseca and Etiqueta Azul, which are estimated to have 68% of Mexico's mineral water market but only 6% of its soft drinks market. Mexico is the world's second largest market for carbonated soft drinks. The consumption per capita is on average 130 Lt a year, 50 Lt less than the US, and it grows 9% annually. [20] Peñafiel is the leader in the Mexican mineral water market. The investment in the manufacturing and launch of larger packages, both refillable and non-refillable, contributed to a strong sales performance, particularly in the second half of 1994, with a 12% increase in sales. Crush was included in Cadbury's acquisitions since it is distributed by Aguas Minerales in its operating regions and through Aga bottlers in new territories. In the sparkling water segment, Aguas Minerales dominated, with about 70% of the market in 1992. [21] After the acquisition by Cadbury Schweppes a new brand, Aguafiel, was launched.

This acquisition was among the largest by an overseas company of a Mexican business. The Mexican acquisition came about because Femsa was switching resources from soft drinks into banking, creating an opportunity for Cadbury. Femsa is the largest Mexican beverage and bottling company. About 18 months before the sale of Aguas Minerales, Femsa took on a large debt when acquiring a 56% stake in Bancomer, the second largest bank in Mexico, for US$2.88 billion. In 1993, after the deal with Cadbury, Femsa agreed to sell 30% of its soft drinks division to Coca-Cola for US$195 million. [22] Femsa was the owner of the Coca-Cola franchise in Mexico which accounts for 50% of Mexico's soft drinks sales.

Diageo

In 1926 Maxwell Joseph established his own property firm, Grand Metropolitan. In Mexico, Grand Metropolitan operates through franchises of Burger King and Häagen-Dazs; Green Giant is a maquiladora and it is seen as a subsidiary of Grand Metropolitan's US company, Pillsbury. The only direct investment was in José Cuervo. In

1964 Heublein began to import tequila from Cuervo to the US, and a decade later, to some European countries. After Heublein was acquired by IDV in 1988, a commercial link started and Cuervo was exporting tequila to IDV and IDV was exporting its products to Mexico through Cuervo. In 1991 Heublein Inc. acquired a 45% stake in José Cuervo. The agreement gave Heublein the exclusive right to import and market José Cuervo in the US; IDV was allowed to expand Cuervo's distribution worldwide. This deal strengthened the long-standing relationship among the companies. Tequila's exports started rising, from 28.5 million litres in 1983 to 47.3 million litres in 1993. [23]

During the 1960s Guinness through its spirits arm, United Distillers UD, was exporting its products to Mexico but, because of the need to have a better control of the market, they decided to establish a subsidiary. UD arrived in Mexico in 1992, through a wholly owned subsidiary. By 1994 it had a 41% market share of whisky, with an estimated sale of 880,000 cases annually. Its portfolio comprises fourteen well known brands, including Johnny Walker and Buchanans. It imports other spirits such as Hennessy cognac, Finlandia vodka, cherries Magno and Veterano, Campari, Gordon's and Tanqueray gins.

The merger of Guinness and Grand Metropolitan was announced on the 12th of May, 1997. In Mexico both companies, UD and José Cuervo, were still operating separately. Diageo only held a 45% stake in José Cuervo while it owned UD a 100%. José Cuervo's perception was that because UD was stronger in Asia and the Pacific and IDV in Latin America, their geographical scope was complementary. For Cuervo, the logical step was that UD became part of the Cuervo operation, because UD was smaller and the infrastructure and network of Cuervo were bigger. For UD Mexico, the merger with Cuervo seemed more complicated because Cuervo was an independent company and Cuervo and UD operated under different conditions.

Tate & Lyle

In 1870 Henry Tate built his own sugar refinery in Liverpool and formed Henry Tate & Sons. Abraham Lyle also started a refining business with his sons; in 1881, he bought Odam's and Plaistow Wharves on the Thames and built his own refinery. Tate was producing sugar cubes, while Lyle's specialisation was golden syrup. At the beginning of the First World War both were successful family businesses. In 1918 Earnest Tate approached Charles and Robert Lyle about the possibility of a merger. The two businesses complemented one another and they could share technical expertise. The negotiations dragged on until 1921 when Tate & Lyle came into existence. [24]

On the 16th of December, 1994, Tate & Lyle announced the acquisition of a 49% stake in Grupo Industrial Azucarero de Occidente in Mexico for £35.8 million. After the peso devaluation, it was necessary to make some adjustments to the original agreement but Tate & Lyle decided to continue with the transaction. The Sáenz family continued to own the majority share. Grupo Azucarero de Occidente had an estimated 7% of the Mexican sweetener market. The total market produces approximately 4 million tonnes of refined sugar a year. The top five sugar processors account for 60% of total Mexican output and 64% of refined sugar production, of which Occidente had under 15%. Occidente had two mills in the north-eastern state of Tamaulipas and one in Jalisco state. Tate & Lyle's investment had two immediate benefits. Firstly, it allowed Tate & Lyle to expand in an emerging market. Secondly, it would enable the group to take part in the expanding soft drinks market in Mexico. A growing demand was expected in the food processing and retail grocery markets. Occidente had a target production of 350,000 tonnes for the year 1998. [25] Tate & Lyle was only involved in the decision making process of Grupo de Occidente when there was need for investment. The Sáenz family controled the everyday running of the company. When Tate & Lyle invested in Grupo de Occidente it already had some investment in Mexico. During the 1970s, Staley invested in Mexico and it held 50% stake of Almidones Mexicanos, Almex, which was a corn plant producing HFCS -high fructose corn syrup. After the acquisition of Staley by Tate & Lyle there was major investment in Almex and the plant became bigger and more important. Tate & Lyle had 50% of Almex, plus their stake in Grupo de Occidente.

Unilever

Margarine Uni, a Dutch firm, came up with the idea of amalgamating with Lever Brothers and the merger was consolidated on the 2nd of September, 1929, under the name in English and Dutch respectively of Unilever Limited and Unilever NV. In Mexico, Unilever set up a soap joint venture during the 1950s but it was not until 1965 that the company was officially established with Zwanenberg, a meat processing business. [26] Throughout the years the acquisitions and movements of the group internationally have allowed the Mexican operation to inherit other businesses. In 1989 the various Unilever interests in Mexico ceased to function as separate entities and were organised into Unilever de Mexico. The various companies now became divisions of one company. This change gave Unilever more efficiency, stronger negotiation power with suppliers and customers and saved them time and resources. Unilever increased its interests in Mexico during the privatisation of the state owned companies. At the beginning of the 1990s, they acquired 'Industrias Conasupo' edible oil refiners and pasta makers. This acquisition gave Unilever better market coverage in central and southern Mexico. [27] The products of this company include crude refined vegetable oils, vegetable shortenings and pastas for soup. In 1990, Unilever bought seven Mexican companies from 'Valores Industriales', Clemente Jacques brands which are producers of tomato based sauces, chile products, marmalade, vinegar and processed foods, Mafer salted snacks, La Caperucita cheeses and animal feeds. [28] The Chairman of Unilever de Mexico stated that the move was going to boost its sales by over 25% in 1990 alone. Unilever also made acquisitions in the ice cream industry. Through a joint venture with Grupo Quan and Grupo Industrial Bimbo they already owned 51% of the shares in the ice cream market leader Helados Holanda. In 1998, Unilever acquired the rest of the shares. The deal included the local bakery brand, Carrancedo. [29] As a result of global restructuring, Unilever Mexico sold the chemicals division and also Zwanenberg the meat processing business at the beginning of 1997. In contrast they bought the margarine Mexican producer, Iberia.

The Impact of Political-Economic Risks on the Multinationals

In this final section an examination will be made of the information provided in the first four sections to discover if there is a common view expressed by all the parties questioned; if there are divergences in the material and what are the reasons for these divergences.

The parent company and the subsidiary are in a tight economic partnership and the success of this partnership is essential to the health of both parties. There is one vital difference; the Mexican subsidiary must succeed in Mexico; the multinational hopes to succeed in Mexico but a failure in Mexico, though it may damage the multinational, will not destroy it. This leads us to understand that greater sensitivity to Mexican conditions would characterise the local management, whilst the parent company focuses upon more global concerns. It is also clear that the MNC is able to exit a country and locate its resources somewhere else, but, as it will be explained, using Cadbury's case, once a multinational enters a country it is not that easy to exit.

The multinationals have a common view of the desirability of investment in Mexico; without exception, they see the geographical situation of Mexico as a great advantage in developing their business and using the country as a manufacturing base. This point of view was mostly expressed by the parent companies, which have a wider view and see Mexico as part of their worldwide strategy. The proximity of the large, developed North American market, which was reinforced by the signing of NAFTA and the possibility of using Mexico to extend their business in South America was agreed by all. As has been stated, this geographical position is undermined by the lack of proper communications with South America. However, since the geographical consideration was a major common denominator for all the MNCs, it must be assumed that they are aware of this difficulty and have plans to deal with it.

Equally the MNCs valued the size and structure of the Mexican market itself; a large, relatively youthful population promises a growing market as Mexico moves from the position of a developing nation to that of a developed nation. Because of their common hope for a better future, the parent company was prepared to accept some risk in the here and now. Although, for all MNCs, having a large market is beneficial, none seem to care about the disadvantages of this growing population. The most obvious is that unemployment might increase and the disparities between the rich and the poor will limit the domestic market and that affects negatively the sales and profits of any company. In fact it is the same MNCs that contribute to the increase in unemployment when they restructure their companies, as happened with Allied Domecq.

A second area of attraction was the high quality of Mexican management and the high level of skill of the Mexican workforce. Though this is a positive feature, it has a number of qualifications, which must be taken into account. These qualified personnel will be remunerated at a lower level than similar employees in developed countries, which reduces production costs, but the domestic purchasing power will be weak. All the companies are expecting a gradual improvement in the Mexican economy to produce a population which is better able to buy the goods produced by their subsidiaries.

The economic improvement referred to will have another effect; it will enable the Mexican government to invest more in the infrastructure and in particular in education. Though all agreed that the workforce was qualified, they said that the qualified group in the population was small and expanding companies had to compete for the small number of suitable applicants available.

Although all the parent companies agree on the advantages of the location of investment in Mexico, different companies were attracted by different features. Allied Domecq stressed that in a competitive world, it is necessary to be where your competitors are; Unilever sees an advantage in working in a country in which the bulk of the population is highly concentrated in three large cities, which could lead to economies of scale. Obviously for Cuervo and Domecq, who are involved in the sale of spirits, Mexico is the sole producer of tequila, the sale of which is growing worldwide.

This leads us to a consideration of NAFTA: all the companies examined stressed their hope that NAFTA would be a stabilising influence in both politics and the economy in Mexico. This was the general reaction, though NAFTA would affect different companies in different ways; Unilever would only benefit from the general stability, while Tate & Lyle would find NAFTA a positive safeguard to their future development. It is possible to say that NAFTA's effect on the subsidiaries will depend heavily on the nature of the structure of the MNC. The indirect benefit of this agreement is the certainty that this close alliance with the US will guarantee that there will be no going back on all the policies that had been put in place as part of the neoliberalist process. The particular benefit all MNCs would like to see is an improvement in the standard of living, which should be reflected in an expansion in their business.

NAFTA was clearly linked to another major event which took place in the period which we have examined, the peso devaluation of 1994. The rescue package negotiated by the US government prevented the Mexican economy from major disaster and started a slow revival. All the companies which we have examined were badly damaged by the peso devaluation and have had to adopt different strategies to cope. This raises an interesting question; to what extent had both the multinationals and the local subsidiary being affected by the general euphoria which prevailed in Mexico in the early part of 1994? Had any of the companies really expected the sudden collapse in the Mexican economy? In view of the fact that all took a period of time to organise their response, it seems obvious that the devaluation was unexpected. This would seem to contradict the assertion of the companies that they had plans and strategies to cope with any eventuality.

Some of the companies said that they have been long enough in Latin America to know how to cope with changes; however all of them were affected at least by a drop in sales, which would not be the case if they had been better prepared. This contradicts the view expressed by Cadbury and Unilever. All the companies were attracted to Mexico by the booming economy of the early 1990s. They thought that the economy would continue to improve and were certain that the political and economic changes promised stability. They failed to anticipate the collapse of the peso.

The peso devaluation, which was an economic event, was partially caused by events in the political field and was carried out by politicians. This was the greatest shock for the companies in the period studied and reminded them, very forcible, that they operate in a political economic nexus. No company wants to operate in an uncertain world and all have a strong wish for a stable economy in which to operate. Though all expressed their confidence in their ability to deal with whatever situation arose, we think their experience with the peso devaluation may call this competence into question. It is no surprise that companies stressed the stabilising possibilities of NAFTA.

The peso devaluation was an event with general and particular effects. All the MNCs suffered a drop in profits. The companies experienced different effects depending on the nature of their business and their reactions were framed accordingly. Allied Domecq was forced to bring its Mexican subsidiary more into line with multinational practice. Unilever, which, at a global level, was restructuring its business, speeded up the process in Mexico to come out of the crisis in a less harmful way. Tate & Lyle, paid less pesos for its share in Grupo Sáenz and did not consider the devaluation as a deterrent to carry on with this transaction. At the subsidiary level, the responses were more particular and examples were given about the different tactics adopted. At the end of the day, the subsidiary is the one that has to take the decision on how to react. All the multinationals stressed that they would basically support their local managers in their decisions.

The MNCs said that they were not interested in local politics; they had to deal with the political situation wherever they encountered it. Nevertheless, in the case of Mexico, as some of them mentioned, the collapse of 1994 arose from the political and economic situation of the country. It is contradictory for the MNCs to deny their interest in local politics when the local situation can so seriously affect their profitability. Their repeated assertions that they look for stability is in fact a statement that they look for stability in the political situation; they do have an interest in local politics. The various statements where they talked about having a good relationship with a certain political hierarchy or being able to ask the British Ambassador to lobby for them, demonstrates that they do care indeed about the politics of the country. This highlights the interest of the multinationals in the developing state of the Mexican political system. All believe that a multi-party democracy, which was evolving in Mexico, would provide a more stable economic situation. The parent companies interests were on the structural political transformation rather than being concerned with specific office-holders. Though none of the subsidiaries mentioned the next major hurdle, the presidential election in the year 2000, all the parent companies were very aware of this election; they would see the election of a non PRI president as positive proof that Mexico was becoming the developed country on which so much of their future prosperity will rest.

The view of the multinationals about the political future differed from the view of their Mexican subsidiaries. The subsidiaries are confident that the opening up of the economy to world trade meant that Mexico was much more a part of the world economy and this in itself promised stability. They thought that the reforms had gone too far for them to be reversed; Mexico was committed to a new way. For the subsidiaries, the multinational presence itself was a stabilising factor, while the parent companies saw the elections as a crucial moment in the political and economic evolution of the country. It was the test that would prove whether Mexico was continuing to evolve.

Once again there is a certain contradiction in the views expressed. All the MNCs originally invested in Mexico because the country was offering all the necessary elements for them to operate: clear regulations, improvement of the economy and political stability. It is only after the 1994 crisis that the multinationals seemed to re-consider this condition and even to assert that the coming into power of another party would be beneficial. Whatever the PRI has failed to do, one can not deny that it has provided stability to the country. Other Latin American countries have suffered military dictatorships and revolutions; this has not been the case in Mexico. In those other countries, the MNCs had to abandon their businesses because of the political and economic chaos. The PRI had certainly provided stability for a long period and it was in the past years that the politics of the country seemed to be entering a new era. Because of their long tenure of power, they were the only party with the experience of running the country. There was no guarantee that another party would improve the current state of the economy. If another party would come to power in the year 2000, Mexico, in the short and medium term, would enter a transitional period, which will have disadvantages. A price will be paid by both the Mexican population and the businesses operating in the country.

The fact was that the Mexican government was preparing itself for the 2000 elections. In the middle of June, the Mexican government asked its international lenders to make available at least US$11 billion. This was part of a package in which the IMF, the central banks of Canada and the US, the World Bank, the Inter American Development Bank and the US Export Import Bank will have ready for Mexico; this package amounted to US$23 billion. This was basically to avoid a financial disaster such as that of 1994. [30] Mexico's President at the time, Ernesto Zedillo, praised himself as being the only president who would quit office without causing financial turbulence.

All the MNCs were aware of the current problems of a developing economy such as Mexico; present instability, inflation and some uncertainty about the political and economic future. Though there was the hope that in ten or fifteen years time Mexico may have reached the stage of being a developed economy, this is not certain. There is always the possibility that any government will be tempted to take a short term, short sighted view of a problem, answer it in a way that will solve the problem for the present but will make the future more dangerous. Without exception the companies made reference to the future using words such as 'uncertainty', 'things could be better', 'risk', 'concern' and 'instability'. These terms imply a doubt about what the near future will bring and even if some of them seem to be prepared for another collapse, all want to be sure that in the long term political and economic stability will be guaranteed.

Those companies who have invested in Mexico are not looking for an immediate return, this is the US way, but they were looking for a steady development of the Mexican economy in a longer time frame. Even in developed nations, there is always the problem of the tension between the 'have's' and the 'have not's'. This problem is much greater in a developing nation, and the existence of a large, poorly paid, or even unemployed population is a spectre which looms over the future of Mexico; one company even said 'Mexico City is the time bomb ticking under the future of Mexico'. Inequality is both a political and economic challenge and one that must be overcome to secure the future of Mexico.

The solution to some of the problems that faced Mexico were postponed until after the election. The voters had expectations and the government did not wish to remind the population of the inequalities and poor conditions in which they had been living. The last presidential elections, 1994, made it evident that Mexicans had become more politically aware and this puts pressure on the government. The fear of anti-government demonstrations if PRI were to win in the year 2000 was very real.

It is interesting that, with the exception of Unilever, who clearly stated that they have strategies to cope with possible future variations in the political or economic situation, none of the MNCs commented on this. We would assume that all companies of this size also have similar strategic future planning. No company was prepared to reveal their future strategies but it is clear that the answer of the multinational may not always satisfy the local subsidiary. It is clear that, if the electoral watershed is successfully negotiated, the parent companies are confident about the long term prospects.

It is obvious that the relationship between the multinational company and its Mexican affiliate is controlled by the financial relationship between the two. Each of the six companies which we have examined is structured in a different way and follows a different strategy of investment. Unilever Mexico is a wholly owned subsidiary of Unilever plc; it was set up to sell and to manufacture the products of the plc in Mexico; in the thirty years in which they have traded in Mexico, Unilever has followed a strategy of buying local brands which fit in with their core lists of products. During the years that Unilever has been in Mexico, they have experienced different changes in the political economy of the country.

The parent company stresses that it is the task of the Mexican management to manage in Mexico but according to the strategy of the parent company. They wish to domesticate the Mexican company as far as this is possible, with a total Mexican management. Despite the fact that the internal structure of Unilever is confusing and has been criticised, is has proved effective, at least in the case of Mexico. A Mexican was appointed chief executive of Unilever Mexico. The control over the subsidiary is exercised directly from London, through the Latin American Business Group; this distance has not affected the performance of the subsidiary. Unilever Mexico has followed the multinational strategy of concentrating on its core business and has bought and sold Mexican companies in line with this strategy.

All the companies studied invested in Mexico after 1990 except Unilever which established its first company in the middle of the 1960s. Unilever's years of experience have made a difference and probably account for the almost perfect understanding between the parent and its subsidiary. In terms of the impact of and responses to the 1994 crisis, this company seems the least affected and best able to cope with the economic situation.

Domecq Mexico wants to use all the skills and techniques of their multinational parent to improve their situation in Mexico and to market their products in the world market. In this they have the full support of their parent company, who hoped to modernise without destroying the Mexican flavour. Domecq Mexico is in a transitional period, in which managerial modernisation is the name of the game. The modality adopted was that of interlocking managerial boards with cross-representation between the parent and the subsidiary. Since the acquisition, Domecq Mexico has been through a painful process of integration with the multinational. Both parent company and subsidiary know that there was a strong objection on the employees side in Mexico to changing the structure and way of operating the company. The British management was seen as a 'stranger', with a vision of improving profits but forgetting the fact that, in a family business, it is important to have the consensus and support of the employees to make change effective.

Tate & Lyle have long followed the policy of acquiring a share in the world market by buying a large minority stake in local sugar companies. Grupo Sáenz maintained a majority share in their company but relied on the support of Tate & Lyle to help them to modernise their business. This strategy had been successful and there was a fruitful relationship between the international company and its local partner. Part of this success might be to the cross-board representation, which gives the parent company significant control over major investment decisions. Tate & Lyle's target is not only growth through acquisitions but to transform themselves into a more efficient sugar producer. The case of this company is special and is the one which best expresses the sensitivity of agribusiness to politics. As they stated, sugar is a staple product and therefore consumption will not decrease but, at the same time, the government has to secure its supply and might restrict its import, set up tariff barriers and even control prices. This is clearly foreseen and understood by Tate & Lyle because they are already investing in all the forms of sweetness and would be ready to import and export from the US to Mexico and vice versa. This might help us to understand why at the time of peso devaluation they were prepared to continue with their investment. Economic liberalisation was a major factor in their decision to invest in Mexico; first, because of the privatisation of the sugar mills; second, because all the measures the Mexican government had taken were sufficient signs to Tate & Lyle of the clear intentions of the government to move towards a more liberal economy. Tate & Lyle's major concern is a change in government policy. This company diversifies the risks in two ways; it invests in all possible means of production of sweetness and it looks for a local partner.

The other two companies which we have examined, Diageo and Cadbury Schweppes, present a very different picture. Before the merger of Guinness and Grand Metropolitan, Grandmet had followed the same strategy as Tate & Lyle, buying a large minority holding in an old Mexican company, Cuervo. The reason that Diageo kept its Cuervo investment was the growing importance and consumption of tequila in the world market. It is time to analyse this fact, step by step. As Allied Domecq mentioned above, the drop in sales was reflected, during the 1994 crisis, by the changing pattern of consumer choice. This means that when a particular drink, in this case tequila, becomes fashionable it spreads easily and quickly in the global market. In the US, this consumption is partly affected by the large population of Latin Americans living there but there is no guarantee that this consumption will continue to rise or that the emergence of another spirit will not dim the popularity of tequila. The heavy reliance of both Allied Domecq and Cuervo on this spirit poses threats and risks that they do not seem to judge important, since they are directing large resources in developing this product. It is important to mention that from the 1st of July, 1999, tequila is an 'origin denomination' spirit and no-one in Europe will be able to use this name without the authorisation of the Mexican government. This is part of the negotiations that were taking place between the EU and Mexico towards a trade agreement. [31] This is good news for both Cuervo and Sauza, Domecq's tequila brand, since they together handle 80.5% of the total export market.

The future plans of Diageo will depend on the outcome of the legal battle with Cuervo. UD Mexico will continue to operate independently, as it has been doing but they were badly affected during the 1994 crisis, because all their product is imported and the price increased immediately. Diageo mentioned different actions taken to counterbalance the economic crisis but they did not give any hint of possible withdrawal, which is in itself good, because it means that regardless of the downturns, they are interested in keeping their subsidiary. Another reason could be that, if the negotiations with Cuervo did not turn out to be what Diageo hoped, UD could be handling the imported brands that used to be part of Grandmet.

The problems with Cadbury Schweppes and its wholly owned subsidiary were very different; Cadbury Schweppes, as a multinational, decided on a new world strategy; this involved the selling of their worldwide brands to Coca-Cola. This sale has been opposed by many governments, who fear that it would establish a monopoly for Coca-Cola in their national market; Mexico was one of the countries which had rejected the plan. This is a perfect example of the way in which even the most powerful multinational must take account of the policies of national governments, which Cadbury Schweppes has singularly failed to do: they may wish to carry out their international strategy but they will not be able to do it in the way that they had arranged.

It is surprising that both Cadbury Schweppes and Coca-Cola did not foresee the possible reactions of governments to their deal. The only explanation we can suggest is that Cadbury and more especially Coca-Cola thought that they were so powerful that they became confident in their ability to dominate any market and any government. It is clear that Cadbury did not consider all the possible scenarios when deciding to exit the Mexican market. They stated they knew Latin America well and yet their Mexican operation failed to produce the profits that they expected and they also failed to foresee the opposition of the Mexican government to their merger plans.

It has been shown that political-economic risks are not the same for all companies. The six MNCs examined were drawn to Mexico by the prospects of a strong, emerging economy at the beginning of the 1990s. Unfortunately the year 1994 illuminated the deficiencies of the country; Mexico had still a long way to go before it could be considered a 'safe and reliable' location for foreign investment. All companies were not affected in the same way; the dissimilar reaction may be explained by such factors as the ownership, the management structure and the nature of their products. A positive sign was the willingness of the MNCs to continue investing and their hope that the situation would improve. The British government was also optimistic and saw Mexico as an important investment recipient country. It was interesting to see how much was expected from the elections in the year 2000. For Mexicans, it represented an opportunity to put and end to a party dictatorship but for the MNCs it was an event that might brought better operating conditions for their businesses.

Assessing the Role of Risk in Growth and Development: Evidence from Latin American, African, and Asian Countries

Phillip LeBel
Montclair State University,USA

Abstract

Globalization through international trade and investment does not lead automatically to higher rates of economic growth. Models, which focus solely on traditional economic variables, often miss important institutional considerations that are essential to an effective transition to higher rates of economic growth. In turn, models that focus exclusively on institutional variables often exclude how institutional behavior affects the level of risk. In this paper, we examine traditional and institutional models of economic growth with and without explicit consideration of risk using a sample of 63 countries from Africa, Asia, and Central and Latin America for the 1980-2002 period. Using panel regression analysis, we find that risk is an important determinant of economic growth and that policy measures that take risk into account are an essential step to successful economic globalization.

Introduction

Does risk affect the rate of economic growth? The short answer is "yes" in that greater risk reduces economic growth through its impact on the costs of economic transactions. Since globalization can expose an economy to additional risk, how countries manage risk can have significant consequences on the rate of economic growth, particularly at a time when the role of international aid has become part of a renewed public policy debate[i]. Interestingly, much of the research on economic growth and political reform has proceeded with little direct consideration of how risk can arise and what institutional measures may be needed for its effective management in the efficient allocation of resources. In this paper, we use a sample of 63 countries in Africa, Asia, and Central and Latin America to examine how risk can explain differences in economic performance. Our findings help in understanding what measures may be needed for risk management within the context of continuing policy reforms.

Institutional Considerations in the Framework of Economic Growth

Growth theory can be distinguished between traditional and new formulations. While traditional theory has emphasized the growth of inputs and technological change through saving and trade, the new growth literature places emphasis on endogenous feedback effects. De la Croix and Michel [*2002*], and Aghion and Howitt [*1998*] provide useful syntheses of the new approaches to growth. In most of these formulations, little attention is given to the incorporation of institutional variables, a consideration that becomes particularly important when growth theory is applied to economic policy.

Incorporating institutional variables in the theory of growth owes much to Williamson [*2000, 1975*], Barro [*1998a, 1998b*], Temple [*1999*], and Easterly [*2001*]. Although focused initially on economic institutions, there also has been growing attention given to political institutions and governance [*Carlsson* and *Lundström, 2002; Saint-Paul, 2000; Persson* and *Tabellini, 2000; Ayal* and *Karras, 1998; Barro, 1996*]. While this literature provides a greater understanding of growth and development, we still confront significant gaps in policy implementation, as the recent critique of globalization by Stiglitz [*2002*] has shown. We consider some of these critiques in terms of economic and political institutions.

In his review of the new growth evidence, Temple [*1999*] notes the direct positive importance of international trade, investment in education and physical capital, technology adaptation and innovation, financial intermediation, and preventing excessive increases in income inequality as key factors in determining differential rates of economic growth. He finds that population growth rates and the presence of formal democracy are less important, even though these variables figure prominently in the formulation of domestic and international aid policies in many countries[ii].

Economic institutions favorable to economic growth can be subsumed under a grouping of economic freedom[iii]. Economic freedom, which includes property rights and judicial independence, can be constricted either by international aid, or by the lack of local participation and accountability in the political process. Jones, Hellman and Schankerman [*2000*] demonstrate that corruption and state capture arise more easily when accountability is low. In turn, De Soto [*2000*] emphasizes the importance of property rights by pointing out that weak regimes skew access to credit and thus limit the efficient allocation of resources.

In terms of political variables, increasing attention has been given to democracy as a determinant of economic growth, and to whether international aid plays a constructive role. Acemoglu [*2002*], Acemoglu, Johnson and Robinson [*2001*], and Barro [*1999*] find that democracy associates positively with economic growth, but much of the evidence turns on whether one is relying on what journalist Fareed Zakaria [*2003, 1997*] calls 'illiberal' as opposed to liberal democratic institutions. Some measures of democracy rely essentially on the frequency and transparency of electoral systems, and do not take into account the importance of an independent judiciary and property rights, nor of civil and political rights. Growth may falter, as resources are miss-allocated under nominally democratic but effectively corrupt regimes.

Much of the concern over illiberal democracy dates to Krueger's 1974 essay on rent-seeking behavior by political elites. Acemoglu and Verdier [*2000*] measure the tradeoff between market failure and corruption. In the presence of weak institutions where corruption and market failure is widespread, civil wars can ensue as well, as noted in Collier and Hoeffler [*1998*], Eldabawi and Sambanis [*2000*], Ellman and Wantchekon [*2000*], and Jenkins and Kposowa [*1990*].

As to international aid and its effect on growth, the evidence is mixed. In the post World War II Cold War era, international private capital flows were limited, and much development initiatives were driven by international public aid. Following the end of the Cold War, greater emphasis has been given to international private flows. A number of studies have pointed to weak links between the level of international public aid and rates of economic growth and development [*Easterly, Levine*, and *Roodman, 2003*; *Barro, 1998a*; *Casson, 1986*; *Collier* and *Dollar, 2002*; *Collier* and *Dehn, 2001*; *Deverajan, Rajkumar,* and *Swaroop, 1999*; *Guillamont* and *Chauvet, 2001*; *Hansen* and *Tarp, 2001*; *Hansen* and *Tarp, 2000*; *Knack , 2000*; *Lensing* and *White, 2001*; *Mosely, Hudson,* and *Horrell, 2001*]. While the performance of international aid is not our central concern here, the question is why it has been less effective than many of its proponents have claimed.

One finding is that international aid can undermine political accountability [*Knack* and *Keefer, 1995*]. In turn, low accountability can lead to political instability. Mbaku and Paul [*1989*], demonstrate how political instability creates additional opportunities for corruption and inefficiency. Easterly [*2001*] and Huther and Shah [*2000*] further examine the links between corruption and international aid and efforts to promote democratic reform. Consistent with other findings, they note that aid does not necessarily lead either to improved economic or better political governance.

In contrast, Burnside and Dollar [*2000*] find a positive impact of international aid on economic growth. In turn, given growing concern over international security, there has been a new willingness to re-craft increased levels of international aid, notably the U.S. commitment to the Millennium Challenge Account [*Radelet* and *Herring, 2003*][iv]. While much of the recent interest in international aid is its potential in establishing improved governance, in our view, greater attention to how governance affects the level of risk can be even more critical to its success.

How important, then, is democracy to economic growth and development? While there is a direct relationship between democracy and development, whether democratic political reforms should proceed economic reform is still subject to debate. Comeau [*2003*] and Boko [*2002*] find that democracy expands the level of per capita income, even though some qualification may be needed[v]. As Barro [*1998a*] notes, what is more important, is the emphasis on the corollary institutions of civil society such as civil and property rights, and an independent judicial system, which together can determine the success of democratic reform in achieving both economic freedom and economic growth[vi].

Linking Risk to Institutional Models of Economic Growth

If the evidence linking democracy to economic reform is mixed, one reason may be that insufficient attention has been given to the role of risk. Indeed, Temple [*1999*] notes in his conclusion, one of main reasons why growth rates differ is that macroeconomic stability differs across countries[vii]. This now is changing, particularly in light of the East Asian financial crisis of 1997. In their review of the effects of financial globalization on developing countries, Prasad, Rogoff, Wei, and Kose [*2003*] note that financial integration can increase macroeconomic volatility, whether measured in terms of rates of growth of GDP, exports, or consumption. Fosu [*2002*] finds that political instability affects exports even more than GDP growth. In turn, Athanasoulis and Wincoop [*1997*], and Wincoop [*1999, 1994*] find that sharing economic risk can reduce growth uncertainty, and that measures to do so can increase social welfare in terms of higher levels of per capita income and wealth. This approach builds on a framework first put forth by Obstfeld [*1994*].

There are two basic and complementary approaches to the incorporation of risk in globalization models. One is the construction of instability indices of an output variable such as GDP or exports and then to explain this in terms of standard variables such as the degree of trade openness and financial integration. In a perfect market, asset prices incorporate such risks. For example, a country's external borrowing rate should embody a risk premium, just as an internal lending rate should do. Yet in the presence of imperfect information, asset prices do not fully embody risk and a miss-allocation of resources may result.

Another approach is to define an index of aggregate risk that incorporates a weighted mix of economic and political factors. The World Bank routinely takes into account sovereign debt ratings by private firms in its assessment of lending decisions. It also is paying closer attention to country composite risk, which becomes useful as a broader tool that incorporates political and economic factors. Moreover, country composite risk indices also may be useful where sovereign debt markets do not exist or work in fairly imperfect markets. Because we are interested in the broader dimensions of risk in the context of globalization, we use a country composite risk index for our analysis.

As we have pointed out, risk raises the cost of economic transactions. Other things equal, increases in the level of risk lower a country's rate of economic growth. Since there are many forms of risk, it is useful to note the various forms in which it can arise, as we illustrate in Fig.1.

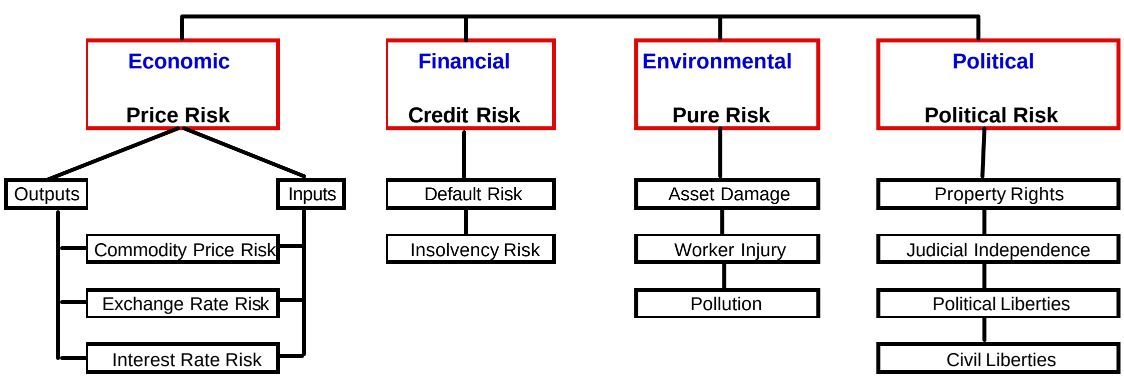

FIGURE 1
FUNCTIONAL CATEGORIES OF RISK

If there is a limitation to using a country composite risk index, it primarily does not separate the sources of risk into their respective sub-categories. Secondly, it may be considered as a "soft" variable in that it does not reflect directly observable behavior such as a coefficient of variation of GDP or export growth rates. Third, it generally relies on weights that are applied uniformly across countries in time and space when the evolution of determinants may vary. Despite these limitations, we find that a country composite index can be used to derive empirical support for the importance of risk management strategies in the context of globalization. We use the International Country Risk index for this purpose[viii].

Fig. 2 illustrates the basic relationship between country composite risk and real per capita GDP. Table A.3 in the Appendix lists the 63 countries used in the analysis, along with specification of the geographic panel groupings. For our present purposes, these geographic groupings do not rely on policy samples of reforming and non-reforming countries.

For our analysis, we are interested in the relationship of country composite risk not only to real per capita GDP, but also to standard determinants of economic growth, notably the national saving rate and the degree of trade dependence. Trade dependence captures some but not all of the dimensions of financial integration. For our purposes, trade dependence serves as a proxy for globalization of an economy.

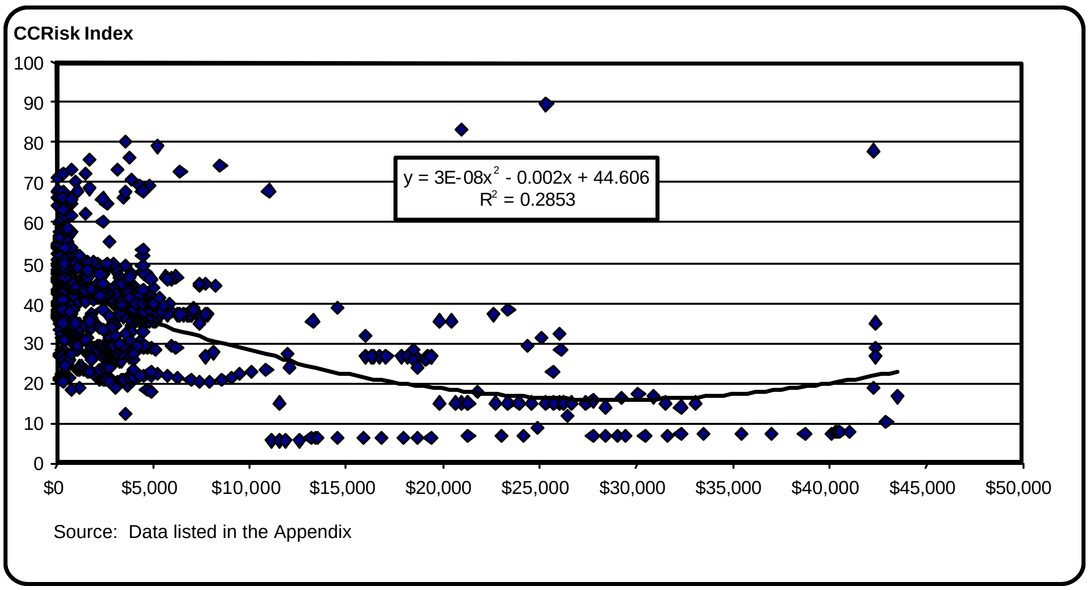

FIGURE 2
COUNTRY COMPOSITE RISK AND PER CAPITA GDP

Figures 3 and 4 summarize the basic relationship between country composite risk and the gross national saving rate and between country composite risk and the degree of trade dependence. While they reflect the global sample only, our econometric estimates provide panel separations by regions.

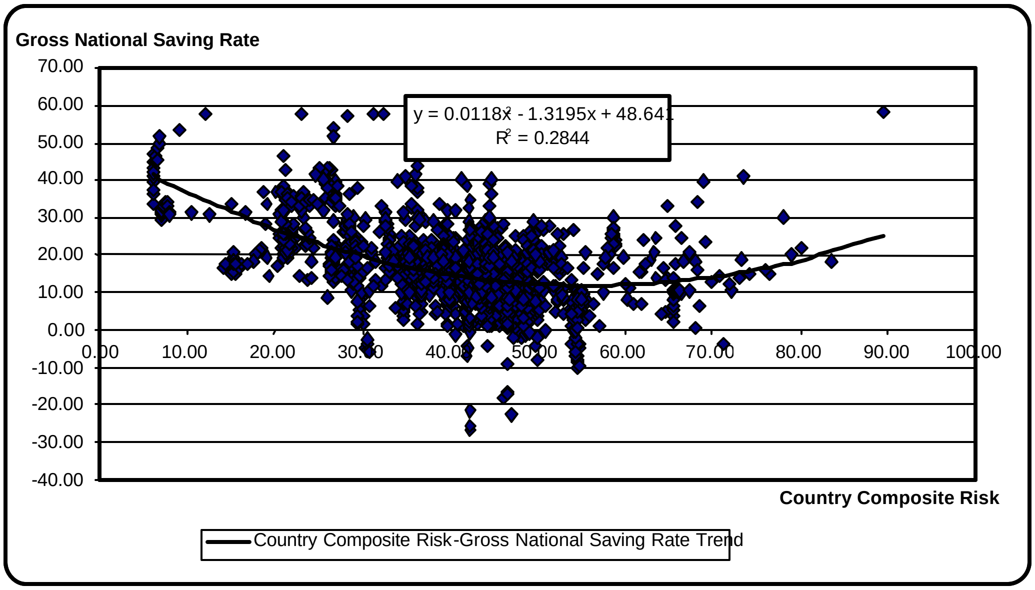

FIGURE 3
COUNTRY COMPOSITE RISK AND THE GROSS NATIONAL SAVING

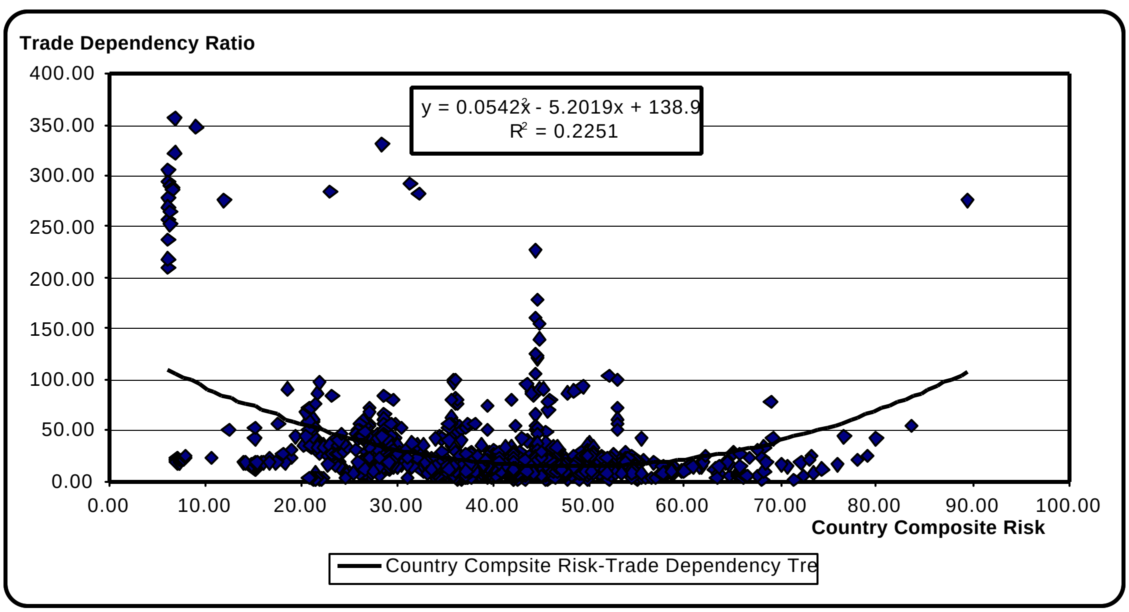

FIGURE 4
COUNTRY COMPOSITE RISK AND TRADE DEPENDECY

Given the inverse relationship posited in the pooled sample, we seek to examine the determinants of country composite risk, and how they determine in turn economic behavior across the respective regions; in our sample of East Asia, Sub-Saharan Africa, and Central and Latin American countries.

Modeling Risk in Economic Growth

We outline here three models of economic growth, beginning first with a traditional formulation of growth under globalization. In turn, we then modify this framework to include institutional variables. We then incorporate aggregate risk. In each stage, we derive random effects panel regression estimates, and report with respect to pairing Granger causality tests statistics from the pooled samples consistent with the sequential modeling framework illustrated in Fig. 5 below. In each case, the dependent variable on per capita real GDP, and all variables are expressed in log values.

In the absence of specific consideration of risk, a country's rate of economic growth depends in the first instance on a set of basic economic variables. These variables include the national saving rate, the level of trade dependency, the overall tax burden, the external debt service ratio, and interest rate differentials. Trade dependency serves as a proxy for globalization, while the savings rate, tax burden, debt service ratio, and interest rate differentials reflect a mix of domestic and international policy determinants of growth.

Other things equal, the saving rate relates positively to the growth of per capita income, as does the level of trade dependence. As to the tax burden, globalization implies in principle a reduced role by the public sector. However, the tax burden can relate positively to the growth rate of per capita income as long as public sector intervention is used to enhance the productive capacity of the economy. Thus, while we include the tax burden as a measure of public sector intervention, we leave open the question of whether it contributes positively or negatively to the growth rate of per capita income. We include an economy's external debt service ratio to capture the effects of public sector misallocation as well as imperfections in the mix of internal incentives on economic efficiency. Finally, we include interest rate differentials as an indication of the degree of local economic competition[ix].

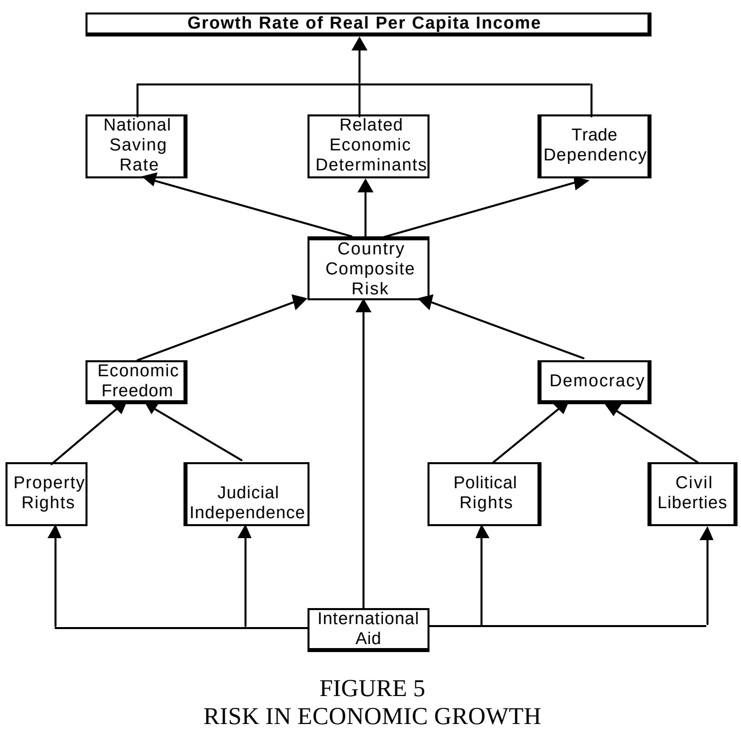

FIGURE 5
RISK IN ECONOMIC GROWTH

Based on our sample, we summarize estimates from the random effects panel regressions for all 63 countries, as well as for geographic sub-samples for the 1980-2002 period, in Table 1 below[x]. Below each regression coefficient is the corresponding computed t value, as well as the Granger null causality F tests for 2 period lags[xi]. All regression estimates are based on log values. The dependent variable is the log of real per capita GDP.

SEE	0.5340	0.4586	0.1467	0.1453

Standard policy prescriptions follow directly from this first model. They include measures to raise the national savings rate, measures to expand international trade in the economy, raising taxes while reducing government spending to reduce the debt-service ratio. They also include measures to lower interest rate differentials between the international and domestic economy (which implies for the respective regions, adjusting interest rates to stimulate investment spending)[xii]. Results for all regions are statistically significant and provide support for traditional approaches to policy reform, as countries move toward globalization.

While the standard model explains much of the variation in growth rates, it does not include major institutional variables. Moreover, while results are statistically significant, Granger causality test levels are not statistically significant in several cases. We note that for Africa, except for the savings rate and the debt-service ratio, other variables do not meet the Granger null at the 5 percent level or better. For Asia, Granger null tests fail for the savings rate, trade dependence and the debt-service ratio. For Central and Latin America, all variables satisfy the Granger null causality test, except by the saving rate.

Specification of Institutional Considerations in Estimates of Economic Growth

As a second approximation, we reformulate our model of economic growth to include institutional variables. In terms of institutional variables, the most frequently cited are economic freedom and democracy. The assumption here is, that economic growth will be greater not just in terms of a higher savings rate and greater trade dependence, but also the higher is the level of economic freedom and the level of democracy.

Adjusted R^2	0.8615	0.9006	0.8774	0.8542
SEE	0.2101	0.1466	0.1631	0.1629

We can define economic freedom in terms of three components: property rights, judicial independence, and the lack of corruption. In turn, democracy consists of political rights and civil liberties. We thus drop the role of taxes, the debt service ratio, and interest rate spreads by substituting economic freedom and democracy as determinants. Regression results are shown below in Table 2. As in the first model, the dependent variable is the log of real per capita GDP.B

In this version, the savings rate and trade dependency are statistically significant for all regions, even though Granger causality tests are weak for trade dependency. As to the institutional variables, economic freedom reduces the rate of economic growth in Asia and in Central and Latin America, while democracy appears to reduce the rate of economic growth in Asia and is statistically insignificant in Africa. When the savings rate and trade dependency are dropped, economic freedom and democracy do expand the rate of economic growth, but democracy is not statistically significant for Africa, Asia, and Central and Latin America, as are Granger null causality test results.

The Role of International Aid

One of the major debates on globalization is the role of aid in promoting economic freedom, democracy, and growth as globalization proceeds. Since economic freedom and democracy often are the focus of international aid, we reformulate our institutional model to include their impact on the rate of economic growth. We do so in two steps. The first is to examine the significance of aid directly on the rate of economic growth, followed by the significance of aid on the savings rate and on the level of trade dependency. Results are summarized in Tables 3 and 4. The dependent variable is the log of real per capita GDP.

Results in Table 3 provide evidence that international aid reduces the rate of economic growth at statistically significant levels across all regions, even though economic freedom and democracy appear to contribute to a higher rate. The question is how and why does this result appear?

We find that international aid reduces the rate of growth in real per capita GDP through its effects on the saving rate and on the level of trade dependency. We regress to international aid separately on each of these variables to test this hypothesis, results for which are reported in Table 4.

While Granger null causality tests do not provide conclusive evidence for the estimates in Table 4, international aid does not provide conclusive evidence of a positive effect on the rate of economic growth. This finding is consistent with the emphasis on privatization as part of globalization. It also is consistent with the notion that historically, international aid has been designed to accomplish a multiplicity of outcomes, of which the concern for economic growth has been balanced with concerns for international security, among other considerations.

If economic growth is but one of several objectives of international aid, what, then, of the role of international aid in promoting one of its pre-requisites, namely, economic freedom, or its role in promoting democracy, which is often cited as one of its major objectives. We reformulate our estimates to provide separate estimates of the impact of international aid alone on economic freedom, and separately on democracy. Results are reported in Table 5.

The impact of international aid on economic freedom and democracy is mixed. While not statistically significant for Asia and Central and Latin America, international aid appears to reduce economic freedom in all regions. While international aid represents an aggregate of public capital from all sources including multilateral and bilateral programs, the negative impact of aid on economic freedom seems surprising. Given the time period under review, since the first ten years corresponded to the end of the Cold War era, it may be that aid was less focused on the pre-requisites for economic growth than it has since become.

The impact of aid on democracy is also somewhat surprising. It exerts a negative influence in Africa, even though there is a positive association for other regions. However, the results are statistically insignificant for the global sample, for Asia and for Central and Latin America. Taken together, we find the impact of international aid on economic growth, economic freedom, and democracy either negative or weakly positive. In our view, one reason for this finding may be that the impact of aid on risk has not been taken more explicitly into account.

Factoring Aggregate Risk into Economic Growth

We now reformulate our growth model using an index of country composite risk as a determinant, results for which are reported in Table 6. Holding constant the level of risk, the national saving rate and trade dependency exert a stronger influence on the rate of growth. Moreover, the higher is the level of risk; the lower is the rate of growth, given a region's saving rate and trade dependency level. We qualify these findings in noting, however, that country composite risk is not statistically significant in the Asia and Central and Latin America panels.

We further examine separately the impact of risk on the saving rate and on the level of trade dependency. Results are reported in Table 7. Here we find that risk exerts a negative impact on the savings rate in all regions and is statistically significant in all cases except Africa. In turn, risk exerts a consistently and statistically significant negative effect on the level of trade dependency in all regions, even though Granger null tests are not statistically significant for Africa.

We now revisit the role of international aid and ask whether international aid increases or reduces the level of risk. Results are reported in Table 8. While the Granger null cannot be ruled out for Central and Latin America, international aid increases country composite risk at statistically significant levels in all of the panel estimates.

One has to ask what are the purposes of international aid. We have noted the perverse effects on the national saving rate, on trade dependency, and risk in Tab. 4 and 6, as well as the weak effects on economic freedom and democracy in Tab. 5. We conclude that while international aid may have short-term beneficial impacts in such forms as humanitarian assistance, the net effect does not strengthen the rate of growth for countries that increase their participation in the global economy.

Determinants of Aggregate Risk

What determines the level of aggregate country risk? While there are many components, we focus on the components of economic freedom and democracy as determinants of its level, holding constant the level of international aid, results for which are reported in Tab. 9.

Holding constant the level of international aid, stronger property rights and judicial independence are important determinants that reduce the level of country composite risk. While the Granger null tests do not hold for aid in Central and Latin America, and while the Granger null is not satisfied for property rights in Asia, and for judicial independence in Central and Latin America, all results are statistically significant. This suggests that economic reform, whether sustained through international aid or through domestic measures alone, should place priority emphasis on strengthening property rights and judicial independence, which reduces the level of risk, and thus raises the growth rate of per capita income.

The results for the democracy determinants are much weaker. While the expansion of civil liberties reduces the level of risk in African, Asian, and Central and Latin American countries, the results are not statistically significant nor do they meet the Granger null causality test. As to political rights, while their expansion also reduces country composite risk, the results are not statistically significant, and only for the global sample does the result meet the Granger null test.

Should countries ignore political reform in pursuit of economic growth and development? Clearly the answer is no unless greater democracy reduces the rate of economic rate of growth by some significant level. On the other hand, it is clear that expanding economic freedom through strengthened property rights and judicial independence can lead to significant outcomes on the rate of economic growth.

Strengthening property rights and judicial independence represent important steps in the expansion of economic freedom, which in turn expand the rate of savings and the level of trade dependence[xiii]. These variables carry more important, positive impacts on the rate of growth than efforts to raise the saving rate and trade dependency alone. In terms of risk management tools, it is important not just to emphasize property rights and judicial independence. It also is important to strengthen financial integration. Yet for financial integration to succeed, it also is important to expand ways of managing risk. This can occur not just through deposit, life, and property insurance programs, but also through the extension of risk management products to other stages in the resource allocation process. Shiller (2003) points to an expanding range of contracts through which we can better manage risk. The question is how to translate these innovations into useful products that can be used in the global economy, particularly those developing economies who are engaged in reforms designed to increase their participation in international trade and investment.

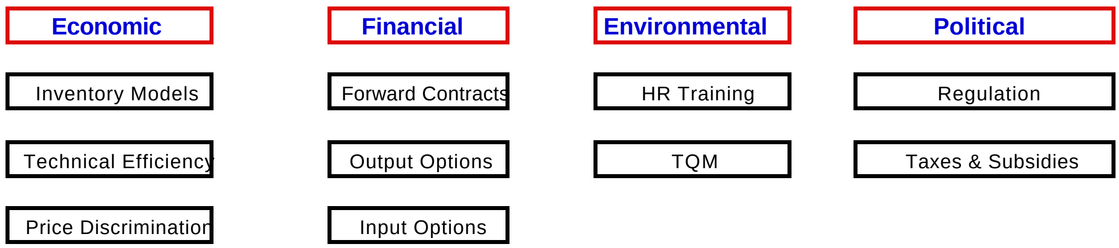

FIGURE 6
STRATEGIES FOR RISK MANAGEMENT

Figure 6 illustrates the range of areas for which risk management innovation strategies are appropriate. As globalization proceeds, for countries that depend on a focused range of exports, creating and sustaining markets for forward and futures contracts represents an important complement to the ongoing process of promoting foreign direct investment and the promotion of local equity markets.

Conclusion

As the literature on financial economics has shown, while risk cannot be eliminated, it can be minimized through diversification, through the creation of risk management contractual instruments, and through prudential management of economic policy. In turn, risk management also implies good governance of the political sphere, which is where concern over democratization comes into play. Democracy per se does not imply a higher or lower level of risk since countries may choose policies that are inconsistent with achieving sustainable rates of growth.

The challenge of globalization involves not just expanding international trade and investment. It also involves risk. Successful globalization will require a reformulation of economic policy to take into greater consideration the role of risk. Until now, most policies for globalization have been established either on purely economic determinants alone, or with some role for institutional reform. The next step is to factor risk more explicitly into the process of economic policy and institutional reform.

Appendix

Data Sources

Data used in this analysis have been compiled from several sources. We list below the variable and the source. All variables have been transformed into log values. The time period selected is 1980-2002.

End Notes

ii International aid, which has declined as globalization has proceeded, has recently been seen as an important instrument for undertaking sustainable political transitions, although its effects are subject to much debate. Much of this debate has arisen in the recent U.S. decision to launch the MillenniumChallenge Account aid initiative.

ii In the new institutional economics literature, the level of democracy is not easily measured. At one level is the tracking of elections in terms of participation rates, frequency, and other indications of popular participation. Ted Robert Gurr's Policy project has provided an important benchmark in the measurement of political regimes, and has a useful website with country-level estimates:

http://www.cidcm.umd.edu/inscr/polity/index.htm At the heart of the political economics literature is the debate on whether political democracy is exogenous or endogenous to growth. Much of the literature can be traced to Friedman's 1962 essay on *Capitalism and Freedom*, and which was expanded to international economic development with *Free to Choose* (1991). However, Friedman's point has been restated in terms of the distinction between whether economies have policies that support the necessary conditions for democracy and in turn whether those policies are conducive to economic growth

[iii] A more explicit definition requires specification of incomplete markets and the theory of contracts (Salanié, 2000).

[iv] Some of this interest may have been driven by security concerns following the events of September 11, 2001, but the agenda also seeks to encompass some of the governance issues in a more systematic way than has been done in the past.

[v] Comeau uses Raymond Gastil's Index of Political and Civil Liberties to derive a positive relationship between democratic institutions and economic growth for a sample of 82 countries in four continental regions. Boko uses the Freedom House survey of political and civil liberties (the successor to the Gastil survey) and the Polity98 indicators of democracy noted above to derive a positive relationship between democracy and economic growth for a sample of 20 countries in Africa. The measurement problem here is complicated by what Fareed Zakaria noted in his 1997 essay in *Foreign Affairs*, "The Rise of Illiberal Democracy." Zakaria pointed out that the policies designed to promote open and frequent elections misses the important corollary condition of the defense of civil and property rights, whose existence depends in turns on the existence and functioning of an independent judiciary operating under internationally recognized standards of law.

As to population growth, most studies confirm that strong efforts to restrict population growth work less well than efforts to promote education and economic growth, which in turn affect the choice of family size. Whether this justifies deliberate efforts to restrict access to information on family planning is, however, a different matter.

[vi] Barro (1998b) cites Milton Friedman's 1962 *Capitalism and Freedom* as a forerunner of many of the ideas that have guided the research on the new institutional economics of growth. However, he seeks to distinguish between the exogeneity and endogeneity of democracy. Barro cites Seymour Martin Lipset's 1959 observation by Aristotle that prosperity inspires democracy, meaning that democracy per se is endogenous to growth. This reinforces the notion in the previous reference that sustaining civil and property rights under an independent judiciary is an important precondition not just to growth but to the emergence of democracy in its fullest potential.

[vii] What makes this even more interesting is that the literature on financial economics is replete with measures and models of risk, yet there is little obvious effort to link this literature to traditional and new institutional models of economic growth.

[viii] International Country Risk Group index, World Bank, Washington, D.C. We have inverted the ICRG scale of 1-100 so that a higher number indicates higher levels of risk.

[ix] This measure is based on the difference between the LIBOR and the local mean central bank lending rate.

[x] Data sources and scales used are listed in the appendix.

[xi] Although Granger null causality tests may have a downward bias in a pooled sample, we report them nevertheless to provide some indication of the robustness of the reported t-statistics.

[xii] We have not specified other monetary variables such as the inflation and foreign exchange rate, but standard policies include emphasis on reducing the rate of inflation as well as adjusting the foreign exchange rate to internationally competitive levels.

The Risk Management of Taiwan's Venture Capitalists Invested in China: A Process Perspective

Chung-Chu Liu
Ming Chuan University, Taiwan
Shiou-Yu Chen
National Taiwan University, Taiwan
Regina Chen
Taiwan International Securities Corp., Taiwan

Abstract

The transition from plan to market has become a dominant theme in China in the last two decades. A growing body of literature on the process of this transition has been produced. However, the issue of uncertainty and risk for foreign venture capital firms and other equity investors in the market has been neglected. The uncertainty and risks are emerging at a number of levels and areas. This article try to use a process perspective to identify the uncertainty the risks facing by Taiwan venture capitals operating in China and furthermore, offer some alternative solutions for every uncertainty or risk that we have found. Qualitative and open-ended responses to questions were collected from 13 VC principals, agent, and third-party. The content analysis method was adopted to examine the data collected. We offer some suggestions and solutions to manage these uncertainty and risks.

Introduction

Motivation

New businesses are subject to more market risk than established businesses because they are often exploring markets where competitive equilibriums among buyers, suppliers, potential entrants, current competitors, and product/service substitutes have not been established (Porter, 1980). Providing venture capital is a new financial services that has emerged in the sixties in the United States, came over to the United Kingdom in the seventies and developed in Continental Europe in the eights. The venture capital funds are managed by small teams of highly qualified venture managers, general partners of the fund, who will generally receive a part of the raised capital gains as an incentive. Its main objective is long-term capital gains to remunerate risks (Tyebjee & Bruno, 1984; Fassin, 1998).

Prior research has identified two types of risk relevant to venture capital investment: agency risk, which pertains to risk caused by divergent interests between venture capital firms and their portfolio firms, and market risk, which pertain to risk related to unforeseen competitive conditions affecting a market (Fiet, 1995). Clercq, Goulet, Kumpulatinen, and Makela (2001) propose that Fiet's concept of market risk covers two dimensions of risk, business risk and systematic risk. Business risk pertains to a lack of knowledge about the competitive conditions in a specific market, whereas systematic risk pertains to risk stemming from external factors not under the control of the venture capitalist (e.g. technological obsolescence). Both dimensions of market risk may have a detrimental effect on a given industry, company stage of growth, or geographic region. Based on these concepts of risk, Clercq, Goulet, Kumpulatinen, and Makela (2001) hypothesize that in an effort to achieve superior returns on portfolio company investments, venture capitalists will choose either a specialization strategy in order to control for agency risk and directly control for business risk, or a diversification strategy to control for systematic risk and indirectly control for business risk.

Purpose of Study

Because venture capital financing involves making decisions under conditions of high uncertainty, previous research has focused on the use of several criteria to determine whether or not to invest in a particular company: the venture's expected risk and return profile, the attractiveness of the product or market, the quality of the venture's top management, and the fit between the team's skills and the venture's apparent needs (Tyebjee & Bruno,1984; Goslin & Barge,1986; Hisrich & Jankowicz,1990). Rational decision-making models which follow a step-by-step and logical sequence have been used to describe the venture capital decision-making process (Tyebjee & Bruno, 1984). Frederiksen (1997) concluded that venture capitalists will not necessary engage in a logical step-by-step process when faced with decision characterized by a high degree of uncertainty. Further understanding of the venture capitalist's decision making process may arise when considering whether different factors become important during different stages of evaluation. For example, Zacharakis & Meyer (1995) found that the focus is initially on product and market characteristics, and later shifts more to the characteristics of the entrepreneur and the management team.

A review of the literature as above identified a number of factors that are deemed to be important in the evaluation of venture capital proposals. The most important of these were high risks, high expected returns, the lack of alternate traditional sources of capital and other non-financial factors such as the competence of management. Therefore, the purpose of this paper is, firstly, to briefly review those factors importance in venture capital risk management by process and secondly, to suggest some solutions for risk management when processing venture capital.

Literature Review

Risk of venture capital

Venture capitalists can be defined as any individuals or institution which provides "debt or equity capital for the growth of small business at any stage before going public" (Knight, 1973). Venture capital investing can be defined broadly as "investment by professional investors of long-term, risky equity finance where the primary reward is an eventual capital gain, rather than interest income or dividend yield" (Wright and Robbie, 1997; Parker & Parker, 1998). Fassin (1998) defined "Venture capital as a new financial service operates in the market of providers of funds and in addition in the market of service." Acker (1991) defined the venture capital industry has to position itself into a niche with other providers of capital. Therefore, this new service needs also a lot of general marketing communication: the promotion of venture capital as a specific product within the financial products or services.

Fiet (1995) compares risk avoidance strategies employed by business angels and venture capital firm investors. It finds that differences in their approaches to evaluating risk lead them to hold predictably different views of the dangers of market and agency risk. Market risk has been described in the strategy literature as the degree of uncertainty associated with gaining a competitive advantage due to environmental factors. The following potential indicators of market risk were thought to be among the most promising of those found in previous conceptual research: 1. Technical obsolescence can cause losses when entrepreneurs invest in specialized assets.2. Many competitors increase the difficulty of colluding to increase the level of joint profits.3. Many potential, new competitors increase the prospects that additional new firm will be bidding to provide more products/services at lower, more competitive prices.4.Many substitute product/ service blur any distinction is output held by supplier.5. Weak customer demand for a product or service cause sellers to offer concession that increase risk of market losses. 6. Market attractiveness is a function of its size, growth and accessibility and on the existence of a market need. The concept of agency risk has been described by financial economists, but only a couple of known studies have attempted to apply it in the venture capital arena (Barney, Busenitz, Fiet, Moesel, 1989; Fiet, 1991). The following potential indicators are extensions of those found in the mainstream literature and were selected for further study: 1.Potential dishonest entrepreneurs increase the risk that they will deliberately withhold information that is critical to equitable contract negotiation. 2. Entrepreneurs knowing more than venture capitalist about the enterprise constitute a form of information asymmetry that creates an agency risk when entrepreneurs are opportunistic. 3. Great distance to be traveled between the venture capitalists and the entrepreneur's enterprise increase the likelihood that less frequent monitoring will permit loss. 4. Short-term self interest seeking by the entrepreneur inhibits joint profit maximization for both the venture capitalists and the entrepreneur. 5. Numerous entrepreneurs to be monitored increase a venture capitalist's span of control and decrease the time that can be spent monitoring each venture.6. Not performing as agreed may result from either unforeseen circumstances or from self-interest seeking with guile.7 Game playing is a form of intentional self-interest seeking. There is a substantial evidence to indicate that venture capital firm investors view market risk as more threatening than agency risk. They may worry less about agency risk because they are able to protect themselves through the use of boilerplate contractual terms and conditions that they append to each venture capital agreement. Boilerplate reduces the cost of protecting themselves against agency risk by generating economies of scale in the writing of contracts (Fiet, 1995). Tybee & Bruno (1984) examined how venture capital firm investors evaluate the risk of a deal. They found that the venture capital firm investor's evaluation consisted of five assessment stage: market attractiveness, product differentiation, managerial capabilities, resistance to environmental threats, and anticipated cashout potential. Each of these stages evaluated market risk with the exception of managerial capabilities, which is an agency issue. In general, however, venture capital firms seem to be assessing market factors more than agency factors. Buhnka & Young (1987) concluded the loss percentage risk at different investment stages as follows:

TABLE 1 THE LOSS PERCENTAGE RISK AT DIFFERENT INVESTMENT STAGES

Investment stage	Risk of investment loss
Seed stage	66.2%
Start-up stage	53%
Second stage	33.7%
Third stage	20.1%
Exit stage	20.9%

Risk Management of Venture Capitalist

Reid, Terry & Smith (1997) has examined a sample of paired investor-invested relationships in the U.K. venture capital industry, with a view to analyzing how risk is managed, within a principal-agent framework. The involved analyzing risk management under four heading: expected return, portfolio analysis, screening, and risk sharing. The following conclusions emerge under each of these headings. 1.Expected returns: (1) Both investors and investees perceive themselves to be exposed to significant levels of risk; (2) Investees are inclined to considers their risk exposure to be irreducible; investors are more inclined to feel risk can be managed; (3) Investees take it for granted that risky situations involve an upside and a downside; investors are more inclined to seek means of enhancing the upside and attenuating the downside; 2.Portfolio balance: (1) Investors seek to construct a balanced portfolio, offsetting good outcomes against bad, by avoiding single sector and single technology investment involvements; (2) The average portfolio size falls short of that suggested by diversification considerations because of organizational feature; 3.Screening: (1) Risk/return analysis is widely used by investors; (2) Progression between perceived risk classes of investors is not proportioned . It may be subject to jumps; (3) At high level of risk, many projects are un-fundable, even to venture capitalists, as required IRRs are perceived as unbounded; (4) Investors assume investees will overstate returns and understate risks. They attempt to limit adverse selection by rigorous screening and carefully due diligence, leading to just 3% of proposal being backed; (5) Investees know investors screen with a fine filter and set high hurdle IRRs, and respond by over optimism in formulating their business plan. This partly sustains investor's expectations of adverse selection. 4.Risk sharing: (1) Invetsees overestimate potential rewards to investors, and investors overestimate risks of investees; (2) Investors seek risk-sharing benefits from their relationships with investors; (3) Both investors and investees dislike fixed pay-off arrangement for investees, feeling they disturb incentives on both sides; (4) Investees are sufficiently exposed to risk, post-contract, to sustain effort. Fassin (1998) provided a synthetic view on the venture capital process: Funds Raising, Deal Generation, Screening/ Analyzing, Investment, Monitoring, Exit. Once the team is formed, the primary task is funds raising. The complex and difficult exercise of funds raising from the team towards potential investors in venture capital funds: financial institution (bamks, insurance companies) and industrial institutions (big company). In order to select the possible investment

Methodology

Data Collection

The least structured form of interviewing is the non-structured or nondirective interview. Here no pre-specified set of questions is employed, nor are the questions asked in a specified order. Furthermore, no schedule is used. With little or no direction from the interviewer, respondents are encouraged to relate their experiences, to describe whatever events seem significant to them, to provide their own definitions of their situations, and to reveal their opinions and attitudes as they see fit. The interviewer has a great deal of freedom to probe various areas and to raise specific queries during the course of the interview. There are three interviewing method as above. The researcher asked interviewees to gather together for focused interview, but they refused to get together because of secrets. So, the researcher used the in depth interview and nondirective interview.

Sample design

We had in-depth interviews with 15 interviewees with either investment or market survey experience in China or having lived in China for some period of time. After obtaining their consent, we taped their reports for about 32 hours, which were later converted into written notes of 65 pages coded by serial numbers. We also requested background information of their companies and gathered press cuttings to complement the content of our interviews. When such initial decisions have been arrived at the researcher is ready to develop a list of interview questions or areas for observations. The initial questions or area for observation are based on concepts derived from literature or experience. Since these concepts, as you know, do not yet have proven theoretical relevance to the evolving theory, they must be considered provisional. Nevertheless, they provide a beginning focus, a place for the researcher to start (Strauss & Corbin, 1990). The content of our interviews consisted of the following aspects: 1. what risks you meet in every stages of venture capital? 2. How do you manage the risk in every stages of venture capital?

With respect to sampling, researchers must at first define the outline of the subjects in their studies to pinpoint their research groups. Then they determine their data profile (observations, in-depth interviews or literature analysis) based on the availability of the data and researchers' schedule. By taking the above sampling principle into account, we outlined our interviewees' profile based on purposive sampling method: 1.Members of Taiwan Venture Capital Association; 2.With experience in conducting business survey, participating in investment decision making and residing in China for several years; 3.Working at well-established firms (which would enable us to obtain valuable information for our analysis). Thanks to assistance from Taiwan Venture Capital Association and several VC firms, we conducted our interviews with the 13 persons working in the Taiwan VC industry. We interviewed the following 13 persons with impressive VC background; these are their sample profile as follows:

TABLE 2 THE RESEARCH SAMPLES

Code	Job Title	Sex	Age	tenure	education	Principal/agent
A	Chief Secretary	Female	45	16	Master	Third-party
B	President	male	52	25	Master	agent

L	President	male	45	15	Master	agent
M	Vice President	male	48	22	Master	agent

Data analyzing- Content analysis

Content analysis allows the investigator to observe a communicator's public messages at times and places of the investigator's own choosing. The procedure also allows him to carry out his observation without fear that the attention will bias the communicator, something that would be more difficult if the analyst were trying to watch at the scene (Budd, Thorp & Donohew, 1967). Berelson defined content analysis as a research technique for the " objective, systematic, and quantitative description of the manifest content of communication (Berelson,1952)? Holsti (1969) defined content analysis is any technique for making inference by objectively and systematically identifying specified characteristic of messages. No content analysis is better than its categories, for a system or set of categories is, in essence, a conceptual scheme. The analyst looks for classification categories in the nature of the research problem itself (Budd, Thorp, Donohew, 1969).We conclude six stages by above mentioned :1 Fund Raising**:** teams towards potential investors in venture capital funds: financial institutions, industrial organizations; 2. Deal generation: teams has to attract proposals from potential entrepreneurs; 3. Screening/ Analyzing : searching and accessing a great number of proposals and to the best deals ; 4.investment : venture capital fund managers select portfolio composition carefully. 5. Monitoring: venture capital funds do provide an active help and advice to their investee companies. 6. Exit: venture capital fund managers have to be very active is when they want to sell the company, either to a private investor or through an initial public offering (IPO) on the stock market (Fassin, 1998). We give definitions of every category and some example then began to code.

The smallest segment of content counted and scored in content analysis in the coding unit. The most common coding units are words, a theme or assertion, a paragraph, an item, a character, group, object, or institution, and space or time. While counting specific words is one of the easier forms of content analysis, it does not provide the analyst with as much information as some other methods. This study is used theme as unit of measurement. According to categories as mention above, we have 360 themes. Random sampling 90 themes from 360 themes to be pretest by researcher, two interviewees.

Reliability & Validity

A composite reliability coefficient may be computed by the following formula in which N denotes the number of judges. I choose two judges to count the pretest reliability. According to interview records, the number of sentences is 90. I count the reliability as follows:

TABLE 3 THE PRETEST RELIABILITY OF THIS STUDY

	Researcher	Judge 1
Judge 1	0.82	---
Judge 2	0.84	0.85

According to the formula, the average inter-judge agreement is 0.84, and the composite reliability score is 3(0.84)/1+2*0.84=0.94.The reliability is appropriate. I continue to the whole reliability. A composite reliability coefficient may be computed by the following formula, in which N denotes the number of judges. I choose all samples and two judges to count the reliability. According to interview records, the number of sentences is 360. I count the reliability as follows:

TABLE 4 THE RELIABILITY OF THIS STUDY

	Researcher	Judge 1
Judge 1	0.80	---
Judge 2	0.82	0.81

According to the formula, the average inter-judge agreement is 0.81, and the composite reliability score is 3(0.81)/1+2*0.81=0.927.The reliability is appropriate. Next, we concerned about the validity of this study. It also sometimes referred to as content validity, has most frequently been relied upon by content analysis. If the purpose of the research is a purely descriptive one, content validity is normally sufficient. Content validity is usually established through the informed judgment of the investigator. My research interviewed some experts in Taiwan who were experience, so this should be enough.

Result

Risks in the process of venture capital

This purpose of this paper is, firstly, to briefly review those factors importance in venture capital risk management by process and secondly, to suggest some solutions for risk management when processing venture capital. According to Fassin (1998), there are six stages of venture capital process as follow; we gave some scores by interviewees' responses:

TABLE 5 RISKS IN THE PROCESS OF VENTURE CAPITAL

	Funds Raising	Deal Generation	Screening/ Analyzing	Investment	Monitoring	Exit
A	3	3	3	3	4	5
B	3	3	3	4	5	5
C	3	3	4	3	5	5
D	3	3	3	4	4	4
E	4	3	4	3	4	5
F	3	3	4	3	4	5
G	3	3	3	4	5	5
H	3	3	4	4	4	5
I	4	3	3	4	5	5
J	3	3	4	4	4	4
K	4	3	4	4	5	5
L	3	4	4	4	5	5
M	3	3	4	4	5	4
	Funds Raising	Deal Generation	Screening/ Analyzing	Investment	Monitoring	Exit
Scores	42	40	47	48	59	62
Sequence	5	6	4	3	2	1

1: not very important 2::not important 3::important 4:middle important 5:very important

The result shows, sequence of importance of risks is exit, monitoring, investment, screening/analyzing, funds raising, and deal generation. The sequence is different form Buhnka & Young (1987). Their research emphasis risk on former stages but our research is on latter stages. Based on Regina, Chen, Liu (2003) suggested most Taiwanese VC firms prefer to build an overseas holding company to invest in China in a bid to hedge risks caused by inadequate exit mechanism and tightly foreign exchange control. Even if they are not allowed to transfer any of their original investment money, they still can have a full control of their capital inside China.

Risk Management in the process of venture capital

We concluded the 13 interviewees whose experiences of risk management in the process of venture capital in China.

TABLE 6 RISK MANAGEMENT IN THE PROCESS OF VENTURE CAPITAL IN CHINA

	Risk	Risk management
Funds Raising	Percentage of joint venture Government regulatory Exchange Ownership	Clear funding goal Exchange into RMB Trust
Deal Generation	Honest cooperation Conflict in concept Conflict in language Conflict in culture Personal moral Personal capability	Guanxi set up Careful recruit and select Investigate for family
Screening / Analyzing	No standard format of statement Dishonest in financial statement Cheat in financial statement	Trust set up Account audit Internal audit
Investment	Industry choice Company choice Selection portfolio composition	Make money industry Industry trend
Monitoring	Problem in Operation Dishonest in financial statement Cheat in financial statement	Branch set up Spend time for supervisor Communication Account audit
Exit	Price of target Percentage of equity shares IPO	Negotiation MBO Sell out

According to the result, in the fund raising stage, the risk management policy emphasis on clear funding goal, trusts build. In the deal generation stage, the risk management strategy focused on guanxi set up, carefully recruit and select good partners. Using account audit and internal audit to help evaluate related proposals plays an important role in screening/ analyzing stage. Choosing the making money industry is essential for investment stage. In order to prevent cheating, spend time for supervisor and account audit is necessary. At last, negotiation, management buy-out is good methods for risk management in the process of venture capital. This study used qualitative approach method to make conclusion on risk management methods of venture capital in China.

Conclusion & Suggestions

Conclusion

In order to boost operating efficiency and continue to expand business in an increasingly competitive global market, enterprises must go global. To achieve this goal, enterprises must adopt a successful entry mode. Taiwan Venture Capital industry has played a critical role in the rapid development of Taiwan's IT industries. To get a better understanding of how the VC industry in Taiwan has succeeded in this respect, we have conducted a research and interviewed 13VC professionals were interviewed with respect to their progress in moving into Mainland China. Then we have sorted and analyzed the information and data thus collected with advanced methods. In the end, we have come to the following conclusions: 1. the sequence of importance of risks is exit, monitoring, investment, screening/analyzing, funds raising, and deal generation; 2. we suggest some solutions for risk management of venture capitals invested in China.

Suggestions

Based on our research results, we would like to suggest the government, the VC industry and academic community take the following actions: firstly, thanks to the tax incentive plan initiated by the government, Taiwan VC industry was able to enjoy significant growth in terms of fund size and number of registered VC firms over the past decade. Now with the tax incentive gone, source of VC capital is expected to decline as institutional and individual investors have no incentive to invest in VC funds. As such, Taiwan's VC community is concerned about their future and has started to look elsewhere for investment opportunities. Therefore, we suggest that the government put further stimulating measures into place, speed up bank reform and open up financial market, so that new capital infusion can be directed into VC funds and Taiwan VC firms can continue to keep their roots in Taiwan. Secondly, this paper provides an empirical analysis of risk management arrangement adopted in the relationship between the venture capital investor and his investees by process perspective, it also give some solutions for businesses that are interesting to invest in Mainland China from all over the world.

Strategic Control as a Critical Part of Strategic Management

Jan Papula
Comenius University in Bratislava, Slovak Republic

Abstract

Strategic control is presenting an integral part of strategic management and critical part of strategic management process. Under conditions of an uncertain and dynamic environment, managers often seek strategic control as an important way for enhancing and developing strategic management of their organization. There are many differences between operational and strategic control. In the theory of strategic management there are four basic types of strategic control: premise control, strategic surveillance, implementation control and special alert control. Each of this four types strategic control are important for successful strategic management of organization.

Strategic Management under Conditions of an Uncertain and Dynamic Environment

Competitive advantage is considered the basis for superior company performance. To perform at such a level consistently, a firm often has to pay attention to the evolving system of competitive advantages. Managers now face the task of creating and developing system of strategic management as a process that allows continuous management change and adaptation to a dynamic environment. Managers must recognize and cope with multiple states of coexisting stability and instability and be flexible in making rapid and effective changes.

Under conditions of an uncertain and dynamic environment, managers often seek to enhance their firm by developing control in management, specially strategic control in strategic management.

Strategic control consists of determining the extent to which organization's strategies are successful in attaining its goals and objectives. If the goals and objectives are not being reached as planned, then the intent of control is to modify the organization's strategies and implementation so that the organization's ability to accomplish its goals will be improved.

Operational and Strategic Control

Before we proceed to scan the term Strategic Control, we need to start with explaining what "control" is. Control, in the business administration sense, is most often discussed in the context of operational management or budgeting. In the control of operating and budgeting expenditures, the focus is usually for a time span of a year or less. Quantitative measurements are used to determine whether actual expenditures are exceeding planned spending, the emphasis is on internal operations. Corrective action is often taken after the budget period has elapsed.

But in strategic control, the focal time period usually ranges anywhere from few years over a decade, qualitative and quantitative measurement are taken, management assesses both internal operations and the external environment. The process is ongoing, because top management cannot wait for several years to evaluate results.

TABLE 1. DIFFERENCES BETWEEN OPERATIONAL AND STRATEGIC CONTROL

Operational control	*Strategic control*
Time period is usually one year or less	Time period is lengthy – ranging for a few years
Measurements are quantitative	Measurements are qualitative and quantitative
Concentration is internal	Concentration is internal and external
Corrective actions may be taken planning period have elapsed	Corrective actions are ongoing

Operational control systems require systematic evaluation of performance against predetermined standards or targets. A critical concern here identification and evaluation of performance deviations, with careful attention paid to determining the underlying reasons for and strategic implications of observed deviations before management reacts. Some firms use trigger points and contingency plans in this process. [3]

Strategic controls are intended to steer the company toward its long-term strategic goals. Strategic controls to meet top managements' needs to track the strategy as it is being implemented, to detect underlying problems, and to make necessary adjustments. These strategic controls are linked to the assumptions and the key operating requirements necessary for successful strategy implementations. Ever-present forces of change fuel the need for a focus of strategic control.

The "quality imperative" of the last 20 years has redefined global competitiveness to include reshaping the way many businesses approach strategic and operational control. What has emerged is a commitment to continuous improvement in which personnel across all levels in an organization define customer value, identify ways every process within the business influences customer value, and seek continuously to enhance the quality, efficiency, and responsiveness with which the processes, products, and services are created and supplied. This includes attending to internal as well as external environment.

Strategic control is a crucial part of strategic management process. Strategic management process consists from four basic parts (Fig. 1):

1. Environment scanning
2. Strategy formulation
3. Strategy implementation
4. Strategy control

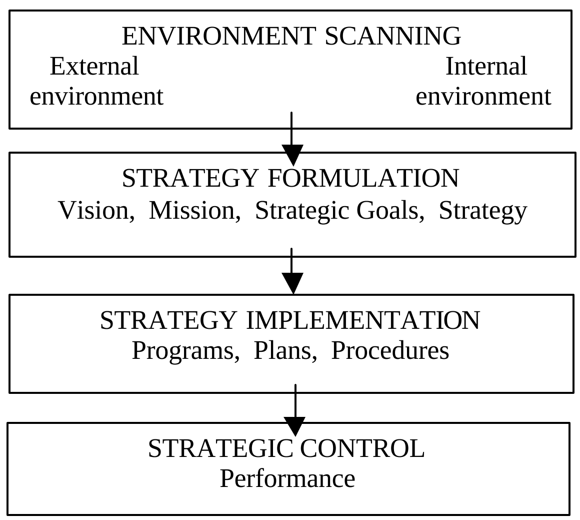

FIG. 1. FOUR BASIC PARTS OF STRATEGIC MANAGEMENT PROCESS [2]

Establishing Strategic Control

According to John A. Pearce II. [4] The control of strategy can be characterized as a form of "steering control". Ordinarily, a good deal of time elapses between the initial implementation of a strategy and achievements of its intended results. During that time, investments are made and numerous, projects and actions are undertaken to implement strategy. Also during that time, changes are taking place in both the environmental situation and the company's internal situation. Strategic controls are necessary to steer the firm through these events. They must provide the basis for adapting the firm's actions and directions in implementing its strategy to these developments and changes.

The four basic types of strategic control are (Fig. 2):

- ??Premise control – is assumption testing
- ??Strategic surveillance - is the open-minded monitoring of the internal and external environments to see if any assumptions you made about your strengths, weaknesses, opportunities, and threats have been violated.

?? Implementation control - depends upon your willingness to admit that your assumptions may be inaccurate when subjected to the day-to-day meat grinder test.

?? Special alert control - is simply a system designed to monitor your key assumptions that are critical to the success of your strategic plan, which assumes that you have identified those key assumptions.

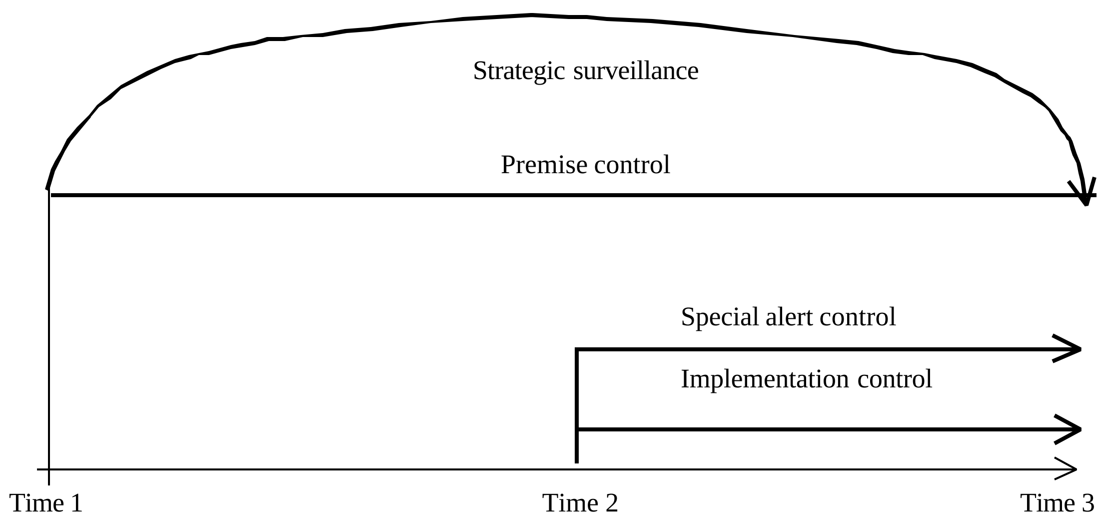

FIG. 2. FOUR BASIC TYPES OF STRATEGIC CONTROLS [4]

a) Premise control

Every strategy is based on certain planning premises – assumption or predictions. Premise control is designed to check systematically and continuously whether the premises on which the strategy is based are still valid. If a vital premise is no longer valid, the strategy may have to be changed. The sooner an invalid premise can be recognized and rejected, the better are the chances that an acceptable shift in the strategy can be devised.

Strategies are often based on numerous premises, some major and some minor, about environmental and industry variables. Tracking all of these premises unnecessarily expensive and time consuming. Therefore, managers must select for tracking premises whose change is likely and would have a major impact on the firm and its strategy.

b) Implementation control

Strategy implementation takes place as series of steps, programs, investments, and moves that cover over an extended period of time. Special programs are undertaken. Functional areas initiate strategy – related activities. Key people are added or reassigned. Recourses are mobilized. In other words, managers implement strategy by converting broad plans into the concrete, incremental actions and results of specific units and individuals.

Implementation control is the type of strategic control that must be exercised as those events unfold. Implementation control is designed to assets whether the overall strategy should be changed in light of the results associated with the incremental actions that implement the overall strategy. Prudential's updating of cost and revenue projections based on early experiences with regional home offices is an example of implementation control.

Two basic types of implementation control are:

?? monitoring strategic thrusts

?? milestone reviews

Monitoring strategic thrusts

As a means of implementing broad strategies, narrow strategic projects are often undertaken – projects that represent part of what needs to be done if the overall strategy is to be accomplished. These strategic thrusts provide managers with information that helps them determine whether the overall strategy is progressing as planned or needs to be adjusted. Although the utility of strategy thrusts seems readily apparent, it is not always easy to use them for control purposes. It may be difficult to interpret early experience or to evaluate the overall strategy in light of such experience.

One approach is to agree early in the planning process on which thrusts or which phse of thrusts are critical factors in the success of the strategy. Managers responsible for these implementation controls single them out from other activities and observe them frequently. Another approach is to use stop / go assessments that are linked to a series of meaningful thresholds (time, costs, research and development, success, etc.) associated with particular thrusts.

Milestone reviews

Managers often attempt to identify significant milestones that will be reached during the time a strategy is being implemented. These milestones may be critical events, major resource allocations, or simply the passage of a certain amount of time. The milestone reviews that then take place usually involve a full-scale reassessment of the strategy and of the advisability of continuing or refocusing the firm's direction.

c) Strategic surveillance

By their nature, premise control and implementation control are focused controls; strategic surveillance, however, is unfocused. Strategic surveillance is designed to monitor a broad range of events inside and outside the firm that are likely to affect the course of its strategy. The basic idea behind strategic surveillance is that important yet unanticipated information may be uncovered by a general monitoring of multiple information sources.

d) Special alert control

Another type of strategic control, really a subset of the other three, is special alert control. A special alert control is the thorough, and often rapid, reconsideration of the firm's strategy because of a sudden, unexpected event.

Table 2 summarizes the major characteristics of the four types of strategic control

TABLE 2: THE MAJOR CHARACTERISTICS OF THE FOUR TYPES OF STRATEGIC CONTROL [6]

Basic Characteristics	***Premise control***	***Implementation control***	***Strategic surveillance***	***Special alert control***
Object of control	Planning premises and projections	Key strategic thrusts and milestones	Potential threats and opportunities related to the strategy	Occurrence of recognizable but unlikely events
Degree of focusing	High	High	Low	High
Data acquisition	Medium	High	Low	High
Centralization	Low	Medium	Low	High
Use with:				
Environment factors	Yes	Seldom	Yes	Yes
Industry factors	Yes	Seldom	Yes	Yes
Strategy-specific factors	No	Yes	Seldom	Yes
Company-specific Factors	No	Yes	Seldom	Seldom

All four types of strategic control share common purpose: to asses whether the strategic direction should be altered in light of unfolding events. Strategic controls are designed to continuously and proactively question the basic direction of the strategy. Strategic controls are needed to manage the strategic process effectively.

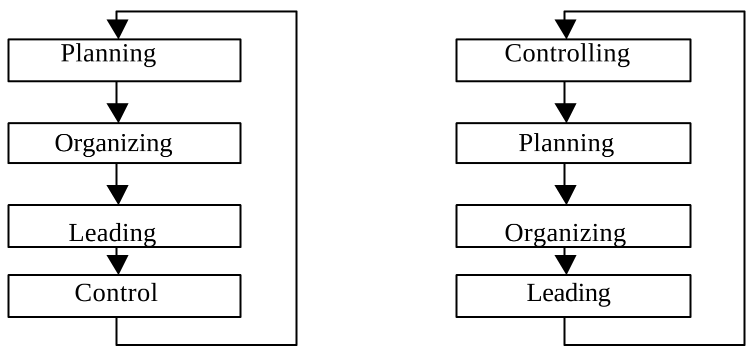
Moving Towards Strategic Controlling

Strategic control in the classical approach can be defined as, "the critical evaluation of plans, activities and rules, thereby providing information for future action". [5]

The limits of traditional control systems are overcome in part in a strategic control system by employing a feed-forward approach that is future-directed and anticipatory. “In its essence, engineering feed-forward control aims at meeting the problem of delay in feed-back systems by monitoring inputs and predicting their effects on outcome variables”. [1] Changes in internal and external circumstances need to be monitored on continuous basis and strategic direction evaluated critically in the light of those changing conditions.

“Controlling” as a term, which is contradistinguished from traditional “control” classified as one of main managerial functions. Traditional control is characterized as ex post control, and is classified as the last phase in management process. Controlling is first of all a preventive control and composes the starting point or the information source for planning.

FIG. 3: EX POST CONTROL AND PREVENTIVE CONTROLLING IN MANAGEMENT



Classification of controlling as a vanguard or a base for planning in the managerial process indicates its role and mission, which is derived form its priority orientation for identification and analyzes of problems and gaps, and searching for solutions.

Controlling is within the process of management focused on detecting problems, which occurs by realization of present plants due to internal and external factors. Relevant and early warnings and information providing by controlling and his reporting could be used at process of actualization of plans, still during planning period.

Prediction the future and the impacts of the factors in the future is a problem, which is still bigger and strategy and strategic management require to sensitively and carefully weigh the decisions, regard to existing risks, and searching and valuating existing alternatives.

The Importance of Competence Management for Corporate Innovation

Martin Rahe
EADA, Spain

Abstract

Statistics show that on the one hand innovative output in Spain is poor and on the other hand the changing environment (globalisation, enlargement of the EC etc.) requires intensive efforts to increase the innovative capacity. To improve the situation for Spanish companies a change process is necessary that tries to change the chip towards a culture of innovation. This means finally stepping into new markets with new products or develop new work processes. From a microeconomic point of view, the task is to create and foster competencies in the companies that help to develop an innovative culture. This means to manage competence potentials of the staff involved in innovation and to think about ways of learning and personnel development.

1. Introduction

There is no doubt about the importance of innovation for economic growth. In economic theory technological knowledge is introduced as a further factor in growth theory and also policymakers try to create business environments that are considered to be useful to foster innovation. The concept of national and regional innovation systems tries to coordinate the innovation process among the different innovation agents in a more efficient way. A critical point is the transfer of knowledge and technology in the system, in particular between the public sector, like universities and public research institutes, and the private corporate sector.[1] Technology Parks play an important role in promoting technology transfer. Figures show that most of the research in the most developed countries is done in private companies, about 76% in the United States, 69% in Germany and about 72% in Japan.[2] This shows that technology transfer, only seen as transfer from public to private organisations, plays a minor role. More important in this sense is the transfer within the private sector from private research institutes or companies to companies. Therefore, discussing the system and its efficiency means to discuss as well the efficiency of the innovation management in the private companies.

There is extended literature about the different approaches of innovation management. They analyse innovations from different point of views:

- ?? Studies about determinants of adoption and diffusion of innovations analyse the innovation process from the very beginning until its implementation and differentiate between two levels of aggregation. The adoption process refers to the individual that takes notice of the novelty, test it and adopt it. This incident always occurs independently from process or product innovations. The sum of positive adoption decisions describes the diffusion level of the novelty[3].
- ?? The evolutionary theory explains innovations as a result of competitive pressure and sees innovation as a tool to maintain the competitive edge and to assure the survival of the firm. In this sense, innovations grow endogenously as a corporate need.[4]
- ?? The description on the innovation process explains
    - o the different steps from the beginning (idea generation) to the end (market implementation)[5],
    - o the impact of decision making processes in the company on innovation[6],
    - o different types of innovation[7],
    - o resource planning and uncertainty[8].

These approaches explain the innovation process without spending too much time and space in analysing the aspect of competence. A research study, already done in the 60s and 70s at the University of Sussex, reflects among others also the aspect of competence and points out that knowledge is a central criteria of innovation success. The study, known as the SAPPHO-project, investigated success factors of innovation. The purpose is to find a positive relation between company characteristics and successful innovations.[9] The critical point is that innovation success seems to be easily reproducible once the company accomplishes with certain conditions of success, not taking into account that every company is its own world. The limitation of success factor research is shown by studies that focus on innovation barriers.

Reality shows that innovation policy is more than accomplishing with a list of critical issues. The starting point is that each innovation must be managed and that the core ingredient of innovation is competence. Instead of talking about technological knowledge as a component of innovation easily to handle, such as the growth theory is doing, this paper discusses in detail the aspect of individual competence and problems and ways of managing it in order to be innovative. The assumption is that by managing competence the company reduces organizational slacks, improve the transparency of internal processes and the assignment of human resources to innovation processes and, finally, improve the efficiency of the setting-up of innovations.

2. Key Factors of Innovation

Following the approach of national or regional innovation systems and taking into account the importance of the corporate sector, then each company should be considered to be a sub-system, whose innovative functioning has an influence on the innovative performance of the region or the country. Innovation analysis has to consider all those corporate activities that influence innovation and are usually described as innovation management.

The success of innovation depends basically on three factors that are related to the effectiveness of the operational innovation management: the market, the corporate configuration and the timing. If one of these issues is poorly managed, the impact of innovation on costs, market penetration and sales will be lower than possible. Operative innovation management is a central issue in achieving innovative sustainability because it marks behaviour and thinking, creates norms and conditions and, finally, institutionalises an innovative culture in the company. The underlying assumption is that the huge number of individual activities within a corporate organisation merge over time into a firm´s culture. If innovative capacity is a firm´s goal, operative management has to set institutional assignments that specify the norms of behaviour with respect to innovative curiosity and interest. Operative innovation management is successful when singular activities and events turn into a holistic culture of innovation. Although, two types of innovation can be divided, product and process innovation, the performance of the three factors mentioned above.

A new product cannot be launched successfully into the market, if it does not fit the market needs. To develop and produce a new product (product innovation) the company needs support systems such as technology and must involve the product development into strategic plans and tactical operations. As a future "star" in the company´s portfolio, an innovative product must be regarded as core element in the product range. Knowing the market and having prepared the internal configuration of the company, the time-to-market period can be reduced significantly, which is, within the competitive environment, a key element.

The same happens with process innovation; market, configuration and timing are crucial for innovative success. The market puts pressure on production processes, so that costs and quality have to be adjusted to market needs. The corporate configuration prepares the "grounds" to avoid innovation barriers in the company and the timing determines how fast employees are able to work in new processes and how fast new processes can be integrated into the already existing workflow.

The corporate configuration

It refers to the company´s unique personality that has to be carefully designed according to its strategic choices and managed properly in order to achieve a competitive advantage. Important aspects of the corporate configuration are:

- ?? Philosophy: The fundamental beliefs that unite the components of the company, enabling them to act as a whole.
- ?? Culture: Defines components and their relationship to each other. In this sense culture expresses a set of institutional norms.
- ?? Policy: Specifies boundaries on the design and prosecution of strategy, tactics, logistics and tasks.

The market

Innovation management is necessarily linked to market issues. Innovations are worth if they are driven by the customer value chain and, therefore, are business opportunities.[10] Something new that does not fit with the market demand is perhaps an innovation but without any market value and therefore without any economic benefit for the company. While the corporate configuration prepares the grounds to be innovative, the market evaluates if the innovation is worth it or not. This requires a deep understanding of what customers value in a product or service as "desired outcomes".

The timing

As a third element, the timing affects the innovative performance of a company. Two aspects must be considered:

- ?? The time-to-market span and
- ?? the first mover advantage.

The time-to-market span includes the time that is needed to transform an idea into a concrete product. This can be divided into four steps: market information, planning, implementing and commercialising. A long time span results in high development costs and includes the risk of bringing something onto the market that a competitor has introduced already earlier.

Being first, enables a company to gain valuable experience, create barriers and make the market entry for competitors more difficult.

To be successfully innovative, the company has to manage a set of activities that affect creativity and innovation and create an innovative atmosphere. These activities "situates individuals in collective contexts, where interaction is mediated through technology, language and symbolic artefacts"[11]. The activity theory points out that these collectives itself can create tensions and contradictions that are the origin of innovation and knowledge creation. This means that the source of innovation is, on the one hand, the market and, on the other hand, the corporate organization itself. The task of innovation management is to give space to creativity and novelty and to bundle and direct innovation capacity effectively and efficiently.

A reliable innovation management depends on individuals able and willing to work within an open and team oriented environment. Considering individual competence as crucial for innovation, a company with a low innovative output should analyse its human capital, the way how people behave and how they work together, before analysing market aspects or changing the corporate configuration. To be innovative, a company should be aware of individual competence and individual willingness to use the competence.

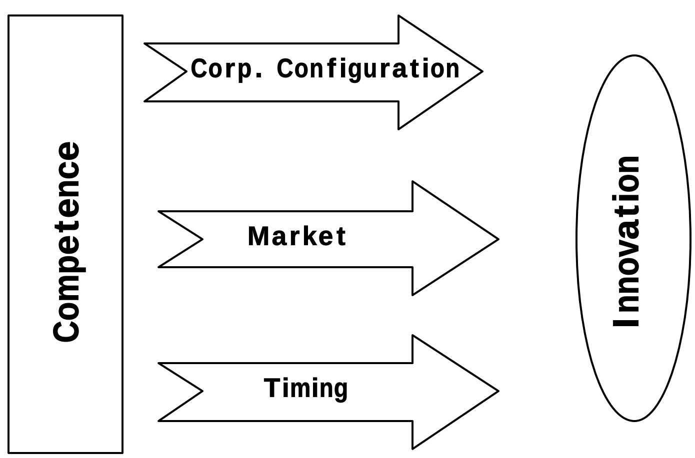

Fig. 1: COMPETENCE AND INNOVATION

3. A Pathological View on Individual Competence

As mentioned above, innovation depends on people’s competence, therefore, there should be special emphasis on the analysis and management of individual competence. But to manage competence means knowing the competence that is unified in the company. The following example about the implementation of a technological innovation underlines why it is important having an idea about what people can do or not do:

Imagine a medium-sized company which is threatened by its competitors and which start thinking about rising its efficiency by implementing a new machine in the company’s workflow. Managers and administrative staff travel around, visit trade shows and fairs, gather information and start calculating the costs. After some time a blueprint is presented to the top-management. The top-management accepts the proposal and a purchase order is sent out to the supplier. During the time of delivery the company carries out some reforms of the physical environment (junction, change in construction) to make sure that the new machine can be successfully integrated in the workflow. At this time people in the company take notice of some changes and curiosity rises. When the new machine arrives, expectations are high and people show a certain amount of enthusiasm. In such a situation, disappointment or frustration by managers as well as by the workstaff arises if they encounter problems in working with the machine. Finally, training is needed. This is the experimental phase, which means that the output that reaches the market is poor and that a lack of competence becomes visible.

Often, the implementation of technological innovation follows the same way that is described in the example above. Everything is planned, except the perhaps most important aspect, the intersection of employee and machine. What happens is that people experiment and try to check out how to work with it. It is a kind of arrangement between individual and machine and can be considered as self-learning, but nevertheless the company loses time and money. The result is an organizational slack. Such a reactive adaptation behaviour is caused by a wrong human resource policy or a lack of involvement on the part of the human resource department in the innovation process. This posterior adaptation process shows that employees are capable of managing situations that are beyond the routine and that their potential competence is bigger than their actually used competence.

A needs´ analysis of individual competence helps to avoid an expensive and time consuming process of trial and error. Global competitive pressure causes the factor time to become ever more important and correct planning and anticipation of problems in the production process is crucial for maintaining the competitive edge.

Talking about individual competence means, first of all, to define what we understand by this. In economics, psychology, sociology and pedagogy a lot of different approaches exist and different technical expressions like competence, capability, qualification, knowledge, etc. provoke conceptual confusion. Following White, Chandler and others, individual competence includes ability, knowledge and motivation.[12]

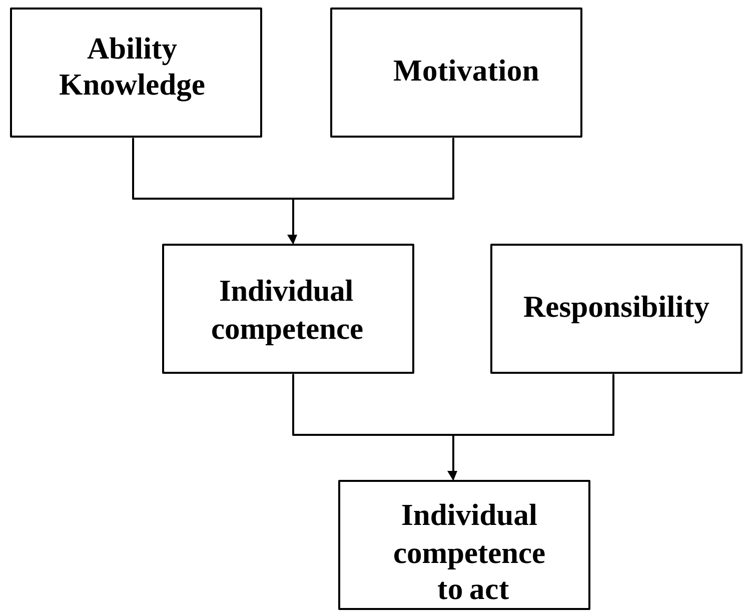

Fig. 2: COMPETENCE AND ACTION

Knowledge

Knowledge is the sum of accumulated information about reality, people, values, activities, etc. and is a condition for perception and behaviour. Nonaka introduced into the discussion the concept of tacit and explicit knowledge. His point is that there is on the one hand knowledge that can be systematically learned and transmitted by verbal communication (explicit) and, on the other hand, knowledge that must be experienced during the work process.[13] This differentiation is important because it shows the limitations of institutional training programs.

Ability

Ability is the sum of physical and psychic conditions used to carry out a certain task. Sometimes the individual is not aware of his or her abilities, because they are not frequently used. But such a "passive ability" can be recovered quickly if it should be needed.

Motivation

Motivation is the willingness of doing something. In case of technological innovation the employees should be open and interested in working under new conditions. Motivation is an essential prerequisite of using knowledge and ability. Individual competence depends on knowledge and ability, which become firm competence when the individual is willing to share his knowledge with others. Synergies through knowledge sharing create organizational competence that is more than the sum of individual competence.

Considering these aspects managing competence means to organize abilities and knowledge in a way that the individual can achieve his proper objectives and that the company can benefit from these synergies. The art of management is not to motivate people but to awaken their individual motivation by creating an environment (corporate culture) in which people identify themselves with the company. In this sense, motivation is an essential ingredient of competence.[14] In addition to this a limiting factor in the company is the responsibility which defines how far individual competence is usable in the company. Motivation as a limiting factor of the individual and responsibility as a restriction belonging to corporate decisions causes that the competence potential of the employees is bigger than the actually demonstrated competence.

In reality, a lot of things are not planned but spontaneously managed. This is, for example, the case when employees need to adapt to technological innovations without having previously had an introduction on how to work with it. Then, they have to find ways of spontaneous learning on the job. If this is unplanned, the employee uses his knowledge and abilities to adapt to the new situation. It is a kind of individual flexibility reserve and it is *this* flexibility reserve which keeps the process running.[15] People show that they are able to manage new situations that are beyond the routine by using their competence. A proactive human resource policy must identify this reserve and should consider it as one further starting point in the planning process of innovations. Innovations, then, are driven by the potential of individual competence. The difference, compared to the traditional approach, is that

1. the human factor is integrated in the process right from the beginning and not considered as a reactive variable and
2. that instead of actually used competence on the job, the potentially available competence is regarded.

This potential oriented approach reduces the implementation costs of technological innovations by planning the adaptation process of the employees and by knowing what can be carried out with the existing personnel.

Following this idea, the effectiveness and efficiency of innovation is strongly related to the management of competence. To reach a sustainable competitive advantage, based on productivity and/or product diversification, a company needs to invest continuously. Due to this, to be continuously innovative means to improve continuously the individual competence of employees and to manage it in an innovation oriented way. In this sense, personnel must be an integral part of innovation policy from the very beginning. It should be accompanied by a strategic and proactive human resource policy.[16]

Examples show that often companies do not make big efforts to manage competence in the company, even if they are aware of organizational slacks. The quality director of a Spanish automotive company with about 150 employees mentioned in an interview that there are a lot of unplanned processes and dynamics in the company and that improvisation is a common tool of management. In his opinion the level of control is low but, nevertheless, things are running well, because everybody knows his job. He stated that more than 90% of all orders are done in time. The company is aware of the importance of people´s skills but there are only few trainings, usually done by the providers, and knowledge management is almost inexistent.

Under stable conditions there is nothing to worry about, but the question is what happens if the environment changes and forces the company to react with internal or external adjustments. Are responsibilities still well distributed? Knowledge management helps to identify the capacity of a company to react and reduces reaction time.

Another problem that mentions a top manager from a Spanish sticker company with about 200 employees refers to the fact that, often, employees reject training programs. He sees this as a phenomenon that becomes worse from year to year. The consequence is that the implementation time of a new machine in the production process is sometimes longer than it was planned. In his opinion, this is something that goes ahead with the declining attitude of pro-activity and shows a lack of interest in work. This goes over into a lack of motivation and finally into a loss of competence.

These examples show that the reason for inefficient and ineffective innovation policies is a lack of managing competence, which includes the management of knowledge as well as the management of motivation. In this sense, individual competence is the central driver for innovation.

4. Competence Management as a Tool of a Potential-Oriented Innovation Policy

The question that arises is to become aware of that what the employees are potentially able to do. Focussing on knowledge and its differentiation, a crucial management issue is to motivate people to externalise their knowledge, especially their tacit knowledge, and that this knowledge is placed at the firm's disposal. The challenge is to find ways of:

?? incentivating employees to collaborate. "If people don't want to share, they are not going to do it even if you have the last technology in the world. People won't share if they don't see what's in it for them.” (Giovanni Piazza, Ernst&Young).

- ?? managing technically the amount of externalised knowledge and of
- ?? how to externalise tacit knowledge, which is highly dependent on the individual.

Due to the two types of knowledge, Nonaka identifies four different possibilities of knowledge transmission:

- ?? From tacit to tacit, which means, share experience and create new tacit knowledge.
- ?? From tacit to explicit, which is the sharing of tacit knowledge under the purpose of conceptualising and formalizing it.
- ?? From explicit to explicit, which is the creation of knowledge through classifying concepts.
- ?? From explicit to tacit, which converts explicit in tacit knowledge through learning-by-doing.

If the purpose of knowledge management is to make knowledge accessible, then management has to focus (a) on converting tacit into explicit knowledge and (b) on conceptualising and classifying explicit knowledge. The target objective is to have a structured base of explicit knowledge that results from a process of externalisation of knowledge. During this process, knowledge converts from individual into collective and becomes a visible competence of the company.

An important prerequisite of managing knowledge is the motivation issue. Talking about knowledge management means talking about the entire concept of knowledge and motivation.

In science and policy, a number of articles are published about knowledge management dealing with the problems of improving communication and storing knowledge, in particular tacit knowledge. Two different concepts of knowledge management are usually considered:

- ?? Personalization concept => managing the communication flow between the employees,
- ?? Codification concept => managing knowledge databases.

The personalization concept brings people together, creates networks and arranges an environment to support communication. The idea is that by linking people together, tacit knowledge can be shared. There is no central concept of externalising and sharing knowledge. It remains individual, but the employee is incentivated to share knowledge with others on a personal level. The workflow in companies using this concept is individualistic and very few standardized. These companies have highly customized products and services. Typical for this concept are flexibility and creativity to solve unique customer problems. The disadvantage of this concept is that the company does not really become aware of the knowledge potential due to the fact that there is no information storage. Consulting firms like McKinsey or Bain&Company are following this concept.

The codification concept codifies, steers, disseminates knowledge in electronic documents and allows its reuse. This IT-based strategy tries to separate the knowledge from the individual by a formal documentation system. Employees can benefit from information, experience, feedback, opinions and/or instructions from people working in similar projects without getting in contact with them. The advantage of the codification strategy is that even if the employee leaves the company, his knowledge or, at least, the externalised part of it remains in the company. This is important if we consider knowledge as an important asset of a firm. Disadvantages are the tendency of bureaucratisation and the problem of converting tacit knowledge into electronic documents. If the codification strategy means person-to-document, then more documents are circulating and more time is needed and more people are occupied only for managing this process. This can produce opposition and barriers to express knowledge.

Both strategies can also be used in common if a company´s business consist of creative as well as routinized work processes. Sectors that are highly competitive, where the life-cycle of a product is short, where the time-to-market period of a new product is short as well and where some work processes are being repeated, a combination of both strategies can be beneficial. The communication technology company Oracle is following this strategy. Based on the findings of Senge and Nonaka/Takeuchi, Oracle has transmitted academic concepts into practical management tools to increase its innovative capacity and keep playing a major competitor in communication technology services. Key issues are the management of employees´ knowledge through the creation of cross-functional practice communities. People from different functional areas come together, share their knowledge and work in project groups to generate new ideas or improve the workflow. Using Oracle´s technology these groups work together even if they are geographically located in different countries. The company´s Intranet portal enables employees to introduce and store knowledge into a commonly used data base, accessible for every employee all over the world. Apart from this, the portal is also used as a communication platform, where the diverse work groups (practice communities) have the opportunity of chatting among each other. Aware of different professional experience Oracle delegates responsibilities and distinguishes between:

?? The knowledge management sponsor, whose principal function is to coordinate and manage the activities of the practice communities.
?? The KM Lead promotes all activities related to knowledge creation. He is a mediator between the KM sponsor and the content provider.
?? Subject matter experts, who are experts in concrete web topics, like web cash.
?? Portal managers, responsible for the technical functioning.
?? Content leads, which are responsible for everything related to the content.
?? Content providers, which can be every employee of Oracle.

Based on a broad consensus the top management transmits his vision of the business to the lower management and gives support to innovation activities. KM-Management in Oracle is an integrated approach which combines aspects from the personalization as well as the codification concept and involves every employee in its KM by giving people a certain role. The combination of personalization and codification strategy is Oracle´s answer to market conditions that requires creativity, speed and a certain level of standardization. To make sure that people are motivated to contribute to the system, innovative contributions are economically rewarded.

5. Conclusion

The management of knowledge is an integral part of the innovation process and gives insight into the company´s knowledge potential. If the incentive structure or the organizational culture motivates people to share their knowledge with others, then, a first step is taken in capturing the competence potential of a company. As mentioned before, these reflections consider explicit and tacit knowledge as important objects of knowledge management but, without the individuals´ motivation to express knowledge, the whole knowledge management process fails. Knowledge and motivation create a company´s competence and must be managed. Competence management needs, in addition to knowledge management, the management of incentives. If this is done continuously, the company is informed at any time about the potential competence of its staff and is able to plan technological innovation on the basis of market requirements and people´s potential competence from the very beginning.

Increasing transparency of competence reduces organizational slacks, reduces costs and makes the company more efficient. Therefore, knowledge management which includes the issues of motivation and personal responsibility does not affect only the innovative capacity of a firm but is also a tool of effective cost management.

Power and Games in Organizations

Ralf Peess
Comenius University in Bratislava, Slovak Republic

Abstract

The bureaucratic organisation of the state once was classed as model of rational task fulfilling. Those contemplative times when the employees of the economy aimed their activities at the example of official however have long passed. The relations have nearly reversed. The public administration is learning from the economy. Today's examples come from the internal company management- and organisation theory. Being bound to rules and calculability - as in the bureaucracy theory by Max Weber - no longer are valid as guarantors of good administration.

Introduction

Rather today the once highly praised formal rationality of the public administration is regarded as hindrance for efficient and civil-friendly task fulfilling. The principle of constitutional state and principle of democracy face an example of the state as economic enterprise. What is shown are changes of the task perception as well as the management forms and the organisation construction. According concepts are being discussed since some time and in many places already applied.

In the past years the modernisation efforts on all levels of the public administration have spread "like wild-fire". The communities have advanced the most in the development; at least the reform efforts are examined, documented and promoted the most, while this is not (yet) the case to such an extent on national level.

After initial euphoria in the communities, however disillusionment and a consolidation has occurred. Reason for these manifold problems are reservations, fears and oppositions on all administration levels, as the employees regard the New Management Model (NSM) as a pure rationalisation concept and the Middle-Management fears a loss of status and power. This shows the "modernisers" that the realisation process of the concepts in the administration is as least as important as it's content. That is why "the micro-political processes of the participation of the employees in the work process and in the work situations of the public sectors gain significance".

The personnel representatives present a central acteur these processes, as due to their position in the administration they are to act to well being of the employees as well as the departments. For being able to effectively perceive the interests of the employees, beside defined legal tasks and rights for taking influenced, informal contacts and information are an essential factor. Which position influence possibilities of the personnel representatives take, depends on it's self-image, e.g. as modernisers or traditionalists and their co-operation with their social partner (e.g. department).

For this, service- or other agreements can be concluded by the actors, so-called rules, also for striving for a balance between rationalisation winners and – losers, with increase of efficiency and effectiveness of the administration action. However this requires a considerable split between the personnel and the economic aspects of the modernisation.

Micro-political starting point

Proceeding for the micro-political statement by Crozier/Friedberg (1993) among other the actor-referred analysis of the modernisation process is in the foreground. It's game concept is to serve as basis for the analysis, as it is "nearly ideal suitable for a actor-centred starting point, which wants to explain the structured, organised and interdependent acing of several actors in the federation". It is about the present these processes from the point of view of the actors (personnel representation and department management) and it's relation to each other.

The starting point of a "sociology organised acting" is to present a "realistic point of view of organisation", which equals a bureaucracy critic, which is independent of the actors handling.

Organisation form social constructs which are created and marked by the organised handling of it's members. Crozier/Friedberg present the opinion that an organisation only exists through the partial targets and rationalities which exist in the scope of acting individuals and groups and that an organisation not so much but rather exists despite the acting of it's members.

The strategic concepts, on which Crozier/Friedberg base their organisation analysis, are power, strategies and games.

For Bosetzky micro-politic is the effort to use system-own materials and human resources for reaching personal targets, especially of the advancement in the system itself and in other systems, as well a for securing and improving the own subsistence conditions.

For Neuberger the micro-politic means a collective name for all the strategies and games, which thereby come into question for bringing through own projects or preventing foreign ones. Small posts are to be occupied or to defend against arbitrariness or wanting to use useful chances; will (cannot) not always go the open lying way, but will see itself obliged to take detours, side paths, short-cuts or secret paths.

Power for Crozier/Friedberg is "the raw material of collective acting and therefore has to be in the centre of every serious analysis". To influence others means to get in relation with them, only through this the power of a person A can unfold over a person B. Therefore power is a relation and not an attribute of the actors. Power "basically is nothing else than the always contingent result of the mobilisation of the uncertainty zones of the actors controlled in a set game structure for their relations and discussions with the other participants in this game".

Power not at all is only to be seen negatively and repressively, but as basic aspect of every social relation. Every actor who wants to remain autonome, has to maintain space and with this his skills, his good will power, his behaviour regarding others uncertain. No situation in an organisation however puts an actor under pressure; he always keeps some freedom and negotiation elbow room.

Due to this elbow room every actor has power over other actors. The power is even larger, the more relevant the controlled uncertainty source by him for others is. So this means "Uncertainty of aspects of the problems, is power from the point of view of the actors".

Uncertainty, i.e. uncertainty regarding his concrete solution possibilities" can exist in two different ways: "Objective" uncertainties are brought up through the "technical, economical etc characteristics of these problems", while "artificial " uncertainties through the re-defining and re-structuring of the handling fields arise, for being able to work off and solve the games or negotiations.

Crozier/Friedberg make a distinction in four large sources of power:

1. Those which come from the holding in of a specific knowledge and the functional specialisation;
2. Those which are bound to the relations between organisation and it's environment, or rather it's environment segments (environment seaming point);
3. Those which come from the control of information- and communication canals (information control);
4. Finally those that arise from the existence of general organisational regulations (organisation regulations).
5. However the authors are of the opinion that these uncertainty sources not alone are derived from the power or even calculated. As everywhere exists a uncertainty source and it gains significance in the organisation processes only so far as the actors really use them when following it's strategies.

With strategies the actors follow their interests for reaching the targets. An actor on "rarely has clear targets and evenly less coherent and consistent plans; these are multitude, more or less significant in many ways, explicit and oppositional". They underlie multitude influences which before cannot be seen, through which constantly changes of acting and targets may arise, e.g. also in means becoming targets.

The target of the actor always remains active, also when it is always restricted and limited and can change in the course of his acting. His behaviour is always aimed at two sides, an offensive one which is marked by the fact that it is to lead to an improvement of the situation and a defensive one, which is to lead to his maintaining and extending of his freedom, that means of his acting ability.

Games not only refer to a harmless-easy playing, relaxed passing time or target- and interestless practicing and enjoying, but can also be "dead serious". Games in the organisations can also be: clever production, creative move and merciless competitions. Games present an essential instrument of the organised acting, which were developed by humans for regulating their co-operation.

Games combine freedom and compulsion with each other. The player remains free, but has to , if he wants to win, follow a rational strategy, which corresponds to the game and has to keep to it's rules. As long as the actors want to continue the game, they at least have to supply the necessary contributions and resources for the successful existence of the organisation.

Games are also marked through formal and informal rules, which also can be unnoted, changed or taken over by new rules or extended, with the target to maintain the relations between actors and to secure the participation in the game respectively the continuing.

Games are marked by the following characteristics:

1. Rules

   Here it is to be distinguished between object- and meta rules.

   Object rules characterise the concrete game (Chess has other rules than skat .

   Meta rules refer to the general behaviour like fairness, truthfulness, exactitiy, team ability, competition etc.

   It has to be made sure that the rules are known, accepted and kept to. Furthermore the rules have to be made known at the beginning of the game (activate) or agreed. The game can only commence, when explicitly or implicitly the rules were acknowledged/recognized. Regarding the keeping to the rules, often special institutions (referees, penalties, exclusion etc.). Agreed or known meta rules can also be laid down to which extent object-hurts (e.g. cheating) are tolerated.

2. Game situation and –material

   Beside the rules the game is also marked through concrete equipment. Here it is laid down, how the material game conditions are to be regarded (size and constituency, type of cards or figures or similar). It also has to be laid down, if the game is to be held before viewers or not. Rules and game constituency limit the game from daily situation respectively other games.

3. Time to play

   Beginning, end and time of the game can be determined before or made dependent of certain results. Also breaking conditions or the stopping respectively changing of single players has to be agreed.

4. Admission conditions and roles of the participants

   It is to be laid down under which conditions who is allowed to play. Thereby certain qualifications, performance documentations, personality characteristics (age, sex etc.), group membership etc. can be set. Also it can be determined that there are different roles and who is allowed to take them on respectively has to. The admission conditions can be called back, if lacking suitability, severe superiority, mis-behaviour can be noted, also they can be called back from just one side.

5. Target of the game

   The game target can also be fixed through general rules. Targets are e.g. the number of goals, to remain last or similar. However attempts have to be made to clearly determine the target of the game and inform all participants of this.

6. Result of the game

   Hereby it is about reward and penalties; they can either be material or symbolically or both, e.g. documents wins, exclusion etc.

7. Game tactics

   Games have to have a certain multitude significance. There are not to be any clearly determined action routines, with this the possibility arises to implicit the selection of proceeding, tactics and also the secrecy before the other players, they can be of different transparency. Strategies refer to the setting of whole game moves (e.g. aggressive, defensive, conventional, etc.).

   The named rules can without problem be transferred to “games in organisations”, mostly however not all listed aspects are used, but only the most important.

Organisation games can be divided as follows:

I. Games in which opposition against authority is made

1. Opposition games

   Here there are two versions, in one subtle opposition is made (miss-interpret , manipulate, undergo, exaggeratedly execute etc.), in an aggressive one open mutiny and rebellion arises (strike, sabotage, open disobedience)

II. Games against the opposition games

2. Conter-revolutional games

   Here the uproar (see 1) is fought against or stopped from the beginning. The typical bureaucratic way is to break opposition against authority with even more authority, e.g. with draconistic sanctions, strict surveillance or preventing controls. A political reaction would be to split the other side, to cut them off from information, to produce a multitude significance etc.

III. Games for creating power

3. Sponsor-protégé-game

   A person hangs on to an advancing person or to somebody who is already on top and shows loyalty as a return for a part of participation in power. The patrons fight for their protégé, place them strategically and give them the title of being powerful protectors.

4. Coalition-games

   These games are mainly only played under equally levelled, who make a net of relations with other persons in strategically important positions and with those persons who could supply them with resources (information or similar)

5. Area foundation game

   Single persons secure themselves a largest possible number of followers to extend their sphere of influence.

6. Budget game

   Here it is about establishing a position which one already holds. The target of the game is to reach more, whether it is positions, rooms, equipment, resources of any kind and especially financial means. The game however is highly formalised and known to all people using tactics; you always have to demand more than you need (because this in any case is cut percentually); you always have to prove things rationally, disguise the true situation, use up all means by the end of the year and similar.

7. Expertise-game

   Here an own specialist behaviour is exaggerated or played, inevitability and non-replaceability stated, knowledge played or kept back also extern experts are drawn.

8. Dominance game

In this game the own power is fully played or let out on others for scaring them.

IV. Games for fighting rivals

9. Line-against-officials game

   The officials often have information, which they can play against the line and they can try and dis-power them.

10. Rivalising-side-game

   This game if often the result of area foundations- and coalition-games. There are two fiendly sides, which fight themselves in nill-sum-games e.g. the “old gard” and the “new ones”.

V. Games for realising the organisational change

11. The strategic-candidate-game

   With strategic candidates not only persons are meant in who career hopes are placed, but also proposals, projects or similar. This game normally be divided through three phases: First a “candidate” has to be found, then he has to be sold as important respectively valuable and then brought through, for then self hanging on.

12. The tell-tale game

    If in an organisation a norm has been hurt, but this was to be kept secret respectively hidden, then insiders can use their knowledge i.e. pass it on to externals, for bringing them to intervene or the mobilise an opposition.

13. The young fake-game

    This game is an extreme version of the opposition games, hereby it is about a radical change. The existing power relations and orders are to be broken through a kind of state game. This game is often prepared by high ranked organisation members in secrete circles and leads to a revolution.

If you want to examine the way of functioning of the organisations a case study procedure is recommended, as the only possible starting point of such examinations can only be the attitudes and behaviour ways, short, the visible strategies of the organisation members. You have to try to connect the specific elbowroom of the organisation members with the resources and compulsion, through inductively reconstructing the structures, consistence and rules of the games, which regulate their co-operation.

Administration reform processes very well can be considered as games in the organisations.

Power: Uncertainties and their control

An actor gains power over other actors when he can control uncertainty sources, which are important of others. Uncertainties consist in administration reform processes (modernisation processes) in multitude way and type.

The most important uncertainty sources are the content creation of the concepts, their realisation and the implementation with the creation of acceptance. For the department managements also the personnel representations are a uncertainty source, as through their formal participation rights restrict the direction right of the employer and with this make the reform process more difficult or can even prevent this.

Through this the personnel representation as the control over an uncertainty source, namely the agreement of itself, under which you could class the fourth power source, if you regard the co-determination as an organisational rule. Furthermore the personnel representations can also control information- and communication canals, as the stand between management and employees and thereby can also take on a mediator role for both sides.

Bogumil/Kißler have distinguished between three types of basic action examples with the personnel representation: traditional, compensational and progressive form of the interest representation politic.

Traditional interest representations restrict on the status quo of securing the working conditions and to drive away new dangers. They do not develop an independent reform idea, the co-creation demand overstretches them and their participation practice on the reform field therefore is defensive. The compensating interest representation under-stands itself more as a mediator in conflict situations. As the working conditions are not regarded as problem field of the personnel representation work, they concentrate - more from the defensive – more on the reachable with the income- and employment politic risks of the reform idea. Progressive interest representations want offer the creation freedom, which the reform concepts as well as with the conception also still during the realisation, through an offensive participation practice use together with the base and to extend the contrary-power in the administration reform. They see themselves challenged and concipate own reform ideas or at least set the general conditions for the realisation of the reform ideas.

The personnel representation has the decisive task with the creation of acceptance or mobilisation of opposition against modernisations with the employees in the authorities.

The recognition of it’s significance in the modernisation process however does not automatically mean that they want to or can perceive these tasks, that means if they want to realise their power in action. This mainly depends on the attitude and targets of the different actors, which mark their action and with this their strategies.

Strategies: attitudes and targets

All actors follow strategies for following their interests, but which not always are clear and marked, but often diffuse, oppositional and sometimes not even conscious. With this they more move the attitudes and targets in the centre of the action of the actors, which due to manifold influences can constantly change.

Starting point or result of the following of strategies are the attitudes of the actors regarding the “game” administration reform.

I.e. that the actors have to adapt their strategy dynamically to the respective situation, also when principally follow a different strategy. The behaviour of actors with this always remains also free and not determined. The personnel advisors follow the strategies offensively and defensively at the same time, by trying to improve their and the situation of the employees in the administration reform processes without giving up their elbowroom or their action ability, but through this extend this.

However the relation of offensive and defensive mainly depends on action and the strategies of the social partners and the superior political level.

Games: Procedure and rules

The actors do not act fully isolated, but are also dependent of the acting of other actors and the dealing with each other. With this the games move into the centre of interest perception and the handling of the actors, by combining the freedom of self-acting with the obligation of "game rules" and of the strategies of other actors.

Decisive for the creation of the games are the attitudes regarding the respective social partner, which are presupposition but also result of the co-operation.

Very strongly dependent is the attitude on both sides of the respective experiences with the acting persons, which does not draw behind a general judgement of the social partner, but a differentiation according to the single persons. Thereby it is shown the more co-operative the respective social partner behaves, the more positive is the own attitude and the more successful the modernisation process is judged.

Game rules within the scope of the administration reform

Game rules are the other side of the freedom of the acting of the actors: they form the compulsion, which steers the games in structured ways and is to offer the security for participation in the games and for the arbitrariness of the others, as also can serve for the conflict regulation.

As game rules are to be named:

?? The holding of agreements based on common trust;
?? Information from the meetings are normally to be dealt as confidential until a official agreement has been made, the information of the other personnel advisory members however are not concerned by this ;
?? The personnel advisory takes part as full member in meetings and committee, i.e. he receives all information which the other participants receive;
?? Momentarily obligation with the decisions: The participating personnel advisory board normally cannot co-decide for the personnel advisory committee, but only for itself, i.e. the last decision therefore has to be made by the PR-committee;
?? For conflict avoiding in the committee an open discussion is made and problem solution in meetings;
?? Conflicts or problems firstly have to be dealt with in bilateral conversations between the social partners.

The progressive personnel advisory board has thereby to fulfil three role expectations:

?? As co-manager he is obliged from the point of view of the administration management, to support the result-open process in content, to approve of it, to secure the acceptance for the reform in the staff and to contribute to a most possible errorless realisation.
?? As moderator he becomes an important connecting person between department management and the employees, by judging targets and measures of the administration, to inform employees about this and to emphasise the steering group respectively the service department management the reform climate in the basis.
?? As interest manager he has to make sure of a balance between the administration- and employee interests. This in no way is simple, as the PR has to take up different interest situations of the employees and present, that means that nothing else but to use the winners and to protect the loser.

From this in the reform process the following effects respectively conflicts can arise:

?? In the perception of the staff the border lines between personnel representation and department are blurred; as the reform following can no longer be classed clearly to one or the other. This especially is the case with negative reform results (performance condensation, additional strain, etc.) as these (can be) lead back to the PV. It does not play a role if the leading back is acknowledged or not.
?? If the personnel representation becomes promoter of the reform, is may happen that the employees no longer dare to consult the personnel advisory board with their problems.

?? The personnel representation at the same time can also be a “general font of the critic” in the reform process, as it normally is the only instance which takes on the problems of the employees, i.e. the personnel representation can happen to become in the “centre” of the modernisation winners and-losers and the reform process as such.

Conclusion

Only through including of the actors can the deficits of the modernisation-processes remedied or prevent. That is why “the micro-political processes of the participation of the employees in the work process and in the work situations of the public sectors gain significance”. The personnel representatives present a central acteur these processes, as due to their position in the administration they are to act to well being of the employees as well as the departments. For being able to effectively perceive the interests of the employees, beside defined legal tasks and rights for taking influenced, informal contacts and information are an essential factor. Which position influence possibilities of the personnel representatives take, depends on it’s self-image, e.g. as modernisers or traditionalists and their co-operation with their social partner (e.g. department). Through an active participation in the decision committees the personnel representation can emphasise it’s demand on the co-creation and it can use the chances of the administration reform for improving the working conditions.

Is Individual Management Style Variance Gender Dependent? A Case of Slovak Republic

Stanislava Luptáková
Comenius University in Bratislava, Slovak Republic

Abstract

The presented paper examines whether there is a difference in style in which female and male managers approach their subordinates. The study was conducted on a sample of 512 Slovak respondents working at all managerial levels. The objective is to identify whether there are any differences in communication, decision-making, delegation, and managerial style between male and female managers. The study is based on an analysis of attitudes of managers towards various aspects of their work; it does not examine how their subordinates view them. The results indicate that out of the managerial population, female managers make up 23.86% of the sample with greater participation in foreign companies than in local companies. Concerning the style of management, the study finds that female managers are more impersonal during formal communication in performance appraisal. Also they tend to delegate, empower, and trust their subordinates more than their male counterparts. However, there are no significant differences in the way both male and female managers approach decision-making.

Introduction

Countries of Central and Eastern Europe have had a long tradition of including women in workforce. During the communist era, the state planned economy required 100% full-time employment, thus both men and women had to play an active role in the workplace. The motto "everybody has aright to work" had gradually evolved into "everybody has the obligation to work". This has created different dynamics of the employment mode than could be noticeable in the countries where women only gradually started entering the workplace after the WWII, from the beginning opting for more flexible work arrangements such as part-time work. The gradual inclusion of women into the workplace asked for role clarification and even anti-discrimination acts. Even today, when women are actively employed in the USA and Western Europe (the proportion of women aged 16 – 65 is 67.1% and 54.9% respectively)[1], the majority of human resource management and organizational behavior textbooks discuss the issue of women at work as an issue organizations need to address.

Over the past decade, the significant socio-political changes in the Central and Eastern Europe have also caused changes in the employment mode that reflect women. Compared to the countries of Western Europe and the USA, there has actually been some withdrawal from active labor force among the female population in Slovakia[2] (54,0% in 1997 to 51,8% in 2001). Moreover, the career advancement opportunities are now made based on individual contribution and merit[3] rather than on political membership, which had been the career advancement prerequisite before 1989. There has been an increase in the number of women entering into managerial positions, yet that does not mean that they are given the same opportunities or that they are rewarded the in same way as their male counterparts[4].

Numerous studies (of mostly Anglo-Saxon provenience) have focused on gender differences and their impact on managerial style, discussing who is abetter leader or amanager or analyzing how men and women approach different managerial situations. A study by Powel, Butterfield and Parent[5] shows that a good manager is still viewed by both males and females as possessing predominantly masculine characteristics. It is so despite the continuous increase of female presence in managerial positions. Thus, women need to portray themselves in a way that is consistent with masculine characteristics such as competitiveness, ambition and assertiveness. Nelson and Quick[6] state that women leaders are more likely than men to include and energize people, helping them feel important. Yet, as managers they may be less effective when it comes to delivering negative feedback to their subordinates. Atwater, Carey and Waldman[7] found that women are perceived to be less fair and less effective when disciplining their subordinates. They attribute this mainly to biases from subordinates but also to the differences in behavior of female and male managers. When assessing performance, women tend to act on a basis of equality and are thought to be less sensitive to the causes of certain type of performance. Thus, if the performance is poor they tend to punish it equally regardless of cause, whereas men would investigate and differentiate among poor performers[8]. A study by Statham[9] shows that female managers focus more on tasks to be accomplished and interacting with their subordinates while male managers are more engrossed by themselves, emphasizing the power they have. According to Calhoun and Smith[10], women, contrary to men, enter negotiation settings with higher concern for the other's outcomes. All these studies suggest that female managers demonstrate more empathy and collaborative attitude in the style they handle people, yet when it comes to focusing on goals and performance they accept a stricter role.

Most studies attribute the differences between male and female managers to the process of socialization that starts in early childhood and determines the values, attitudes and beliefs of people. The "proper" roles in society are developed in family through reinforcing certain behaviors, through fairy tales and/or religion. The majority of fairy tales are governed by kings and the best recognition girls can hope for is getting married to (or rather being given to as a reward) a smart, courageous prince who has just saved the kingdom. Observing their parents, family members and friends further strengthens the stereotypes that young people gain. If, for example, the children are used to seeing their mothers go to work every day and hold professional positions within organizations, then the girls would take it as "normal" to aspire for professional full-time positions and boys would find it "normal" to have female co-workers and superiors.

From the early childhood, men and women are socialized differently, expecting men to be competitive, assertive, and courageous while leading women to be more sensitive, warm, supportive, submissive, and passive. People build their expectations on what roles men and women should play in the society and how they should behave in their roles. In this, national culture plays an important role in forming the attitudes towards many aspects of working life. The culture that is more egalitarian would place fewer barriers for women to enter managerial positions and in such an environment women would understand their options and opportunities. In egalitarian environment, women would make choices voluntarily and would perceive fewer outside barriers to their decisions.

In the region of Central and Eastern Europe, the period of communism that lasted over two generations has introduced compulsory employment mode for both men and women. Women have taken professional positions, however, their access to leadership positions has been constrained. Also, in line with Anglo-Saxon literature, there is a difference between typically male and typically female jobs[11]. Female type occupations have less prestige, less power and make less money than male type occupations. Women also do not frequently hold executive positions in organizations or high-ranking political positions and generally it is thought that women need to show more effort in order to break the glass ceiling and make career advancement.

Thus drawing on theoretical concepts and the specifics of the environment, the aim of this study is to determine whether there is a difference between male and female managers. As the role of a manager is perceived as masculine, we believe that female managers would need to balance their focus on people and goals with an aspiration to be perceived in line with the masculine role. Based on the other studies, we believe that female managers will be more involved in both dealing with subordinates, trusting them and achieving goals through an consultative approach. On the other hand, we believe that when it comes to formal interactions during performance appraisal, women will try to accommodate the role of a critic in restricting to formal evaluation of goals and keeping the relationship neutral by focusing on the evaluated person. This can serve as a shield from being seen as unfit for a managerial position. Thus, we formulate the following hypotheses:

H_1: Female managers will show stronger tendency to delegate and empower in their managerial style then male managers.

H_2: Female managers will show stronger inclination for consultative decision-making style then male managers

H_3: In assessing performance, female managers will show more equalitarian approach in dealing with their subordinates

Questionnaire and Research Sample

The questionnaire consisted of three parts. In the first section, we asked for demographic data such as gender, the managerial position of the respondent, ownership of the company, seniority, and age of respondent. The second part consisted of 30 statements that the respondents had to evaluate on a five point Lickert scale and the third section offered statements with a range of answers. In the third part, the respondents could give multiple answers with which they agreed. For the purpose of this study, we focus the analysis only on those questions that directly or indirectly deal with aspects of managerial work, such as delegation, empowerment, communication, decision making and managerial style and analyze and compare data for each subgroup.

The total number of questionnaires sent was 718. They were sent to 52 companies with a final count of returned, filled-out questionnaires amounting to 512 from 35 organizations. This represents a 71.31 % return rate on individual participants and 67.3% on the companies. The enterprises actively involved in the research cumulatively employ 11,765 people. We consider this sample sufficient for an analysis.

The demographic characteristics of the respondent group were as follows. There were 115 (22.55%) top managers, 205 (40.2%) middle managers, and 190 (37.25%) line managers. The group consisted of 390 (76.32%) male respondents and 121 (23.86%) female. Out of the sample, 64 (12.52%) were younger than 30, 190 (37.18%) were from the group 31 – 45 years of age, and 257 (50.3%) people were older than 45. There were 432 respondents from Slovak companies and 72 from those with capital investments from abroad. There were 13 foreign companies and 22 Slovak companies represented in the sample. The most frequent number of direct subordinates was four, indicating a rather narrow span of control. The extreme numbers of direct subordinates, however, ranged from 1 to 135. There were 511 respondents who identified their tenure, out of which 33 (6.46%) have worked less than one year for a company, 101 (19.77%) who work 2-5 years with the company, 123 (24.07%) who work 6-12 years with the company, and 254 (49.71%) who work longer than 13 years with the company.

The respondents in the survey were exclusively in managerial positions and regarding their particular style of management, there are no responses gathered from their subordinates. Thus the possible gender differences are of self-evaluative nature and would represent the managers' understanding of their role and job, their attitudes to goals and the people they manage. As attitudes influence behavior, we believe that these self-descriptions and statements of preferences in style of management are sufficient to draw conclusions on the style on management executed by the respondents.

Analysis of Female Representation in the Sample
